It is not too early to begin to think of the best place to spend your summer vacation. Do not leave this matter until the last moment, make up your mind in a hurry and then—regret for the next six months that you did not take more time in making your decision. And while you are thinking of this matter it will pay you to investigate some of the many hundred beautiful resorts situated along the line of the New York Central & Hudson River Railroad. You cannot get a better list to choose from. If you want a gay social time, and can afford it, take the New York Central to Saratoga, Lake

George, Lake Champlain, or the Thousand Islands. If you want a quiet, rustic time, you can find it in one of the many small villages scattered through the Adirondacks, the Catskills, or the Berkshire Hills. The New York Central lines will take you into the heart of these famous regions. If you want to spend your vacation in sight seeing, take this same railroad to Boston, Buffalo, Niagara Falls, Montreal, Toronto, Chicago, St. Louis or Cincinnati. In addition to simply taking you to these different places, the New York Central will take you in the best possible manner. It has the fastest and most perfect through train service in the world, with new and elegant sleeping, drawing room and dining cars made by the Wagner Palace Car Company. It has justly been said of this road that, "For the excellence of its tracks, the speed of its trains, the safety and comfort of its patrons, the loveliness and variety of its scenery, the trade and importance of its cities, and the uniformly correct character of its service, the New York Central & Hudson River Railroad is probably not surpassed by any similar institution on either side of the Atlantic."

For further information about any place along this road apply to George H. Daniels, General Passenger Agent, Grand Central Station, New York City.

### A SHORT DESCRIPTION.

A short description of the Lake Shore & Michigan Southern Railway will not be uninteresting to any one who is thinking of taking a business or pleasure trip from New York, Boston or Buffalo to Chicago.

This railroad is the only double track line between Buffalo and Chicago, and in connection with the New York Central and the Boston & Albany railroads, forms the only double track route between Chicago, New York City and Boston. It is the most interesting route between the East and West, traversing the richest and finest portion of the Middle States. In the opinion of those experienced in travel, it has no superior in perfectness of roadbed, punctuality and elegant service and the comfort and care of its patrons.

Leaving Buffalo the line traverses the picturesque south shore of Lake Erie through the Western Reserve, passing on its way a large

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged  
 in any branch of street railway work, and will gratefully appreciate any marked  
 copies of papers or news items our street railway friends may send us, pertaining  
 either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supply or material, we can save you  
 much time and trouble. Drop a line to THE REVIEW, stating what you are in the  
 market for, and you will promptly receive bids and estimates from all the best deal-  
 ers in that supply. We make no charge for publishing such notices in our DAILY  
 BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. JUNE 15, 1897. NO. 6

POSTAL car service on street railways has proved even  
 better than anticipated and has certainly come to stay. The  
 service is being increased as rapidly as appropriations will  
 permit. Baltimore is the latest, with four cars serving the  
 city and near by suburbs.

THE decision of the Indiana Supreme Court on the 3-cent  
 fare law was handed down on June 11. The law is pro-  
 nounced constitutional, the court holding that the legislature  
 may do anything with street railways except confiscate them  
 or prescribe unreasonable rates of fare, and no claim was  
 made that a 3-cent fare is unreasonable (!) An appeal to  
 the Federal Supreme Court will be taken.

MOTOR cars, which at one time were heralded as the com-  
 ing competitor of the street car, do not appear to be keep-  
 ing up their pace. A few are running in the larger cities,  
 but even the wealthy have not invested to any discoverable  
 extent in this novel type of transportation. In England it  
 is stated they are much less numerous on the streets and  
 highways than six months or even a year ago.

THE attention of our readers is particularly directed to  
 the circular letter issued by the committee of the Street Rail-  
 way Accountant's Association published on another page.  
 Accountants are greatly interested in the subject as is evi-  
 denced by the symposium on "Cost per Car-Mile vs. Cost

per Passenger" and we trust that the railways will give all  
 the assistance possible to the committee in its endeavors to  
 collect the information desired by it.

NO SMALL interest and curiosity has been awakened as to  
 the future of gas engines for stationary power of consider-  
 able quantity, and whether they are destined to become desira-  
 ble for railway work on small lines. Some of the promises of  
 the gas engine men are quite attractive, even outside the gas  
 belt, where of course, the system would operate to greatest  
 advantage. It can hardly be recognized as a competitor  
 with the steam engine; but rather, like water power, as  
 coming in to share in a part of the natural increase and  
 growth in power production.

BICYCLES, not motor cars, are cutting a large figure in  
 street railway earnings. The effect last year was distinctly  
 noticeable, and the wheel season opens with greatly aug-  
 mented numbers. The wheel as a means of daily trans-  
 portation between home and office or shop is daily increas-  
 ing, and to all appearances is destined to increase. As the  
 number of riders grows larger the demand for smooth pay-  
 ing on arterial lines will gather strength, and it really looks  
 as though wheelers were likely to get about all they ask.  
 The effect of bicycles on pleasure riding in all our large  
 cities is startling, and we may well ask, where is it going  
 to end?

THE most important application of electricity to steam  
 roads is the installation on the New York, New Haven &  
 Hartford, which has been inaugurated during the past  
 month between Hartford and New Britain, Conn., the  
 steam service being unchanged, however. A long estab-  
 lished steam locomotive passenger service is thus placed in  
 direct competition with its new rival. To what extent the  
 substitution of the latter for the former will be ultimately  
 carried is not at present a certainty, but enough has been  
 demonstrated to clearly determine that for suburban work,  
 the motor and not the mogul will be selected. Just now the  
 transformation seems to be gaining, though slowly, but is  
 nevertheless making sure and definite progress, and very  
 soon the steam roads will be racing each other in the effort  
 to get their electricity first.

THE Allen bill, successor to the recently defeated Hum-  
 phrey bill, passed the Illinois House on June 4, and was  
 signed by the governor on June 9; it takes effect on July 1,  
 1897. From a street railway standpoint it is in some  
 respects a much more favorable law than the Humphrey,  
 which was so blindly opposed by alleged reformers, assisted  
 by Chicago aldermen. By the Humphrey bill the legis-  
 lature would have extended existing franchises 50 years upon  
 the payment to the city of \$2,000 per mile of single track,  
 and a percentage of gross earnings, which in counties hav-  
 ing a population of more than 200,000 increased from three  
 per cent for the first 15 years to seven per cent for the last  
 15 years. As it proposed to leave hoodle alderman high and  
 dry on the beach they naturally fought it. The Allen bill  
 authorizes city councils to extend existing franchises 50  
 years, prevents a reduction in the 5 cent fare for 20 years,  
 and says nothing about compensation. The bill will permit  
 assurance of stability to street railway properties which will  
 enable them to proceed with desired improvements and  
 extensions, not otherwise possible.

GOVERNMENTS and municipalities do not, and as a matter of fact cannot operate as economically as corporations. The most impressive example of this is the announcement of the Brazilian government that it desires to be relieved of the operation of its railroad system comprising some 14,000 miles, the object being to relieve the tax payers of a large annual deficit. William E. Curtis to the Chicago Record says:

"Government operation of railways, which is advocated by many people in this country, has not proved successful in Brazil, the chief reason being the difficulty of keeping politics out of the management. The Central road, for example, which used to pay nine per cent dividends, is now a burden upon the government to the extent of two or three millions a year, which is entirely due to politics and the employment of incompetent men for political reasons. The same is true of other railways, and, although they have been very important in the development of the resources of the country, it is believed by the wisest men that they would serve this purpose equally well under private management. In addition to the government system of 14,000 miles, there are about 4,000 miles under private management, most of which is subsidized. Several of these roads are paying good dividends; others, which have a six per cent guaranty, do not call upon the government for more than two or three per cent."

TORONTO after taking a popular vote three times, has now declared in favor of Sunday cars by the small majority of 479. The contest was keen, almost bitter, and public meetings during the week, and sermons on Sundays were employed to defeat the effort. Fortunately for itself, as for all concerned, the opposition failed to hold its own. We cannot overlook the strange inconsistency of many of the objectors to Sunday cars who see no harm in private carriages on the same day, although a carriage requires one servant to carry four people while the street car accommodates 50 and uses only two employes. It was not so bad in the old horse car days, but now with the rapid transit which electricity has brought it is positively sinful to compel the working classes to remain cooped up in a hot city during summer months, when for a few pennies they might spend several hours in the country. Provision certainly should be made, and generally is, for a division of the Sunday work so as to divide it as evenly as possible, and allow for a certain number of days off for rest during the month. By a singular coincidence the first Sunday the cars ran, the rain fell incessantly all day, so that the cars were largely used by church goers, sightseers and pleasure parties remaining indoors. The earnings of the first Sunday were donated to the city hospitals.

### STREET RAILWAY ACCOUNTANTS' ASSOCIATION.

The following circular letter has been addressed to all the street railways in the United States and Canada by the committee of the Accountants' Association which was appointed to consider the question of a standard system of accounts and kindred subjects:

ST. LOUIS, June 10, 1897.

DEAR SIR:—A meeting of some 40 gentlemen, representing many of the large street railway properties in the country, all interested in a uniform, comprehensive and economical system of accounting, was held in Cleveland, Ohio, March 23 and 24, 1897. A permanent organization was perfected known as the Street Railway Accountants' Association of America, the aims and objects of which are clearly defined in the copy of the constitution and by-laws enclosed herewith.

At the suggestion of Mr. H. J. Davies, of Cleveland, upon motion of Mr. E. D. Hibbs, of Jersey City, a resolution was unanimously

adopted appointing a committee to consider the question of a standard system of street railway accounting, covering the classification of operating expense accounts, classification of construction and equipment accounts and form of annual report, in a comprehensive and concise manner, which will enable the managements of the different roads to make quick and just comparisons, thus forming a uniform basis for the interchange of information between companies, when such is desired.

The committee was instructed to correspond with the officers of all street railways, earnestly request that for their mutual interest and good, they acquaint us with their methods and system of accounting, furnish us with a set of blanks and forms used by their companies covering the classification of operating expense accounts, classification of construction and equipment accounts and form of annual report, with the special request that they give us the benefit of their experience, help us with their advice and suggestions, to enable the committee to make such recommendations as they may deem advisable and proper, and report at the next meeting of the association to be held at Niagara Falls, October 19, 20, 21 and 22, 1897, when the report of the committee will be discussed and some action taken.

The committee desires to assure you that any information that may be given them, as well as all blanks and forms entrusted to their keeping, will be treated as strictly confidential and will not go outside of the three members whose names appear on this letter.

We trust that you are in sympathy with and heartily endorse the aims and objects of the Street Railway Accountants' Association of America, that if your company is not a member, you will have them join at once and be represented at the next meeting.

Your prompt and favorable reply will be gratefully appreciated by the committee and will materially aid and expedite the successful completion of the work assigned to them.

Relying on your co-operation and valued assistance, and thanking you in advance for any courtesies you may extend, we are,

Very respectfully,

C. N. DUFFY,

WM. F. HAM,

J. F. CALDERWOOD,

Committee.

Please address all communications to C. N. Duffy, 3800 Easton avenue, St. Louis.

Secretary Brockway, Toledo, reports a very gratifying number of inquiries regarding the association from roads which contemplate becoming members. During the past month the following have filed applications for membership:

The People's Railway, St. Louis.

St. Louis & Suburban Ry., St. Louis.

New Orleans Traction Co., New Orleans.

Lowell, Lawrence & Haverhill Street Railway, Lawrence, Mass.

The inquiries from eastern roads are especially numerous and leave no doubt as to a large additional membership soon, from that direction. The program for the October meeting is making excellent progress and will furnish information of the greatest value. Scarcely a road is so small it can afford to miss this work.

The good result in dollars and cents of the March meeting of the accountants, is already becoming manifest. One auditor wrote the secretary recently that he had already effected a saving to his road of \$70 in the two months since the meeting, as a direct result and application of one pointer he received at that convention. This is but the beginning of numerous improvements and economies possible in the accounting department as the scope of the association broadens.

W. C. Weaver resigned as travelling auditor of the Western Weighing Association to become auditor and assistant superintendent of the Northeast Electric, Kansas City.

## ELECTRIC TRACTION ON THE NEW YORK, NEW HAVEN & HARTFORD.

In the discussions as to the relative economy of electricity and steam on those roads which cover territory where a frequent and high speed suburban service is required it has been pretty well demonstrated that the advantage would without doubt lie with electricity were a new equipment to be installed, but that in many, perhaps most instances, the economy of operation over steam is not sufficient to pay the fixed charges on the capital invested in the steam equipment at present used and which would need to be thrown away. The question of the preference of the patrons of the line and the competition of trolley lines which will inevitably parallel the existing steam roads must however be

line between Hartford and Berlin which was officially opened on May 11, 1897.

This new section is the longest section of any railroad in the world, hitherto exclusively operated by steam locomotives, to be equipped for electric traction; the total distance is 12.3 miles divided in two parts; the first running from the power house at Berlin to New Britain, 3 miles, and the second extending from New Britain to Hartford, 9.3 miles. The road from Berlin to New Britain is single track; from New Britain to Hartford double track, the east-bound track only being devoted to electric service. In the operation of this road the electric trains will run from Berlin to New Britain and back. The trains from New Britain to Hartford and back will run as a separate service, the change of cars being made at New Britain.

TRAIN, MOTOR CAR AND PASSENGER COACH, N. Y., N. H. & H. R. R.

considered, and such a preference will compel the use of electricity on many lines where present economy would not justify the new installation, in order that future losses may be lessened.

The New York, New Haven & Hartford Railroad by reason of the small territory covered when compared with the mileage of the system and the very large ratio which its passenger traffic bears to the total was in a position to suffer from street railway competition, or if it were shown to be profitable to operate its lines electrically, to check such competition and retain the passenger traffic to the profit of its own stockholders. The conditions were realized by the management and the Nantasket Beach line was equipped electrically and put in operation in 1895. That section was 7 miles long and the following year an additional  $3\frac{1}{2}$  miles were equipped with the third rail conductor. The experience gained on this line has led to the adoption of the third rail for the electric

The train schedule is given in the following order of the company:

"Commencing on or about May 11, 1897, an additional express line will be put in operation between Hartford and New Britain for passengers without baggage, using electricity from a third rail. No intermediate stops will be made. Only special tickets specifying electric service will be accepted. The rate of fare upon the electric trains will be ten cents, subject to change without notice. No change in existing steam passenger schedule, service or rates will be made. Electric trains will leave Hartford and New Britain every twenty minutes.

"In explanation of the clause stating that only special tickets specifying electric service will be accepted, the management have decided that as this electric service is in the nature of an experiment, they should keep the two classes of service, steam and electric, entirely separate, and with that end in view, have decided that tickets, whether local, trip or commutation that have been issued for the regular steam service, in which there will be no change whatever will not be good or accepted on the electric trains.

"Passengers wishing to use the electric service will be required to purchase tickets, which will be collected before they enter the train.

No baggage, bicycles or express matter will be carried. Electric trains will leave Hartford and New Britain every 20 minutes, schedules to be issued later, but it is understood that they will start early enough in the morning to accommodate the business travel between New Britain and Hartford and will run late enough at night to accommodate theater or other evening parties."

The steam service consists of 8 trains per day each way between Hartford and New Britain and 14 trains each way per day between New Britain and Berlin.

The power station for the two sections is at Berlin the

BOILER SETTINGS.

extreme end of the line; it is the third built by the company and is known as No. 3.

Ground was broken on December 18, 1896, and on May 10, of this year the track construction and station were so far advanced that a successful trial trip was had and a car ran over the line into Hartford via New Britain.

The power station as built is of brick, 105 ft. wide and 113 ft. long. A little over one-half of the intended station has been erected; one end is of wood, which will be removed when the whole building, 200 ft. in length is built. The frame work and roof trusses are of steel, built by the Berlin Iron Bridge Company; heavy steel girders support the weight of a 35-ton traveling crane, thus relieving the brick walls of much stress.

A 26-in. brick wall extends lengthwise through the building rising to the peak of the roof, 60 ft. high. On one side of this wall, in front, is a heavy floor supported on iron beams, 14 ft. above the basement. On this floor is the engine room, the engine and generator foundations extending from the basement up to it. These foundations are about 30 ft. square and consist first of four feet in depth of stone work laid in cement in the ground, and on that is the foundation proper of brick grouted in Portland cement and 14 ft. high, each containing upwards of one half million bricks. The boiler room occupies the rear half of the building and contains no floor. This places the boilers somewhat below the engines. The roof is of Georgia pine covered with slate. A bow window with a small roof is on the front in which is placed the switch board. The brick chimney is an exceedingly massive one, 125 ft. high and 15 ft. in diameter, at the base. It is round with a curved overhanging top.

The engine room contains two 1,500-h. p. cross-compound condensing improved Greene engines 28 and 48 x 48 in., running at 100 r. p. m. Direct connected to each engine is a General Electric 850-k. w. generator. The dynamos are over-compounded and furnish current at 600 volts at no load and 650 volts at full load. The engine fly wheels are of cast iron in four segments and each wheel weighs 52 tons. The shafts with armatures and crank discs attached weigh 58 tons each. When the station is enlarged two more of these generating sets will be added, making 6,000 h. p. available. The switchboard is the General Electric standard heavy service railway board of black enameled slate. There are four generator panels, a totalizing or station panel for indicating and recording the entire output, and two feeder panels. All are fitted with Weston illuminated dial instruments. General Electric circuit breakers, switches and a Thompson recording wattmeter of 10,000 amperes capacity are used. In the basement are two large Deane condensers and a special system of valves and piping by which the engines may be run non-condensing if desired, or either side of an engine may be run without the other.

In the boiler room are installed 10 horizontal return tubular steel boilers, especially stayed and braced for high pressures, built by Edward Kendall & Sons, of Boston. These boilers are in two batteries of five each. Across the top of the brick settings of each battery, at right angles to the boilers are a pair of iron girders from which each boiler is suspended by four hangers, thus leaving them perfectly free to expand in any direction without coming in contact with the settings. The boilers are fitted with steam nozzles, from which 9-in. copper bends rise, turning an arc of 90° and connected with the main steam header through a heavy gate valve. These copper bends are seamless drawn pipes and were bent cold with heavy copper flanges brazed on. Embedded in the division walls between the furnaces of the different boilers are 6-in. thin iron pipes, four to each boiler, opening into the ash pits and extending up through the walls to the top of the setting. Here a brass ring per-

SWITCH BOARD, BERLIN POWER STATION.

orated on its lower side is placed and connected to the high pressure steam supply. This gives a circle of fine steam jets which blow down the pipes, drawing air with them, forming the system of forced draught. The necessity for

forced draught will be understood when it is known that the company does not burn coal in any of its power stations, but the cinders or sparks which have once been through the fire boxes of the steam locomotives and dumped from the extension fronts. Thousands of tons of these sparks are available and the saving in fuel is enormous.

The system for handling coal and ashes was made by the C. W. Hunt Company, of New York. It consists of two narrow gauge tracks running parallel to the boiler fronts

THIRD RAIL AT SWITCH.

one near the rear wall of the building where coal is run through holes into the coal cars, which hold one ton each. This track passes over scales where the coal is weighed and the car is then switched onto another track, passing directly in front of the furnaces. The coal is then shoveled directly from the car into any furnace requiring it. Ashes are conveyed in a small dump car running on the same tracks. All cars are pushed by hand. A Locke damper regulator is used to work the main damper.

All the piping, valves, etc., are standard extra heavy and correspond closely to that called for in all U. S. Government work. The main steam header to which the boilers are connected by the 9-in. copper bends is 20-in. extra heavy wrought iron pipe. This pipe is about  $\frac{3}{4}$  in. thick and guaranteed to stand a pressure of 250 lbs. per sq. in. It is divided into three sections by two 20-in. extra heavy gate valves weighing nearly three tons each. This header is supported on brackets bolted through the division walls and steel columns of the building. There are two primary and one auxiliary heaters through which the exhaust from the engines, condensers and feed water pumps passes.

The feed water is thus raised in temperature to nearly 200° F. before entering the boilers. Steam is supplied to the high pressure cylinder of each engine by an extra heavy 12-in. wrought iron pipe which leaves the steam header vertically through a 12-in. stop valve, and passing through the division wall bends downward through 90° to the throttle valve on the cylinder. The Holly gravity drip return system is used to return all condensation from steam pipes to the boilers. The engines, besides having the usual oil cups are also supplied with an extension automatic oiling system in which oil flows down from an elevated tank through a large number of pipes to each bearing or pin that needs oil. It then runs down to a filter in the basement, from which a small pump takes it and forces it up to the tank to be used again.

The third rail system of the company is remarkable for its simplicity and practicability. The question of leakage or of insulating a positive conductor carrying 600 volts from a negative ground return has been solved to the company's entire satisfaction.

The whole three rails have been submerged for a distance of 200 ft., and several feet of the third rail have been found lying in the mud. The loss in the first case was not serious and in last case only a few amperes. In dry weather there is absolutely no loss and none can be seen on the instruments when it is raining heavily.

The third rail is similar in shape and weight to that used on the stretch of track between East Weymouth and Nantasket Junction on the South Shore Branch of the Plymouth Division of the N. Y., N. H. & H. R. R. In cross section it resembles a flattened "A" and weighs 93 lbs. to the yard. It is laid on blocks of wood impregnated with insulating material, but not fastened to them. The blocks are only about one-half as high as those used at East Weymouth, allowing 1 $\frac{5}{8}$  in. from the cave of the third rail to the tie, and in some places only 1 $\frac{1}{2}$  in. This reduction in the height of the insulating block is due to the fact that no greater height could be allowed in view of the height of the service rails. The top of the third rail is about 1 in. higher than the level of the tops of the running rails. The conductors are bonded, not by the ordinary leaf or stranded copper bond, but by plates of sheet copper  $\frac{3}{8}$  in. thick, 12 in. long and 4 $\frac{1}{2}$  in. wide. These are fastened to the underside of the third rail joints by means of a drop-forged iron angle-plate bolted by 16 bolts, 8 for each copper plate, on each side of the third rail joint, the nuts being outside of the rail. Each bond has a capacity of 900,000 circular mils; the total bond at each joint having about twice the carrying capacity of the rail itself, while its measured resistance is less than an equal length of the 93-lb. third rail. One of the most striking facts in this installation is the absence of feeders, entire dependance being placed on the carrying capacity of the well bonded rail.

On the Berlin branch are four grade crossings; on the New Britain and Hartford line 18. At all of these cross-

TRUCK OF MOTOR CAR.

ings the third rail is omitted, the circuit being continued underground by two stranded bare copper cables of 500,000 c. m. and in some cases 850,000 c. m. These cables are first drawn into creosoted wooden conduits filled with an insulating material made of residuum and asphalt. They are then laid in creosoted wooden troughs, in turn filled with the same compound and then boxed over and buried. The broken ends of the third rail are fitted with wooden inclines or approach blocks to allow the shoe to rise upon the rail

without danger of catching and breaking. The service rails are carefully bonded with two very short bonds at each joint of 500,000 c. m. each, placed in the flange of the rail under the angle-plates.

The motor equipment will consist at first of five motor cars. These are open cars 50 ft. in length used last season at Nantasket but deprived of the trolley. Each car weighs about 32 tons. Each is equipped with two G. E. 2,000 motors and two "L" series parallel controllers. The car cut-out is a "K" automatic circuit breaker fixed beneath the hood. Each motor car is fitted with air brakes, two gongs and a chime whistle. Air for the brakes and whistle is furnished by a vertical double cylinder air pump driven by a motor automatically controlled by special switch which is opened when the pressure in the main tank reaches 90 lbs. and closed when it falls below that. These motor cars pull a standard combination baggage and passenger coach as a trailer.

Contact is made with the third rail by means of sliding shoes. These are of cast iron, 12 in. long and 4 in. wide, weighing about 20 lbs. They are suspended by two links from a casting fastened to a beam set immediately beneath the king pin of each truck, connection between motor and shoes being made by flexible cables. The distance between the two shoes is about 33 ft.

Many of the grade crossings are wider than this and to avoid carrying the train over the crossing by momentum another shoe is fitted to each truck of the second car of the train, a connection running from this shoe to the motors. Thus, by the time the last shoe has left the third rail at one end the first shoe is in contact with the next section of the rail.

The question of the safety of the public was not the least important which demanded the attention of the officials of the New Haven Road and the greatest precautions are taken. At the Berlin and Hartford stations, the third rail section is fenced in on both sides. At New Britain, where the lines of the New Haven and New England systems converge, in addition to the fence, a method which almost amounts to interlocking is adopted. In the Y formed at the convergence of the roads is the switchman's tower. From the section of the rail entering the station cables run underground to a switchboard in the tower, by which the third rail may be connected to or disconnected from the circuit. As the train comes to a stop in the station, the third rail is cut out, and is not thrown into circuit again until the outgoing train is ready to start. The chance of accident is thus reduced to a minimum.

The entire work was carried out under the direction of Col. N. H. Heft, chief of the electrical department of the company.

### OHIO STATE MEETING.

President A. A. Anderson announces the annual meeting of the Ohio State Tramway Association will be held at the Chittenden Hotel, Columbus, on Monday, June 14, and desires a large attendance. Timely topics will be discussed and the local members hope to welcome at least one representative from every road in the state.

The work of cast-welding by the Falk process of the Union Traction lines, Philadelphia, is under way.

## ACCUMULATORS.

### Their Application to Central Station Lighting and Power.

(Read before the Canadian Electrical Association, by W. A. Johnson.)

Considerable misconception seems to exist in reference to the cost of installing a storage battery. Like all good things having value, accumulators are not given away, and the station manager who is waiting for them to get cheaper is letting one-third of the earning power of his station go to waste. Local conditions of course determine the capacity and consequent cost of battery, but in general terms, the cost may be stated to be less in most cases than the cost of generating plant.

When it is desirable to increase the capacity of a station, it means besides new dynamos, increase in engines, boilers and all steam appliances, and usually alterations in the building, and while the output of the station is increased, the general efficiency remains about the same, and oftentimes the running expenses of a moderate sized station is greater per h. p. output, owing to the increase in the working staff.

On the contrary, to increase the capacity of a station with accumulators requires as a rule no alteration or increase of existing steam plant, no new dynamos, and usually, owing to the small space required, plenty of room can be found in the station for the storage battery.

When such a change can be made, what are the results? The available output of the plant has been largely increased. No increase in working staff is required. The operating expenses are no higher than before. The all round efficiency of the station is fully 30 per cent more, and consequently, the profits are enlarged by nearly the same proportion. The plant can thereafter give uninterrupted service, 24 hours per day, every day in the year, as the battery is always available when a temporary shut down of the machinery is necessary. The regulation of the voltage to the lamps is kept constant, more perfect than can be possible when no batteries are used, as the battery is a regulator to the whole system. When motors are operated, this is a big advantage.

No gas company would, for a minute, consider the operation of its plant without a storage tank; just think of the large increase in retorts and men to keep up a constant gas supply, without a storage tank. Most waterworks systems require a reservoir, and yet electrical people, who are supposed to keep abreast with the times, try to get along without a storage tank to fall back upon for hours of maximum, minimum or average demand.

The central station manager will answer that he does not know the cost of maintenance and is waiting for the other fellow to prove the case. The other fellow has proved it. In Germantown, Pa., there has been a battery having a capacity of 120 h. p.-hours, in use for over three years, or long enough to give a fair idea of the cost of renewals. The management of the large stations in Boston, Brooklyn and New York, however did not await the results in Germantown, but put in large batteries from one to two years ago, and these have since been doubled, and in one case, enlarged for the fourth time.

But interested parties can go back of the returns from the United States for further evidence of the practicability of accumulators. In Germany, France and England, they have been largely used for years past. Out of a recently published list of thirty cities in Germany, only ten are without accumulator plants. The population of these cities ranges from 4,000 to 350,000. This shows that there is hardly a town or city electric plant but can use accumulators to advantage.

I mention the following among American companies who have put in large batteries and the capacity installed as rated in h. p.-hours:

COMPANY.	H. P.-HOUR CAPACITY.
Hartford Electric Company.....	3,000
Boston Edison Company, four batteries, a total of.....	7,400
New York Edison Company.....	3,200
Brooklyn Edison Company.....	1,600
Germantown Electric Light Company.....	300
Electric Railway, Light & Power Company, Anaconda, Mon.,	500
Woonsocket Electric Machine & Power Company.....	400
Easton (Pa.) Edison Company.....	200

These last three plants are used both for railway and lighting work. As good an illustration as I can give of the application of the storage battery to railroad work is to refer to the equipment of the Union

Traction Company of Philadelphia, which uses a battery of 400 h. p. hours for keeping up the pressure at the end of a feeder at a point about 11 miles from the power house, the new extension continuing several miles beyond; in this case the battery took the place of a new power house or what amounted to the same thing, an increase at the old power house with enlarged feed wires. It was found that the cost of copper feed wire to operate from the main power house, alone, would have cost four times the total cost of the battery. Previous to the installation of the battery, the pressure at the end of the feeder formerly in use, frequently varied as much as 50 per cent, the battery however gave practically a steady pressure at all times. Railway men need not be told how much better for their motors and controllers the maintenance of a standard working pressure is, than one which falls so low as to require an increase in the current passed through the apparatus, of from 50 to 100 per cent. In the above case, the load varied from 100 to 700 amperes, and with the feeder of a capacity at a constant load for 400 amperes, the demand upon the power house was at all times equal and independent of the changeable load on the batteries.

Under such an arrangement, the power house generator always operates at full load and highest efficiency and the battery acts as a cushion to the engine when the line circuit breaker opens from any cause.

Some of the electric street railways in Canada, serve a district up to 7 miles from the power house, as originally laid out, and in all cases extension will be called for to reach suburban points at a greater distance and to connect through as radial lines to still more distant points. In such work, the accumulator plant at the end of a feeder is destined to be an important factor in the near future, and the little trouble in operating a sub-station for this work is very satisfying to the purchaser, as the battery is automatic in charge and discharge, the only attention required being the usual occasional testing of the e. m. f. of the individual elements and the keeping of the electrolyte to the standard specific gravity (1.200). The sub-station apparatus and connections are very simple, being only the main switch, ammeter, circuit breaker, voltmeter and recording voltmeter. The flow of the current to the line being always proportionate to the demand. One central station can therefore take care of any number of accumulator sub-stations, and the area which can profitably be covered with continuous current either for railroads, lighting or power greatly increased.

The claim has been made, and experience seems to prove it true, that it costs practically nothing for the energy stored in accumulators in the average lighting, power or railroad station, whether operating on a 12 or 24 hour basis, as, if judgment is used in proportioning the size of the battery to the generating plant, the battery is always being charged during light load and discharged during hours of heavy load, and owing to the all round higher efficiency, the amount of coal burned will be about the same and the current given off from the batteries will represent net profit.

While the above is a simple way of putting it, the following gives in figures the actual conditions obtained in a plant now working.

Total time of operating steam plant 9 hours.	
Total steam plant required, dynamos working at an efficiency of 90 per cent.	93 h. p.
Total steam plant required if battery is not used.	165 h. p.
Saving in steam plant.	72 h. p.
Total dynamo capacity required when using battery.	62,500 watts.
Total dynamo capacity required without battery.	111,250 "
Saving in dynamos.	48,750 "

In this case the battery was in service a total of 18½ hours and during 15 hours the battery served the entire plant.

In making provision for a storage battery the room provided should if possible have a cement or tile floor, and should be well ventilated. Owing to the compact form of the elements, sufficient room can usually be given when arranged in tiers, one above the other. The space required for a battery capable of giving 400 h. p. for one hour, is 14½ by 20½ inches per element and as 248 cells would be used on a 500-volt system only about 630 square feet would be necessary, this being for a battery of fairly large capacity, in fact being equivalent to that installed by the Union Traction Company in the before mentioned instance.

A suitable battery having been purchased it requires as careful attention as is given to any other class of electrical or steam apparatus, and no more, and yet this attention is very simple, but it must be given as required, otherwise the results would be similar to that caused

by neglect of a dynamo or steam boiler. There has been no instance where a properly constructed battery that has received fair treatment has failed to give good results. Attention should be paid to the proper strength and nature of the acid, the specified gravity of the acid being tested at regular periods; the individual testing of each cell by a low reading voltmeter is the keynote to successful battery operation. While in general the reading of the voltmeter connected with all the elements will give sufficient information, yet the occasional individual testing of each element prevents any single cell from being allowed to work at a disadvantage. The chloride type of negative plate has been found to be most satisfactory, and is largely in use for central stations. The positive plates generally used with chloride negatives are of the Tudor type, and are capable of giving a very high discharge, their capacity being at nominal rating from 3 to 5 ampere-hours per pound of element. Such a battery is not liable to buckle or sulphate. There are numerous small water-powers that have not been considered as applicable to electric lighting owing to the small power available, but if 20 h. p. can be obtained for 24 hours per day and if a battery is used in connection therewith, 120 h. p. is available for four hours, or sufficient for the requirements of a fair sized town. I know of one instance, in a town of from 8 to 10,000 inhabitants where a water-power of 50 h. p. is available, and not used at present. This power if stored in batteries would give 200 h. p. for six hours, or sufficient to supply all the street, commercial and residential lighting which is now operated by steam.

## THE CHICAGO CITY RAILWAY POWER HOUSE.

Commenting on the controversy between R. J. Hill, chief engineer of the Chicago City Railway, and Pierce, Richard-son & Foster, the Chicago engineering firm, in regard to the new power station, Power, editorially, says in part:

"It is to be regretted that these engineers did not rise to the occasion and furnish a comprehensive analysis of the present and what may be termed the modern plant, as adapted to the case in hand, instead of dealing principally with the details of piping, the class of boilers used, the advisability of an economizer, etc., questions which would apply equally to either plant. They say little in detail upon the main issue as to the comparative efficiency of the two classes of plant, but arrive at the following conclusions:

"First. That a plant of the same capacity could have been installed in about one-third the space.

"Second. That such a plant as we have outlined (a compound condensing direct connected plant) could be operated at anywhere from 25 to 50 per cent greater economy in fuel.

"Third. That a great saving would have resulted in the first cost of land, foundations and buildings, which savings would have largely, if not entirely, offset any increased cost of machinery due to using types better adapted for your needs.' \* \* \* \*

"If on the other hand, Mr. Hill is correct in his estimate that a compound condensing direct connected plant, land and buildings included, would have cost \$600,000 (as against \$345,000 for the present plant) he appears to be justified in his selection of the cheaper machinery with fuel at the price given, inasmuch as his costs of operation, labor, repairs, etc., will certainly be no more with the simple station. If fuel cost nothing, one would buy the cheapest kind of an engine that would run his work without regard to its efficiency.

There is evidently a price for fuel so low that the increased efficiency attainable by a high-class engine is not sufficient to pay the fixed charges on its increased cost. Whether Mr. Hill is within that limit with coal at \$1.10 a ton and the present price at Chicago of real estate and machinery, is a question which only a careful analysis of figures not at our command can predetermine and only the future can demonstrate. The several costs of operation of the station aggregate .6385 of a cent per kilowatt-hour. Will our readers in compound condensing direct connected plants send their costs for the same items for comparison?"

The Suburban Railway, of St. Louis, is said to have obtained control of the Houseman air line, parties interested in the Suburban having purchased the bonds of the latter.

**GAS ENGINE AT LANCASTER, O.**

In connection with the article on "Gas Engines," by W. F. Kelly, which appears on another page, a description of the engine of the power plant of the Lancaster (O.) Traction Company, of which Mr. Kelly is president, will be of interest. This company operates from three to five cars over about four miles of track, and as there are some long eight per cent grades it is readily seen the conditions require an engine which is above all capable of close regulation.

Feeling that the cost of operating a steam plant would be so great as to be prohibitive for a small road under the conditions at Lancaster, the management decided that the gas engine was the only alternative. With no precedents to follow, and even with no gas engine of sufficient size on the market, Mr. Kelly entered into negotiations with the Western Gas Construction Company of Ft. Wayne, Ind., which agreed to build a suitable engine. It was installed in the summer of 1896, and after a few minor difficulties, due to the fact that the machinery was new and that the engineer was without experience with gas engines, had been overcome, the engine was put in successful operation, and for six months has been running without any delay or interruption whatever, and has demonstrated its ability to handle the rapidly fluctuating load of a street railway.

The engine is shown in the illustration. It is known as the American Kilmarnock, and is a single-cylinder double-

acting engine. It develops about 130 indicated h. p., and gives at the brake 110 h. p., being rated at 100 h. p. It runs at 180 r. p. m., and is belted to an 80-k. w. Thomson-Houston 6-pole generator.

The general dimensions are as follows: Cylinder 16 in.

LOAD DIAGRAM, LANCASTER, O.

by 20 in. stroke. Diameter of piston rod, 3 in. Diameter of shaft, 7 in. Diameter of fly-wheels (two), 8 ft.; face, 16 in.; both faced for belts. Length of engine over all 15 ft. 11 in.; width over fly-wheels, 6 ft. 10½ in.; height of center line above foundation, 3 ft. 5 in. The total weight of the two fly-wheels is 13,500 lbs.; the total weight of the engine, 34,000 lbs.

The cross-head is of cast steel, and the bearings through-

GAS ENGINE AT POWER HOUSE OF LANCASTER TRACTION COMPANY.

LOAD DIAGRAM, GAS ENGINE PLANT, MARIETTA, O.

out of phosper bronze without habit. Porcelain ignition tubes are used. The starting device is positive in its action, natural gas under high pressure being used. The governor is an electrical one and very sensitive, being guaranteed to regulate within two per cent. The load varies from zero to 180 amperes, and the time required to find the point of equilibrium is but one-sixth of a second.

The load diagram shows the heavy fluctuations. It should be remarked the heavy drops in voltage are due to an overload rather than to poor regulation. The gas consumption is given at 16 cu. ft. per brake h. p. per hour.

There are installed in the plant of the Marietta (Ohio) Electric Company two engines, also built by the Western Gas Construction Company. One is of 130 and one of 90 h. p., both belted to a jack-shaft. The generators are one 100-k. w. Walker and one 100-k. w. Stanley alternator. The lighting and railway loads are taken from the jack-shaft, and although it has no fly-wheel the incandescent lamps do not show the effect of the varying railway load. These engines are similar to the one at Lancaster, but compressed air is used for starting.

## THE BOSTON ELEVATED.

It is probable that Boston will have an elevated road at least 10 miles long. A bill granting a charter to the Boston Elevated Railway Company has been passed by the Massachusetts House. Four of the 10 miles to be built at once or a forfeit of \$500,000 paid, and the remaining six miles must be constructed within the coming three years; the tenure is for 25 years. One amendment to the bill provided that the line should be considered as a railroad instead of a street railway.

## MUST PAY SUBSCRIPTIONS TO STOCK.

When the road to Westerville from Columbus, O., was planned a subscription of \$35,000 was made by local capitalists but only a part of it paid in. When this line was merged into the Columbus Central Railway suit was brought by the latter company to collect the outstanding subscriptions. A test case was brought against J. M. Dumm and a verdict for the company resulted. It is expected that the rest of the \$12,000 not yet paid will be received as the result of this suit.

## A RAILWAY BUILT IN A NIGHT.

The Suburban Railroad Company of Chicago has been desirous of laying track through Riverside, connecting Harrison and West 48th street with the Desplaines river. The citizens of Riverside did not look with favor upon this proposal and an injunction was secured restraining the railroad company from using the streets of the town. This injunction expired June 8, and the very minute the legal restraint terminated 500 expert trackmen began work with a will. All night long they toiled, and before 10 o'clock in the morning five miles of track, with trolley wire and all connections, were ready for the trolley cars. When the residents started to their places of business in the morning they were surprised to see "clanging, sputtering trolley cars flying through the village."

W. B. Bradbury, a San Francisco millionaire, was sentenced to 2 1/2 hours imprisonment in the county jail for expectorating on the floor of a street car. It was his second offense.

## REPAIRS ON THE LIVERPOOL OVERHEAD RAILWAY.

There are several essential features in which the equipment of the Liverpool elevated railway differs from that on the Chicago elevated roads. As may be noted from the description and illustrations in the REVIEW of March, 1893, the motors are mounted directly on the axles of the trucks with no gearing whatever. In regard to these motors S. B. Cottrell, engineer and general manager, says, "I consider that the gearless motor is better for our work than a single reduction motor. The cost of repairs to motors is trifling compared to what the cost of repairs of locomotives would be to work a similar service. To effect repairs the wheels and axles are taken out of the truck frames and there

## STREET CAR FOR FIRE ENGINES.

The Wason Manufacturing Company of Springfield, Mass., has recently completed for the Springfield Fire Department the truck car which we illustrate. It is designed to furnish a quick and convenient means of transporting fire engines to the outskirts of a city and to all points reached by street car lines where the engines may be needed. The car consists of two four-wheeled diamond trucks of the ordinary pattern but of a somewhat lighter construction than those used on steam roads, which are surmounted by platforms on which the men can ride with hose, tools, etc., and connected by girders from which is suspended a platform to carry the fire engine. The side girders are built up of two channels separated by suitable distance pieces, and are permanently

STREET CAR FOR FIRE ENGINE—SPRINGFIELD, MASS.

is no difficulty in repairing the armatures on the axles. I do not see that there is any more trouble with the failure of armatures with gearless motors than there would be with geared motors. I do not think that either gearless or geared motors make any difference to the track joints as the blow in either case must be the same."

There is one motor to each car and when two or more cars are in the train there is electrical connection between the cars so that all the motors can be controlled by the motorman at one point. The cars are never run singly except for shunting purposes and all the cars are electrically connected and interchangeable.

The third rail consists of a steel channel, 4 sq. in. in cross section, mounted on porcelain insulators. The surface is about 1 in. above the surface of the track and is in the middle instead of on the outside. In favor of this practice Mr. Cottrell says, "The conducting rail should be, wherever practical, put in the center as we have done here, for we find no difficulty with it even at complicated crossings, whereas, placing at the side and higher than the running rail, would offer many complications at cross-over roads."

attached to the rear platform and connected to the bolster of the front platform so that the fastenings may be quickly loosened and the front truck removed to permit the engine to be backed into place. Suspended from the upper girders and strongly braced are beams 13 ft. long built up of channels of lighter section; these clear the rail by 6 in. The engine platform is of timber, the planks running transversely and resting upon the lower flanges of the inside channels.

As mentioned above one end of the middle platform is lowered to the ground and the front truck run out of the way when it is desired to load an engine onto the car. The mechanism for raising and lowering is very well shown in the illustrations. At each girder are two chains passing over windlasses, and all four of these are given uniform motion by means of a worm and pinion gear, operated by the rod and hand wheels on the front truck. When the girder end is lifted into place in the U which receives it, a bolt is slipped in which relieves the stress on the chains. A winch operated by the hand wheels on the rear truck is used to draw the engine onto the car.

The truck weighs about 12,000 lbs. and the heaviest fire steamer in Springfield weighs 10,000 lbs., so that the car loaded will weigh about 11 tons. No motors are provided on the car and it is the intention to draw it by one of the snow plows of the street railway company which will be housed next door to one of the engine houses of the fire department.

A drill in handling the new car was held on May 6 and demonstrated that very quick work could be done. Beginning with the car standing on the track, the pins were pulled, the platform lowered, the front truck detached and pulled out of the way. Then the engine was backed in front of the platform and drawn into place, the truck run back and connected ready to start. The time required was 2½ minutes. The unloading was accomplished in ¾ of a minute

and the commutator cleaned. The brushes are in duplicate and those not in use are put in a case each compartment having the number of the motor upon it. In this way the same brushes are returned to the same commutators and little trouble is experienced from sparking.

One time the brushes are soaked for one hour in liquid vasoline and the next time in paraffine, heated to the melting point. The vasoline is the better lubricant but its low melting temperature sometimes causes the brushes to run dry when an excessive current heats them. The paraffine wax is not so liable to cause such trouble.

Some inspectors and electricians are disposed to send the armatures into the shop and have the commutators turned down too often. Especially is this undesirable with some of the older styles of commutators as there is little depth to

STREET CAR FOR FIRE ENGINE—SPRINGFIELD, MASS.

and the horses attached and the engine ready to start in ½ minute more.

We are indebted to the Wason Manufacturing Company for the illustrations.

### CARE OF COMMUTATORS.

To get a smooth, shiny dark brown commutator on each motor is the aim of every street railway electrician. In many cases this seems almost impossible and is doubtless due to the inherent defects in the design of the motor. Again, poor carbon brushes, which wear unevenly will cause bad commutators. When the apparatus is of some standard make and all the parts are thoroughly reliable some other cause must be sought for. If the brushes are held in place with the proper tension the source of trouble is probably the lubrication of the commutator. Some lubricants will carbonize and form a tough gummy covering on parts of the commutator and such lubricants should be avoided. At the car barns of the Calumet Electric Railway the brushes of each motor are removed every night

the bars and a few turnings will cut them through. When the brushes are removed a touching up of the rough or high places and replacing the same brushes in the same brush-holders from which they came will gradually wear the commutator smooth and even. In one case where economy was imperative, by this method the commutators on some motors were used until the bars were worn down to 1-16 in. On one large city system the practice is to inspect the commutators every other day and remove the brushes once in six days. The brushes are placed in a perforated can and soaked for four days in machine oil. The can of brushes is then lifted out of the oil bath and the oil allowed to drain for two days. No sand-paper whatever is used for it is claimed that the smooth finish on the brush which comes from contact with the commutator is better than can be attained by any other means and a sand-papered brush will blacken the commutator more or less. Under this system the carbon brushes are good for 30 days service, and the commutators are turned down 1-8 to 3-16 in. once every 13 to 15 months. The commutators have a smooth finish and little trouble is ever experienced with them.

On the suburban roads, although consuming less current than the city lines, the trouble with commutators is more pronounced. This is incident to high speeds where any defect in the commutator causes a jumping of the brushes and excessive sparking. The greater demand for current on the urban lines is largely due to the greater traffic and the frequent stopping and starting but the speed of the commutator is moderate at all times. The commutator is regarded as the weak part of the street railway motor, yet cleanliness, good lubrication and using the same brushes on the same commutator and in the same position will go far in removing all trouble from this source.

### CUSHION CLEANER AT CHICAGO CITY RAILWAY SHOPS.

The Chicago City Railway has recently completed at its shops a mechanical cushion cleaner which effects the desired

blade is bolted. The blades are of hickory 4 in. wide and 24 in. long steamed and bent to conform to the outline of the cushion top; they are slit back as far as the butt-piece, making three fingers 1½ in. wide to each blade. The paddles are kept properly spaced along the shaft by sleeves made of pipe.

When engaged by the cam the paddle is lifted until it stands at an angle of about 80° with the horizontal and then released, when it is drawn by a spring connected at one end to the butt-piece and at the other to the floor, giving a sharp blow upon the cushion; the intensity of the blow can of course be regulated by the tension of the spring. These springs are of ¼-in. wire 2 in. in diameter and 13 in. long.

The cushion frame is 32 in. by 11 ft. 2 in. outside and 17 in. by 10 ft. 5 in. inside; it is hinged to the main frame and when a cushion is to be put in place or removed the frame is dropped as shown in one of the illustrations. When horizontal it is held in place by the two props hinged to the

CUSHION CLEANER—CHICAGO CITY RAILWAY.

object in a manner entirely different from that employed by other cleaning apparatus with which we are familiar. It is a beater operated by power, and is very well shown by the illustrations.

The frame supporting the mechanism is of timber 16 in. wide and about 13 ft. long. At one end is a bracket to support the driving wheel and clutch. The top of this is frame is 38 in. above the floor, to which the legs are firmly fastened. In this frame are mounted two 1¼ in. shafts supported in bearings, 32 in. between centers. To one are attached 20 cams of 2¼ in. throw; they are fixed to the shaft 6 in. apart and spaced 18° apart angularly, so that the extremities of the maximum radii lie in a helix. On the other are pivoted the beating paddles, 20 in number and each actuated by a separate cam. The paddle consists of a blade and a cast iron butt-piece in the center of which is a sleeve slipping over the shaft; on one side is a finger which the cam engages and on the other flat lugs to which the

front edge; ropes leading to counterbalances are attached at the corners to facilitate raising and lowering this frame.

A cover of galvanized iron is placed over the beater and connected at one end by an 8 in. pipe to an exhaust fan, thus carrying all the dust to some convenient place, in this case to the boiler furnaces. The joints between the casing and the cushion frame are provided with gaskets of rubber tubing and all the large openings are closed so that the greater part of the air entering the case is drawn through the cushion itself, preventing the dust from settling. Doors are provided for reaching the mechanism with ease.

Experiments showed that the best results were obtained when the paddles struck 50 blows each per minute, and that four minutes in this machine was ample time to clean the dustiest cushion. The driving mechanism and automatic clutch for stopping the machine after the four minutes or 200 revolutions of the cam shaft is well shown in the illustration. The cam shaft is extended beyond the casing and

carries a clutch, a loose pulley and a worm which gears with a brass wheel having 200 teeth. On the side of this wheel is cast an annular projection  $10\frac{1}{4}$  in. in diameter which is continuous except for about 1 in. When the machine is not working a lug or toe on the foot lever rests in this slot. By pressing down on the foot piece the lever is pulled down, disengaging the lug and at the same time throwing the clutch in gear; during the revolution of the large gear the lug rests on the exterior of the projecting ring until the slot returns to its original position, when a spring throws the lever back and disengages the clutch, stopping the machine.

It is found that with this machine one man can thoroughly beat 12 cushions per hour, that is, 96 cushions or 24 cars per day, where formerly two men beating them by hand cleaned the cushions for but 6 cars. The machine thus replaces seven men and does the work better than they possibly could. While built as an experimental device it has proved to be such a success in practice, that C. E. Moore, the master mechanic of the company, who designed it, will make application for a patent and the machines will be placed on the market. It is almost needless to point out that it can be built for any size cushion.

## GAS ENGINES.

By W. F. Kelly, General Superintendent Columbus (O.) Street Railway.

(Read before the Engineers Club, Columbus, O.)

Like all great inventions, the modern gas engine is the product of the long continued labors of many minds. For two centuries the scientific minds of the whole enlightened world sought to harness flame and gas and make them subservient to the use of man. Until the last quarter of the 19th century, the history of their efforts is one long record of struggle, failure and disappointment. What was apparently simple in theory presented innumerable difficulties in practice. Each time, when success seemed almost certain their hopes were dashed by failure. This failure was due not so much to wrong theory, as to crude and imperfect mechanical design. Each inventor in turn, profiting by the experience and failure of his predecessor, added an improvement here and there, until a practical working machine was evolved. Since that time, development and improvement have gone rapidly and steadily onward, until today, this young giant is a formidable rival of the steam engine and electric motor.

A consideration of the modern, successful gas engine would be incomplete without at least a brief reference to the earlier types. The character and limitations of this paper will not admit of an extended review of their merits and defects, as their chief value to us is in showing by what a long and arduous struggle the present types were produced.

As early as 1680, Huygens proposed using the explosive force of gunpowder as a motive power, and made a series of experiments to that end.

In 1690, Papin, a noted physicist, continued the experiments of Huygens, but instead of burning the powder directly in the cylinder, it was exploded in an auxiliary cylinder, which forced the air out, and on cooling a partial vacuum was produced, which communicated motion to the crank.

In 1704 the first real gas engine was invented by Streets. In this an iron cylinder was heated by fire; turpentine was then dropped in and vaporized by the heated cylinder; air was admitted, mixed with the vapor and the mixture ignited.

In 1823 Brown designed a 3 cylinder vertical engine, in which a flame was used to produce a vacuum instead of steam. Into the cylinders, having a movable cover, was introduced a mixture of gas and air, which was ignited, the air expelled and a partial vacuum produced. By varying the time of these events in the three cylinders, motion was communicated to the crank-shaft. This engine is interesting as being the first gas engine to do real work. A boat was constructed and operated for a short time on the Thames river, and a car-

riage was propelled through the streets of London by an engine of this type.

In 1833 Wright's engine was invented. It used an explosive mixture of gas and air acting directly on the piston; was double acting and water-jacketed, a distinct advance over the then existing types.

In 1838 Barnett added an improvement to the Wright method, by first compressing the gas in the cylinder and using a flame for ignition; which method with some modifications, is essentially the method in use today. He also arranged that ignition of the explosive charge should take place when the engine is passing its centers. The ignition cock by which the charge was fired was exceedingly ingenious, and was in use on many engines until quite recently.

In 1855 Newton improved on the method of Barnett, by igniting the charge by contact with a red-hot closed tube instead of by an open flame. This method is still in use on a number of gas engines today, and in many respects is the most satisfactory and successful yet devised.

In 1857 Barsanti and Matteucci, Italian scientists, designed a type of engine radically different from any yet invented. There were no connecting rod, no guides and no cranks. The piston rod was a rack, acting on a pinion attached to a shaft. The explosive mixture was ignited, the piston forced upward by the expansion of the gases. In falling the rack communicated motion to the shaft.

After more than a century and a half of experiments, no successful gas engine had yet been produced; all of those above mentioned never having gone beyond the experimental stage.

To Lenoir must be given the credit of inventing the first gas engine ever actually introduced for public use. It contained nothing especially novel in design, but more nearly resembled an ordinary high pressure steam engine, with sliding valves to admit gas and air and exhaust the products of combustion. An electric battery was used in igniting the charge. His success was due to a careful working out of the mechanical details, rather than to a superior knowledge of design and construction of the engine. The Lenoir engine was very extravagant in gas consumption—consuming fully five times as much per horse power as the modern type; and yet it was very smooth in operation; there was no noise of explosion, and the accounts published at that day of its operation, state that it was as silent as the best steam engine. A report of 1865 says that 300 or 400 engines, of from  $\frac{1}{2}$  to 3 h. p., were in use in Paris at that time. The Reading Iron Works Company, of England, completed and delivered one hundred engines of this same type. They were used for pumping, in printing offices, bakeries, stone yards, etc.; and some of them have been working more than 20 years and are still in good condition.

In 1867, Otto and Langen, German engineers, reduced to successful practice the theories of the earlier inventors. Their engine was identical in principle with that of Barsanti and Matteucci. They succeeded by the most careful attention to the details of mechanism, where the Italians failed on account of crude plans. This engine was noisy and crude in design, but was vastly superior to the Lenoir engine in gas consumption, requiring less than one-half the amount of gas to produce the same power.

In 1873, Brayton an American inventor, produced an engine which was in many respects better, mechanically, than the Otto and Langen engine, but not economical in gas consumption. Owing to the then high price of illuminating gas and the low cost of coal, there was no demand for an engine of this kind.

The year of our American Centennial marks the appearance of the first gas engine which is nearly like the modern type. It was in every way so far superior to anything that had been produced up to that time, that it was considered as the first successful type of gas engine in America. This was called the Otto silent engine, presumably because it was much less noisy than the earlier inventions. The design was adapted to the use of a cycle, described by De Rochas in 1862, but which was afterward and is now known the world over as the Otto cycle. This engine had improved ignition valves, more perfect mechanical details and governing device, and was noted for its high economy, yielding as it did an indicated horse power on 20 cubic feet of gas. Since that time over 15,000 engines of substantially this type have been manufactured. To the patience and persistence of Otto must be ascribed the success of the modern gas engine. To him more than to any other inventor is due the credit of having made possible the many existing styles of engine now using what is known as the Otto cycle. Strangely enough, Otto attributes his success to the comparatively slow explosion of the

mixed gas in the cylinder rather than to the compression of the charge before ignition.

Turning from this brief historical sketch it is well to consider, briefly and simply, avoiding as far as possible technical features, the theory upon which the gas engine operates.

Gas engines may be divided into three types:

1. Engines igniting at constant volume, but without previous compression.
2. Engines igniting at constant pressure, with previous compression.
3. Engines igniting at constant volume, with previous compression.

Of these three types the third is the best known and most extensively used, and is generally known as the compression type; all the principles being embodied in the well known Otto of today, requiring four strokes to complete a cycle, or not more than one explosion for every two revolutions in the case of the single acting engine.

The steps of the cycle are:

1. Drawing in the charge of gas and air in such a proportion as to give complete chemical union when ignited.
2. Compression during return stroke up to a pressure as a rule of about 60 lbs. per gage.
3. Ignition at dead point when pressure instantly rises to about 100 lbs. per gage for the above compression; also, the temperature to about 2,880° F, estimated; the pressure produced by the explosion depends upon the amount of compression as well as the proportions of the mixture. This ignition is immediately followed by the expansion of the gas for the third stroke, the pressure at the end of the stroke falling to about 25 lbs. per gage.
4. Discharge of the burnt gases from the cylinder during the fourth or last stroke, thus completing the cycle in four strokes or two revolutions.

For complete tests made in 1882 on a 6-h. p. Otto engine by Dr. R. H. Thurston, the disposition of 100 heat units was found to be as follows:

Work indicated in cylinder.....	17.
Heat lost to cylinder walls and carried away by jacket water....	52.
Heat carried away by exhaust gases, (temp. 750°F).....	15.5
Heat lost by conduction and radiation.....	15.5

The actual indicated efficiency was 17 per cent, but with more recent developments the absolute efficiency has been raised to 28 per cent, partially due to increasing the compression.

The most important mechanical features about gas engines are the starting, oiling, igniting and governing devices.

In small engines the starting device is not necessary, as they can be readily started by hand, but in the larger units the failure or partial failure of any one of these features usually results in unsatisfactory service.

The bearings, shaft, connecting rod, bed plate, etc., are not difficult to construct and can be as readily made as the corresponding parts of steam engines.

The question of lubrication is much more difficult. The temperatures in steam engine cylinders are comparatively low, steam is readily condensed into water and lubrication becomes a very simple matter. In the gas engine the temperature in the cylinder at the moment of explosion is probably not less than 2,500 degrees. The oil is instantly vaporized and a fresh supply must at once be admitted; otherwise, there are large friction losses, and cylinder and piston are quite likely to be seriously cut or scored. If animal oil is used, carbonaceous matter is likely to accumulate in large quantities and prevent proper lubrication. Nothing but the best grade of oil, especially compounded for gas engine use, will give satisfactory results for internal lubrication. The various bearing, not exposed to undue heat are of course, lubricated in the usual manner.

Much time and attention has been given by various inventors to a suitable governing device. While the present mechanical device answers very well for mill work or other work where close regulation is not necessary, for electric work an electro-mechanical governing device seems absolutely necessary. Slight variations in speed by means of a multiplying lever make and break an electric contact, which controls the current flowing through an electro-magnet, which in turn controls the gas admission valve. This device is exceedingly sensitive and governs the engine very closely through a wide range of load.

Many ignition devices have been proposed, but for thoroughly reliable service none, perhaps, are so satisfactory as the hot tube as proposed by Newton in 1855. A number of small engines are operating

with an electric spark from a primary battery. While this method has its advantages, it likewise has its annoyances; contact points corrode and require brightening, batteries become exhausted and require renewal, and unless given attention at the proper time, stoppages of the engine may result from failure of the battery. Or, if the battery is not used, a small generator, belted from some portion of the engine may furnish the current. This is more reliable than the battery, but is an additional machine to be maintained. The heated tube of iron or steel is rapidly oxidized and requires frequent renewal. If of nicked steel, they are much more durable, much more expensive and very easily broken. A porcelain tube, of unglazed earthenware lasts indefinitely, and if carefully handled and kept free from moisture, gives very satisfactory results. At Lancaster, Ohio, a tube of this character has been in use nearly eight months, with no apparent deterioration. It has never been touched or removed since placed in service, and seems likely to last indefinitely.

It is frequently asked, how do gas engines compare with steam, as regards first cost, economy, durability, etc.?

Comparing prices obtained from those who deal in both kinds of engines, we would estimate that for the same capacity a gas engine set up in complete running order will cost about 5 per cent more than a high speed, automatic steam engine, with boiler, pumps and necessary equipment, also in complete running order. As compared with a medium speed steam engine with throttling governor, the gas engine would cost about 15 per cent more. Extra heavy, large size gas engines of 100 h. p. and upwards, 50 per cent more.

Information from those who have replaced steam engines by engines using gas, would lead to the conclusion that with natural gas at 20 cents per 1,000 cu. ft. and coal at \$1.10 per ton for slack, or \$1.50 for pea coal, their gas bills average less than their coal bills had formerly done. As these comparisons, however, are usually made with a steam plant that has seen its best days and which was probably poorly designed in the first place, as against a gas engine of modern construction, the comparison is hardly fair, and it is reasonable to believe that there is no material difference in the cost of the fuel where each plant is strictly up to date. Some manufacturers of gas engines guarantee that their engines will not consume more than 15 cu. ft. of gas per indicated horse power per hour.

In cost of attendance the gas engine has a marked advantage. A Columbus manufacturer states that in his work the cost of attendance does not exceed 5 per cent of that necessary for a steam engine. Outside of a few minutes' time in the morning and at noon required for oiling and starting, a good gas engine needs practically no attention. This alone makes the total cost of power in small units by gas engines not over 25 to 30 per cent of similar power derived from steam.

The nature of the valve's motions in gas engines is such that cam motions are almost universally employed, and these are in theory short lived. The work done by these cams, however, is so light in practice that they usually give but little trouble, and outside of the occasional renewal of the ignition devices, which can be done at small expense, we see no reason why gas engines should be harder to keep up, or shorter lived than steam engines.

It seems strange that America, which leads the world in novel, ingenious and useful invention, which has no superior in mechanical design and the application of machinery to the industrial arts, should be so far behind European countries in the application of the gas engines to mechanical uses. Even now the gas engine is a curious and mysterious thing to many intelligent Americans, who are familiar with the use of steam.

No accurate information is available as to the number of gas engines in use in America. Every large city has a number of them, but their use is exceptional rather than general. In Columbus, where natural gas is cheap and abundant, an ideal place for the gas engines, their use is quite limited. The aggregate horse power is estimated at about 600, made up of small units, ranging from 2 to 40 h. p. Most of them are of intermediate sizes, such as 6, 10, 12 and 15 h. p.

Some idea of the extensive use of this form of motive power abroad, may be obtained from the following statements gathered from recent reliable sources.

An English engine maker states that his total sales had at the close of 1894 reached 20,000 installations.

The engineer of the London Gas Light & Coke Company, states that there were at that time 2,500 gas engines in use in London, and he estimated that the number in use in England was not less than 35,000.

In Germany there is said to be not less than 85,000 in use.

J. E. Dowson, an English inventor, and one who has given careful study to the gas engine industry for a number of years, states that in Great Britain and Ireland the number of engines sold and in use up to the present time, represents something like 600,000 h. p., and the gas consumption annually was valued at \$5,000,000.

In Berlin, a city of 1,800,000, it is estimated that there is one gas engine in use to every 1,300 population.

In Hanover, Stuttgart and Erfurt, one to every 600.

In Saxony, famous for its manufactories, one to every 200.

Gas in these various cities costs from 95 cents to \$1.30 per thousand.

The gas engine is not alone adapted to various forms of shop work and light manufacturing, but is now operating and very successfully, electric lighting plants of no inconsiderable size.

In Royan, France, at the Municipal Casino, a splendid pleasure resort on the seashore, with ample grounds, beautifully laid out and brilliantly lighted, there is an electric lighting plant having one 80-h. p. and two 40-h. p. engines. A recent report shows that it is not only operated very satisfactorily, so far as the character of the service is concerned, but is also very economical, and with but small outlay for attendance or repairs.

At Calais, France, the lighting station contains two 80-h. p. double cylinder gas engines, operating in a very satisfactory manner.

Perhaps the most notable installation in the world of a gas engine electric lighting station, is at Belfast, Ireland. This municipality owns the gas plant, as well as the lighting station. It contains four 120-h. p. tandem double acting, two 60-h. p. single double acting and two 150-h. p. four-cylinder vertical single acting high speed gas engines. Reports from the engineer in charge show that the service has proven very satisfactory, and as gas is furnished at cost, the operation is more economical than any other form of motive power.

A singular application of a gas engine is that of a steel express barge, which plies on the Seine between Paris, Rouen and Havre. This barge is 98½ ft. long, 18 ft. beam, and has a capacity of 275 tons, and is fitted with an 80-h. p. gas engine. The gas, which is compressed to a pressure of 1,420 pounds, is contained in small steel tubes, about 16½ ft. long, 10 inches diameter and 5-16 of an inch thick. These tubes are 80 in number and are laid on the deck, partly to avoid occupying valuable cargo room, and to be more easily accessible.

The limited number of gas engines in use in America may be chiefly attributed to three causes; the high first cost compared with steam engines, the high price of gas and cheap coal. These conditions are changing rapidly, and are much more favorable than they were a few years ago. Coal in many places is dearer, wood is scarce, gas is much cheaper, and gas engines are better and much lower in cost. Formerly there were but one or two firms engaged in the manufacture of gas engines, and those of but small capacity. Now there are in America about 50 manufacturers bidding for work; many of them manufacturing but small units, while others are manufacturing engines as large as 100-h. p., and if required are willing to undertake an installation as high as 300-h. p.

The best gas engines now yield a horse power per hour for 16 to 20 cu. ft. of gas, depending largely on the quality of the gas and the type of engine.

The annoyances and delays experienced by power users with the earlier types of gas engines, together with the high price both of gas and engine have done much to discourage and retard the use of gas engines in this country. There is in the mind of the power user a distrust, both as to its reliability and economy, and frequent inquiry is made of those who have been so hold as to purchase them, as to whether or not they are giving satisfaction and if in the light of their experience they would purchase another in the event more power was required.

An intelligent gentleman, who wished to obtain information on this point, sent out the following inquiry to a large number of users:

Do gas engines, as machines, do their work well, and are they all right in themselves? All but three said, "yes" and that the repairs were reasonable, moderate or low. To the inquiry: Do they as a rule give satisfaction? 16 per cent answered "yes."

Aside from the steam engine which has been so long in use, certainly there is no other form of motive power, not excepting the electrical motor which has been recently introduced to the consideration of power users, that can show so successful a record as this.

Dr. John Hopkinson, recently called attention to the fact that illu-

minating gas burned in a gas engine, driving a dynamo, would yield more light than if the gas were burned in the usual way, and there are a number of instances in which the fact has been demonstrated in actual practice.

When gas engines fail to give satisfactory results the failure may generally be ascribed to ignorance or neglect. Gas engine builders make serious blunders and too frequently try to convince the purchaser that they are blameless. On the other hand the purchaser, who after many doubts and fears, has installed a gas engine, expects results not possible with any other form of motive power. In current phrase, any old place is considered good enough for a gas engine; hence it is put in a damp cellar, a dark corner, or a back shed, exposed to dirt and grit, no attention is given to the bearings or oiling or cooling devices, and then some morning he wonders why it doesn't go. He damns the friend who recommended it, as well as the firm that built and installed it. He doesn't know what is the matter with it, and thinks it useless to try and find out. He is ignorant of the most elementary principles of its operation and considers it a mysterious, erratic machine that gets tired and stops to rest in a most exasperating and unexpected manner.

If it were a steam engine or an electric motor he would consider that it required at least some intelligent attention, and if it failed to work, would concede that it might have been neglected, but that there was nothing inherently wrong with the machine. But he thinks any dunderhead can run a gas engine, and if it isn't always ready for duty, it is the inherent cussedness of the machine and not the neglect of the attendant. Had the purchaser sufficient knowledge of the machine to recognize its limitations and consider that it should be properly lubricated, that bearings and valves should be in proper adjustment, that as a machine it requires a fair amount of intelligent attention, there would be less cause for complaint and much more satisfactory results.

It must not be assumed, however, that gas engines are without fault or are not at times apparently erratic in their action. Tight brasses, poor oil, leaky valves, late firing, early firing, late exhaust, cold ignition tubes, variation in gas pressure, sticky governor, insufficient water supply, or some one of a dozen other things might derange the working of the engine. All these things, however, are capable of correction and are not properly faults of the engine.

When it is considered that the use of a gas engine dispenses with boilers, fire, smoke, ashes, engineer, smoke-stack, expensive foundations, valuable room, reduces fire risk, reduces insurance, can be installed anywhere, on the top floor or in the basement, is ready for use at a moment's notice, with no loss of fuel in banked fires during the night or at the noon hour, is clean, economical and reliable, it must be conceded that the gas engine has a wide field of usefulness, and a better acquaintance with its merits on the part of power users, will witness its adaptation and uses in hundreds of places where steam or the electric motor now holds sway.

## A BRAVE SUPERINTENDENT.

A suburban car of the Tacoma (Wash.) Railway Company while running from Steilacoon to Tacoma was held up by a highwayman. He covered the motorman and Superintendent F. A. Dame with a revolver and ordered them to the rear of the car and proceeded to relieve the passengers of their valuables. Superintendent Dame watched for a favorable opportunity and shot the robber, only wounding him. A fusillade followed, Dame, the motorman and one passenger being slightly wounded but Dame's marksmanship was good, for his second shot lodged in the highwayman's abdomen killing him instantly. There were several ladies in the car but they escaped injury. Everyone loudly praised the courage of the superintendent.

As a well filled trolley car on Almonesson road was approaching Woodbury, N. J., it left the track to the great consternation of the passengers, except one kodak fiend, who begged the others to be still till he could get a shot at them. They were so amazed that they obeyed.

## THE ROME LIGHT AND POWER STATION

(From our own Correspondent.)

Probably the Rome power station, interesting for so many reasons, was the first instance in Europe where energy for lighting and tramway purposes was supplied from one center. The success which has attended the system is all the more noteworthy because the supply of electricity to the tramway was never contemplated when the original plant was installed; indeed, the system for two or three years was entirely devoted to lighting and it is only within the last twelve months that energy has been utilized for the tramways.

The main source of electrical energy is at Tivoli some eighteen miles from Rome where a water-fall is utilized; there is also an auxiliary steam station in the center of Rome which is used at times of maximum demand. About 2,000 h. p. is obtained from the Tivoli waterfall, the plant at this point consisting of six 250-k. w. alternators which are direct connected to turbines and run at 170 r. p. m.; in addition, are three continuous current exciters of 27-k. w. capacity each. The power is transmitted to Rome by means of four bare copper wires of a sectional area of 100 square millimetres each and they are supported on poles by oil insulators which have been specially designed by Professor Mengarini. Single phase currents are employed at a pressure of 6,000 volts and a periodicity of 43 cycles per second. Means, however, are provided at the Tivoli end to vary the pressure so as to deliver at the Rome substation current at 4,100 volts under all loads. The loss of energy on the whole length of line is slightly under 18 per cent. The Porta Pia station contains the necessary transforming apparatus which transforms the current down to various pressures for incandescent lighting, for series arc lighting and for tramway purposes.

The current for tramway purposes is transformed into direct current by means of rotary converters and motor generators. Following out the theory of Professor Mengarini, who considers it unwise to use rotary converters of much higher power than 60 k. w., the converters do not in any case exceed that size and larger units than that take the form of alternating motors coupled to direct current dynamos. Current for the rotary transformer is reduced by static transformers to 400 volts and it then enters the armature of the

converter and is commutated at the opposite end of the armature into a direct current of 566 volts. The motor generators consist of a synchronous alternating motor (4,100 volts) coupled direct to a direct current shunt dynamo which generates current at a pressure of 550 volts.

In parallel with the direct current side of the converters or motor-generators is an accumulator battery of 304 Tudor cells. The charging current is 545 amperes and they can discharge 621 amperes for three hours or an emergency discharge of 1,738 amperes can be obtained for a short time; 108 of these cells are connected in groups of three to an automatic switch which cuts cells in and out, by this means

THE ROME LIGHT AND POWER STATION.

keeping the pressure practically constant on the tramway line. The automatic regulator is composed of two solenoids, containing pistons which they suck in or push out as the case may be and which cause a ratchet to move either one way or the other according to the direction of the current in the solenoids. The direction of this current is varied by a small switch which is also worked by a solenoid and which is changed over to the one or the other position, according to the direction of the currents going through it. This current is very small and its direction is regulated by another solenoid which is wound as a voltmeter and which is placed on the terminals of the railway circuit. An ingenious arrangement devised by Professor Mengarini keeps the load on the continuous current generators constant whatever the demand

THE ROME LIGHT AND POWER STATION.

on the tramway circuit may be, this demand being equalized by the accumulators. To start up the alternating current motor a continuous current is sent through the commutator on the generating side and the motor is thus started up and brought into step. The moment this has taken place the continuous current is switched off, the alternating current is switched on and the motor then runs at constant speed and the continuous current side can be switched onto the tramway circuit.

The trolley wire is supported by span wires which are fastened to the sides of the houses. The sharpest curve has a radius of 24 metres and the heaviest gradient is 10 per cent. Fairly heavy rails are used and they are bonded with Chicago rail bonds.

There are at the present time 40 cars on the line and they are each fitted with two 25-h. p. General Electric motors. The price paid for electrical energy by the Tramway Company is equivalent to 3.54 cents per kilowatt-hour and the fact that the system has worked with unvarying success will have much influence on the question of combined stations in England.

### ELECTRICITY INSTEAD OF HAND-POWER FOR TRAVELING CRANE.

In the Western avenue station of the West Chicago Railroad Company, there are two 35-ton traveling cranes of the Walker make. These have been worked by hand until recently. The addition of a 2,000-h. p. unit and some changes with the large generators made it necessary to lift

the bridge and a small counter-shaft with gears was erected to suitably reduce the speed. On the traveler a bracket of bar iron was bolted to the frame and a motor suspended in a manner similar to the suspension on a car truck. As it is necessary to start the traveler slowly and with little jerk a double reduction is interposed between the motor and the gears actuating the carriage wheels. On the other side of the traveler a motor of the same size is attached to the frame and works the hoisting drum.

On the counter-shaft, geared to the hoisting drum, is an automatic brake of ingenious design, the outline of which is shown in Fig. 2. Around the brake pulley, which is attached rigidly to the counter-shaft, is a band of spring steel. The two ends of this band are fastened to a toggle joint connected to a 45-lb. armature of an electro magnet. The coils of this magnet consist of 400 turns of No. 7 B. & S. wire in series with the armature of the motor. When the current is turned on for hoisting purposes the armature of the electro-magnet is drawn up over a 1½-in. air gap and the band around the brake pulley is loosened. As soon as the current is turned off the armature of the electro-magnet drops, turns the toggle joint and clamps the band tight around the pulley, bringing the hoisting drum to rest very quickly. For light work a supplementary hoisting hook has been provided and the wire rope wound around the drum. A pawl is attached to one of the gears so that for lifting light pieces the drum revolves four times as fast as it does for heavy lifting.

A Sprague controller was placed in the cab for each motor, the electrical connections being as shown in Fig. 2.

FIG. 1.—ELEVATION OF TRAVELING CRANE.

the heaviest parts of the machines. This would be very tedious and laborious by hand and plans were made to use electricity for operating one of the cranes. W. A. Hopkins, the electrician at the Western avenue station, designed the electrical connections and John Murphy, master mechanic, arranged the alterations for the traveler and the details of construction. All the material was taken either from the scrap-pile or from the store-room.

A trolley wire, of standard dimensions, was suspended from the roof trusses the entire length of the engine room and connected to a 500-volt circuit. Upon the bridge was mounted an old Nuttall trolley base and rod. Three 15-h. p. Sprague street car motors were used to run the bridge and the traveler and to lift the hook. A cab, 4 x 6 ft. and 10 ft. deep was built at one end of the crane and contains the controllers and rheostats. For moving the crane along the length of the engine room a motor was mounted on the floor of

The current passes from the trolley through a switch and fuse, then through a rheostat into the controllers. A represents the controller for the motor running the whole bridge. The two sets of three field coils are in multiple. Controller B governs the motor running the traveler, the field coils of which are in parallel. Controller C is in multiple with controller B. The resistance is in the form of five Sprague laminated iron rheostats and these are bolted to the walls of the cab.

Between the girders of the crane are strung eight wires which extend the length of the bridge and are connected to two of the controllers. Copper sliding contacts, beneath the traveler, take the current from these wires for the armatures and fields of the motors. Near the two ends of the bridge are little strips of brass, connected by a small wire to two dry cells in the cab and to a door bell. As soon as the wheels of the traveler touch these brass strips the

FIG. 2.—CONNECTIONS FOR MOTORS.

bell sounds an alarm and the traveler is stopped before it reaches the end of the bridge.

These additions to the crane have been made at small expense and yet are very satisfactory. At present one man in the cab can run the crane the length of the engine room, 250 ft., or lift a piece from the floor to the girder in two minutes, whereas formerly it required four men twenty minutes to perform the same operation by hand. No break-downs or trouble of any kind have been experienced with any part of the apparatus.

### THE "PHILISTINES" GET SUNDAY CARS IN TORONTO.

The law in Toronto, Ontario, provides that only once in three years may the people vote on such questions as Sunday cars. Twice the battle has been fought, and lost to the riding public. The recent contest, which was won by the railway party on May 15, was waged the most hotly of any, and public meetings held nightly, with thunders from the pulpit, combined to make a condition like unto the days of Humphrey bills. "The Philistines are upon us" was the cry; and so they were by a majority of 479 in favor of Sunday cars. The history of Sunday cars in Philadelphia, and other large cities which at one time did not allow cars on Sunday, has unmistakably proved that when the car service was put on there was a marked decrease in drunkenness and crime on that day, to say nothing of the physical and moral advantages to the masses who are thus enabled to get out into the parks and country.

### ENGLAND FORCED TO BUY IN AMERICA.

On April 30 the president of the Board of Trade, in replying to a question in the House of Commons, stated that the government was not willing to compel companies applying for railway charters to buy their equipment in the United Kingdom, and added that the Waterloo City Railway had ordered 22 cars in America, because of the seven English firms bidding on the work not one was able to deliver the stock in the time required by the company.

It is stated that as a result of the death of J. A. Rhomburg, president of the Dubuque Street Railway Company, this company will be consolidated with the Dubuque Light & Traction Company. The latter is in the hands of a receiver.

## REPAINTING OLD CARS.

BY CHARLES KOONS.

PART II.

The glory and pride of the painter's profession is to know how to use colors, so that they will not fade and so that they will wear to the full limit of their strength. To do this successfully requires a great deal of thought and study and many practical experiments in testing. All prepared paints of the same name are not always the same; this is true even of the dry pigments, and particularly so with japan or oil colors, and hence the knowledge that the practical painter gains through handling and using the different makes of paint is valuable in many ways. He learns to know the strength and wearing qualities of the standard colors just as a blacksmith learns the strength and properties of different irons and steels, or a builder the properties of the various kinds of timber that he uses; although the painter's trade is more complicated than either and more dependent on the judgment of the color maker.

All the standard colors, and in fact everything else in the color line, are placed on the market ready for use, either in oil or japan. It is an open question with all painters whether this is the wisest course to pursue in preparing some of the delicate colors, as the less japan that is mixed with the lighter pigments the better. The japan has a tendency to turn and darken them, while a lighter medium would keep them from going so quickly. As a rule the whole line of japan colors are ground in probably the same japan by the manufacturer and no distinction made of the separate needs of each color. With the dark colors this is not so important as they all have a tendency to darken with age. There is, however, one exception, vermilion, which should never be mixed with japan of any kind, as it turns quickly enough when mixed with the lightest oils and varnishes and does not need to be helped along with a dark medium.

There are different colored japans on the market and some very light driers called gold size. These latter answer better than japan because of the light color, as the lighter the drier the better for mixing with light delicate pigments. Although there are some very good dark japans they must be used with extreme care when mixed with light pigments. There are also some colors which cannot be ground in oil. Those that are naturally oily when combined with an oily medium will not dry quickly enough for practical purposes in car painting, but answer very well for outside house work where slow drying oil colors are necessary. For the car roof, however, an oil paint is necessary. The constant swinging and twisting of the car causes the roof to give more or less and the canvas to move first one way and then another, which motion will naturally break the paint unless it is elastic enough to spring and give also. The more oil used in making up the paint for the roof the more of the necessary elasticity will it have.

In painting old cars the roof does not generally need more than one coat of paint unless it leaks badly, in which case two coats of heavy oil paint are required. If the old paint is badly cracked so that water comes through it there is only one sure way to remedy it. Give one heavy coat of good graphite mixed in boiled oil and work it into the cracks and crevices. The graphite is the most elastic paint

known and when the cracks in the old paint are filled with it, it holds a long time before it allows the rain to come through. The only objection to it is that the color is a dark slate, but this can be obviated by giving another coat of lead paint mixed in oil, with very little drier as too much mixed with the coat that is placed over the graphite will surely crack and leave the roof in worse shape than before. Roof paint should be made with nothing but oil and pigment as anything else added makes the paint too hard and brittle when dry. If this rule were followed when the canvas is first painted, there will be no need of repainting it so often. All quick drying paints will crack if not protected with varnish, and as it is out of the question to use varnish on this part of the work, the best and only way out of the difficulty is to use an elastic paint as described. The question naturally arises here as to how such a paint can be used because of the short time given for such coatings to dry. Let me answer there should no time be wasted when repainting a car; the roof should be the first thing looked after, and coated just as soon as the car is housed for repairs; good management in the painting department in this respect will readily solve the problem, and cause no delay whatever; the master painter should be governed as to this by the time that is given him to do his work and should mix his coatings accordingly; time is precious in his department and every minute should be utilized.

Let us return to the colors best adapted for street car work. Light delicate colors are not the best for dirty and smoky cities, however much they may be admired when newly painted. Constant cleaning is necessary to keep them looking fresh, and so much soap and scrubbing or cleaning with patent renovators soon kills the varnish gloss and it is not long before the paint is affected; this is an unnecessary injury.

If the colors show dirt easily, it is proof positive that it would be more economical to use another and darker color. Mud and grease may be removed often without injuring the paint and varnish, but smoke and soot must be cut and rubbed off and this in time wears away the varnish and then it is only a question of a little more time when the paint is affected. With dark colors the dirt is not so noticeable and does not need so much cleaning, and as a result dark colors wear better and longer.

There is this objection, however, to the dark colors; they make the car look heavy, and to some people too much like a passenger coach; the light color is better adapted so far as looks go for lightening up a heavy cumbersome looking car. The darker colors can be striped and ornamented so as to give a little relief to the heavy appearance caused by the color, and it is here that the painter's skill and judgment come in; if he cannot remedy the matter he has surely missed his calling, but if he is governed by instructions from the office and is dictated to by people who know more about handling the pen than the brush he is in a bad way and is not responsible. Street railway superintendents should allow the painter some freedom in exercising his taste in decorating the heavy colored street car; that is the painter's business and if he cannot find the remedy, surely no one can.

There is another style that is a happy medium between the dark and light colors; that is to paint the main panel, top belt or letter board, top ends and dash boards a dark, and the window framing, concaves and hoods underneath a light color. Another style, is whatever be the color that is used

on the main panel and letter board, to paint the rest of the car a lighter shade of the same color; if it a deep red, lighten it up with vermilion for concave color; or if blue lighten with lead; if green with chrome yellow with lead; if umbers are used, lighten with yellow. Any of these colors lightened to any shade will harmonize with the same color used pure.

Combinations like green and blue, and red and green are in bad taste; the colors do not harmonize and should never be used. White may be used with all colors; and black for lettering, edging, trimming and the iron work can be used with any color known and always harmonizes and looks well; in fact these are standard color for the car painter, and are used more or less on every car.

In naming these colors for street car work it must be remembered that there is a difference between house colors and colors used for street car work of the same name. All of the common pigments are used in both, such as lead, common chromes, all of the mineral and many of the standard colors, such as indian red, venetian red, lamp black, the ochres and some of the common umbers; but they are mixed in a different way. All of these colors for house work are always mixed in oil, that being the best wearing medium known and needing no protection over the last coat. But with the street car there is a different surface altogether; the wear is ten-fold more severe and the colors need to be of a different nature entirely; the paints must be more substantial and less liable to fade, hence the need of a better quality for all outside colors. The knocks and scraping, together with the continual washing and cleaning from one year's end and to the next that an average street car gets makes the wear far different from house wear. To stand, the surface must be brought up in a more hardened state, and this in turn protected with the best of varnish. The soft pliable nature of the oily coatings that are used on house work makes them very unfit for common street car use, though for house painting there is nothing better.

House colors, as a rule, are the commonest known, and fade very quickly after being exposed and the same colors would never answer for outside street car surfaces; they have not the strength that is necessary for the extra hard wear that a street car gets. In street car work lead is never used except as a base or foundation for some finer white, either flake white or fine zinc being always coated over it for a finish; these do not color or tarnish like the lead.

For the yellows, the house painter invariably uses the common chromes; these all fade more or less in a short time, and are hardly ever used by the car painter except in a way of combination colors for the grounds, or undercoats for more substantial yellows. For the light yellows, English or French yellows in either the milori or finer chromes are much more durable, fading only after long usage and wear, when properly prepared in the proper medium. For the dark yellows, there is only one class of colors that will stand, namely, the cadmiums; the English is the best, although some German cadmiums are very good, but they are not considered sure and reliable; there are many adulterated cadmiums on the market that cannot be distinguished from the real in looks when first used, but the difference is seen when they are exposed to the elements. The only sure way of obtaining the genuine is to purchase it from reliable color houses.

For the greens, instead of the common chromes that are used for all house work, the milori, emerald and zinc greens

are better and more durable; almost any shade needed to taste, can be obtained from these three standards. For the ground work for the above the common chromes may be used; there are still finer colors in this line, but too expensive for street car purposes. For combination colors on this order such as standard Pullman color, used on the passenger coaches of that name, and the umber greens that are used principally on carriage work; the common chromes may be used in either the green or the yellow, but they should be used very charily and only in conjunction with a substantial color as a base for the mixture, on account of the combination of so many different pigments having a tendency to spot so easily. If there is stability in the mixture to keep and hold the colors together it is not necessary to use any fine color in the combination, but unless the painter knows his colors well, it is safest to always use a greater proportion of some substantial color in order to hold it. However, these standard colors in the combination line can always be procured of reliable color houses already for use; they are formed and mixed only after a great many practical experiments, and then are generally tested as to wearing qualities before being placed upon the market; they are generally reliable, more so than the average painter could make with his limited paintshop apparatus. Still, if the master painter is able to prepare and grind his own colors, it is far better to do so, as was noted in the beginning of the article, because he can use the proper medium for each color, which is not always the case with prepared ground paints, they being generally all ground alike in one kind of japan.

For the reds, there are such a variety of vermilion in both the quicksilver and the analine color that it is almost impossible to say which is best adapted for street car painting; almost every paint house has its own vermilion, labeled after its own idea for naming vermilion. There is, however, only one general name for pure vermilion, namely, quicksilver vermilion. All other so-called vermilion are made from a lead base, and colored, principally with analines, to the desired tint or shade. Some of the analine colors are very brilliant and beautiful, but that is all that can be said for them; they invariably fade, and die, and dim away to a pinkish cast that is far worse than no color. The quicksilver pigment will not fade but will turn darker, and in time will lose its vermilion color altogether and become more like venetian red or light indian red; sometimes it blends into two or three different colors, the lower part of the panel turning the darkest, something like reddish brown and blending gradually lighter toward the top. The ground sometimes has some effect on the vermilion and causes it to turn more quickly than it otherwise would. The medium used in under coats should be thoroughly dry before the vermilion coat is put on, because of its tendency to work out through the vermilion coating; this is often the cause of the color turning. The vermilion should also be mixed so that the color dries flat, and thoroughly dry before it is re-coated. The ground best adapted for all kinds of vermilion is venetian red lightened a little with the kind of vermilion to be used over it and with lead. All vermilion should be used just as soon as mixed and thoroughly stirred from time to time while using it, as it is heavy and settles to the bottom, leaving a small proportion of the pigment united with the medium with which it is mixed to rise to the top; this makes the general coat unevenly spread with the vermilion pigment. Carelessness of the workmen in using this,

the most difficult paint to be handled, is one reason why it gives such unsatisfactory results.

The English quicksilver vermilion is the best manufactured, both light and deep, for all outside exposure. The Chinese vermilion is the finest in pigment, but not any more durable on that account. There are any number of American quicksilver vermilions, but none as durable or as reliable as the English. Of the thousand and one cheap vermilions on the market some are good, many pretty fair and many more no account at all. One of the most unscrupulous claims put out by color manufacturers is for the so-called unfading vermilions. There is no such a thing as an unfading pigment of this kind; it is an utter impossibility to keep such a bright color intact from the ravages of sunlight; some are made so as to withstand the elements longer than others, but they will all lose their brightness, and in time their color altogether, the quicksilver pigment turning darker, and all the vermilion made from a lead base and so-called analine colors fading or dimming out into nothing.

The darker reds suitable for car painting such as indian red, tuscan red, aurora red and all the red lakes, are all different in make and quality and also in price, the cheaper the price the more adulterated is the color. The finer reds and lakes being adulterated with lamp black and the analine reds, while the standard reds like indian, tuscan and all straight madder colors are cheapened with mineral pigments "analined" up to the right tint of the pure colors when first used, and sometimes even brighter and more brilliant; but when exposed to the sun's glare for a few weeks these change to different colors altogether.

This brilliancy shown in some cheap colors is misleading and catches the unwary painter by its first appearance; as a rule it is not the brilliant looking colors that are the best or the purest, but those which have a solidity in color that shows body and strength, and this will generally be found true when they are tested.

The blues are not so numerous, prussian, french ultramarine and the cobalts, with two or three chinese blues fill the quota of standard blues; there are others called perfect blue, azure blue, and permanent blue, but they are far from being what their names would imply, and most of them are combination colors tinted and brightened up to suit the name.

There are many imitations of all of these colors for sale, but it is only the pure colors that will stand. The difference between the pure and the imitations can readily be noticed when they are compared with one another.

This about covers the field for colors used for street car painting, although there are combination colors that are leading fads in different parts of the country. There is one in St. Louis called the mahogany; it is far from imitating that wood, but is about as near to it as a straight paint could get. It is of a reddish yellow umber cast, and made with substantial yellow, light and medium raw umber and a little burnt sienna (best quality). It can be lightened with light yellow or deepened with burnt sienna to suit the taste or the painter's idea of mahogany; there is no standard for the color as yet but probably some color house will soon pick it up and make it a leader.

The city council of Des Moines, Ia., has been petitioned by a number of teamsters to grant no permits to the street railway to do teaming or haul coal and other freight for private parties.

## PRIMITIVE RAILWAY APPLIANCES.

BY C. B. FAIRCHILD.

"There is nothing new under the sun" is an expression frequently made by those whose historical researches bring them upon an illustration or description of some mechanical device that contains the essential features of some new invention that is heralded as a useful appliance, sure to work a revolution in present methods of doing things, or highly valuable as a labor saving device.

Again it is often said, "The possibilities of scientific discoveries are beyond all imagination." It is a sign of ignorance and superstition to hold always to the first statement, and deny that nothing new can be, while it is equally a sign of ignorance to receive all new things as really new because they have never before come into one's experience. The new old things, however, may be adopted and serve our purpose just as fully as though they had never before been known to others, or had never been lost and found. It is a curious fact that many so-called modern inventors spend a great deal of time and money developing a device that has been tried and

FIG. 1.

found wanting years before. Some of them, being entirely ignorant of previous experiments along the same line, may justly lay claim to originality, while others, perchance, may know of former efforts along the same line, and thinking to improve on some points, that had baffled some former inventor, may produce a useful device, but not be able to patent it, or if patented, not be able to sustain the claims should the existence of the former device come to the light.

For the above reasons the presentation of some of the primitive railway appliances will prove historically interesting to those who like to watch evolutionary processes, while some of the contrivances, although they may have failed in their object on first application, or turned to very little account, either from inherent defects, or from being only useful under circumstances which rarely occur, may nevertheless exhibit such admirable combination of parts that ultimately they may be rendered subservient to other uses than those which their inventors designed. The statement made many years ago by Sir Humphrey Davy, in regard to experiments in chemistry, applied equally well in mechanics, that, "The history of failures invariably shortens the road to success."

In any event people are disposed to venerate those who express original combinations of genius when founded upon

correct scientific knowledge, because they think it the manifestation of a latent power inherent in man, to imitate for his own use the works of a divine author.

It is claimed by those who have made a careful search that the first account of railways occurs incidentally in the life of Lord Keeper North, which states that railways have been employed from time immemorial in the coal mines of Wales, and also states that about the year 1670 they were made use of at Newcastle upon Tyne for transporting coals from the mines to the shipping in the river.

Wooden rails were employed, so far as the record shows, until 1767, when at Colebrook Dale flat cast iron plates were employed over oak stringers. In 1776 Mr. Carr at the Sheffield Colliery introduced a different form. These were also of cast iron, and the first description of these tram plates, as they were called, states that they were 3 ft. long, 4 in. wide,  $\frac{3}{4}$ -in. thick with a flange (flange)  $1\frac{1}{2}$  in. high. These were designed for flat wheels, the flange on the rail being designed to keep the wheel on the track.

In 1789 Jessop introduced cast iron edge rails with flanges cast upon the tires of the wheels instead of on the rail.

Wrought iron rails or malleable, as they were then called, were probably introduced about 1811, at least in a letter dated May 1819, the agent of the Earl of Carlisle at Tindall Fall states that malleable iron rails had then been employed on a line for about eight years with little wear except creasing. In 1817 a patent was granted to John Hawks of Galehead, Durham, for a method of casting strips of malleable bars on top of a cast base, making the casting embrace the flat or square rolled bar. It is a wonder that this process did not also suggest the cast-weld joint. Up to this time it seems that wrought iron rails were forged out by ordinary blacksmiths. The first successful attempt to roll iron rails and bars of those varied and useful forms, now so common, was made in 1820 by a Mr. Birkinshaw, who was induced to undertake the manufacture, by the recommendation bestowed upon this form of rail by George Stephenson, in a paper descriptive of the Edinburgh Railway. In his specifications Birkinshaw says, "The rails or bars which I have invented are formed as prisms, though their sides need not of necessity be flat. Fig. 1 shows sections of the bar thus formed, the

upper surface upon which the wheel of the carriage is to run is slightly convex in order to reduce the friction and the under part rests on the supporting blocks, which are mounted upon the sleepers. The wedge form I propose, because the strength of the rail is always in proportion to the square of its breadth and depth, hence this form possesses all the strength of a cube equal to its square with only half the quantity of metal, and consequently half the cost. Sufficient strength, however, may be still retained and the weight

FIG. 2.

FIG. 3.

of metal further reduced by forming the bars with concave sides as shown."

A technical publication of about the same period as that of the above patent contains the following two paragraphs relating to the claims made by the inventor.

"It may be deserving of remark in this place that Mr. Birkinshaw suggested at the end of his specifications that his railway bars (18 ft. long) should be welded together end to end continuously so as to form an extensive line without any joint and thus avoid the jolting and concussions consequent upon the carriage wheels striking against the ends of each length of the ordinary rails when they are connected to the chairs."

The editorial remarks are as follows:

"The introduction of this suggestion serves to show what great mistakes are made sometimes by the cleverest men for want of a little reflection, and we make no doubt that the patentee became soon sensible of what most of our readers

FIG. 4.

are aware of, that a rail so constructed without any provision for its expansion and contraction which takes place in the metal from atmospheric changes of temperature, must inevitably soon be thrown into ruins by the twisting of the rail and the continual motion of the chairs and sleepers. And our only motive for noticing so singular an oversight is that the inexperienced and confiding reader of the specifications may not fall into a similar error."

In this record we evidently have the origin of the girder rail, as well as the method of forming bars by passing the metal when heated through rollers. It is interesting to note that there was much opposition to rails of this type on the claim that wrought metal would rust faster than cast metal, and also become splintered by the action of the wheels, and this called forth a long article from Stephenson relating to the questions, in which he remarks, "It has been said by some engineers that wrought iron will exfoliate or separate in the laminae, on that part which is exposed to the pressure of the wheel. This I pointedly deny, as I have closely examined rails which have been in use for years with a heavy tonnage passing along them, and on no part of them

FIG. 5.

FIG. 6.

are such exfoliations to be seen. The effect of the atmosphere on cast and wrought rails is not so different as to be of much moment. I am inclined to think that the effect is prevented on the bearing surface of much used railways by the pressure upon them. One phenomenon, in the difference in the tendency to rust between wrought iron laid down as rails and subject to continual motion by the passage of the carriages over them and bars of the same material either standing upright or laid down without being used at all, is very extraordinary. A railway bar of wrought iron laid carelessly upon the ground alongside of one in the railway in use shows the effect of rusting in a very distinct manner. The former will be continually throwing off scales of oxidated iron, while the latter is scarcely at all affected."

In a description of the Liverpool & Manchester Railway,

FIG. 7.

built by Stephenson, the following particulars are noted. The rails, which were 15 ft. in length and weighed 35 lbs. per yard, rested upon blocks of stone embedded in the road bed and placed 3 ft. apart. Each block contained four feet of stone, and into each block were drilled two holes 6 in. deep and 1 in. in diameter, and into these were driven oak plugs, and the cast iron shoes, to which the rails were immediately fastened, were firmly spiked down to the oak plugs, forming, as the account reads, "a construction of great solidity and strength."

The sectional form of the rail is represented in Fig. 2. A lateral projection was rolled upon one side of the base of the rail, and on one side of the cheek of the chair a cavity is cast equal in size with this projection. On the opposite side of the chair another cavity is cast for the purpose of receiving an iron key. When the rail is laid into the chair, the

key is driven into the cavity, thus effectually securing the rail from raising up.

A Mr. Losh designed a rail with a projection rolled on both sides and made a chair to correspond as shown in Fig. 3.

Wrought iron chairs, which were rolled the same as rails, were patented by Harry Scrivenor, in November, 1832.

The first brake applied to wheels seems to have been invented in 1807 by Le Caan, and was applied to a Welsh cart used upon rails (Fig. 4).

Curiously enough it was of the tandem automatic type, and seems to have been designed for use only when the animal drawing the cart should fall down. The shoe was made of iron and the top turned on a pivot at h, and the lower part was connected by a strong chain, c, to the shaft, d, the shafts being jointed at, i, to the frame of the cart. The description reads: "When

FIG. 8.

the horse is upon it legs, the shaft, chain and brake are in several positions shown by the dotted lines, but should the horse fall, the shafts take the incline position and the brake is thrown under the wheels which it takes off the track. A drag brake of an early period is shown in Fig. 5. The first

FIG. 9.

composite wheel, composed of cast and malleable iron, was designed in 1816 and was made with flanges, Fig. 6.

Robert Stephens patented in January, 1826, a design for a loose wheel to facilitate the rounding of curves, (Fig. 7.)

FIG. 10.

Instead of two wheels rigidly fixed to the axle, Stephens employed two axles mounted parallel to each other. The same illustration shows a journal box having a slot for the

FIG. 11.

journal so that the carriage could pass over uneven places without being derailed.

An oil box was patented in August, 1827, by William Chapman, of Newcastle upon Tyne, having a woolen cloth supported by a weight or spring against the underside of the journal for the purpose of applying lubricants to the same, in an almost identical manner as the felt wicks are now employed.

In 1825 A. M. James patented a system for rounding curves easily, in which were employed rails having ribs or elevations to correspond with grooves and flanges on the peripheries of the wheels, so that the outer wheel would travel on a larger diameter when rounding curves.

In the early history of surface railways, incline rope ways

FIG. 12.

were developed in which the loaded car pulled up the empty ones, and in October, 1821, B. Thompson, of Ayton, took out a patent for applying power to the rope to haul cars over uneven surfaces. Two engines were employed, one to haul the rope in one direction, and one in the other. Thompson also designed curve pulleys. An apparatus was also designed in 1830 (Fig. 8) for gripping the rope to give an intermittent motion to the cars. Another early grip is shown in Fig. 9

A design for propelling a vehicle by means of a stationary chain or rope wound over a wheel on the carriage was patented in 1812 by William Chapman. Both animal and steam power were to be employed. Rack rails were favorite means for securing propelling power and the first rack rail proper was patented in 1811 by John Blenkinsop, of Middleton. In the first experiments the rack was placed to one side of the track as shown in Fig. 10 instead of between the rails as in modern practice. A third rail with friction wheels was also employed, Fig. 11. Propelling wheels without racks were also employed, and one illustrated in Fig. 12 was patented in 1825, by John and Samuel Seward, in which the power was transmitted from the engine to a stern wheel by means of a belt.

(To be Continued.)

## COST PER CAR MILE

vs.

## COST PER PASSENGER.

## A Symposium. Part II.

Continuing the discussion of "Which affords the better comparison, the cost per car-mile run, or the cost per passenger?" begun in the May REVIEW, we submit opinions by well known street railway accountants and managers as follows:

**H. L. Wilson, Auditor West End Street Railway, Boston.**

In reference to the division of operating expenses, I would say that a comparison in either case between different railroads would be of very little use unless the following facts were known:

First. What is the length and equipment of the car.

Second. What is the length of the routes.

Third. What is the speed operated.

If it were possible as it is on the steam railroads to give the passenger mileage, I should say that it would be well to divide it in the cost per passenger-mile, but as this is impossible on the street railway, I prefer the cost per car-mile run.

With us as you know we have something over 300 separate routes. They vary materially in their lengths and of course we keep the earnings per car-mile of each. In many instances these run over the track operated by other lines. We can not keep a separate division of operating expenses by routes but we can by proportioning some accounts, keep it in a general way by divisions and of course even when comparing these we have to take into consideration the physical condition of the different divisions. I think this question will be a hard one to settle satisfactorily to all managers.

**C. N. Duffy, Secretary Citizens Street Railway, St. Louis.**

In response to your request for my views on the subject of which gives the best and fairest expression for comparison, "Operating cost per mile run," or "Cost per passenger carried," I beg leave to say that as between the two, for a basis of comparing the operation of one road with another, I would without hesitation declare in favor of "Operating cost per mile run," assuming of course, that you mean "Operating cost per car-mile run."

It appears to me, that if "Cost per passenger carried" was taken as a basis of comparison, a road enjoying heavy traffic would have such an advantage over a road having light traffic, that a fair comparison would be out of the question, as the cost of carrying each passenger would be increased or decreased in proportion to the number of passengers carried. The number of fare and transfer passengers, and the number of adults and children would also have to be taken into consideration, as having an important bearing on the matter. Then too, local conditions would have a great deal to do with promoting riding, thereby increasing or decreasing the number of passengers to be carried.

For the purpose of comparing results, "Operating cost per car-mile run," as a basis to figure from, is often misleading and unsatisfactory by reason of conditions of operation. The kind of cars in use, whether single or double truck, open or closed, the size of the car bodies, whether or not trail cars are operated, the type and capacity of motors, materially affect "Operating cost per car-mile run," and

should be fully understood and carefully considered in making comparisons.

As a matter of fact, it would seem that there is no satisfactory basis to figure from, in comparing the operation of one road with another, as what has been said about conditions with reference to "car-mile run," or "passenger carried," applies with equal force to "per car operated," or "per mile of single track operated." It will not do to use the basis adopted by our steam railroad friends, "per ton-mile," as we would have to estimate the weight of the passengers, usually averaged at 16 to a ton of 2,000 lbs., and then estimate the average distance each 125-lb. passenger rode.

In order to overcome the difficulties and complications that naturally arise in making comparisons between roads, I believe more satisfactory results could be obtained by giving for a year, month or day, the operating expenses of a road, the miles of single track operated, the number of motor cars operated, giving size, description, weight, separately, type and capacity of motors, the number of trail cars operated, the number of motor car-miles made, the number of trail car-miles made, the number of adult fare passengers carried, the number of children fare passengers carried, the number of adult transfer passengers carried, the number of children transfer passengers carried, the average revenue per passenger, and the average speed at which the cars are operated.

From the data given as outlined above, any or all of the figures could be used to any extent that would be desired, and comparisons could be made on the basis of "per mile of single track operated," "per car operated," "per car-mile run," or "per passenger carried."

**W. E. Baker, General Superintendent Metropolitan Elevated Railway (Electric), Chicago.**

The cost per car-mile (or as you express it "the operating cost per mile run," which I understand to be the same) is the best expression for comparison of operating expenses; from a financial point of view the cost per passenger carried, or the percentage of operating expenses to gross receipts, especially in roads whose business is carrying passengers solely or mostly, is generally looked upon as the most significant figure, as it gives more fully than any other the net financial result. Therefore you will find as a general thing that persons interested solely or mostly in the ultimate financial outcome desire information as to the cost per passenger or as to the percentage of operating expenses, which represents best the financial success or failure of the enterprise from an investor's point of view. You will find on the contrary that operating men, managers, superintendents and others, speak more frequently of the cost per train or car-mile, as this forms the best basis by which the operating expenses or the handling of the property from the superintendent's or operating standpoint can be judged. In other words, the expenses per car-mile represent the degree of economy reached in the operating of a road upon which cost the traffic carried has only an indirect bearing, while the cost per passenger indicates the relation between earnings and expenses from an investor's point of view. Neither one of these statements taken independently will represent fairly from all points of view the condition or prospects of the property. For this reason, therefore, you will find them both frequently used, depending upon the

point of view of the person who is desirous of the information and neither the one nor the other alone will convey an exact or fair basis of comparison, but the two together, with other information in regard to the location of the property and its condition, will give a very satisfactory comparison.

**Dana Stevens, Accountant for Receiver, Belt Railway,  
Washington, D. C.**

For purpose of comparison the "cost per mile run," in my opinion, is better than the "cost per passenger carried."

From an accountant's standpoint, I cannot see that the decision comes within my province, or to any great extent concerns me, as the data, either or both ways, can be readily obtained; the showing only affects the management.

However considered, the comparisons would be of value almost entirely to managers, as a holder of securities and stock or an investor would prefer to look at gross and net earnings, or granting he wished to make a careful investigation as to the proper and economical management of the company's affairs, could judge the physical condition by inspection and obtain a fair idea of cost of operating by comparing the "cost per mile run" with that of similarly equipped lines, of course, considering such main factors as price of supplies and cost of labor at different points.

As to "cost per passenger carried," take for instance two companies in the same city, lines similarly equipped, and giving equally good service; one may run through such a section as to carry passengers at a cost of four cents each, while six cents is the cost per passenger on the other line, owing to present disadvantages, such as running through a new and undeveloped territory, or strong competition, or other causes which the management or owners hope time and first class service from the start will overcome. In the two imaginary cases to publish the "cost per passenger carried" would be very gratifying to the management of the successful line, and, at the same time, manifestly unjust to the manager of the handicapped line, when he could show that he operated his line, giving first class service at a less "cost per mile run" than his competitor, or any similarly equipped lines.

In our monthly and annual reports we show earnings, expenses and net earnings; and per cent of expenses to earnings; earnings per mile run, and expenses per mile run, also mileage, number of revenue passengers, transfers and passes, and total number of passengers; the cost per passenger can thus be readily ascertained by any one so desiring; however, for results, I think it would be found best to compare the cost per mile run with reports of other lines, allowing for conditions in different sections, and, if too high, endeavor by comparisons of subdivisions of expenses to discover just where the leakage, if any, has crept in.

I will be pleased to learn the views of others on this subject, after which I may have to change mine.

**J. P. E. Clark, General Manager, Binghamton (N. Y.)  
Railroad Company.**

In response to your request for an opinion relative to "the best and fairest" basis for comparison, the "operating cost per mile" or the "cost per passenger carried," will say that where only one is used I prefer the latter, for several reasons, the principal one, however, is that the passenger carried is the "stock in trade" and the producing quantity,

therefore is the proper basis on which to compute operating expenses.

In view of the fact that the proportion of trackage to population is widely at variance in different cities—conditions and circumstances being responsible for this result—the "cost per car-mile" does not in my opinion afford the opportunity for as fair a comparison as the "cost per passenger carried." I believe that for the information of the individual street railroad company and a thorough and satisfactory comparison, both are necessary and essential, and can be secured with very little additional work.

The New York State Board of Railroad Commissioners submits a complete and satisfactory comparative table of earnings and operating expenses of street railroads in the Annual Report for 1896, recently issued, compiled from the reports made by the respective roads of the state. I take the liberty of submitting the headings:

Street Surface Railway Receipts, Expenditures per Passenger, Cost of Operation per Car-mile									
Name of Road	Number of Passengers Carried	Total Car-Mileage	Average Earnings per Passenger	Average Cost of Operation per Passenger	Average Receipts per Passenger	Average Expenses per Passenger	Net Earnings per Passenger	Other Earnings per Car-Mile	Total Earnings per Car-Mile
Receipts upon gross fares, upon receipts from all other sources, and upon a special operating fund, including transfers and passes.									
Expenses for fuel, oil, grease, repairs, and other operating expenses, including transfers and passes.									

You will observe from the above that they give "the cost per passenger carried" "the right of line."

### What One Who Signs Himself "Yankee," Says.

Your request for our ideas as to which of the two methods of comparison of operating expenses, viz., upon the basis of the "cost per car mile run," or upon the basis of "cost per passenger carried," came rather in the nature of a surprise to the writer.

In this state, in the blanks furnished to street railways for their annual reports, the railroad commissioners require answers to the following questions, viz.:

- "Number of passengers carried during the year."
- "Number carried per mile of main railway track operated."
- "Number of round trips run."
- "Number of car-miles run."

In the same report are given the earnings and operating expenses, both in detail, also the net earnings.

From the above information, the commissioners compute and publish in their reports the gross earnings, operating expenses and net earnings, per mile of main track operated, per round trip run, per car-mile run and per passenger carried. The writer does not know, however, of any roads in the state that figure for themselves, as a means of comparison, the earnings per passenger carried, and he was not aware, until asked to write on the subject, that roads in any section of the country were in the habit of so doing.

It does not seem to the writer that it can be done in any other way accurately, then upon the car-mile basis. A mile in this country is 5,280 feet.

Expenses must be figured on the same basis as are earnings and a revenue passenger may be one who has paid a 2½ cent fare or a 50 cent fare.

On some of the lines operated by our company, persons paying 4, 5, 8, 10, 12½ and 15 cents, ride on the same car and are each counted as one passenger. Is it not absurd to say that it costs us no more to carry the passenger who paid 15 cents than it does the one who paid the 4 cents? Yet they

were each counted as one in the returns to the commissioners. On other lines passengers make a trip, for which they pay 15 cents, but this is collected in three installments of 5 cents each, and although they make a continuous trip, in the same car, each one is counted a passenger three times and is so included in our reports.

The commissioners, without knowing how many passengers, in the first place, were actually carried, (and the company cannot tell them for the reason that no account is kept which shows the number who make more than one payment) or how many were carried at one rate and how many at another, figure it out that the average receipts and expenses have been so much per passenger.

It seems to the writer that, in order to do this accurately, it would be necessary to reduce the number of passengers carried to a uniform rate, say 5 cents, that is, count two passengers paying 2½ cents each as one, and one passenger paying 15 cents as three, then the average earnings per passenger would be 5 cents, and the expense would be divided between so many passengers paying 5 cents each, if there were no other complications.

It is not the custom with our company to have transfers registered, but many roads do so, and the writer presumes that they are counted as revenue passengers, when riding on a transfer. As a matter of fact, however, unless an additional charge has been made for the transfer, they are, at the most, half rate passengers, on both the original line where the fare was paid, and on the line where the transfers were used. In cases of roads that issue a transfer on a transfer, the passenger should be counted as one on one line, or as one-third of a passenger on each of the three lines on which he rides.

Without going into further details, it seems as though innumerable instances might be cited that would show that it would be almost impossible to obtain the actual earnings or expenses per passenger. There is no such uncertainty to be encountered about figures based on the car-mile run. It is possible to get this information exactly accurate and in consequence the conclusion reached is accurate.

**Morris W. Hall, Secretary Camden & Suburban Ry., Camden, N. J.**

To my mind the car-mile basis is the proper method of calculating expenses, as it gives a more accurate and less variable amount than when made per passenger.

There are certain days in the week when the number of passengers carried will be from 15 to 20 per cent less than on other days, yet the expense of operating is practically the same, as it requires as many cars, crews, and help at the power station as on the days when the greater number of passengers are carried. As the travel on nearly all roads is greater during the summer than in the winter months, if the per passenger plan is used, the expense of operating must show considerably less in the summer than in the winter, while the actual expense varies but little.

The car-mile is better on account of the uniformity, as our records of service for car bodies, trucks, motors, car and trolley wheels, etc., are all kept on this plan and would not give satisfactory information if any other were used.

**F. W. Wood, General Manager Los Angeles Railway Co.**

Replying to your inquiry asking an expression from me as to which is the preferable unit for comparative purposes, "operating cost per mile run," or "cost per passenger car-

ried," I always have my records kept to show both costs, but it seems to me that the "operating cost per mile run" with all its faults and deficiencies is a fairer unit of comparison than the "cost per passenger carried." For instance, I am connected with one small road that gives a reasonable service for its length but through a variety of circumstances has an abnormally small amount of traffic. The superintendent of this particular road has, by careful study and close management, got the operating cost per mile run down to a very low figure and one that compares favorably with other roads. His cost per passenger carried would be abnormally high, not because his expenses are exorbitant or his management bad, but because the number of passengers is small.

It seems to me that it requires a far more intimate knowledge of the local conditions in each case to compare the cost per passenger carried than it does the cost per mile run. In this connection permit me to emphasize the necessity of certain information accompanying all statements of cost per mile run, among which are rate of wages, price of fuel, etc.

**Joel Hurt, President Atlanta (Ga.) Consolidated Street Railway.**

Upon our roads where we have a light travel the most satisfactory method of obtaining the cost of operating the properties is by determining the cost per car-mile for the cars operated. When business increases sufficiently to run up the cost, additional cars are placed upon the road, which has the effect of reducing the cost of operating per car-mile at a time when the increased travel would on the other hand increase the cost of operating per car-mile. No test taken by itself is altogether satisfactory, but the one above referred to is the most satisfactory if one is to be taken alone.

**B. F. Harris, Jr., President Urbana (Ill.) & Champaign Electric Railway.**

I have your request for my opinion on the subject as to whether operating "cost per mile run" or "cost of passenger carried" is the best and fairest expression for comparison. If you wish to decide which one of these items is best for all the roads in the country so that one road may compare its expenses with another, I should say that the operating expenses ought to be estimated on the cost per mile run. For instance, down here in the country on our interurban road we might be operating really at a lower expense per mile run than a large city road, and yet the large city road would really carry ten passengers per car-mile run to where we would carry one passenger. Therefore the showing on its face and the cost per passenger basis would not give one an accurate idea of the actual mechanical operating expense. As a matter of fact I do not consider the question serious, because any street railway company that has a thoroughly ample and accurate accounting system may very easily compute both the cost per mile and the cost per passenger expense. We all know that it costs about as much to run empty motor cars as it does to run cars fairly well filled. As the chief respect in which one road differs from another is in the number of passengers which it carries, the real item for accurate comparison is therefore, in my opinion, on the basis of car-miles run.

**E. S. Doud, Secretary Lehigh Traction Company, Hazleton, Pa.**

If you can have but one item of cost to operate, that of the two submitted the "operating cost per car-mile" would

be preferable for comparison, but I would prefer both, or figures from which I could derive both. I believe that the cost per car-mile does not increase nor decrease proportionately with cost per passenger carried, admitting that cars are put on and taken off as traffic demands.

Some roads are so located that they naturally carry more passengers per car-mile than others, the cost to operate need not necessarily be more per car-mile, and still differ materially per passenger carried. It would show that while it cost two roads about the same to operate a car-mile, one road would, with the same expense, carry many more passengers and of course carry them for less per capita.

The object we are all after is passengers, (by "passengers" I mean those who pay their fares), and I believe that there is not a road in the country operating today but could with ease and comfort carry more passengers than it does, with the same expense, if the passengers were only there and wanted to be carried. It might not cost roads similarly situated .002 difference in operating per car-mile yet the difference in the cost per passenger carried could easily be .01.

It costs to operate whether you carry passengers or not, and although we are after fares, we run our cars, filled, partially filled or empty. Everything that enters into operating expense is going on, passengers or no passengers. Therefore if we know what it costs to operate per car-mile we can determine whether or not we operate as economically as others, or otherwise; and we can't tell it by knowing the cost per passenger.

I believe there are roads that carry passengers for one-half the amount it costs other roads, and I as firmly believe it costs some fifty per cent more per car-mile; it depends entirely upon the conditions.

We are more than likely to become confused in the discussion of the question as put for we naturally argue the income side, or receipts. We drift into a statement like this: If a road received four and a fraction cents per passenger and it costs three or even four cents, it is making money, but does it necessarily follow that the expense per car-mile is less than another road that can't make as good a showing as to profits per passenger?

Some roads keep no record of car mileage but do of passengers carried. Such roads are unable to give cost per car-mile but can give it per passenger carried. I could tell whether or not we carried passengers as cheaply as they did but it would not show me that it costs more or less to operate; except per passenger carried, which would not show what I would like to get at, viz.: Can we manufacture, distribute and use power as cheaply as another? Fuel, water, engineers, firemen, motormen, conductors, oil and waste, heat, repairs to power plant and equipment, etc., etc. The costs that go into operating should be classified alike, otherwise comparisons would be of little or no value.

It may cost a road 9 to 11 cents per car-mile and three or four cents per passenger carried, and another road with the same number of cars, etc., it may cost 12 or 13 cents per car-mile and but two or three cents per passenger carried.

I think the first is operating at less cost, although I believe the second is making the more money. I believe such a showing is not only possible but that it is actually a fact.

It costs more to carry a passenger six miles than it does one mile, but it does not necessarily follow that it costs more

to carry 100 passengers six miles than it does 600 passengers one mile provided accommodations are arranged to meet the conditions.

If one road carried as many passengers per car-mile as another the cost per passenger would compare proportionally with cost per car-mile, but the cost of operating continues, and does not differ so much with the increase or decrease of the number of passengers carried as it does with miles run.

Some roads have long runs with few passengers, others short runs with many, the cost per car-mile might and probably would compare proportionately, but the cost per passenger carried might not.

The cost of operating increases with the car-mileage, but not in the same proportion as with the passengers carried, additional car-miles operated increase the cost, while on the same road added number of passengers carried decreases the cost per passenger.

With very little or no additional expense any road could carry more passengers.

With the operating expense at about 9 cents per car-mile, the expense per passenger carried could easily vary 1 cent. A railway could correctly report operating expense at 10 cents per car-mile and 3 cents per passenger carried, while another road similarly situated could as correctly report operating expense 10 cents per car-mile and 2 cents per passenger carried. The same operating expense, but 50 per cent difference per passenger carried. I would conclude that both roads were operated with the same economy, but that one road had better traffic than the other and was making more money, because it had the passengers and not because it was more economical or better managed.

---

### TROLLEYS GAINING IN ENGLAND.

---

The prejudice against overhead wires is fast melting away in Great Britain, as evidenced by the following from a London daily:

"The long controversy as to the best form of mechanical traction for tramways in our large cities seems to be gradually deciding itself in favor of the overhead electric trolley system. This method has already been adopted in several towns, and the corporation of Glasgow has now resolved to give it a trial, after a year or two of deliberation, since it acquired the local tramways. The Tramways Committee has been authorized to spend about twenty thousand pounds on the establishment of the system on an experimental route, that is, on an isolated section of the lines, about two and one-half miles in length."

There are still some old fossils who are afraid of their shadows, as witness the following extract from an open letter in another London paper of about the same date:

"Amongst the many objections against the introduction of the overhead system is one that I particularly noticed in the working of the said system in the city of Toronto, viz., that as the cars pass along the roads the connecting rod from the top of the car where it joins the overhead wire is continually giving off bright sparks, sufficient to frighten nervous people with the fear of possible danger, and also to startle nervous horses."

Blinders on the "connecting rod," or a pair of blue goggles for the "nervous" writer might solve the difficulty.

## DOES SWEEPING PAY?

We venture the opinion that if more managers would look carefully into the matter of clean tracks vs. dirty tracks and the cost of sweeping vs. the cost of power, that sweepers would be used more liberally than they are now, or at least more track brushes would be used. Since street railways must be operated in all kinds of streets and since municipal management often decrees that streets must remain dirty for want of street cleaning funds, the only loophole of escape for the manager is to clean his portion of the street himself. The question then arises as to how much sweeping and cleaning is justified by the return therefor in dollars and cents. One concrete example will give some idea of the economy of running a sweeper over tracks once a day, where there is moderately heavy traffic. A double track route 5 miles long, running cars at 5 minute headway, at 8 miles per hour for 10 hours of the day, and cars at 10 minute headway 10 miles per hour for 8 hours of the day will require 15 cars during 10 hours and 6 cars for 8 hours of the day. The total mileage during the 5 minute headway hours is equal to the 15 cars in service multiplied by 8 miles per hour, multiplied by 10 hours or 1,200 car-miles. Adding to this the mileage made by 6 cars running 10 miles an hour for 8 hours or 480 car-miles the total daily mileage will be 1,680. Assume that power costs \$.01 per car-mile with a clean track and the power to run that route costs \$16.80 per day. A dirty track may easily make this 20 per cent more, making the amount to be charged to dirty track \$3.26. To run a sweeper once over that route each day would take the time of two men for about one hour, making cost of labor about 40 cents, and allowing 3 cents per mile for power to run the sweeper, we have 30 cents more, or a cost of \$.70 per day to run the sweeper once over that one route to save \$3.26. This, of course, does not include sweeper maintenance, but neither does the other calculation include car wheel, truck and motor maintenance. The amount saved relative to the cost of sweeping decreases as the traffic gets lighter, but there is a considerable margin of economy in favor of the sweeper, even allowing for a considerable decrease of traffic. Besides this there are track brushes to fall back on in case it does not pay to run a sweeper and in many cases sufficient sweeping can be done by a special attachment to one or two cars.

## MICHIGAN LEGISLATION.

The governor of Michigan has approved the bill passed by the legislature amending in several particulars the act under which street railways are incorporated. Corporations organized under the act may do a suburban express business and may carry farm produce, garden truck, milk, merchandise and other light freight, provided that no cars for the conduct of such business shall be operated on any street railway within the limits of any incorporated city or village between the hours of 8 a. m. and 8 p. m. without the consent of the municipal authorities and under such rules as they may prescribe. The Commissioner of Railroads is given authority to make reasonable regulations for the conduct of this suburban express business. A third section provides that any attempt to wreck a street car whereby a passenger shall be injured shall be punished by imprisonment for a term of not less than 10 years.

## A SWITCH TURNING MECHANISM.

The accompanying cuts illustrate a railway switch and operating devices recently patented by R. C. Hart and R. S. Field. The purpose of the whole design is to dispense with the switch-hook and do away with the delay and uncertainty incident to its use. Beneath the car on opposite sides of the truck frame are two vertically moving bolts which are held in the highest position by springs. Levers rest on the heads of these bolts and press them down when necessary to actuate the mechanism. These levers are connected to a handle on the dash which the motorman turns to the left or right depending upon the direction which the switch is to be turned. Fig. 1 is the plan view of the track, showing also a side track and the switch. Between the rails of the main track is placed a cross-head, 1, with a longitudinal groove, 2, on the upper side. The sliding bar, 3, is held in the groove

by cross-plates, 4, and one end is connected to the switch-tongue, 5. In the middle of the sliding-bar is a transverse groove, 6, the side walls of which are rounded at the corners. A lever, 7, is pivoted at the center, 8, from which an arm, 9, extends through the transverse groove in the bar. At each end of the lever a rod, 10, is connected to it and extends backward along the track a short distance where it is pivoted to a dog, 11, which is joined to the inner side of the track in a suitable manner for it to turn. Fig. 2 shows the cross-head, sliding bar, lever and the parts connected therewith enclosed in a casing. If a car, moving on the main track in the direction of the arrow, is to be switched on the side track the lever on the dash is moved, depressing one of the bolts. This bolt strikes the prong, 12, of the dog on the side of the track opposite the arrow. This actuates the lever and arm which pulls the sliding-bar and this moves the switch in position to run the car on the side track.

## DECISION IN THE BEMIS CASE.

The United States circuit court of appeals, April 21, rendered a decision in the case of the Bemis Car Box Company, against the Boston & Revere Street Railway Company, affirming the interlocutory decree of the circuit court granting an injunction and accounting against the defendant for infringing upon claim 1, of patent No. 239,702, for a car axle box invented by Sumner A. Bemis. The defendant was using a box patented and owned by the J. G. Brill Company, of Philadelphia, and the suit was defended by this last named company. Fish, Richardson & Storrow, of Boston, were attorneys for the complainants. Francis Rawle, of Philadelphia, was counsel for the defendant.

## THE USE OF ALTERNATING CURRENT.

Application to Street Railway Service—Phase Relation—Impedance—Capacity—Self-Induction—Wave Forms—Torque.

## PART I.

It is well demonstrated in practice that for nearly every condition of street railway traffic electricity is the most convenient, the least expensive, and in every way the best adapted as a motive power. Direct currents are almost universally used as a means of transmission. In a few cases they have been used with storage batteries, but with indifferent success. In Europe and on two or three roads in the United States the underground conduit has found favor. But these systems are largely experimental and of small consequence compared with the trolley system. This method of street railway propulsion has been developed with wonderful rapidity, and today most of the material, apparatus, and machinery are nearly of standard form, differing only in minor details of design and construction. The continuous current system, with a voltage of 500, was found to be best suited to the general needs of street railway traffic. There is little probability that this system will be replaced by another in our cities, for it is well adapted to the work required, and the machinery is so perfected that it is simple, efficient and durable.

As long as street railway lines are confined to the principal streets of a city their length will not be such as to present troublesome problems in transmission. A voltage of 500 or 550 is sufficiently high, with good bonding, line connection and track return, to insure but moderate loss from fall of potential with moderate investment. The network of intersecting lines, with a well designed feeder system, will keep the copper resistance at a small figure.

When the suburban roads began to stretch out into miles the cost of copper for lines and feeders reached such a sum that it balanced the cost of additional power houses. The losses from transmission were enormous. Cases in actual practice might be cited where the potential at the power house would be boosted to 750 to maintain a voltage of 400 at the terminals of some of the long lines. This drop of 45 per cent means not only a great loss in the operation of the power station, but a great initial investment in station machinery and copper for the conductors. Boosters have come into extensive use on such lines, but they are inefficient and are only employed for the want of something better.

Within the last year engineers have had even more difficult conditions to overcome, as interurban railways have been planned to run longer distances than heretofore, from one city to another. Nearly every city in the United States, whose population is sufficiently large to justify the possibility of even a prospective profit, has electric traction. Railway men appreciate that this field is well nigh exhausted, but the opportunities for building profitable roads between cities and towns not widely separated are very numerous, and the work is going on in nearly every part of the country. The distances are from 10 to 100 miles, and the question of transmission is now of paramount importance. One station, even though centrally located, is quite inadequate. The copper expense to keep a voltage even approximately 500 soon surpasses the cost of power house, machinery and all else. This is readily appreciated when it is remembered that the amount of copper required

varies inversely as the square of the voltage. It resolves itself into this; cost of copper in transmission lines balanced against the initial cost and cost of operation of one or more stations or sub-stations. Some engineers maintain that the length of our interurban lines has not yet reached a point where two power houses, centrally located, cannot supply a direct current of 500 volts with greater economy than any other system. The inertia of practice has much to do with this view, and also the fact that standard machinery, material and apparatus can easily and cheaply be procured. Experience has taught street railway men how to deal with all the peculiarities of such apparatus, and improvements have been constantly made until direct current machinery can be worked with high economy, little expense for repairs and with great reliability. Direct currents cannot be used in railway motors at very high voltage. They are quite difficult to transform, for it can only be accomplished by rotary machines. Moving parts, with the accompanying difficulties of insulation, will not permit the use of high voltages. These characteristics of direct currents have turned the attention of railway engineers to alternating currents for transmission. Perhaps the development of some large water powers, where alternate current machinery was of necessity installed, has much to do with this consideration. The electric roads in Buffalo and in the vicinity of Niagara Falls, those in Salt Lake City, the Dublin-Dalkey Tramways Company, and a number of other lines, have had to deal with alternate current transmission. The Twin City Rapid Transit Company, of Minneapolis, and the Port Huron & Detroit Company will soon make use of high voltage transmission. But one system has as yet been put in practice, and that is the generation of alternate currents at the central station and the use of step-down transformers with rotary converters. This is suited for suburban or interurban lines where direct apparatus is already in service in one or more of the cities or towns connected, as it permits the use of alternate currents at high voltages for transmission and the use of the same direct current motors on the cars.

The advantages of alternate currents resolve into this one thing, to-wit: The facility with which the voltages can be changed and adjusted. On the generators and motors the absence of commutators is a great merit. As an offset to this there are phenomena in the working of alternating currents, such as capacity, self-induction, reactance and resonance,

which render its advantages less, yet these very characteristics are made use of in its regulation. These properties are not so well understood by electrical engineers, especially street railway men, as are those of direct currents, so that there is considerable hesitation about using alternating current machinery. The theoretical consideration of alternating currents is so abstruse that practical men neither have the time nor the patience to give to it, yet the actual operation of alternating current machinery is quite as simple as direct current apparatus. An armature winding in passing through a magnetic field induces an alternating current, and this is only available as a direct current through the medium of a commutator. The flow of an alternating current is illustrated by Fig. 1. When the winding is cut

FIG. 1.

ting no magnetic lines of force no current flows, but as it revolves into a stronger magnetic field and the rate of cutting lines increases, the electromotive force rises in direct proportion, and this may be represented by a sine curve as shown. The electromotive force rises to a maximum, dies away to zero, and is immediately followed by a reversed electromotive force, or for one half-period the current flows in one direction and then in the other. Such a complete set of operations is called a period, or the number of them in a second, is known as the frequency or the periodicity of the current. In Fig. 1 the curve is shown for an alternator generating a current at a maximum difference of 2,000 volts. The length of the line for one cycle would represent .04 of a second if the frequency is 25. If the machine has two poles there would be one cycle completed each revolution of the armature, but if it has four poles there would be two complete cycles. The frequency is equal to the speed per second times the pairs of poles.

FIG. 2.

In the single phase system the windings are all in series, but if the armature be divided into two sections and the leads be brought out to four collector rings another set of curves will result, as shown in Fig. 2. The combination of two simple alternating currents forms a two phase current and in practice one of these two waves is one-fourth of a cycle, or 90°, behind the other, coming to a maximum as the other wave passes through zero.

FIG. 3.

The curves of Fig. 3 represent the waves of electromotive force of a three phase machine, or as the current would come from an armature winding tapped at three equidistant points. Instead of six wires to lead out these three currents, each pair of wires can be so connected with the other two that only three are necessary. By special design almost any number of waves can be secured, but for actual work, the three phase system has all the advantages that could be derived from those having four or more alternating currents and with these the wires become more numerous and complicated. Alternating currents, having two or more waves of electromotive force are called multi-phase or polyphase currents.

In conducting an alternating current a circuit has apparently more resistance than normal with a direct current and this is due to self-induction or to capacity. The self-induction acts as an extra resistance to choke the flow of current. It is due to the magnetic lines threaded through the circuit itself by the current flowing in it. In a simple circuit the number of lines will be proportional to the area enclosed but for a loop of many turns the co-efficient of self-induction is proportional to the square of the number of lines. So

E  
that instead of Ohm's law for current,  $C = \frac{E}{R}$ , the equation  
E  
becomes  $C = \frac{E}{\sqrt{R^2 + L^2 W^2}}$ , where C is the current, R is the

resistance of the circuit, L is the co-efficient of self-induction and w is equal to 2 π times the frequency. This is called the impedance of the circuit. Another peculiarity of the alternating currents in a conductor is the "skin effect" which tends to make the density of the current much greater at the surface and this only makes a part of the cross section of the conductor fully available for conducting the currents. The frequency of the current has much to do with the self-induction, but this can be easily regulated if the current is to be used exclusively for street railway or power purposes. A low frequency is very desirable, not only for diminishing the effect of self-induction, but also on account of the better mechanical design of the generators—fewer poles being used and the generator can be run at lower speed. The effect of impedance, including the size of conductors and the spacing of the same, may be noted by the table which is for a frequency of 40. The figures are the co-efficients by which the ohmic resistance is multiplied to give the correct impedance or resistance of the circuit. In the first column is the size of wire, Brown & Sharp gage, and in the other columns the value for lines conducting the current and separated by the number of inches or feet given at the top of the column.

B. & S.	3 in.	12 in.	100 ft.	1,000 ft.
0000	1.38	1.73	3.13	3.87
000	1.27	1.53	2.59	3.10
00	1.17	1.34	2.13	2.50
0	1.12	1.25	1.83	2.17
1	1.09	1.18	1.58	1.83

The table plainly shows that wires of small diameter should be used and several of them rather than one large conductor, also that the wires should be placed as close together as is consistent with safety. As these factors increase with the frequency this should be as low as the design of the machines permits.

Capacity in a circuit means that some part of the circuit is so shaped that it stores up energy in the form of electrostatic stress when there is a certain impressed electromotive force and as soon as this electromotive force dies away the energy returns to the circuit as so much current. This electrostatic capacity is analogous to a reservoir connected to a gas main and, when a certain pressure is on the pipe will force a certain amount of gas into the reservoir. The quantity of gas in the reservoir will depend on the pressure applied and if this pressure be diminished the gas in the reservoir will return to the mains. This same effect can be produced in an alternating current circuit by introducing a condenser. A condenser is formed by two plates, A, A, of some conducting material and separated by an insulator, B. These plates are connected to the circuit from the generator as shown in Fig. 4. When the voltage is changing, as in Fig. 5, the condenser is receiving its greatest electrostatic charge and this sets up stresses in insulator, B. This energy is returned to the circuit as so much current, depending on the capacity of the condenser which is proportional to the area of the plates. In practice many plates are joined together, thus giving the area of a very

FIG. 4.

large plate. The effect of the condenser is to give a lead to the current curve over the curve of electro-motive force.

The self-induction causes the current to lag behind the electromotive force and decreases the amount of energy transmitted, increases the armature reaction and causes a drop in voltage in the line. In a long transmission the inductance of the line represents a large per cent of the total and the rest is made up of the inductance of

FIG. 5.

the generator, the transformers and the receiving apparatus. Fig. 5 indicates the lag of current behind the electromotive force, this being due to self-induction. Capacity has the opposite effect and acts to accelerate the phase and produces a lead instead of a lag in the current. When the self-induction and capacity exactly balance the circuit is non-inductive and simply obeys Ohm's law. However, for a given frequency, resistance and self-induction, there is one particular value of capacity which would enormously increase the current and voltage as by a sort of resonance. A condenser or a synchronous motor in the circuit will give the capacity effect.

One other feature in which an alternating current differs from a direct current is that the measuring instruments do not give the average value of the voltage or current but the square root of the mean squares of the values, that is, .707 of the maximum values. If the voltage oscillates between + 100 and - 100 the reading would be 70.7 volts. This is due to the fact that the electromotive force and the output of current follow a sine curve. The exact shape of the curve depends upon the design of the machine but for the smooth running of the generators, motors and the line, the simple sine curve is the best. As far as the transformers go the "saw tooth" indicates a condition where the loss from hysteresis is the least. Fig. 6 represents a curve of electromotive force from the Niagara generators, the dotted line being a sine curve.

FIG. 6.

When the torque of a motor is mentioned it means the turning force acting on the armature to cause it to rotate and is equal to the radius of the armature multiplied by the pull of the magnetic lines on the circumference. It is usually expressed as the pounds pull at the end of an arm one foot in length. The torque, expressed in foot-pounds is C N M

—————where C equals the current flowing in the armature,  $8.52 \times 10^6$

M equals the number of armature conductors, M the magnetic flux or the number of magnetic lines and the constant in the denominator reduces the C. G. S. units to foot-pounds. It is essential in the design of machines for street railway or power service that the armature reaction be as small as possible, that is the drop in potential from no load to full load. The induction motors constitute an inductive load which causes a large drop in voltage and the current to

lag behind the electromotive force. This lagging of the current renders a portion of the power of the circuit unavailable and instead of the power being the product of the volts by amperes, it is only the watts times the cosine of the angle of lag. This ratio is called the power factor and must be considered whenever the amount of power to be generated or consumed is calculated. One effect of this is that the dynamo and the line must be of greater capacity than the summation of the motor capacities, inversely as the ratio of the power factor. This power factor is an element in the actual efficiency of the system and in comparing the operation of an alternating current with a direct current motor, the efficiency of the alternating current should be multiplied by the power factor. Fig. 7 shows the efficiency and power factor of a 50-h. p. induction motor.

FIG. 7.

As is seen, the power factor increases with the load and the reason for this is that the idle or wattless current, which results from the lag in the circuit, is supplied no matter what the load on the motor may be. This increases with the load but relatively much slower. In the smaller sizes of motors the power factor is smaller than in the large sizes, sometimes being as low as .60. One way which has been successfully practiced to raise the power factor is to introduce condensers in the circuit, thus giving a capacity which neutralizes the self-induction which is the cause of a low power factor. On a long transmission line the self-induction can be avoided by transposing the position of the wires at intervals.

STANDARD AIR BRAKE CATALOG.

The latest catalog of the Standard Air-Brake Company, 100 Broadway, New York City, is dated the current month and known as No. 6. A comparison of this with former catalogs will show how rapid has been the introduction of air-brakes and that portion containing illustrations of specimen cars demonstrates that the air-brake is a permanent thing on street railways as well as on the steam roads. The application of these brakes abroad has been quite extensive, the stringent regulations of the authorities made with a view to insuring the greatest safety of the passenger making their use a matter of necessity. Numerous illustrations are given which show the different types of compressors, axle driven and motor driven, the controlling apparatus, the brake cylinders and the mode of applying the system to both motor and trail cars. Special sizes are built to meet unusual requirements. The company will be very glad to furnish bona fide inquirers with catalogs on application and also to give those details of construction which it deemed best for its own interests to omit from the catalog.

The pamphlet gives evidence of that careful preparation and painstaking detail which characterizes all the printed matter prepared and issued by General Manager Wessels.

EARLY SUMMER CARS.

The original street or tram car for passengers was designed and built by John Stephenson in 1831 for use on the New York & Harlaem road which was opened for traffic in the following year. This car had a body constructed on

FIG. 1—THE STREET CAR 1857.

the lines of the stage coaches of the time; there were three separate passenger compartments entered from the side, and a seat on the roof for the "coachman." This type was soon modified in many ways and the horse car with a single compartment entered by means of platforms at the ends

FIG. 2—FIRST OPEN CAR, 1859

developed. The early open cars which served to make the journey of the summer patron of the street car more tolerable did not appear until nearly 30 years later, the first one being built in 1859 by the Stephenson Company for the Broadway Railroad Company of Williamsburg, (now Brooklyn), Long Island.

With electric traction the open car became an important

FIG. 3—EARLY BROWNELL CAR.

institution and now the trolley party is a recognized social function. To the suburban and interurban lines of smaller

cities and even in some of the larger ones the purely pleasure riding is an important source of revenue and as the season of the open car approaches it may be of interest to glance at a few of the early cars and see wherein we are better off than we were in this respect.

Fig. 1 is from a photograph of a closed car built by the John Stephenson Company in 1857, and serves to show from what the open car was evolved. Fig. 2 shows a side view of the first open car; the seats and backs were upholstered

FIG. 4—FIRST BRILL OPEN CAR, 1870.

with red enameled cloth stuffed with hair, and the curtains were of red enameled cloth.

The first open cars used in St. Louis were most probably those on the St. Louis Railroad and built by that company in 1866 or 1867. Fig. 3 is from a photograph lent us by the Brownell Car Company and shows the first open car built by it; this car was built in 1868 for the Fair Grounds Railroad of St. Louis, a short line connecting with

FIG. 5—BRILL CAR, 1871.

the Bellefontaine line. This was a short bob-tailed car capable of seating perhaps 16 or 18 persons on the two longitudinal seats. In appearance it very much resembles the early closed car shown in Fig. 1 with a part of the side panels and the window sashes removed.

The first open car built by the J. G. Brill Company is shown in Fig. 4. It was built in 1870, the side posts running down to the sills without panels. Fig. 5 is a car built the following year for use in South Boston and differs but slightly from that shown in Fig. 4; curtains are provided at the sides as well as at the ends. In cars built in 1872 seat end panels were added and the open cars lost a little of their skeleton appearance.

In all the older types the curtains, when any were provided, were either rolled up by hand or as in the case with the duck curtains, merely lifted up and buttoned in place. The first open street car to have spring roller curtains was built by the Stephenson Company in 1883 and is shown in Fig. 7. While this car was a considerable improvement over those of 15 and 20 years previous the contrast is not so marked as between this and the modern open car.

There is little wonder at the absence of anything like pleasure riding up to the time of the first open cars. The

FIG. 6—BRILL CAR, 1872.

little box cars with dim oil light at two corners, and the tedious motion imparted by one or two horses or mules, were not especially inviting. There were no regulations in those days limiting the speed at which a car might travel, for none were necessary or even thought of. The routes were from one-half to one-fifth as long as now, and population in those early days had not congested to the exclusion of light and air and comfort.

With the open car came new possibilities in the line of increased regular, and after a time a created pleasure riding, which assumed very large proportions on hot summer even-

FIG. 7—STEPHENSON CAR, 1883.

ings on such roads as had cable or other mechanical power. The first year the cable was in operation here in Chicago the evening travel on warm nights taxed the car equipment to its utmost capacity, and often lasted until after midnight. People boarded an open car early in the evening and remained in the same seat for several hours. Frequently a car would double back on the return half trip with the same load it carried out. This was in the early 80's. When electricity came into use as a motive power the range of pleas-

ure riding was enormously enlarged, and as a feature of it "trolley parties," which in many cities constitute a large business. But with electricity came also the trouble of changing the car bodies or maintaining a double equipment of trucks and motors, and this has led some roads to adopt a style of box car with large windows, which when let down or removed approaches the open car in freedom of sight and air. Whether in time the open car will drop out of use is a question on which many excellent managers differ, but the probability is open cars will continue in demand and therefore in use.

## ARGUMENT OF THE INDIANAPOLIS 3-CENT FARE CASE.

The manner in which a test case was brought before the Indiana Supreme Court that a state decision as to the validity of the law might be had without putting all parties in contempt of the Federal Court was described in the REVIEW for May. The case was argued on May 19, and a decision is expected in June.

The title of the case is City of Indianapolis vs. John N. Navin; the city attorney appears for the city and argues against the constitutionality of the new 3-cent law and the attorney general appears in behalf of the defendant and speaks in favor of the law. The Citizens Street Railway Company, the party most interested, refused to recognize the proceedings and was not represented by counsel; one of its stenographers was present however and made note of the arguments.

The arguments presented were of very different types and to an unprejudiced reader the manner in which the contentions were presented to the court cannot but appear indicative of the relative righteousness of the claims. That of the city attorney, Mr. Curtis, albeit he was like a cat in a strange garret, having heretofore opposed the interests of the Citizens Company, was a masterly argument against impairing the obligations of a contract by any subterfuge, of so-called general legislation which is both local and special, and was dignified in tone and convincing. That of the Attorney General Ketcham, on the contrary, was more like a populist oration. Among other things he said, "Like the ostrich of old, they (the Citizens Company) are not here. Their heads are in the sand."

## TRACK RENTALS IN DUBLIN.

The negotiations for some time pending between the city of Dublin and the Tramway Company have finally resulted in an agreement which is to the American mind rather more favorable to the city than to the company. The latter has agreed to pay a franchise rental of £500 per annum per street mile of track, with a minimum rental of £10,000; and further the company will maintain the wood paving where it has been laid down by it and will pave with wood all the streets in front of the hospitals in the city near which the company's lines are placed. The city on its part agrees to forego all its rights to purchase the railway for a period of 40 years.

Governor Griggs of New Jersey has signed the Scovel bill requiring trolley cars to be vestibuled in winter.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Vehicle on Electric Car Tracks.*

In the case of a trolley car overtaking another vehicle directly in a line with its progress, and a possible obstacle in its way, a proper regard for the rights of others requires that the car be reduced to such control that it may be brought to a standstill if necessary, before reaching the obstructing vehicle.

It is the duty of others not to obstruct the track, but a violation of such duty does not necessarily constitute negligence as will relieve the trolley company from responsibility for an accident which might have been avoided by the exercise of proper care.

The opinion of the Court is in part, as follows:

The errors upon which counsel for the defendant seem chiefly to rely are first, that stated in the twenty-second assignment, which objected to the charge of the judge that if the truck was visible upon the track from a distance of 500 or 600 feet, being subjected to the risk of danger, it was the duty of the motorman to use all means in his power to bring the car to a standstill. But this statement must be considered in connection with the subsequent application of the law, that "if it appears as a result of the evidence in this case that, immediately upon discovering the wagon or truck of the plaintiff approaching the tracks, the motorman in charge of the car did apply his brakes and did make every effort to prevent a collision, then the company is without fault." There was nothing in the above statements to mislead the minds of the jury. It was simply that at whatever distance from the truck, whether 600 or 60 feet, if the truck was visibly subjected to risk of injury by further advance, it was the duty of the motorman to make every effort to stop his car. Many elements must be considered to determine the risk, as for instance, the speed of the car, the condition of the tracks, the efficiency of the brakes, of the reverse upon the car. It would be a strained construction of such a phrase to understand that whenever, and under any circumstances, a car approached within 600 feet of a wagon on the track it must immediately come to a standstill. By the language used, the jury were substantially instructed that the true rule in regard to trolley cars, as in regard to all other vehicles, should be applied; that when overtaking another vehicle directly in the line of their progress, and a possible obstacle in the way, a proper regard for the rights of others requires that the car be reduced to such a control that it may be immediately brought to a standstill, if necessary. In the case of *Hicks v. Railroad Co.*, 124 Mo. 115, 27 S. W. 542, cited by defendant's counsel as deciding the above rule to be too broad, the car was slowly and carefully following behind a buggy upon the track; and the court said there was no danger of collision in moving the train slowly and cautiously, and not negligently near the buggy. In the case before us the car rushed along without diminished speed, so far as the evidence shows, until within a few feet of the truck, and did not approach it slowly and cautiously with a view to avoiding a possible collision, as was its duty in the exercise of reasonable care. The rights of a street railway company in a public highway, and its obligations, modified by its limitations to the use of a fixed line of track are the same as those of the driver of any other vehicle and both of them, in approaching near to, or attempting to pass the other directly in its path, are required, in the exercise of reasonable care, to keep themselves so far as consistent with a legitimate use of the street, under such control as will

enable them, without willful negligence on the part of others, to avoid collision and damage.

Another of the numerous assignments of error claimed that the trial judge was in error when charging the jury that it was the duty of the defendant corporation to give timely warning—timely signals indicating the approach of its car—so that the persons who were using that portion of the highway covered by the tracks might have timely warning to enable them to avoid danger from the approaching cars. This statement of the law is in accord with the rule laid down in the case of *Traction Company v. Chenoweth* (decided by this court in its term of June last.) It is the only rule consistent with the general principle to be applied to all vehicles traveling upon the public highway. The street trolley has no special right of way accorded to it by law, and the duty imposed upon other vehicles is equally imposed upon it. No vehicle can, without reasonable notice of its approach (what is reasonable notice is a question for the jury), violently run into, force from its way, another having a legitimate right upon the street, without becoming responsible for any damage that may result. In this connection the additional assignment of error may be considered, namely, that the judge refused to charge that, if the motorman gave timely notice, he had a right to assume that the driver of the truck would turn out on time, and it was only when it became apparent to him the latter did not intend to do so, that it became his duty to check the speed of the car. To maintain such doctrine would be to hold that, if audible and sufficient notice was given by a car, it rested solely in the discretion of the motorman to determine when he should begin to exercise care to avoid a collision, and the whole question would be taken out of the domain of issue to be decided by the jury, as to whether or not reasonable care had been exercised, which is the true rule of law, and test of responsibility.

The alleged error in refusing to charge that it was the duty of the driver to look behind from time to time, as well as to listen, so that, if the car is near, he may turn off and allow it to pass without undue slackening of ordinary speed, involves the assumption of many premises and circumstances, the non-existence of which would make the application of such rule illegal and inequitable. In the case of *Traction Company vs. Scott* (N. J. Err. and App.; June 15, 1896) 34th Atl. 1094, it was held that the rule requiring one to look and listen before crossing a steam railway, in order to be in the exercise of ordinary care, does not apply with equal force to one crossing the track of a street railway in a city street, where the company and the public stand upon an equal footing in the use of the highway, and that failure to do so was not necessarily, under all circumstances, negligence, per se.

The second, third, fourth, fifth, sixth, eighteenth and nineteenth assignments are based upon the refusal of the trial judge to charge the jury as requested upon the duty of the plaintiff below to yield the right of way to the defendant. It has already been decided in this court in the case of *Railway Company v. Preston*, 35 Atl. 1119, that it is the duty of the drivers of other vehicles, not to obstruct the trolley company, but at the same time it was held that neglect to fulfill this duty did not necessarily relieve the con-

pany from responsibility for injury caused by the want of care on their part. The offending driver may be punished by action at law, and the obstruction removed by police interference; but the illegal act of the injured party does not always absolve the company from its duty so to act as, if possible, to avoid collision and harm to others. The trial judge covered the points contained in the several requests, upon which the above assignments of error are based, by instructing the jury that other vehicles are subject to a duty to yield to the rights of the company in the use of their tracks, when they have occasion to use them, and under a duty to make no unnecessary obstruction to the passage of cars of the company." The charge of the trial judge stated the law correctly and sufficiently, and the judgment under review should be affirmed.

(Court of Errors and Appeals of New Jersey. Consolidated Traction Company vs. Haight 37 Atlantic Reporter 135).

[NOTE.—Where a wagon traveling in the same direction as the car was first seen by the motorman, going at a speed of seven miles an hour, when ten feet away and the driver was injured, the judgment was affirmed. Appellate Court of Illinois, Calumet Electric Street Railway Company vs. Christensen, 29 Chicago Legal News 319.—ED.]

*Street Railways May be Subject to Inter-State Commerce Act—Road Partly in District of Columbia and Partly in Maryland—Rates of Fare.*

1. The defendant, operating a line of electric railway lying partly in the District of Columbia and partly in the state of Maryland, is subject to the provisions of the act to regulate commerce, although it appears to be constructed upon or along public highways, and is essentially a street surface road for the conveyance of urban and suburban passengers. Yeomans and Prouty, commissioners, dissenting.

2. All internal commerce is either state or interstate. Commerce carried on between the state of Maryland and the District of Columbia is not subject to regulation by Maryland laws, and is therefore within the jurisdiction of Congress.

3. The defendant railway company and a land company owning land and a suburban hotel along the line of railway are distinct corporations, but under substantially the same ownership and control. The land company purchased passenger tickets of the railway company at full rates of fare, and sold them at half rates to guests of its hotel, to persons residing upon land which it had sold or otherwise transferred, and to others, but refused to sell such tickets at half rates to complainant, who, though living in the same locality, resided upon ground not acquired from the land company. *Held*, upon the evidence presented, that no discrimination was practiced by the railway company; that the community of interest between the two corporations resulting from common ownership was not made a device for enabling the railway company to evade its legal obligations; and that the action of the land company in discriminating between persons in the sale of tickets for the benefit of its separate business, is not subject to correction by this commission. Morrison and Clements, commissioners, dissenting.

4. Defendant charged one fare of five cents for the ride in Maryland, and another for the ride in the District of Columbia, selling, however, six tickets for twenty-five cents, good for passage in either the District or State, making a through fare of ten cents, or two such tickets for a continuous ride between Maryland and the District, the total length

of its road being about 7½ miles. *Held*, that unreasonableness can not be presumed from the amount of fare so charged, and the other facts incidentally appearing, no direct evidence upon that question having been presented.

(Interstate Commerce Commission, Willson v. Rock Creek Railway Co. of the District of Columbia, 29 Chicago Legal News 263.)

*Collision of Carriage with Cable Car—Contributory Negligence.*

It is only because the appellant is a railroad that it can be pretended that the collision was without contributory negligence on her part, which bars a recovery: L. S. & M. S. Ry. v. Hessions, 150 Ill. 546; N. C. S. R. R. v. Eldridge, 151 Ill. 542.

She [plaintiff] testified that when she saw the car had slackened up, she started the ponies and began to cross; she was watching the horses and did not look at the car, paid no attention as to how it was coming, at what rate of speed it was coming or how near it had arrived.

Her cousin, a young man who was riding with her, testified that when the horses' heads were north of the north track, he looked both ways to see what was going on and told his cousin to drive ahead. "I thought we could make it because I saw the car slacken up, and I told the young lady to drive across; I knew this was a new team and was afraid of them, as I thought they might get scared at the car, but they did not.

I told her to go across because I thought there was sufficient time to get across."

The distance each had to travel demonstrates that the car must have started before the phaeton. The occupants of the phaeton could see the movements of the car because it was lighted, while the phaeton could be but dimly seen in the obscurity.

The judgment is reversed and the cause is not remanded. (Appellate Court of Illinois, West Chicago Street Railway Co. v. Boecker, 29 Chicago Legal News 287.)

*Notice to Conductor of Intention to Alight—Actions of Passenger.*

The jury had the right, as they probably did, to find from the evidence that one of the conductors or gripman or both had notice from the conduct of the appellee in their immediate presence and sight, that he wished to alight from the grip car as soon as it came to a stop, which the would-be passenger had signaled it to make; and if they, either of them, did have such notice, it was as good as if given by the express warning or notification of appellee.

(Appellate Court of Illinois, West Chicago Street Railway Co. v. Stiver, 29 Chicago Legal News 279.)

An electric line between Detroit and Pontiac having become almost a certainty, the Detroit, Grand Haven & Milwaukee Railroad has reduced its rates to meet the expected competition. The rate to Pontiac is now 25 cents.

The Atlantic Highlands, Red Bank & Long Branch Electric Railway is engaged in a controversy with the township authorities at Eatontown, N. J., and in retaliation for restrictive legislation has raised the rates for school children from half to full fare. Fifty men in the employ of the company are preparing to move out of the township.

**SAFETY DEVICES IN DENVER.**

While the question of how to make a grade crossing absolutely safe has never been solved in an entirely satisfactory manner, there have been many devices introduced which greatly reduce the danger of accidents at such crossings. We illustrate one which has been in use on the lines of the Denver Consolidated Tramway Company and has proved to be very economical and has given satisfaction.

Fig. 1 shows the layout at the crossing. There are two blind curves, one on either side of the railroad track, the entrance to the curves being about 75 ft. from the crossing. The switch points are always set so as to throw the cars into the curve, making it impossible for the car to reach the crossing unless it be stopped at the switch and the setting of the latter changed. The car having come to a stop, the conductor must walk forward to the hand lever and throw the switch. The hand lever is placed on or near the crossing where the conductor has an unobstructed view of all the various tracks. The lever operating the switches has sufficient motion to permit the conductor to stand upright while the car is passing.

The hand lever, H, is bent at an angle of 100° as shown in Fig. 2. It connects, by means of the rod L, which is about 2 ft. long, with a casting, C, clamped to a rod, R, made of 3/4-in. pipe. A motion of the end of the hand lever of 3 ft. will move the rod R 8-in. A coil spring, S, attached to the lever L, pulls the apparatus back to the original position when H is released. The rod R, is carried to the switch points in a plank conduit 1 ft. square and at each end is connected to one arm of a bell crank with arms 8 in. long and at right angles. The long connecting rod is supported in bearings spaced 16 ft. apart. The bell crank at each switch is connected to a cross rod which in turn is connected to a slide holding the loose ends of two 36-in. flat springs, which control the motion of the switch point. These springs are held in place at the opposite ends by studs screwed into the switch casting, and rest against

against the switch point and the wheel flange presses the tongue aside, the spring yielding and returning to place after the car has passed.

These switches were designed by Frederick Simmons, foreman of the company's construction shop. They have been in continuous use for over four years and no repairs have been required; they are easy to operate and require no attention except an occasional oiling of the pivot at the switch tongue. The same safety could be secured by the use of a much cheaper derailing device but it is considered that, when the damage to the cars and the loss of time is taken into

account, this apparatus is the more economical. It is apparent that a similar arrangement could be devised for use at draw bridges, and one that could be worked automatically by the opening and closing of the bridge.

This company has also installed at all its grade crossings a large red signal light consisting of 10 or 12 incandescent lamps. These are burned all the time from dark until the last car is withdrawn and serve to warn the crews that the locality is a dangerous one. These lights are also placed at sharp curves. The West End Company also makes use of similar groups of lamps, but of a yellow color instead of red.

Fig. 3 shows the layout of a very bad grade crossing in Denver, which is protected by the arrangements above described. At this crossing there are 78 passenger trains per day and 64 on Sundays.

**MUNICIPAL OWNERSHIP IN MILAN.**

The street car system of Milan, Italy, which was formerly owned and operated by a private company, was on January 1 purchased by the municipality, which however will not work the lines. There are at the present time 42 miles of single track and the tramway lines in 1896 carried something in excess of 35,000,000 paying passengers. The fare is two cents from the center of the city to the suburbs and a half rate to workmen for one hour each morning and each evening is contemplated. Under the new regime the motive power is to be electricity; one line is already so operated and the work of equipping the others is being pushed as rapidly as possible. The lines are to be operated on the overhead trolley system; the Edison Company is to provide the motive power and all appertaining thereto, the cars and the working force at its own expense, while the municipality will furnish the lines and keep them in repair. The city takes charge of the receipts which are divided on a rather peculiar basis: The company is to receive first 7.60 cents per car-mile for motor cars and 3.88 cents per car-mile for trail cars. The city receives \$873 per mile of single track

the end of a second slide that runs through a cored hole which receives the center pin of the switch tongue.

One of the springs only is in contact with the switch point, and the motion of the hand lever moves the switch point by reversing the position of the bell crank and permitting the other spring to come into play. The one hand lever moves the two switches and as the conductor boards the car as it passes him the switch points have returned to their ordinary positions by the time that the car reaches the farther one, but at this latter the motion of the car is not

per annum. The remainder is then divided between the municipality and the company in the ratio of three to two. It is calculated that the net revenue received by the city under this arrangement will be \$150,000.

Under this novel arrangement, which it may be noted is entirely local, it is quite probable that there will be no disputes between the city and the company when the former wishes the system extended by building lines in new territory where the traffic does not justify the expenditure which question has been the cause of so much strife in European cities.

FENDERS AT WASHINGTON.

Through the courtesy of G. B. Coleman, general manager of the Metropolitan Railroad Co., of Washington, D. C., we are enabled to show the fenders and wheel guards adopted by that road. They have been adopted as a matter of economy as well as of safety and are very satisfactory in operation.

The fender is attached to the underside of the car platform and supported in bearings so that it can be dropped to

FENDER AND WHEEL GUARD, WASHINGTON, D. C.

to the road bed when occasion requires. In its normal position it is carried about 6 in. above the rail and when used is dropped to the rail so that a person when prostrate on the rail can be picked up. In its normal position a person standing would be tripped up but is protected from the dash board and bumper by a galvanized fabric suspended from springs and running to the basket of the fender.

It is operated by a knee lever which is directly in front of the motorman, entirely out of his way while running his car, but is always ready for action. This lever is in the form of a T and a quick movement of the knee will always find it. It can be shifted from one end of the car to the other so as to be entirely out of the way of the conductor or passengers getting on or off the car.

The fender can be folded against the dash or transferred from one end to the other. To guard against its being caught in the paving or in a switch, it is supplied with egg-shaped rollers which will prevent it from catching. The fender is not in any way attached to the dash board thus it

causes no stress on it. On cars having considerable oscillation it is supplied with a non-oscillating rod connected to the truck frame, which reduces the oscillation to a minimum.

The photographic view shows the general appearance and

FENDER.

the line drawing illustrates the mechanism. The wheel guard shown on the same car is counterbalanced so as to be held normally about 6 in. above the rail and is entirely automatic. A gate or tripper is suspended from the underside of the car platform and is connected to the guard by rods. The moment an object strikes this gate it starts the

WHEEL GUARD.

guard to the rail and at the same time an automatic lock follows the guard and it is locked to the road bed. The guard is attached to the pilot board or truck frame thus preventing any oscillation. The movement of the guard is positive and does not depend upon gravity. To reset the guard when down it is only necessary to release the lock and the counterbalance brings the guard to its normal position.

COST OF TRACK IN KANSAS CITY.

The following is an itemized estimate of the cost of construction of the track recently laid by the Metropolitan Street Railway Company of Kansas City, Mo., (described in the REVIEW for March, page 140).

COST PER MILE OF SINGLE TRACK.

Rails 161 tons at \$35.....	\$ 5,635.00
Joints 174 (cast weld) at \$4.....	696.00
Cost of excavating at \$1 per yard.....	3,000.00
Track laying, lifting and lining 15 cents per lineal foot.....	1,581.00
Cost of oak blocks, tie rods and bonds.....	500.00
Cost of concrete for beam at \$6 per cu. yd.....	6,000.00
Cost of renewing pavement over beam at \$2 per sq. yd.....	2,000.00
	<b>\$19,415.00</b>
Labor of putting in concrete and pavement included in above.....	

Anticipating a vestibule law in Massachusetts, the Springfield companies are experimenting with vestibules.

## MUNICIPAL OWNERSHIP OF TRAMWAYS AT HUDDERSFIELD, ENGLAND.

Huddersfield was a pioneer in municipal ownership and its experience has not been such as to offer encouragement to other cities. Municipal ownership is a favorite plan in this city as all the principal public monopolies, such as water works, gas works, electric lighting station, markets, abattoir, depots, baths, hospitals, lodging houses, etc., belong to the municipality. The city has a population of about 100,000 spread out over a considerable area.

Early in the 80's after an unsuccessful negotiation with

engineers receive \$6.25 and conductors \$5.05 a week. During the past year there was a total of 423,564 car-miles run. The itemized expense in dollars per car-mile run is given in the table.

Locomotive power.....	.081
Traffic.....	.024
Maintenance of ways and works.....	.017
Repairs of engines and cars.....	.056
Management.....	.012
Rents, rates and taxes.....	.013
Compensation.....	.004
Miscellaneous.....	.006
Interest and sinking fund.....	.213
Depreciation.....	.0342
Total.....	.3158

With these advantages for economical operation there must be something wrong to get such a poor showing. If money talks it must cry out loudly in protest against municipal ownership in Huddersfield.

## AUTOMATIC STREET RAILWAY SWITCH.

The illustrations represent an automatic street railway switch invented by Thomas Griffin. In Fig. 1 the main track and a part of a switch are shown, together with the switch mechanism enclosed in a casing under the surface. The plate T, is rigidly attached to the shaft underneath it as is also the lever U. Levers V and V are connected to each other and to the switch W, as shown. In Fig. 2 a section of the casing, with tilting plate, shaft and levers are shown. On either side of the shaft upon the tilting-plate are posts supporting plates R, which are above the surface. From

some tramway promoters the corporation decided to construct its own tramways for passenger and freight service, special permission having been secured from Parliament. The track, of standard gage, 4 ft. 8½ in. was constructed of 43-lb. rails fastened to metal chairs placed at intervals of 3 ft. The roadway was excavated to a depth of 6½ in. below the level of the rails for the paving and two trenches were cut, one under each rail 18 in. wide to receive two continuous beds of concrete 7 in. deep. Ten miles of such track were constructed and steam locomotives were purchased to operate the cars.

Heavier cars and engines were required and these proved too severe for the track construction. New 98-lb. rails were laid at great expense. New lines were built and extensions made until the length of track is a little over 22 miles, nearly all single track. The rolling stock consists of 26 locomotives and 26 double deck bogie cars. A map of the lines is shown in the cut.

The financial statements indicate that the city has not made a success of the system. Although, as Mr. Pogson, the general manager says, the grades on the lines are quite heavy and the districts are rather sparsely settled, yet it would seem that a city of 100,000 inhabitants should support a tramway system only 22 miles long especially with a considerable freight traffic. The capital expended has amounted to a little over £138,861. With the exception of 1897 there has been a deficit every year since 1882 amounting to as much as £16,626 in one year. The total operating expenses have been £395,327 and the total receipts £178,758, leaving a deficit of £126,569 for the tax payers to make up. Being public property there were no taxes or percentages of receipts to pay and wages are very low. The

the car body the segment-gear H, is supported and connected by a shaft to a lever which the motorman operates from the front dash. This segment is normally held in proper position by a spring behind it and not shown in the cut. Fastened to the same yoke are the two segments P, P, and upon each is a projecting arm with a wheel at the end. The manner of operation is as follows: When a car is coming towards the switch the motorman turns the lever and the segment rotates one of the pinions until the wheel is in position next to the ground. This wheel strikes one of the surface plates, moving the tilting-plate which throws the switch by actuating the levers connected to it. The lever on the dash is moved to the left or right depending upon whether the switch is to be opened or closed.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

## Cooling Condensing Water.

The illustration from La Nature shows very clearly the apparatus for cooling condensing water for reuse, designed by Chalsgny & Co., which has met with much favor in France and is installed in a number of lighting stations and several of the government arsenals. The apparatus consists of a large steel box filled with perforated trays of the

COOLER FOR CONDENSING WATER.

form shown by means of which the water is broken up into drops and exposed to the cooling action of the air which is forced upward through the box. The fan or ventilator for circulating the air requires from one to two per cent of the total power of the principal engines. The loss of water by evaporation is but three or four per cent. The box is mounted on a masonry foundation so constructed as to serve as a reservoir for the water after its passage through the cooler. Before being withdrawn from the reservoir the water is passed through a number of compartments filled with coke and with sponges which thoroughly filter it.

\* \* \*

## Arndt's Econometer.

The illustration of the "econometer," as the apparatus is called, is reproduced from the description furnished by the American manufacturer. This is a gas weighing balance which reads in percentage of carbon dioxide present instead of in ounces or grains, and gives a continuous indication of the composition of the gases passing through it. The method of operation is readily understood from an inspection of the sketch. The chimney or flue is tapped at a convenient point, and the gas led in the path indicated by the arrows through filters of excelsior and cotton wool and through a drier filled with calcium chloride, to a balance case

which is air tight except for an opening at E. The gases enter the balance case through the pipe A, and are carried up into the top of the bulb C, by the pipe B. The return to the stack is through the pipe G, a sufficient difference of pressure being maintained by an aspirator at H. In order that the bulb C, may be quite free to move the entrance to the exit pipe is enlarged at D; as any escape of the furnace gases from the bulb must be prevented to secure accurate weighings the opening at E is closed with cotton wool, which permits some air to enter, and the aspirator is adjusted so air from the case is drawn into the exit pipe at D, thus insuring the presence of atmospheric air only in the balance case.

The apparatus is erected in the boiler room where it will be in plain view of the fireman. In passing through the piping and filters the gases taken from the stack are cooled down to the temperature of the boiler room, so that in the balance case there is a simple operation of weighing a definite volume of the furnace gases in air of the same pressure and temperature. The bulb itself is balanced by suitable counter weights. The principal difference between the air within the bulb and the surrounding medium is in the carbon dioxide in the former, and it is evident that the position of the pointer when the balance is in equilibrium will vary as the proportion of this element varies in the gases to be weighed, and that the scale may readily be graduated to read in percentage of carbon dioxide present. The percentage of carbon diox-

ide present in turn depends upon the amount of air admitted to the furnace, and the reading of the econometer is a constant guide to the fireman in manipulating his dampers. This apparatus has met with favor abroad, and it is found that with good firing and damper regulation the percentage of carbon dioxide registered is as high as 10 or 15; the latter figure is that corresponding to an air supply 30 per cent in

excess of the theoretical requirements and is as low as it can be reduced in practice. The counter weights are adjusted at intervals, usually once a week, access to the case being had through the opening at K, otherwise stopped by an air-tight cork.

The apparatus is also available for detecting leaks in the furnace setting and for determining the most economical size for the grate; if too much steam is generated when a high percentage of CO<sub>2</sub> is shown it means that the grate will bear shortening.

#### Separation of Oil from Exhaust Steam.

In a paper on the separation of oil and grease from exhaust steam read before the American Society of Heating and Ventilating Engineers, William J. Baldwin states that his study of the question leads to the conclusion that it is useless to attempt this separation by what may be called mechanical means, such as straining or deflecting, or hanging so-called condensing or roughening surfaces within bulbs unless the

bulbs are so large as to make the separation take place by settlement; and that when the bulbs are of large size there is no need of any obstruction within the chamber except water to intercept the liquid oils. It is only necessary to change the direction of the steam by a simple elbow so that the entrained water and liquid oil shall be projected vertically downward against the surface of the water in the bottom of the receptacle, which will retain both the water and oil. It was found that the lighter oils could be caught and held in the apparatus by an arrangement of dams. For the use of these it is necessary that the separator have a constant water level. The arrangement of the dams is shown in the cut; the several dams at E are about 3 in. deep with the upper edges projecting slightly above the surface of the liquid, while that at D is set higher with the object of preventing the oil from flowing back over the surface of the grating formed by the low dams at E. In the preliminary experiments it was found that when a puff of exhaust steam

entered the bulb the oil receded to the sides of the chamber, leaving a clear space on the surface of the water for the reception of the oil; as the thickness of the oil film on the surface increased, the efficiency of the separator decreased, indicating that the oil adheres to water more readily than to oil and it was this fact that led to the design of the dams. In practice both the oil and the water flow under the dam D at each puff of the exhaust; the oil accumulates at the surface at c and the water flows back in an under current at d.

#### Cost of Power.

The following extracts from a lecture on "The Electrical Transmission of Energy," delivered at the Reussleair Polytechnic Institute by Dr. Charles E. Emory are valuable as giving the latest estimates of costs made by that eminent authority.

"The accompanying table shows the cost of steam power under conditions differing as to type of engine and amount of power required. The calculations are based upon coal at \$3.00 per ton, which will apply to a large number of locations. The table shows that the cost per h. p. for a working year of 308 days (which excludes Sundays and holidays) and for 10 hours per day, is as shown in column 12 from \$75.46 down to \$21.38. The latter result can, however, be obtained under experimental conditions. For every hour in the year these prices would become \$213.00 and \$61.00 respectively. The cost per h. p. per hour given for the large engine is 0.69 cent. In ordinary practice with variable power such cost is about one cent per h. p. per hour, or \$30.80 per h. p. continued for 10 hours per day and 308 working days in the year. For small engines this cost will be increased to about 2.5 cents per h. p. per hour or \$77.00 per h. p. per year. For very small engines the prices will be still higher.

"At a number of points in different parts of the country, water power has been developed in considerable quantities at from \$8.00 to \$12.00 per h. p. per year, the cost being made up by allowing 5 per cent for interest, 2.5 per cent for sinking fund, 1.5 per cent for repairs, 1 per cent for insurance, or a total of 10 per cent on the cost, with 75 cents per h. p. for attendance, oil, etc. \* \* \* The full cost of the work at Niagara Falls has not been published, but estimating from general information it is thought that the hydraulic development for 80,000 to 100,000 h. p., to include head and tail races, head gates, wheel pits, wheels and mechanical means of transmission from the wheels to the dynamos, together with the necessary buildings, water rights, promotion expenses, should not cost more than \$30.00 per gross h. p., or \$42.75 per net h. p. delivered. It is probable, however, that to secure capital for such an enterprise the original cost, represented by the securities issued, would be considerably greater than stated. Moreover, it would not be practicable to develop at once the whole of such an enormous power, though the principal portion of the expense would necessarily be incurred at the outset. These considerations might raise the cost of plant to \$80.00 per net h. p. delivered.

"At present prices it is considered that the cost of local electrical transmission will not exceed \$10.00 per net h. p. The total cost of plant would then on this basis be \$120.00 per h. p. and allowing interest and fixed expenses as before, and \$1.50 per h. p. for running expenses, makes the yearly

cost \$13.50 per h. p. With the cost price as low as this, the power company should afford to sell at a profit power for \$15.00 to \$18.00 per net maximum h. p., and the advantages to consumers would be very apparent compared with 24-hour steam power every hour in the year for \$61.00 to \$88.00 per h. p. or even 10-hour working day steam power at \$30.80, or for coal at \$1.50 per ton, say, \$25.00 per h. p. per year.

“Long distance transmission in large units differs only from local transmission in requiring the employment of longer electrical lines and the use of step-up and step-down transformers previously referred to. The double set of transformers in large units will cost only about \$11.00 per h. p., and for transmission of 20 miles at 10,000 volts the copper in the line will cost about \$21.50 per h. p. The total cost of the hydraulic and electrical development should not exceed \$150.00 per h. p. delivered, so, calling the cost of attendance \$2.50 per h. p. and deducting the interest and fixed charges as before, the yearly cost would be only \$17.50 per h. p. Promotion expenses, the interest accumulating on bonds during construction, and other expenses incident to financing a large operation of this kind would probably increase the cost greatly, still it would appear that the transmitted power should be sold for \$20.00 or at least \$25.00 per net h. p. in large units along the high tension lines, which would still show an advantage over steam power developed with coal at \$3.00 per ton, and at the worst stand on an equal footing with 10-hour steam power developed in large units with coal at \$1.50 per ton above stated.

“Everything considered, it may be assumed that prices will be adjusted so as to make it advantageous for large consumers to use the power, and the high tension lines be run to their premises for that purpose. A large expense is necessary, however, to distribute such power to small consumers. Two methods of distribution are practicable, one to reach the power houses of companies already installed and utilize their lines, the other to transmit the power locally through lines at lower tensions, though much higher than have been employed until quite recently. If such distribu-

tion be attempted through companies already installed, as first assumed, their plants have already cost several times as much as we have estimated for the entire transmission plant, and interest and dividends must be paid on the whole capital invested, consequently a saving of \$5.00 or even \$10.00 per h. p., would not be such a proportion of the necessary total cost, including interest, as to make a great difference in the charges to small consumers.

“If the average powers during each hour be summed for the entire year, the total horse-powers per hour, for that time, will, in most cases, be found not greater than if the maximum power were continued for 10 hours per day during the working days of the year, or for 35.2 per cent of the total time. This 35.2 per cent is called the “power factor,” and is generally expressed as the relation between the average power and the maximum power, which would give the same result. It follows that if for each maximum horse-power, only 3.08 h. p.-hours were developed in the year, or the same as for a 10-hour day, the cost at one cent per h. p.-hour would be only \$30.80 per year, and therefore the charge for water power, although available every hour in the year, must be sufficiently less than \$30.80 per year to warrant the change, although the same user of steam power could afford to pay \$87.60 per h. p. per year if he used the power every hour in the year.

These considerations are well illustrated by the contract recently made by the Cataract Construction Company with the Buffalo Street Railway Company. The railway company is to be furnished 1,000 h. p. day and night, for \$40.00 per h. p. per year, and apparently pays \$45.00 per h. p. for apparatus, 10 per cent of which on basis stated in text, makes the total cost \$44.50 per h. p. per year. If 1,000 h. p. of steam were actually used every hour in the year, it would cost, at one cent per h. p. hour, as stated, \$87.60 per h. p. per year; so the railroad company has made a good bargain even if 1,000 h. p. are not used all the time. Additional power is to be furnished for \$36.00 per h. p., equivalent to \$40.50 with fixed charges added as above. The load of the railroad, less 1,000 h. p. must show a very low power factor;

\*As stated in the text, the coal per hour has been calculated on a conservative basis designed to represent average practice rather than the results possible with apparatus in perfect condition. The basis is 42 pounds of feed water per H. P. per hour for line A, 22 lbs. for line B, 18 lbs. for line C, 15 lbs. for line D, and 14 lbs. for line E, and evaporations per pound of coal of 7½ lbs. for line A, 8.25 lbs. for line B, and 8.5 lbs. for the remaining lines. With engines of the kind stated, proportioned for the work and in good condition, the water consumption should be 2 pounds less for each engine, and an evaporation of 9 pounds of water or better per pound of coal could frequently be obtained. As the costs are generally stated for the indicated horse-power, it should be noted that a friction of 10 per cent has been assumed to cover losses not only in the engine, but due to transmission to a jack shaft. For engines running 24 hours per day, the allowance of 10 per cent of the fuel for starting and stopping fires should be decreased. Engines generally keep up their economy for long periods, but the amount of coal is frequently increased by carelessness in connection with the selection of the fuel, the firing, care of boilers, &c.; so, even if the engines require 2 pounds less water than assumed, the coal required generally costs fully as much as stated.

but if it be as high as 35.2 per cent, this represents, as explained, a cost for steam power of only \$30.80 per year per maximum h. p., showing that 24-hour power can be furnished advantageously by transmitted power, but that questions arise for 10-hour power or variable power of an equivalent number of horse-power hours."

## THE STEAM END OF AN ELECTRIC PLANT.

BY A. M. WICKENS.

(From a paper read before the Canadian Electrical Association.)

Our friends, the manufacturers of dynamos, tell us with some considerable pride of the rapid advancement in this class of machinery, and claim to be able to make a generator that has an efficiency of 95 per cent. This statement, I believe, is reasonably borne out, and leaves us in the position that if we expect any further economy we must look to the prime movers or engines and boilers for it, unless our electrical engineers can approach the glow-worm in efficiency, which makes its light with about one three-hundredth part of the force used in our ordinary incandescent lighting plants—or should the electrical engineer reach, in the near future, vacuum illumination, without incandescence, we should have a light at  $\frac{1}{6}$  or less of the present cost for power. But during the time these inventions are being perfected we must do the best we can with our steam engine and boiler as prime movers in hundreds of our electrical plants. There are many engines running today that are running with an efficiency of from 70 to 80 per cent; notwithstanding this the waste between the coal pile and the dynamo pulley reaches  $\frac{7}{10}$  of the total heat in the coal. Our steam engine is only a heat engine, and is subject to many losses—in fact, in some of the old engines, with large cylinders, and slow piston speeds, the water consumption was as high as 60 lbs. per hour per h. p., while today, with our higher boiler pressures and faster piston-speeds, with early cut-offs, we reduce that to 12½ lbs. water per h. p. per hour.

The heavy cylinder losses in the old, slow-running engines caused engineers, as far back as 1825 to 1836, to look for higher pressures, and at the latter date Mr. Perkins in London succeeded in using pressures from 500 to 1,500 lbs. per sq. in. Some of the earlier engines gave 5,000,000 foot-lbs. per hundred lbs. of coal. Watt built engines that gave a duty of 100,000,000 to 120,000,000 foot-lbs., while some of the modern compounds give from 130,000,000 to 150,000,000 foot-lbs., thus showing a reduction in fuel from 12 lbs. per indicated h. p. to 1½ lbs. or even 1¼ lbs. for each h. p. The ratios of expansion have also materially increased—from two-fold to twenty-fold—and thermodynamic considerations say we should still increase the number of expansions. The engineer in striving after too many expansions may find himself over weighted with engine friction and internal wastes by using too many cylinders to accomplish his object. A recent engine built at Sibley College, with four cylinders, operated under 500 lbs. pressure, at high speed, is claimed to have developed a h. p. with less than 10 lbs. water per h. p. per hour. It is, of course, fitted with re-heaters between each of the cylinders, and is carefully covered to prevent loss of heat by radiation.

Our greatest loss is the loss of the latent heat in the

steam discharged into the atmosphere or condenser, and as far as known is unavoidable. The combustible in one pound of coal will give about 14,500 heat units. A well-designed and properly set boiler will deliver to the engine for work in the cylinder 70 per cent or 10,000 heat units for each pound of coal burned. If this were all utilized we would have a h. p. for 0.26 of a pound of coal per hour. But by the highest engine efficiency yet attained we use 1½ lbs. coal per h. p. hour, or only about 17 per cent of the energy delivered by the boiler is converted into mechanical work. It is safe to say the average engine of the best makers, running in the electrical plants in Canada, requires at least 3½ lbs. coal per h. p. per hour, thus discharging into the atmosphere over 90 per cent of the energy supplied by the boiler. There are cases where the coal consumption is even higher than 9 lbs. per h. p. per hour, but these are either the result of avarice or ignorance—avarice in men who are imbued with the idea that a cheap boiler and engine is an economical machine and that it can be operated by cheap labor; and ignorance on the part of men who claim to be engineers, but who are only dabblers in mechanics, slick salesmen or merely stoppers and starters in the engine room.

The evaporation of water per lb. of coal varies to an alarming extent, and goes from 5 or 6 lbs. to 10 or 11 lbs. of water per lb. of coal. Among the various causes for this, are the different calorific values of the coal itself, the difference in the construction of the boilers, the numerous different kinds of setting, and most of all the kind of a fireman who is shovelling the coal into the furnace. The average evaporation with ordinary return tubular boilers does not exceed 6 lbs. water per lb. of coal burned. If the boiler is well set and well fired an evaporation of 8 lbs. water can be obtained. This supplied to an engine giving a h. p. for 3½ lbs. coal per hour, would represent a water consumption, as per indicator card, of 28 lbs., and is called good practice. If we increase the evaporative capacity of the boiler and evaporate 9 or 10 lbs. water, we are making a great saving. Again, if we increase the efficiency of the engine until we only consume 15 lbs. of water, we have also made a saving that will look well at the end of the year's accounts. Even with our best arrangements our heat losses are great, and engineers are looking for further improvements.

Among the most recent is the superheating of the steam, a plan that was very fully tried and discarded about 30 years ago. The practical difficulties supposed to be prohibitory to the use of superheated steam, seem to have been overcome, later experience having shown that by purifying feed water the parts of the superheater do not show signs of scaling, burning or other injury, and with the improved lubricating oils no further difficulty need arise in the pistons or wearing parts of the cylinders. In a recent paper on superheated steam engine trials, read before the British Institution of Civil Engineers, by Prof. William Ripper, the author says: "The heat expended in superheating reduced the amount of heat employed in evaporation of water; but the heat so diverted for the purpose of superheating, was shown to be productive of a considerable gain in thermal efficiency. Thus an expenditure of 5, 10 and 15 per cent of the furnace heat to superheat gave a net gain of 12, 28 and 70 per cent respectively of the work done for the heat supplied. When the load on the engine was fairly constant very little regulation of the superheat was necessary, and the temperature of the superheated steam in the

coils remained remarkably steady. When the steam was superheated it was in a more stable condition than without superheat, and if the steam contained sufficient excess heat, the steam in the cylinder could be rendered dry at cut-off and release, thus removing all water in the cylinder, which is the great loss in the cylinder, also reducing the amount of heat exchange between the steam and the cylinder walls. One example shown was with steam at 120 lbs. pressure per sq. in. superheated to 674°F., which in use reduced the steam consumption from 38.5 lbs. to 17.05 lbs. per indicated h. p. per hour. The rate of decrease of steam consumption being approximately uniform within certain limits, the best results were obtained when the steam was supplied at about 650° F. at the engine. It is also important to cover cylinders and pipes with good non-conducting material to maintain the high temperature as long as possible."

This shows that engineers are looking for higher temperatures without increase of pressure as one means of improvement and economy.

For the larger electrical plants, that is those of one or two thousand horse power—we need hardly say very much, because they generally have some one at their head with sufficient engineering ability to make a fairly economical running plant—that is, if the board of directors will allow them to spend enough money for this purpose. These larger plants are usually in our cities, where ground is valuable, and oftentimes water for condensing purposes is not obtainable. To these plants a way is open for cheapening the cost of operation by adopting a water-cooling tower and circulating pump, the cost and operation of which was so carefully gone into last year by E. J. Philip in his paper on that subject.

The smaller stations—and their number is nine-tenths of all our electric plants—are in a somewhat different position; in fact, many of them are paying a very small return for the money invested. The problem for many of them is: What can I do to make ends meet? In many cases this is not surprising to the engineer. The plant perhaps consists of one, two or more engines, bought more with a view to saving first cost than anything else. The boilers are also the same—perhaps overrated as to capacity; the setting of each is poor, and their relative positions are bad; chimney drafts not good; boiler tops and domes uncovered; steam pipes bare, feed water pipes bare, and a few small leaks here and there of steam and water—the whole topped off with an engineer (?) at the munificent salary of \$1.00 to \$1.25 per day of 12 or 13 hours. No part of this plant is clean, and in engineering cleanliness is next to godliness; the man has neither time nor inclination for such work. The boilers are dirty, too, for want of cleaning out and the proper appliances to do it with.

Let us see what some of these things mean in coal. In the first place, a badly set boiler with a few small cracks here and there will not evaporate more than 4 or 5 lbs. of water with 1 lb. of coal, while a well set and well fired boiler of the same kind will most likely reach 7 or 9 lbs. water with 1 lb. coal. This is a loss of from 25 to 35 per cent. The main steam pipe is uncovered. What does that mean in coal? We will suppose the steam pipe is four inches diameter and 40 feet from boiler to stop valve at engine. Each square foot of this pipe will condense ½ lb. of steam per hour, and each foot in length represents one square foot of surface; we have 20 lbs. steam per hour lost. An all night run will average 11 hours per night, and the

steam lost per year is 80,300 lbs., and, with your poor evaporation, 8 to 10 tons of coal per year. If your steam pipe is large and longer than the above, it will cost correspondingly more. If your pump pipes and heater are bare, the loss from this will be from 30 to 40 degrees to your feed water, which means respectively 3 and 4 per cent of fuel. If you are burning 2½ tons coal per day, this means a ton of coal every 10 days. If the domes and boiler top are uncovered, and the boiler is 6 x 14 ft., you will have 90 sq. ft. exposed, and the loss in coal will be double the loss in your steam pipe—say 19 tons coal per year. The conducting power of scale is very low being to that of iron, according to D. Rogers, as 1 is to 37½. Nystrom tells us that with clean plates ¼ in. thick, steam at 75 lbs. pressure can be produced by heating the plates to about 325 degrees, while if ½ in. of scale intervenes, it will be necessary to heat the plates up to 700 degrees, very nearly a low red heat, and a heat at which the iron becomes granular and brittle; a scale 1/8 in. thick requires 15 per cent of fuel extra.

The troublesome substances in our feed waters are earth, clay, bicarbonates of lime, sulphate of lime, chloride or sulphate of magnesium, carbonate of soda, magnesia, dissolved carbonic acid and oxygen, iron and acid. These substances can all be treated in such a way that they will be removable. Some require caustic soda and lime, some need barium, others require chlorides; all organic matter needs alum or fessic, and should be filtered.

If boilers are kept clean and well fired, the saving in coal amply pays for the cost, leaving a good margin of profit for the proprietor. A small leak through the exhaust valve of the engine soon makes itself apparent in the coal pile. Badly set engine valves are often prolific sources of loss; I have corrected engine valves and made a saving in coal of 12 per cent.

To the owners of the smaller plants I would say, make the best of what you have got; stop all the small leaks and losses; get more of the heat in the coal into the engine, and and keep the engine right. If you are burning 1,000 tons of coal per year you can save at least 25 per cent or 250 tons, by keeping everything right; 250 tons of coal means in many places \$1,000. This in many places can be saved by expending 40 or 50 per cent of it the first year—after that it should all be saved. Get a thoroughly well posted engineer to look over your plant and advise you as to where savings can be made; don't go to a civil engineer or to an electrical engineer; consult a mechanical engineer. If you had a bad fever you would not go to a dentist for treatment. Go to the right kind of an engineer, pay him for his advice and follow it, and make an ordinary electric plant a reasonably good paying investment.

One of the most significant results of the opening of the Cleveland & Chagrin Falls line on May 1, was the reduction of rates on the Cleveland, Canton & Southern Railroad to meet the rates established by the trolley line. On the same date the Akron, Bedford & Cleveland pnt on half-hourly trains from 5:30 a. m. to 10 p. m.

The capitalists interested in the Richmond (Va.) Traction Company are elated over the failure of L. H. Hyer's attempt to have the organization of the company set aside, and the issue of \$300,000 of bonds and \$500,000 of stock canceled. The decision of the United States Court of Appeals will probably be reviewed by the Supreme Court.

## EUROPEAN STATISTICS.

The Sheffield Corporation has just published a most interesting document on electric tramways and some of the figures given are well worth quoting. It will be remembered that the decision of the Sheffield Corporation to adopt electric traction was only arrived at after a most exhaustive inquiry into the working of the various systems both in Great Britain and on the Continent. The figures unmistakably show the heavy first cost of the conduit system and will no doubt prove useful to those in England who advocate the system under all conditions.

Town.	Cost of construction per mile, overhead system.	Cost of construction per mile, conduit system.
Berlin (data by company)....	£2,300	£6,450
Berlin (data by Siemens & Halske).....		About £4,000 or £5,000 more per mile of double track than for the overhead line.
Berlin (data by the Union Electric Company).....		About four times as much as overhead.
Blackpool.....		£7,084 (single.)
Brussels (data by the Municipal Engineer).....	Line proper, £1,100 Electrical appliances... 1,150 Engines and cars, not buildings.. 2,860	
Budapest (data by one of the companies).....	£5,410	£19,600 (double.)
Dresden (by the company) (Does not include paving and rails, estimated at £4,500 per mile, single.)	With poles, £2,900 With rosettes, £2,624	£4,587 to £6,944 £7,040 to £7,020
Milan (data by the Union Company).....		About four times as much as for overhead.

The cost of laying cable lines, not including power station or cars was, per mile of single track, £11,000 at Birmingham and £10,000 to £11,000 at Edinburgh.

The following is a synopsis of the more important information as to the cost of operation and the receipts:

	Expenses per car-mile.	Receipts per car-mile.
Birmingham, cable.....	10.86 cents.	23.72 cents.
Birmingham, accumulator...	36.86	31.40
Blackpool, gas (including repairs, lighting and cleaning),	9.00	....
Bristol, electric.....	11.00	....
Bristol, horse.....	16.00	....
Dresden, electric and horse.....	12.00	21.60
Dresden, electric.....	7.72	....
Edinburgh, cable.....	11.00 to 12.00	21.06
Edinburgh, horse.....	20.78	30.00 to 32.00
Milan, electric.....	7.60	12.00
Milan, horse.....	9.00	12.00
Remscheid, electric.....	8.00	11.00
Rouen, electric.....	20.68	18.00
Sheffield, horse.....	....	27.76

One of the most remarkable figures is that showing the heavy cost of the accumulator system in Birmingham where, notwithstanding the large receipts of 31.40 cents per car-mile there is a loss of 5.16 cents on every car-mile run. It should be explained that in many Continental towns wages for labor are very low. In Budapest for instance the wage of a laborer is only about 1 cent per hour and that of a rail layer 6 to 7 cents.

## FLOOD EMERGENCY BRAKE.

The illustration shows the emergency brake invented by Patrick Flood of the mechanical department of the Albany Railway, and in use on the very heavy grades on this road since August, 1895. The construction is readily seen from the cut; the brake is simple and durable and can be placed on any truck. The lever which applies the brake is on the front dash where it is under the control of the motorman at all times. As soon as the lever is released the shoes are at

FLOOD EMERGENCY BRAKE.

once forced under the wheels by the spring attached to the cross bar; flat wheels are an impossibility as the shoes are forced under the wheels, lifting them from the rails. A car can be stopped on heavy grades in a very few feet and without injury to itself or to the passengers. As a service brake for use on grades it is very satisfactory in operation; when it is desired to stop, the motorman shuts off the current and applies the brake; when the momentum is lost the car slips back a few inches and comes to rest on the shoes.

## FIRE AT LOUISVILLE.

The repair shops of the Louisville Railway Company, located at 17th and Walnut streets were burned on May 23; the loss was approximately \$50,000, partially covered by insurance. Among the property totally destroyed were 100 new motors. An order to replace these has been given and arrangements made for a temporary repair shop, so that the patrons of the line will suffer but little inconvenience. Several firemen were severely injured by the falling walls of the building.

## WATER POWER IN SOUTHERN CALIFORNIA.

The Southern California Power Company has been very successful in securing purchasers for the power generated at the Santa Ana cañon and transmitted to Los Angeles and vicinity. Contracts have been closed with the West Side Lighting Company, of Los Angeles and with the Pasadena Electric Light & Power Company, and negotiations are pending with the Los Angeles and the Pasadena & Pacific Railway Companies for the use of power.

Gov. Black has signed the bill allowing the elevated roads of New York and Brooklyn to operate trains on the bridge.

## ELECTRIC RAILWAYS—HOW TO MAKE THEM A COMMERCIAL SUCCESS.

Extract of a Paper Read before the Canadian Electrical Association, by C. E. A. Carr.

For an electric railway to be a commercial success depends not only upon the economy and efficiency of its power house, and of the roadway upon which to operate the cars, but "How to make it a success" is the query that taxes the brains of general managers and superintendents throughout the country. How to increase the receipts, without materially increasing the operating expense, are the questions the directors ask at every meeting.

A certain degree of revenue is the reward of all street railways that run cars up and down the thickly populated streets of any of our larger cities, but is it the success, commercially, it might be? There is an old story told of a toad, that stood on the bank of a brook, with its mouth wide open, waiting contentedly for flies to come his way. It seems unnecessary to say that the toad died of hunger.

The attitude of many electric railways today, is not unlike the unfortunate toad, and while life may be sustained months, perhaps years, death, in the form of the receiver, comes too often.

It is not enough that we carry our regular customers. These come to us anyway, and it is to these that we look for a guarantee of our operating expense. The profit or success of the railway lies in the margin of how many we can induce to become patrons, and thereby increase the regular revenue. This may be accomplished by various means. The railway company, like any other business concern, has goods to sell, in the way of rides, and no doubt there are times in the day when the manager feels that he is overstocked, and is inclined to put on "Bargain Matinees" to get a full car. He should advertise and let the people know there is an electric railway in town; that its business is to carry people from place to place comfortably and quickly, and that they can't afford to walk; that the time saved in riding will more than pay the fare. There are various ways in which to do this, and methods may be adopted so that the cost is very slight.

One very good way is to issue annually a handsomely illustrated booklet, which contains cuts of all the interesting points touched by the cars, briefly telling how to get there. The different firms supplying the company with materials will advertise for the asking, and the cost to the company is practically nil. This style of advertising is particularly valuable to strangers and tourists. The railway company in London, Ont., issued just such a little booklet as I mention, about a year ago, and it was a daily occurrence to see a group of strangers taking a ride around the Belt Line with book in hand, pointing out the various public buildings, parks and squares, as the car went along.

A specially illuminated car for trolley parties is a profitable source of revenue, and the effect of the colored lights along the line, as the car passes, is very pleasing. It is a good way to advertise, and tends to popularize the service. Many electric railway companies establish parks at the end of one or more of their lines, and provide amusements in the way of hand concerts, etc. This brings considerable increased revenue, at a time of day when cars would otherwise be running light. To what extent a railway company should provide attractions for its patrons, must depend

largely upon local conditions. Some companies claim to have profited by this departure, while others have an adverse experience. It is more desirable to have the amusements provided by some one else who thoroughly understands it, the company making certain concessions in the way of issuing coupon tickets for admission. In this way, the railway runs no risk and profits pro rata on all increased business.

The selection of employes has more to do with the success of an electric railway than anything else. The idea that any one can run a street car, has, in many cases, resulted in the employment of incompetent, careless and ignorant men who, through these qualities, have brought the railway into public disfavor. Conductors, motormen, inspectors and shopmen have the power to earn or lose money; make the railway popular or odious with the public; keep claims for damages at a minimum or make them a burden, and very often their selection does not receive the care that is exercised in the purchase of ordinary supplies. Every employe should be considered an agent of the company, and should not only be sober and intelligent, but have good judgment and a cheerful disposition. Loyalty to the company he serves, should be his first motto.

With the whole army of employes, loyal, faithful and devoted to their duty, gross earnings will steadily increase and operating expenses be at a minimum, and the stockholders would no longer need to ask if the road was a success.

The growing demand of the public for better accommodation and luxury in the matter of travel and speed, must be met by giving them better cars, more comfortably furnished and more expensively fitted than heretofore. By supplying these demands the company will add largely to its revenue.

## IMPROVED SAFETY DEVICE FOR ELECTRIC CIRCUITS.

In a paper on this subject before the Franklin Institute, L. G. Rowland describes a safety system of his invention which is especially applicable to trolley lines. The purpose is to open the circuit as soon as the trolley is broken

or grounded. The connections for such a system are shown in the figure where A represents the feeder and B the trolley wire. The electro-magnet C, is differentially wound and when the currents are passing through the coils they neutralize each other and the magnet is not energized.

From the trolley wire one circuit extends through one resistance, R<sup>2</sup>, through one of the magnet coils and wire G, to the rail. The wire D, is also connected with the trunk line through a switch contact and to the other winding of the magnet C; the trolley B, and D having a common connection with the trunk line A, through the wire M. The feeder A is a common source of supply for the two circuits, which pass in opposite directions around the coils of the electro-magnet. In the common connection M, to both circuits is a switch, E, which is normally closed and controlled by the armature N, of the electro-magnet.

When the magnet becomes energized, it is but slightly so and not strong enough to trip the switch, which must, therefore, have a powerful spring to ensure opening it quickly. The lever P, has a projection T, in the line of the movement of one end of the lever N. Both levers, at this point, carry contact points normally out of contact with each other. A wire from one side of the resistance R, in circuit D, passes to the lever P, and from the sliding contact S, on resistance R, a wire passes to the lever N, through the signal magnet U. If the trolley is broken the magnet is energized by the current in circuit D, which attracts the armature N, so that the contact on it and that on the lever P, are brought together. This allows the current to pass to the magnet C, through wire V, magnet U, wire W, to the sliding contact S, and resistance R, wire D, and draws up the lever N. It acts on the projection T, draws up the lever which trips the catch and allows the switch E, to open the circuit. At the same time the current passes through the magnet U, of the signal device, releases the mechanism and signals the number of the box to the station or to the repair wagon. This signal passes over an independent circuit, preferably a closed metallic circuit.

A telephone connection can be made in each box, permitting conversation between that point and the station. In each box there is a signal key, K, which when pressed, opens the switch and notifies the station at the same time. In case of a fire this would render that section of the trolley wire dead and subsequently there would be no cut wires to repair.

### AUTOMATIC CONTROLLING VALVE AND ELECTRIC GOVERNOR.

For convenience and safety it is better to have an automatic mechanism to control the pressure in the air reservoirs for the brakes on the elevated trains rather than have the motormen attend to it. The cut shows a device invented by J. B. Knudsen which has worked quite successfully on one of the cars on the Lake Street Elevated for some time past.

The upper part of the cut represents a plan view of the device with a cross section of the controlling valve. The vertical cylinder is connected at the bottom to the air reservoir. To get a differential spring action so as to give a maximum and minimum pressure a spring is behind the piston and fastened to the spindle between two nuts is a phosphor-bronze disc. In the horizontal cylinder is a piston and attached to it is a spring whose tension is a little less than that of the spring in the vertical cylinder. The piston rod is connected to the contact piece, but insulated with a block of fiber. This brass contact piece is pivoted to a porcelain plate and at the lower end is a spring which holds it in proper position. The connections to the mains are as shown. Just above the point of contact is an air nozzle which is at

the end of the pipe running from the base of the vertical cylinder. On the head at the end of the piston rod from the horizontal cylinder is a raised surface. When the piston

moves towards the left it causes the vertical spindle to rise and open the valve in the air pipe.

When the mechanism is in the position shown in the cut the circuit is closed and the motor and air pump are working with the pressure in the reservoir increasing. As soon as the air pressure reaches the designed maximum it overcomes the tension of the spring and diaphragm in the vertical cylinder and raises the piston which opens the ports and the air passes into the horizontal cylinder. This forces the piston of the horizontal cylinder to the left which breaks the contact and stops the motor. The air from the nozzle blows out the arc. For service on the elevated road the springs and diaphragm are set for a maximum of 60 lbs. and minimum pressure of 52 lbs.

### LOW OPERATING EXPENSES.

In regard to the operating expenses of the Calumet Electric Railway, Chicago, published in the March REVIEW, page 176, one of our readers requests information as to number of cars operated, miles of track in use, whether single or double, grades, distance between power house and the terminus of the road, price of coal, and length of time in operation.

This company operates 75 miles of track, all of it double except one mile. The number of cars in use varies from 37 in winter to 200 in summer. There are practically no grades on the line. The distance from the power house to the farthest terminal is 5½ miles. The coal used costs from \$1.15 to \$1.50 per ton. This road began operating in 1891 and has constantly extended its lines, having 10 miles in 1892, 23 miles in 1893, 53 miles in 1895 and 70 miles in 1896.

John Mac Fayden, general superintendent of the Chester Traction Company, Chester, Pa., advises us that on that road the operating expenses for the year 1896 averaged \$.0759 per car-mile. The company operates 28 miles of track, only two of which are double track; at the extreme end of one division which is 8 miles from the power house is a 6 per cent grade 1,500 ft. long; there are several other grades of from 8 to 10 per cent; the average number of cars operated is 28 per day.

## METROPOLITAN (N. Y.) WINS UNDERGROUND SUIT.

The suits brought by three taxpayers in New York City who sought to enjoin the Metropolitan Company from introducing the underground trolley system on 6th and 8th avenues has been decided in favor of the company by Justice Beach, of the New York Supreme Court. The contention that the change from horse to electric power could not be made without forfeiting the franchise, the original franchise having prescribed horse power only below 59th street, was decided adversely to the plaintiffs, it being held that the change of motive power is a part of the "regulation" of the railway and a matter within the control of the legislature and not of the local authorities. "The right to a change of motive power does not affect the original grant." The second question dealt with by Justice Beach was the jurisdiction of the Board of Electrical Control and he held that the board was organized for the purpose of regulating all electrical conductors for the transmission of "sound, heat and light," and that conduits for carrying electrical power for traction were not within the classes mentioned. The right of the city to purchase the road for the actual cost of construction plus 10 per cent, as set out in the original resolution of 1851 was held invalid; as all franchises granted by the city prior to 1854 are invalid, the reservation as to the purchase must share the same fate. The franchise was legalized by the laws of 1854, in which no purchase clause was incorporated.

The case will probably be taken to the Court of Appeals and the Metropolitan Company is not expected to proceed with the work of installation until the final decision is rendered.

## LITTELL ON LONDON TRANSPORTATION.

H. M. Littell, who is now traveling in Europe, was approached by a reporter for the London Mail, shortly after his arrival, and the following published interview was the result:

"If you care for my opinions," said Mr. Littell, "you may have them. They are perfectly unbiased, for I am in no way concerned with any English undertaking. It strikes me, as I presume it does every other American, that your system is crude and primitive. I am astonished that in an old rich city like this you have no better facilities for traveling between the places of residence and the places of business. Why have you no tram cars on the Strand?"

"Of course, you will say that traffic is so congested there that the thing is not to be thought of. So said the merchants on Broadway. They bitterly opposed our scheme for a cable railroad there; said it would interfere with their business, and made other frivolous objections. The company carried its point—and its railroad. What was the result? The congested traffic was relieved to an amazing extent, and the facilities for business, instead of being curtailed, were increased. Today I do not believe there is a single merchant who would not fight for a retention of the system, were any misguided person to attack it.

"Here you have a great many blockades—blocks, don't you call them? Three, four and five 'buses are abreast, hansom cabs fill up the rest of the space, and the traffic is stopped for a quarter of a mile back. Lay tram-lines along the Strand, Piccadilly and Regent street, and you would never find more than two cars abreast. And think of the vehicles of which you would rid the streets. Cabs and 'buses would go by the hundred. Then there is the greater speed of traveling. Cars only stop at street corners, and for such time as is sufficient to allow passengers to enter and leave. Your 'buses are rarely full. They hang along the curbstone, and stop, and stop, and stop, and very slow you travel. Such tram cars as you have do not bring

you to the center of the city. Do any trams run to Trafalgar square, and if not, why not?"

"Why, I repeat, have you no tram cars on the Strand and Piccadilly? I see many reasons why you should have, none why you should not. Your streets are broad, clean and in every way excellent. I do not know your tramway people here, but if they are of the same class as those in our country, they would be very ready to lay tracks if permission were given. You English say that there are hansoms everywhere, and that they cost next to nothing. My experience is that they cost a good deal. Your 'buses, also, I regard as very expensive. Some 'bus fares I find are fourpence, fivepence, or even sixpence. In New York, by the use of transfer tickets, you can ride half a day for five cents. The charge is uniform—five cents whatever the distance. Does it pay? Of course it does. It educates a man to the conveniences of riding. He rides short distances as well as long. And he is not going to waste half a day on a car for the fun of the thing."

Mr. Littell paused. Had he said his worst, or were there other criticisms? There were others. "Now in our cars," he continued, "You ride in comfort, and enjoy the view. What is the view from the inside of a London omnibus? Somebody's pills, and somebody else's soap. In New York you hire advertising 'buses for the day. Here the American sees a 'bus rumbling towards him, and has not the remotest notion whether it's a 'bus for Piccadilly circus or a 'bus for anti-billious pills. The place for advertisements is the newspaper.

"The electric car would not be nearly so dangerous on your principal streets as your 'buses are. When the horses skid there is a pretty fair momentum on a 'bus. And coming to the worst, I would as soon be run over by a road car as a 'bus any day. In neither case should I take much interest in street traffic afterwards.

"And have we no advantages to bless ourselves with? What, for instance, of the fatal accidents in New York of which we hear?" "I have never yet heard of a man, woman or child, being killed by contact with the trolley wire. I find a strong prejudice in England against the overhead wire. If that is so much disliked you have the underground, the conduit system, as an alternative."

"Then it is not a fact that you allow as many people to ride on your cars as can hang on by the skin of their teeth?" "That is so," said Mr. Littell. "I admit you do not do it here. But labor is cheaper in England than in America, 'buses are not as dear as cars, and you have no expensive tracks to maintain. No, London is a great city, the most interesting I ever saw, but its transportation system is about the worst."

## LIVERPOOL PURCHASES THE TRAMWAYS.

The Liverpool Tramway & Omnibus Company has agreed to sell and the city to purchase all of the property and assets of the Company for the sum of £567,375 (\$2,758,000) the transfer to be made on August 31, 1897. The company operates 40 miles of routes with 67 miles of track, 201 cars and 76 omnibuses; the company owns 3,500 horses. Several of the provisions of the agreement are noteworthy: The present directors of the company are retained to manage the business for five years and are to receive the same compensation as at present. If at the end of this period, or before, the services of the directors are no longer required they are to receive the capitalized values of annuities equal to the present compensation and terminating in 1915. The directors are not to engage in any enterprise which shall compete with the city in the tramway or omnibus business. The present auditors of the company if not continued in their offices are to receive annuities equivalent to their present incomes, and the solicitors also. Every servant or officer of the company other than those mentioned shall, if he so desire, be taken over by the corporation on the same terms as to position and salary as those under which he was employed on March 16, 1897.

### Chicago.

CHICAGO.—A new management has taken hold of the disused Northern Electric Railway connecting Moreland with Hanson Park, and after making repairs will begin operation with five cars.

CHICAGO.—Receiver John C. McKeon, of the Calumet Electric Railway, petitions the federal court for leave to borrow \$185,000, of which \$30,000 is for a new car barn, \$14,000 for a new power house, \$4,000 for additional tracks, \$700 for general repairs and \$800 for motor equipments.

CHICAGO.—The Midland Transit Company's application for right to build a street railway in Wabash avenue from Lake to 23rd streets to supply a downtown terminus for the Chicago General Railway, the General Electric Railroad and other suburban lines, has been referred to a sub-committee of the council.

CHICAGO.—The county commissioners have granted the Chicago, Blue Island & Harvey Railway permission to build in Western avenue, between Blue Island & Harvey. The company is required to illuminate its right of way with arc lamps situated not more than 500 ft. apart. A. G. Spalding asks the Federal Court to assign to him the Harvey Transit Company's franchise, for which the Chicago & Englewood Electric Street Railroad Company agreed but failed to pay \$10,000.

### Colorado.

FLORENCE, COLO.—M. Bines, Andrew Ralston and others have incorporated the Arkansas Valley Railway, Light & Power Company with \$750,000 capital.

BOULDER, COLO.—The Western Electric Transit & Power Company has been incorporated to build railways. Capital, \$100,000; incorporators, Edward B. Goodwin, M. J. Danford and others.

CRIPPLE CREEK, COLO.—The city council has granted C. F. McBall and C. E. Rolley a franchise to build an electric or cable railway. Their deposit of \$500 will be forfeited if the road is not in operation by August 1, 1907.

DENVER, COLO.—The Denver, Cripple Creek & Southern Railroad Company has been incorporated to build a steam or electric road from Garo to Canyon City. Capital stock, \$1,000,000; incorporators, Charles T. Case and George S. Freeman of Colorado; Charles E. Funk of Chicago, and Frank W. Corrigan of St. Louis.

DENVER, COLO.—Six miles of track have been completed for the Golden Circle Electric Railroad, and cars are expected to be running very soon. The Colfax Electric Company asks right of way on Alabama street for three miles of road, and has drawn plans for an enlargement of its car barn. The Denver City Railroad Company contemplates purchasing grip cars. The Denver Tramway Company will purchase 36 ft. double track combination cars. Its Cook's Addition line will be equipped with electricity and operated with three cars.

### Connecticut.

BRIDGEPORT, CONN.—The Bridgeport Traction Company will begin at once the work of extending its lines from Southport to Westport.

### District of Columbia.

WASHINGTON, D. C.—The Capital Railway has nearly completed its line to Congress Heights.

WASHINGTON, D. C.—Stockholders of the proposed Washington, Woodside & Forest Glen Electric Railroad held a meeting, May 17, in the office of B. F. Leighton, corner of 4½ and D. streets, N. W.,

and decided to issue \$40,000 in bonds. This and other subscriptions will be handed over to Horace S. Cummings, president, and Charles P. Williams, general manager of the Brightwood Railroad Company, who will let the contracts for the construction of the line.

### Georgia.

SAVANNAH, GA.—Herman Myers and J. H. Fall have sold the properties of the Savannah Traction Company to the Savannah, Thunderbolt & Isle of Hope Railway Company, thus effecting a practical consolidation of all Savannah Street railways. The latter company will elect a new board of directors, and it is expected that George Parsons will be president, J. H. Fall of Nashville, vice-president, and Capt. J. H. Johnston, general manager.

### Illinois.

FULTON, ILL.—Kustes & Houghton have purchased C. W. Carroll's lease of the street lines and are now running cars.

SYCAMORE, ILL.—John B. Whalen, of Sycamore, is promoting an electric line from Streator to Geneva Lake via Marseilles, Sandwich, Hinckley and Sycamore, with power house at Hinckley.

EAST ST. LOUIS, ILL.—M. Harrold, superintendent of the East St. Louis Electric Street Railroad, plans extensions in two directions, and will ask the city council for permission to construct.

GALESBURG, ILL.—The Knoxville city council has granted the promoters of the railway right to run through the public square. After consulting the Galesburg company the promoters will begin work.

### Iowa.

BURLINGTON, IA.—The Burlington Electric Street Railroad is erecting a brick addition to its car house, 51 x 117 ft., costing \$5,000. Main street will be double-tracked and the rails replaced with 70-pound.

SIoux CITY, IA.—The county commissioners have granted the South Sioux City Traction Company right to construct an electric railway to Crystal Lake on condition that the road be in operation within six months.

CEDAR FALLS, IA.—C. W. McElyea has returned from his eastern trip convinced that compressed air is the motive power for street railways, and has accepted his franchise with the intention of using this power. He was especially pleased with the operation of the American Air Power Company's cars in New York and Washington.

### Kansas.

WICHITA, KAN.—The Wichita Electric Railway Company has leased its lighting plant, fixtures and franchises for ten years to the Wichita Gas, Electric Light & Power Company.

GALENA, KAN.—John M. Cooper, of Baxter Springs, is president and C. W. Daniels, of Baxter Springs, is secretary of the Southeast Kansas Electric Railway Company, which was recently incorporated to build between Galena and Baxter Springs.

### Kentucky.

COVINGTON, KY.—Directors of the recently incorporated Crescent Springs & Erlanger Street Railway Company have elected Monte L. Green, president; W. H. Baker, vice-president; J. J. Graf, secretary; and R. H. Crisler, treasurer.

ASHLAND, KY.—The Ashland & Catlettsburg Street Railway Company contemplates extending through Kenova, Central City, Ceredo and Huntington. Right of way has been obtained in Kenova and negotiations are pending with officials of Central City and Huntington. If the present plans are carried out there will be a continuous street railway from Hanging Rock, O., to Huntington, W. Va.

COVINGTON, KY.—The Crescent Springs & Erlanger Electric Street Railway Company has been incorporated to build seven miles of road from the eastern terminus of Ludlow, through Bromley and Crescent Springs to Erlanger. Capital stock, \$10,000; incorporators, R. H. Crisler of Ludlow, Jesse and Mount Green, John F. Walton, John Graf, J. C. Keck and J. A. Seissinger of Crescent Springs.

### Maine.

BANGOR, ME.—Stockholders of the Bangor, Orono & Oldtown Railway voted May 18 to build two more miles of road in Bangor.

BANGOR, ME.—It is said the Bangor Public Works Company will purchase the new Bangor, Hampden & Winterport Electric Railway.

WATERVILLE, ME.—I. C. Libby offers to rebuild, re-equip and extend the Waterville & Fairfield Electric Railway, which is in a bad way, financially and physically.

BANGOR, ME.—Work is to begin in two months on the electric road connecting Bangor with Glenburn, Kenduskeag, Corinth and Charleston. Surveys are being made over the line, which is to be 26 miles long. F. O. Bend of the Penobscot Central Railway is interested.

PORTLAND, ME.—The Westbrook, Windham & Harrison Railway Company, which was recently incorporated with \$300,000 capital stock, has elected the following directors; Arthur W. Merrill and William M. Bradley of Portland; and J. C. Scates, president; C. B. Woodman, vice-president; C. M. Waterhouse, treasurer, and J. H. Tolman, secretary, all of Westbrook.

### Maryland.

BALTIMORE, MD.—Mayor Hooper has signed the ordinance giving the Central Railway Company right to lay track in several streets.

BALTIMORE, MD.—The consolidation of the Baltimore Traction and the City & Suburban Companies is said to be practically settled, there remaining only the ratification by stockholders.

### Massachusetts.

MERRIMAC, MASS.—The Haverhill & Amesbury Street Railway is to be extended a distance of nine miles from Salisbury to Hampton.

AMHERST, MASS.—J. A. Noble will build a car house 66 x 26 ft. for the new electric road. O. A. Howard has been appointed superintendent.

WOBURN, MASS.—The larger of the two car barns of the North Woburn Street Railway Company was burned on the night of May 23 causing \$2,000 loss.

BROCKTON, MASS.—The East Bridgewater & Brockton Street Railway Company has given a check for \$10,000 as a forfeit if the road is not built within 18 months.

BROOKFIELD, MASS.—A pleasure resort will be established by the Warren, Brookfield & Spencer Electric Railway on the shores of a lake, where a site has been leased.

BOSTON, MASS.—With a view to extending its line the Wellesley & Boston Street Railway Company asks permission to increase its capital stock from \$30,000 to \$100,000.

AMHERST, MASS.—Directors of the Amherst & Sunderland Street Railway are considering the extension of their line to a pleasure resort, which they propose to establish.

MANSFIELD, MASS.—Frank Mead and D. A. Brooks, of Braintree, Mass., are interested in the Mansfield & Norton Electric Railway Company, which has applied for a franchise.

NATICK, MASS.—The Natick & Cochituate Street Railway Company has been granted the franchise to extend its track to Saxenville, and the location having been practically settled, work will be pushed as soon as material can be secured.

MILFORD, MASS.—The selectmen voted May 11, to grant the Milford & Upton Street Railway Company a location. W. D. Leahy, of Milford, says work may begin immediately if the terms of the franchise are satisfactory to the company, of which he is a director.

WESTFIELD, MASS.—The state railroad commissioners, having granted the Woronoco Street Railway permission to increase its capital stock from \$50,000 to \$100,000 and double the amount of bonds, the six miles of extensions will be constructed this summer.

BROCKTON, MASS.—The Brockton & East Bridgewater Street Railway Company has been incorporated to build a line between the two cities. Capital stock, \$50,000 incorporators, W. L. Douglas, John J. Whipple, William Jones, C. C. Merritt, George J. Morse, M. C. Hinds and Joshua Dean.

WHITMAN, MASS.—The selectmen have granted the Whitman & Rockland Street Railway Company right to lay tracks from the Bridgewater to the Abington lines, including the privilege of paralleling the Brockton Street Railway for over a mile, if the latter will not permit operation of cars over its tracks.

MILFORD, MASS.—The Milford, Hopkinton & Westboro Street Railway Company has been incorporated to build a road this summer between the towns. Right of way will be obtained and franchises asked for. Capital stock, \$120,000, most of which has been subscribed; incorporators, C. W. Shippee, J. Allen Rice, H. D. Bowker, C. L. Clafin, L. E. Coolidge and others.

WORCESTER, MASS.—The Worcester & Marlboro Street Railway Company has organized under its charter by electing the following officers and directors: President, J. Russel Marble; vice-president, Otis E. Putnam; secretary, Robert P. Clapp; directors, J. Russel Marble, Otis E. Putnam, John C. McInnes, and Rufus S. Woodward, of Worcester; C. O. Green, of Shrewsbury; George L. Smith, of Westboro, and S. Reed Anthony, of Boston.

### Michigan.

PORT HURON, MICH.—The City Electric Railway Company has been granted a new 30-year franchise.

ADRIAN, MICH.—No bids having been received May 25, the receiver's sale of the street railway has been postponed.

DETROIT, MICH.—Pontiac has finally granted a franchise to the Oakland Railway providing a 10 cent fare to Birmingham.

MUSKOGON, MICH.—The Muskegon Street Railway Company has given a mortgage for \$25,000 to the Portland (Me.) Trust Company.

HOLLAND, MICH.—Objectors to C. M. Humphrey's proposed electric road having been won over it is expected that work will soon begin.

SAGINAW, MICH.—A receiver has been appointed for the Consolidated Street Railway on petition of the Boston Safe Deposit & Trust Company.

SAGINAW, MICH.—The Union Street Railway Company has given the Union Trust Company of Detroit a chattel mortgage to secure \$42,000 of indebtedness.

ST. JOSEPH, MICH.—James Brooks, receiver of the St. Joseph & Lake Shore Street Railway, has been authorized to sell the rails, ties and planks at private sale. No offer of less than \$3.50 per ton as they lie will be accepted for the rails.

DETROIT, MICH.—Monguagon township has given a franchise to the Detroit & Toledo Electric Railway Company, notwithstanding the fact that an exclusive 30 year franchise has already been granted the Wyandotte & Detroit River Electric Railway.

FLINT, MICH.—The city council favors granting John E. Nolan a new franchise in place of the one which has just expired. Since receiving the franchise two years ago Mr. Nolan has not been able to interest capital for construction owing to the hard times.

ST. JOHNS, MICH.—Promoters of the electric road from Lansing to St. Louis have appointed the following committee to push the project: O. P. DeWitt, St. Johns; Senator Mudge, Maple Rapids; Editor McCall, Ithaca; Mr. Seaver, Pompeii, and Mark Woodruff.

**BENTON HARBOR, MICH.**—Cleveland capital is now said to be backing the Benton Harbor Electric Railway & Transit Company. J. W. Hamilton, of Chicago, is president; H. D. Deam, of Chicago, vice-president; W. H. Hollis, of Illinois, secretary, and C. G. Davis, of Cleveland, O., treasurer. Several hundred teams are at work on grading.

**DETROIT, MICH.**—John B. Dyar, chief promoter of the big Detroit-Port Huron Interurban Electric Railroad, on May 13, transferred property and securities valued at \$200,000 to a trustee for the benefit of creditors. For 20 years Mr. Dyar has been a successful business man of Detroit, and his embarrassment at this time is due to his connection with the electric railway scheme.

## Minnesota.

**STILLWATER, MINN.**—The city council has voted to give a bonus of \$5,000 to anyone who will purchase and operate the street railway.

**ST. PAUL, MINN.**—The Twin City Rapid Transit Company has practically consented to build a portion of the desired electric road to St. Anthony Park.

## Mississippi.

**MERIDIAN, MISS.**—John Kamper of Enterprise, has purchased the electric line of W. R. Hall, and will invest more capital in improvements, including a new corliss engine, rails for an extension and additional cars.

## Missouri.

**ST. LOUIS, MO.**—The Fourth Street & Arsenal Railroad will be sold June 29, under foreclosure of second mortgage.

**KANSAS CITY, MO.**—Rumor has it that a great interurban electric railroad is to be built between Kansas City and Leavenworth. Colonel D. A. McKibben, Major John M. Long, Harvey M. Rush and George W. Kirstead are said to be interested.

**ST. LOUIS, MO.**—The Lindell Railway is arranging with the Missouri Pacific Railroad to give a suburban service to Kirkwood. The steam road will put in service a number of light trains transferring passengers to the Lindell at Vandeventer avenue station, thus offering strong competition to the St. Louis Suburban, whose stockholders recently acquired the Houseman air line with a view to employ it as a feeder to their line.

**ST. LOUIS, MO.**—The House of Delegates has read a second time the bill authorizing the North End Electric Railway to construct a line from the river to Forest Park. A bill has been introduced authorizing the Southern Electric Railroad to extend its double track line from Seventh and Howard streets. The House has passed an ordinance authorizing the North & South Railway Company to construct and operate lines over certain streets in St. Louis.

**KANSAS CITY, MO.**—Robert Gillham, receiver of the Northeast Electric Railway has turned the property over to the Northeast Electric Street Railway Company. Mr. Gillham took charge of the road in October, 1895, and has rehabilitated the line, converting a burdensome "lawsuit" into a well equipped and paying property. On July 30 the road was sold under foreclosure of mortgage to the Jarvis Conklin Trust Company. Last November the reorganized company was incorporated with \$500,000 capital stock.

**ST. LOUIS, MO.**—The St. Louis, Clayton & Creve Coeur Lake Railroad Company has filed articles of incorporation with the secretary of state. Twelve miles of electric road will be built to carry passengers and light freight. Capital stock, \$120,000, of which \$12,000 has been subscribed and 5 per cent paid in. Incorporators, George W. Baumhoff, 50 shares; Charles Hodgman, 50; Samuel Barnes, 5; John L. Miers, 5; Luther S. Handy, 5, and Lon O. Hocker, 5, all of St. Louis. The St. Louis & Meramec River Railroad Company will ask the Kirkwood trustees for a more liberal franchise in place of the present one, which contains burdensome conditions. President Case says the road will undoubtedly be built through to Kirkwood.

**KANSAS CITY, MO.**—The Riverview power station of the Metropolitan Street Railway has been placed in operation. Cars are running on the new West Side line to Kosedale. The extension talked of by the residents of Bonner Springs has not yet been considered by

the directors, but will be in the future. It would be eight miles long. S. L. Conklin, of New York, has been in Kansas City to talk over various extensions of the Northeast Electric Railway, in which he is a large stockholder. Superintendent J. H. Pickering, of the Kansas City & Independence Air line, is watching the experiments in the East with compressed air with a view to adopting air motors to run the trains in place of steam. The change will not be made before next fall.

**ST. LOUIS, MO.**—Directors of the Southern Electric Railroad contemplate extensions, and will probably petition the municipal assembly for a franchise at an early date. The present terminus at Broadway and Howard is to be moved northward near Bellefontaine and Calvary Cemetery. The Northern Central Electric Road will get right of way and apply for a franchise to extend its line into St. Louis county. George W. Baumhoff, of the Lindell Railway, has received assurances from the St. Louis County Court that a franchise would be granted for a street railway from Delmar and Adelaide avenues to St. Charles rock road. A branch line will also extend from the Delmar boulevard and connect with the Cross County Railroad, for which a franchise was granted some time ago.

## Montana.

**ANACONDA, MONT.**—An extension of 15 miles will soon be made by the Anaconda Electric Railway, Light & Power Company. Some new cars have been ordered.

## Nebraska.

**NORFOLK, NEB.**—The franchise, cars, mules and all appurtenances of the Norfolk Street Railway were recently sold for \$55.

## New Hampshire.

**EXETER, N. H.**—John Giddings & Son, of Somerville, Mass., have the contract to construct the power station for the Exeter Street Railway.

**EXETER, N. H.**—The Exeter Electric Railway Company's petition to issue \$100,000 of bonds and an equal amount in stock to cover the cost of the new road was heard May 5 by the state railroad commissioners.

**PORTSMOUTH, N. H.**—Manager A. F. Gerald, of the Portsmouth, Kittery & York Beach Electric Railroad, says that work will immediately proceed, the supreme court having denied the petition of York Harbor residents for an injunction restraining construction.

**DERRY, N. H.**—The new Chester & Derry Electric Railway Company at its first annual meeting elected the following directors: Cassius S. Campbell, Frederick J. Shepard, Greenleaf K. Bartlett, Charles Bartlett, Arthur H. Wilcomb, George S. West and Watters W. Goldsmith.

**CHARLESTOWN, N. H.**—E. C. Crosby of Brattleboro, Vt., M. A. Coolidge of Fitchburg, Mass., and a third party, have acquired the Springfield & Charlestown Electric Railway. They will complete the road at an expense of \$40,000. At the start the road will be equipped with six cars, part freight and part passenger. Two generators will be put in the power house at Springfield, one for water power and one for steam. While Adna Brown has been elected president of the new company it is understood that Mr. Crosby will be the active manager.

## New Jersey.

**JERSEY CITY, N. J.**—The Consolidated Traction Company contemplates constructing a line through Greenville to Jackson avenue.

**CAMDEN, N. J.**—Work on the new car barn, machine shop and paint shop of the Camden & Suburban Railway, on Newton avenue is progressing.

**ELIZABETH, N. J.**—The Union County Board of Freeholders will present a bill to the Legislature authorizing them to construct and operate a street railroad on any of the county roads and to lease same for term of years.

## New York.

**COHOES, N. Y.**—The Cohoes City Railway Company contemplates erecting a power station of its own.

ALBANY, N. Y.—The Albany Railway has filed its acceptance of the franchise granted by the city of Rensselaer.

BUFFALO, N. Y.—The Buffalo Traction Company has filed a map of the first 15 miles of streets on which it proposes to build.

WESTFIELD, N. Y.—The Westfield, Mayville & Chautauqua Motor Railroad Company has accepted the franchise granted by Mayville.

RIVERHEAD, N. Y.—Consents are being obtained by President Solomon P. Brooks for the trolley line from Riverhead to Westhampton.

OLEAN, N. Y.—The car barns of the Olean & Bradford Electric Railway are fast nearing completion. The track work also has made great progress.

PENN YAN, N. Y.—William H. Tylee, of Penn Yan, has made a call on stockholders for 30 per cent of their subscriptions to the new electric railway.

PENN YAN, N. Y.—The Penn Yan & Keuka Park Street Railway Company has been granted an additional franchise to operate over Hamilton street.

NYACK, N. Y.—T. F. Odell, of the board of trade, is conferring with the Christian Alliance with a view to the construction of an electric road in Nyack.

MECHANICVILLE, N. Y.—The Stillwater & Mechanicville Street Railway Company has filed with the secretary of state a certificate of its proposed extension in Mechanicville.

PORT JERVIS, N. Y.—Franchises will be asked by the Port Jervis Electric Street Railway Company. Ex-Gov. Waller is president of the company which was recently incorporated.

ROCHESTER, N. Y.—An extension costing \$80,000, direct from Rochester to Manitou Beech is contemplated by the Rochester, Charlotte & Manitou Electric Railway Company.

BUFFALO, N. Y.—Engineer Nott, of Hamburg, has begun the final survey of the Buffalo, Hamburg & East Aurora Electric Railroad preparatory to advertising for bids for construction.

NIAGARA FALLS, N. Y.—James H. Rand, president of the Tonawanda Railway Company, has applied for right to build and operate an electric road on Portage road, Parkard road, Ferry, Main and Niagara streets to Riverway.

NEWBURGH, N. Y.—Judge Dykman has granted an injunction restraining the city from selling the Newburgh Electric Railroad. The road is in arrears for taxes and paving assessments and was advertised to be sold to satisfy the city's liens.

WAVERLY, N. Y.—The Waverly, Sayre & Athens Electric Railway Company has acquired a controlling interest in the electric light and power company. The two plants will be consolidated. Other important deals are being considered by the railway company.

SEA CLIFF, N. Y.—The North Side Construction Company has been incorporated to build electric and compressed air railroads, lighting and power plants, water works, etc. Capital stock, \$5,000; incorporators, C. E. Silkworth, John Graham, George Muller, of Sea Cliff, James Norton and William Schoelles, of Sea Cliff.

ONEONTA, N. Y.—The Oneonta & Otsego Valley Railroad Company has been incorporated to build ten miles of road, connecting Oneonta with the intersection of the stage road from Oneonta to Laurens. Capital stock, \$100,000; directors, Frank Gould, A. D. Getman, A. C. Lewis, Parker Wilson and others, of Oneonta.

NEW YORK, N. Y.—Justice Beach has dissolved the injunction restraining the Metropolitan Street Railway for installing electricity on the Eighth avenue horse line. Work will soon commence. It is said the Metropolitan has acquired control of the Central Crosstown line, thus shutting off the Third Avenue Railroad from valuable connections.

OSWEGO, N. Y.—Justice Wright has granted Receiver Tidman, of the Lake Ontario & Boulevard Railroad Company, authority to issue \$50,000 of receiver's certificates with which to build the extension to Minnetto, put in a power plant, buy fare registers, car fenders and everything needed to make the road a first class institution and a paying enterprise. Mr. Tidman has perfected arrangements for negotiating the certificates.

LYONS, N. Y.—The Lyons & Sodus Bay Electric Railroad Company has applied to the trustees for right to construct and operate a surface railway upon Geneva, Phelps, Broad and Water streets. The incorporators are George W. Knowles, William S. Gavitt, Daniel Moran, James W. Putnam, W. H. Baltzel, F. W. Chamberlain, H. F. Zimmerlin, Richard F. Forgham, A. L. Hoffman, O. F. Thomas, J. F. Guenther, W. H. Egan, George Rankert, G. W. Hattler, Charles T. Ennis, B. Hammond, E. W. Hamm, S. C. Redgrove, V. R. Howell, M. C. Taylor, W. Van Camp, George H. Baltzel, C. R. Sherwood, J. S. Jordan.

NEW YORK, N. Y.—The Union Railway Company is distributing rails for six miles of double track trolley line in Jerome avenue. The overhead material will be supported on center poles. An extension of its lines on the east side of the city directly west to connect with the Jerome avenue road is also planned. The work is expected to be finished by July 20. Henry J. Braker offers the city \$1,000,000 each for the franchises of the Sixth and Eighth Avenue Railroad Companies; but the sinking fund commissioners think they have no power to act and will not consider the offer without an opinion from the corporation counsel.

SARATOGA, N. Y.—Robert B. Smith, of Hackensack, N. J., Charles G. Farwell of Boston, Alfred B. Thatcher, C. Herckenrath, W. S. Jenks, Charles H. Davis and S. R. Berton of New York, and Theodore F. Hamilton of Saratoga, have incorporated two companies to construct surface roads in Saratoga. They are the Saratoga Traction Company, capital \$50,000, to build 2.5 miles of road from Broadway and Congress streets to the Kissingen, Geysler and Vichy springs, and the Saratoga Lake Railroad Company, capital \$150,000, to build a line from the same point in Saratoga to Moon's corners, on the west side of Saratoga Lake.

## Ohio.

LIMA, O.—The Lima Street Railway asks permission to extend its tracks on Wayne and Pine streets.

SPRINGFIELD, O.—R. B. Coover and C. S. Olinger have applied for right of way for an electric road to Vienna.

EAST LIVERPOOL, O.—The new owners of the East Liverpool & Wellsville Street Railway will make repairs and add new equipment at a cost of \$40,000.

DAYTON, O.—The Dayton & Western Traction Company has accepted its franchise from the county commissioners, giving a bond for \$10,000 to guarantee completion before July, 1898.

DAYTON, O.—Dr. J. E. <sup>1</sup>Lowes, president of the Dayton & Western Traction Company, states that work will begin shortly and will be completed November 1, if present arrangements are carried out.

CLEVELAND, O.—The Cleveland, Painesville & Eastern Railroad has been granted a franchise to run a loop down Lake road, connecting Willoughby and Nottingham, with privilege of carrying light freight.

SPRINGFIELD, O.—The Montgomery county commissioners have granted the Dayton & Springfield Interurban an extension of time from September 1 to October 1, in which to have the first mile of the road completed.

EAST LIVERPOOL, O.—Herbert Payson, trustee for bondholders, on May 5, bought the East Liverpool & Wellsville Street Railway for \$102,000 at sheriff's sale. The road had been appraised at \$151,000. Among those present were Tom L. Johnson, H. J. Davies and Charles Brooks, representing a Cleveland trust company.

BUCYRUS, O.—W. E. Haycox has closed arrangements for beginning work on the Bucyrus & Gallion Electric Railway, and expects that cars will be running before snow flies. Engineers E. B. Shifley

and H. V. Flickinger will have the route staked out within two weeks, when it is promised that material for construction will be on the ground. The power house is to be located in Bucyrus, on a site not yet selected.

## Pennsylvania.

UNIONTOWN, PA.—Operation has been resumed on the Uniontown Railway, which was recently sold by the sheriff.

READING, PA.—Stockholders of the East Reading Electric Railway have voted to increase the bonded debt \$25,000 to pay for the extension to Carsonia Park.

READING, PA.—The Reading & Boyertown Electric Railway Company will pay the Oley Turnpike Company \$25,000 for right of way from Black Bear to Jacksonwald.

PHILADELPHIA, PA.—The West End Traction Company has been incorporated. Capital stock, \$10,000; incorporators, William S. Carrigan, Harry S. Bottomley, Charles K. Chandler, Robert P. Cregar and H. C. Owen.

PITTSBURG, PA.—The Bellevernon & Eastside Street Railway Company has been incorporated to build and operate five miles of road. Directors, George D. Jenkins, president, H. R. Meyers, O. M. Hartley, N. E. Clark and O. M. Henderson.

MEADVILLE, PA.—The Meadville Traction Company has been incorporated to operate between Meadville and Cambridge Springs. Capital stock, \$350,000; incorporators, F. R. Shryock, Charles Fahr, George D. Trowen, H. H. Thompson, John J. Shryock and Cyrus See.

PHILADELPHIA, PA.—Stockholders of the East Penn Traction Company met recently at 1315 Arch street and voted to increase the capital stock from \$350,000 to \$416,000, and to issue an equal amount of bonds. About 200 men have been placed at work by the contractors.

PITTSBURG, PA.—The Central Traction Company asks the council for an extension of its tracks. The Beechwood Avenue Railway Company has applied for right of way. Franchises are also asked by the West End, Mt. Washington & Banksville Street Railway Company.

PITTSBURG, PA.—Suburban extensions will be carried out this summer by the Pittsburg & West End Passenger Railway Company, and the Second Avenue Traction Company. The Pittsburg, Allegheny & Manchester Traction Company will make a new mortgage for \$200,000 to fund its floating debt.

WEST NEWTON, PA.—The West Newton Passenger Railway Company has accepted the franchise granting right of way over Second street, giving a bond for \$10,000 to guarantee that work will be begun in six months and that cars will be running within a year. The line will connect with the Second Avenue Traction of Pittsburg, thus forming a direct route 33 miles long.

PITTSBURG, PA.—Three street railways were incorporated May 20, The West End, Mt. Washington & Banksville Street Railway Company, of Pittsburg, capital, \$12,000. This line begins at a point on Woodbine avenue in the Thirty-sixth ward, at the terminus of the track of the Pittsburg & West End railway, and runs to Virginia avenue and Kearsarge street. The president is John C. Reilly; directors, Thomas S. Bigelow, W. J. Burns, J. D. Callery, E. S. Reilly, W. J. Burns, Jr. The Carnegie, Heidelberg & Bridgeville Street Railway Company, of Carnegie, capital, \$30,000. This line runs from Washington avenue and Main street, in Carnegie, to Third and Main streets. The officers are the same as in the above company. The McKeesport, Monongahela & Finleyville Street Railway Company, the line of which runs along the river road near Dravosburg, through Midlin and Jefferson townships to Monongahela borough, with a branch to Finleyville; capital, \$10,000. The president is J. L. D. Speer; directors, Joseph H. Moore, M. M. Bunting, David Jenkins, William K. Rowe.

## Tennessee.

JOHNSON CITY, TENN.—J. E. Brading will lease the Johnson City & Carnegie Street Railway, of which he has been appointed receiver, and operate cars after June 1.

## Texas.

PALESTINE, TEX.—The Palestine Street Railway & Electric Light Company has petitioned for franchises.

BEAUMONT, TEX.—Fred Zoiner of South Dakota asks an electric railway franchise. Together with S. M. Peters, R. G. Jenkins and O. W. Putnam he has formed the Beaumont Electric Railroad Company.

## Vermont.

ST. ALBANS, VT.—Alfred A. Hall, George W. Crampton and W. Tracy Smith are interested in a proposed electric road to St. Albans Bay, 2.5 miles long.

## Virginia.

STAUNTON, VA. R. D. Apperson, general manager of the City Street Car Company, writes us: "We are in the market for 50, 56 or 60-lb. relaying rail 'I' for immediate delivery at this point, together with all the necessary fastenings. Prices and all information must be sent at once."

## Wisconsin.

MILWAUKEE, WIS.—Receiver J. W. Bingham has applied to the court for permission to sell the Milwaukee & Wauwatosa Motor Railway.

MILWAUKEE, WIS.—Right to build an extension on Jackson street has been granted the Milwaukee Electric Railway & Lighting Company.

OSHKOSH, WIS.—A bond for \$2,500 was given May 5 by the electric road to indemnify the city on account of tearing up the streets, and the Electric Installation Company was permitted to resume work.

EAU CLAIRE, WIS.—The Chippewa Valley Electric Railway Company has been incorporated to operate a street railway and lighting plant. Capital stock, \$100,000; incorporators, A. J. Keith, W. C. Donovan and C. E. Kelsey.

GREEN BAY, WIS.—The Fox River Electric Railway Company has taken an option on the plant of the Green Bay Gas & Electric Light Company. The option holds good until July 15, and will probably lead to the consolidation of the two interests.

OSHKOSH, WIS.—An ordinance has been introduced in the city council to declare the franchise granted James K. Tillotson in full force and effect. The franchise was assigned by Tillotson to the Citizens Traction Company, which is now building the road.

## Canada

LONDON, ONT.—About \$10,000 will be expended on extensions by the London Street Railway Company.

LONDON, ONT.—The London Street Railway Company is expected to build a line to Lucan, for which permission was granted by the Legislature.

WINDSOR, ONT.—The Windsor Electric Railway Company expects to go ahead with the contemplated extension to Chappels and the loop line in Walkerville.

HAMILTON, ONT.—The Hamilton & Dundas Railway has submitted plans to the city for the conversion of its dummy line to electricity in connection with the Radial Electric Railway.

HAMILTON, ONT.—The stock of the Hamilton, Chedoke & Ancaster Electric Railway has been placed in the hands of William Strong to be disposed of. About \$15,000 of the total \$100,000 has already been subscribed. The following directors have been elected: Edward A. Clifford, Ancaster, president; Edward Henderson, Ancaster, vice-president; Rev. W. R. Clark, Ancaster; F. Snider, Hamilton; B. W. Donnelly, Ancaster; W. F. Walker, Q. C., solicitor and secretary, Hamilton; T. S. Bell, engineer, Hamilton.

**RAILWAYS FOR GHENT.**

The city of Ghent has prepared specifications and invited proposals for the construction and operation of seven lines of street railways aggregating about 14 miles of single track, to be operated by electricity either with storage batteries alone or by a mixed system such as is employed in Hanover, as the overhead trolley will not be permitted in the central portion of the city. The concession will be granted to the successful bidder for a term of 50 years, the city retaining the privilege of purchasing the road at any time; if purchased before 20 years, the company will receive the capital invested plus 20 per cent; if after 20 years, the company will receive for the remainder of the term an annuity equal to the average net revenue for the 5 years preceding the sale, plus 10 per cent, or the capital of such annuity computed with interest at 4 per cent.

Bidders must submit proposals upon stamped paper not later than July 5, 1897, and must specify the system of operation proposed and the per centage of the receipts that they engage to pay the city (the minimum is fixed at 20,000 francs per annum), and deposit 200,000 francs with the National Bank of Belgium as a guarantee of good faith.

Those interested can procure copies of the specifications and the stamped paper for the proposals through the Belgian consuls.

**BUILDING FOR EXHIBITS, A. S. R. A., AT NIAGARA.**

The local committee at Niagara Falls, which has in hand the furnishing of a home for the convention of the American Street Railway Association at its October meeting in that city, has abandoned the project of erecting a building for the purpose, and instead has bought an unused armory.

CONVENTION AND EXHIBIT HALL AT NIAGARA FALLS.

When enlarged as proposed the building will be 132 x 132 ft.; it is now 90 x 132 ft. It is within 10 minutes' walk of the hotels, and street and steam tracks will be brought into the building. Business sessions will be held in the room in second story, seating 300; entrance to this room is by stairs inside the building. The building is on Walnut avenue with fronts on two cross streets also. Temporary street car tracks will be laid at both sides and in front, or as as much as necessary to accommodate all cars, sweepers, etc. The portion of the building shown at the left has a sloping roof,

FLOOR PLAN EXHIBIT BUILDING.

14 ft. high at the sides, with a large skylight and side windows; the larger room is 16 ft. high at the sides and well

Side Elevation

lighted by side windows. The building is steam heated. We understand both exhibit rooms are free from posts, the roofs being trussed.

**CENTRAL ELECTRIC SPLICERS.**

The Central Electric Company, of Chicago, is laying special stress upon its trolley wire splicers, three forms of which are shown herewith. They are made of special drawn tubing and offer a very smooth passage to the trolley

wheel. The company is also offering to the trade some special wire splicers, made of drawn tubing, which are considered unique in design, and motor bearings which are very superior in finish and wearing qualities.

A systematic scheme for swindling the street railway company by means of bogus transfer tickets was unearthed by the police and the railway officials in Toronto.

THE SIMPLEX TELEPHONE.

Through the courtesy of A. A. Anderson, general manager of the Mahoning Valley Railway Company, Youngstown, O., we have received some views illustrating the telephone system installed for that company by the Simplex Interior Telephone Company, of Cincinnati, in 1896. This emergency telephone was briefly described on page 310 of the REVIEW for May. The distance from the Youngstown power house to the power station in Niles is about 9½ miles; 27 cut-in boxes and two terminal stations were put in on this line. In the city and suburbs where there are

NO SPITTING IN MINNEAPOLIS CARS.

The effort to stop the disgusting habit of spitting in street cars and public places is making most satisfactory and encouraging progress. Already in a large number of cities the nuisance is either abated or practically so. It will soon be considered so ill-mannered to spit in a car that few will do so for the shame of the thing and for others who apparently have no sense of decency, suitable laws are being enacted and what is better, enforced. The example of a wealthy but stubborn man in San Francisco, who upon being fined for the offense went out and deliberately committed a second offense in the first car he found, will have a big moral effect. He was as promptly arrested and given 24 hours in the county jail.

While the Minneapolis ordinance is not very delectable reading, we print it as a guide to any of our readers who contemplate securing similar legislation in their own city. It will be noticed the law is specifically for street cars when in service.

AN ORDINANCE

To Prohibit Spitting and Depositing Sputum, Spittle, Saliva, Phlegm or Mucus Upon the Inside or Platforms of Street Cars, When In Use on the Streets or Highways in the City of Minneapolis and Prohibiting the Defilement of Such Cars When So in Use:

The City Council of the City of Minneapolis do Ordain as follows:

Section 1. Any person who shall spit or expectorate or deposit, or place any sputum, spittle, saliva, phlegm or mucus upon the floor, or inside furnishings, or equipment, or in any place upon the inside, or upon any platform of any street car while the same is in use upon any of the streets or highways in the City of Minneapolis, after being requested by the conductor in charge of such car not so to do shall be deemed guilty of a misdemeanor.

Sec. 2. Any person who shall defile any street car while in use upon any street or highway in the City of Minneapolis, by spitting upon the floor or inside furnishings or equipment, or in any place upon the inside, or upon any platform of such car, or by any other means, or in any other manner shall defile such car so that the same shall be unclean for use as a street car, or so as to interfere with the comfort or well being of passengers thereon, shall be deemed guilty of a misdemeanor.

Sec. 3. Any person who shall violate any provision of any section of this ordinance shall, upon the conviction thereof before the Municipal Court of said city, be punished by a fine not to exceed ten dollars for each offense, and upon default in the payment of such fine, may be imprisoned until such fine is paid, but not to exceed ten days.

Sec. 4. This Ordinance shall take effect and be in force from and after its publication.

The two tons of copper wire stolen from the Hartford Street Railway, May 8, were recovered in Philadelphia.

REPORTING TROUBLE.

ordinary exchange telephones available for the use of the train crew in case of accident none of the emergency cut-in boxes are put up; on the rest of the line they are placed at intervals of about 1,500 ft. The Mahoning Valley Company advises us that the system has given excellent satisfaction and that it considers it indispensable to the operation of an interurban road. The illustrations are self-explanatory and show the receiver and transmitter, the cut-in box and the manner of using the system.

When it is desired to be able to signal both ways on such a system it is only necessary to put in a magneto at the central station and extension bells at the various sub-stations, the sub-station calling central with battery key the same as the emergency boxes.

CUT-IN BOX AND RECEIVER AND TRANSMITTER.

## AMERICAN WORKS OF THE FUEL ECONOMIZER COMPANY.

In designing the manufacturing plant of the Fuel Economizer Company of Matteawan, N. Y., and of which we present some illustrations, the general manager of the company, A. H. Blackburn, endeavored to so arrange the works, that receiving the raw material at one end, it should be passed along from shop to shop, and finally emerge as a finished product with the minimum possible amount of handling. With this object in view the foundry is placed directly behind the machine shop, and as the castings come from the foundry they go to the cleaning shop, and thence to the machine shop. Here they are machined and passed to the hydraulic presses, the sections there being pressed together, and after being tested are ready to be loaded on to cars for shipment.

The machine shop and foundry cover a space of 50x360 ft., and are so arranged that either or both can at any time be enlarged to double their present capacity, and the present convenient and economical plan of handling material preserved. The pattern shop and boiler house are in separate buildings, the latter having a switch to deliver coal into the boiler room. The draughting room is on the second floor of the well lighted office building. The shop buildings also were designed with a very large window space.

The works are located along the railroad, with a switch running into the yard. Taking advantage of a natural incline of the lot a gravity system of switching has been arranged inside of the yard, by means of which cars placed at the end of the yard by the switch engine may be loaded and switched from one track to another, thus allowing the loading and shifting of a number of cars during the day without requiring the engine. In addition to the railroad

THE FUEL ECONOMIZER COMPANY.

facilities afforded, the location on the Hudson river makes it possible to make many shipments by water, all the raw material being received by water.

In both the foundry and machine shop the latest improved machinery has been installed in order that the work may be turned out at a minimum cost. Air hoists are used throughout for handling material, and have proved very successful. The compressor was furnished by the Ingersoll-Sergeant

Drill Company, and the hoists by the Whiting Foundry Equipment Company, which also furnished one of the cupolas. Molding machines are used in the foundry. The shops are lighted by electricity, arc and incandescent lamps being used, and in case of a breakdown in the lighting plant the lights can be switched on to the street circuit.

The very general use in which the Green economizers

OFFICES OF THE FUEL ECONOMIZER COMPANY.

have come in England and Europe bids fair to be repeated here, where thousands of horse power are being installed each year. The company has a large number of sales offices, the western territory being in charge of Stanley Green, Chicago, who has made a fine record.

## NEW HOSE BRIDGE.

The accompanying cut illustrates a hose bridge which has been patented by Messrs. Flannery and Fromm, and which has been given a trial in the East. Both the management of the street railway company and the fire department speak highly of it as a successful device for preventing blockades, when it is necessary to carry lines of hose across railway

tracks. Little in the way of description is needed to make clear the manner of its application. By means of the racks and gears the bridge may be expanded laterally to fit any gage from 34 to 62 in. and when adjusted to the proper width it is locked in place by jam nuts. Being only 34 in. wide when closed up, it is readily handled on the repair wagon.

Mrs. Susan St. John was awarded \$25,000 for injuries from being thrown from a North Chicago electric car.

## PLEASURE RESORTS.

The opening of street railway pleasure resorts and park attractions has been a little late this year on account of the late spring in many portions of the North, but is now fairly under way, and the public are once more spending afternoons, Sundays and evenings at these popular places. In some instances, last year, the results from a financial standpoint were disappointing to managers, and several even closed the season with an actual loss. This can be explained by the industrial stagnation, the counter attractions of a political campaign, and to some extent by a lack of experience as to what were really the most profitable attractions. As a rule light opera or anything on an elaborate scale should not be attempted in any but large cities, and not there where other similar summer attractions are running at the usual play houses. A good variety program, including some instrumental music, has generally proved profitable, as the performance can be made continuous for several hours with a comparatively small number of not very expensive people. Fire works when they do succeed are very profitable, but the expense is considerable and the uncertainty of what the weather may be, always makes this attraction a doubtful one. Where the resort is a large one a wise plan is to rent out as many concessions as possible, thus relieving the company of a large amount of detail, and leaving it free to put all its energies and money into one or more chief attractions.

The Woronoco Street Railway Company has obtained control of the Woronoco Park at Westfield, Mass., and will turn it into a pleasure resort for its patrons. The pavilion has been leased, refreshments will be served and special attractions presented.

At the Coney Island terminus of the Nassau Electric Railroad a large passenger station is being erected with a frontage of 160 ft. on Surf avenue and two well lighted promenades, one leading from the cars to Surf avenue and the other from the avenue to the waiting room.

The Galveston City Railroad Company had made improvements to the Olympia beach resort by providing bathing facilities, refreshments, etc. This will be an especially attractive place during the warm weather when bathing is in favor.

In addition to the many amusement features at Ross park the Binghamton Street Railroad Company has purchased three new graphophones and a large kinoscope and appliances for operating the same. These instruments will be used both at the Casino and at the park afternoons and evenings and exhibitions will be given free of charge. The street railway company has issued 3,000 copies of a handsomely illustrated publication, descriptive of Binghamton and its attractions.

The Fairmount Park Transportation Company of Philadelphia has purchased an 18-acre tract of ground bordering on Fairmount Park, and will convert it into a pleasure resort for the patrons of the road. The park, which was opened the first of this month, will hereafter be known as "Woodside." A casino building is being erected, 100 x 200 ft., and on this will be a roof garden. Among the amusement features that are to be provided will be a scenic railway, carrouzels, Edison's novelties, bicycle track, public bath house and an artificial boating lake. A concert band has also been engaged for the season.

The Hamilton (Ont.) Radial Electric Railway Company has procured a strip of land 600 ft. long on the lake beach,

and will erect a large hotel and summer garden with a theater in connection. It is expected that this will make one of the finest resorts in Canada.

The Union Traction Company of Philadelphia has signed a contract with Walter Damrosch, the famous musical director, to furnish music at the new Willow Grove Park for the summer. It is proposed to erect an elephant 100 feet high within the park.

As a great drawing card at Lake Erie Park, near Toledo, the Casino Company will erect a scenic railway at a cost of \$20,000. The structure will be 800 ft. long and will afford a ride of 3,500 ft. The railway resembles the switch back, but is built on a far more elaborate plan. After one or two breath-taking ascents and descents the car shoots into a tunnel, dark as midnight, and then suddenly passes into a room brilliant with electric lights.

The Holyoke Street Railway Company recently purchased a large orchestrino which will be placed in the new

IN INEXPENSIVE PAVILION.

pavilion on Mt. Tom during the summer. The instrument is the finest ever imported into this country and has all the instrumentalities of a complete orchestra.

Hyde Park is a very attractive summer resort near Austin, Texas. The Rapid Transit Railroad has added many things to enhance its beauty, and the people of Austin show their appreciation by visiting it in large numbers. The park and lake are lighted by arc lamps, croquet and lawn tennis grounds are laid out and a zoo has been started at one end of the park.

Birmingham, Ala., is favored with several pleasure resorts, and the Birmingham Railway & Electric Company has given every facility to the citizens to enjoy these parks. Special rates and other inducements are offered to church, Sunday school, society and club picnics to Hawkins Springs, Avondale, Ensley Bridge and East Lake. Vitascope exhibitions, band and orchestra concerts are given free of charge. General Manager McClary distributed buttons with the inscription, "Go to East Lake" and a colored view of the lake and pavilion.

Dubuque, Ia., has in prospect a resort of unusual size and beauty. The Dubuque Street Railway Company is asking for an extension of its franchise and promises if its request is granted to at once build a summer park. This park, to be known as "Lakeside," will be located near Thompson's mill, a place well suited naturally for an ideal resort. A dam will be constructed forming a lake of 200 acres, electric

launches, bath houses and facilities for aquatic sports being provided. The overflow of water from the dam will be utilized for generating electricity to light the park and furnish any other power required. The lake will be stocked with fish. Driveways, an observatory and other improvements will be made.

An illustrated pamphlet on Cayuga Lake Park is distributed by the Geneva, Waterloo, Seneca Falls & Cayuga Traction Company. Cayuga Lake is in the western part of central New York and is a sheet of water of surpassing beauty. The trolley cars of the Traction Company can be boarded at Geneva, Waterloo or Seneca Falls and after a delightful ride through several towns and villages and along the Seneca river, the passengers are carried into the park. An opera house, toboggan slides, boat houses, a bicycle track and athletic grounds afford amusement and recreation for the visitors.

Early this spring the Utica Belt Line Street Railroad Company purchased a tract of 40 acres on the east bank of Oriskany pond, a few miles out from the city. Summit Park is the name of the new resort. The railway company has spared neither time nor money in making the park attractive in every way. An expanse of still water, a mile in length, affords excellent facilities for boating; refreshment booths, dancing hall, band stand, water tower, observatory, summer theater, bicycle and racing track all contribute to make the park very inviting.

The Columbus (O.) Street Railway Company has published a little booklet, profusely and handsomely illustrated. The views are of shady nooks, the walks and drives, and the river flows past Olentangy Park. A number of the photographs were taken by Secretary P. V. Burrington. Each picture is accompanied by an appropriate quotation of poetry. These attractive pictures would certainly inspire a visit to the park.

J. W. Gorman, the pioneer in furnishing outdoor summer amusements, and who now makes a specialty of furnishing high grade entertainments and strictly desirable and taking performances for street railway resorts, has issued his annual of summer attractions. The pamphlet, which is fully illustrated, presents a fine assortment from which to select, and offers a wide range of entertainments. The attractions are all of a really good grade, selected with care, and guaranteed by Mr. Gorman to be exactly as represented. A copy will be sent to any manager by addressing J. W. Gorman, 180 Tremont street, Boston.

One of the most attractive things to small children and which can be supplied at practically no expense, is a large pile of clean sand. In resorts where there are no sand beaches a space should be set aside for this, and the sand removed and replaced several times during the season in case it becomes dirty. In Golden Gate Park, San Francisco, this is done, and daily attracts a large number of children.

The universal verdict from managers has been that the largest revenue earner in a resort is the "merry-go-round," or riding gallery. The children and young people never seem to tire of this attraction, nor are older people averse to frequent rides. They are operated by a motor using little power, and as built by the Armitage-Herschell Company, North Tonawanda, N. Y., are attractive, elegant and durable. One manager informs us he paid for his installation in less than three months last season.

Music of almost any kind, vocal or instrumental, is always good, and indeed a necessity at park resorts. August Pallman, 70 Franklin street, New York, is a large importer of mechanical organs of every variety from the penny-in-the-slot machines up to the large orchestrons operated by steam or electric power, and representing a full brass band. His instruments are proving very successful money earners in numerous street railway parks.

Norman & Evans, Lockport, N. Y., are well known builders of riding galleries, which are best operated with a motor from the trolley circuit. These attractions are money makers and no resort is really complete without one.

A. Elhogen & Co., 39 Third avenue, New York, are in position to save the railway manager lots of annoyance in securing performance attractions, having 50 standard shows from which to draw, and several hundred high class, sensational attractions. They guarantee their work, and have been established nearly 20 years. A recent novelty which is making money is the criteriascope, charges for which are moderate.

## THE ALLEN LAW.

Sec. 1. Be it enacted by the people of the State of Illinois, represented in the general assembly. That the title of an act entitled "An act in regard to horse and dummy railroads," approved March 10, 1874, in force July 1, 1874, be and the same is hereby amended so as to read as follows, viz.: "An act in regard to street railroads."

Sec. 2. That sections 1 and 3 of said act be and the same are hereby amended to read as follows:

Sec. 1. Any company which has been or shall be incorporated under any special or general law of this state for the purpose of constructing, maintaining or operating any horse, dummy or street railroad or tramway, may enter upon and appropriate any property necessary for the construction, maintenance of its road, and all necessary siding, side tracks and appurtenances, and may, subject to the provisions contained in this act, locate and construct its road upon or over any street, alley, road or highway, or across or over or under any waters in this state, in such manner as not to unnecessarily obstruct the public use of said street, alley, road or highway, or interrupt the navigation of such waters.

Every corporation may operate its railroad for the transportation of passengers and the United States mail.

Every such street railway may be operated by animal, cable, electric or any other motive power that may have been or shall hereafter be granted to it by the proper public officers or authorities, except steam locomotive engines.

The tracks of such street railway shall be laid as near the center of the highway as practicable, except at curves, and when more than one track is laid the said tracks shall be laid parallel and in such manner as to leave a space of at least four feet between the said tracks, and no car shall be operated with an overhang of more than twenty-two inches outside of the outermost edge of the rail of the tracks upon which said car shall be operated.

No street railroad corporation shall have the right to enter upon, appropriate or use the whole or any part of the property or tracks of another street railroad owned or used by it in the operation of its road, except to cross the same at any necessary angle, without the consent of the corporation whose property or tracks it seeks to use.

All street railroad corporations shall have the right to contract with each other for the use of their respective tracks or to lease to each other or to purchase from each other any portion or the whole of their property or tracks upon such terms and conditions as they may agree upon for the purpose of operating the same. And every such corporation shall have the right and authority to consolidate its stock, property and franchises with any other like corporation; provided, however, that no such corporation shall consolidate with any other corporation running a parallel or competing line.

In case any such consolidation shall take place, sixty days' notice thereof shall be given in the manner and form as prescribed in sec-

tion 15, chapter 114, of the revised statutes, concerning the incorporation of railroad companies.

All contracts, leases or purchases heretofore made by or between such corporations shall be valid the same as if made subsequently to the passage of this act.

Sec. 3. No such company shall have the right to locate or construct its road upon or along any street or alley, or over any public grounds in any incorporated city, town or village, without the consent of the corporate authorities of such city town or village; nor upon or along any road or highway or upon any public ground without any incorporated city, town or village except with the consent of the county board.

Such consent may be granted for any period not longer than fifty years on the petition of the company upon such terms and conditions not inconsistent with the provisions of this act, as such corporate authorities or county board, as the case may be, shall deem for the best interests of the public.

Provided, that no such consent shall be granted except upon the petition of the owners of land representing more than one-half of the frontage of the street, or so much thereof as is sought to be used for street railroad purposes, and when the street, or part thereof, sought to be used shall be more than one mile in extent, no petition of land owners shall be valid unless the same shall be signed by the owners of the land representing more than one-half of the frontage of each mile and fractional part of a mile, if any, in excess of the whole miles, measuring from the initial point named in such petition of such street or of the part thereof sought to be used for street railroad purposes; nor unless at least ten days' public notice of the time and place of presenting such petitions shall have been first given by publication in some newspaper published in the city or county where such street railroad is to be constructed, and except upon the condition that the company will pay all damages to owners of property abutting upon the street, alley, road, highway or public ground upon or over which such street railroad is to be constructed which they may sustain by reason of the location or construction of the street railroad, the same to be ascertained and paid in the manner provided by law for the exercise of the right of eminent domain.

Every grant of authority which shall hereafter be made by ordinance to lay street railway tracks in any street or highway which shall be granted without a full and strict compliance with all of the requirements of the law shall be void, and any corporation acting or attempting to act under any ordinance hereafter granted, granting to such corporation authority to construct and operate a street railroad, where such corporation has not strictly complied with every requirement of the law pertaining to such grant, may be enjoined from exercising any rights or privileges under such void grant, at the suit of any abutting land owner.

Provided, that no owner of property fronting or abutting upon any street where it is proposed to construct or operate a street railway shall, after having petitioned the city council or other proper corporate authority, as the case may be, as required by law, be permitted to revoke or cancel such signature to such petition after the said petition shall have been filed with the said city council or city clerk or other corporate authorities, as the case may be.

The right to charge a fare of 5 cents given under any existing ordinance or grant of right to construct and operate a street railroad shall remain, and such rate of fare as is now charged shall not be lessened or increased during the life of or the remainder of the term of such ordinance or grant.

The city council or other proper corporate authorities, as the case may be, shall have the power, without said petition of said land owners, to extend any ordinance heretofore granted and now in force, granting the right to construct and operate a street railway in any street or highway at any time before its expiration, for a period of not longer than fifty years.

In every ordinance so extended for carrying passengers on the street railroad operated under such ordinance, and where an ordinance shall be extended, the rate of fare shall be 5 cents during the first twenty years of the period of such extension; provided, however, that the rate of fare shall not be fixed by said corporate authorities in any case for a period of longer than twenty years, and the fare so fixed shall in no case exceed 5 cents for a single ride within the limits of any city, town or village.

The city council or other proper corporate authorities shall have the power to fix the rate of fare to be charged in any ordinance hereafter granted, provided such rate shall not exceed 5 cents, and when

the rate is so fixed it shall not be lessened by the said city council or other corporate authorities, as the case may be, at any time during the period of twenty years after the passage of the said ordinance.

## MOTOR FOR STOW DRILL.

In previous issues we have published illustrated descriptions of the combination of electric motors and the Stow flexible shafting for portable machines for drilling, reaming, tapping, calking, etc., where access to an electric current may be had. The Stow Manufacturing Company, of Binghamton, N. Y., placed its apparatus on the market about four years ago, and while it has given the best of satisfaction, since that time a demand has developed for a dust and water proof motor which the company has met by the motor which is shown here.

The frame is in the form of a hollow cube with inwardly projecting poles. At each end is a circular opening over which is bolted the end plate supporting the bearing; by merely changing the end plates to bring the oil chambers into place, the motor may be run in almost any position. One of the end plates is extended into a short cylinder,

STOW IRON CLAD MOTOR AND DRILL.

forming a case for the commutator and brush holder. The field coils are protected by metallic cases, but can be easily moved. In sizes below 2 h. p. the motors have two and in the larger sizes four poles. The portable motors are fitted with truck wheels, leg, eye bolt, side brackets, reel, 20 yards of insulated wire and one set of reduction gears. Material and workmanship are of the best; mica insulation; rheostats protected by an iron case; gears covered. When desired, motors of this type for direct connection will be furnished. Selig, Sonnenthal & Co., 85 Queen Victoria street, London, are the European agents of this company.

The bill providing for free transfers on the West End road of Boston failed in the Massachusetts Senate by a vote of 25 to 11.

Judge Watson of the Supreme Court of Maine has ruled that a passenger standing on the platform of a street car may not recover damages by reason of being thrown off when going around a curve.

## PERSONAL.

O. A. Harlow of Miller's Falls, has been appointed superintendent of the new electric railway at Amherst, Mass.

C. K. King, secretary of the Ohio Brass Company, Mansfield, O., was a REVIEW caller when in the city a few days ago.

William Keutgen, secretary of the Staten Island Electric Railroad Company, is very ill; he was operated upon for appendicitis.

Jacob Mellinger, superintendent of the York (Pa.) Street Railway Company, was married to Miss Elmira Eyster at Lancaster.

J. R. Ledyard has been appointed superintendent of the tracks of the Cincinnati, Covington & Newport Street Railway Company.

W. H. Hansell, president of the Hansell Spring Company of Newark, N. J., was a caller on the REVIEW when in Chicago last week.

James G. Church has resigned as counsel for the Nassau Electric Railroad Company, of Brooklyn, and is succeeded by John F. Brennan, of Yonkers.

C. P. Holcomb has been elected general manager of the Holmsburg, (Pa.) Tacony & Frankford Electric Railway Company to succeed E. R. Gilbert who has resigned.

Superintendent Chambers, of the Erie Construction Company, is supervising the building of the Buffalo Traction Company's road, and after its completion will become general superintendent.

Lincoln Van Cott, formerly chief traveling auditor for the New York Central Railroad has left that road after 12 years service and on May 20 took the position of purchasing agent for the Brooklyn Heights Railroad.

T. Howard Atkinson, vice-president of the East Penn Traction Company, has been given the additional duties of general manager which include the construction of extensions to the railway and the operation of the entire road.

Frank S. Given, superintendent of the Columbia and the Donegal lines of the Pennsylvania Traction Company, was married to Mrs. Mary Gordon Schram. After a tour of the Western cities they will make their home in Columbia, Pa.

E. J. Wessels, general manager of the Standard Air-Brake Company, sailed for Europe on the Majestic on June 2, in the interest of the air-brake business which has greatly increased from the time he first went over the ground in person.

Maurice J. Hart, who some months ago was indicted for the alleged bribery of the New Orleans city council, by using \$100,000 to secure the passage of a franchise, has been acquitted. His accuser confessed to perjury when placed on the stand.

J. C. Hutchins, vice-president of the Citizens Street Railway, has been elected vice-president of the Detroit Electric Railway. It is expected that he will remove the offices of the new company to the foot of Woodward avenue and consolidate them with the offices of the Citizens Company.

Judson J. Coleman, who has been manager of the Allentown & Lehigh Valley Traction Company for many years, will sever his connection with the company July 1, but will continue in street railway work with another company. A. F. Walters will perform the duties of the office left vacant and in addition will attend to his present work as secretary. James Uhl of Brooklyn, is to be the new superintendent.

Frank X. Cicott has resigned his position with the Ansonia Brass & Copper Company to take effect July 1, and will organize a European company to handle American electrical apparatus abroad as general agent, an enterprise which he has been contemplating for some months past. Mr. Cicott has had several years of commercial and journalistic experience abroad and is familiar with European conditions, thus possessing exceptional facilities to make this project a success.

A. L. Mason, whose resignation as president of the Citizens' road, Indianapolis, was noted last month, has resumed his law practice. When he accepted the presidency four years ago the position required but a portion of his time, and was not expected to interfere seriously with his professional work. The duties increased until all his time was taken up with the road. When his resignation was offered the new board urged him to accept a re election which was declined. Mr. Mason has long enjoyed a lucrative law practice, in which he has been engaged for the past 18 years, and was formerly a partner of the late Senator Joseph E. McDonald and the late Hon. John E. Butler.

W. S. Jewell, general manager of the Toledo Traction Company, and recognized as one of the fast rising young men in railway operation, has presented his resignation to take effect July 1. The announcement will be learned with genuine regret by the fraternity, as it was by the company he leaves; but Mr. Jewell received such a flattering offer from another concern he was unable to decline it. He becomes the general superintendent of the Marsden Company, of Philadelphia, which is made up of many of the heaviest capitalists there. The company is working the Marsden process, which reduces corn stalks and produces cattle food and corn cellulose. The latter is made from the pith and is capable of almost endless utility. Among other uses it has been adopted as a cushion to the armour plate for war vessels.

## NEW PUBLICATIONS.

R. H. Derrah, clerk to the president of the West End road of Boston, has issued the second edition of the "Street Railway Guide for Eastern Massachusetts," compiled by him. Price 10 cents.

"Industrial Railways" is a handsomely illustrated pamphlet of 50 pages describing the light railways and rolling stock therefor manufactured by the C. W. Hunt Company, 45 Broadway, New York.

The University of Minnesota has sent out the annual catalog with announcements for the year 1897-98. An attendance of 2,647 indicates that the university is prosperous. The mechanical and electrical engineering courses are well patronized. Prof. Geo. D. Shepardson is in charge of the electrical department.

A very complete catalog has been issued by the University of Wisconsin. The schools of mechanical and electrical engineering are thorough and complete in theoretical and practical work. D. C. Jackson, professor of electrical engineering, has done much in late years to raise the standard of practical work in his department.

We are in receipt of the fifth publication of the Year Book of the Society of Engineers of the University of Wisconsin, which is issued by the society, being edited by a committee appointed from the various technical departments of the University. All the subjects in the present number are of interest to engineers. The price of the Year Book is 50 cents, 60 cents postpaid.

We acknowledge the receipt of Duncan's Manual for 1897, the twentieth annual issue of this publication, giving statistics of the tramway and omnibus companies of the United Kingdom and the foreign and colonial companies registered in England. The total tramway mileage open for traffic is given as 1,009 miles for 1896 as against 982 for 1895, which as stated is much smaller than the increase in population would warrant.

The Economist of Chicago, has published an "Investor's Supplement" which contains much valuable information for those interested in the operation and financial condition of leading Chicago corporations, including the street railway companies. The statistics of these corporations show the amount of capital stock, bond issues, dividends, ranges of quotations on all stocks that have been bought and sold on the Chicago Stock Exchange each year since 1891 and other information obtainable. Maps of the various street railway systems in Chicago are shown and in addition a double page map of the four elevated roads including the Union loop. This publication does great credit to the Economist and is an indication of the enterprise and progress of the paper.

**Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.**

The City Guide Book to Atlanta, mentioned last month was issued by the Atlanta Railway Company, of which F. M. Zimmerman is superintendent.

Mrs. Clifford Baldwin has recovered \$900 against the Fairhaven & Westville (Conn.) Railroad because the conductor failed to assist her to alight.

The Springfield Street Railway Company has placed an order for rails amounting to \$25,000. The reconstruction contemplated this summer will require an expenditure of \$50,000.

The Manhattan Elevated, New York city, has decided to adopt the third rail electric system, and will proceed at once to put the work under way. Estimated cost of construction, \$7,000,000.

The Oshkosh Electric Railway Company has received permission to lay T-rails in paved streets, on the condition that a timber will be laid alongside the rail as was done on the other paved streets of Oshkosh where T-rails are laid.

The Electric Car Sprinkling Company will sprinkle the streets of Springfield, Mass., during the coming season, and on May 20 closed a contract with the Springfield Street Railway Company to furnish the power. These sprinklers have been used in New Haven and give excellent results.

The Bridgton (N. J.) & Millville Traction Company has recently suffered the loss of over 2,300 ft. of its copper ground-return wire which was dug up from its tracks and carried off. Once before the company lost 13,000 ft. of its wire and the thieves are now serving terms in the penitentiary.

An amiable settlement has been reached between the bondholders and the unsecured creditors of the Mount Lowe (Cal.) Railway and the threatened litigation is averted. The creditors will scale their claims one-half and accept for the balance bonds in the new company which is to purchase the road at a foreclosure sale.

The power house, of the Union Traction Company, Philadelphia, which was destroyed by fire last March is being rapidly reconstructed. It was found that the boilers were not materially injured by the fire and that the engines can be repaired. A 1,500-k. w. generator and engine will be placed in the station on Delaware avenue.

Trolley lines connecting Newark and Paterson, N. J., have been in operation for several weeks but a change of cars was necessary; now through cars are run, the crews changing at division points however. The fare is 17 cents from any part of Newark to Paterson; 5 cents to Belleville; 7 cents to Passaic, and 5 cents to Paterson.

The Columbus (Ga.) Railroad Company operates the street railway system as well as the belt railroad around the

city. The street car tracks are of standard gage and are used by the company in transferring freight to the warehouses and factories. This work has been done by a dummy engine but the company contemplates using an electric motor for this purpose.

The Connecticut Senate has passed a bill providing that every person whose duty it shall be to collect fares or tickets on any street railroad car who shall intentionally neglect to register as soon as received by him any fares or tickets so received on the register provided for that purpose, shall be fined not more than \$50 or be imprisoned not more than three months or both.

According to the State Board of Assessors of New Jersey there are 613 miles of trolley lines in the state which have been built at a cost of \$80,011,559, an average of \$130,000 per mile of track. During the past year the total receipts were \$5,770,171, an increase over the preceding year of \$713,573. The expenditures were \$3,546,168 and the dividends amounted to \$124,220.

Another deadlock has been reached in the troubled career of the municipal lighting plant at Middleboro, Mass., and the town may have to go without light. Becoming discouraged because of the excessive cost of operating, the town recently appointed an investigating committee which recommended a number of changes; but as these changes could not be carried out for the estimates made by the committee, the manager called a halt. Two of the three members of the Lighting Board have resigned and as at least two are required to sign checks, the one who remains can do nothing.

The Walker motor which was installed in the 52nd street station of the Chicago City Railway in 1894 has been idle for about a year. For this reason it has been supposed that this experiment of driving a cable by an electric motor was a failure but such is not the case. The extensions to the electric lines have been so numerous that all the current from the old station was needed. Now that power is furnished from the new station this motor is again in operation and is satisfactory in every way. The current is supplied from the generators in the station across the alley from the cable plant. The saving in labor for station attendance is \$18 per day and more than compensates for loss incident to the several conversions of energy. The installation was fully described in the REVIEW of August, 1895.

The Citizens' Street Railroad of Indianapolis, has elected a new directory, as follows: Kennedy Crasson, W. W. Kurtz, R. H. Rushton, W. C. Huston, Joseph S. Neff, F. Dundore and W. J. Turner, all of Philadelphia. Mr. Crasson was chosen president; W. F. Milholland, secretary and treasurer, and Miller Elliott, superintendent. Of the old board, F. Dundore and W. J. Turner are the only ones remaining, Mr. Clay having died recently and Augustus L. Mason, H. Sellers McKee, Murray A. Verner and W. L. Elder having resigned. Mr. Mason was invited by the new board of directors to retain the presidency, but declined, as he desired to devote himself exclusively to the practice of law in the corporation branch of which he has, during the past 18 years, won a high reputation. Although retired, Mr. McKee continues to be the heaviest stockholder.

## SPEED OF CARS.

On May 25, the Supreme Court of Pennsylvania reversed the decision of the lower court in the case of Katie Kline, by her father, vs. the Electric Traction Company of Philadelphia on the ground that negligence on the part of the motorman had not been proved. Judge Williams, in discussing the question of speed said:

"We are not prepared to lay down any rule in regard to the rate of speed at which an electric car may be run between crossings. All that can be safely said upon this subject is that the car must be kept well in hand, and that the speed must not be so great as to make this impossible, or to endanger the safety of the public using the streets with responsible care. But these passenger railways are created to facilitate the movements of the general public, and to

## CRANE AT GARFIELD PARK

Traveling cranes have become a necessary appliance in the larger power and lighting plants. In handling the heavier parts of dynamos and engines the old style methods have become too slow and costly to be retained. The cut herewith illustrates a moderate capacity hand power traveler in the new lighting plant at Garfield Park, Chicago, one of the most modern plants of the kind in the country. The crane is of two tons capacity; 43-ft. span; all motions are operated by hand chains. It was manufactured and erected complete with tracks, by the Whiting Foundry Equipment Company of Chicago, with works at Harvey, Ill., which makes several types of hand power and electric cranes especially adapted to power house service, both for lighting and street railway plants.

GARFIELD PARK LIGHTING STATION, CHICAGO.

furnish rapid transit for citizens from their homes to the business centre of the city. They are practically indispensable in all great cities. The cars move upon a track from which they cannot turn, which is plainly visible, and which is prepared with a view to the rapid movement of cars upon it.

"Upon a careful examination of this record we are unable to find any evidence of negligence on the part of the defendant sufficient to justify the submission of the question to the jury. The injury was not inflicted at a crossing where the passage of pedestrians should be looked for. The child was upon the sidewalk, until it ran suddenly on the track and was struck on the instant of reaching it. The immediate cause of the injury was therefore her own thoughtless act for which the defendant is in no way responsible and no act of negligence on the part of the motorman being shown, there can be no recovery."

## SPRINGFIELD (VT.) ELECTRIC RAILWAY REVIVES.

The building of a trolley line was commenced last year in Springfield, Vt., a manufacturing town of 3,000 inhabitants, but from lack of funds the project was abandoned. Recently E. C. Crosby and M. A. Coolidge secured a controlling interest and will finish the line. Passengers, freight and mail will be carried and connection will be made with the Boston & Maine Railroad. Water power from the Black river will be utilized although this will have to be supplemented by a steam plant. The new officers are Adna Brown, president, and Messrs. Crosby and Coolidge, directors.

Concessions for a system of trolley lines will be granted in a short time by the municipal government of Jassy, Roumania.

J. M. Jones' Sons of West Troy, N. Y., have shipped 10 cars to the Syracuse Rapid Transit Railway, Syracuse, N. Y.

J. D. Murray, of New Brunswick, N. J., is constructing a 3-mile extension for the Bennington & Woodford Electric Railway, Bennington, Vt.

The Wheeler Rail Joint Company, of Marion, Ind., has secured the contract for joints to go on the Marion, Anderson & Indianapolis Railway.

The Mertes Manufacturing Company, of Allegheny, Pa., manufacturer of gears and pinions reports a steady increase in the number of orders booked.

Meaker stationary registers have been adopted by the Denver City Railroad, West End Street Railroad and the Colfax Electric Railroad, Denver, Colo.

The Laclède Car Company, of St Louis, has the contract to furnish 15 closed and 25 open cars for the new Falls Road Electric Railway at Baltimore, Md.

The Portsmouth Street Railway Company, Portsmouth Va., has contracted with the Virginia Electrical Engineering Company for the equipment of its line.

The Colfax Electric Railway, Denver, Colo., has equipped all of its motor cars with the United States electric heater made by the Ohio Brass Company, Mansfield, O.

Stanley Green, western sales manager for the Fuel Economizer Company of Matteawan, N. Y., has sold 3,000 h. p. of Green's economizers to the South Side Elevated Railroad, Chicago.

The steady trade in "Dermaglutine" pinions which A. Grotzinger & Sons of Allegheny, Pa., report is good evidence that their customers appreciate the general excellence of these goods.

The Peckham Motor Truck & Wheel Company of New York, has recently received several orders for trucks from Japan, and the company reports its general foreign trade as being very good.

C. W. Blakeslee & Sons, of New Haven, Conn., have been given the contract to construct eight miles of electric line for the Portland & Yarmouth Street Railroad Company, at Portland, Me.

The annual meeting of the General Electric Company was held May 11, at Schenectady, when the old board of directors was unanimously reelected. At the meeting 210,000 shares were represented.

William Sharp, lately the western representative of the McEwen Engine Company, has accepted the position of Chicago selling agent for the Weston Engine Company, with offices in the Fisher building.

For an interesting discussion of paints for exposed iron and wood work and carbon paints in particular, our readers are referred to "Nobrac," the pamphlet published by the Patterson-Sargent Company, Cleveland.

J. G. White & Co., of New York, are rushing the work on a contract which they took recently to lay track and erect overhead material on three miles of road for the Portsmouth & Port Norfolk Electric Railway at Portsmouth, Va.

The Case Manufacturing Company, Columbus, O., has recently shipped a 15-ton, 3-motor electrical crane to the Pratt & Cady Company, Hartford, Conn., and a 15-ton power crane to the Damascus Bronze Company, Pittsburg, Pa.

S. C. Strock, dealer in poles and ties, heretofore at 50 Broadway, New York, has removed to the new Bowling Green building, 11 Broadway. He reports that orders are larger and of a better nature than they have been for a long time.

The Crane Company of Chicago will furnish the high pressure valves and piping for the Cleveland & Lorain Street Railway and also the connections for the engines of the People's Railway, Dayton, O. G. A. Hurd secured the orders.

The E. P. Allis Company of Milwaukee reports the following among recent orders: Four 1,200-h. p. direct connected engines for the new electric railway in Sydney, N. S. W.; four 1,200-h. p. direct connected engines for the Alley L, Chicago.

The Central Railway of Baltimore has awarded the contract to lay rails and put up overhead work for the Belaire road extension to Josiah L. Blackwell and David E. Evans & Co. The rails will be supplied by the Pennsylvania Steel Company.

The Falk Manufacturing Company, which is making the special work for the Oshkosh electric road, has recently received a contract from the Madison City Railway Company, which is to extend its lines to University Heights and Wingra Park.

The Armitage-Herschell Company of North Tonawanda, N. Y., has sent out a large colored lithograph illustrating a steam driven gallery or merry-go-round on the grounds of a pleasure resort. Either steam or electricity can be used as motive power.

The Washburn & Moen Manufacturing Company, Worcester, Mass., has discontinued its Scranton office and will handle that business from Philadelphia. A branch has been opened in Boston in order to accommodate the increased business there.

Fred C. Wilson & Co., of Boston, Mass., have received the contract to build the Oxford Central Electrical Railroad between Rice's Junction and Norway, Me. Including branches to South Waterford and East Stonham, the distance is 21 miles.

Graphitoleo is a preparation of pure flake graphite and petrolatum manufactured by the Joseph Dixon Crucible Company, of Jersey City, N. J., and very highly recommended as a lubricant for bicycle chains. It is conveniently put up in collapsible tubes.

L. N. Walker & Son, of Philadelphia, have begun work on their contract to build the electric road between Meadville and Edinboro, Pa. This is a part of a big interurban, work on which was delayed owing to a misunderstanding with the original contractors.

The Dorner & Dutton Company has been incorporated at Cleveland, O., to manufacture and deal in electric street railway supplies. The capital stock is \$50,000, and the incorporators are J. H. Van Dorn, E. J. Leighton, H. H. Hodell, W. A. Dutton and H. A. Dorner.

The Mitchell Tempered Copper Company, Corry, Pa., reports that its pure copper commutator bars are giving perfect satisfaction. It has recently filled the third order within sixty days for a Michigan road, and a fourth order within a month for a New York concern.

The Morrin "Climax" boilers installed by the Clonbrock Steam Boiler Company, of Brooklyn, at the Tennessee Centennial Exposition at Nashville, are giving entire satisfaction and receiving much attention from visitors. This company, it may be remembered, was awarded the entire boiler contract by the Exposition Company.

The headquarters of William S. Reed & Co., who have the contract to build and equip the Milwaukee & Waukesha Electric Railway, are at 1610 Great Northern Office building, Chicago. Mr. Reed states that work will begin about May 27, or as soon as specifications can be prepared.

A. Elbogen & Co., 39 Third avenue, New York, theatrical booking agents, report a good business demand for summer attractions for summer pleasure resorts. They will be pleased to enter into correspondence with street railways and quote the terms of the artists whom they represent.

The Garton-Daniels Electric Company, Keokuk, Iowa, reports an exceptionally large and increasing business. The sales of lightning arresters for April were more than double the best month in the history of the company, while the foreign shipments have been particularly gratifying.

Brownlee & Co. of Detroit report an active demand for wooden trolley poles of their various patterns and for cross-arms. The firm has just closed a contract with the New York & New Jersey Telephone Company for 70,000 arms, the manufacture of which will require 800,000 ft. of lumber.

McIntosh, Seymour & Co., of Auburn, N. Y., have opened an office for sale of their products in New York City and contiguous territory in the Havemeyer building, room 1211, 26 Cortlandt street, the Pierce & Miller Engineering Company having ceased to handle their engines on May 20 last.

The St. Louis Iron & Machine Works of St. Louis, are building two rolling mill engines for the plant of the Consolidated Steel & Wire Company at Pittsburg, Pa. One is a tandem compound condensing corliss of 1,800 h. p. and one a cross compound condensing corliss of 2,200 h. p.; the shipment will weigh 300 tons and require 16 cars to transport it.

The Standard Air-Brake Company closed the month of May by securing an additional order from the Colonies for 28 air-brake outfits for electric motor and trail cars and an order for additional motor car air-brakes. These brakes have been in use in the Colonies for three years and the latest orders emphasize the success of the apparatus.

In the two years that the New York Switch & Crossing Company, of Hoboken, N. J., has had its automatic electric track switch on the market it has been tested and found practicable, durable and economical by many roads, among them the Brooklyn Heights and Brooklyn City & Newtown, Brooklyn and the North Hudson County of Hoboken.

The St. Louis and Chicago agencies of the Abendroth & Root Manufacturing Company, 28 Cliff street, New York, has recently sold boilers for installation as follows: Schwartzschild & Sulzberger, Kansas City, 1,500 h. p.; Cincinnati Street Railway Company, 1,300 h. p.; Danville Gas, Electric Light & Street Railway Company, 600-h. p., and the Green Wood Fiber Company, Chicago, 700 h. p.

The International Hotel, Niagara Falls, secured for the headquarters of the American Street Railway Association during the convention, was the headquarters for the National Electric Light Association and all speak very highly of the manager, S. A. Greenwood, and the accommodations. Mr. Greenwood has only recently taken the management but he has had a long experience and is well fitted for the position.

The New York Electro Vapor Motor Company has been incorporated to build and equip railroads. The capital stock is \$100,000 and the incorporators are Thomas D. Hoskins of Brooklyn, William H. Goff of Brooklyn and Christopher Longstreet of New York. Mr. Hoskins is already well known in the street railway field as the inventor of a gas motor which has been tried in California and Ohio.

Hirsch Bros. & Co., investment brokers of New York and Chicago, have placed the securities of the Waterloo & Cedar Falls Rapid Transit Company, Waterloo, Ia., and of the Mason City & Clear Lake Traction Company, Mason City, Ia., two new roads, notices of which have appeared in recent numbers of the REVIEW. Patrick Henry Hirsch is the resident member of the firm at New York, and Paul E. Hirsh at Chicago.

George H. Pugh and James P. Orr of Pittsburg have invented a combined annunciator and advertising cabinet for use on street cars. The device is set in motion by a push button or a bell rope connection and stops automatically as soon as a new card or leaf swings downward and displays the next stop. Two cards are displayed at the same time, the "stop" card and the back of the next one; the backs are utilized for advertising purposes.

We are in receipt of a handsomely illustrated catalog from Mayer & Englund, Philadelphia, manufacturers of electric railway materials and supplies. It is Part I of the General Catalog and is devoted to overhead insulation and construction material. The firm is furnishing to the railways doing business with it a cloth bound mechanical binder into which any subsequent catalogs can be inserted, and the literature thus accumulated in one volume.

The Hansell Spring Company reports that it has recently secured a large building in the rear of the present location, Nos. 7 to 13 Ward street, Newark, N. J., which increases the floor space of the plant by 25 per cent. Sales for May were larger than for any previous month and many orders were booked ahead. Recent orders have been received from the General Electric, the Walker, the Peckham and the Bemis Car Box companies, and from a number of railway companies direct.

We have received from the J. A. Fay & Egan Company, of Cincinnati, a copy of the new poster exhibiting the wood working machinery manufactured by the Egan Company. This is probably the most complete of its kind ever published and gives illustrations of 135 machines together with memoranda as to special features and capacity, and will prove most convenient for reference. These have been prepared for general distribution and the company will be very glad to send them to interested parties.

The Cambria Iron Company has been shipping for some time to the Metropolitan Street Railway, of New York City, rails and material on account of the new work, which we recently noticed in full. The Cambria Company has a contract to furnish about 3,300 tons of these rails, together with almost an equal amount of other material, consisting of slot rails, conductor bars, conduit plates, tie rods, bolts and nuts, wedges, washers, hook bolts, etc. The rail section, owing to its peculiar shape, resembling a foot when inverted, has been dubbed the "Tribly Section."

The Simonds Manufacturing Company, of Pittsburg, Pa., reports that it has a large number of orders on its books and contemplates putting in new gear cutters and turning lathes. The company asks the indulgence of all who have suffered delay in shipments because it has just completed moving its machinery and stock into its new shop, which is that formerly occupied by the Westinghouse Machine Company at 25th and Liberty streets. The new shop covers three times the floor space that was in the old one, and being equipped with large traveling cranes much larger work can be readily handled.

The New Haven Register Company, New Haven, has closed good orders as follows: for the Consolidated of Pittsburg, for all of the 230 new cars in addition to the New Haven machines already in use; for the Market Street road, San Francisco, 200 double registers, fare and transfers ordered by wire, making 550 in use by that system. General Sales Agent Loper has also closed contracts for double registers, 5-cent fares and school tickets for the entire system of the Louisville road, and for the entire equipment of the People's Railway and the Dayton Traction Company, both of Dayton, O.

A neat and handsome catalog has been sent by Warren Webster & Company describing the oil and steam separators made by this firm. In tests and in practise the steam separators have proven well adapted to furnish commercially dry steam under all the variable working conditions of any plant. When the exhaust steam is to be used for raising the temperature of water or for heating buildings the oil separator is designed to estrand the cylinder lubricant and any other oils that may be present in the steam, thus insuring clean tanks, radiators, etc., and furnishing relief from obnoxious odors incident to the presence of oil.

Edward P. Sharp, manufacturers' agent, 909 Morgan building, Buffalo, N. Y., advises that he has recently sold two 22-ft. second-hand Pullman car bodies to the Anaconda (Mont.) Street Railway Company, after repainting and equipping them with motors, and two from the same lot to the Metropolitan, of Toronto. Mr. Sharp has a number of Edison No. 6 and F-30 motors which were part of the equipment of the Syracuse Consolidated, some Westinghouse No. 3 motors and extra armatures and a large amount of material for old style motors, all of which is offered at very low prices. The Macallen sheet mica insulators can also be supplied at low rates.

After sharp competition the McGuire Manufacturing Company has been awarded the contract for the electric trucks which are to displace the steam trucks now in use on the 120 cars of the Alley Elevated of Chicago. The success of the McGuire truck on the Brooklyn Bridge, which is perhaps the severest service in the country, probably decided the award. The McGuire Company has also secured the contract for 102 trucks for the Consolidated Traction Company of Pittsburg. Orders for 100 or over equipments are rather scarce these days and that two such orders should go to the same company in one week is certainly complimentary.

H. W. Burgett, of Brookline, Mass., represents the syndicate which has taken the contract to build ten miles of standard gage electric road from Waterbury to Stowe, Vt., for the Mt. Mansfield Railroad Company, of which P. D. Pike is president, C. L. McNahon, vice-president; F. O. Burt, treasurer, and L. C. Moody, secretary, all of Stowe. The cars will be 42 ft. long, with a baggage compartment, and be equipped with two 40-h. p. motors. A freight car will be equipped with powerful motors to haul the freight or passenger cars of the Central Vermont Railroad over the line when necessary. The pleasure travel to Mt. Mansfield is expected to be very profitable.

The Automatic Circuit Breaker Company, of Newwayo, Mich., is advised by the Attica Electric Light Company, Attica, Ind., as follows: "We have one circuit that reaches so high above station that every storm touches it, and heretofore in the past nine years have lost four armatures through lightning, and before putting on your circuit breakers were practically worried to pieces by every flash of lightning for fear of damage to a costly armature. This last year we have got over our worry on that score, as our lines have been hit with lightning repeatedly in one night, and in one case 20 lamps in series smashed and circuit knocked out, but circuit was broken every time and armature saved."

Louis Enricht, 1413 Chamber of Commerce, Chicago, has been awarded the contract to completely construct the 39 miles of single track for the Indianapolis, Anderson & Marion Electric Railway, giving \$20,000 bond to have the road in operation by August 12, 1897, with the Fidelity & Deposit Company of Baltimore as surety. Mr. Enricht has let the following sub-contracts:—grading, Cochran & Ross, Chicago; tracklaying, Parker & McNair, Chicago; trolley and feed wire, American Electrical Works, Providence; overhead material, Ohio Brass Company, Mansfield; boilers, engines and steam fitting, Chandler & Taylor, Indianapolis, and generators, motors and car equipments, Westinghouse

Electric & Manufacturing Company. Frank A. Maus and other capitalists of Indianapolis have advanced Mr. Enricht about \$65,000 cash on his contract, the balance being notes of the company secured by first mortgage bonds of the railway. Said bonds are given only as collateral and revert back to the company when the notes are paid.

The Christensen Engineering Works, Milwaukee, are making very satisfactory progress in introducing their air brake for street cars. Catalog A, just issued, is an interesting pamphlet of 28 pages, fully illustrated, and is a practical discussion of the air brake problem in addition to a detailed description of the Christensen brake. Either axle or direct motor driven compression is furnished as desired, although for heavy cars running at speeds upwards of 25 miles per hour the motor compressor is advised. The pamphlet should be carefully studied by every manager. Among recent installations of this brake is an order for 14 motor and 10 trail cars for the Chicago Suburban, where the brakes are giving splendid service on high speed cars. The Chicago office is 1402 Fisher building.

The South Side Elevated Railroad Company of Chicago has let contracts. The 190 x 120-ft. power house at State and 40th streets will be equipped with four 1,200-h. p. cross-compound condensing engines, built by the Edward P. Allis Co., of Milwaukee, direct connected to four 800-k. w. generators supplied by the Westinghouse Electric & Manufacturing Company of Pittsburg. Chain grates, fuel economizers and cooling towers will be employed. The Johnson Company of Johnstown, Pa., will furnish the 40-lb. rail in 60-ft. lengths, and J. M. Atkinson & Co., of Chicago, their horseshoe rail bond. Cables of 500,000, 1,000,000 and 1,500,000 circular mils will be supplied by the Western Electric Company of Chicago. Frank J. Sprague, of New York, will equip six cars for an experiment with his system of train control.

The Standard Paint Company, 81 John street, New York, reports that the demand for the P & B products among electric railways was never better than at present. The tape for electric railway use is furnished in any width desired and is guaranteed free from rubber or anything that will carbonize or dry out; it is extensively used in connection with the P & B compound for re-insulating cables. The company is ready at all times to furnish gratis, express prepaid, a sufficient quantity of any of the materials manufactured by it to enable bona fide inquirers to make practical tests. A new specialty is the water paint called "magnite;" it is made in several shades as well as white and when in a liquid form flows freely and gives a smooth, even, water-proof finish. It is admirably adapted for the inside of car barns, power houses, walls, etc.

The Ball Engine Company, Erie, Pa., reports the following recent shipments of engines for electric purposes: Vulcan Coal Company, Treveskyn, Pa., one 225-h. p. engine, direct connected to generator; Queen City Electric Light & Power Company, Clarksville, Tenn., one 125-h. p. engine; Langhorne (Pa.) Electric Light & Power Company, third order, one 200-h. p. engine; Maxwell House, Nashville, Tenn., third order, 125-h. p. direct connected to dynamo; Rockville Water Works, Rockville, Md., one 80-h. p. engine; Wilmington Gas Light Company, Wilming-

ton, N. C., third order, one 500-h. p. cross compound engine; Pennsylvania Tube Works, Pittsburg, Pa., one 60-h. p. engine; Seaboard Air Line, Portsmouth, Va., one 70-h. p. d. c. to dynamo; Apollo Iron & Steel Works, Apollo, Pa., fourth order, one 150-h. p. vertical cross compound, direct connected to alternating machine; Kirk's Soap Factory, Chicago, one 50-h. p. engine, d. c. to dynamo; Lexington Hotel, Richmond, Va., one 40-h. p. engine; Congo Mining Company, Congo, O., one 175-h. p. engine; Wainwright Brewing Company, Pittsburg, Pa., one 80-h. p. engine; Fox Pressed Steel Company, Pittsburg, Pa., one 100-h. p. engine; F. O. Horton Cement Company, Binnewater, N. Y., 60-h. p. engine; Lakewood Hotel & Land Company, Lakewood, N. Y., 165-h. p. tandem compound engine.

The reputation which the Central Electric Company enjoys, is evidenced by the many large orders received for trolley bushings, bearings and overhead materials. It has lately made some very large shipments of overhead materials to Europe, and is continually receiving congratulatory information relative to shipments. The following is the substance of a letter received from one of its customers which shows the high esteem in which the Central Electric Company is held by those with whom it transacts business:

"Central Electric Co.—Gentlemen:—The 500 commutator bars ordered by us some time ago are received. They look so nice, and fit so well, that we herewith send you our order for 500 more, which we hope you will fill at your earliest convenience. They are the best looking bars we have ever had, and I do not believe there is any question about their efficiency. This order completes my promise of a thousand, but you will receive another order from us for more, before long.

Yours truly, President and General Manager."

The company feels very much gratified with its railway business and the marked success with which its several specialties have met. It is carrying in stock a complete line of Bound Brook trolley bushings and is prepared to furnish Bound Brook motor bearings which are of the highest grade. It is also western agent for the De Witt sand boxes, and has lately received some very large contracts for deliveries of these boxes. The changeable electric head light is manufactured by Crouse-Hinds of Syracuse, N. Y., for which it is the western agent, and it is constantly equipping entire roads, with this head light. Samples are sent on trial to responsible parties, and it claims that thus far it has never sent out a sample with any other result than that of receiving the order for the complete equipment of the road. Among the foremost of its specialties are the Billings & Spencer products, the drop forged copper commutator bars manufactured under the Billings patent. It has lately received some very fine contracts for commutator bars, and from the orders which are now on hand for future deliveries of overhead materials, supply parts and commutator bars, the outlook is encouraging. It is very anxious to secure specifications, and requests for prices, as it claims it is in a position to offer inducements.

Joseph A. Rhomberg, president of the Dubuque Street Railway, died suddenly of heart disease on May 17. He had been prominently identified with various interests in that city for many years and practically owned the road. He had resided in Dubuque since 1850, and was a man of remarkable energy and persistency.

# Removal Notice.

~~~~~

We beg to announce that we have removed from the Betz Building, to 10 So. Tenth Street, Philadelphia, where we have established a large and commodious warehouse. We now have in stock a full line of material manufactured by the well-known Companies we represent, together with a Full and Complete Stock of Electric Railway Material and Supplies for immediate shipment. Our facilities for handling our rapidly increasing business are now strictly first-class.

MAYER & ENGLUND,

10 South Tenth St.

Philadelphia, Pa.

WRITE FOR LATEST PRICES. IMMEDIATE SHIPMENT FROM STOCK.

## 3-CENT FARE WINS IN INDIANA.

State Supreme Court Upholds Constitutionality of the  
3-Cent Fare Law.

In the May REVIEW the history of the Indianapolis case was brought down to the point where a test case on the 3-cent fare in Indianapolis had been carried into the supreme court of the state. This court, on June 11, handed down its opinion sustaining the law. We quote from the ruling as follows:

"It is insisted by appellant (the City of Indianapolis) that the act of 1897 is unconstitutional because it impairs the obligation of a contract. Counsel for appellant do not point out any contract the obligation of which is impaired by said act.

"If it is the contract under which the street railway company took possession of the streets of Indianapolis and constructed its tracks, it is sufficient to say that the city was not authorized to enter into any contract which would prevent the legislature from legislating upon the subject of fares. It is settled law that the legislature has the power to reasonably regulate the rates of fares for transportation of passengers within the state on street railways. (Hockett vs. State, 105.)

"The right of the legislature, however, to regulate the fare upon street railroads organized under the act of 1861 does not depend upon the reservation of the right to amend or repeal the act in section 11 of the act. That power would exist even if the right to amend or repeal the act had not been reserved. In order to exempt a common carrier from legislative control over its rates of fare it must appear that the exemption was made in its charter by clear and unmistakable language, inconsistent with the exercise of such power of the legislature.

"Appellant had the power to prescribe the terms upon which and the time for which a street railroad company organized under said

act of 1861 should occupy the streets of said city, but such contract when made was subject to the right of the legislature to amend or repeal said act at its discretion; and no contract made by the city with a street railroad company could prevent the exercise of such power by the legislature.

"It is clear, therefore, that said act of 1897 does not impair the obligation of any valid contract of either the state or appellant."

On the question of special legislation the court says:

"It is next insisted by counsel for appellant that said amendment is a local and special act, and is therefore in conflict with section 13 of article 11 of the constitution, which provides that corporations other than banking shall not be created by special act, but may be formed under general laws.

"The power to declare a statute unconstitutional is one of the highest intrusted to a judicial tribunal, and is only to be exercised with the greatest care, and only when there is no doubt of the unconstitutionality of the law. If there is any doubt in the mind of the court as to the constitutionality of a law it must be resolved in favor of its validity. To doubt is to resolve in favor of the constitutionality of the law.

"It is not necessary, under the provisions of section 23 of article 4, declaring that all laws shall be general and uniform throughout the state, that legislation concerning cities should operate uniformly on all the cities in the state to make it general. A law which applies to cities having a population of 100,000 or more when there is but one such city, but is so framed as to operate on all other cities in the state as they acquire the necessary population, is a general law, because it operates upon all cities alike under the same circumstances.

"Neither is it necessary that a law concerning the fares to be collected by street railway companies shall operate uniformly on all street railroads in the state. It is sufficient if it operates alike upon all such companies under the same circumstances and conditions. Such a law is general with the meaning of the constitution.

"When, therefore, a local or special law is enacted upon a subject not enumerated in section 22, and it is the expressed opinion and

## ELECTRIC STATION MANAGERS:

**YOU CAN'T AFFORD TO WASTE YOUR EXHAUST STEAM,**  
which you are doing, when you can sell it at a large profit. Many Street Railway and Electric Light Companies are making handsome dividends from this source.

**YOUR COAL BILL WILL BE NO HIGHER.**

These are some of the street railway companies that have adopted our systems:

Springfield, (Ill.) Elec. Lt. & St. Ry. Co.  
Terre Haute Electric Railway Co.  
Danville Gas, Elec. Lt. & St. Ry. Co.  
St. Joseph Street Railway Co.  
Ottumwa Electric Railway Co.

If these are not near you, write us and we will send you addresses of users in your vicinity.

## ONE MANAGER SAYS:

"Have been operating the steam plant five years, warming between four and five million cubic feet of space. Income from steam heat over \$12,000 per annum, all from exhaust steam, except from \$200 to \$300 additional fuel in consequence of steam line. Carry five to ten pounds back pressure, according to temperature outside, and only need to increase boiler pressure same amount. Have already paid for the entire installment of the steam heating system out of the additional profits since we put it in. We have no trouble or expense from leaky joints, and we do not employ any additional help in operating the plant over what we formerly employed for our lighting and street railway service."

**AMERICAN DISTRICT STEAM CO., Lockport, N. Y.**

judgment of the legislature that a general law cannot be made applicable, this judgment is not subject to be reviewed by the courts.

"The legislature of 1861, by passing the act for the incorporation of street railroad companies, could not and did not deprive any subsequent legislature of the right to determine whether a general law of fixing the maximum fare on street railroads could or could not be made applicable. If the act in controversy is not a general law, as insisted by appellant, then under the authorities the enactment of the same is the expressed opinion and judgment of the legislature that a general law could not be made applicable, and this judgment cannot be reviewed by the courts.

"It follows that the act approved March 8, 1867 (acts 1867, page 201), so far as involved in this case, is constitutional and valid. Said act rendered the ordinance regulating the payment of a fare of 5 cents invalid and of no effect. Appellee was entitled to be carried for the fare of 3 cents fixed by the act in controversy, and was not liable for a refusal to pay more than that, for the reason that the ordinance requiring the payment of a fare of 5 cents was rendered invalid by said act."

The company will at once apply to the federal court for further proceedings, which it can do by amending its complaint to show the enforcement of the law would reduce receipts below actual operating expenses. The attorney-general will apply to Judge Showalter for a modification of his decision in accordance with this decision and to dissolve the restraining order.

If the city wins it means a virtual confiscation of the road.

## OBITUARY.

Tobias Roach, for over 32 years connected with the street railways of Troy, N. Y., died on June 5 after a protracted illness.

Silvanus S. Riker died at the Hotel Buckingham, New York, on June 6 at the age of 75. Mr. Riker was president of the Washington & Georgetown Railroad in 1874.

J. D. Chandler, president of the Nashua Street Railway, Nashua, N. H., died June 3, at the age of sixty-seven, leaving a wife, two sons and a daughter. He was president of the Nashua Board of Trade, and for 26 years had been auditor of the New Hampshire Fire Insurance Company.

Charles R. Kellogg, manager of the Waterloo (Ia.) Street Car & Omnibus Manufacturing Company was found dead in his room at the St. James, in Minneapolis, on May 29.

Frederick M. Laughton, ex-mayor of Bangor and president and general manager of the Bangor Street Railway Company, the first trolley line in Maine, died on May 27 after a short illness at the age of 53.

John Radel, former owner of the Newark & South Orange Street Railway, died at his home in Newark on May 9, at the age of 74. Mr. Radel was a Bavarian by birth, but came to this country early in life; he entered the street railway field in 1876 and in addition to the line above mentioned was interested in street railways in New Brunswick and Bridgeport, Conn.

## ONLY \$25 TO SAN FRANCISCO.

From Chicago via the North-Western Line (Chicago & North Western Railway), the famous "California in 3 Days" Route, June 29 to July 3, inclusive. Choice of routes. No change of cars. Similar rates will be made eastbound. For full information apply to 216 Clark street, or ticket agents of connecting lines; or address W. B. Kniskern, Chicago, Ill.

It seems to be quite a fad in some places to turn the street cars over to some charitable organization of ladies and give the proceeds to some worthy cause. On Decoration day the G. A. R. ladies managed the cars on the West Penn Railroad between Creighton and Natrona. The money collected was added to the fund to erect a soldiers' monument in Tarentum cemetery. The regular motemen assisted the ladies in handling the cars, and no accidents happened. Much enthusiasm was stirred up in the community over the innovation, and every one took a trolley ride.

Peyton J. Clark, superintendent of the Tacoma Traction Company, was recently severely injured by being thrown from the top of a car.

### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any subject or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. JULY 15, 1897 NO. 7

INTENDING exhibitors at the Niagara Falls convention in October are reminded that reservations for exhibit space and hotel accommodation should be made at once.

AS ONE reads of the immense crowds drawn to the Queen's Jubilee, he cannot refrain from a mental estimate of what the receipts of a big trolley system in London town would have been.

AN electrical contemporary in England on reading in an American journal of recent experiments with a so-called kinetic motor on a New Jersey line, is surprised and says: "It is not a little strange that in America, where electric traction has been so much developed, there should still be so many other motive powers tried on traction work."

It forgets we have a Keely motor also.

THE friends of "reform" and advocates of "local self government" having achieved their object in defeating the Humphrey bills and placing the Chicago city council in control of street railway franchises instead of a state commission, appear to have placed the city in a state similar to that of the frogs after Jupiter has granted their prayer and sent King Stork to reign in place of King Log.

SUCH people as were in hopes to see some electric conduit construction in Chicago, may have to postpone the realization of such expectations indefinitely. The General Electric

road which started out with a conduit ordinance of some 60 miles has been to the city council and in the end will probably be made happy by authority to use overhead wires instead. The storage battery road's turn will probably come one of these days, and then it will be all trolleys on the surface and third rails on the L's, in Chicago.

AT this writing Indianapolis does not yet know whether it has 3-cent fares or not. Judge Showalter went to that city and heard arguments and has the matter still under consideration. If the new law can be made to hold, there will shortly be one town without a street car service unless it can employ labor at about 75 cents per day. Not even a street railway can long keep up a 5-cent style on a 3-cent income. But perhaps a 3-cent service is what the people there want.

THE necessity for additional interurban lines is more and more forcing recognition from state legislatures, and will continue to do so until in every state suitable provision is made for country railways. In Wisconsin at the recent legislature positive provision was made for securing rights of way, and electric roads were specifically empowered with all the rights of eminent domain enjoyed by the steam roads. In Pennsylvania a bill which conferred condemnation powers upon electric lines, was defeated, undoubtedly through steam road influence. The matter, however, is by no means settled but will continue to come up at each succeeding legislature until electric roads are granted such rights.

ADDITIONAL evidence is at hand showing the declining interest in horseless carriages. The Engineer, London, a year ago offered prizes aggregating over \$5,000 to the contestants in a road race. Although there had been 72 entries during the year, only five competitors appeared at the appointed date, and the race was declared off. The Engineer says editorially: "Our essay . . . has placed the world in the possession of the facts concerning the motor car industry in this country. There is at present no such industry. There is no such thing as a thoroughly satisfactory self-propelled vehicle. . . . We have every reason to believe that the best England can do at present was shown at the Crystal Palace, and, in the opinion of three most competent engineers, the carriages shown were so imperfect, so unsuitable to the fulfillment of the purposes which a motor car ought to serve, that they would not submit them to further trial."

THE reports of the mercantile agencies continue week by week to show a steady increase in volume of business, and prices are strengthening in some lines of trade. The very noticeable advance in quotations of favorite railroad stocks, during the past 60 days, is specially significant. The advance ranges up to 14 points, and is not the result of manipulation or the London exchange. On the contrary it is the natural, healthy result of increased business carried and in sight. The price and demand for meats, both dressed and on the hoof are excellent, and the foreign shipments from Chicago are stronger than any time during several years past. The demand for provisions in the manufacturing states is also increasing, which is the result of increased employment of labor in mills and factories. Secretary Gage's speech was opportune, and even the interminable tariff bids fair to be fairly rounded up and settled. For all of which let us be devoutly thankful, and each add his word

of encouragement that will help drive back into oblivion the ghost of lost confidence.

The outlook for street railway enterprises is growing better, and by another spring we should see a very considerable amount of new work laid out and financed. It will be largely of an interurban character, but such lines are needed and in many places can be made successful.

There is one lesson the American people will do well to learn out of all the trials incident to the past four years, and that is the lesson of economy. As a nation, individuals and corporations had fallen into many forms of extravagance. During the hard times many went to the other extreme, and with the return of the pendulum it is well to profit by the experiences of the past. Brighter days are certainly here with the golden promise of brighter still to come.

In these days a manager is obliged to constantly study every possible means for increasing his traffic.

Street railways have not been exempt from the inroads which the bicycle has made on the livery business, and the competition thus afforded has drawn from what has always been the most profitable business of a road, that of pleasure riding. Obviously the thing to do is to make the best possible virtue of the necessity, by arranging to carry wheels for pay. In many cities the best wheeling grounds are some distance out, or reached only by riding over rough, unpleasant, or streets occupied by traffic teams. Where such are the conditions a good business can be done in providing facilities for carrying wheels either in a special car or on the dash. In Pittsburg one line runs a large number of bicycle cars, which have been provided by slight changes in old cars which otherwise would have gone out of service entirely. The demand for dash racks has already called out several manufacturers who offer to furnish the equipment at a reasonable price. Several roads have devised and built their own racks in the company's shops.

So far as we can learn the scheme has proved satisfactory alike to the company and the public, and the general adoption of the plan seems likely and desirable.

AMERICAN made electric railway apparatus is beyond any question the best in the world. The demand here has been so great, and the requirements insisted on by railway managers such that the standard has steadily and rapidly been advanced to a point of high perfection. The same statement applies with equal force to the great variety of smaller supplies which are less conspicuous but hardly less essential to the operation of a well operated line. In the point of manufacture we lead the world, and while the manufacturers of Germany are very good imitators, which some even insist is carried to the extent of actual piracy, and while they have the advantage of cheaper labor, the fact remains that ours is by long odds the best of all. Our manager friends across the water will find in buying for electric railway service, from a brake handle to a generator, it pays to buy the best. In many cases the difference in price between the foreign and American made supplies is very slight, but even when our prices are higher, time will undoubtedly prove the economy of using the American made article. America leads the world in electric railways; and naturally American manufacturers also lead the word in the excellence and superiority of their railway supplies.

The time will possibly come when "as good" will be made abroad but it will be a long time, for our American

manufacturers have already the advantage of 10 years' experience, and are quicker to see improvements and utilize them. In the meantime our best advice to new foreign roads is, use American apparatus and you will have the best on earth.

A SUBJECT which may well command the study of American managers, is that of a more permanent track construction, such as has been the practice in England and the continent for years, in which no easily perishable material is employed. In our own rapidly growing cities where the capacities of water and gas mains reach their limits with unexpected frequency, and a false idea of economy permits the construction of sewers altogether too small, there has been little encouragement to managers to warrant the more expensive, though more economical, if undisturbed, concrete construction. Our streets are no sooner paved than they are dug up to make room for some kind of a "main" and the expenditures to which our street railways have been put by these "improvements" which are seldom any improvement to the railway, has mounted into vast sums of money. On the other side it requires all kinds of "pulls" of the biggest kind to secure a permit to open up a street. Even so far back as when George Francis Train and Charles Hathaway built the first street railway in England the law was invoked and executed upon them for "tearing up the Queen's highway."

However, as we grow older it is to be hoped and expected that we too, will some day become reconciled to streets without the appearance of a recent cyclone, and as we do we may look forward to a track construction deserving of the name "permanent way."

MUNICIPAL ownership of lighting plants has now for some years been the popular demand, and at the present time the leaders in this movement are casting their eyes upon the street railways, and the promise is made that benefits without number will flow from their operation by municipalities. Inasmuch as there are no municipal street railways in this country, recourse is had to European cities for the necessary glowing statistics with which to dazzle the unsuspecting taxpayer. European statistics are without doubt of great interest, but the conditions obtaining there are so different that they are of little value as showing evidence of what we may expect in this country. This fact is, however, an advantage to those who quote them. The history of how the 3-cent fare bill was defeated in the Missouri legislature, which we publish in another column, shows that the honest supporters of measures inimical to the railways are glad to be convinced of their error, and it will only be necessary to place the truth before the man who has most to lose, the taxpayer, and he will put a quietus upon the scheme. Having no municipal railways here, we can not compare the actual results obtained with the promises which are held out to us, and it is in order to profit by the experience of the municipal lighting plants. We publish an abstract of the paper on municipal lighting read before the National Electric Light Association, by W. Worth Bean, president and general manager of the St. Joseph & Benton Harbor Electric Railway & Light Company, and recommend its perusal to the advocates of municipal railways. The same principles would apply to municipal ownership of railways, only to a vastly greater extent in proportion to the larger number of employes and investment involved in the latter. Mr. Bean ably demonstrates that all is not gold that glitters.

## DATA FROM POWER STATIONS.

The methods of keeping accounts for the steam roads have passed through an evolution until now nearly every spike and pound of coal have a record at the general office. A great deal of attention has been given to locomotive performance. Each engine of each division, each month has a complete record of the passenger, freight or switch mileage, the amount and cost of waste, oil, coal and other supplies, labor and material for repairs and the wages of the engineer and fireman. Then the cost per mile run for these separate items is figured out. A summation is made for the whole division and a comparative statement is prepared for the system. With such a record it is easy to tell whether or not the different divisions are being efficiently managed. These statements, which are on blanket sheets, are sent to each master mechanic and are also exchanged between the different roads. Although no two roads have exactly the same system of accounts yet the statements admit of quite accurate comparison.

Records for power house performance are analogous to those of locomotive performance and the street railway men have followed the practice of their steam railroad brethren in many particulars. There is one difference and that is the street railway managers treasure their reports and seldom permit the records to go outside of their own hands. Power house equipment, methods and appliances for keeping records and systems of accounts have changed so rapidly that comparisons were hardly fair or desirable. Occasionally a monthly or annual statement was given out but not much faith was placed in them. If the record was a good one it was generally believed that the manager took a particularly favorable time when repairs were light and fuel cheap to publish the figures. The output of the station was generally read in volts and amperes which is a tedious and unreliable method. In contrast to this, with wattmeters which are so common now, an absolutely correct reading can be taken once in 24 hours and the day's operation figured on the kilowatt-hour basis. In addition to this, coal scales, record blanks and graduated oil tanks add much to the reliability of the records.

Already some of the most progressive managers feel the need of comparing the records of their stations with those of other stations operating under similar conditions. This exchange of data is going on between a few managers although the statements are not so complete as those of the steam roads. The statement is generally itemized as follows:

|                                                   |          |
|---------------------------------------------------|----------|
| Cost of Electrical Output per Kilowatt-hour:      |          |
| Fuel .....                                        | \$ ..... |
| Labor .....                                       | .....    |
| Supplies (oil, waste, etc.) .....                 | .....    |
| Water .....                                       | .....    |
| Repairs .....                                     | .....    |
| Total .....                                       | \$ ..... |
| Output of station in Kilowatt-hours:              |          |
| Gals. of cylinder oil per 10,000 k. w. h. ....    | .....    |
| Gals. of lubricating oil per 10,000 k. w. h. .... | .....    |
| Lbs. of water per lb. of coal .....               | .....    |
| Lbs. of coal per k. w. h. ....                    | .....    |

Although there may be a different system of accounting for each company yet this blank could be filled out from any good record. The value of such a statement made at regular intervals, everyone in charge or interested in power house operation can appreciate.

## TRACK ELEVATION IN CHICAGO.

Many of the crossings of the 1,200 miles of steam railway tracks in Chicago with the city streets and the street railways have become very dangerous, as most of them are at surface grade. To alleviate this as many as 39 street viaducts were built, but this plan was found unsatisfactory on account of their difficult grades and damage to adjacent property. A different policy was adopted by the city and ordinances were passed requiring certain railroads to elevate their tracks at dangerous points. The climax of this legislation was the "O'Neill Ordinance," which provided for the elevation of all the railroad tracks within the city limits, but the provisions were so onerous and unreasonable that they have never been carried out. The railroads of their own volition have elevated about 42 miles of track at great expense, but traffic has been greatly facilitated and the expenses incident to grade crossings have been done away

WEST CHICAGO TRACKS AT ROCKWELL STREET.

with. The work of elevation is carried on without interfering with the regular traffic. Sand filling is used except at the intersection of streets where steel viaducts are built supported on stone abutments.

The street railways are interested in this elevation as well as the steam roads, for the city ordinances explicitly provide that the street railway companies shall make the grade of their tracks conform to that of the street and repave the street between tracks at their own expense.

When the work began on the track elevation of the Chicago & Northwestern and the Pittsburg, Cincinnati, Chicago & St. Louis railroads there was a conflict between these roads and the West Chicago Street Railroad. The city ordinance provided that the railroad tracks at the intersection of West Madison street should be 12 ft. 6 in. above the surface of the street, the tracks being elevated 9 ft. and the street depressed 3 ft. 6 in. The task of depressing the cable tracks to conform with the street grade was an expensive undertaking and required considerable time. It was proposed by the street railway officials that the railroad elevate temporarily the viaduct 3 ft. higher than required, and thus comply with the ordinance, until work in depressing the cable tracks could be completed, the street railway com-

pany being willing to bear all the necessary extra expense. For some unknown reason, or, perhaps, no reason at all the railroads refused to accept this offer, and without a word of warning placed a steel girder on abutments across Madison street. As the girder was only 9 ft. above the cable tracks the cars could not pass. To insure a complete blockade and forestall interference while putting the girders in place the railroads switched lines of freight cars loaded with stone on the steam tracks across the streets. The street railway company obtained a temporary injunction from Judge Gibbons, but the work had progressed so far that the railroad could not be restrained. One illustration shows the blockade on West Madison street and the passengers transferring from the cars on either side of the railroad. After a delay of two days a crossover switch was put in place just west of the railroad tracks and the cars on that section of the track continued running.

Underlying the crossing is a solid bed of masonry to give

built up to the bottom of the column or the column is lengthened. The elevation will soon be completed and as far as the work has progressed there has not been even a rivet loosened and no interference of traffic.

#### CLEARANCE CARDS.

The decision of the Appellate Court of Illinois in the case of Charles Jenkins against the Cleveland, Cincinnati, Chicago & St. Louis Railroad is of interest to street railways, as in all probability the same rule will be applied to them if a similar case should arise. Jenkins was a freight conductor and was discharged by the company which declined to give him a clearance card or letter of recommendation required by railroads of applicants for employment who have worked for other roads. Being unable to secure employment elsewhere he sued the company for damages. The finding of the lower court was in his favor, and the decision was sus-

RAISING METROPOLITAN ELEVATED AT ROCKWELL STREET.

rigidity to it, in fact, it is so unyielding that its maintenance has proved very expensive. The excavation has to be made into this solid stone and mortar. To give the proper grade, the tracks have to be depressed for about 100 ft. on either side of the crossing. The Rockwell street station of the street railway company is within this distance, and the lowering of the tracks will necessitate changes of the tracks and turnouts from the station.

Changes in the grade of the steam roads will also affect the tracks of the elevated roads. The second illustration shows the tracks of the Metropolitan West Side Elevated being raised. It is necessary for the bridge over Rockwell street to be lifted 6 ft. 4 $\frac{7}{8}$  in., and to give a uniform and easy grade the whole structure will be raised for a distance of 2,300 ft. The peculiar design, rigid connections being omitted every third span, and the substantial construction enable this work to proceed without interfering with the regular traffic. Around each pair of iron columns a heavy frame work is built; hydraulic jacks are used to raise each section 2 in. at a time, and it is then blocked up, the structure having enough flexibility to permit of a distortion of 2 in. When the section is at the required height the piers are

tained on appeal. The court held "that as it is the general custom among railroad companies to grant and demand these letters of clearance, there is an implied provision in the contracts between them and their employes, although no expressed provision be made therein concerning the matter, to grant their employes letters of recommendation for the purpose of enabling them to secure employment elsewhere."

#### CELLULOID DESTINATION SIGNS.

A destination sign that is very plain and easily read at a distance, both day and night, is employed on the Des Moines City Railway, of which W. G. Owens is superintendent. The letters are cut out of a wood board and this board painted black. For a suitable background white celoid is fastened against the back of the board to make the lettering stand out white and clear, both by day and by night. The sign is put up directly in front of the dome lights, and clear glass is put in the front of the dome in place of the colored glass usually employed. Thus a legible sign is secured without any changes in the lights on the car.

## MUNICIPAL LIGHTING.

From a paper read before the National Electric Light Association by W. Worth Bean.

The subject to which I would respectfully invite your attention is one of the most vital questions, and of the most momentous importance—not only to the profession to which we have the honor to belong, but also to various commonwealths of which it is our pride to be citizens—that has ever arisen in this advanced electrical era. Municipal ownership of electric lighting plants, the most discussed of all the questions of municipal polity, is the more insidious that it comes dressed in the sheep's woolly garb of a philanthropist, which to the uninitiated and ignorant has an alluring and plausible aspect, but to the experienced are plainly visible the wolf's deadly fangs, which have, in every instance, sooner or later lacerated the taxpayer. The authors and promoters of this alluring scheme are either visionary theorists, who have no practical knowledge of its manipulation, or unscrupulous politicians who, desiring to pose as benefactors to the municipality, hope to ingratiate themselves in the hearts of the voter and thus secure political plums for themselves and their henchmen. That there are many honest supporters of this political fad who, having been deceived by beautiful but false reports from cities which are experimenting with this question, are misled by political demagogues, is undeniable.

The tidal wave is sweeping over our land, and certain municipalities are now on the crest, but it will not need the average period of depreciation in a plant for the wave to subside and leave the wrecks stranded with increased burdens and depleted treasuries. Already cities have sold their plants, paying dearly for their experience, and others are looking for buyers, in order to unload their "white elephants." Municipal ownership is contrary to the spirit of republican institutions.

Government, whether national, state or municipal, was instituted for the purpose of protection and not production. It would be just as reasonable for the city to enter any pursuit, such as farming, or as a grocer, or keep a sawmill to saw its own material for sidewalks or paving, or manufacture shoes for its citizens, or run a saloon for the profit there is in it, as for it to enter the field of lighting. Just as sure as a nation becomes a commercial producer, competing against its own citizens, just so sure will the seeds of own disintegration be sown.

Municipal ownership is a source of danger to the commonwealth, in that it affords a great opportunity for fraud. Municipal corruption is so common and so well known that it needs no argument to prove the danger of opening a new avenue of power in the hands of unprincipled public officials. In this business there are a number of important, and ought to be well salaried, offices, which can be used to great advantage by political manipulators to further their own ends to the detriment of the city. In the State of Michigan one political party had been in power for 34 years until 1891. A member of the old party was elected to the Senate and introduced a bill to benefit Coldwater, Mich., and this has been the Mecca of the municipal advocates ever since. It has been the oasis in the desert where they could get sweet morsels to roll under their tongues to advocate the scheme of municipal ownership. I venture to say that more than a score of towns and cities have charged up expenses for the

examination of this delectable plant, and from their own printed statements I am willing to qualify that the figures are not as they should be made. Reports come from Grand Haven, Mich., that through political influence a competent electrical corps has been discharged to make room for inexperienced friends of the "powers that be." "To the victor belongs the spoils" is a policy followed with unswerving fidelity by a great many city officials. Scandals from our great cities in regard to employes, inspectors, officials and boodle aldermen, should teach us to avoid throwing this enterprise, involving hundreds of thousands of dollars, and positions of the utmost importance to the city, into the maelstrom of municipal politics.

Municipal ownership is unjust to the electrical plant now in the field. The central station man has, through his industry, ingenuity and executive ability, built up a large enterprise. The city has invited him to invest thousands of dollars, not only of his own money, but also the money of its own citizens, with no immediate show of dividends, and, in some cases, barely sufficient income to pay the running expenses and interest on the bonds during a period that will amount from one-half to the whole of the average amount of time allowed for depreciation of the plant. The central station man during this time has been harassed with the anxiety of meeting the fixed charges, maintaining the credit, providing a reserve fund to meet loss by fire, wind storms and burned-up apparatus, and cheering up despondent stockholders who have nothing to show for their money but the rosy-hued prospect that, at some time in the near future, there will be an adequate dividend to compensate them for their risk, and now, when these hopes are about to be realized, in a modest degree, they are confronted by municipal ownership. He must either compete with the city—which, through ignorance, will furnish lights below cost—or sell out. The latter proposition is impossible, for he cannot hope to dispose of a plant that has depreciated 50 or 75 per cent without great loss, therefore he is compelled to continue in business with his former heaviest consumer, now his strongest competitor, with the prospect of having to renew his plant within a very short time, at a heavy expense, and knowing full well that there is room for but one paying plant in a city of that size. Such conduct on the part of the city amounts to the indirect confiscation of property; obtaining a competent and effective service for years without profit, holding out the alluring representations of a future gain.

Municipal ownership is unjust to the taxpayer. That through ignorance or willful errors in keeping accounts it is certainly true, in most cases, that lights are furnished to the city and private patrons at a loss, and the deficits charged to some other accounts. Very few of its citizens are able to take the lights at the reduced price, for the great majority of its citizens are day laborers, who are paying for their homes, and cannot afford to take the lights even at any price, but who eventually must help to carry the burden of the ever-increasing loss, thus making the many help pay for the luxuries of the few. Municipal ownership has cost the city of Hamilton, Ohio, \$575,000. It is reported that an order has been made to discontinue the electric lights, on account of lack of funds. This has been a very expensive experience for Hamilton, and the taxpayer who has burned nothing but an oil lamp now helps to pay the bill.

The result, in most cases, will be less efficient service than under the competitive system. Central station men who

have been in the business for a long time, and who have had years of experience, are, without doubt, the most competent to give the best service of the times. He surrounds himself with expert electricians and a corps of able assistants who have been educated in the business and retain their position by the strictest attention to duty. He is continually devising means for improving his service, not only in employes, but also in the latest improved machinery. On the other hand, municipalities change their officials frequently, and new men take control. Councilmen who oftentimes are not even good business men, and have no knowledge of apparatus and electrical affairs, pass on the purchasing of supplies and the competency of electricians and engineers, deposing experienced incumbents and apportioning political plums to friends of but ordinary ability. The men now in control attempt to compete with electrical experts and competent engineers of long experience, and about the time when they are beginning to understand their plant and how to save loss—in a year, or possibly two—the council changes, and they must step down to make way for those of even less ability. Again, in smaller cities councilmen are often elected on the single issue of economy, and in order to fulfill the expectations of their constituents, they must cut expenses. The first attack is made on the official salaries, which results in filling responsible positions with inefficient men. Experts cannot afford to educate themselves for positions, commanding low salaries and subject to the vicissitudes of municipal politics, and we all know too well the cheap men in this business are the most expensive. Then, again, the economical councilmen will object to improving the plant, which will require vast sums in replacing that which has but lately cost so much, and for which they have not as yet finished paying. This is especially so if the improvements are demanded in a time of financial depression, and when taxes are already too high.

The glowing reports from cities that are experimenting with this question are unreliable and misleading, except to the electrical profession. In some cases, where the plant is new and there is no perceptible depreciation, and where they have providentially escaped accident or disaster, no doubt these statistics are honestly, though ignorantly, compiled, deceiving the taxpayers into the belief that their venture is a glorious success. The engineer's salary and the coal bill are often charged to the water department, and the water consumer helps pay the electric light bill.

In most instances the item of interest on the outstanding bonds is charged instead of interest on the entire plant, and 4 per cent depreciation is charged, whereas from 10 to 15 per cent, should be the rate. In some cases losses by fire are not accounted for; in others accidents are never charged. The loss to the city of the taxes that would be paid in by a private corporation is not computed, and in a great many cases the accounts are so mingled with other departments that it is impossible for even the officials themselves to tell how much the lights for street purposes cost the city.

I have personally visited Niles, Kalamazoo and South Haven, Mich., and I know that these cities are paying more for their lights than their official reports show that they cost, and yet they are considered among the list of those who are successful with municipal lighting. The city of Detroit has probably the finest equipped plant in the State of Michigan, and operated under the most advantageous circumstances, and yet she pays \$100 in round numbers per lamp for 1,483 lamps, under municipal ownership, while St. Joseph

and Benton Harbor, under the relentless pressure of a private corporation, only pays \$90 on an average, for sixty-two lamps. Tipton, Ohio, and Marquette, Mich., had serious accidents, and the deluded taxpayer, with his eyes partly open, refuses to vote more money for such a hazardous enterprise.

At this present writing municipal lighting has not passed through its most dangerous period, and it is difficult to predict its final result. It is now but at the dawn of its existence, but a December day will be long in comparison with the life it has to run, for when bonds are to be redeemed, accidents befall the plant, and a depreciated plant is to be renewed, then comes the trying ordeal, and woe be to the city that has not provided against that day, but has wasted its substance in riotous living, for then it will be found to have nothing left for its existence but the husks of "Municipal Lighting."

### SLOT RAILS AS TRACK RAILS.

The slot rails used in cable track construction certainly has a very positive individuality, so much so in fact no one has been able heretofore to study up any other use to which they can be put. As the rolling of slot rails calls for special rolls and a special run, they are always made only to order and none kept in stock at the mills, hence in the early days of cable building roads frequently ordered a considerable tonnage in excess of present needs in order not to be left without a supply.

At that time also it was estimated the life of the slot rail would exceed that of the track rail, but no one expected they would practically never wear out. Such, however, has been the subsequent history of their use, and probably 98 per cent of

all the cable slot rail in Chicago is practically as good today as it was when laid 10 or 15 years ago.

The Market Street road in San Francisco recently found itself in possession of a large tonnage of these slot rails which had never been used, and as its new lines are all on grades adapted to electricity, there will be no occasion to use this iron in new cable construction. Then the question arose what to do with them. Some one ingeniously conceived the idea of using them as track rails, something heretofore impossible from the form of the section. This has been accomplished by cast-welding at the joints, thus forming a wide base to support the slot rail, which is a Z section. The work is being done by the Falk Manufacturing Company, under the direction of its San Francisco office in charge of Ira Bishop.

The City Electric Railway of Port Huron, Mich., will henceforth issue no more passes. Last year the passes given away amounted to \$1,700.

## BICYCLE RACKS IN TORONTO.

The illustration shows the bicycle racks designed at the request of the Toronto Street Railway when that road decided to experiment with carrying wheels on its cars. The frame of the rack is of wood, there being two or three vertical pieces according as it is to carry two or three wheels. At the bottom of each vertical piece iron rods project with a block at the outer ends, which are supported by light chains. The rear wheel of the bicycle rests in this support and the front wheel is clamped to the vertical piece of the frame. Two of these racks are carried on the car, attached to sockets fixed to the dash at the rear end. In Toronto where trail cars are operated during the busy hours of the day, both the motor and trail cars are fitted with

TORONTO BICYCLE RACK.

sockets so that the racks may readily be transferred from one to the other when occasion demands. These racks have given satisfaction in service, carrying the wheels with perfect safety and without scratch or strain.

A Connecticut firm will manufacture the racks for this country.

## A PLEA FOR PERMANENT ROADBED.

### EDITOR REVIEW:

In your issue, under date of June 15, I notice the opinions of presidents, vice-presidents, railway managers and superintendents given upon the expenditures and costs of operating street railways. And by them all there seems to be a slight reference made to gross earnings; the opinions herein referred to will be found on page 375, under the title of "Cost per Car-Mile vs. Cost per Passenger."

This is a very broad subject which should be brought down to a more pointed and definite argument; simply showing cost of maintenance after construction and equipping a road. Here is where the money lender is looking for information, and as a money lender I ask for some information through the columns of your valuable REVIEW.

I will first quote a few facts, and ask of you is there not some way to overcome the great outlay for expense of constant repairing and re-construction of street railways. In Philadelphia, when the railway people do all the work themselves, it costs from ten to twelve thousand dollars per mile to construct their railway, without any equipments. Now, the writer holds some street railway securities, and I am perplexed to know, why it is that our roads, which have been

laid for less than two years, are now being torn up to repair the joints. Can this not, in some way, be prevented or overcome? Then I look into the near future, when there must be an entire reconstruction of the whole roadbed, simply because the rails are without a foundation, the wooden ties having all vanished through decay. And it is well known to all of us, who invest our money in this direction, that the cost of this reconstruction exceeds first, or original cost of construction; yet we are satisfied with the amount of interest which we receive from our investment, notwithstanding all of these disadvantages, which are so broad that they are undeniable. And again, I ask: Would it not be much better for the holders of bonds and stocks of street railways, if the above superintendents and managers would place themselves on record, in advocating and adopting some method of permanent roadbed for street railway construction, whereby the cost of maintenance would be a thing of the past.

Just here—to illustrate—I find it does not cost me very much to buy a team of horses for my family's use, but to keep them will cost me very much more. In talking with a friend, who is well versed in banking interest, upon this particular subject, he gave very freely his views, and said that he quoted the views of some strong banking houses, both of New York and Philadelphia; his remarks narrowed down to a very small space by saying: "Permanent road beds must be had, and when the street railway men attain them, their bonds will be much more valuable."

I hope to gain some information through the STREET RAILWAY REVIEW, of which I am a constant reader. There are very many millions of dollars invested in street railways, all of which are laid upon perishable foundations. Hence the subject matter of this letter is well worthy of immediate and careful consideration. I acknowledge that my investments in street railway securities are profitable, yet I fully realize that if the cost of maintenance were not so great, my securities would be much more valuable.

I should be very happy to take up the question of permanent roadbed with some of our railway managers, superintendents, presidents or engineers, and argue the matter from every standpoint, through the STREET RAILWAY REVIEW.

HUGH PHILLIPS.

## STREET CAR LICENSE IN PHILADELPHIA.

The street car companies of Philadelphia are compelled to pay a license fee of \$50 for every car in service. The Union Traction Company owns 1,500 cars and pays a tax on 1,200, the remainder being held in reserve. On special occasions it is desirable to put on a large number of extra cars to accommodate the traffic. As an instance, on Memorial day 250 additional cars were needed, but the license was so excessive that the company did not feel justified in paying more than \$5,000, the amount required for 100 cars. As a consequence the cars on all the lines were greatly overcrowded and the passengers suffered great inconvenience.

To remedy this evil and not make the provisions of the ordinance so burdensome to the company a new ordinance has been introduced into the council providing that on holidays or at other times when a large number of cars is required, that a license of 25 cents a day shall be paid. This will be more just to the street railways and an encouragement to give ample facilities for the traffic.

## INCLINE RAILWAY UP MT. TOM.

Mt. Tom is the highest mountain of the Holyoke range, the summit being 1,218 ft. above sea level. From the top is an extensive view. On clear days the gilded dome of the state house at Hartford, 35 miles distant, is plainly visible. The inclined railway which was opened for service on June 26 is an addition to the extensive park, 600 acres, of the Holyoke Street Railway. The road was built by the Mt.

MT. TOM RAILROAD.

Tom Railroad Company, but this company has the same officers and, with one exception, the same directors as the former, and the road will be leased to the Holyoke Street Railway. The Mt. Tom company also has 365 acres in park. The Holyoke company operates electric cars from the city to Mountain Park, as it is called, where connection is made with the incline. Electric cars from Springfield and the smaller towns in the contiguous territory make good connections with the Holyoke line.

The road is operated on the balance system, but with two

MT. TOM PAVILION ON THE SUMMIT—1,218 FEET ABOVE SEA LEVEL.

cars instead of one car and a dummy. The two cars are attached to the ends of a cable, and the necessary power applied by the motors on the ascending car. The cable is

of steel,  $1\frac{1}{4}$  in. in diameter, composed of 6 strands of 20 wires each; at the top it passes over an 8-ft. sheave. Telephone wires connect with telephones in both cars in order that the motorman may operate them in unison. The two cars are named "Rowland Thomas" and "Elizur Holyoke," after the commanders of two surveying parties which tradition says made surveys of the mountain about 1650.

The cars were built by the Wason Manufacturing Company of Springfield, Mass., and excel in taste and finish other mountain cars in New England. Each has 12 benches and will seat 84 persons. Each car is lighted by 15 incandescent lamps. The cars are open on one side only; our illustration shows the closed side.

The trucks were also designed and built by the Wason company and in them and the turnout are embodied the most interesting mechanical features of the installation. The line drawing shows three views of the truck, which is symmetrical about the centre line except that the motor at each end is hung in front of the axle, and there is no cable attached at the rear end. The total length of the truck is 35 ft. 6 in. and the width from centre to centre of the truck sides 6 ft. 2 in. The truck sides are 22 in. deep with 6-in. channels at the top and 4-in. channels at the bottom. The wheel base is 20 ft. measured horizontally, and with a vertical distance between wheel centers of 33 in. when the tops of the spring planks are horizontal. This slope of the truck is 13.75 per cent, the average grade of the line. The four wheels are 33 in. in diameter, and those on the inner side (the side toward the other car when passing) have an exceptionally wide tread, 6 in. The object of this will be seen on examining the view of the turnout; the

TURNOUT—MT. TOM RAILROAD.

switch-rails are stationary and the car is thrown onto the proper track by the guard rail shown in the foreground of the illustration, which engages the outer edge of the tread

of the wide wheel and forces it over so that the flange catches the switch rail.

At the turnout short sections of the running rails are omitted to provide a way for the cable and allow the car to pass without injuring it. To carry the car a section of rail is laid  $1\frac{1}{2}$  in. outside of the switch rail and extra wheels provided on the truck. These wheels are 24 in. in diameter and run loose on fixed axles placed 2 ft. behind the axles, one at each end of the truck.

Each truck has two G. E. 1,000 motors, one to each axle. The speed is 800 feet per minute, 9 miles per hour. The greatest precautions have been taken to provide against accidents, and each car is equipped with hand brakes, electric brakes designed by the General Electric Company, and an automatic device similar to the Sprague safety brake for elevators. For this last a third rail is laid between the running rails, and when the speed of revolution of the car wheels exceeds the maximum allowed, the regulator releases a powerful clutch which grasps the third rail. In addition to these an automatic brake or retarder for braking the cable is placed at the summit. The weight of the car and truck is 25,000 lbs.

The road is 4,900 ft. long, with a total rise of 700 ft.; the

minimum grade is at the lower end, 7 per cent for 300 ft. and the maximum is 21 per cent. There is but one curve; it has a radius of 1,910 feet. The gage is 4 ft.  $8\frac{1}{2}$  in.

Nearly all of the embankments are of trap-rock and the cuts are through the same material. The track is laid with 56-lb. T-rail on 6 x 6-in. southern pine ties, 2 ft. between centers. These are bolted to 6 x 10-in southern pine stringers, which in turn rest on heavy chestnut mud sills.

At the summit the company has erected a pavilion securely anchored to the rock large enough to accommodate 500 guests. This building is 76 x 92 ft. on the ground, of two stories, with ample piazzas on both floors around the whole building, and a cupola 25 x 31 ft. On the first floor are the restaurant, dining room, parlors, etc., on the second a hall with stage, and two smaller rooms; the kitchen is in the basement. The cupola is used for an observatory and is provided with good telescopes.

At present water is carried to the summit in tanks but a pipe line is to be laid and a motor pump installed to furnish the supply.

The fare is vastly less than that usually charged on mountain railways, being 25 cents for the round trip including the freedom of the pavilion with its musical and other attractions.

The time occupied in building was five months and the cost nearly \$100,000.

We are greatly indebted to William S. Loomis, president and William R. Hill, treasurer, for data and courtesies extended, and to the Wason Manufacturing Company for views and description of the trucks.

### TO PROTECT PEDESTRIANS IN NEW ORLEANS.

In order to protect the pedestrians of New Orleans against their own carelessness an ordinance has been introduced in the city council which provides that it shall be "unlawful for any person to loiter or play on such parts of any neutral ground, levee or street on which steam or electric cars are operated." A fine of from two to ten dollars is provided as a penalty.

Cars of the Citizens' Railway are running on the lines of the Detroit Railway while the cars of the latter company are being overhauled.

SHEAVE AND BRAKE AT SUMMIT.

CAR.

## RECENT DEVELOPMENTS IN CHICAGO.

Street railway gossip has formed an unusually interesting subject of conversation in Chicago during the past month—not only among street railway men, but the general public as well. On the passage of the Allen bill local securities advanced, and many expected President Yerkes would at once apply for the 50 year extension which that law permits. He has not yet done so and appears to be in no great haste. A striking feature of the Allen bill was the provision made for leasing or consolidation of companies, and that this will eventually be availed of to bring all the city transportation lines into one organization there is no doubt, and Mr. Yerkes will be in control of such consolidation. This is expected to include all the surface and elevated lines within the city proper, and their suburban connections. With the North and West Chicago systems and their numerous suburban connections, and the Lake Street elevated, and the Union Loop elevated, there remain but three prominent properties to secure—the City Railway, and the Metropolitan and Alley L's. Both the latter are in receivers' hands.

There has been great curiosity as to what the General Electric road would do and who is behind it. The recent victory which this company won in the Supreme Court of the state, against the City Railway has put it a long way ahead in its possibilities. The company has for a long time given out that J. Pierpont Morgan stood ready to take its bonds and has for months stated it was about to begin construction. A permit was taken out but no work done beyond breaking ground. Probably it could legally maintain the point of having begun work. The numerous suits have, however, given it very reasonable excuse for the delay to date. The history of the scheme is interesting. The ordinance was secured by some well known politicians for the very apparent purpose of disposing of it. As the franchise brought its lines to the heart of the city and paralleled the City Railway's great system from Jackson street to 63rd street, that company was naturally the most likely buyer, as it was by all odds the most interested competitor. It is rumored on what is very good authority that the franchise was offered the City Railway at the outset for \$50,000. The company, however, refused to consider what it not improperly branded a species of blackmail, although the franchise ought to have been worth that to anybody as it will be no difficult matter to raise the necessary money to build the road when once it is out of the courts and perfects its title. This it now claims to have done. The effect of this possible competitor located between the great arteries of the State street cable and the Clark street electric lines of the City Railway was soon felt in the steady depression of the City Railway stock, which in spite of its big business steadily dropped until it had fallen off over 50 points and at one time was temporarily even lower. Before the dropping process had gone very far it is said the City Railway concluded to accept the \$50,000 offer only to discover the price had gone up to \$100,000. This was too much, and that deal failed. One or two other offers and refusals are reported but each time the price was raised over the previous one, until now it is understood the General Electric would not take less than a million.

In the meantime there are more than rumors that Mr. Yerkes is after the City Railway; just how far these negotiations have progressed is guarded as a state secret, and indignantly denied by City Railway stockholders who say

there is nothing in it. Nevertheless it seems more than likely that such will be the eventual outcome, and the time will not run into many years, either. The REVIEW has met with little encouragement among street railway people here in its belief that Yerkes controls the General Electric; and while we are confident he had nothing to do with its inception and early history we venture the prediction that eventually it will be seen that at the present time and from now on it will have to do as he says. One of the strongest proofs of this was the ease and rapidity with which the General Electric had its original franchise revised and changed to permit to use overhead wires in place of the conduit system, an ordinance the mayor vetoed and has now been placed on file for further action.

During the past week there have been lively times growing out of the suit brought by Henry Brandenburg, inventor of a conduit system which at one time he expected would be adopted by the General Electric. Later it was announced the Love system would be used. Brandenburg charges Lucius Clark, who is now one of the bright lights in the deal, with having swindled him out of his stock in the original company, which he states was to have been one-fourth. He also goes further and professes to reveal a boodle scheme by which the ordinance was secured, and makes some very pointed charges against certain aldermen. Clark replies with a threat to have Brandenburg prosecuted for alleged forgery, and further intimates that the City Railway is prodding Brandenburg on and furnishing him the sinews of war. At all events matters cannot go on this pace long before somebody will get in a tight place.

The Alley L has arranged for a sufficient amount of its \$750,000 reorganization bonds to warrant it in going vigorously ahead with its electric installation. Connection has not yet been made with the Union Loop, with which it will have to connect before it can do a profitable business.

Work has been pushed with great energy on the Union Loop, and the station building has progressed with astonishing rapidity. The feeders are in and connected and operation is promised in less than a month. There is every indication that the promise to have it running by August 1 will be fulfilled.

A rumor was industriously circulated by the daily papers that the City Railway was about to displace all its cables with electricity. Several of the directors who were seen by a REVIEW representative absolutely denied any such intention. Electric motors have for some time been used instead of engines in the 52nd street station, driving the cables on State from 39th to 63rd, but the other plants are hardly so situated as make an enlargement of this plan desirable as yet.

## TROLLEYS REDUCE RAILROAD FARES.

The passenger representatives of the Cincinnati railroad lines at a recent conference decided to reduce the rates on all their suburban trains to meet the increasing competition of the electric lines. This reduction of rates will be followed by a quickening of their schedules and increasing the train service. It is stated that if need be the railroads will carry passengers for less than cost and even up on freight rates to the suburbs. The electric cars seem to be preferred to the railroad coaches and the most effective way for the railroads to meet trolley competition is to give patrons the same kind of service.

BEHR MONORAIL SYSTEM.

The engineering feature of the Brussels International Exhibition, which serves as its Eiffel Tower or Ferris Wheel is the Behr monorail railway. Engineering of London has in recent issues given complete illustrated descriptions of this very interesting feature and we reproduce a few of the cuts and a short description. The inventor, F. B. Behr, became interested in the Lartigue monorail railway in 1885 and since that time has devoted himself to perfecting a monorail system which could be profitably applied for the transportation of passengers at high speed, and the outcome of the present extensive experiment which he has undertaken at great cost will be watched with much interest.

Mr. Behr has built a track having a total length of about three miles, consisting of two parallel straight portions connected at the ends by curves of 1,600 ft. radius which are joined to the straight track by transition curves. This track is erected in an inclosure adjoining Tervuren Park at Brussels. The construction of the permanent way is shown in Figs. 1 to 6.

Besides the single rail which is placed at the top, there are attached on each side of the trestle-work, at a, b, Figs. 1

supported on insulators secured to the sleeper by stud bolts, the conductor rail being held by two screws provided with spring washers. Copper strips form the connections between the conductor lengths. The cross ties are 1.524

FIG. 7—CAR FOR BEHR RAILWAY.

meters long on the straight track and 2.059 meters on the curves.

Fig. 7 is an exterior view of the car which Mr. Behr expects to propel at 100 miles per hour. It is 58 ft. long and 11 ft. wide, framed entirely of steel. The bottom edge is 7 in. clear of the sleepers; the floor level is 5 ft., the bearing rail being 4 ft. 1½ in. above the sleepers. Fig. 8 shows the arrangement of the seats and disposition of the motors and guide wheels. The car seats 100 persons.

The car is supported by eight wheels, 4 ft. 6 in. in dia-

DETAILS OF TRACK—BEHR RAILWAY.

and 2, two rails of a special section, and laid flat with the heads outwards. These serve as guide rails, on which 16 pairs of small inclined wheels mounted on the carriage take a variable bearing as the train is in motion. The triangular members of the trestle are about 4 ft. high, the distance from the top of the sleeper to the bearing surface of the rail being 1.250 meters. The standards are placed at distances of 1 meter (39 in.) apart, except at rail joints, where the distance is made one-half. Fig. 2 shows the arrangement, and from this it will be seen that the joint standards are strutted back by angle-irons to the foot of each adjacent standard. Fig. 1 also shows the manner of attaching the lateral guide rails and the braces that stretch across from one leg of the standard to the other. Figs. 4 and 5 are enlarged views of the carrying rail, which is of ordinary section, and 82 lbs. to the yard. Fig. 5 shows the attachment between the rail and the head of the standard.

Fig. 3 is a view of the lower part of a standard; It will be seen that an angle-iron extends across the standard and is riveted to it; angle-irons, forming bearings for the foot of the guide rails, are also attached to the standards. The rails are bolted to the cross bar of the standard. The conductor is attached to the sleepers, as shown in Figs 1 and 6. It is

FIG. 8—CROSS SECTIONS OF CAR.

meter, mounted in two four-wheeled trucks which are coupled at the centre by means of a universal joint. The very short axles of the wheels run in boxes mounted on pedestals that are riveted to the main frame, and the carriage is hung on the boxes by means of cast steel curved hangers to springs, one on each side of the wheels, the springs being beneath the axles. Roller bearings are used throughout. There are four electric motors, placed in the hold of the carriage. Two wheels of each truck are driven, the two outer wheels running free. The motors are of the four-pole type, with toothed armatures wound with Eickmeyer's coils. Each motor is designed for developing 150 h. p. when furnished with a 700-volt current and running at a speed of 600 r. p. m. The motors are bolted to the lower deck of the carriage, and a rigid distance-piece connects the motor shaft with the axle of the driven wheel, the speeds of each being equal. Motion is transmitted to the axles from the motors by steel chains. The total weight of the car is 123,000 lbs.

Hand brakes only are used but when it is desired to stop the louvre plates at the front end are opened and the air resistance aids in reducing the speed.

### HOW SOME BAD LEGISLATION WAS DEFEATED IN MISSOURI.

The history of the introduction and consequent defeat on passage, of a legislative bill, usually is marked by many interesting circumstances, the story of which seldom reaches the public at all. Many a man has served his state or country well, without ever being known as the public benefactor he is.

The past winter was phenomenal in the number of legislative bills, throughout the country, which were aimed directly at and inimical to street railways. Missouri was no exception to the rule and brought out its fair quota. Among those were two bills, one known as the Dunn 3-cent fare bill; and the other taxing franchises. Fortunately alike for the companies and the public, both were defeated. The reduced fare bill explains itself; the franchise tax was intended to be an additional burden compelling the assessor to assess street railway properties at not less than 100 per cent (and as much more as they saw fit) whereas all other assessments were being made on a basis of not more than 40 per cent current value. This meant the street railways should pay tax on \$2.50, where everybody else paid on \$1.00. These were the startling conditions which the street railways of Missouri had to face; and the bill if passed, meant a practical confiscation of all the properties.

F. B. Brownell, president of the Brownell Car Company, and for years vice-chairman and treasurer of the State Republican Committee, is a man who thoroughly believes that our political parties will never be cleansed of the men who engage in politics from motives of personal gain, until they are displaced by honest, fair minded and just business men; and he has for years practised what he preaches, often at the sacrifice of his own personal interests. It was in this dilemma that some of the street railway managers turned to him to help save them from ruin. Mr. Brownell at once set to work at the unpromising undertaking. When he first took the matter up with Mr. Dunn the 3-cent fare bill had already been ordered to engrossment in the House. Mr. Dunn evidently was working in good faith, and the task of

proving to him his mistake was no easy matter. Mr. Brownell gathered data and presented it in such undeniable force, not only to Mr. Dunn, but others in the House, that it convinced them a gross wrong would result from the passage of the bill. This missionary work was so well performed that Mr. Dunn was converted and arose in the House and defeated his own bill. The local papers took advantage of the change to heap reproaches upon Mr. Dunn, asserting he had been bought off by the railways. In spite of all their insinuations and aspersions, however, he stood firm and was more pleased at its death than he had been when it was auspiciously christened.

When the case was first presented to Mr. Dunn, he wrote, "I honestly believe it is a right measure, but if I am mistaken in that judgment I shall regret introducing the matter." When the smoke of battle had all cleared away he again wrote Mr. Brownell a very frank and cordial letter, expressing appreciation of the latter's hard work, and which reads as follows:

ST. LOUIS, Mo., March 20, 1897.

Hon. F. B. Brownell, Dear Sir:

I am reminded that I owe you my personal thanks for the trouble you took this winter in getting me rightly informed regarding street car fares.

Your very exhaustive letter respecting my 3-cent bill, in reply to my inquiry, and your subsequent conversation a few days later, were the earliest as well as the most convincing arguments showing the inaccuracy of the figures and claims of the State Labor Report, a document which I had previously been led to regard as reasonably correct.

Your letter led me to further information which, I may say, was in the same line with yours but added nothing of importance to the ground covered by you, thus I was forced to candidly doubt my own bill, and when it came to final vote I so expressed myself to the House, and in the same connection I publicly impeached the Labor Report before the whole House, a somewhat notable fact, of which no St. Louis paper took any notice.

Of course I personally voted for the bill; first, because it was my bill, and second to give the lie to the Post Dispatch calumny.

Your letter and subsequent conversation guided me to the course I eventually pursued, and which I think was right, and I again express my obligations to you for the trouble you took.

Very sincerely yours,

EDW. J. DUNN.

The service rendered by Mr. Brownell is by no means confined to the limits of his own state, for had the bills become laws the precedent and example would have been used with strong effect in every other state.

### STEAM ROADS STILL ON TOP IN PENNSYLVANIA.

The bill pending in the Pennsylvania House to give trolley companies the right of eminent domain on rural roads was, on June 17, defeated by a vote of 103 to 58. The result of this is that all plans for many lines which were contemplated will be abandoned until at least two years hence, when it is to be hoped the legislature will incline more kindly to the trolley. With the present law the steam roads which own their rights of way in fee find but little difficulty in blocking all interurban electric roads which would offer competition.

The Electric Railway Company of the United States, office No. 1 Broadway, New York, has been dissolved by Judge Truax. Arthur Ingraham is made permanent receiver. The liabilities are \$28,250 and assets, \$5,041.

## THE EFFICIENT TRANSMISSION OF POWER TO STREET RAILWAY LINES.

BY R. W. CONANT.

No doubt there are some of the readers of this journal who glance from the heading to the array of formulæ and mathematics contained in this article and decide that they have not time to peruse the subject further. The table on page 443, however, has in it something that interests most of us, that is, the dollar sign. And to those who have had occasion to sign the bills for copper for a street railway, nothing more need be said regarding the importance of the subject.

The efficient transmission of power to street railway lines is a broad term and will here be limited to the system which is in use by the majority of street railways, that is, the medium voltage, direct current transmission. Efficient transmission implies first, that the cars should be operated, and second, that they be operated economically. Reliability of operation is greatly to be desired and experience has shown that cars may be operated in the most reliable manner when the lines are divided into insulated sections. As to whether the gain in this case warrants the additional feeders required, is a question that is governed by the conditions. It will be assumed that the line is sectioned, but the conclusions reached may, by slight modifications, be made to cover those which are not.

The economical transmission has usually been held to be incompatible with reliable or satisfactory car service. In the light of recent experience, this will be seen to be erroneous. How much copper shall be employed is the question to be solved. It is only those who have had this question practically before them, who know what its answer involves.

The amount of copper to place as feeders depends primarily on the number of cars at any one time in the section and their distance from the source of power. Return copper depends upon the nature of the rail return rather than on economical principles. What happens when we have too small an amount of copper in our feeders? Unsatisfactory service on account of low voltage at the cars, but more than this, increased expense to do the amount of work required on account of the loss of power. Suppose there is 20 per cent loss; this means a larger power station equipment, more expense for fuel, but less for copper. If we increase the copper, we diminish the cost but not proportionately, and soon the limit is reached beyond which it does not pay to spend more money for copper.

Various formulæ and curves have been published from time to time showing the relation between the per cent loss and cost of copper for feeders, but as a certain loss has to be assumed in order to use them, they are not in themselves sufficient for the proper design of a feeder line. The formulæ employed in this manner and the necessary calculations made, the user is deceived into the belief that he has figured the correct amount of copper. He might just as correctly have guessed that he would spend about so much for copper in the first place and have been much nearer right than in putting up all the copper required by the formulæ when worked out on an assumed loss which is much too small.

Other curves and formulæ have been constructed by a

mis-application of Thompson's law, making the cost of the lost power equal to the interest and depreciation on the copper. This gives a so-called economical drop per mile of a constant number of volts, say 50. That this method is incorrect may be seen by assuming a case of 500 volts initial potential with a line 10 miles long. Under such conditions  $10 \times 50 = 500$  volts, or the power all used up by the time it reaches the end of the line, which would hardly be called a paying investment. It is hoped in what follows, by a solution of a few special cases, to illustrate a method which may be useful to all engaged in this branch of street railway work. The assumptions made must be verified and changed if necessary, for each individual case. Those given are what the writer has used in certain instances and have been found to be correct for certain lines which have come within his experience. The mathematical derivation is given further on.

Formula No. 1.

$$c. m. = \frac{1.5 P A M G^2}{V^2 (G-1)} \dots \dots \dots (1)$$

where

- c. m. = cross section of feeder in circular mils,
- P = power delivered to cars in watts, nominal,
- A = specific resistance of copper per mile-mil,
- M = distance to center of load, miles,
- V = pressure at the power station in volts,
- G = economical constant,
- 1.5 = a constant representing the ratio between total drop and feeder drop.

The properties of G are somewhat peculiar and interesting. It may have any value between 1 and 2, not a very great range, but sufficient to make the expression  $\frac{G^2}{G-1}$  of a very considerable range.

The factors which enter to determine the value of G are as follows:

- M, the distance described above.
- C, the cost of copper in dollars per mile-mil. This cost does not include the cost of insulating or installing the copper, so that if a mile of 500,000-c. m. bare copper is worth \$900.

$$C = \frac{\$900}{500,000} = \$ .0018$$

The next quantity which enters into the value of G is the sum of the interest and depreciation in per cent on the above copper expense. Call this D. In arriving at a value for D, we must consider what the money is worth for uses other than purchasing copper. The supposing that we assume that it is 6 per cent and allow that the depreciation of copper is 1 per cent, making allowance for the possible fall in price, then  $D = 10$  per cent.

Next comes the question of insulating and installing the copper, which will be treated under two heads. First, when the line is overhead and second, when it is underground, these being the two cases which it is required to solve in street railway practice.

First, line overhead: We wish to ascertain what portion of the expense of insulating and installing is increased as we increase the cross section. As, in general in street railway practice, the tendency is to run one size of wire only, the insulation is directly proportional to the cross section, for with two 500 feeders there is twice as much insulation as with one, and we assume that no intermediate sizes are installed. Similarly the expense of stringing, including the labor, pins and insulators is proportionately increased, but the expense of poles is not so increased, and therefore should not be included. Assuming that \$500 will cover these expenses per mile of 500,000-c. m. overhead feeder, then

$$\frac{\$500}{500,000} = \$.0010 = E_o, \text{ which is the next quantity entering into } G.$$

Next the sum of the interest and depreciation on the above amount.

Interest = 6 per cent and depreciation = 9 per cent, a total of 15 per cent =  $F_v$ .

Second, line underground. For underground feeders, following above reasoning,  $\frac{\$2,500}{500,000} = \$.0050 = E_u$ .

In arriving at the sum of interest and depreciation on the above amount, we may consider \$2,500 made up of two parts, viz., \$1,500 for insulation and lead, with an interest and depreciation charge of 10.6 per cent and \$1,000, which is conduit expense proportional to cross section, with an interest and depreciation charge of 8 per cent so that 9.6 per cent is  $F_u$ , i. e., 9.6 per cent of \$2,500 = sum of 10.6 per cent of \$1,500 and 8 per cent of \$1,000.

The reason for taking only these expenses which are proportional to the increase of cross section, is that the formulae connecting the quantities have been derived on the assumption that the cross section is varied and fixed at such a point as will make the sum of the expenses a minimum.

$A$  = the resistance of a unit length and cross section of copper. This per mile-mil is 57,850 =  $A$  for commercial copper.

The next quantity entering into the value of  $G$  is the constant 2.25.

This appears on account of the fact that the rails are used as a return. It is arrived at in the following manner: Assume that the return drop is one-half of the feeder drop. This is true for a great many cases but will vary for different localities. Under these conditions the total drop is  $\frac{3}{2}$  of the feeder drop. Our economics are directed towards the feeder loss rather than the return loss, for the rails have such a low resistance when properly bonded, that, except in special cases, the placing of copper in parallel with them to return current is an idle expense, so far as the saving of power is concerned.

It would be far more profitable to place it on the feeding side of the line, but as we shall see, even this does not pay after a certain amount of copper has been installed. In obtaining the formulae, fixing the relation between the quantities discussed and  $G$ , the operation performed to obtain 2.25 is  $(\frac{3}{2})^2 = 2.25$  or in other words 2.25 is the square of the ratio of the total drop to the feeder drop.

$H$  is the time factor of the energy lost in the feeder and  $I$  is the cost per unit of time of a unit of this energy in coal, labor and supplies.

From the load curves for representative days throughout the year,  $H$  may be determined for any feeder. Assume that it has been found to be  $\frac{1}{3}$  of the number of hours in the year (8,760) and that  $I = \$.000007$  per watt-hour.

Assume that it costs \$.100 per watt installed =  $J$  for the necessary generating plant to produce the power lost in feeders.

$K$  = the interest and depreciation on this expenditure, which assume 15 per cent.

$V$  is the voltage at the bus bars at power station described above.

The complete formula for determining the value of economical constant  $G$  is

OVERHEAD LINES.

$$G = 1 + \sqrt{\frac{2.25 M^2 A (C D + E_o F_o)}{2.25 M^2 A (C D + E_o F_o) + V^2 (H I 8760 + J K)}}$$

UNDERGROUND LINES.

$$G = 1 + \sqrt{\frac{2.25 M^2 A (C D + E_u F_u)}{2.25 M^2 A (C D + E_u F_u) + V^2 (H I 8760 + J K)}}$$

These are somewhat formidable looking expressions so that it may not be amiss to solve them for one case to illustrate the method.

The only difference between the overhead and underground formulae is in one term, so that the overhead only will be carried through in detail. The letters in the formulae have been described above, but are tabulated below for reference.

- $G$  = economical constant required.
- $M$  = distance to centre of load (assume four miles).
- $A$  = specific resistance of copper per mile-mil = 57,850.
- $C$  = cost of copper in dollars per mile-mil = .0018.
- $D$  = interest and depreciation on above amount = .10.
- $E_o$  = cost of insulating and installing copper overhead per mile-mil = .0010.
- $E_u$  = cost of insulating and installing copper underground per mile-mil = .0050.
- $F_o$  = interest and depreciation on above amount for overhead lines = .15.
- $F_u$  = interest and depreciation on above amount for underground lines = .096.
- $V$  = voltage at bus bar (assume 550).
- $H$  = time factor of energy lost in feeder = .333.
- $I$  = cost of producing this energy per watt-hour = .000007.
- $J$  = cost of generating plant per watt installed = .100.
- $K$  = interest and depreciation on plant (assume .15).

Substituting the figures for the letters, we have for

OVERHEAD LINES.

$$G = 1 + \sqrt{\frac{\sqrt{2.25 (1)^2 57850 (.0018 \times .10 + .0010 \times .15)}}{2.25 (1)^2 57850 (.0018 \times .10 + .0010 \times .15) + (550)^2 (.333 \times .000007 \times 8760 + .1 \times 15)}}$$

Reducing,

$$G = 1 + \sqrt{\frac{2082600 \times .00033}{2082600 \times .00033 + 302500 \times .03542}}$$

$$G = 1 + \sqrt{\frac{687.258}{687.258 + 10714.55}}$$

$$G = 1 + \sqrt{\frac{687.258}{11401.808}} = 1 + \frac{26.21}{106.77} = 1.2455$$

UNDERGROUND LINES.

$$G = 1 + \sqrt{\frac{2082600 (.00018 + .0050 \times .096)}{2082600 (.00018 + .0050 \times .096) + 10714.55}}$$

$$G = 1.337.$$

Now having determined the economical constant, we are ready to find the cross section of the feeder. This will be worked out on a per car basis assuming that a car takes 15,000 watts = P. Substituting in the formula

$$c. m. = \frac{1.5 P A M G^2}{V^2 (G-1)}, \text{ we get for}$$

OVERHEAD LINES.

$$c. m. = \frac{1.5 \times 15000 \times 57850 \times 4 \times (1.2155)^2}{(550)^2 \times .2455} = 108760$$

UNDERGROUND LINES.

$$c. m. = \frac{1.5 \times 15000 \times 57850 \times 4 \times (1.337)^2}{(550)^2 \times .337} = 91318$$

Having the circular mils, we desire to know the voltage at the centre of the load under these circumstances. Let

X = feeder drop,

P, V, A, M, c. m., same significance as above,

Y = current,

Z = final voltage at center of load,

Then

$$X = \frac{Y A M}{c. m.} \dots \dots \dots (2)$$

$$YZ = 15000 = P \dots \dots \dots (3)$$

$$Z = V - \frac{3X}{2} \dots \dots \dots (4)$$

Three equations containing three unknown quantities, which by elimination give

$$Z = \frac{V}{2} + \sqrt{\frac{V^2}{4} - \frac{1.5 P A M}{c. m.}} \dots \dots \dots (5)$$

Substituting for OVERHEAD LINES.

$$Z = \frac{550}{2} + \sqrt{\frac{(550)^2}{4} - \frac{1.5 \times 15000 \times 57850 \times 4}{108760}} = 411 \text{ volts}$$

UNDERGROUND LINES.

$$Z = \frac{550}{2} + \sqrt{\frac{(550)^2}{4} - \frac{1.5 \times 15000 \times 57850 \times 4}{91318}} = 412 \text{ volts.}$$

The work of finding Z may be simplified as follows :

By solving equation (1) for G and combining with equation (4) we find that  $GZ = V$  or that G is also the ratio between the initial and final voltage. The short method then for calculation of Z is, for

OVERHEAD LINES,

$$Z = \frac{550}{1.2155} = 452 \text{ volts ;}$$

and for UNDERGROUND LINES,

$$Z = \frac{550}{1.337} = 412 \text{ volts.}$$

It is then apparent that under the conditions assumed one 500,000-c. m. feed wire will economically supply power for 4.6 cars at a distance of four miles from the power station with overhead lines and give satisfactory service so far as the voltage is concerned. The same c. m. underground will supply power economically for 5.5 cars at the same distance.

The following tables and the curves show for the overhead and underground lines the cost of feeding copper per car, the number of cars per 500,000-c. m. feeder, the economical constant G, the per cent loss in feeder, and the volts obtained at the center of load, for all distance from 1 to 5 miles.

| Dist. to Center of Load, Miles. | Economical Constant G. | Cir. mils in Feeders. | No. of Cars per 500,000 c. m. Feeder. | Cost of Feeder Copper not including Poles or Conduit. | Voltage at Center of Load. | Per cent Feeder Loss. |
|---------------------------------|------------------------|-----------------------|---------------------------------------|-------------------------------------------------------|----------------------------|-----------------------|

| 1                               | 1.0885                 | 57600                 | 8.67                                  | \$ 276                                                | 505                        | 5.45                  |
| 2                               | 1.176                  | 67100                 | 7.45                                  | 644                                                   | 468                        | 9.95                  |
| 3                               | 1.250                  | 80000                 | 6.25                                  | 1150                                                  | 437                        | 13.70                 |
| 4                               | 1.337                  | 91300                 | 5.48                                  | 1753                                                  | 412                        | 16.71                 |
| 5                               | 1.408                  | 105000                | 4.75                                  | 2520                                                  | 391                        | 19.30                 |

For the benefit of those who care to follow through the derivation of the formula, the following steps are given :

We require first an expression giving the annual expense of the power lost in the feeder.

VY is the power in watts at the power station end of feeder and P is that delivered at the car end of feeder, so that VY - P is the total power lost in transmission, and we assume in this particular case that 2/3 of it is lost in the

feeder and the rest in the return; so that

$$\frac{VY-P}{1.5} = \text{loss in feeder} \dots \dots \dots (6)$$

The expense of this is evidently given by the expression

$$\frac{VY-P}{1.5} (1118760 + JK) \dots \dots \dots (8)$$

Next we require an expression for that portion of the annual expense of the feeder line which is dependent upon the area of conductor employed.

This evidently is

$$c. m. M (CD + EF); \text{ but from equations (2), (3) and (4)}$$

$$c. m. \frac{1.5 Y^2 A M}{VY-P} \dots \dots \dots (7)$$

which substituted above gives for annual copper expense

$$1.5 Y^2 AM^2 (CD + EF) \dots \dots \dots (9)$$

To make the sum of (8) and (9) a minimum, differentiate with respect to Y, equate the derivative to zero and solve for Y, when the following results:

$$\frac{YV}{P} = 1 + \sqrt{\frac{2.25 AM^2 (CD + EF)}{2.25 AM^2 (CD + EF) + V^2 (1118760 + JK)}}$$

which is put equal to G.

Equation (7) may be reduced to

$$c. m. = \frac{1.5 P A M \frac{Y^2 V^2}{P^2}}{V^2 \left\{ \frac{YV}{P} - 1 \right\}}$$

and with G substituted for  $\frac{YV}{P}$  becomes Formula (1), giving most economical value for c. m.

**ELECTRICAL INTERESTS IN SIAM.**

Electricity is making steady, and even surprising advance in the far east, of which we are apt to think as slow and unprogressive. In a personal and entirely unofficial letter to the editor of the REVIEW, Hon. John Barrett, who so ably represents this country as United States Minister to Siam, writes from Bangkok; and the contents are so interesting we cannot refrain from sharing it in part with our readers.

Mr. Barrett states there is only one street railway in Siam. Its official name is "Bankok Tramways Company, Ltd." This is doing a very extensive business and runs from one end of this great city to the other. Although Siam may be regarded in America as an out of the way place, its capital, Bankok, was the first city in Asia to make a thorough test of electric street railways, which proved a decided success from the start.

This company is made up principally of Danish, Americans and Siamese stockholders. The road was put down, the power house erected and machinery installed, and rolling stock furnished originally by an American firm, who sent out an engineer to superintend the work. The present manager is a Dane, W. F. Jacobsen, and the chief engineer also a Dane, A. Hansen. The president of the board of directors is an American, T. Heyward Hays.

The company was originally organized with a capital stock of about 300,000 ticals (approximately 100,000 gold dollars.) Since organizing it has made one issue of 100,

000 ticals debentures and is planning to make another issue of 100,000 ticals debentures. These debentures are issued for the purpose of greatly improving the road, adding to the rolling stock and constructing new buildings and bridges.

The company as intimated above has been very successful from the beginning and has paid as high as 18 per cent per annum on the investment and not less than 10 per cent. All the new machinery, engines, and car trucks have been purchased in America, and it is probable that on account of the high standing of American manufactures in this line, future orders will be placed in the United States. Viewed as a whole he considers the company as well managed, representing a secure investment of capital, and has a favorable future before it, provided conservative men control it.

There are, of course, two classes of persons among the stockholders; one that wishes to pay as high dividends as possible, turning every cent into profits, creating no reserve fund, and generally neglecting those principles which govern successful companies in America and Europe; and the other that is perfectly satisfied with a legitimate income of 5 to 10 per cent, believes firmly in creating a reserve fund, and wishes to put a proper portion in excess of legitimate income into permanent improvements. It is probable that the latter element will have its way.

On fete days and special occasions the cars are as crowded as those in Chicago. The Siamese are different from the Chinese; the Siamese take to new systems of rapid transit at once and have no prejudice against them although they are lazy people; but the Chinese, as proved more than once in China, are prejudiced against these systems invented by "foreign devils." The Siamese government readily granted the concession for this electric street car line, and the king regards the enterprise with favor. The American, Dr. Hays, mentioned as president of the directorate, takes a great interest in the success of the line, and is one of the largest individual stockholders. The manager, W. F. Jacobsen, and the engineer, A. Hansen, are both capable men; the former being quite well known among electrical manufacturing establishments in America because of several visits there on business.

In this connection it may interest our readers to know that an American engineer, Lawrence E. Bennett, has secured the concession for the electric lighting of all Bankok, which is one of the most important rights that the Siamese government has given to a foreigner in many years.

In conclusion Mr. Barrett says: "Let me through your agency recommend American manufacturers to keep an attentive eye on this far Eastern field, this whole coast line from Vladivostock to Singapore; because it presents, in my opinion, one of the greatest opportunities for the advancement of American foreign commercial interests. In special reports and articles in various periodicals written by me by request, I have endeavored to awaken interest throughout the United States in this field. Whether these have come to your attention I do not know, but I trust that you will not fail to preach the 'gospel' of commercial conquest in the Asian Pacific until the exporters and manufacturers of the United States have succeeded in getting a fair share of the rapidly developing trade."

Tourists in Denver who wish to see the sights of that city without too much exertion have been met half way by one of the street railway companies which has fitted up a special car for their use; its name is "Seeing Denver."

### SOME STREET RAILWAY BRIDGES.

With the development of suburban and interurban electric railways the question of bridges was added to the already large number of perplexing problems which the successful railway manager must solve. On strictly urban lines especially in the larger cities, the bridges over which the street cars run were, almost without exception, sufficiently strong to permit the use of even the heaviest electric cars with perfect safety, but on country roads where the general traffic is not so heavy it has in most instances been necessary to strengthen existing bridges or else to build new ones.

In large cities the bridge question arises where the city wishes the street railway to assume the maintenance of the bridges or perhaps to build other and larger ones. The North and West Chicago roads have expended several hundred thousand dollars for bridges in consideration of franchise grants from the city. When the electric line was laid across the Chicago river at Clark street, the old bridge at that point was moved to Dearborn street and a new one

design from the ordinary highway bridge for general traffic except that they are designed for heavier loads and have incorporated in the floor system the longitudinal beams for the support of the rails before mentioned. Where the bridges are for the sole use of the railway, they are more often plate or riveted girders than the pin connected. As before stated the interurban electric lines have tended to improve the highway bridges because they are usually in charge of competent engineers who see to it that the old bridges are strengthened in a proper and scientific manner or if new ones are to be built, they are in accordance with the best engineering practice and not left to the whims of county officials with no knowledge of bridge construction.

This subject of bridges has been the cause of a great many disputes between the railway companies and the municipal and county authorities with whom they have had to deal. The questions on which issue is taken are those regarding the manner in which the company is to occupy the bridge, that is, where the tracks are to be laid, the proper distribution of the cost of maintenance, and, where a new

MAIN STREET BRIDGE, LA FAYETTE, IND.

with wider drive ways erected at Clark at the cost of the railway.

Inquiries addressed to a number of the companies engaged in building bridges show that in their opinion the extension of trolley lines has had a very beneficial influence upon the character of the highway bridges built at the present time, as many of them are constructed with a view to their possible occupancy by trolley lines.

While there are some bridges in existence today which are so crudely constructed, either through the ignorance of the builders or because of their desire to furnish the least possible bridge for the money, that a reconstruction is a primary requisite to make them safe for the running of electric cars, the majority of them have been built under fairly good specifications and need but little in the way of strengthening. The trusses, as a rule, being heavy enough to carry the load, the alterations made consist in putting in heavier floor systems, and in almost every case it is necessary to provide longitudinal girders for the support of the rails so that the latter shall have the tops flush with the planking or pavement. When, however, the trusses are weak, the usual plan is to construct an additional truss.

When new bridges are constructed they differ little in

structure is necessary which is to be used by the railway and for general traffic also, the division of the cost between the two parties. The arrangements which the companies are able to effect with the authorities depend largely upon how badly the public wants the service that the railway is to give. In most cases an equitable agreement can be made, the rule being that if the alterations or the new structures are necessary solely because of the use of the highway by the electric line the latter bears the cost thereof; where they are demanded by the public for general traffic purposes as well as for the railway a portion of the expense may be borne by the county or city.

The bridge over the Wabash river at La Fayette, Ind., is a good example of one to which a third truss was added. Two views are shown, one of the bridge as when first completed, and one showing the additional truss. As may be supposed the conditions were quite peculiar to make this addition to an entirely new structure necessary. A horse road, beginning nowhere and ending nowhere, was built in 1881; this was converted to electricity in 1887, an extension to West La Fayette and Purdue University being built at the same time. On the west side of the river the approach to the bridge is over an embankment half

a mile in length, and the railway only laid its track here after a strong opposition from the farmers was overcome. At that time there was a wooden bridge with the two wagon ways separated, so that double tracks over it were a necessity. This bridge was replaced by a new one of iron in 1891 and a second dispute ensued as to whether a street railway "corporation" was to be permitted to occupy the bridge "built by the people's money," a compromise being finally effected and the railway laid on one of the foot ways. As this foot way was outside of the trusses and the floor system had been designed for foot passengers and not electric cars, it was soon found that some other arrangement would have to be made. The county refused to allow the tracks in the wagon way and the company declined to strengthen the floor system at its own expense. After a deadlock for two years or more, during which time passengers were compelled to get out and walk over the bridge, the question was settled by lengthening the piers and erecting third trusses. The cost of this addition was equally divided between the county and the company.

Another illustration shows the bridge built over the

BRIDGE OF THE TOLEDO & MAUMEE VALLEY RAILWAY.

Maumee river at Maumee City by the Toledo & Maumee Valley Railway Company at a cost of \$20,000. The piers of the county bridge at that point were extended and the new structure erected thereon, it being otherwise independent of the former. This was done in order that there might be less danger from the ice gorges which form when the ice in the river breaks up each spring. This road, as probably most of our readers will remember, is a belt line 20 miles long running from Toledo on both sides of the river, to Maumee City on one side and to Perrysburg on the other, with an extension of 13 miles to Bowling Green.

The Sandusky, Milan & Norwalk Electric Railway was compelled to strengthen the floor of one iron bridge on its line by placing wooden stringers under each rail. They were built up of 2-in. planks 14 in. wide bolted together so as to break joints. When completed they formed continuous girders 10 x 14 in., extending the total length of the bridge, 175 ft.

On page 36 of the REVIEW for January, 1897, is view of a plate girder bridge built for the Aurora & Geneva Railway by the Wrought Iron Bridge Company of Canton, O. It is designed for a uniformly distributed load of 100 tons a concentrated load of 50 tons.

In reply to an inquiry the Second Avenue Traction Company, of Pittsburg, states that it has built one bridge, a double intersection through bridge designed for a live load of 1,800 lbs. per lineal foot together with two cars 25 ft.

BROAD STREET BRIDGE, ATLANTA, GA.

long, with 7-ft. wheel base and weighing 12 tons each. In old structures the trusses were generally found satisfactory, but the floor systems weak. The floor beams were strengthened and 9-in. girder rails laid thereon, these being used both as rails and as girders. The rails are always used in as long lengths as possible. Up to spans of 10 ft. the rails were used as girders without trussing. For spans of greater length the rails were trussed and when thus strengthened have been used for 17-ft. spans. The flooring was relaid with details of joists to suit the 9-in. girder rails. This company has found that these heavy and continuous 9-in. rails very materially reduced the vibrations even of apparently weak highway bridges, and with the new flooring put the bridge in condition to better resist the shocks from general traffic.

The Atlanta (Ga.) Consolidated Street Railway Company as a consideration for the privilege of equipping its lines electrically agreed to pay \$5,000 toward building a new bridge on Broad street when the city should decide to replace it. The bridge shown was built in 1895, the railway company fulfilling its agreement. It is 142 ft. long and 70 ft. wide; the weight is 300 tons; no new masonry was required and the cost was \$22,200. It was built by the Edgemoor Bridge Company and designed for a live load of 100 lbs. per sq. ft. The paving is vitrified brick laid in concrete on a buckle plate floor. The Consolidated owns the exclusive street railway privileges for this bridge and all except two of its lines cross it.

FORSYTH STREET BRIDGE, ATLANTA, GA.

Another illustration shows the Forsyth street bridge built by the Phoenix Bridge Company in 1892-3, and occupied by the Atlanta Railway Company which secures the privileges for an annual rental of \$750 paid to the city. This bridge has a buckle plate floor and is paved with vitrified brick laid in concrete; it is designed for a live load of 100 lbs. per sq. ft. It was built for the purpose of doing away with the grade crossing of Forsyth street with the railroad tracks leading to the Union Depot. The cost complete, including masonry, was \$1,30,000.

### THE HANOVER ELECTRIC RAILWAY.

The Electrical Review of London publishes the results and conclusions reached by F. Ross, who conducted some extensive experiments upon the Hanover Tramways; the report of Herr Ross was published in the *Elektrotechnische Zeitschrift*, Vol. 18, p. 178. The tests were made with the assistance of Professor Heim of the Technical High School, Hanover, and Herr Volkers of the Union Elektrizitäts-Gesellschaft.

The mixed system was introduced in the summer of 1895 when it was desired to extend the electrical working of the lines to the central part of the city. The municipal authorities refused to permit the overhead trolley, and storage battery cars with fixed charging stations were contemplated, but before the adoption of this system that of adding batteries to the cars and charging from the trolley when running on the suburban sections of the road was tried experimentally, and was so successful that the "mixed" system was adopted.

In January, 1897, there were 12.8 miles of track with overhead conductors and 10.6 miles worked by the accumulators. The batteries are charged during trips which vary from 1.7 to 1.8 miles and the discharging takes place on runs which vary from 3 to 7.2 miles. The power station equipment comprises four engines, each driving a 150-k. w. Siemens & Halske dynamo, and water tube boilers.

The cars for the mixed system have two longitudinal seats accommodating 20 passengers. Under the seats are 208 Tudor cells in vulcanite boxes; the total weight of the batteries is about 2½ tons. On the platform is a lever switch with two positions, charging and discharging, and a regulator with six contacts besides the zero position. On the overhead lines but five points are used, 1 to 1 with diminishing resistance, and 5 without resistance added. When the battery is switched in it is first applied in halves arranged in parallel, then the resistance in circuit is diminished as the controller handle is turned to 5, and finally on 6 the two halves of the battery are placed in series, which is also the arrangement when charging.

Experiments on the consumption of power gave results as follows: Average power for car with seven passengers and without batteries on the overhead section, 795 watt-hours per car-mile at a speed of 9.15 miles per hour; no stops. Same with weight equal to that of batteries added, 795 per car-mile at a speed of 8.15 miles per hour. With all stops made the power was about 900 watt-hours per car mile. On the accumulator section, with all stops made the mean value for the power required was 610 watt-hours per car-mile at a speed of 5.8 miles per hour. The smaller power on the accumulator section is partly attributed to the decreased speed, but principally to the greater efficiency of the arrangement.

The mean of eight charging and discharging runs placed the efficiency of the battery at 71 per cent, but as these were made under very favorable conditions it is thought that in practice it is not well to reckon on more than 70 per cent. When the tests were made two kinds of battery elements were used; in the older cars the nominal capacity was 20 ampere-hours, and the time of discharge 1 hour, and in the newer 25 ampere-hours. The weight was the same in both, the difference being in the extent of surface. Capacity tests showed the output of the old style batteries to vary between 20 and 25 amperes; experiments to ascertain whether the capacity of the battery is maintained after being in use for a considerable time are now under way.

Brake experiments placed the efficiency of the motor and reducing gears at 53.7 per cent with 50.4 volts and 65.2 per cent with 318 volts. The better efficiency with low voltage is supposed to be due to less loss in the gearing at low speeds.

The use of accumulators on the cars was found to exercise a very favorable influence on the utilization of the machinery at the central station. They acted, in fact, as equalizing batteries, and greatly reduced the variations of the load.

In January, 1896, the station output was 58,590 kilowatt-hours, and the watt-hours per kilogram of coal 321; the accumulator car-miles were 8.6 per cent of the total. In October the output was 136,821 kilowatt-hours, the watt-hours per kilogram of coal 181, and the accumulator car-miles ¼ of the total. From this the conclusion is drawn that the accumulators have a very beneficial effect on the station economy.

The cost of maintenance and attendance for the batteries has been found from an experience extending over several months to amount to .33 cent per accumulator-kilometer.

From the above data, Herr Ross considers he is justified in drawing the following conclusions: Taking 10 per cent as the rate for interest and depreciation, and adding the cost of attendance and maintenance, the cost works out as .63 cent per car-kilometer. Taking also into account the increased cost due to renewals and greater consumption of current, and allowing for the better utilization of the central station, the total cost per car-kilometer rises to 1.25 cents.

A comparison is then made with the estimated cost of a conduit system to replace the accumulator system. He finds that for interest and depreciation alone, with the conduit system, the cost per car-kilometer would amount to 5.5 cents, which, he remarks, would have made electric traction impossible.

Comparing, now, the Hanover mixed system with a system in which the overhead conductor is used throughout, he finds that interest and depreciation in the latter case will amount to .75 cent per car-kilometer. Subtracting this amount from the cost of the accumulator working, the difference is only .50 cent per car-kilometer; and if the cost is distributed over the total car-kilometers supplied, the difference is less than .25 cent.

No marked effect on the wear of the rails, owing to the greater weight of the cars, has been observed in Hanover.

While we hesitate to criticise the work of Herr Ross without a full knowledge of the facts and conditions involved, we hesitate to believe that the increased station economy of 37 per cent was due to the increase in the accumulator car mileage instead of to the increase in the station output. The Metropolitan road of Washington, D. C.,

reduced its coal per h. p. per hour 30 per cent by increasing the total output from 3,400 to 13,400 electrical h. p.-hours per day and as the output of the Hanover station was more than doubled we are of the opinion that the effect noted is due in a greater part to this cause than to the action of the accumulators in acting as regulators for the station load.

The figures given for the interest charges for a conduit system, 5.5 cents per car-kilometer, being four times as much as the total cost of operation and maintenance of the accumulator system, we think require further explanation.

### HEVNER CONCRETE CONSTRUCTION.

The illustrations show the construction of the permanent roadways invented by Peter Hevner and known as the Hevner system. Fig. 1 is a cross section of the roadbed for an electric conduit system; concrete strengthened by tie rods

HEVNER SYSTEM.

and bars is used as a substitute for the iron yokes heretofore used in conduit construction. The concrete yokes are spaced just as the iron ones would be; concrete piers are provided to support the rails but the layer of concrete surrounding the metal lining is continuous. It is proposed to form conduits in the concrete to receive electric wires where it is not desired to place them in the larger conduit. The same

FIG. 3.—ADJUSTABLE RAIL.

construction is of course equally well adapted to a cable line.

Fig. 2 shows the construction of track in which the rails are supported on concrete piers spaced at intervals of 4 ft. Where this construction does not furnish sufficient support to the rail a continuous beam of concrete is placed under each. In

both cases the rails are held in place by  $\frac{3}{4}$ -in. bolts tapped into iron yokes which are molded into the piers, or into the beams at distances of every 5 ft. when that construction is used.

This roadbed has been tried in Rochester and Syracuse, N. Y., and is pronounced very satisfactory by both the city engineers and the street railways.

The inventor has also designed an adjustable rail, Fig. 3, which is supported in chairs and bolted to them, the chairs themselves being bolted to the yokes molded into the concrete beams. At the joints the chairs are of such form that no other fish plate is needed; between joints the chairs are solid castings.

### THIRD AVENUE, N. Y., LOSES.

On July 2, 1895, the Third Avenue Railroad Company of New York made application to the Common Council for the right to build certain extensions, aggregating 11 miles in length. The proposed lines were all connected except that from 125th street to 116th street on Manhattan avenue which was separated from the others, thus making two extensions for which, under the railroad law, franchises could not be sold at the same time. The company proposed to grant a perpetual right of way over its tracks in 125th and Manhattan streets so that the proposed extensions might be connected. This proposition was accepted by the city and the franchises granted in September, 1895.

Suit was brought by a lessee of some abutting property and an injunction granted against the company in December, 1896. The case was carried to the Court of Appeals where the decision was as follows:

1. The Common Council of New York cannot make valid a sale of more than one extension of an existing railroad at the same sale to be struck off upon one bid, when the extensions are separated from each other in such a way that they can only be operated together over the lines of an existing road.
2. A sale made in this way vested no right in the Third Avenue Railroad to build any of the extensions above 162d street, on Kingsbridge road.
3. The Common Council has no power to impose as a condition of consent to the sale of an extension that a railroad shall pay into the city treasury a sum of money in cash within a certain time, in addition to the percentage of gross receipts bid by it upon such sale.
4. The sale of the franchise to the Third Avenue Railroad was void, and vests no right to build such extensions.
5. The condition in the Common Council resolution that not more than five cents shall be charged for a continuous ride on the Third avenue line only to or from the extension is valid.
6. If the Common Council did not make such a distinction for fares on extended lines the grant would even then be invalid.

The Third Avenue Company had already spent over \$2,000,000 in view of the extension but the greater part of it was for railway property and real estate which will be valuable in any event.

It is stated that the Kings County Elevated Railroad Company has decided to supercede steam with electric traction. The Sprague unit system is favored, but nothing will be done until experience shows how successful this method is to be on the Alley "L" of Chicago.

The City & Suburban Railway Company of Baltimore has put four new mail cars in service. Two will run between Towson and Catonsville and make 20 round trips a day. The other two will run between Roland Park and St. Helena and will make, daily, 11 round trips.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

Another inventor, a Mr. Guattari, is in the field with the promise to save 50 per cent of the coal now used in the generation of steam. The method is to saturate the feed water with two or three times its own volume of a mixture of carbonic acid gas and ethylene chloride; when the water is so impregnated "the generation of pressure is rendered possible with an expenditure of heat energy much less than required with ordinary steam." It is apparently overlooked that the steam engine is a heat engine, and if but little heat is required to generate pressure but little will be there to be transformed into work.

\* \* \*

Considerable discussion has arisen in England because of the data published in regard to the Coathridge Electric Supply Station where three 120-h. p. gas engines were replaced by a steam plant after a trial of 16 months. The cost of fuel was reduced from 5 to 1.7 cents per kilowatt-hour and the cost for oil, waste and stores from 2.5 to .68 cent; the output however was much larger during the period when steam was used and this fact may have some bearing upon the poor showing made by gas. Notwithstanding the contemplated abandonment of gas engines at some other similar plants, there appears to be ample evidence that under suitable conditions well designed gas engines work economically and give satisfaction.

\* \* \*

A new method has been devised for utilizing waste mica, of which there is a considerable quantity wherever commutators are made or repaired. This scrap mica is finely subdivided and quilted between galvanized wire netting, making a flexible, fire-proof mat which is a good non-conductor of heat. These mats are made in comparatively small sections and attached by means of iron hooks to iron bands circling the boiler. They are secured to steam pipes by lacing round the boot hooks, which are rivited up the seams at convenient intervals and can be made to conform to any shape of fitting. One advantage of this kind of cover is that it can be easily and quickly removed and the shell of the boiler or the steam pipe can be examined and repaired, then the mats can be replaced.

\* \* \*

In discussing the "Generation of Electrical Energy for Tramways" before the Institution of Electrical Engineers, England, E. T. Carter called attention to a method of governing devised by him which has the advantage of keeping the point of cut-off within the economical range. In each individual engine there is a considerable range of power over which the steam consumption is very nearly constant per horse-power per hour, but above or below which a change of load causes a rapid increase in the steam consumption, due at one end to the reduced expansion and at

the other to the excessive temperature range in the cylinder. In the case of an engine cited by Mr. Carter this economical range was from 38 h. p. to 52 h. p., the maximum power being 80 h. p. Between the limits given the engine runs at normal speed; if the load increases above 52 h. p., the speed is increased and if the load decreases below 38 h. p. the speed is decreased to that extent necessary to keep the point of cut-off the same as at normal speed. This method of governing would only affect the speed of the engine when the variation was not transient or momentary in character. Sudden and temporary changes of load are dealt with by the governor changing the point of cut-off in the usual manner the speed being unaffected, but when the changes in load are for longer periods the governor alters the speed as described. At the same time, of course, the field excitation would be automatically controlled so that the change in armature speed would not change the voltage on the lines.

\* \* \*

The strictures passed upon the horse-power as a unit of power by W. H. Price in his "Watt Anniversary Lecture," appear to us to be well grounded in one particular only and that one fault is the result of applying a word in common use as the name of a definite thing as the name for a new thing which never was and never purported to be the same as the old one. Five kinds of horse-powers are quoted and electrical horse-power named as a sixth one; to these might have been added boiler horse-power as a seventh. If the watt is to supplant our present unit as a measure of the rate of doing work we shall be better off, only in that there is no animal of that name. There would be the same necessity for an indicated watt, a brake watt, an electrical watt and a boiler watt; we already have the actual watt and the nominal watt, as witness the 100-k. w. generator which will work constantly under an overload of 50 per cent. Whether we use the British horse-power defined as 33,000 foot-pounds per minute or the watt defined as 44.25 foot-pounds per minute as our unit of power is a matter of indifference except that the horse-power is not uniform throughout the world as is the watt; this is due only to the fact that the watt has been defined since scientific men have appreciated the advantages of uniformity. And even if we had a uniform power unit it would do us but little good until uniformity is secured for all units. This is one of the reasons urged for the adoption of the metric system by English speaking peoples, but the reasons against it are as weighty today as when John Quincy Adams made his report in 1821, (see paper by G. W. Colles, Transactions American Society of Mechanical Engineers Vol. XVIII, page 192,) and we hope that the time may be long deferred. The suggestion that the product of the power by the time be given a distinct name is well worthy of adoption; although kilowatt-hour is only another name for foot-pound, it is a more convenient one

and conveys a distinct and useful idea. In Glasgow it was proposed to call the Board of Trade unit, or kilowatt-hour, a "kelvin" which is certainly much to be preferred to the clumsy compound word; the even more clumsy horse-power-hour or horse-power per hour deserves a distinct name and for this perhaps "rankine" would be as appropriate and convenient as any.

\* \* \*

Perhaps it would be well to learn to correctly use the units that we already have before it is decided to adopt new ones. A notable example of the misuse of terms is to be found in a paper presented at the last meeting of the American Society of Mechanical Engineers advocating the heat unit as the basis for rating the performance of power plants, where the author used kilowatt and kilowatt-hour as synonymous, saying that the present way of stating performance is in "kilowatts per pound of coal, per cubic foot of gas, etc."

\* \* \*

A correspondent in Bay View, Wis., advises us of the good record made in the power house of the Fox River Electric Railway Company which he attributes to the absence of any "technical graduated college students." The company operates 14.5 miles of track; the rolling stock consists of 15 motor cars, two of them open cars, and eight open trailers. In the power house are two tubular boilers, 60 in. x 16 ft., one 250-h. p. Stirling boiler, two Ball & Wood tandem compound condensing engines, 11 and 18 x 16 in., two bipolar 50-k. w. and one G. E. 100-k. w. generators. The plant was started June 10, 1891, and it is stated that there has not been a single delay to cars which could be charged to the power house.

\* \* \*

#### Steam Turbines.

The success with which steam turbines have been used in England for driving electrical machinery makes it evident that this prime mover must receive more consideration in the future than has been given it in the past. There are three well known types of steam turbines on the market, two of which the Parsons and the Dow are quite similar in principle and differ from the De Laval. This last corresponds more nearly to the Pelton water wheel in its action, the steam being introduced into the turbine case through nozzles and directed to buckets placed on the circumference of a wheel; after the steam has passed through the buckets it is exhausted, to a condenser or to the atmosphere as the case may be. The other two types are called compound turbines because after passing through one turbine and giving motion to it with a consequent loss of velocity the steam is carried through a passage of larger cross section where it recovers its velocity by virtue of expansion and is then admitted to a second turbine with orifices enough larger than the first to accommodate the increased volume; after passing through succeeding turbines until the volume has reached the maximum allowed by the conditions of practice the steam is exhausted. By thus compounding, the steam is after a manner worked expansively.

In the Dow turbine the flow is radial from the center outwards. The moving disk has cut in it a number of concentric grooves and a number of spiral grooves along which the steam flows; the stationary disk has concentric projections and a set of spiral grooves. When placed face to face

the spirals run in opposite directions so that the passage for steam is a broken one and motion of the free disk results from the steam impinging upon it at an angle the same as motion results in a siren. Fig. 1 is a section through the two disks showing the passage ways. By placing two turbines on the same shaft the end thrust of one is made to neutralize that of the other.

The early forms of the Parsons turbine were "parallel flow" that is the flow of steam was parallel to the axis instead of being radial. There were a number of disks, half of them keyed to the shaft and half fastened to the casing of the motor; Fig. 2 will serve to show the disks and Fig. 3 the arrangement, the dotted lines in Fig. 3 indicate the path open for the flow of steam. By using two sets of disks with steam admission at the center the end thrust is neutralized. In later designs by Mr. Parsons of turbines of the parallel flow type there are more than one set of turbines placed one after the other on the same shaft; each set taking steam from the preceding one.

The steam entering by an inlet all around the shaft, passes through the successive turbines of gradually increasing area of passage-way, and is expanded by small incre-

ments of volume at each turbine, till it arrives at the next series of turbines; these are of larger diameter, and consequently greater peripheral speed and capacity, and they allow of further gradual expansion. The steam then flows to the last series of turbines, where, the expansion being completed, it passes to the exhaust-pipe. The rows of turbine blades are formed of hard brass, and accurately shaped; those keyed onto the shaft project outwardly, and nearly touch the case; those keyed into the case project inwardly between the moving rows and nearly touch the shaft. The turbines are so proportioned that the steam passes from one row to the next throughout the entire turbine with the most suitable velocity for economical working under the prescribed conditions. In the later designs the thrust is taken on rotating or dummy pistons and not neutralized by making the steam flow through two similar sets in opposite directions.

Mr. Parsons has also designed compound steam-turbine of the "radial flow type" in which the rows of turbine blades are keyed into and project from the faces of moving discs attached to the shaft and fixed discs attached to the casing. The course of the steam is outwards, through the rings of blades, then inwards, and again outwards through the blades on the succeeding disc, and so on, and the expansion is completed in passing outwards through rows of turbine blades on both sides of the large disc. The end pres-

sure is here, as in the case of the parallel-flow type, balanced by a revolving piston. The bearings are of special but simple construction. Around the bush in which the shaft revolves, are placed three concentric loosely-fitting tubes, truly bored and centered; the action of these tubes being to form concentric extremely thin layers of oil around the shaft, which acts as a cushion and prevents hammering or vibration of the shaft arising from any small errors of balance that may be present in the moving parts. The bearings are kept continually supplied with oil by a pump, and in the case of large plants, an oil-cooler is fitted, through which the pump forces the oil to the bearings. Generally the bearings are fed from open oil-boxes, but sometimes they are closed, and the oil forced in under considerable pressure.

The governor chiefly used has been one in which the steam-admission valve is worked by a steam relay, the valve of which is controlled by a solenoid, and the action has been rendered more sensitive, and the economy of the motor at light loads improved, by superimposing a reciprocating motion to the position of the relay valve, the action being to eliminate friction and stop hunting, as well as to admit the steam in blasts at full pressure, and of larger or shorter duration, according to the work required from the motor. In some cases the solenoid has been replaced by a centrifugal governor of ordinary type.

The first compound steam turbine direct connected to a dynamo was built in 1884; it ran at 18,000 r. p. m. and gave 6 electrical h. p. Within the last five years turbines developing from 500 to 700 h. p. have been installed. At present there are 30,000 h. p. of turbines in England.

Fig. 4 is reproduced from the Electrical Engineer, London, and shows one of four units in use at the Hotel Cecil, London. It is a 75-k. w. Parsons parallel flow turbine direct connected to a 75-k. w. direct current dynamo. There are 35 rows of blades and the speed is 1,000 r. p. m.

FIG. 4—75-K. W. UNIT PARSON'S STEAM TURBINE.

The supply of steam is not continuous but an impulse is given once in 21 revolutions. For the month of April, 1897, the output of the station was 58,016 kilowatt-hours with a load factor of .395; the costs are itemized as follows:

|                                |              |
|--------------------------------|--------------|
| Coal (\$5.00 per ton).....     | 1,124 cents. |
| Water.....                     | .118         |
| Oil and waste.....             | .106         |
| Wages.....                     | .711         |
| Supervision.....               | .270         |
| Repairs and maintenance.....   | .272         |
| Works cost.....                | 2.991        |
| Interest and depreciation..... | 1.022        |
| <b>Total</b> .....             | <b>3.926</b> |

It should be stated that the average cost per kilowatt-hour for repairs and maintenance for the six months preceding was but .130 cent. The units or kilowatt-hours are those used, not those generated.

Fig. 5 shows the consumption of a 200-k. w. turbo-generator, 1,000 amperes at 200 volts; the turbine is a Parsons parallel flow.

The latest field entered by the steam turbine is that of marine propulsion and the results obtained are extremely

FIG. 5 WATER CONSUMPTION, 200-K. W. TURBINE.

interesting. The "Turbina" and the results of the tests made are described by the inventor of the turbines, Mr. Parsons, in a recent paper before the Institution of Naval Architects. The boat is 100 ft. in length, 9 ft. beam and 49.8 short tons displacement. The boiler is of the water tube type, designed for a working pressure of 225 lbs.; the heating surface is 1,100 and the grate surface 12 sq. ft. The condenser has 1,200 sq. ft. of cooling surface. The fresh water tank and hot-well contain 250 gals. The draught is forced by a fan.

When built a single motor designed to develop 1,500 h. p. at 2,500 r. p. m. was used but the loss due to "cavitation of the water" or the hollowing-out of vacuous spaces by the screw blade proved to be very great. After a series of very interesting experiments, it appeared that for all screws there is a limiting speed depending upon the slip ratio and the thickness of the blade, beyond which a large loss of power will occur, and the single engine was replaced by three, each driving a screw of reduced scantling and conditions of working closer to those of ordinary practice.

The approximate weights are given in short tons:

|                                                               |             |
|---------------------------------------------------------------|-------------|
| Main engine.....                                              | 4.1 tons.   |
| Metal of machinery, boiler, screws, shafting, tanks, etc..... | 24.6        |
| Hull complete.....                                            | 16.8        |
| Coal and water.....                                           | 8.4         |
| <b>Total displacement</b> .....                               | <b>49.8</b> |

Trials were made April 1, 1897, and the following data given:

|                                                              |             |
|--------------------------------------------------------------|-------------|
| Mean revolutions of engines.....                             | 2,100       |
| Steam pressure in boiler.....                                | 200 lb.     |
| Steam pressure at engines.....                               | 130 lb.     |
| Vacuum at exhaust of engines.....                            | 13 1/2 lb.  |
| Speed of boat.....                                           | 31.01 knots |
| Calculated thrust horse-power.....                           | 916         |
| Calculated indicated horse-power.....                        | 1,576       |
| Consumption of steam, reduced to basis of 31.01 knots.....   | 25,000 lb.  |
| Consumption of steam per indicated horse-power per hour..... | 15.86       |

On April 10 a speed of 32.75 knots, 37.75 miles per hour, was reached.

The three turbines are designed to give approximately the same power and are worked in series; each is a compound steam turbine and the final expansion of the steam is to 100 times its original volume. The thrust of the screw is balanced by the thrust in the turbine.

The "indicated" horse-power in these tests was found as follows: From experiments on a model the thrust h. p. required to give a speed of 31.01 knots was calculated to be 946 h. p. The thrust h. p. was assumed to be 60 per cent of the indicated h. p. giving for the latter 1,576.

### RESULTS WITH GAS STREET CAR MOTORS.

In a paper before the Society of Civil Engineers of France, A. Lavezzari presents some data regarding the tramways which use the Lubrig gas motor for traction. The author states that while experiments have been made with many different motors, the Lubrig system or, as it has now become, that of the Gas Traction Company, is the only one which has worked under actual conditions on railway lines. The first experiments with this motor were made in 1891 but none were put in service until July, 1894, at Dresden.

The system is now used in three cities: At Dresden are 2.1 miles of track and four cars so operated. At Dessau there are 3.7 miles of track, 13 motor and seven trail cars; the cars seat 16 passengers with standing room for 12 more. At Blackpool there are 7.8 miles of track; when first opened there were but two cars, each for 40 passengers, but recent additions to the rolling stock have been made and 16 of the new cars are larger, holding 52 persons. Illustrated descriptions of the gas motor cars at Dessau and Blackpool were published in the REVIEW February, 1896, page 67 and August, 1896, page 499.

In Paris one double-deck 42-place gas motor car has been given a trial.

The following data are quoted:

|                                                                             |                |
|-----------------------------------------------------------------------------|----------------|
| Weight empty.....                                                           | 15,432 lbs.    |
| Weight loaded.....                                                          | 22,046 lbs.    |
| Power of motors.....                                                        | 10 to 15 h. p. |
| Revolutions per minute, 100 when car is at rest, 250 when car is in motion. |                |
| Volume of reservoirs.....                                                   | 44.14 cu. ft.  |
| Pressure in reservoirs.....                                                 | 142.2 lbs.     |
| Capacity of water tanks.....                                                | 22.5 gals.     |
| Mean speed per hour.....                                                    | 9.9 mi.        |
| Gas consumption per car-mile.....                                           | 31.25 cu. ft.  |
| Distance without recharging.....                                            | 13.6 mi.       |

For the other systems the gas consumption is given as 36.37 cu. ft. per car-mile at Dresden and 28.98 at Dessau the figures in both cases including the gas used by the compressing engine at the central station, which at Dessau is said to be about 10 per cent of the total. For Blackpool the figure given is 30.12 cu. ft. per car-mile.

In conclusion Monsieur Lavezzari says:

"The data given indicate that gas traction merits an honorable place among other systems. It is easily operated everywhere, is not costly and is reliable. The central station and the personnel are of but little importance. Nearly all centers of population are supplied with gas works, but in the event that the tramway company could not purchase gas

at a reasonable rate it could manufacture the gas itself; the process is simple and cheap.

"However this system, which is yet young, like all others must be improved in order to arrive at perfection. For my part I only consider the present cars as a happy demonstration that the problem is worthy of being studied, and think that to make a really practical system there is much to be perfected. In practice an ordinary gas engine has been taken and with scarcely any modification has been mounted on a car; this is about the same as if one equipped a locomotive with a stationary engine; the requirements are not the same and it is necessary to design machines suited to the special conditions.

"The principal fault with this system is that the cars can not ascend heavy grades unless the motor is made too powerful for the ordinary working conditions. It would also be well to be able to stop the motor entirely when the car is stopped in order to avoid the vibration and noise that occur at present. And finally the machinery of transmission is open to several improvements; the noise made by clutches and gears when the car is in motion is very disagreeable; this perhaps might be remedied by using pinions with teeth of wood."

### ELECTRIC-STEAM COMBINATION IN ST. LOUIS.

An agreement has been reached between the Missouri Pacific Railroad and the Lindell Railway Company of St. Louis, whereby the passengers between the city and the towns along the Missouri Pacific as far as Meramec Highlands, 15 miles from the Union station, will be given a better service at a lower cost than formerly. Short steam trains will be run at frequent intervals from Meramec Highlands to Vandeventer station, three miles within the city limits and three and one-half miles from the business center. The advantage of having the trains stop at this point is that they will thereby be kept out of the crowded yards at the Union station. At Vandeventer station passengers will take the Chouteau avenue division of the Lindell for downtown, or the Vandeventer avenue division for West End points. There are 15 stops on the steam road and the run is to be made in 25 minutes; the street car portion of the route will be covered in the same time. The time from Meramec Highlands to the downtown terminus by electric car alone is 1 hour and 45 minutes, and it is expected that the saving in time effected and the low fare (25 cents for the round trip from Meramec Highlands and 20 cents for the round trip from Webster and nearer points) will give the combined roads nearly all the through business. In addition to that from the resident population of 50,000 served by the lines, considerable traffic is expected from the pleasure riding to the hotel, park and picnic grounds at Meramec Highlands.

When the St. Louis & Suburban Railway was completed about two years ago, the Missouri Pacific and the St. Louis & San Francisco Railroads, which it paralleled, were both compelled to abandon over one-half of their suburban trains, and the Missouri Pacific welcomes this arrangement, as it will enable it to recover some of its lost business.

The Consolidated lines in Pittsburg carried 40,000,000 passengers last year.

calorimetric tests shows the interesting fact that the total calorimetric values of coals vary but little, and that a decrease of fixed carbon does not reduce the heating power of the coal in proportion to the increase of volatile combustible matter, while on the other hand repeated tests prove that the industrial value of coals decreases almost in the same proportion that volatile combustible increases. The extensive tests of European coals made by Schurer-Kestner in 1868, and afterwards collated by Grüner, gives us most interesting and valuable information on this point.

For industrial purposes Grüner divided these coals into five distinct classes, according to the quantity of fixed carbon contained in the combustible of each.

Class 1: When the total combustible of the coal was composed of 50-60 per cent fixed carbon.

Class 2: 60-68 per cent " "

Class 3: 68-74 per cent " "

Class 4: 74-82 per cent " "

Class 5: 82-95 per cent " "

Taking the lowest of each of these classes, he gives the elementary analysis and percentage of total combustible in each class as follows:

TABLE OF INDUSTRIAL VALUE OF COALS,  
as per Grüner's classification.

| CLASS. | Fixed Carbon,<br>Per Cent Total<br>Combustible. | Volatile Combustible<br>Total Comb. | Hydrogen Per Cent<br>Total Comb. | Oxygen and<br>Nitrogen Per Cent<br>Total Comb. | Actual Value<br>in B. T. U. | Industrial<br>Value in<br>B. T. U. | Industrial<br>Value Per Cwt.<br>Actual. |
|--------|-------------------------------------------------|-------------------------------------|----------------------------------|------------------------------------------------|-----------------------------|------------------------------------|-----------------------------------------|
| 5      | 82.                                             | 8.                                  | 4.5                              | 5.5                                            | 16,560                      | 10,368                             | 62.6                                    |
| 4      | 74.                                             | 14.                                 | 5.5                              | 6.5                                            | 16,740                      | 10,506                             | 63.3                                    |
| 3      | 68.                                             | 16.                                 | 5.0                              | 11.                                            | 15,840                      | 9,676                              | 61.                                     |
| 2      | 60.                                             | 20.                                 | 5.8                              | 14.2                                           | 15,300                      | 8,756                              | 57.2                                    |
| 1      | 50.                                             | 22.                                 | 8.5                              | 19.5                                           | 14,400                      | 7,716                              | 53.6                                    |

We can safely take it as an established fact that the heating power of fixed carbon will remain constant. The same can be said of hydrogen in the absence of oxygen in the combustible, and the heating value of the hydrogen in the combustible will decrease in proportion to the increased percentage of oxygen within the combustible. Both Dulong and Mahler recognize this fact, and construct their formulas accordingly. It will be observed that both the calorimetric and industrial value of Grüner's class 4 is higher than class 5, although the percentage of fixed carbon has decreased 8 per cent. The industrial heating value, however, has not increased in proportion to the increase of hydrogen in the fuel, while actual heating value by calorimeter fully accounts for such an increase. Although the difference is but slight in this particular case, it points to a very significant fact, which is more clearly exemplified in the following three samples of coal; that is, that the actual calorific value of coals decreases in nearly the same proportion as the neutralizing effect of the oxygen on the hydrogen increases, and that the industrial heating value of the coals under the boiler decreases as the proportion of volatile carbon increases.

We have this strongly exemplified in our daily practice. It requires but ordinary observation for us to readily see that anthracite coals produce practically no smoke, semi-bituminous coals very little, while bituminous coals produce dense, black clouds of smoke varying in density and volume according to the quantity and composition of the volatile combustible matter in our fuel. An examination of the

sooty deposit formed by the condensation of the smoky products proves it to be largely composed of minute particles of carbon which is combustible, proving to us pretty conclusively that the cause of the decrease in industrial heating value is loss of heat from the carbon of our coal, due to the extremely volatile nature of the carbon in combination with hydrogen as hydrocarbons.

It has been said that the industrial value of a coal for steam-making purposes is practically fixed by the percentage of fixed carbon in the fuel. A review and close examination of Grüner's tables of the results of tests on European coals, and verified as being practically correct by similar tests made by Johnston on American coals at a more recent date, shows us we cannot take this method of determination as a permanent basis for calculation with any degree of accuracy. In Grüner's anthracite class 5, industrial heating value of coal only equals 83.3 per cent of the heating value of the fixed carbon, with Berthelot's determination as a standard.

In semi-bituminous class 4, industrial value equals 97.7 per cent of heating value of fixed carbon; in bituminous classes 2 and 3, 97.1 per cent and 99.6 per cent—showing us that if we undertake to fix industrial value of coals without reference to volatile combustible matter, we are liable to rate anthracite varieties too high.

Bearing in mind these facts relative to the heating value of the volatile combustible, it becomes markedly difficult to construct a formula applicable to a proximate analysis.

It has been established fairly satisfactorily, however, that volatile matter of similar composition will give off like quantities of heat. Goutal kept this fact prominently before him, as also the fact relating to fixed carbon, and consequently gives in his formula a series of constants for the determination of the heating power of the volatile combustible. While these constants might be improved upon by division into shorter sections, the results are nevertheless near enough the theoretical value for ordinary purposes.

The adoption of the principles underlying Goutal's formula, and multiplying by the average percentage of efficiency of the various classes of coals for industrial steam-making purposes as determined by Schurer-Kestner on European coals and Johnston on American coals, leads me to the belief that a formula constructed as follows will be of especial benefit in enabling engineers to arrive at the steam-making capacity of their coals.

$$Q = 14,652 f. c. + A \times \text{volatile matter} \times B,$$

Where A equals 23,400 when volatile combustible is equal to from 2 to 15 per cent of total combustible,

A equals 20,000 when volatile combustible equals from 15-30 per cent of total combustible,

A equals 17,100 when volatile combustible equals from 30-35 per cent of total combustible,

A equals 16,200 when volatile combustible equals from 35-40 per cent of total combustible,

Where Q equals industrial value of coal for steam-making purposes, and where

B equals .61 when fixed carbon equals 82-90 per cent of total combustible,

B equals .65 when fixed carbon equals 74-82 per cent of total combustible,

B equals .662 when fixed carbon equals 68-74 per cent of total combustible,

B equals .588 when fixed carbon equals 60-68 per cent of total combustible,

It equals .551 when fixed carbon equals 50-60 per cent of the total combustible.

In reviewing this formula I may say I was guided in its construction by the fact that the heating value of the volatile combustible is a constantly changing quantity, but remains constant in accordance with its composition of the elements, and that these elements occur in practically fixed proportions, determined by the total volatile combustible matter in the coal.

With this formula and the proximate analysis before us, we are readily enabled to determine, which of two coals is likely to be the most economical and best suited to the conditions under which combustion must take place, and will, I hope, be found useful in arriving at the real value of a coal submitted for inspection.

## LEGALITY OF CITY CAR LICENSES.

The question as to whether a city may legally assess and collect a license tax on street cars when no provision for such a tax was made in the ordinance granting a franchise to the railway company is one of so much importance to street railways that we quote in full one of the latest decisions on this subject. The title of the case is *City of Springfield vs. Frank Smith* (secretary and manager of the Metropolitan Street Railway), decided at the April term of the Supreme Court of Missouri. The opinion by Theodore Brace, J., is as follows:

The plaintiff is a city of the third class, with express power, by ordinance, to grant the right to any person or corporation to buy and construct street railroads in any street in said city, and to regulate and control the use thereof. R. S., 1880, Sec. 1576. To levy and collect a license tax on "street railroad cars" operated by any corporation, lb. 1506, and to levy and collect taxes for general revenue purposes on all mixed, personal and real property within the limits of the city taxable according to the laws of the State, lb. Sec. 1405.

The defendant is the general manager and secretary of the Metropolitan Street Railway Company, which by assignment succeeded to all the rights, privileges and franchises granted, by the city, to the Citizens' Railway Company, and the Woodland Heights Rapid Transit & Improvement Company, and under the direction and management of the defendant, was operating its street cars in said city at the time the complaint herein was filed; without license, as required by the ordinance of said city, approved April 5, 1892, (Chap. 15, Art. 1 R. O., 1892), Sec. 7 of which provides inter alia that "No person, corporation or company shall use, run or drive or cause to be used, run or driven for hire, pay, profit or compensation any street car \* \* \* without a license therefor from the City the charges for such license shall be for each street railroad car or coach of whatever kind ten dollars per year." \* \* \* and Section 21 of which imposes, a fine of not less than five nor more than \$100 for the violation of the requirements of Sec. 7.

The defendant was arrested upon a complaint for the violation of this ordinance; fined \$100 in the Recorder's Court from which he appealed to the Greene County Criminal Court, where, upon a trial de novo, he was again found guilty and his punishment assessed at a fine of \$50. From the judgment of which court he appealed to the St. Louis Court of Appeals, by which Court the cause was transferred to this Court on the ground "that the questions arising for decision involve the construction of certain provisions of the constitution of this State."

The only defense made to the action is a claim of exemption by the Metropolitan Street Railway Company from the operation of this ordinance by reason of the acceptance by it, and its assignors of two prior ordinances of the City, approved October 3, 1886, the conditions of which have been duly performed by them. These ordinances were of like tenor and effect, one relating to the Citizens' Street Railway Company, and the other to the said Transit & Improvement Company. The former is as follows

"Be it ordained by the City Council of the City of Springfield as follows:

"Sec. 1. That the Citizens' Street Railway Company be and is hereby permitted to change its motive power from horse and mule power to electricity motor power as provided for in the acts of the General Assembly of the State of Missouri, approved March 18, 1887.

"Sec. 2. Said Citizens' Street Railway Company shall in the change of its said motive power, do and perform all work upon its superstructure and tracks in a way and manner so as not to stop or materially interrupt ordinary traffic and travel upon the streets occupied by it until the grades of the streets are established; in all cases where improvements are provided for or contemplated, and all places of change, erection of poles and work necessary for such change of motive power shall be done under the supervision of the street committee of the city, to the end that said railway may be operated when said motive power is changed without damage to person or property, and in a way to impede ordinary traffic and travel on the streets as little as possible. Provided, that said street railroad company shall keep the street between its tracks and for two feet outside of the outside rail thereof in the same condition as the remainder of the street is kept by the city.

"Sec. 3. The said street railroad company shall charge not more than 5 cents for a single trip one way, or \$1 for 25 trip tickets, and not more than one half the regular fare for children under 12 years of age, and nothing for children under 3 years of age.

"Sec. 4. That inasmuch as the contemplated change of motive power will be attended with expense, it is further provided that this privilege to operate said electric motor power on the streets now occupied by said Citizens' Street Railway Company shall continue for 35 years from the publication of this ordinance. And said Citizens' Railway Company shall have the right and privilege within the present and future corporate limits of the city of Springfield, Missouri, and the additions thereto, of building, erecting, laying, operating, maintaining, repairing and using electric apparatus and appliances, electric machines, engines and apparatus, towers, masts, lamp posts, lamps, posts, poles, wires, pipes and all other machinery, apparatus and appliances necessary and convenient for the use and application of electricity for the purpose of lighting and of using, operating, renting and applying such electric machines, electric apparatus and appliances, towers, masts, lamp posts, poles, wires, pipes and apparatus and appliances for the purpose of conveying and supplying electric currents for light and power for hire and use in any and every capacity for which electricity is now or may hereafter be used; and of so using and occupying the streets and alleys of said city of Springfield for said purpose, and for the erection of towers, masts, posts, lamps, poles, etc., thereon and the laying of wires and pipes therein, and for repairing the same without injury or detriment to private rights or property of individuals or corporations or without public detriment, except temporary inconvenience caused by the erection of such towers, masts, lamp posts, poles, and the laying and running of such wires and pipes and repairing of same—all to be done under the police regulations of the city. Provided, that such change of motive power shall be made within one year after the street improvements on the streets are completed by the city, otherwise the city reserves the right to repeal this ordinance as to the streets occupied by said company upon which such motive power has not been so changed."

It is contended that these ordinances granting powers and franchises to the said two companies, the benefits of which passed to the Metropolitan Street Railway Company, constitute contracts between the city and these companies, as to which, the said provisions of Secs. 7 and 21, of Art. 1, Chap. 15 of the ordinance of 1892, are void, under Art. 1, Sec. 10 of the constitution of the U. S. prohibiting laws impairing the obligation of contracts.

It seems to be conceded in the argument of the learned counsel for the defendant that if the right to levy the tax in question is a reasonable exercise of the police power of the city, then the ordinances of 1886 can afford no defense to the action; since it was not within the power of the legislative authority of the city to exempt the franchise thereby granted from the operation of the governmental power of the city, to regulate the use thereof. But it is contended that the ordinance in question is an exercise of the taxing power of the city, for the purposes of revenue, and not of the police power for the purpose of regulation, hence was the subject of contract, and was in fact contracted away so far as the Metropolitan Street Railway Company

is concerned by the ordinances of 1889, which it is contended constitute a contract for that purpose within the protection of the provision aforesaid of the Federal Constitution. In support of this contention we are cited to a line of cases of which *Mayor, etc., vs. Second Av. R. R.* 32 N. Y. 261, is the leading one. But in the view we take of this case, a review and discussion of those cases in which express power to levy and collect a license tax was not given, is deemed unnecessary. It is beyond question, that by the sections of the statute cited, the plaintiff city was invested with express power not only to tax the property of street railway companies for revenue purposes (Sec. 1495) but to tax, license and regulate the business of running street railroad cars in the city (Secs. 1506 and 1576). That the state may collect an ad valorem tax on property used in a calling, and at the same time impose a license tax upon the pursuit of that calling, and may delegate such power to a municipal corporation, is well settled law in this state. *Aurora vs. McCannon* (decided March 9, 1897) and cases cited. Express power having been granted to the city in this instance by Sec. 1506 to levy and collect a license tax on the running of street railroad cars for hire in the streets of the city, there is no necessity of deducing such right from the general police power of the city. It may be exercised as granted, either as a police regulation or for the purpose of raising revenue within constitutional limitations. Conceding, for the sake of argument, that the tax imposed by the ordinance is for revenue purposes, and not simply for the purpose of police regulation, and conceding further that the ordinances of 1879 constitute a contract quoad the matters therein treated. If such contract, when properly construed, is an agreement on the part of the city not to levy and collect such tax thereafter, then such contract might to that extent be held to be ultra vires and void, upon the authority of *State vs. Han. & St. Joe R. R. Co.*, 75 Mo. 208, and not within the protection of the Federal Constitution. There is no necessity however for so ruling in this case, for the reason, that the so-called contract when properly construed cannot be so interpreted. The principle upon which such contracts are to be construed with reference to the taxing power, are well settled, they are to be liberally construed, in favor of the public—"grants of this class are not to be extended by construction beyond the plain terms in which they are conferred but should be strictly construed against the corporation or those claiming under the grant." *City of Wyandotte vs. Corrigan* 35 Kansas 21. They are special privileges, as to which "Nothing is to be taken as conceded but what is given in unmistakable terms, or by an implication equally clear. The affirmative must be shown, silence is negation and doubt is fatal to the claim." *Fertilizing Co. vs. Hyde Park* 97 U. S. 650; *Newton vs. Commissioners* 100 U. S. 561; *Rice vs. M. & N. R. R. Co.* 1 Black, U. S. 358; "Exemptions of this kind are to be strictly construed, the rule being that the right of taxation exists unless the exemption is expressed in clear and unambiguous terms." *Railway Co. vs. Philadelphia* 101 U. S. 528; *Delaware Railroad Tax*, 18 Wal. 206. Illustrating the application of these principles, in *Wyandotte vs. Corrigan*, 35 Kansas 21, a case quite analogous to the one in hand, it was held that where an ordinance granting a street railway franchise for 21 years providing how and when the road shall be constructed, how it shall connect, that the tracks and the street between the tracks shall be kept in repair and up to grade, and regulating the price to be charged for fare of passengers; such ordinance will not exempt the corporation from reasonable regulation by the city in the operation of the road, nor will it prevent the city from levying and collecting a license tax thereon, by ordinance subsequently passed, in this case was \$100 per annum. In the city of *New Orleans vs. Railroad Company*, 40 La. Ann. 587. It was held that "a contract conferring the right to lay and operate a street railway without dispensing with the payment of a license, is not impaired by the exaction of such license;" and in that case a license tax of \$2,500 per annum was sustained, and going further in the same direction it was held by the same court, in the city of *New Orleans vs. Railroad*, 42 La. Ann. 4, that "A contract between a municipal corporation and a railroad company by which the latter pays a bonus for the franchise therein conferred by the city, cannot be construed as conferring an immunity from the payment of license on its business by the company, in the absence of an express stipulation to that effect in the contract." In *Railway Co. vs. Philadelphia*, 101 U. S. 528, it was held that when the charter of a railway company provided that it should pay a license fee of \$30 per car per annum required by the ordinances of the city, its charter rights were not impaired by a subsequent statute and ordinance requiring the payment of a license fee of \$50 per car per

annum. In a recent work on street railway law, Booth, Sec. 281, the following rule is deduced from the authorities: "In construing the charter of a company conferring authority to construct and operate a street railway, the right to exact license fees will not be denied because it has not been expressly reserved in the grant; and when the contract between the city and the company does not in terms dispense with the payment of a license the rights of the latter are not impaired by a subsequent ordinance requiring such payment." The ordinance under which the defendant claims exemption in this case has been set out in full, and applying to it these principles of construction, no argument is required to demonstrate that it does not by the terms used, nor by any fair implication therefrom, exempt the street railway company from the license tax which the city was expressly authorized to impose, and subject to which power the company took the franchise therein granted. The cases of the *State ex rel vs. Corrigan Street Railway Company*, 85 Mo. 263, and *City of Kansas vs. Corrigan*, 86 Mo. 67, in neither of which was the question of the power of taxation involved, are not in point in this case. The ordinance imposing the tax being valid, it became the duty of the company to take out the license required thereby, in order to protect its employes from the penalty imposed for the violation thereof, and the defendant having been guilty of such violation by running its cars without such license, was properly fined. *Wyandotte vs. Corrigan*, 35 Kansas 26.

The judgment of the Criminal Court of Green County is therefore affirmed. All concur.

## ELECTRIC RAILWAY IN SIBERIA.

Up to the present there has not been even a horse street railway in Siberia, but an electric line is now building in Vladivostok. The manager is Madame Zehof, whose portrait we publish. She is a woman of business ability, a good purchasing agent and although surrounded by a staff of clerks keeps a close watch on details. The superintendent is E. Jouravliov.

MADAME ZEHOF.

Vladivostok which is thus to be the pioneer in street railroading in Siberia is the chief naval station of Russia on the Pacific coast.

The name is vlad, to have, and vostok, the orient; that is, to have the orient, a name which must have an ominous sound to Japanese and Chinese ears. It was founded in 1861, on the northwest coast of Muraviev peninsula, on the Golden Horn bay, Gulf of Peter the Great, Sea of Japan. It is to be the terminus of the trans-Siberian railway now building. The present population is about 16,000, nearly half of which is military.

E. JOURAVLIOV.

Like all towns in Russia and Siberia the houses are built far apart as a protection against fire (houses being for the most part of logs, a fire would be very disastrous, especially in winter), and covers a large territory in proportion to its population, and thus offers an inviting field for street railways.

PRIMITIVE RAILWAY APPLIANCES.

BY C. B. FAIRCHILD.

(Concluded.)

In the early history of surface roads numerous devices were proposed to combine animal and mechanical power to the propelling of vehicles. These were generally called mechanical travelers. Fig. 13 illustrates such a device which was patented in 1819, the design being an attempt to imitate the action of the legs of a horse in walking. Fig. 14 shows another, which curiously contained the germ of

tube, and causes the carriage to advance at about four times the velocity of the horse, or at ten miles an hour." With the advent of steam, mechanical travelers or rather designs for the same became quite common. The supposed necessity for some form of propulsion was based upon the then prevalent idea that locomotive wheels could not take hold of a smooth rail with sufficient friction to draw or propel a vehicle. To show how firm a hold this idea had on the public mind at that time we quote the following from a prominent publication:

"It appears that notwithstanding the great exertions on the part of the inventor, Mr. Stevenson, to bring his locomotive into use on the different railroads now either constructing or in agitation, it has been the opinion of several

FIG. 13—MECHANICAL TRAVELER, 1819.

FIG. 15—PORTABLE TRACK, 1821.

several modern practical devices. Here is shown the first tube or conduit, also a combined freight and passenger car, a double deck car, and a sleeping car, for the enclosed portion on the upper deck contained sleeping berths. This device was the subject of a patent granted William Frances Snowden of Oxford street, London, in December, 1824, and is described as a new invented wheel way and its carriage. "The carriage consists of two stories, the upper one for passengers, containing both inside and outside berths, and the lower one for merchandise, which is deposited on a circular floor around which two horses are made to walk, being yoked to the opposite extremities of a horizontal lever that turns a vertical axis, to which is connected multiplying gear

engineers that they do not possess those advantages which the inventor had anticipated; indeed, there cannot be a better proof of the doubt entertained regarding their utility than the fact that it has been determined that no locomotive engines shall be used in the projected road between Newcastle and Carlisle, since, had their advantages been very apparent, the persons living immediately on the spot in which they are used, viz., Newcastle, would have been acquainted therewith. The principal objection appears to be the difficulty of surmounting even the slightest ascent, for it has been found that a rise of only  $\frac{1}{8}$  in. in a yard, or 18 ft. in a mile, retards the speed of one of these engines in a very great degree, so much so indeed that it has been con-

FIG. 14—MECHANICAL TRAVELER, 1824.

FIG. 14 A—FIRST CONDUIT, 1821.

that causes the mechanical horse in the hollow trough and the carriage above to move at any predetermined velocity. The toothed wheel 'takes' into the rack on the side of the

sidered necessary in some parts where they are used, to aid their ascent with their load by fixed engines which drag them forward by means of ropes coiled around a drum."

FIG. 16—GORDAN CARRIAGE, 1822.

Following the introduction of mechanical travelers, various designs were presented for a carriage that should carry its own track, and so facilitate its passage over rough ground. It is interesting to know that this line of work is still a favorite line with some so-called inventors, and only recently a trial was made of a similar device. Fig. 15 illustrates the first of these machines, which was patented in 1821 by John Richard Barry of London.

The carriage is provided with an endless pitched chain, carrying anti-friction wheels attached to the same axle as the running wheels. Under the carriage are arms so bent

FIG. 17—"PERPETUAL RAILWAY," 1830.

or curved as to be clear of the wheels in their revolution. There are also large wheels at each end of the carriage for the link chain to pass over. A horse or other power being applied to the rails of the carriage, each pair of wheels passes under the carriage by the action of the chain. When the wheel strikes an impediment, instead of being propelled over it, it stops against it while the carriage proceeds as though the road were level, until the chain in its revolution lifts up the opposed wheel, and the object is passed without violence and without extra power, so claimed.

Fig. 16 illustrates a similar device by David Gordon in 1822. The main wheel of the machine consists of a large hollow cylinder about 9 ft. in diameter and 5 ft. long, having its interior circumference provided with a continuous

FIG. 18—ANTI-FRICTION ROLLERS.

series of cogs in which are made to work the cogged running wheels of a locomotive. The power being communicated to the small wheels, causes them to revolve and to climb up the internal rack of the large cylinder, compelling the latter to roll forward and propel the vehicle.

In 1825 George Cayley of Brompton, proposed the use of an endless chain with small rollers at right angles to the running wheels. The rollers form a continuous series on both sides of the carriage and come successively in contact with the ground and step over the obstacles that may lie in their path. The small rollers were placed at right angles to the carriage so that it could move sideways.

In 1830 an American inventor received the great seal on

FIG. 19—ANTI-FRICTION ROLLERS, 1825.

an English patent for a device similar to that of Mr. Gordon described above, and described as a perpetual railway (Fig. 17). The wheels were formed with a circular rib placed round the interior of the felloes upon which small wheels with grooved peripherys were intended to run. The small wheel, it was claimed, would bear its portion of the weight of the carriage and run upon a smooth surface, while the large wheel is passing over uneven ground.

Anti-friction rollers were first introduced in 1825 by a Mr. Brandreth of Liverpool, Figs. 18 and 19. Many other modifications of this plan soon followed. The next type was that of wheelless carriages, a kind of sledge. One known as Rangle's safety rotation railway is illustrated in

FIG. 20—SAFETY ROTATION RAILWAY, 1840.

Fig. 20. This consists of two lines of fixed wheels along the roadway. The wheels were placed twelve feet apart and were formed like a double pulley having the same bearing. These were connected by belts and moved by power communicated at one end. The car being placed on the upper periphery of the wheels, was carried from one end to the other, and was stopped by raising the body far from the wheels by means of a brake mechanism.

A cyclopede, Fig. 21, was devised by Mr. Brandreth probably about 1825. This is another form of mechanical traveler, and is probably the origin of the modern tread power now so extensively used. It consists of a chain plat-

FIG. 21—CYCLOPEDE, 1825.

form having a series of friction rollers, from which through the medium of a spur wheel, power was transmitted to the wheels of the carriage. The horse being yoked to the frame, communicated the power by treading the movable platform. As first designed, this device was intended to run upon a track, so that it comes under the head of primitive railway appliances. It is interesting to note that the attempt to introduce travelers of this kind brought out from a prominent contemporary writer a disapproval of all attempts at horse locomotion, except the use of his legs, "experience having proved 'in his opinion', the utter vanity if not impiety of all propositions of the kind." He instances the velocipede as the most promising of all and yet a failure. He deduces "that the inexplicable vital principle bestowed by the omnipotent God upon his creatures cannot be surpassed by man's utmost knowledge in mechanical science."

The first proposition to employ compressed air for locomotive as well as in stationary engines is found in a patent granted George Medhurst in 1799. He employed windmills for compressing the air so as to make it from ten to twenty times more dense than it is in its natural state, and then conducted it to a cylinder. Other similar schemes soon followed.

An atmospheric railway on another plan was built at Norwood Scrubbs, on a line belonging to the West London Railway Company. The line was about half a mile long. The plan employed a 9-in. iron tube placed in the roadbed in which was a close fitting piston, which was moved by exhausting the air from one end of the tube, and to which

the car was attached. The tube had a grooved slot along its upper surface through which the shank of the piston passed. The slot was closed by means of a valve of leather strengthened by plates of iron flat on the outside and forming the segment of a circle on the inside. The valve being treated with a composition of bees wax and tallow rendered the tube comparatively air tight. It was claimed that a half vacuum could easily be obtained and that the car was moved at a good rate of speed. A second line on the same principle was constructed in Dublin, Ireland, in 1843, and several others followed. Prominent engineers at the time gave the scheme favorable reports.

Elevated roads appear to have been first patented in 1821 by H. R. Palmer, an engineer of the London Dock Company. He proposed a single track structure on which the wagons were placed in pairs, Fig. 22, on the opposite sides of the rail. It is amusing to note that the inventor proposed to employ both animal and wind power, the latter by means of sails, which could be spread should a favorable wind spring up, "and the horse put into one of the cars, where over his bag of corn he might regale and invigorate himself for fresh exertion, should the wind fall off." (Fig. 23.)

FIG. 23—ELEVATED SINGLE TRACK ROAD.

A means for removing snow from the rails was described in a patent granted in 1831 to a Mr. Grim of Bury. He proposed to dissolve the snow by making the rails hollow and causing hot water or steam or hot air to pass through them so as to keep them at a temperature above freezing. Boilers for generating the steam were to be placed two or three miles apart. The ends of the rails were to be joined by close fitting copper tubes with means for expansion. Instead of hollow rails, the inventor also proposed iron pipes laid alongside the rail through which the steam should pass.

Fig. 24 illustrates a design for a fire escape, being a modified form of a device patented in 1813 by Thomas Roberts. This principle might possibly be employed in the construction tower or trolley repair wagons. As will be seen, the device is constructed on the principle of the lazy-tongs and is mounted on a four-wheel carriage. At the top is a platform with a folding bridge or gangway. The platform is raised by means of a pinion meshing into a pair of toothed quadrants which have arms welded to the lowest lever bars. Motion being given to the pinion by the winch the two quadrants are moved in opposite directions, and the series of levers are opened or closed like so many pair of shears. A counterpart could be provided to one side and

FIG. 22—ELEVATED SINGLE TRACK ROAD, 1821.

connected by cross bars and the pinions actuated by a common axle.

While disappointment has been the bitter fruit of many pioneers in this interesting branch of mechanical science,

FIG. 24—TOWER WAGON, 1813.

who shall say that the devices here illustrated have not been stepping stones in the process of evolution, which has brought modern transit facilities to their present advanced state, or that they may not yet figure in the progress which is yet to be made, for the development is yet going on with rapid strides.

### A PROTECTED THIRD RAIL SYSTEM.

The illustrations represent the K. A. K. third rail system for elevated railways and lines operating under steam road conditions. One shows the track rail, guard rail outside and the covered third rail, also the contact shoe in position. The third rail is a steel angle and is mounted on fiber or other insulating material. The posts are supported on iron chairs at the outer ends of the ties and the rail is bolted to

the posts, the bolt heads being counter-sunk so as not to interfere with the contact shoe.

The other is a similar construction for the application of the third rail to steam roads. The wooden cover to the third rail is partially removed so that the form and fastenings of the rail may be shown. The wooden cover serves the purpose of preventing persons from coming in contact with the rail, keeping the rail dry and also the posts which act as insulators. The rail is supported on the ends of the ties outside the track so that it can be erected and fitted complete ready for operation along any line of track using steam without interfering with traffic during construction. At crossings and other points where the third rail could not extend copper cables are carried underground and the train coasts over the break.

The contact shoe is shown in the cut. It is connected to the car truck by a spring and is in contact with the under and inner surfaces of the angle of the third rail. Messrs Krotz, Allen and Kelly are the promoters of the system.

### ROLLER BEARINGS.

The theoretical advantages of substituting rolling for sliding friction in bearings of all kinds are so apparent that it is rather surprising that it has not been found practicable to extend their application to the rolling stock of railways to a greater degree than has been the case. W. B. Marshall before the Institute of Civil Engineers states that the experiments with tram cars using roller bearings show that on a grade of 1 in 20, 23 per cent less power was required starting than with the ordinary type; on a grade of 1 in 40, 50, and on a grade of 1 in 80, 60.4 per cent less. The Corporation of Blackpool has equipped some of its cars with roller bearings and the consulting engineer certifies to a saving of 30 per cent in the work of axle friction. The Liverpool Overhead Railway began experimenting in 1895 and is gradually placing the bearings on all its rolling stock. The Waterloo & City Railway has specified roller bearings for all the stock ordered by it. On steam roads the record appears to be equally good, as the Brighton & Kemp Town reports that an experimental train of six carriages which has been running for two years shows a saving of from 12.5 to 15 per cent in coal consumption under disadvantageous circumstances.

The question of whether the wages of street car conductors are subject to garnishment is to be tested in the courts of Georgia.

K. A. K. THIRD RAIL—FOR STEAM ROADS—FOR ELEVATED TRACKS.

## THE BIRMINGHAM TRAMWAY REPORT.

The sub-committee on tramway traction, consisting of two aldermen and two councillors of Birmingham, has submitted a report on the tramway systems of Bristol, Blackpool, Paris, Rouen, Brussels, Vienna, Budapest, Dresden, Berlin, Hamburg and Bremen, which is in a terse but lucid style.

FIG. 1—CLARET-VUILLEUMIER SYSTEM.

Although some of the matter has already been published in the REVIEW yet a part of the information and the ideas of the

committee deserve further attention, and the following is extracted from the report:

At Blackpool in addition to the electric conduit system the Gas Traction Company is operating two gas motor cars. During the few months these cars have been running the cost of gas, repairs, etc. has been at the rate of 9 cents per car-mile. Ordinary coal gas is used, reservoirs in the cars receiving the gas from the storage cylinders at the station at 135 lbs. pressure. Each car is fitted with a double cylinder gas engine, which is under the car seat, the fly-wheel being enclosed in a recess formed in one side of the car. The engine rotates constantly even when the car is standing still, and the motion is communicated to the car wheels by gearing thrown in and out. In ascending a grade a supplemental set of gearing is thrown in, giving greater tractive effort and less speed. However the committee does not recommend this system for Birmingham on account of the limited storage capacity of the cars.

In Paris the fireless locomotives attracted attention. The reservoir corresponds to the boiler on an ordinary locomotive and is charged with water at a very high temperature and pressure, enough energy being stored to run about 10 miles. The emission of great volumes of steam was an objectionable feature.

The Mekarski compressed air cars are in operation in Paris on a line six miles in length. Two charging stations

FIG. 3—CLARET-VUILLEUMIER DISTRIBUTOR.

equipped with compressing machinery, keep the 11 cars supplied with air. The storage capacity of the reservoirs in each car is about 100 cu. ft., the air having an initial pres-

sure of 850 lbs. which drops to 250 lbs. per sq. in. at the end of the trip. The cars are very heavy weighing 33,600 lbs. loaded and are expensive in construction and operation, making the system entirely unsuited for heavy traffic in a large city.

The storage battery cars received some attention and it was found that this form of traction had never been used with marked success. Recently a new form of battery, designed by M. Pescatore, has been introduced which promises to be slightly successful. It is a combination of the Planté and the pasted or grid plate and is capable of being charged with very heavy currents without danger. The

FIG. 2—CLARET-VUILLEUMIER SYSTEM.

cells are not removed from the cars for recharging as the process requires only 10 or 12 minutes and such a charge is sufficient to operate a motor and trailer, with 50 passengers, a distance of 10 miles. Four cars are now in use but others are being built. Each car is fitted with 200 cells arranged under the seats and at one end is small electric fan which draws the acid fumes out of the car. Two positive and three negative plates in an ebonite box constitute a cell. The battery of 200 cells weighs 7,800 lbs., has a capacity of 12 h. p. and the cost is about \$1,500 per car. It is stated that the cost for operating expenses and for repairs is six cents per car-mile. It is very doubtful if this battery is suited for heavy traction or on considerable grades.

The next method of traction described is the Claret-Vuilleumier surface contact system, the construction of which may be seen from Fig. 1 and Fig. 2. From the station current is conducted to distributing boxes which are at intervals of 110 yds. along the track. In each box is a ring, Fig. 3, consisting of 20 insulated copper contact surfaces, 19 of which are connected by small cables, each to one of the pairs of contact-plates in the street surface. The twentieth contact surface in the ring of the distributor is insulated except the moment when the car is passing out of one section into the next and then it serves to bridge over the gap between the two sections. There is movable arm pivoted at the center

of the ring and in permanent connection with the main feeders. The outer end of the arm makes connection with the 20 contact rings successively and in so doing puts the corresponding contact-plates in electrical connection with the mains. The iron contact shoe along the bottom of the car is of sufficient length to make connection with two of the plates at the same time. On the twentieth point the current passes on to the next distributor, ensuring the continuity of the service. On account of the current passing through one point of the distributor at a time and as each point connects with but two contact-plates, it follows that only one pair of contact-plates can be in the circuit from one distributor, consequently two cars cannot be on the same section at the same time. These sections can be made of any desired length but the shorter and more numerous they are the more costly the construction. The rails form the return circuit. The cost of construction is approximately \$11,500 per mile of double track. In a general way the system is satisfactory; the distributing mechanism seems to be durable and precautions taken to minimize the danger from live contact-plates assure safety. On the main lines where cars fol-

In Brussels there are 10 miles of trolley lines which are in successful operation. In the business streets the tracks are in the center, with span wires to hold the trolley. Recently a telephone wire grounded a trolley line and killed two horses. To prevent further accidents of this kind the overhead wires are being protected, by fixing on the upper sides of them strips of wood wherever they pass under the telephone or the telegraph wires. This increases greatly the unsightly appearance of many parts of the line. Two conduit systems are under construction, one five miles and the other one and a half miles. These are similar to the Budapest conduit in design, the conductor being under one of the rails and the slot forming a groove for the wheels. The conduit was built in one of three different ways; of concrete formed around molds, which are removed as the mass becomes hard; of concrete blocks formed in molds and brought to the line ready to be put in place, the conduit being formed of two blocks, one on each side; or of brick work; this last seems to be adopted around the recesses in the conduit in which the insulators are placed. The conductors, which weigh 20 lbs. to the yd., are carried on insulators suspended from the top of the conduit. Neither of the conduit systems are in operation.

With the exception of an experimental trolley line a mile and a half in length, all the tramcars in Vienna are worked by horses. The company's concession has a long time to run yet and no arrangements have been made for replacing horse by mechanical traction.

The conduit lines of Budapest have been fully and frequently described and it is well known that their operation has been successful since the construction in 1889. Fig. 4 is a view on one of the principal streets of Budapest representing the cars and tracks of the conduit system. The municipal authorities have fixed a zone, including the business and more populous districts, in which overhead construction is forbidden. On account of its cheapness and facility of building the company prefers trolley construction. Some difficulty has been experienced at times, owing to mud and dirt getting in the conduit, but better design and greater cleanliness will obviate these difficulties. On Andrassy street the city would not permit a surface railway and the company was forced to build a double underground line  $2\frac{1}{4}$  miles in length. A description of the construction may be found in the May REVIEW. The two conductors are suspended from the roof of the tunnel, contact being made by crossbars on the top of the car. At places where the conduit and the overhead construction join, the collectors are lifted out of the conduit by means of a winch handle inserted in the side of the car and the sliding trolley is released so as to bring it in contact with the trolley wire. As the conduit slot is  $1\frac{3}{8}$  in. wide the collector can be lifted out at any point. Sliding bar trolleys are used in place of trolley wheels which simplifies the overhead work. The tramway company is soon to change the remaining 57 miles of horse car lines to electric traction, 15 to be conduit and 42 trolley.

Of the 100 miles of tramways in Dresden, 32 are now operated by the trolley, a short section less than a mile in length by accumulators, and one-half mile by underground conduit. It has been determined that the storage batteries consume 20 per cent more current than do the same cars worked from the trolley or the conduit system. In the conduit construction the slot is outside the track, the outer edge of the rail forming one side of the slot. Cast iron yokes

FIG. 4.—BUDAPEST.

low one another closely the sections would have to be very short.

Paris seems to be a veritable museum of traction systems, gas, compressed air, surface contact, storage battery and steam being in use. Lastly the committee describes the Serpollet steam cars. The steam generator consists of a number of small flattened tubes, U shaped in section, exposing a large outer surface to the action of the fire but inclosing a very small space inside. When a small quantity of water is injected into these tubes it is immediately vaporized and the steam so formed strongly superheated. The regulation of the engine is accomplished by controlling the amount of water passing into the tubes. The steam generator only occupies a space 6 ft. 9 in x 2 ft. 3 in. and is 3 ft. 6 in. high. It contains no space for water, and as there is no chance for an explosion there is no provision for safety valves, pressure or water gauges or feed pumps, and it requires no attention on the part of the driver. The engines are under the car, and have been so constructed as to drive the car by a sprocket chain, but the new engines will be connected to cranks on the axles. The motor cars weigh about 29,000 lbs. At present there are 40 in service and 60 more in the course of construction. These cars with a trailer have no difficulty in ascending grades as great as 5 per cent.

are fixed 3 ft. 6 in. apart, the tops of them carrying cast iron troughs 9 in. wide and filled up with asphalt to the street level; these troughs form the top part of the tube conduit. The rails constitute the return circuit. Sliding bar trolleys are preferred to wheels. These are of three different kinds; one is a trough-shaped bar of aluminum alloy, the trough being filled with grease, some of which is left on the wire. The other two bars are of a soft alloy, one of them being designed so as to spread or scrape off the excess of grease that may be left by the first bar. These bars are used on alternate cars so as to keep the trolley wire in good condition. The bars last about six months and are very cheaply replaced. The shape and size of these trolley bars is shown in Fig. 5. Electro-magnetic as well as hand brakes are applied to these cars. Guard wires are required, three or four being placed side by side and about one foot apart and connected together by short cross wires. The tramway company has no station, the current being supplied from the municipal power plant.

In Berlin and suburbs there are 150 miles of tramways, mostly worked by horses. There a few miles of trolley lines, one route being supplemented by storage battery cars.

FIG. 5—CAR WITH BAR TROLLEY.

There are two or three lines of conduits but this form of electric traction is not favored by the authorities as it necessitates the asphalt streets being torn up for a considerable length of time. The trolley wire is divided into sections of 500 to 600 yds. in length, which are connected to the underground feeders. The fire department is provided with keys and at marked posts where the feeders are connected the current can be cut off at times of fire. The tramway company pays to the city eight per cent of its gross receipts or a sum approximately \$500,000 a year. In the agreement for an extension of its franchise the company agrees to pay the city eight per cent, and after six per cent on the capital has been paid to the shareholders, the balance of the profit is to be equally divided between the shareholders and the city.

Accumulators proved a failure at Hamburg and now the 90 miles of tramway are operated exclusively by trolley. The traffic amounts to 50,000,000 passengers per annum, the city receiving 9¼ per cent of the gross receipts or about \$115,000 a year. The current is supplied from the

power station of a separate company which has the concession for the supply of electricity throughout the city. There are 250 motor and 160 trail cars which were built by the tramway company. Repairs to the equipment and even the uniforms of the conductors are made at the company's works.

In Bremen 6½ miles of tramways are of the overhead system and the remaining 14 are worked by horses. One condition which is peculiar to Bremen is the excessively narrow streets, some not being more than 20 ft. wide from house to house. In such cases the rails are laid close up to the curb on one side of the road and in some parts two lines are laid but are so close that only one track can be used at a time. The span wires are fastened to rosettes fixed in the walls.

In the summary of its report the committee considers electric traction preferable to all others. All inquiries developed the fact that as storage batteries were not suited to operate on grades exceeding two or three per cent this system can not fulfill the conditions required in Birmingham. The choice practically narrows down between the trolley and conduit. The committee tried to ascertain the comparative cost of construction, but this could not be done, as one engineer estimated the cost of each to be about the same and another one said that the conduit would be from four to five times as expensive as the trolley. Except for first cost and a prolonged disturbance of the streets the committee favored the conduit. Considerable stress was laid on the disfigurement of the streets by the overhead construction, the danger of broken trolley wires and the electrolysis of gas and water pipes. The tenor of the report is that the conduit system is best suited to the needs of Birmingham.

The original proposition of the City of Birmingham Tramways Company was based upon the condition that eight miles only of the road were to be worked on the conduit system and 29 miles by overhead trolley, and it could not agree to build all conduit lines in accordance with the recommendation of the committee without greater concessions than the city council was willing to make. Also the company demanded that the road be built and maintained by it and not by the city as it declined to provide funds for some one else to spend. Being unable to agree the city directed the company to withdraw the bill pending in Parliament and the present status is the same as a year ago except that the present company has succeeded to the Birmingham Central Tramways Company.

#### EAST OAKLAND (CAL.) ROAD TO BE SOLD.

Damage suits, a falling off in business and the very heavy expense of litigation in which the East Oakland Electric Railway Company has been involved have compelled the receiver who was appointed three years ago to issue receiver's certificate for \$18,000, which represents the excess of expenditures over receipts in that time. The California Safe Deposit & Trust Company recently foreclosed in behalf of the bondholders but the date of the sale has been deferred by mutual agreement of the interested parties.

W. G. Cummings, superintendent of the Newcastle (Pa.) Traction Company was arrested for "disorderly conduct" which consisted in posting bills in the interest of the company on the company's poles.

## THE TELEPHONE IN CONNECTION WITH WHEATSTONE BRIDGE FOR SHOP MEASUREMENTS.

Measurement of resistance of motor field and armature coils in electric railway shops has in the majority of cases in the last few years we believe been done by the drop of potential method by using a low reading voltmeter to measure the drop of voltage between the terminals of the coil to be measured and sending a heavy current through the coil. This method, employing as it does, nothing but portable instruments which can be handled by ordinary employes around the shop has found favor because it is the one most likely to give fairly accurate results under all circumstances. The laboratory method of using a Wheatstone bridge for resistance measurements has been used to some extent in electric railway shops but in general has been looked upon as less desirable than the voltmeter method because a galvanometer is commonly employed in connection with it and the magnetic disturbances around the plant make the action of a galvanometer anything but certain and not very conducive to the good temper of the operator. If however a telephone receiver be substituted for the galvanometer of a common Wheatstone bridge, the bridge

method becomes much more reliable for practical work. The principle of the Wheatstone bridge is well known and the accompanying

diagram will make it plain to those not familiar with it. A and B are two equal resistances. In series with A is the coil the resistance of which is to be measured. In series with B is a box of resistance coils of known resistance which can be varied at will. The current from the battery shown then has two available paths, one through A and the unknown resistance, the other through B and the known resistance. It is now evident that if the unknown resistance to be measured and the known resistance opposite to it are exactly equal the two circuits are in perfect balance and an equal current will flow through both of them. If when they are in such balance a delicate galvanometer or a telephone receiver be connected across between c and d no current will flow through such instrument. But if the resistances are unequal then the two circuits are out of balance and current will flow through the telephone receiver one way or the other because there will be a difference of potential between the points c d of the circuit. It is only necessary then when testing the resistance of a coil to change the variable known resistance until it is just equal to the unknown resistance. When this point has been reached it is made evident by the fact that no click is heard when the telephone circuit is closed at c indicating that no current flows through the telephone circuit. The resistance of the coil is then of course known to be just equal to that of the known resistance against which it is balanced.

As long as a galvanometer is used to determine when the electrical balance has been secured there is much uncertainty in its action around a shop where there are heavy currents and large magnets near by. Much of this uncertainty is eliminated by the substitution of a telephone receiver for the galvanometer as the receiver is not influenced by external

magnetism to any extent. The Wheatstone bridge is thus made a practical shop instrument, and in some cases it will probably be found more satisfactory than the voltmeter method which requires heavy currents—these heavy currents being usually obtained from a 500-volt circuit, which voltage is unpleasantly high for some classes of shop testing. The bridge involves the use of only a small battery, a telephone receiver and a box of calibrated resistance coils. Great care must be taken with the contacts, a care not so necessary with the voltmeter method. Each method has its proper place. The bridge with telephone is used in the shops of the Omaha & Council Bluffs Railway & Bridge Company of which W. S. Dimmock is general superintendent and Israel Lovett electrician.

## A HINGED CONDUIT.

In the construction of a conduit on an electric system the tendency is to make it considerably smaller than in the cable construction. This makes drainage, cleaning and repairs to the conductors difficult. The experience has been in some places that sand, dirt, snow and rubbish on the streets work into the conduit and in this is difficult to remove. The conduit system has been in operation for some time in Blackpool, England, and trouble resulted from the above causes. To obviate these difficulties the electrical engineer designed a conduit so that one of the slot rails could be hung on hinges. A short section of this style of construction was put down

SINGLE TRACK CONDUIT—HINGED COVER OPEN.

and is reported satisfactory in its operation. It is called the "Mapple" hinged conduit system, the designer giving his name to it.

The cut shows the manner in which the slot rail may be raised and the whole conduit exposed. One side of the slot rail is hinged to the the yokes and is divided up into convenient lengths, 6 ft. or more. When the conduit is closed the rail is keyed firmly in position so that there is no danger of its accidentally getting out of place.

Negotiations are pending for the consolidation of the People's Railway and the City Railway, of Dayton, O.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Rights of Electric Railway and Traveler in Street.*

An electric street railway has no right to the use of the street as a highway superior to that of a person driving on such highway.

The Court said in part:

In the defendant's argument there is one claimed rule of law underlying it, which runs all along through, and upon the correctness of which its claims upon both these classes of assigned errors must stand, if they can be sustained at all. The court had held that the plaintiff had the same right to drive his wagon in Congress street that the defendant had to propel its cars there; that the defendant had no right to the use of the street as a highway superior to that possessed by the plaintiff or any other traveler. To this rule the defendant objected, and in its brief the objection is stated in this way: "We complain that the court, in weighing the conflicting evidence in this case, denied to us the benefit that arises out of the proposition that the defendant's right to the use of that portion of the highway occupied by its tracks was superior to that of Laufer's at the time he turned over upon the east-bound track." All the assignments of error in the two classes which we are now considering are framed upon the theory that the proposition so stated is correct in the law. If, on the other hand, the rule applied by the court is the right one, then the defendant has nothing in this part of the case of which it can justly complain. In its argument the defendant has sought to enforce the correctness of its proposition in various ways, and to strengthen it by the citation of authorities. In some parts of the argument it is stated as though the defendant, as a corporation, had a superior right to the highway over other travelers. This claim cannot be supported, as the charter of the defendant gives it no such superior rights. Its charter authorizes it to lay its tracks in the streets, and to run its cars over them for the carrying of passengers, but gives no rights in the streets greater than an omnibus company engaged in the same business would have. The streets of Bridgeport are public highways. They have been made such by appropriate proceedings. Every traveler has an equal right therein, and to every part thereof, with any other traveler. The legislature could not give to the defendant any right superior to that of other travelers in any part of a public highway, even if it should make the attempt, without providing that such superior right be taken by condemnation, and the payment of damages to the land owner. It is sufficient for the present purpose to say that it is not claimed the legislature has attempted to do any such thing. In other parts of the argument the claim is stated as though a car of the defendant, while passing along a street, had a right upon its tracks superior or paramount (the latter word being used in the sense of the former) to that of other travelers. But if the defendant, as a corporation, has no right in the street superior to that of any other traveler, it is certain that one of its cars has no such superior right. Congress street, in the city of Bridgeport, is a public highway. It is such a highway, because, and only because, every traveler has an equal right in it with every other traveler. If a car of the defendant has in that street any right superior to the right of the humblest person who has occasion to travel in it, then it is not a highway. A highway is a public way

open and free to any one who has occasion to pass along it on foot, or with any kind of vehicle. In every highway the king and his subjects may pass and repass at pleasure. 3 Bac. Abr. 494; Holt, C. J., in *Reg. vs. Saintiff*, 6 Mod. 255; 4 Vin. Abr. tit. "Chimin Common"; 1 Swift, Dig. 106; 3 Kent, Comm. \*132; Ang. High. Sec. 1, 2; *Harding v. Medway*, 10 Metc. (Mass.) 469; *State v. Harden*, 11 S. C. 360, 368. The late Chief Justice Butler, in a case tried a few years before his death, where a collision in a highway between a heavily loaded team and a light wagon was the subject of inquiry, charged the jury in this way: "In the actual use of a common and public highway, every person has an equal right to use it for his own best advantage, to suit his own convenience or pleasure, but at all times with a just regard to the like rights of every other person. So far as rendering himself liable to damages is concerned, a man may drive fast or slow, with a light wagon or with a loaded team, with a well-broken horse or with an ill-broken one, along a crowded thoroughfare as well as a vacant street, provided he does not interfere with the just rights of any other person. If a man wishes to drive fast, he must do so with respect to the rights of those who drive slow. If he desires to drive slow, he must do so with respect to those who desire to drive fast. The loaded team and the light wagon must each pay a due regard to the rights of the other. If one drives in a crowded street, he must exercise care not to endanger other travelers. If he drives an ill-broken horse, he must keep it so well in hand as not to expose others to unreasonable hazard." This is an accurate statement of the law, when applied to the different forms which travel in a highway may take. At that time electric street cars were not known. But the rule so given has only to be extended a little to include such cars. They have a common right in the highway with every other traveler, and they must be so managed as not to interfere unreasonably with the like rights of others. Every person, in the use of a highway, is bound to use it with reasonable care. A traveler and a railroad company, when using a public highway in common, must each look out for the presence of the other,—the one, to avoid being injured; the other, to avoid inflicting injury. *Hanlon v. Railway Co.*, 104 Mo. 382, 16 S. W. 233. The strongest case cited by the defendant on this part of its argument is *Ehrisman v. Railway Co.*, 150 Pa. St. 180, 24 Atl. 596, where it is said that the electric car in the street has a superior right over that of the traveling public. But in what the superior right consists is explained in another part of the opinion, i. e. that it is the duty of a foot passenger, or of one using a horse and wagon, to afford the car an undisturbed passage along its track; that is to say, that the car should be allowed the preference, in passing along on its track, over other travelers. This duty is no more than the application of the rule of reasonable care. In the exercise of reasonable care, it would be the duty of a foot passenger or of the light wagon to turn out of the way of the car with all reasonable quickness, so that the car would have an unobstructed passage. The car, from its weight, size, and the character of the track on which it runs, cannot turn out; and so reasonable care requires the traveler, who can readily turn out, to do so, and

that the car, which cannot turn out, shall be so managed as to afford such traveler a reasonable opportunity for that purpose. An electric car has no paramount right to the street, if "paramount" means that it has a greater right than others who are in the street. "Whenever a wagon or other vehicle is on the track in advance of a car, it is bound to get out of the way, and not obstruct the passage of the car." *Railway Co. v. Whitcomb*, 66 Fed. 915, 920. "The public have the right to use these tracks (the street railway tracks) in common with the railway companies, and \* \* \* it is the duty of passenger railway companies to exercise such watchful care as will prevent accidents or injuries to persons who without negligence upon their own part, may not at the moment be able to get out of the way of a passing car." *Gilmore v. Railway Co.*, 153 Pa. St. 31, 33, 25 Atl. 651. "The citizen has the same privilege to use the street for travel that the street railway company has for propelling its cars thereon, and the railway company has apart from its franchise to lay its rails, no right to the use of the street as a highway superior in any degree to that possessed by the humblest individual. The franchise to lay its rails upon the bed of a public street gives to the company no right to the exclusive use of that street, and in no respect exempts it from an imperative obligation to exercise due and proper care to avoid injuring persons who have an equal right to use the same thoroughfare. It is bound to take notice of, recognize, and respect the rights of every pedestrian or other traveler; and if, by adopting a motive power which had increased the speed of its cars, it has thereby increased, as common observation demonstrates, the risks and hazards of accident to others, it must, as a reciprocal duty, enlarge to a commensurate extent the degree of vigilance and care necessary to avoid injuries which its own appliances have made more imminent." *Cooke v. Traction Co.*, 80 Md. 551, 554, 31 Atl. 327. "The right of the railway in the street is only an easement to use the highway in common with the public. It has no exclusive right of travel upon its track, and it is bound to use the same care in preventing a collision as is the driver of a wagon or other vehicle." *Rascher v. Railway Co.*, 90 Mich. 413, 51 N. W. 463. "Although, as has been seen, the public have a right to use the whole of the street for travel, and the fact that a portion of it is occupied by the tracks of a street railway company does not deprive them of this right, and they can exercise it in common with the street railways, yet there is this exception: that, as the street railway car cannot leave its track to turn out, it has a paramount right to use that portion of the streets covered by its tracks, but only in so far as that it is the duty of the other teams or travelers to turn out in reasonable time to allow the electric car to pass and avoid accident. The motorman of a car, however, if he sees that the traveler is not turning out, must, on his part, do what he can in the way of stopping the car to avoid collision." *Crow. Electricity*, Sec. 741; *McGee v. Railway Co.*, 102 Mich. 107, 112, 60 N. W. 293; *Montgomery v. Railway Co.*, 103 Mich. 46, 61 N. W. 543; *Beach, Contrib. Neg.*, Sec. 89; *Adolph v. Railroad Co.*, 65 N. Y. 554; *Barker v. Savage*, 45 N. Y. 191; *Belton v. Baxter*, 51 N. Y. 245; *Quinn v. Railroad Co.*, 134 N. Y. 611, 31 N. E. 629; *Carr v. Railway Co.*, 163 Mass. 360, 40 N. E. 185; *Railroad Co. v. Hanlon*, 53 Ala. 70, 81; *Shea v. Railroad Co.*, 44 Cal. 414, 428.

We think the word "superior" or "paramount" when used in the cases cited by the defendant as descriptive of

the rights which an electric car has in a street, means no more than is said in the quotation from *Croswell on Electricity*; that is, that the right which such a car has in a street is only that other travelers shall turn off from its track in reasonable time to allow it to pass, but that the car itself must be so managed as not to do any unreasonable injury to other travelers, and must be stopped if it appears that the other traveler is not turning out. And then the difference between those cases and the cases cited by the plaintiff is in the form of expression and not of real meaning. All the cases then mean the same thing; that is, that the right which an electric car has in a highway is not in its nature higher than the right with the others, in the exercise of which the electric car and the other traveler shall so conduct themselves as not to interfere unreasonably with the just rights of each. *Butler, C. J.*, in the passage above quoted, said that, in the exercise of their common right in a highway, "the loaded team and the light wagon must each pay a due regard to the rights of the other." So the electric car and the other traveler must each pay a due regard to the rights of the other in the exercise of their common right to use the highway. We are very clear that the defendant's argument in this behalf cannot be sustained, and that the court committed no error in holding that the right of the defendant in Congress street at the time of the accident was, in contemplation of the law, no greater than the right of the plaintiff.

(*Supreme Court of Connecticut, Laufer v. Bridgeport Traction Co.*, 37 Atlantic Reporter, 379.)

#### *Motorman Confronted with Sudden Emergency.—Error of Judgment.*

A railway company is not responsible for an accident resulting from an error of judgment on the part of a motorman during an emergency brought about by the carelessness of the plaintiff's intestate. In such a case, where the negligence of the deceased, in the first instance, is fully established, and the subsequent carelessness of the motorman, resulting in the accident, depends upon doubtful and conflicting evidence, the defendant is entitled to have the jury fully and explicitly instructed as to the rule of liability above stated; and failure on the part of the trial judge to give such instruction upon request is reversible error.

(*New York Court of Appeals, Bettenger vs. Cross Town Street Ry. Co.*, 17 New York Law Journal 491.)

#### *Erection of Trolley Poles—Effect of Ordinance Requiring All Wires to Be Underground.*

Acts 1890, c. 271, amending the charter of the Baltimore City Passenger Railway Company, and authorizing it to use improved methods of traction, and any system of propulsion which the mayor and council may authorize other corporations to use within the city, when supplemented by Acts 1892, cc. 210, 232, authorizing other companies to use the trolley system, authorizes such company to erect trolley poles in streets, since they are a necessary part of such a system.

Acts 1890, c. 370, giving the mayor and council of Baltimore power to require all wires to be placed underground, does not authorize the erecting trolley poles in the streets under a charter power to use the trolley system, where the city council has taken no action under such act as to trolley wires.

(*Court of Appeals of Maryland, Hooper, Mayor v. Baltimore City Passenger Ry.* 37 Atlantic Reporter, 359.)

## ADVERTISEMENTS IN STREET CARS.

It is presumable that the value of space in and on street cars for advertising was first thought of in connection with the signs and placards which envelop the old omnibuses especially those in London. The street cars in the United States were not extensively used as a medium of advertising until the last six or eight years. At first this privilege was let to advertising firms at a ridiculously low sum but the street railway companies soon realized the possibilities of such a source of revenue. As soon as the first contracts expired a great many of the companies in the large cities managed the advertising in their own cars. Advertisers were not slow to recognize the value of this medium. Thousands of persons were on the cars each day and as a rule there was nothing to hold their attention. Anything that would catch the eye was sure to make an impression on the minds of those going to and from work or on business and especially women on marketing and shopping tours.

Then the question came up, where to place the advertisements and where they should be forbidden as it would not do to make the handsomely painted and decorated cars unsightly by putting signs promiscuously on the inside and outside. It was found that the most conspicuous and convenient place in the cars is in front of the panels between the side windows and the ventilating windows of the cars. Strips are so fastened to permit cards, upon which are printed the advertising matter, to be held in front of panels. The cards average 11 x 21 in. although in some of the newer and more commodious cars there is room for placards 16 x 24 in. The length is not arbitrary but a standard is adopted probably to give uniform rates in advertising and perhaps to make the arrangement more pleasing to the eye. In the largest cities the rate for such sized cards is about 1½ cents per day per car and a contract is signed for three, six or 12 months. Hand bills are sometimes hung up so that each passenger may tear one off and read it at his leisure. Placards are also hung on the strap rail. On the outside of the cars banners may be fastened to the roof, hangers attached to the dashboard and tin signs tacked to the step risers and illuminated signs are sometimes hung on the trolley cars at night. When a circus or other great attraction comes to a town for a day or two not unfrequently whole cars are rented, gorgeously decorated and run over the whole system without accepting passengers. For such concessions as these street railways often receive fancy prices.

### CAR ADVERTISING ABROAD.

Information has been available from numerous tramway companies in Europe in regard to their advertising. W. Berghaff, of the Berner (Switzerland) Tramway-Gesellschaft, says that an advertising agency attends to the letting of space and placing the signs. The size of the signs is regulated by the manager of the railway company but the construction and material of the signs which are made of wood, pasteboard, glass engraving, etc. are left to the agency. The places available for signs are the rectangular panels above the windows, the panels above the doors, the ceilings except the space occupied by the time tables, the ceilings of the platform roofs, the window panes and the roofs of the cars. The system was inaugurated seven years ago and while there was some adverse criticism in the papers

yet the patrons soon became accustomed to the signs and no objection is now made.

In the future there will be no more signs on the tram-cars in Barcelona, Spain, for in the opinion of General Manager Morris such advertising does not pay.

Quite in contrast to this opinion is that of the secretary of the Dublin United Tramways Company who thinks that advertising is most remunerative and causes little trouble or expense, and this company has had an experience of 20 years in this line. The company deals with the advertisers direct through a separate department of its staff. On the inside of the cars cards are affixed to the roofs on frames and transparent labels are fastened to the window panes; on the exterior, boards are attached to the hand-rails and on the risers of the roof stairs. The outside advertisements are painted on boards supplied and fixed by the company and the inside cards and transparencies are supplied by advertisers, subject to the company's approval. The rates vary slightly, averaging for outside boards about £4 per annum each and for cards, labels, etc. 10s. per car. The contracts are generally for a term of three years.

The Allgemeine Lokal- und Strassenbahn-Gesellschaft,

ADVERTISING ABROAD.

Chemnitz, Germany, has permitted placards on and in the cars since the lines were started in 1880. On the inside the roof is covered with advertising and in two windows on each side of the car ground glass signs are hung. On the outside the doors are available and on exceptional occasions, such as horse races, shows, etc., special posters are carried under the windows. The advertisements must be well printed and neat in appearance and must not contain anything indecent or illegal. The contracts are usually made for one year. Advertisements which do not look well or show age the company has a right to remove by the terms of the contract. The advertisements are printed paper mounted on card board, enameled metal plates and painted metal signs.

The Hamburg-Altonaer Trambahn-Gesellschaft does all its advertising through an advertising agency and this plan has been in operation since 1887. Cards and signs of paper board are permitted on the inside and on the rear end of the outside of the cars. The contracts hold for five years.

On the municipal tram-cars of Glasgow no advertisements are permitted.

The London Street Tramway Company lets the advertising privilege to an agency for a lump sum per year which amounts to about 15 per cent of the net advertising receipts. Medical signs are not allowed nor anything which is objectional to public morality although no interference has ever been necessary in this respect. The inside panels of the roof, the outside of the cars and the tops of the windows are occupied by transparencies. For 25 years this system has been in practice and has given satisfaction.

The Liverpool Overhead Railway Company, ever since its opening in 1893, has granted the advertising franchise to an agency. Signs of galvanized iron and card board are permitted on the inside panels of second class cars only and in no case are the windows covered. General Manager Cottrell considers that all advertising inside the cars should be reduced to a minimum as at best it is objectionable.

The City of Birmingham Tramways Company turns its advertising business over to an agency for a fixed rental per annum. This one advertising firm in Birmingham holds such rights on cars and omnibuses in 30 cities in England which indicates that the transportation companies do not as a rule conduct this part of their business for themselves. In Birmingham the advertising cards and signs are placed both on the inside and on the outside and vary in size and material. The rates depend on the position, size and artistic taste of the signs and the districts through which the cars run.

The cut represents a London car with advertisements on the outside. All the advertising of this line of cars, as well as that of nearly every other system in London is handled by an agency. The entire cost of preparing, painting and maintaining advertisements is borne by the company except preparing cards, bills, glass and enamel plates. Any gold leaf work or illustration is charged at actual cost. For a sign board, 22 in. by 14 ft., the charge would be \$80 a year. Painted staircase bands, 12 in. by 4 ft., cost \$40 per annum; step risers, 7 by 15 in., \$1.25, and cards on the inside, 8 by 25 in. or thereabouts, \$3.50 per year. Special terms are quoted in proportion to the amount and length of contract.

Although advertising has not been successful everywhere yet it can hardly be questioned that in a prosperous and populous community it is a valuable medium to the advertisers and can be made a source of considerable revenue to the street railway companies.

### CONSOLIDATION IN BALTIMORE.

After discussing consolidation for several years a satisfactory arrangement between the Baltimore Traction Company and the City & Suburban Railway Company was reached and the deal completed on June 17. The new company, which is known as the Baltimore Consolidated Railway Company, has an authorized capital of \$10,000,000, and a mortgage has been executed to secure an issue of \$12,000,000 of bonds which will be exchanged for the obligations of the old companies as the latter become due. The total mileage of the Consolidated is 184.34 miles. The officers are Nelson Perin (president of the City & Suburban), president; William A. House (president of the Traction), vice-president and general manager; F. S. Hambleton, treasurer; T. C. Jenkins, secretary.

One of the first changes made by the Consolidated was to abolish the sale of six tickets for 25 cents; this rate was established by the City & Suburban before the fares to out-

lying points were reduced from 10 to 5 cents and it was found that the burden was too heavy and constantly increasing. Transfers will also be limited to a single transfer for each fare, and the routes rearranged so that all portions of the city may be reached with the one transfer. This step was necessary because of the abuses to which the old system was subjected by passengers who took advantage of busy hours to give the conductor old tickets.

### J. E. GRIST.

James Edward Grist, mechanical engineer and superintendent of the Pennsylvania Iron Works Company, Philadelphia, died on May 23, of Bright's disease.

Mr. Grist was born in Wolverton, England, in October, 1854, and was the son of B. W. Grist, vice-president and general manager of the Pennsylvania Iron Works Company. He came to this country with his father at an early age. After a preparatory education and studies under private tuition, he entered the shops of his father at Reading, Pa., where he remained until he had served his apprenticeship. Developing marked ability in this direction, he

JAMES E. GRIST.

rose rapidly until he obtained the position of the superintendent of the shops. In 1887 the firm of B. W. Grist & Co. was consolidated into the Pennsylvania Iron Works Company, Philadelphia, and Mr. Grist was offered and accepted the position of superintendent of that company, which position he held with merited success until 1894 when he resigned to accept the position of mechanical engineer and superintendent of motive power and mechanical equipment of the Philadelphia

Traction Company which position he held for two years, when he resigned to accept the position of engineer-in-chief of the Pennsylvania Iron Works Company, which desired his services in the construction of several very large steam and power plants which it was erecting. He conducted this work up until the time of his death. Mr. Grist was a great student, having taken a special course in mechanical engineering and higher mathematics at the University of Pennsylvania under the tuition of Prof. Goodspeed.

His loss will be keenly felt by the many who knew him, as he was not only congenial but, having a fund of information at hand, a most interesting companion, and his death has caused a vacancy in the profession of his choice which it will be hard to fill.

The Pennsylvania Railroad Company made an effort to prevent the East Penn Traction Company from laying its tracks along Bridge street in Morrisville, Pa. The city authorities granted to the street railway company a franchise along this street, and the citizens are very desirous of having the line constructed. The Pennsylvania sent 200 Italians and yard men to interfere with the workmen of the Traction Company, but the street railway men held their ground and the work continued.

## SOME REMARKS ON STREET RAILWAY REPAIR SHOP MANAGEMENT.

BY FRANK B. PORTER.

In order to successfully operate street railway repair shops, all methods of procedure should be reduced to system, after it has been demonstrated that such methods are applicable, and effect a saving in time or labor. Let us consider a few of these methods which have been commended and adopted by some systems, but which, in the large majority of repair shops, have not been tried.

In nearly all shops the larger and more expensive tools used in setting up the motor, are kept in stock and furnished to the workmen, such as chain blocks, chain block stands, armature slings, special large wrenches, etc., but it is usually customary for the repair men to furnish individual tools, smaller tools that come into more frequent use, as pliers, hammer, screw driver, etc.

It has, however, been the writer's experience that many men when hired come to work with a very limited supply of tools, which is naturally to be expected, as extra men are employed when there is a rush of work, such as changing over from summer to winter cars, and vice versa, and a month afterwards, when the work is completed, discharged. This also happens at the close of a busy season, on the adoption of an improved motor with less wearing parts, on retrenchment by the management, etc., consequently an employe feels that he cannot afford to fully equip himself with tools. He borrows until he has some assurance as to the permanency of his position. The old hands, however, gradually acquire the needed supply, hence, when a crew (usually two men, one being in charge) is sent to repair a motor, or truck, change an armature, or put on new brakeshoes, there commences a hunting for a certain sized wrench they lack, a borrowing of this or that tool from some one else, which consumes time that might have been employed in doing the work. Twenty minutes is sometimes spent in this manner and the repairs made in ten, after what is wanted is found. There exist shops in which, without exaggeration, one-third of the working day is spent in the getting together of the tools and material required on the work of the other two-thirds. This is plainly a waste in efficiency of the working force. More men are employed under this condition of affairs than would be needed if each man's time was utilized in actual repairing, and consequently the expense of maintenance is largely increased.

I would suggest as the best remedy for this state of affairs, that the management keep in stock, boxes with their necessary equipment of tools, to be furnished and charged up to the repair men, when they are put to work. A number should be painted or stamped on each box, and every tool it contains should be stamped with the same and with the company's name. The shop foreman should inspect these equipments at stated times, say on the first and fifteenth of each month, and a man who was short of the equipment charged to him, if he could not produce the missing tool, or tools, after a reasonable time, should have their actual cost to the company deducted from his pay. Tools worn out, or broken in fair service, without abuse, to be renewed at the company's expense. This latter, however, would prove a very small item. If it is thought best to reduce the force at any time, the equipment of the men who are laid off can be examined, and if found complete, credited to them. They

may then be placed in the storehouse and issued again when necessary. These tool boxes need not be large, expensive affairs, indeed it is preferable to have hand boxes, that the men can take from car to car with them, as they complete repairs on one and are sent to another. They should, however, be provided with lock and key, otherwise the man has no assurance as to the safety of his tools.

As to the number and kind of tools to be furnished, the list here given, while being comparatively inexpensive, will fill the usual requirements. If tools of special design, for work on a certain class of motors are needed, they can be added.

### TOOL LIST.

|                                                        |                                |
|--------------------------------------------------------|--------------------------------|
| 1 Ball-peen hammer.                                    | 1 Screw driver 12-in.          |
| 1 Pair 8-in. side cutting pliers.                      | 1 " " 4-in.                    |
| 1 Monkey wrench 12-in.                                 | 1 Cold chisel 12x 5/8-in.      |
| 1 " " 5-in.                                            | 1 Cape chisel.                 |
| 1 Set double end steel S wrenches, 3/8 to 1 1/4-in.    | 1 Round nose chisel.           |
| 1 Drift punch 1/2-in. steel drawn to 3/8-in. on point. | 1 Key punch.                   |
| 1 Bearing scraper.                                     | 1 14-in. double cut flat file. |
| 1 Oil can, 1/2 pint.                                   | 1 14-in. half round file.      |
| 1 Ball insulating tape.                                | 1 14-in. Stills-n wrench.      |
| An assortment of cotter pins.                          | 4 Motor brush carbons.         |
|                                                        | 4 Two-way connectors.          |

The large tools before mentioned, known as shop tools should be supplied in sufficient quantity so that when several crews want, say a pair of chain blocks at the same time, one would not have to wait on another. Also these tools and appliances should be kept in a certain, suitable place, or places, to which they must be returned when finished with, and not left where last used, as is sometimes the case and which necessitates a hunt.

Again in the matter of material used, there is in most shops a chance for improvement. In many cases when something is wanted, as a gear, or bearing, a repair man goes to the foreman, who gives him an order on the storehouse, but should this foreman happen to be out on the road, trying a car, as is sometimes the case, there is a delay and two men may be idle until he returns.

Somewhere in the shop, in which the work is being done, there should be a room partitioned, or fenced off, supplied with the necessary shelves, racks, bins, etc., and used as a sub-storeroom. Let a man be put in charge of this whose business it is to see that the stock is kept up, drawing from the main storehouse. He should not leave this storeroom during the working day, unless someone be first called as a substitute. Here the repair man may come and receive what is needed, upon writing out an order, stating car and truck number for which it is wanted, and also returning the old material which it replaces. It is not good practice to have such a storeroom with no one in charge, allowing the men to go in and help themselves, as is sometimes done, for it is the writer's experience in such cases it is usually in admirable disorder, the hand cannot be laid upon what is wanted and the object of the sub-storeroom, that of speedy supply, largely frustrated. Again such a method is a direct temptation to a man who may want a few bolts or screws, to fix this or that at home, who would never go to the length of presenting a formal, fraudulent order for them.

The person in charge of the sub-storeroom, by means of the order, can also keep account of all material used on the cars, and each car separately, if so desired, and if the duties of his position are not sufficient to keep him fully employed,

he spare time can be utilized in checking up the men's time, etc.

Certainly the foreman of the repair shop should pass on the repairs of each motor and instruct the crew what parts to replace, but in the process of repair, as a bolt or screw may be needed, to chase off after an order from the foreman, whom it may take sometime to find, and then perhaps half a block to the main storehouse after the material, is nonsense and a waste of time that might be more usefully employed.

The practice of keeping a scrap pile of bolts, etc., and having the men hunt it over when in want of a certain sized bolt, or nut, is not to be commended, for the equivalent in money of the time spent in pawing over this pile, would purchase a dozen of the needed bolts. All old material should be taken to the sub-storeroom, as before mentioned, where it should be sorted over and that which may be used again, in case of emergency, placed in its respective rack, or bin, as second hand material, and the rest relegated to the scrap pile, which need never be hunted over, after this sorting. Damaged bolts, or nuts may be sent to the bolt cutter, and when cut over, returned to the sub-storeroom and put in their places in the bolt rack to be reissued upon order.

There should be absolutely no cause for a repair man to spend time in looking for anything, all material being kept at the sub-storeroom, himself having the smaller tools more frequently used, and the other or shop tools being kept in regular places.

By systematically following the above methods, a considerable saving in labor will result, in a few months more than compensating for the slight expense incurred upon introduction.

Another suggestion which the writer would like to make is in regard to personnel of the repair men employed in the erection or dismantling of the motor, such as occurs in changing armatures, fields, gears, etc. It has been before noted that they are usually divided into crews of two men each, one man being the master workman, and the other his helper. The master workman is generally one who has had considerable experience in motor repairing, but usually is not a machinist. The helper, also not a machinist, may have had experience, or may have lately seen a street railway motor for the first time.

When it is necessary to employ men for repairing, and experienced ones are not available, it will be found to the interest of the management to hire mechanics, preferably machinists, if possible. The repairs to street railway motors come largely within the machinist's trade, as the fitting of bearings, gears, keys, etc. The machinist is also conversant with the individual manufacture of each machine part, for he has turned bearings in the lathe, cut gears in the gear cutter, and planed the keys in the planer, or shaper. This preliminary training fits him to easily and intelligently grasp all of the principles of motor repair and turn out better work than the man who has come from other vocations.

It is true that the machinist must also serve a short apprenticeship, in order to learn somewhat of the electrical nature of the motor, the importance of insulation in certain places, an idea of the path of the current through the motor, the characteristic actions of a motor with burnt out armature coil, or short circuited field, etc. After this is obtained he should be advanced to a master workmanship as soon as practical. The electrical knowledge of the repair man in this department usually is and need not be other than meager, for the skilled electrical work does not come within

his sphere of usefulness, the winding of armatures and fields, car wiring, testing, etc., being done in other departments by specially trained men. Four-fifths of his work is that of the machinist. The increase in wages demanded by trained help would be more than compensated for in the ultimate improved character of the work turned out. A permanent master workman's helper, however, need not be a machinist, but a bright man with good mechanical ideas, and a fair amount of manual dexterity, and there is, or should be, a difference in the wages received by workman and helper.

In the round house of some street railway repair shops, where untrained men have been employed, it has been found expedient to employ a machinist as a fitter and inspector. Each crew summons him when something is to be fitted, as a gear or bearing. This is done by him, or under his direction, he also inspecting all work before it is pronounced completed. This method may commend itself to some.

Still another idea, which will be found advantageous in practice, is the carrying of an extra list of repair men, similar to the extra list of motormen and conductors, though certainly on a smaller scale, proportionate to the number of men employed on repairs. These extras to report to the master mechanic, or assistant, at a stated time, morning and night, then if there are vacancies in the shop force by reason of sickness, or otherwise, the place of the missing man can be supplied, and in this connection it may be stated that the writer has known of many instances where a repair man after working from 7 a. m. to 6 p. m. during the day, has been called upon to return and work 10 hours that same night, in place of a night man who was sick; he is aware of a case where a man was discharged for refusing to return. This is bad practice, and under proper management unnecessary. It is not to be supposed that a man who has worked 10 hours at fatiguing work during the day, can do justice to his work for another 10 hours the same night; it will necessarily be slighted. A fresh man should be available and the company is the gainer, the wages presumably being the same in each case.

In cases of severe storms, when many motors are crippled, the force of extras may be called upon if needed, also at times of special work, as the changing over from summer to winter equipment, before alluded to, and upon any permanent vacancy in the shop, there is a trained man ready for the place, the oldest extra receiving steady employment.

Again in many street railway repair shops, it is customary to have seven working days in the week. It is doubtful if this is necessary. If the work cannot be done in six days, by working all the extras Saturday it seems as if the shop might be closed on Sunday. This would also be a matter of economy, for the increased expense incurred by reason of a few extra men working Saturdays, would be more than counterbalanced by a saving of one-seventh in the shop pay roll, caused by stopping all work one day. That the men would return to work Monday morning in much better condition for another week's labor, it is needless to argue.

It might be found desirable to keep a wrecking crew in attendance Sundays, in case of a blockaded line, by reason of cars off of the track, etc., but it is not a necessity, for in some systems the wrecking car is placed in the car house Saturday eve, and if called out Sunday is manned by the foreman of the train crews and some of his assistants. The getting of a street car on the track requires but little training or experience. After a few trials the motorman, with

the proper equipment of jacks etc., contained in the wrecking car, is as expert as the shop hand.

Certainly if men are worked 10 hours at heavy, laborious work, they should have one day off in seven, and if the management requires the presence of all on Sundays, they should be granted a day off during the week, a systematic routine being followed. Here again is seen the convenience of having an extra list.

The improvement in methods of shop management here noted are practical and easily applied, and will be found to effect a saving, both in efficiency of the work of the men, and the cheerfulness and care with which the work is performed.

## MINERAL PRODUCTS OF THE U. S.

The Department of the Interior has recently published a table showing the quantity and the value of the minerals mined in the United States for the calendar years from 1887 to 1896, inclusive. A comparison between the present production and that of 10 years ago for a few of the more important products may be of interest.

|                                                     |             |                  |
|-----------------------------------------------------|-------------|------------------|
|                                                     | 1887.       | 1896.            |
| Pig iron, long tons,                                | 6,417,148   | 8,623,127        |
| Value, dollars,                                     | 121,625,800 | 90,250,000       |
| Per ton,                                            | 19.00       | 10.46            |
| Copper, pounds,                                     | 185,227,331 | 453,007,139      |
| Value at New York, dollars,                         | 21,115,916  | 48,698,267       |
| Per pound,                                          | .114        | .107             |
| Aluminum, pounds,                                   | 18,000      | 1,500,000        |

| Value, dollars,                                     | 84,542,181  | 81,415,785       |
| Per ton,                                            | 2.25        | 1.69             |

## BEVEL GEAR BRAKE HANDLES IN VESTIBULES.

The Des Moines City Railway has a bevel gear brake wheel and handle in its vestibuled cars that works so nicely as to almost be an improvement on the common lever brake. To avoid having the vestibules project out in front of the dash to provide for the brake handle as is usual when the dashboard is retained on cars provided with home made vestibules, the brake wheel and handle is placed close up against the vestibule wall with its axle horizontal and the brake staff is geared to it by a bevel gear. It is found by having the brake wheel in this position that it is easier to handle quickly than when worked in a horizontal plane. The bevel gear works very easily and each journal is provided with two bearings, one on each side of each gear wheel, so that the arrangement is thoroughly substantial. Of course the brake was put on in the first place to secure more room in the vestibule and to provide against the necessity of making a projection in the vestibule, but at the same time another desirable point seems to have been secured, viz., ease and rapidity of operation.

On June 5 the Rockford, Ill., street cars were turned over to the Ladies' Aid Society and the latter netted nearly \$1,000.

## FENDERS AT YOUNGSTOWN.

The half-tone illustration represents the type of fender which has been applied to the cars of the Youngstown (O.) Street Railroad Company. There is a great variety of platforms on the cars and it was necessary to so design the attach-

FENDER AT YOUNGSTOWN, O.

ment for the fender that it would be interchangeable from one car to another. The cars are not turned around at the ends of the lines and it is necessary for the motorman to change the fender from one end of the car to the other. The two cuts show in detail the malleable iron bracket and the wrought

iron head of the fender iron. From the design it is readily seen the fender can be easily and quickly removed. The fenders are carried from 6 to 8 in. above the rail and cannot be dropped any lower.

The fender proper is made of oak, iron clad at the corners, and the net work is of rope.

In service it seems to answer every requirement. General Manager Anderson wrote that one of the cars collided with a bicycle rider, and both the young man and the wheel were picked up by the fender without injury to either. Only the interurban road between Hazelton, Youngstown, Brier Hill, Girard and Niles is now equipped but the other lines will soon have this type of fenders.

## THE COLOR LINE IN GEORGIA.

It appears that the question of accommodating a mixed population on the street cars is still giving trouble in Georgia. The state law requiring that railroad companies shall provide separate cars or compartments and conductors to assign passengers to their respective cars, and conferring police powers upon them is applicable to street, electric and dummy roads; but apparently this law is not enforced on the street railways as rigorously as some desire and hence dissatisfaction has arisen.

## CIRCUS ADVERTISING AT MINNEAPOLIS.

Last month it so happened that two of the largest circus and menagerie aggregations in the country were billed for Minneapolis at the same time, and this circumstance was the means of bringing in a rather unexpected profit to the Twin City Rapid Transit Company. One circus secured before the other all the bill boards in the city and this forced the tardy one to seek some other form of advertising. Being shrewd advertising managers they naturally looked first to the street railway. It is safe to say that the result as it finally appeared on the streets was fully equal to stationary bill board advertising. Bill boards were made the exact length and height of some of the company's long double truck cars. These when done compared favorably as to size with an ordinary circus bill board and were fastened onto the sides of several long cars. These cars were run through the streets for advertising purposes only and carried no passengers. The bill boards being the full length and height of a car, the combination was a very imposing affair when in motion. The advertisements of the circus were also generously scattered through the regular passenger cars.

## FRANCHISES IN NEW YORK.

The charter of Greater New York provides that street railway franchises granted by the Municipal Assembly shall not be for a longer period than 25 years, with the proviso that the grant may contain provisions for a renewal at a fair revaluation for another period of 25 years. Grants may also provide that at the end of the term the property shall vest in the city either without compensation being made, or it may provide that the city shall purchase the property at a fair valuation.

If by virtue of the grant or contract the plant and property are to become the city's, without money payment therefor, the city shall have the option either to take and operate the property on its own account, or to renew the said grant for not exceeding 20 years upon a fair revaluation, or to lease the same to others for a term not exceeding 20 years. If the original grant shall provide that the city shall make payment for the plant and property, such payment shall be at a fair valuation of the same as property excluding any value derived from the franchise; and if the city shall make payment for such plant and property it shall in that event operate the plant and property on its own account for at least five years, after which it may determine either to continue such operation on its own account, or to lease the plant and property and the right to use the streets and public places in connection therewith for limited periods, in the same or similar manner as it leases its ferries and docks. Every grant shall make adequate provision, by way of forfeiture of the grant or otherwise, to secure efficiency of public service at reasonable rates, and the maintenance of the property in good condition throughout the full term of the grant. The grant or contract shall also specify the mode of determining the valuations and revaluations therein provided for.

It is claimed that by the terms of the charter the present Board of Aldermen is deprived of its power to grant franchises and that there can be no more grants until the Municipal Assembly goes into power on January 1, 1898, which is to the disadvantage of roads seeking extensions.

## THE BUFFALO FENDER.

The fender herewith described is one designed by R. Dunning, master mechanic of the Buffalo Street Railway Company and has a very creditable record. The cut shows the netting and the frame work which is 2 ft. 5 in. by 6 ft. 2½ in. The frame is made of second growth of hickory, 1½ x 1½ in., with light malleable iron corners. All parts of the frame work are sawed and tenoned to templates or gages so that all parts are interchangeable. The rope used as netting is known as ¼-in. ratline and is very cheap and durable. The support to which the netting frame is bolted

is made of crucible steel, ¾ in. x 2 in., the upper plate being 5 ft. 1 in. and the lower one 3 ft. 9 in. long. These plates are easily bent over a form and the two men are capable of turning out enough in a day for 50 guards. Along the front of the frame and extending 18 in. on each side is fastened a 1½-in. three ply rubber hose by fill bolts spaced 18 in. apart. The pockets which receive the guard are made of malleable iron and are arranged so that the guards are interchangeable on all the cars. On the Buffalo lines the guard is changed from one end to the other at each terminus. This is easily and quickly done and necessitates but one fender for each car. The guard is held about 6 in. above the track. Since the Buffalo cars have been so equipped 323 persons have been picked up safely.

## BACK PAY FOR ALLEY "L" EMPLOYES.

When the Chicago & South Side Rapid Transit Company commenced operation in January, 1893, a sliding scale of wages was agreed upon, the company signing individual contracts with the men. This agreement was not adhered to and in the controversy which followed some of the men surrendered their contracts. When, in 1896, the bondholders brought suit to foreclose, the employes who had retained their contracts petitioned the court to have their claims for back pay made a prior lien on the assets of the company. The decision of the master in chancery to whom the matter was referred is that all employes are entitled to pay for two hours extra per day and those who retained their contracts to extra compensation according to the sliding scale for the term of three years.

## STREET RAILWAY MAIL SERVICE JURISDICTION.

The postal authorities have decided to place all street car mail service employes under the direction of the postmaster of the city in which they are employed. The crews of street postal cars are detailed from the railway mail service but by virtue of this order they will report to the postmaster when so detailed.

THE USE OF ALTERNATING CURRENT.

Comparative Amount of Copper Required — European Dynamo Construction—Some Illustrations of American Dynamo Practice—Lightning Arresters—Types of Transformers—Transformer Losses.

PART II.

In transmitting electrical energy for power purposes single phase alternating currents are hardly to be considered, the choice lying between the two and three phase systems. The weight and cost of generators is nearly the same for each but the copper used in the lines is less for the three phase system as shown in the following table:

|                                         | A | B   |
|-----------------------------------------|---|-----|
| Single phase.....                       | 2 | 100 |
| Single phase.....                       | 3 | 32  |
| Two phase.....                          | 3 | 72  |
| Two phase.....                          | 4 | 100 |
| Three phase (Y connection).....         | 3 | 25  |
| Three phase ( $\Delta$ connection)..... | 3 | 75  |

In column A, the number of wires for the line is given and B indicates the per cent of copper used in the trans-

FIG. 8—WESTINGHOUSE GENERATOR.

mission lines, the copper required in the two wires of a single phase system being taken as 100 per cent. In actual practice allowance would be made for the loss due to self-induction and other causes which increase the amount of copper.

An alternating current generator or motor is composed of two principal parts, a stator and a rotor. In the United States the practice has been to make the armature the rotor, or the moving part while in Europe it has been the reverse.

FIG. 9—SECTION AND ELEVATION OF GENERATOR.

At Niagara, however, the armature is the stationary part. The advantage of having the stator for the alternating circuit is that it can be safely insulated for very high voltages.

A Westinghouse type of two phase, steam driven generator is shown by Fig. 8. The laminated pole pieces are built up of steel punchings, riveted together and the yoke is cast solidly about them. The field current is supplied from a rotary transformer and passes through one winding on each pole piece. As can be seen in the cut the armature core is built up on a hub and spider, and contains 92 slots for the bar armature winding. The winding is divided into four parts and connections are made to the four collector rings. This machine has an efficiency of 95 per cent with an output of 400 amperes at 240 volts and a frequency of 50. For the larger sizes of alternators rotary converters are used to excite the fields.

Figs. 9, 10, 11 give a good idea of recent European practice in the construction of three phase generators. These

FIG. 10—DIAGRAM OF THREE-PHASE GENERATOR.

FIG. 11—VERTICAL SECTION.

dynamos are now being put in place at Rheinfelden on the Rhine, where a fall of from 8 to 16 ft. is to be utilized to generate about 11,000 h. p. This installation was recently described in the London Electrician. The current is to be used for lighting and power purposes, a large aluminum and calcium carbide works are now building and electric railways connecting Basle with Zurich and Constance are to be constructed. These different kinds of service had to be considered when designing the dynamos. A frequency of 50 was decided upon and a difference of potential of 3,900 volts for each phase or 6,800 between each pair of mains. The dynamos are of the inductor type and will give 61.5 amperes at that voltage, or 720 k. w. apparently, but with a power factor of .8 and an efficiency of about 92 per cent. No step-up transformers will be used. The 20 machines will be excited by three rotary converters. As shown in the cuts the fields form the rotor and are supported by the verti-

cal shaft running from the turbine. About the armature rings A A, are wound the coils which fill in the slots L L; the exciting coil M, is attached rigidly to the case. Thus the seven pole pieces revolve and the points of highest magnetic induction in the armature change periodically. The displacement of the coils with respect to the poles enables a polyphase current to be collected. The magnetic circuit is indicated by the dotted lines in Figs. 10 and 11.

FIG. 12—S. K. C. GENERATOR.

Fig. 12 represents a 600-k. w. alternator made by the Stanley Electric Manufacturing Company with the armature drawn apart. The field coil is wound on a copper spool and is stationary in the center of the machine sur-

FIG. 13—NON-ARCING METAL LIGHTNING ARRESTER.

rounding the inductor. The stationary armature is made of iron laminae in which are grooves to hold the small coils. This construction permits thorough insulation and the generation of high voltage, as much as 10,000 when desired. By means of levers or wheels the armature may be drawn apart and all the coils made easily accessible. From half to full load these generators have an efficiency of from 80 to 95 per cent and regulate very closely.

Two or more alternate current generators of approximately the same frequency and voltage can be run in parallel and their currents will be added algebraically. They

can not be connected in series because the machine whose electromotive force is lagging will be retarded and fall farther behind until the phase is opposite and no current passes.

The generators in an alternate current system are usually of high efficiency and admirably suited to the work, but as soon as the current leaves the collector rings the serious problems arise for the electrician.

In deciding upon the voltage for the transmission line the additional cost of step-up and step-down transformers for high voltages should be balanced against the added cost of copper for a lower potential. For distances of 10 miles and over it is economical to use a voltage of 10,000 with step-down transformers. If a three phase system be adopted

for transmission the load should be distributed equally between the three branches, not only in size but in kind. A non-inductive load on one wire and an inductive load on the other will cause an unbalancing. However, for street railway work the load on each line would be the same and little trouble would be experienced from this source.

With transmission lines one serious problem has been the protection of the apparatus against lightning. Several arresters have been devised which answer the purpose very well. The Wurts arrester is shown in Fig. 13 and consists of parallel cylinders of "non-arcing" metals, such as combinations of zinc and antimony. When a static discharge takes place the flash is instantaneous and is not followed by an arc. The lightning discharge passes across these air gaps in preference to entering the coils of the machine for these possess great self-induction to a highly oscillatory discharge of lightning. Acting on this principle "choke-coils" are introduced into the line. These consist of a few circular turns in circuit

which have little self-induction with the normal current and frequency, but when a lightning discharge is passing over the line the self-induction becomes very great. Fig. 14 represents a lightning arrester made by the Siemens & Halske Company for alternating currents of high potential. The distance between the wires at the nearest point is about .04 in. for each 1,000 volts on the line. When an arc is formed an ascending current of warm air and the action of the current in the wire cause the arc to rise and break on account of the separation of the wires.

FIG. 14—S. & H. LIGHTNING ARRESTER.

FIG. 15—GARTON ARRESTER.

The Garton lightning arrester is shown in Fig. 15. Its construction is such that it offers to the static discharge a non-inductive path to the earth. It is composed of a solenoid, plunger or armature, carbon discharge points, an air chamber and a non-inductive discharge path. When not in action the arrester carries no current and is alive at the

moment of operation only, when it requires about one-half an ampere for operation. These arresters are made for direct and alternating currents of high and low potential and also for different frequencies. The same principle is involved for the various currents and tensions, the difference in the arrester being only in the adjustment and resistance. A kicking coil is placed between the apparatus and the arrester, i. e. the coil is cut into the main circuit carrying the current, while the arrester is tapped to the feeder or line, on the line side

FIG. 16—G. E. TRANSFORMER COILS.

of the kicking coil, thus the inductive effect of the kicking coil tends to drive back the discharge to the arrester.

While arresters protect the apparatus yet it is desirable, if possible, to keep the discharge entirely off the line and this has been accomplished by running an iron wire on the top of the poles above the transmission lines and grounding it carefully at intervals. This practice has been successful on the Niagara, the Montmorency and other large transmission lines.

Although alternators are designed for voltages as high as 10,000 yet as a rule, step-up transformers are employed to raise the voltage from about 2,000 to 10,000 for the line. At the other end step-down transformers are used to lower the voltage to about 500 for rotary converters or for power purposes. The General Electric type of transformer for long distance work is represented by Fig. 16. This is known as the natural draft transformer and voltages are successfully reduced from 10,000 to 125 without intermediate apparatus. The eight coils are mounted firmly upon an iron base and covered with corrugated iron sheeting. The primary, or 10,000 volt circuit coils are well taped and bound and insulated from each other by thick layers of felt.

Figs. 17 and 18 show the Westinghouse type of self-cooling transformer in which oil is principally relied upon for insulation. The coils are wound with few turns per layer and many layers, being separately insulated and placed vertically in position which arrangement allows a ready circulation of oil at the end of the transformer. The high voltage coils are connected in series and divide the electromotive force among a number of coils, thus reducing the stress within each coil. There are many good features in the use of a first class oil, having a high fire test, as it permeates every crevice between the wires and coils and it does not break or

crack as do other insulators. In large transformers special provision must be made for radiating the heat generated, for the surfaces are quite small in proportion to the power transformed. Some are provided with an air blast or have natural ventilation. When oil is used with an open design of coils and the case is properly formed there will be a steady circulation and the oil will conduct the heat from the wires to the surface of the case.

In the primary circuit, the low voltage coil in a step-up transformer and the high voltage coil in a step-down transformer, energy is consumed, and in the secondary almost an equal amount of energy is produced, the power being transmitted in the form of magnetic lines through the iron core from the primary to the secondary. The transformer is a very efficient piece of mechanism; in the large types but two and sometimes as little as one per cent of the energy transformed being lost.

This is divided up between the  $C^2 R$  loss or the energy lost in heat in the circuit and the heating, resulting from the magnetic reversals in the iron.

The magnetic loss is due to the cross flux between the primary and secondary, surrounding one coil only, without being interlinked with the other. This is but a small por-

FIG. 17—WESTINGHOUSE TRANSFORMER COILS.

FIG. 18—WESTINGHOUSE TRANSFORMER.

tion of the total flux. The magnetic cross flux is proportional to the current flowing in the circuit and constitutes the so-called self-induction of the transformer. The loss in the iron is practically constant, regardless of the load, for the frequency remains the same but the heating effect in the circuit is proportional to the square of the current. Great care should be exercised in the selection of the iron for the laminated cores, for the core loss may become a considerable factor. Some iron when subjected to alternating magnetism becomes fatigued, magnetically, and after a short interval of service the core loss may increase 25 to 100 per cent. When properly designed, transformers require little attention few repairs, and form the strongest feature about the transmission system. They can be so insulated that enormous potentials, above anything now discussed, can be transformed with safety. Should it be desired to generate the current with two phase machines and have a three phase transmission, as is the case at Niagara Falls, transformers can be designed to receive the two-phase current at, say, 2,200 volts, and transform it into a three phase current of 11,000 volts.

### WOODEN TROLLEY WIRE HANGERS AT DES MOINES.

For about five years past the Des Moines City Railway has had some wooden trolley wire insulating hangers in service, and the results have been so satisfactory that this form of hanger is used on all new work and all repair work on that road. The hanger is the design of W. G. Owens, superintendent, by whose courtesy we are enabled to show the accompanying engraving of one of these hangers

It is made of selected oak and is painted for protection against the weather. A slot is cut in one side into which the nut which holds the clip bolt is inserted. This slot is filled with a tight fitting wood plug. The arrangement is shown by the sections herewith illustrated. A wooden strain insulator is also used by this road. It is surprising how well wood stands up under 500 volts. In some cases this combination of wood trolley wire hanger and wood strain insulator is used on iron bridges with success.

In a suit against the Third avenue road of New York for damages the plaintiff having lost an eye by being struck with a span wire which broke, the decision adverse to the company was reversed and a new trial ordered because of error in the charge of the trial judge. An electric light wire was carried on the same pole which supported the span wire, and it was not proved that the accident was due to any negligence of the railway company.

### KITE CAUSES A BLOCKADE.

About a year ago it was discovered that the cause of trouble which some western roads had with the brakes on their freight cars which did not release properly was due to wasps. The insects deposited their larvæ in the passage through which the air escaped from the cylinder. This was thought to be an extremely novel enemy to railroading, but the Chicago City Railway reports an equally unexpected cause of delay though it is not of the same nature. Recently the wreck wagon was called out to care for an electric car which was reported to "run all right once in a while and then stop altogether." The motors, controller and wiring were inspected and found all right and then the trolley wheel was examined and it was found to be wound about half full of soft cotton twine, part of a kite string that had been picked up. The car would run only when the trolley was pressed to one side so as to let the upper part of the flange of the wheel make the contact.

### MANAGERS EXCUSED FROM JURY DUTY.

It has been discovered, and the discovery was in the nature of a surprise, that in California superintendents of street railways are exempt from serving as jurors. The statute was first brought to the attention of the court when invoked by E. P. Vining, general manager of the Market Street Railway Company.

### FRANCHISE FORFEITED.

All street railways do not pay and some times they cease operation. One that found the expense of operation too heavy is the Tower & Soudan Street Railway of Minnesota. The decision of the supreme court in the case of the city of Soudan against the receiver for the forfeiture of the franchises of the company was decided in favor of the city. The ordinance granting the franchise expressly provided that in the event of the company failing to operate the road for the period of one year all rights granted to it should revert to the city.

### ASSEMBLY HALL FOR THE CONVENTION.

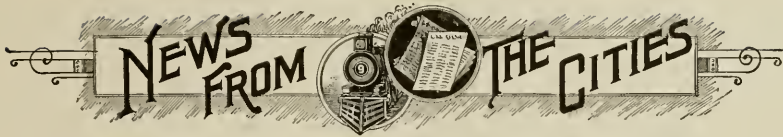

The illustration shows the arrangement and dimensions of the second floor of the building provided for the accommodation of the American Street Railway Association at the

SECOND FLOOR OF CONVENTION HALL.

coming convention in Niagara Falls. The assembly hall in which the business sessions will be held is 35x46 ft., and is reached only through the exhibit room.

# NEWS FROM THE CITIES

## California.

LOS ANGELES, CAL.—E. P. Clark has accepted his franchise for an electric railway over Daly street.

SALINAS, CAL.—The first assessment of 10 per cent has been paid on the stock of the electric car line from Salinas to the beet sugar factory.

VENTURA, CAL.—The Ventura Street Railroad has been purchased by Mr. Lloyd. The road is 1.25 miles long, and was built nine years ago at a cost of \$10,000.

LOS ANGELES, CAL.—E. J. Baldwin is said to contemplate constructing an electric railroad from the Santa Anita Canyon to the northern end of the San Gabriel Canyon.

BERKELEY, CAL.—Citizens of West Berkeley talk of forming a company to build a car line. One of those interested is Walter N. Heywood of the West Berkeley Improvement Club.

SAN FRANCISCO, CAL.—Nicholas Ohlandt and J. A. Buch have been given judgment against Behrend Joost for \$279,108, the amount borrowed by him to build the San Mateo Electric Railway.

LOS ANGELES, CAL.—The Los Angeles & Redondo Railway Company has not yet determined to electrify, but steps will be taken to this end at no far distant date. As yet no contracts have been entered into for electrical equipment.

OAKLAND, CAL.—A big central power house will be built to operate all the lines of the city, except the Haywards, which have been recently acquired by the Realty Syndicate Company, a corporation controlled by F. M. Smith, Frank Havens and others.

OAKLAND, CAL.—E. C. Harlow has been appointed commissioner for the sale under foreclosure of the East Oakland Street Railway. Judge Ogden awards the California Safe Deposit & Trust Company, which brought suit several months ago, \$240,641, and attorney's fee of \$7,000.

REDDING, CAL.—An electric road is to be built from Redding into Trinity county by the recently incorporated Cosmos Land & Water Company. Capitalists of San Francisco and Los Angeles will establish a water power electric plant at the confluence of the McCloud and Pitt rivers, to operate the proposed railway.

LOS ANGELES, CAL.—E. C. Webster says the work of extending the local electric lines will begin on the arrival of Col. C. W. Smith. The loop on North Los Robles avenue will be constructed and the other extensions will rapidly follow. A cargo of ties has already arrived in Los Angeles and the rails are on hand.

SAN FRANCISCO, CAL.—Engineers are running lines for the new road which the San Francisco & San Mateo Railway Company proposes to build. The entire system is to be reconstructed, beginning with the main line on Harrison and Guerrero streets. As soon as this is completed other routes will be looked after and franchises obtained for extensions. It is expected that a number of new cars will be constructed.

LOS ANGELES, CAL.—Stockholders of the Temple Street Cable Railway have handed the road over to the bondholders. The line is one of the oldest in the city, but for a considerable distance ran through a sparsely settled district, and the receipts constantly fell below operating expenses, low as these were. For a number of years the stockholders have kept the road in operation only by paying assessments of about \$10,000 a year.

## Chicago.

CHICAGO.—The Jefferson street line of the West Chicago Street Railroad is to be equipped with electricity.

CHICAGO.—The rumor extensively circulated that J. P. Morgan and C. T. Yerkes contemplate consolidating the Chicago lines is false.

CHICAGO.—Stockholders of the rehabilitated Northern Electric Railway have elected George M. Huss, 153 LaSalle street, president, and Paul Dickinson, secretary and treasurer.

CHICAGO.—Promoter Lucius Clark has worked out a scheme by which the Chicago Passenger Traction Company may build the road for which it was two years ago granted a franchise in the northwest-ern part of the city.

CHICAGO.—The General Electric Railway Company has been granted the right to install the overhead trolley in place of the Love conduit system, which was originally planned. Mayor Harrison has vetoed the ordinance granting extensions to the Chicago General Railway Company.

## Connecticut.

NEW HAVEN, CONN.—Permission to extend to Pond Lily has been given the New Haven Street Railroad Company.

TORRINGTON, CONN.—Car service has begun on the new Torrington & Winchester Street Railway. The branch to Highland Lake is not yet completed.

HARTFORD, CONN.—The Hartford Street Railway Company and the Central Railway & Electric Company of New Britain, have placed in operation their joint through line from Hartford to New Britain. The fare is 15 cents with privilege of transfer in either city.

HARTFORD, CONN.—The third rail electric road to New Britain is now being double-tracked by the New York, New Haven & Hartford Railroad. Extensions to Bristol and Plainville are contemplated, making 22 miles operated by this system, all paralleled by trolley lines.

NORWICH, CONN.—An electric power plant will be placed in the shops of the Norwich & Worcester Railroad to supply current for the 14 miles of third-rail road which the N. Y., N. H. & H. R. R. expects to build on the east side of the Thames River. This is to forestall the Montville Railroad Company, which has a charter for a trolley parallel between Norwich and New London.

HARTFORD, CONN.—A meeting was held June 15 at the office of the Hartford Street Railway to organize the Bloomfield, Tariffville & East Granby Tramway Company, recently chartered by the state. Connecting with the Hartford Street Railway at Albany avenue the line will run through West Hartford, Bloomfield Centre, Scotland, Tariffville, Spoonville, East Granby and Rainbow. The incorporators are Henry C. Douglass and S. B. Douglass of Windsor Locks, J. Cleveland Capen, George F. Capen and H. R. Mills of Bloomfield, Jeffrey O. Phelps, Jr., George D. Curtis and D. F. Keenan and John A. Crilly of Hartford, and Charles A. Griswold, Frank A. Strong and R. F. Way of West Hartford.

SUFFIELD, CONN.—The Selectmen having approved the plans of the Springfield & Southwestern Street Railway work is to begin immediately. The road must be in full operation between the Massachusetts State line and West Suffield, a distance of ten miles, on or before June 1, 1898. It is the plan of the company to eventually connect with the Hartford Street Railway; also to build from the Massachusetts line to a point opposite Springfield, from which point they hope to gain an entrance to that city. The temporary organization of the company was recently perfected, with a capital stock of \$100,-

000, about \$45,000 of which has been paid in. The temporary officers are: President, H. K. Ford, of Suffield; secretary, E. P. Bartholomew, of Springfield; treasurer, A. Lyon, of New York. The company will soon be reorganized, and it is understood New York and Philadelphia capitalists will have control.

### Colorado.

CRIPPLE CREEK, COLO.—Tracklaying and the erection of overhead material for the Cripple Creek District Railroad has begun. Two carloads of rails have arrived, and the generators have been erected in the plant of the Fremont Electric Light & Power Company. It is claimed that cars will be in operation before August 1.

### District of Columbia.

WASHINGTON, D. C.—The Capital Railway Company expects to build two branch lines this year, and has just filed a \$300,000 mortgage to raise the money.

WASHINGTON, D. C.—The Washington & University Railroad Company has applied for incorporation. The company contemplates building a system of street railways to carry freight and passengers and to be operated by any power other than steam. Incorporators, J. D. Croissant, Frederick C. Kennedy, A. O. Humphrey, David B. Stone, J. S. Pierson, J. L. Tait, John J. Flynn and Charles S. Lord.

### Florida.

PENSACOLA, FLA.—The railway and dummy line of the Pensacola Terminal Company was sold by auction June 8 for \$55,000, which will cover all debts except the bonds, which amount to nearly \$200,000. The road was bought by W. H. Bosley, banker, of Baltimore, who is the largest bondholder. The change to electricity which has been contemplated for many months will now be carried out.

### Georgia.

ATLANTA, GA.—The Atlanta & Douglasville Railway Company has been incorporated to build the line noted in the BULLETIN some time ago. Capital stock, \$375,000; incorporators, J. S. James, C. D. Camp, R. E. James and A. E. Watson, of Douglasville; Simon Baer and Charles Pratt, of Atlanta; George L. Bell, of Gainesville; T. L. Galloway, of Decatur; George F. Payne, William D. Gharkey and Charles G. Witter, of Philadelphia.

### Illinois.

AURORA, ILL.—The Aurora & Geneva Railway Company has certified to an increase of capital to \$100,000.

AURORA, ILL.—Aurora has granted a franchise to the Aurora, Yorkville & Morris Electric Railway Company.

AURORA, ILL.—Montgomery village council has granted a franchise to the Aurora, Yorkville & Morris Electric Railway Company. The petition for a franchise in Aurora is now in the hands of the council committee.

GALESBURG, ILL.—Surveyors have begun work on the electric road to Knoxville. Knoxville's council has accepted the bond given by the Galesburg Electric Motor & Power Company, and the line will be in operation by September 1.

KANKAKEE, ILL.—The Kankakee, Wilmington & Morris Electric Street Railway Company has been organized at Joliet to build 50 miles of road from Kankakee to Morris, passing through Bulhomias, Deselen, Richey, Wilmington, Braidwood, Braceville, Diamond, Sufferinville, Coal City and Carbonville. Right of way will be obtained without delay and work on the line will be commenced next spring. Capital stock, \$50,000; incorporators, Thomas J. Deven, Chicago; Frank B. Handwerker, Morris; August D. Ehrich, Kankakee; Jacob A. Henry, Joliet; P. J. Cromwell, J. L. Lewis, and C. L. Bennett, Wilmington.

### Indiana.

GOSHEN, IND.—Assurances have been given that the Goshen Street Railway will be extended to the lake before another season.

RICHMOND, IND.—Farmers have a scheme to build an electric road from Richmond through Webster, Economy and Losantville to Muncie.

VALPARAISO, IND.—Samuel Massey, of Kansas City, Mo., is said to represent capitalists who contemplate building an electric railroad to connect with Chesterton and Porter.

CROWN POINT, IND.—Among those interested in the proposed electric road to Hammond and Cedar Lake are M. T. Hart, John Brown, L. D. Wolf, J. G. Strabel and Robert I. Bates.

NEW ALBANY, IND.—Bondholders of the New Albany Street Railway Company are arranging to pool their bonds. During the three years in which it has been operated by Receiver McLeod the road has just about paid expenses.

MARION, IND.—Work has been resumed on the Indianapolis, Anderson & Marion Electric Railway, Engineer Louis Enrich having arrived with \$15,000 and paid off the men. The trouble is said to have been caused by a dispute with the contractor and will not occur again.

CROWN POINT, IND.—It is said the county commissioners have granted a franchise to Chicago capitalists for an electric road between Hammond, Crown Point and Cedar Lake, to share the summer traffic to the latter resort, which has hitherto been monopolized by the Monon Railway.

FORT WAYNE, IND.—The ordinance requiring fenders on street cars goes into effect July 1. As yet the company has done nothing toward placing them on the cars except to investigate several kinds. The receivers will soon take some action toward paying off claims of the local creditors.

INDIANAPOLIS, IND.—A second application was made, June 7, for a receiver for the Indianapolis & Broad Ripple Rapid Transit Company. It is alleged the company's indebtedness for running expenses is \$20,000, and that it has issued bonds for \$400,000, secured by a mortgage on all its property.

### Iowa.

BOONE, IA.—The council has passed over the mayor's veto the franchise granting the Boone Street Railway right to operate with electricity.

BOONE, IA.—President L. W. Reynolds, of the Boone Street Railway & Light Company, says the company is prepared to change the motive power from horse to electricity.

DUBUQUE, IA.—The ordinance extending the charter of the Dubuque Street Railway has passed its first reading. Its final passage will permit the company to establish a pleasure resort and enable it to float bonds with which to pay creditors and absorb a rival line.

### Kentucky.

FRANKFORT, KY.—Charles R. Crane, of Springfield, O., has purchased the Frankfort Street Railway at auction for \$10,000. The road is being repaired, equipped with new cars, etc., and will be placed in operation in July by the recently organized Frankfort & Suburban Street Railway Company, of which C. R. Crane is president; Patrick McDonald, vice-president, and J. T. Buckley, secretary and treasurer.

LOUISVILLE, KY.—Stockholders of the Louisville Railway meet June 10 to consider the conversion of \$500,000 common into preferred stock. The \$250,000 thus obtained will be expended for fifty new cars and the electrical equipment of the remaining mule lines.

### Louisiana.

NEW ORLEANS, LA.—The Orleans & Jefferson Railway Company has been incorporated to build an electric line on Napoleon avenue. Capital stock, \$250,000; incorporators, William R. Hall, president; Robert R. Zell, vice-president and Cyrus B. Buchanan, secretary.

NEW ORLEANS, LA.—The ordinance granting the Crescent City Railroad Company right to operate over some of the Carrollton Railroad Company's tracks has been defeated in the city council. Instead an ordinance was reported instructing the city attorney to bring suit to test the validity of the Crescent City Company's claims on Carrollton avenue.

**Maine.**

**WINDHAM, ME.**—Windham has voted against the proposition to lend its credit to the proposed electric road.

**KINEO, ME.**—O. A. Dennen, Kineo House, Moosehead Lake, is said to be interested in a project to build an electric road connecting the summer resorts on Moosehead and Cumberland Lakes.

**BANGOR, ME.**—A new company is to be formed to carry on the construction of the Bangor, Hampden & Winterport Electric Railway. Among those interested are James H. Cutler, of the Bangor Street Railway, and the Hon. Henry W. Mayo, of Hampden.

**BIDDEFORD, ME.**—Twenty miles of electric road will be built from Biddeford to Standish by way of Saco and Buxton, by a company recently incorporated with \$250,000 capital stock. Among the incorporators are Charles S. Hamilton and William A. Roberts, of Biddeford; James Bradbury Oliver and E. B. Loring, of Boston.

**NORWAY, ME.**—Parties interested in the proposed Oxford Central Electric Railroad have formed the Oxford & Welchville Electric Railroad Company to build three miles of road. Of the \$25,000 capital stock \$8,000 has been paid in. Incorporators, John B. Robinson, Charles L. Turgeon and George W. McFadden, of Auburn, and Fred C. Wilson, of Norway.

**Maryland.**

**BALTIMORE, MD.**—The new track to be laid on Paca street by the Consolidated Railway Company is to be completed August 1.

**BALTIMORE, MD.**—Permission to erect poles and wires within the city limits has been given the Falls Road Electric Railway, which is being constructed by J. G. White & Co., of New York.

**FREDERICK, MD.**—A power house will be built on the top of Catoctin Mountain by the Frederick & Middletown Electric Railroad. Engines and boilers of the Electric Light Company will be installed in the new power house.

**Massachusetts.**

**AMHERST, MASS.**—The Amherst & Sunderland Electric Railway was formally placed in operation June 16.

**FALL RIVER, MASS.**—Negotiations for the consolidation of the Fall River Street Railway and the Globe Street Railway have been resumed.

**WORCESTER, MASS.**—The Blackstone Valley Street Railway Company has changed its name to Worcester & Blackstone Street Railway Company.

**EAST BRIDGEWATER, MASS.**—The East Bridgewater Street Railway Company has just purchased a site on which a barn will be erected immediately.

**WORCESTER, MASS.**—Negotiations are pending for the sale of the Worcester & Blackstone Street Railway to the Worcester Suburban Street Railway Company.

**MILFORD, MASS.**—The Milford & Upton Street Railway Company is said to be negotiating for the purchase of the power plant of the old Milford & Hopedale Company.

**BRIDGEWATER, MASS.**—The Bridgewater, Whitman & Rockland Street Railway Company is taking steps toward incorporation. Ten per cent of the stock has been paid in.

**SPRINGFIELD, MASS.**—Directors of the Springfield Street Railway have authorized the president and treasurer to build the proposed car barn. The building will be 169 x 190 ft.

**BROCKTON, MASS.**—The Brockton, Bridgewater & Taunton Street Railway was formally opened June 14, thus completing a direct line of electric railway from Boston to Taunton.

**AMHERST, MASS.**—A pleasure resort has been established by the Amherst Electric Railway Company. The travel already exceeds the most sanguine expectations of the projectors.

**BOSTON, MASS.**—William A. Gaston, president of the Boston Elevated Railway, says construction will begin without delay, and that the West End Street Railway will be leased forthwith as permitted by the elevated road act which has been signed by the Governor.

**MILFORD, MASS.**—The selectmen will not require the Milford & Upton Street Railway Company to put up a cash forfeit of \$3,000 and will be satisfied with macadamizing in place of paving. Having received these concessions the promoters promise to have the road built by October 1.

**BROCKTON, MASS.**—The Brockton, Bridgewater & Taunton Street Railway Company will petition the railroad commission to approve the present issue of \$200,000 worth of stock and for an increase of \$50,000. A mortgage will be given the American Loan & Trust Company to secure an issue of \$200,000 bonds.

**MIDDLEBORO, MASS.**—The Taunton & Middleboro Street Railway Company has been incorporated to build 11 miles of electric road from Middleboro to Bridgewater, with connection with Brockton and Taunton. Capital stock, \$150,000; incorporators, Stephen F. O'Hara, of Middleboro, and Sidney T. Nelson, of Lakeville.

**ONSET, MASS.**—Stockholders of the East Wareham, Onset Bay & Point Independence Street Railway Company have refused the request of the directors for a receiver. At the request of the minority there was added to the directory, J. Q. A. Whittemore of Newton, Isaac B. Eldridge of East Wareham and Hardy Smith of Onset Bay.

**WINTHROP, MASS.**—The Winthrop Street Railway Company has been incorporated to build eight miles of road. Capital stock, \$80,000; directors, W. G. Wheildon, William W. Davis, Edward F. Draper and Aaron R. Sanderson of Boston; Samuel G. Erwin of Winthrop; George S. Forbush of Brookline, and Charles E. Folsom of Winchester.

**BRIDGEWATER, MASS.**—Stockholders of the Bridgewater, Whitman & Rockland Street Railway Company voted June 30 to pay up all the stock and to begin construction as soon as preparations could be completed. President, William A. Tucker, of Boston; secretary, George A. Butman, and treasurer, Charles A. Wilson. Directors, J. T. King, C. S. Stevens, R. W. Nutter, C. F. Allen, George J. Morse, C. H. Wilson, George A. Butman, William A. Tucker and Fred O. Hinds.

**Michigan.**

**JACKSON, MICH.**—Receiver W. A. Foote of the Jackson Street Railway, plans a thorough rebuilding of the system.

**SAGINAW, MICH.**—The council has passed the ordinance declaring the franchise of the Union Street Railway Company forfeited.

**DETROIT, MICH.**—Springwells township has granted the Detroit Electric Railway a 30-year franchise for an extension on Michigan avenue.

**SAGINAW, MICH.**—The Union Street Railway Company has applied to the supreme court for a temporary injunction to restrain the city from tearing up its tracks.

**BATTLE CREEK, MICH.**—E. E. Downs and F. N. Rowley are said have to sold their interest in the street railway to eastern capitalists, who are to build the interurban line.

**NILES, MICH.**—Peter English, of Benton Harbor, is said to have interested eastern capitalists in the proposed electric road from Niles to Buchana, Barren Lake and South Bend, Ind.

**PORT HURON, MICH.**—Judge Fred S. Wheat, of Caro, has obtained franchises in Lexington, Moore, Custer, Watertown and Elmer townships for the proposed electric road to Port Huron.

**HOLLAND, MICH.**—The Holland & Lake Michigan Electric Railway Company has been incorporated to build through to Macatawa Park. Capital stock, \$150,000. George E. Kollen is interested.

DETROIT, MICH.—Fred J. Blakeley, representing Pack & Everett of Detroit, has been looking into the construction of an electric railway from Detroit to Romeo via Utica.

BENTON HARBOR, MICH.—Stockholders Henry D. Deam, Andrew H. Deam and John Mears of the Benton Harbor & Eastern Electric Railway, have brought suit against President John W. Hamilton, Treasurer C. G. Davies and Secretary W. H. Hollis, charging them with making improper issues of stock for the alleged purpose of enriching themselves.

JACKSON, MICH.—William Foote has been appointed receiver of the Jackson Street Railway, the Fidelity Loan & Trust Company having commenced a foreclosure of \$150,000 mortgage bonds, on which \$4,000 interest is due and unpaid. The road has been running behind for three years and is in a dilapidated condition. The negotiations for its sale, which have been in progress for some time, have failed.

### Mississippi

JACKSON, MISS.—C. W. Howard, of Chattanooga, Tenn., has been granted a franchise to build an electric street railway. Northern capitalists are said to be interested with him.

### Missouri

SEDALIA, MO.—Lightning on June 18 burned out all the generators of the Electric Railway, Light & Power Company.

KANSAS CITY, MO.—The axles under the new cars of the Metropolitan Street Railway are being replaced by larger ones.

ST. LOUIS, MO.—The Lindell Railway has closed the deal for the purchase of the electric and cable lines of the Missouri Railroad Company.

ST. JOSEPH, MO.—It is expected that the contemplated improvements and extensions of the St. Joseph Street Railway will soon be carried out.

JEFFERSON CITY, MO.—Hon. S. W. Cox will submit a proposition for an electric railway to the council. If a liberal franchise is granted sufficient capital is promised by D. W. Cox of Harrisburg, Pa.

KANSAS CITY, MO.—Getty & Hutchings, attorneys of Kansas City, Kan., represent eastern capitalists who contemplate building 20 miles of electric road connecting Kansas City with Leavenworth and Fort Leavenworth.

KANSAS CITY, MO.—General Manager W. H. Holmes of the Metropolitan Street Railway, says that an extension of the Troost avenue cable line to Forest Hill is one of the improvements contemplated. It will probably be made this summer or fall.

ST. LOUIS, MO.—The St. Louis, Fenton & Southwestern Railroad Company has accepted the franchise granted three months ago for 44 miles of electric road between St. Louis and Morse's Mill. Construction must begin within six months and be completed within two years.

### New Jersey

CAMDEN, N. J.—The Camden & Suburban Railway will build a 4-mile extension from Collingswood to Haddonfield.

ELIZABETH, N. J.—Permission to extend its tracks through three streets is asked by the Westfield & Elizabeth Street Railway Company.

RED BANK, N. J.—The trolley company has accepted a franchise over the highway now occupied by its tracks. The company agrees to pay \$250 annually and to maintain 12 electric lights.

NEWARK, N. J.—The Consolidated Traction Company will extend its Clinton Township line to Elizabeth street, Irvington, before October 1, a franchise having been granted by the Irvington trustees.

JERSEY CITY, N. J.—Stockholders of the Consolidated Traction Company met June 17 to ratify the purchase of the line from Newark to Passaic, operated by the Passaic & Newark Traction Company.

NEW BRUNSWICK, N. J.—The ordinance for the extension of the Brunswick Traction Company's line through Raritan Township has passed its second reading. The line will be single track with turnouts.

ROSELLE, N. J.—The New York & New Orange Railroad Company has been incorporated to build between Roselle and New Orange. Capital stock, \$100,000. President, Robert Grimes, Elmira, N. Y.; vice-president, Dennis Long, Union; treasurer, W. S. McCord, Elmira, N. Y.; secretary, C. W. Manahan, East Orange.

PATERSON, N. J.—The Saddle River Traction Company has been incorporated with \$100,000 capital stock, of which \$25,000 has been paid in. The incorporators are Gen. Bird W. Spencer, Michael F. Burns and Gilbert S. Bogart. Gen. Spencer was president of the Passaic & Newark Electric Railway, which was recently sold to the Consolidated Traction Company.

### New York.

BUFFALO, N. Y.—Ground has been broken by the Buffalo Traction Company for its new system.

LYONS, N. Y.—The Lyons & Sodus Bay Electric Railroad Company asks right of way through Wayne also.

ALBANY, N. Y.—The Greenbush & Nassau Electric Railway Company has accepted its franchise and given bond.

BROOKLYN, N. Y.—The Brooklyn City & Newtown Railroad has filed a certificate showing its proposed extensions.

BROOKLYN, N. Y.—Southampton has granted the Riverhead, Quogue & Southampton Railway permission to build.

NEW BRIGHTON, N. Y.—The Staten Island Midland Railroad has received permission to double-track its line on Clove road.

GREENVILLE, N. Y.—The Greene County Traction Company has been reorganized, only one of the old directors remaining.

SYRACUSE, N. Y.—The Lakeside Railway franchise has been extended. Construction is now required to begin July 1, 1898.

BUFFALO, N. Y.—Control of the Buffalo, Bellevue & Lancaster Electric Railway has been acquired by the Buffalo Railway Company.

BUFFALO, N. Y.—Trustees of Depew village have voted to grant the Buffalo & Depew Railway Company a franchise for the proposed electric road.

POTSDAM, N. Y.—H. A. Odell, of New York, has been looking over the ground to determine whether an electric road to Colton would be a paying proposition.

AUBURN, N. Y.—The state railroad commission has denied the application of the Auburn & Western Railroad for right to build an electric line to Seneca Falls.

WHITE PLAINS, N. Y.—The White Plains & Elmsford Electric Railway Company has placed its line between White Plains and Tarrytown in successful operation.

HUDSON, N. Y.—E. S. Benedict, superintendent, says that the Hudson Electric Railway will ultimately be extended to Chatham. The extension to Claverack will probably be made very soon.

OSWEGO, N. Y.—Receiver Tidman finds himself unable to negotiate the certificates of the Lake Ontario & Riverside Railway except at a discount of 2 per cent, which he is unwilling to give.

BUFFALO, N. Y.—The state board of railroad commissioners on June 30 hear the application of the Buffalo, Hamburg & East Aurora Railway Company for a certificate of public convenience and necessity.

**NEW YORK, N. Y.**—The state railroad commission has granted the Metropolitan Street Railway Company right to change from horse power to the conduit electric system on its 4th and Madison avenue lines.

**ONEONTA, N. Y.**—E. A. Mathews, of Binghamton, who constructed the Binghamton, Lestershire & Union Electric Railway, is soliciting subscriptions to the stock of the proposed Oneonta & Otsego Valley Railroad.

**WELLSVILLE, N. Y.**—E. C. Bradley, James Macken and John McEwen, are a committee to solicit funds for the construction of the proposed electric railway from Wellsville to Bolivar. It is estimated that \$160,000 will be required.

**BROOKLYN, N. Y.**—D. O. Mills' purchase of \$1,000,000 of its bonds has supplied the Rapid Transit Company with funds for improvements, new cars and to pay the expense of equipping for the operation of through cars to New York.

**NEW YORK, N. Y.**—An issue of \$12,500,000 of 5 per cent bonds is announced by the Metropolitan Street Railway Company, the proceeds to be used in equipping the Fourth, Sixth and Eighth avenue roads with the conduit electric system.

**BUFFALO, N. Y.**—The town board of Tonawanda has granted a franchise to the Tonawanda Electric Railroad Company, thus completing George P. Smith's long-desired right of way between Niagara Falls and Buffalo. Work must begin at once and be finished in 10 months under penalty of forfeiting \$20,000.

**MARCELLUS, N. Y.**—The Marcellus Electric Street Railway Company has been incorporated to build 2.5 miles of road from the New York Central station at Camillus to Marcellus, Onondaga county. Capital stock, \$60,000; incorporators, Townsend K. Cheyney, Howard M. Fordham and L. J. Chase, of Buffalo; E. Moir, L. N. Mogg, J. M. Seymour, Charles Brown and Edmund Reed of Marcellus, and J. G. Stevens of Syracuse. Mr. Moir was chosen president, Mr. Mogg vice president, E. Reed secretary, and J. M. Seymour treasurer.

**BROOKLYN, N. Y.**—The DeKalb Avenue & North Beach Railroad Company has been incorporated to build an electric railway from the terminus of the DeKalb avenue line to North Beach on Flushing Bay, a distance of six miles. The road will be controlled by the Brooklyn City & Newtown Railroad Company. Capital stock, \$200,000; directors, Henry B. Hyde of Bay Shore, Louis Fitzgerald, Alfred Wagstaff, Duncan B. Cannon of New York City; John N. Partridge, John L. Heins, Thomas Clark, Jr.; Thomas Ennis and George W. Benton of Brooklyn.

**SARATOGA, N. Y.**—The Saratoga Northern Railway Company has been incorporated to construct 11 miles of standard gage electric railway from Saratoga Springs to the village of Winton and Mt. McGregor. Capital stock, \$1,000,000; incorporators, Charles E. Arnold, H. McGonegal, L. C. Jordan of New York; J. B. Hampton of Philadelphia; A. C. Kaufman, H. H. Schaff, Edward R. Manice of Pittsfield; J. B. Robertson of New Haven, Conn., and A. J. Voyer of Albany. This corporation is formed for the purpose of acquiring the property and franchises of the Mt. McGregor Railroad and of the Saratoga & Mt. McGregor Railroad Company. The Mt. McGregor is a narrow gage road, and has a charter authorizing the construction of a road from Saratoga to Lake George. Eventually it is proposed to rebuild this road by making it a standard gage and to extend it to South Glens Falls in Warren county.

## North Carolina.

**MORGANTON, N. C.**—T. K. Bruner of Raleigh is interested in a project to build 40 miles of electric road from Morganton to Blowing Rock. It is said capitalists of New York, Raleigh and Morganton are forming a company with \$300,000 capital stock.

## Ohio.

**COLUMBUS, O.**—The fender ordinance has been revived, in force the Columbus Central Railway to adopt life guards.

**CLEVELAND, O.**—The Cleveland & Southeastern Electric Railway Company has been granted an extension of 60 days time in which to begin construction.

**TOLDO, O.**—Receiver L. S. Baumgardner, of the Put-in-Bay Electric Railway, sold the lease of the line until October 1 to James S. Keith of Port Clinton.

**CINCINNATI, O.**—The Cincinnati & Miami Valley Traction Company has finished its power plant at Busenbark. The car barn at Trenton has been completed.

**DAYTON, O.**—Frank Turner, city engineer of Dayton, is president of a company of capitalists who propose to build an electric line from Dayton to West Milton and Greenville.

**CINCINNATI, O.**—A. Hickenlooper of the Cincinnati, Hamilton & Dayton Traction Company offers to build a road to carry passengers from Carthage to a connection with the Consolidated at Avondale.

**TUSCARAWAS, O.**—A consolidation of the Tuscarawas Street Railway, operating between New Philadelphia and Uhrichsville, and the Tuscarawas Electric Railroad, operating between Canal Dover and New Philadelphia, is pending.

**CLEVELAND, O.**—The county commissioners have granted the Cleveland & Eastern Electric Railroad Company a franchise to construct 51 miles of road through Cuyahoga County to Orwell, O., with the privilege of carrying barrel and package freight.

**CINCINNATI, O.**—Right of way from Hamilton to the county line has been given J. C. Hooven, president of the Cincinnati & Hamilton Electric Street Railway Company. He agrees to have the road finished within 16 months and in operation two months later.

**CLEVELAND, O.**—The Cleveland & Akron Suburban Electric Railway Company has been incorporated to build and operate a line between the two cities. Capital stock, \$500,000; incorporators, Harry C. Mason, William C. Gayer, Dr. J. C. Fritch, J. A. Spitzig and Frederick L. Taft.

**MANSFIELD, O.**—The Richland Railway Company has been incorporated to build between Mansfield and Shelby. Electricity or steam will be the motive power. Capital stock, \$10,000; incorporators, Charles W. French, A. W. French, L. Walker, V. A. Dehnel, and H. C. Workman.

**ASHLAND, O.**—The Tri-City Electric Interurban Railway Company has been incorporated to build between Loudonville, Ashland county, and New London, Huron county. Capital stock, \$10,000; incorporators, Bert J. Hank, Edwin J. Bert, G. A. Ullman, J. R. Swartz, E. F. Shelley, S. J. McCready, Thomas Brown, Thomas M. Beer, H. A. Thomas, O. S. Cartle, jr., S. C. Frank, E. J. Grossarp, J. W. Brinder, G. Hess, S. H. Grabill and J. F. Johnson.

**CLEVELAND, O.**—With the franchises recently granted and the rights of way obtained from private parties the Cleveland, Painesville & Eastern Electric Railroad will control the passenger and package freight traffic along the lake shore east of Cleveland. The privileges conferred by the last grant will be exercised by the immediate construction of the extension from Nottingham to the city, to connect with the St. Clair line of the Little Consolidated.

## Pennsylvania.

**LANCASTER, PA.**—The city council has passed an ordinance compelling the Pennsylvania Traction Company to adopt fenders.

**POTTSTOWN, PA.**—The Ringing Rocks Electrical Railway Company is meeting with success in getting right of way for the extension to Swamp.

**GETTYSBURG, PA.**—The Gettysburg Electric Railroad was sold by the receiver June 10 to the West End Trust Company of Philadelphia for \$50,000.

**PITTSBURG, PA.**—The Fidelity Title & Trust Company on June 11 was appointed receiver of the McKeesport, Duquesne & Wilmerding Street Railway.

**POTTSVILLE, PA.**—The old power house of the Schuylkill Electric Railway at Pottsville, was destroyed by fire on the evening of July 3. All traffic was suspended.

COLUMBIA, PA.—Receiver Given has authority from the circuit court to extend the Lancaster & Lititz Railway as soon as a satisfactory ordinance is passed by Lititz council.

PITTSBURG, PA.—The Braddock & Homestead Street Railway has been placed in operation. Mellon Brothers, bankers, own the line, which is three miles long. J. C. Ross is manager.

DOYLESTOWN, PA.—Wheeler & Boody, who have the contract to build the system of the East Pennsylvania Traction Company, have issued an execution against the company on a judgment for \$16,215.

WILLIAMSPORT, PA.—The Montoursville Passenger Railway Company has been incorporated to build from Williamsport to Montoursville via Loyalsock. Capital stock, \$75,000; president, William Massey.

TYLER, PA.—The Tylerdale Belt Line Railroad Company has been incorporated to operate 1.5 miles of electric road. Capital, \$15,000; incorporators, Samuel Hazlett, George L. Hayes and Samuel Workman.

PITTSBURG, PA.—Stockholders of the Pittsburg, Allegheny & Manchester Traction Company have accepted the offer of \$41 for their holdings, and the line will be consolidated with the United Traction Company.

PHILADELPHIA, PA.—J. L. Stadelman of Bala, Pa., and W. A. Stadelman of 26 Cortlandt street New York, are said to be interested in the Philadelphia & Merion Electric Railway Company, which is to build six miles of road.

EASTON, PA.—The Northampton Electric Railway Company has been incorporated with \$300,000 capital stock by James Kerr of Clearfield, George S. Good of Lock Haven, J. Frank Snider, A. O. Smith and G. S. Hues of Clearfield.

PHILADELPHIA, PA.—The ordinance granting the Moyamensing Avenue & Penrose Ferry Passenger Railway Company an extension of time to July, 1898, to complete its system, has been favorably reported by the council committee.

BEAVER, PA.—The Beaver & Vanport Electric Railway Company has been incorporated to build and operate two miles of road between the two towns. Capital stock, \$12,000; directors, J. M. Buchanan, W. A. McConnell, J. H. Wilson, A. T. Anderson, Beaver, and J. T. Taylor, Monaca.

EASTON, PA.—The Easton, Palmer & Bethlehem Street Railway Company has been incorporated to build 12 miles of road between Easton and Bethlehem. Incorporators, W. B. Ferguson, Boston, Mass., president; Charles F. Barnes, Plymouth, Mass., treasurer; Frank E. Lowe, Greenfield, Mass., Michael P. McGrath, George A. Murch, Wesley A. Kendall, and C. A. Richardson, Worcester, Mass., and N. S. Myric, Boston, Mass.

DANVILLE, PA.—J. M. Fitzgerald and Elias Nesbaum, representing the North Susquehanna Street Railway Company, are getting consents for a regrant of the franchise which has lapsed owing to failure to begin construction within a certain time. Starting at Riverside the line, after taking in the principal streets of Danville, will pass on to Bloomsburg and Espy, a branch diverging at Rupert for Catawissa. The cost is estimated at \$200,000.

### Tennessee.

CHATANOOGA, TENN.—Extensive repairs are being made on the Market street line of the Chatanooga Electric Street Railway Company.

CHATANOOGA, TENN.—M. F. Penfield is promoting a plan to buy and operate the Lookout Mountain Broad Gage Railroad. Sam W. Divine and associates are figuring on acquiring the road and equipping with electricity. It would then be operated in connection with his proposed line from the city to the Chickamauga Military Park.

CHATANOOGA, TENN.—The Chattanooga & Lookout Mountain Railroad was sold June 22, by the Union Trust Company of Philadelphia, to the Chattanooga & Lula Lake Railroad Company, which

operates the new incline to the mountain. The price was \$15,000. The road was built in 1888, and is ten miles in length. The new owners will equip and operate the road.

### Texas.

DALLAS, TEX.—C. H. Alexander and I. G. Randle are said to have purchased the track, rolling stock and good will of the Dallas Consolidated Street Railway. They pay \$145,000 and assume \$30,000 floating debt.

BEAUMONT, TEX.—The council will refuse the application of F. Zoiner and others for an electric railway franchise, and consider a petition from other parties who offer to begin work within 30 days, a much shorter time than that desired by Mr. Zoiner.

### West Virginia.

WHEELING, W. VA.—The Wheeling Railway Company's franchise ordinance has been rejected by the council.

CHARLESTON, W. VA.—Receiver C. B. Couch asks the court for authority to sell the Charleston Street Railway.

WHEELING, W. VA.—The Wheeling & Elm Grove Electric Railway ordinance has passed both branches of the city council.

### Wisconsin.

OSHKOSH, WIS.—The new street railway has been placed in operation by the Citizens' Traction Company.

FOND DU LAC, WIS.—Elihu Colman has filed an acceptance of the street railway franchise, but the capital for construction has not yet been obtained.

MILWAUKEE, WIS.—The purchase of the Milwaukee & Wauwatosa Motor Road by outsiders is a blow to the projected Milwaukee & Waukesha Railway.

MILWAUKEE, WIS.—C. F. Rosenkrantz, attorney, purchased the Milwaukee & Wauwatosa Motor Road, June 26, for \$43,500. His clients are not known.

RACINE, WIS.—Creditors and others interested in the Belle City Street Railway met in Chicago, recently, and arranged a reorganization which will be carried out July 1.

MILWAUKEE, WIS.—Henry C. Payne has concluded negotiations with Cleveland capitalists for the formation of a company to build an interurban electric railway in the Fox River Valley.

MILWAUKEE, WIS.—The Milwaukee Electric Railway & Light Company is said to have perfected plans for the construction of a line between Milwaukee and Waukesha, with subsequent extensions to Pewaukee and Oconomowoc.

NEENAH, WIS.—It is said that Henry C. Payne, of Milwaukee, has purchased the Menasha & Neenah Street Railway of Ferdinand Schumacher, the oatmeal miller of Akron, O., with the object of making it a part of his proposed interurban electric railway.

NEENAH, WIS.—Henry C. Payne of the Milwaukee Electric Railway and M. J. Degnon, railway builder of Cleveland, O., have spent two days inspecting the route of a proposed interurban railway from Neenah to Kaukauna. Mr. Payne says that if the council will grant a satisfactory franchise they will construct the road in 60 days.

RACINE, WIS.—Receiver Hiram F. Smith's petition for an order to sell the Belle City Electric Street Railway has been approved by Judge Fish. The bondholders will bid in the property, and will very soon make improvements costing \$20,000. In addition to the bonded debt of \$300,000 there are other debts aggregating \$32,000.

RACINE, WIS.—The Milwaukee, Racine & Kenosha Electric Railway announces the completion of its subway at South Milwaukee and the operation of its cars between Racine and the city hall in Milwaukee. The extension from Racine to Kenosha is being graded and is expected to be completed within 60 days. The distance is 12 miles and Matthew Slush, president, Racine, is in the market for ties, poles and other material.

## WATCH TOWER PARK.

Black Hawk's Watch Tower, situated at the junction of the Rock river with the Mississippi, is a place made famous by its association with the great Indian warrior. The natural beauty of the surrounding country, together with the historic associations, makes it an ideal place for a park. Amusement features of every kind have also been provided. One illustration shows the new Blackhawk Inn which is a fine building, 60 x 75 ft., encircled by verandas on both floors, and

BLACK HAWK INN.

replaces the one burned last year. The main dining room occupies the first floor and the ball room the second. There are also small dining rooms to accommodate 6 to 12 each, which are separated by folding doors, and these can be thrown open so that supper parties of 40 to 50 may be served. The 15-ft. verandas are covered with comfortable chairs and settees, where patrons may sit and listen to the concerts of the band in the music pavilion and enjoy the scenery of the Rock river. Then there are the "chutes," the toboggan slide, roller coaster, the merry-go-round, the

SCENES AT WATCH TOWER PARK.

shooting gallery, bowling alleys, museum, open air theatrical performances, swings, swimming, boating and bathing to delight the visitor.

This beautiful park is the property of the Tri-City Railway Company, Davenport, Ia., of which James F. Lardner is secretary and treasurer. The company has provided ample facilities for carrying passengers to and from the park. Cars leave the Tower every 10 minutes.

## MEETING OF OHIO STATE TRAMWAY ASSOCIATION.

The sixteenth annual meeting of the Ohio State Tramways Association was held at Columbus on June 14.

During the morning the visitors were entertained by the Columbus Street Railway at the hands of W. F. Kelly, the superintendent, and a trip was made to Olentangy Park, the summer resort operated by the company. After luncheon at the Hotel Chittenden, Fred N. Bendelari of the Columbus Central Railway escorted the party in the company's special car Minerva to Minerva Park, the resort of this company, where the afternoon was very pleasantly spent. The meeting was not largely attended but what was lacking in numbers was made up in quality. Quite a number of supply men were present and contributed their usual share to a good time.

The business meeting was held at the Chittenden in the evening and officers elected as follows: A. A. Anderson, Youngstown, president; T. R. Catlin, Canton, vice-president; F. J. J. Sloat, Akron, secretary and treasurer. As Columbus is centrally located and convenient from all points in the state it was decided to hold the next convention there on June 8, 1898. The new officers have not as yet outlined the plans for the next meeting but it is their intention to have some specially prepared papers read on that occasion.

## BOSTON TERMINAL BIG CONTRACT LET.

Westinghouse, Church, Kerr & Co. have received the contract to equip the great station of the Boston Terminal Railway Association with electric locomotives, electric light, heating and refrigerating apparatus and interlocking switches. The electrical apparatus will be supplied by the Westinghouse Electric & Manufacturing Company; heating and refrigerating equipment by the Westinghouse Machine Company, and the switching system by the Union Switch &

Signal Company, another Westinghouse interest. All of the steam railroads entering Boston have united to build one terminal station which is to be the finest in this country. No expense will be spared to make it a model of safety and convenience. The selection of their machinery reflects great credit on the Westinghouse companies, more especially as there was practically no one other competitor able to supply the whole equipment.

Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.

The Westinghouse Electric & Manufacturing Company on June 22, declared a quarterly dividend on its preferred stock of  $1\frac{1}{2}$  per cent.

The 20th convention of the National Electric Light Association was held at Niagara Falls, June 8, 9 and 10, the attendance being large, and the meeting a success.

At the annual meeting of the stockholders of the Barney & Smith Car Company, Dayton, O., the directors were all re-elected, as were also the officers of the company.

On July 7, a car on the Inter-Urban Electric Railway ran through the open draw of the iron bridge two miles south of Bay City, Mich., and seven persons were drowned; others were injured.

Among the entertainments in honor of the Mystic Shriners when at Detroit last month was a monster trolley party. There were 53 gayly decorated cars in line and the guests numbered 2,350.

I. D. Ralph, president of the Owosso & Corunna Traction Company, has sued J. H. Copas, an alderman of Owosso, for \$20,000 damages for slanderous epithets applied to him at a council meeting.

It is reported that Henry A. Butters, of Oakland, Cal., together with some other Americans, forming a syndicate, has received concessions for constructing a street railway system in Johannesburg, South Africa.

The street railway of Appleton, Wis., will establish, in conjunction with the firm of Dorst & Rutledge, a summer, outdoor theater at Garfield park near the end of its line, where vaudeville performances will be given nightly.

Last summer one of the cars of the Coney Island & Brooklyn Railroad company ran over the foot of a little girl. It was necessary to have four of her toes amputated and for this loss she was awarded \$1,631 by a New York jury.

The new directory of the Metropolitan of Kansas City is composed of Charles Francis Adams of Boston; S. B. Armour, P. A. Valentine, of Chicago; C. F. Morse, W. H. Holmes, C. F. Holmes, J. K. Burnham, Chester A. Snider, and Wallace Pratt.

The employes of the Citizens Street Railway Company, Muncie, Ind., made a request for an increase in wages and this was granted by Secretary Geo. F. McCulloch. The advance amounts to  $7\frac{1}{2}$  per cent. and was gratefully received by the men.

In Brooklyn open cars are not permitted when the temperature is below  $60^{\circ}$  F. and June 8 was cold enough to bar open cars. One train crew was prosecuted, but the case dismissed because the ordinance had not been properly advertised as required by law.

The Waverly (N. Y.) Electric Light & Power Company has passed into the hands of the Waverly, Sayre & Athens Railway Company. The officers of the new company are A. C. Wade, president; P. L. Lang, vice-president; A. N. Broadhead, secretary and treasurer.

D. K. Carter, one of the jury is a \$35,000 damage case against the Chicago City Railway, was charged by one of the company's attorneys with soliciting a bribe, offering to secure a disagreement or a small verdict for the plaintiff. He was sent to the county jail for six months.

The Passaic & Newark Electric Railway sprinkles the streets occupied by it in Passaic under a contract with the city which pays for the service. In order to distribute the water over the entire street each sprinkler is equipped with a motor pump to give the necessary pressure.

The Southern Electric Railway Company, St. Louis, reports a very gratifying increase in traffic during the past three months. This has been sufficient to justify the company in ordering 10 new double truck cars and to have the single truck cars rebuilt, lengthened and equipped with two trucks.

The street railways connecting Duluth and Superior, Minn., will henceforth issue free transfers at all times so that the fare from any point in Superior to any point in Duluth is 10 cents. A year ago the plan of giving free transfers between the hours of 6 and 8 in the morning was adopted.

The Connecticut Senate has passed the bill amending the railroad law so that no street railway is to be built between towns or so as to parallel existing steam or street railways without the consent of a judge of the superior court. The bill is said to be satisfactory to both the steam and electric interests.

Through his own carelessness a man in Portland, Ore., lost a leg and sued the street railway for big damages. In view of the facts the jury could not do otherwise than return a straight verdict for the defendant, but added the hope that the company would pay costs, buy a wooden leg and give him employment.

The Milwaukee, Racine & Kenosha Electric Railway Company has constructed a culvert under the Chicago & Northwestern Railroad tracks, and the first through car from Milwaukee to Racine was recently run over the line in 90 minutes. The cars hereafter will make hourly trips between the two cities.

The Connecticut Senate modified the vestibule bill reported by its committee and as passed, vestibules are not made compulsory for cities of less than 50,000, but left to the discretion of the railroad commissioners. It was pointed out that more accidents occurred with vestibuled cars than without and that in many places the use of vestibules would greatly increase the danger.

The lower court has decided against the Citizens Railway Company, of Knoxville, Tenn., and denied its right to lay a track in Depot street, for which it had received a franchise, on the ground that its charter from the state did not contemplate a

line in that street and consequently the franchise from the city was void. In other words a corporation must ask for all it wants and can not take more as a gift.

The tax assessment of the Des Moines City Railway Company has been more than trebled this year and the company has decided to collect more money to pay the taxes. Tickets, which have been sold six for 25 cents, are withdrawn and hereafter a straight five cent fair will be collected.

The Ohio Supreme Court has rendered a decision to the effect that the Main Street Line of Cincinnati is a trespasser and must cease operating south of Liberty street. This ends a 7-years' legal fight. The city and the Consolidated Street Railway are now free to arrange for various extensions of the latter's lines, including the Mt. Auburn line, upon which work will be commenced immediately.

The San Francisco & San Mateo Electric Railway Company has made considerable progress in the reconstruction of its entire system. The main line, running on Harrison and Guerrero streets, between the ferry and 13th street, will be the first to be completed. The branch lines will then be rebuilt and application for additional franchises will be made. A number of new cars will be added to the equipment.

The Hamilton (Ont.), Grimby & Beamsville Electric Railway Company has published a folder giving information regarding Hamilton and the towns and parks in that vicinity. A time and special rate table is also given. On the reverse side are some views of picturesque scenes along the route and a colored lithograph gives a good idea of the beautiful country and towns through which the line passes for 23 miles.

An ordinance was passed at Lansdowne, Pa., compelling the Delaware County Electric Railway company to stop its cars at each street crossing and imposing a fine of \$5 for each violation. A suit to sustain the ordinance was lost by the town and Judge Clayton said that such an ordinance was unheard of even in cities where the streets had many times the traffic in Lansdowne and hence burdensome and unnecessary.

The suit against the Nassau road of Brooklyn brought by one of its conductors who attempted to save himself from falling by holding to one of the route signs on the car and which gave way, has been dismissed. The company claimed that the sign was to tell the destination of the car and not to keep people from falling off, and that it was no negligence on the part of the company if it was not securely fastened, and the court took the same view.

It appears from data collected and published by Gilmore Brown, engineer, of Wheeling, W. Va., that of the 28 cities in the United States having a population in excess of 100,000 by the census of 1890, 19 have all street railway tracks of standard gage, 4 ft. 8½ in. St. Louis, New Orleans and Denver have three gages, 3 ft. 6 in., 4 ft. 10 in. and 5 ft. 3 in., the two former predominating. Philadelphia, Baltimore, Cincinnati and Pittsburg have the 5 ft. 2 in. gage exclusively.

The Alley "L," Chicago, is to make a trial of an open car for the elevated service. One of the regular cars was

damaged by fire and in repairing it some alterations are to be made in the arrangements of the windows. The windows will be considerably larger than those at present and can be let down behind the panels. Instead of having the seats extending along each side they will be arranged crosswise, except for a short space at each end. It is expected that this car will be very attractive to the passengers.

The government of Nicaragua has granted a concession to Messrs. Barling & Davis to build an electric road from Rama or some other point on the Escondido river to Lake Nicaragua. It is stated that the lines will pass through some rich sections of country and good mineral lands. It is expected that the power can be furnished by water falls which are within close proximity to the proposed line. Large land grants also are a part of the concession. Isham Sedgwick, of Richmond, Ind., is president of the company.

The experiment of placing ordinary street letter boxes on the street cars which was inaugurated at Des Moines, Ia., on April 19 has shown that this service is greatly appreciated by the public. Fifteen cars were equipped with the boxes and on the first day the total number of pieces of mail matter collected was 215; on May 28 the total was 1,434. In the outer districts where there are but two collections by carriers per day a gain of 24 hours is made on letters for the East deposited after 3 p. m. The department will extend this service as rapidly as possible.

Two St. Louis school lads, who were ambitious to become motormen, slipped into the car barn of the Mound City Railway Company and proceeded to operate a car within its narrow confines. The car was soon beyond control and butted into the wall. After rebounding the trolley came into contact with the wire and again lunged into the wall. After this maneuver was repeated once or twice the wall gave away and the car went through and into the alley. The boys have not been heard of since and the street railway company has to pay rather dearly for their experience.

The Metropolitan Street Railway Company of Kansas City has been confronted with a rather peculiar kind of trouble. Along some of the suburban lines the woodpeckers, which are numerous in that locality, bore into the trolley poles and build their nests. These holes are of considerable size, and permits water to accumulate at the heart of the poles. In a short time the poles rot and break off. Along the line between Kansas City and Independence the company sent out a man with a shot gun, and a large number of the birds were killed and the nuisance abated. This is the only remedy that has been found so far.

On account of an extended trip in Europe, contemplated for rest and the recuperation of his health, Alfred Hand, president of the Ithaca (N. Y.) Street Railway Company, has sold out his interest to E. G. Wyckoff and H. Berg-holtz of Ithaca. E. G. Wyckoff was chosen both as a director and president of the company. Congressman William Connell resigned as director and Chas. J. Rumsey of Ithaca was elected to fill the vacancy. Cornell University has invested \$62,000 in bonds of the company and this is considered a tribute to the good financial standing of the street railway, as the University authorities are very cautious about investments.

## THE SWEET RAIL DRILL.

## THE RATING OF BOILERS.

The illustration shows the rail drill invented by Arthur J. Sweet of Ann Arbor, Mich., and manufactured by the Michigan Manufacturing Company of Ypsilanti, Mich. The attachment and adjustment are controlled by the vertical lever; when the lever is dropped back the drill is withdrawn from the work. But three seconds are required for adjusting or releasing the drill. The frame is cast in one piece and the construction is very simple so that a common laborer can run them. To reduce friction a special ball bearing is placed at the rear of the drill shaft. There are  $\frac{1}{2}$  in. play between the drill point and the arms so that there is no difficulty in placing the drill in position on the largest gir-

SWEET RAIL DRILL.

der rails. The drills used are either No. 1 or No. 2 taper shank standard sizes from  $\frac{3}{8}$  in. to 1 in. in diameter. Allowing labor at 15 cents per hour it is quite possible to drill holes up to  $\frac{5}{8}$  in. diameter for less than  $\frac{1}{2}$  cent apiece, and 1-in. holes for a trifle more than that amount. These machines are made in two sizes, No. 1 being specially designed for T-rails and No. 2 for girders. Special designs for drilling structural iron and steel for buildings have given excellent satisfaction. The weight of this drill is about 150 lbs. When it is desired to move the machine it may be turned upside down and the balance wheels used as a truck.

## CONSOLIDATION OF LARGE COMPANIES.

The offer of the Pennsylvania Iron Works of Philadelphia to issue its preferred stock in exchange for the stock of the Siemens & Halske Company of America has been accepted by the holders of a majority of the stock of the latter company and the two companies will henceforth work in harmony with the prospect of a complete consolidation at an early date. The two companies will receive all the business for engines and electrical machinery for the roads controlled by the Philadelphia syndicate in which C. T. Yerkes is interested.

Recognized authorities on steam boilers recommend that in ordering a boiler the heating surface per rated horse power should be specified because of the fact that different builders rate their boilers differently, and the minimum is usually placed at  $11\frac{1}{2}$  sq. ft. per boiler h. p. or an evaporation of 3 lbs. of water from and at  $212^{\circ}$  F. per sq. ft. of heating surface per hour. At the same time and in connection with this recommendation the results of economy tests of boilers are quoted which show that one boiler may evaporate the same amount of water with a pound of coal and yet evaporate from two to three times as much per sq. ft. of heating surface.

The actual power in the engine cylinder which a given boiler develops depends upon the engine in which the steam is worked; the water which a given boiler will evaporate per sq. ft. depends upon the heating surface. A gentleman of an inquiring turn once asked the writer how long it would require for the Clark street tunnel under the Chicago river to fill with water if a hole were to be broken in it, and added that he meant an averaged sized hole. The rule of  $11\frac{1}{2}$  sq. ft. per h. p. may refer to average heating surfaces.

Power for July says editorially: "The capacity of a boiler is its ability to evaporate water into steam, and when a purchaser is stipulating for a boiler of given capacity he should lay more stress upon the evaporative capacity of the boiler which he chooses at a given rate of efficiency than upon the amount of surface furnished, giving due consideration to the fact that at the capacity stipulated the efficiency of the boiler has not commenced to fall off."

## LARGE ORDER FOR WESTINGHOUSE COMPANY.

The annual stockholders meeting of the Westinghouse Electric & Manufacturing Company was held at the company's works in East Pittsburg on June 23. After choosing directors, the old board was re-elected, the announcement was made that the company had on June 19 been awarded the contract for fifteen 5,000-h. p. generators which the St. Lawrence Construction Company is to install at its plant at Massena in northern New York. This is the largest single order for electrical apparatus ever placed and the amount directly involved is about \$750,000. This order together with that the Cataract Construction Company for five 5,000-h. p. generators for the Niagara Falls plant, which are now well under way, brings the aggregate capacity of the generators ordered of the company this year to 100,000 h. p.

These orders cover only the generators, and there will necessarily be required other apparatus of equal capacity for the utilization of the electrical energy produced by these great generators and the Westinghouse officials expect that a large proportion of the additional apparatus will be ordered from that company by reason of their having already secured the contract for the principal apparatus.

It is reported that the contractor who is working on the trolley road building between Morrisville and Doylestown, Pa., was kept a prisoner in his hotel by a mob of Italians who wanted money for work done.

FOREIGN FACTS.

Leads has completed the Kirkstall extension of its street railway.

Plans are being discussed to construct an electric railway from Salerno to Cava dei Terroni, Italy.

Derby council has voted in favor of the plan to construct a light electric railway from Derby to Ashbourne.

The proposal to build an electric railway from Bray to Glendolough is approved by the commissioners of Bray.

An English syndicate has obtained the concession to build 40 miles of electric railway in Barcelona and its suburbs.

Glasgow has appointed a sub-committee to arrange for the building of the new electric line between Springburn and Mitchell street.

Blackburn corporation has been recommended to accept the bid of Siemens Bros. & Co. for the construction of the electric railway.

The British Electric Traction Company has applied to the Dudley council for the right to construct a system of trolley lines in that district.

Vienna has authorized two lines of electric railway extending into the suburbs. The contract will probably be given to Siemens & Halske.

The city authorities of Cologne have asked for bids on the construction of 12 miles of electric railway, estimates to be in by September 3.

The Bristol Carriage & Tramways Company has applied for permission to build an electric line from Bristol to Hanham, a suburb.

The Halifax Corporation Tramways Act granting power to borrow £20,000 with which to install electric motive power, has passed Parliament.

Ratepayers of Ramsey, Isle of Man, have expressed themselves in favor of the proposition to build an electric railway from Ramsey Bay to Queen's Pier.

Permission to operate its Burslem lines with steam power has been granted the North Staffordshire Tramways Company, pending their equipment with electricity.

Trolley cars will soon be running on the island of Java. The Union Electrical Company of Berlin has the contract for the construction of 10 miles of electric line in Batavia.

Local authorities of the Dudley, Eng., district, where it is proposed to convert the steam railway to the overhead trolley system, made a visit of inspection recently to the Douglas & Lacey Electric Railway.

At Dublin a 4-mile extension of the United Tramway will be built to Sutton Cross Roads, there to connect with the electric railway around Howth, which is to be built by the Great Northern Railway Company.

Ramsgate council has approved the application of the Isle of Thanet Light Railways Company for authority to construct the proposed electric railway from Pegwell through Ramsgate, Broadstairs and Margate.

Birkenhead council has rejected the proposals of three firms to operate the street railway with electric power. The committee, however, favored the proposition of James Ross, of Birmingham, who wished to introduce the overhead trolley.

J. H. Madden, U. S. consul at Smyrna, Turkey, writes that there are but two street railways in that province, and these are both in the city of Smyrna. These lines are of small importance, as the Turks feel little need of rapid locomotion.

Arrangements are again being made to construct the underground electric railway in London, from Moorgate street to a junction with the Great Northern Railway near Finsbury Park. Parliament is asked an extension of time in which to complete the work.

Ghent, Belgium, has settled the details on which bids will be accepted for the construction and operation of an extensive street railway system. Storage battery cars will be operated in the center of the city, while in the outlying districts the overhead trolley will be permitted.

Plymouth, Eng., council has voted to equip immediately one section of the street railway for electricity at an expense of £7,500, of which £3,300 will be required for the overhead trolley construction, £3,750 for five cars and £450 for rail bonding. The question of equipping another section at an expense of £12,000 has been postponed.

To provide an adequate supply of water the municipal government of Cape Town has built a reservoir with a capacity of 225,000,000 gallons on the summit of Table Mountain. A water power plant has been constructed on the pipe line running from the mountain to the Molteno reservoir. Electricity will be supplied to light the city and to operate the street railway system.

The Karlsruhe Street Railway Company, of Karlsruhe, Germany, writes us that the conversion of its horse and steam railway into an electric line will be commenced in the fall of this year. Of the 9 miles of road one half will be equipped with the overhead trolley, the remainder with the conduit. Three engines, aggregating 450 h. p. will be installed in the power station to operate the 30 motor cars.

While excavating on a line of the Belt Railway Company, Lexington, Ky., one of the workmen struck what appeared to be a piece of pipe. It proved to be a 61-lb. dynamite cartridge and a terrific explosion followed, killing five of the negro workmen and fatally injuring the sixth. The police are inclined to think that the bomb was placed there by some one hostile to the railway company, but it might have been accidentally left there by the workmen of the Cincinnati Southern Railroad when previously excavating in the same neighborhood.

## THE CENTRAL LONDON RAILWAY.

It would be difficult to secure more satisfactory evidence of the high esteem in which American electrical machinery is held abroad than in the fact that the entire electrical equipment of the Central London Railway, the latest of the underground lines of London, is to be American. The contract with the exception of the elevators, has been taken by the British Thomson-Houston Company representing the General Electric Company, and the elevator contract by Frank J. Sprague.

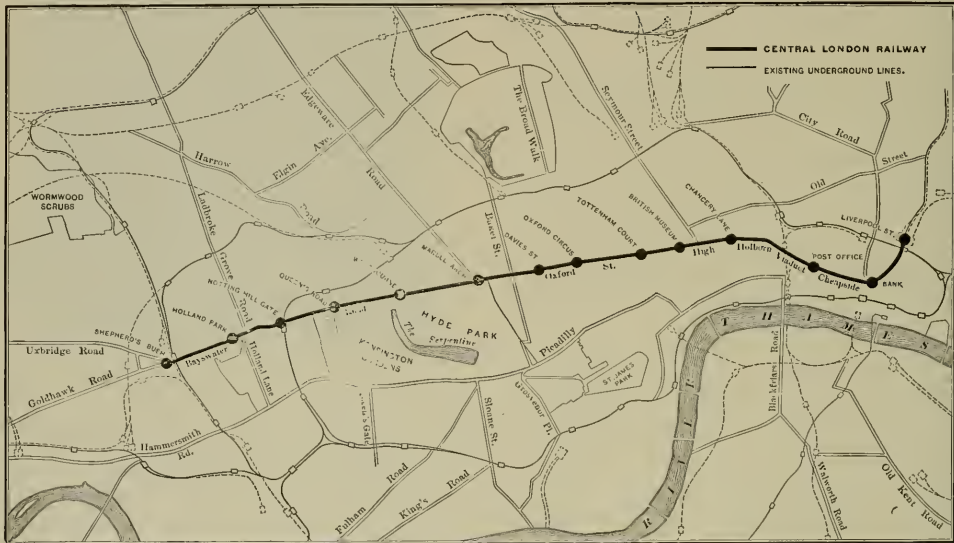

The road is  $6\frac{1}{2}$  miles long from Liverpool street to Shepherd's Bush, making 13 miles of single track. At the underground central station now building between the Bank of England and the Royal Exchange the road will receive passengers from three railroads and as the traffic at this point is very much congested the company is constructing a series of subways immediately below the surface for the convenience of its passengers in reaching the station.

The road is double track throughout, the two lines being

Locomotives instead of motor cars will be used. Each will consist of a sheet iron cab containing the controller, instruments, air-brake, sand boxes, etc., and mounted on a locomotive truck. There are to be four G. E. 56 motors one to each axle, giving a total drawbar pull of 14,000 lbs. The locomotives are to weigh 35 long tons and each train is to consist of seven cars seating 336 persons and weighing loaded, 105 long tons. It is estimated that the road will carry 43,000,000 passengers per annum at an average fare of four cents.

The generating station is to be located at Shepard's Bush. Six 1,300-h. p. Allis engines, each direct connected to an 850-k. w. G. E. dynamo, constitute the power station equipment. The dynamos run at 94 r. p. m. with a frequency of 25 and initial voltage of 5,000. There are to be four substations equipped with step-down transformers and rotary converters. The line voltage is to be 500.

The elevators, of which there are to be 49 will be of the double drum type and run at a speed of 150 ft. per minute. The capacity of each is 15,000 lbs.

MAP SHOWING ROUTE OF THE CENTRAL LONDON RAILWAY.

laid in separate tunnels of  $11\frac{1}{2}$  ft. internal diameter except at the stations where they are widened to 21 ft. for a distance of 375 ft. At each station are four vertical shafts, two 23 ft. in diameter and 87 ft. deep and two 18 ft. in diameter and 76 ft. deep; the larger contain two entrance and two exit elevators and the smaller ones spiral stairways. The route and location of the 14 stations are shown on the map.

The rails weigh 100 lbs. per yard and are laid on cross-ties. The third rail system of contact will be used, and the line sectioned and the feeder system controlled by signal boxes. In order to retard and accelerate the trains more easily at stops there is a 3 per cent grade on each side of each station; it is estimated that by this plan a saving of one-third of the power otherwise necessary for the acceleration of the trains will be made. The schedule speed will be  $14\frac{1}{2}$  miles per hour with stops of 20 seconds.

## X-RAYS AND DAMAGE SUITS.

During the trial of David Deatur vs. Minneapolis Street Railway Company, the plaintiff claimed that among other injuries, he had received a fracture of the bone at the hip joint. This was denied by Dr. Fitz-Gerald who made an examination for the company. The X-ray picture settled conclusively that there was no fracture but that a bullet, lodged near the hip joint, was the cause of the particular complaint on the part of Captain Deatur. He suffered from other injuries and damages sustained but his chief grievance seemed to be that his wooden leg had been broken.

The Metropolitan of Kansas City contributed \$10,000 to a fund for building a convention hall in that city.

FRANCHISES TO INDIVIDUALS IN ILLINOIS.

The question has been asked us whether Section 1 of the new Allen law is to be construed as limiting the granting of a franchise for a street or interurban railway exclusively to an incorporated company organized for that express purpose, or whether it was consistent for the proper authorities to grant a franchise to one or more individuals. In the section in question, which we quote, it will be noted no reference is made to "individuals" but only to a "company." The section reads:

Sec. 1. Any company which has been or shall be incorporated under any special or general law of this state for the purpose of constructing, maintaining or operating any horse, dummy or street railroad or tramway, may enter upon and appropriate any property necessary for the construction, maintenance of its road, and all necessary siding, side tracks and appurtenances, and may, subject to the provisions contained in this act, locate and construct its road upon or over any street, alley, road or highway, or across or over or under any waters in this state, in such manner as not to unnecessarily obstruct the public use of said street, alley, road or highway, or interrupt the navigation of such waters.

Undoubtedly one of the best authorities in the country on street railway law is Judge Egbert Jamieson of Chicago, who is the general counsel for the North and West Chicago Street Railroads. In answer to the above question he says:

"In reply to your question 'whether or not the Allen bill is to be construed as making it unlawful for county supervisors or city councils to grant a franchise for a street railway to one or more individuals,' I answer: In my opinion, the horse and dummy act as amended, (Allen bill), extends and applies to persons or individuals as well as to incorporated companies, and that the proper corporate authorities may now, as heretofore, lawfully license one or more individuals to construct and operate a street railroad.

"Every lawful business may be conducted by an individual or individuals, but it is not every such business that may be carried on by a corporation. The statute makes certain exceptions. A statute that prohibited any lawful business from being conducted except by an incorporated company would be clearly unconstitutional and void. The mere omission in the statute of the words 'person or persons' in connection with the use of the words 'corporation or company' does not limit the power to grant a license for a street railroad be incorporated companies only. The words 'corporation or company' would be construed as extending or applying to individuals as well as to corporate bodies."

In direct confirmation of this opinion Hon. Edward C. Aiken, attorney general, advises us under the same date, as follows:

"In determining the right of the common council in cities and of county boards to grant franchises to street railway companies on and over the streets and highways under their respective control, other provisions of the law than those contained in the so-called 'Allen bill' must be considered.

"Sec. 4 of Art. 11 of the Constitution of 1870, and clauses 9, 21, 25 and 90 of Sec. 63 of the General Incorporation Act all relate to the same subject matter and should be considered and construed together with the provisions of the so-called 'Allen bill.'

"I am of the opinion that the last named act does not deprive the common council of cities or the county board, of the right to grant street railway franchises to individuals

upon like terms, conditions and restrictions as if granted to incorporated companies."

PERSONAL.

H. M. Littell has returned from his European trip.

James H. Cronan has been appointed engineer and superintendent of power house of the Winsted & Barrington (Conn.) Street Railway.

W. D. Ray, general manager of the Everett (Wash.) Railway & Electric Company resigned July 1, and will shortly return to Chicago.

D. H. Goodrich, secretary of the Omaha Street Railway spent a week in Chicago visiting relatives and friends, the first vacation in three years.

Henry O. Rodgers, for many years division superintendent of all the horse lines of the Market Street system of San Francisco died last month at the age of 64.

James D. Parker, the new secretary and superintendent of the Sandusky, (O.) Milan & Norwalk Electric Railway has taken up his duties with the company.

John A. Brill, vice-president of the J. G. Brill Company, last month returned from a tour of Great Britain and the Continent; he was greatly benefited by the trip.

Columbus R. Cummings, of Chicago, owner of the Grand Rapids, Mich., Street Railway, and financial backer of the South Chicago, died on July 12, after an illness of several months.

H. R. Conklin, formerly superintendent on the Jefferson Avenue Railroad Company, St. Louis, has been appointed general manager of the Citizens' Traction Company, Oshkosh, Wis.

Wm. B. Walker resigned as director of the Chicago City Railway Company and E. G. Hamilton was chosen as his successor. Mr. Walker expects to make his home hereafter in Boston.

E. D. Dubois, who recently went from Chicago to Muncie, Ind., to take up the duties of superintendent of the Citizens' Street Railway Company was seriously prostrated by the heat last week.

William Keutgen, secretary of the Staten Island Rapid Transit Company, died on June 9, having failed to recover from an operation for appendicitis. Mr. Keutgen was 46 years of age and had been with the company ever since its organization.

E. E. Downs, formerly general manager of the electric street railways of Lansing, Kalamazoo and Battle Creek, Mich., has severed his connection with these companies and is now with the interurban road now building between Indianapolis, Anderson and Marion, Ind.

J. F. Heyward, formerly general manager of the City & Suburban of Baltimore, was elected secretary of the Consolidated when the former company was merged in the latter but resigned, asking to be relieved on July 1; the reason given by Mr. Heyward is that he preferred to continue in the operating branch of street railroading. Thomas C. Jenkins, the son of George C. Jenkins the superintendent of motive power, has been elected secretary of the Consolidated.

The many friends of Clemeat C. Smith, superintendent of the Falk Manufacturing Company, will learn with deep regret of the death of his brother, Walter C. Smith. He was in charge of the construction of a road at Norfolk, Va., and with a party of friends went bathing in the shallow water near Crane Island Light, in the Elizabeth river. While swimming he was taken with cramps and lost before help could reach him. The body was recovered five days later and brought to Milwaukee for interment. The deceased was a young man of much promise, and his sudden death lends unusual sadness to the termination of a bright future.

The Davis Rail Brake Company has been incorporated at Detroit, Mich., to manufacture street and steam car brakes.

The Pennsylvania Steel Company is supplying the 64-lb. T and the 88-lb. girder rail for the new Falls Road Electric Railway at Baltimore, Md.

Smethurst & Allen of Philadelphia have the contract for all the overhead work on the big interurban of the Meadville Traction Company at Meadville, Pa.

The Automatic Electric Traction Company has been incorporated at Chicago. The capital stock is \$30,000, and the incorporators are Zebulon Foster, Edward Foster, Stanton Foster and William G. Foster.

The Ball Engine Company, Erie, Pa., is building two 125-h. p. horizontal tandem compound engines which will be used for the electric transmission of power and light in a large works in the city of Moscow, Russia.

Macartney, McElroy & Co., of New York, have been awarded the contract to supply all of the material required and to construct eight miles of road for the Sherbrooke Street Railway Company, Sherbrooke, Que.

The Columbia Brake & Supply Company has been incorporated at Chicago to manufacture street car brakes. The capital stock is \$100,000, and the incorporators are William G. Price, John J. O'Keefe and Charles Atkinson.

The Western Gear Company of Milwaukee, Wis., has established an eastern office for the sale of its well known motor gears and pinions. George C. Ewing, 8 Oliver street, Boston, Mass., is the company's eastern representative.

The C. L. Pullman Car Company has been incorporated at Chicago to manufacture and sell street cars. The capital stock is \$5,000,000, and the incorporators are Charles L. Pullman, E. C. Pullman, G. E. Highley, H. J. Furber and George S. Steere.

The American Electrical Works of Providence, R. I., manufacturers of bare and insulated wire, always issue attractive advertisements and when the occasion offers patriotic ones. For the 4th of July their announcement is a copy of "The Star-Spangled Banner."

The Western Gear Company of Milwaukee, Wis., has quite a handsome souvenir for its patrons. It is a silver cigar holder and ash receiver which may be clamped on the edge of a desk. This token of esteem the company would be pleased to send to its friends on application.

The business of the Wenstrom Electric Company of Baltimore is being mismanaged and Christopher C. Shriver, a stock holder, has petitioned the Circuit Court to have a

receiver appointed. Judge Dennis signed an order to show cause why a receiver should not be appointed.

The Ohio Construction Company has acquired the Menasha & Neenah Street Railway, at Menasha, Wis., and within sixty days will build an interurban line through the city. Interested with Henry C. Payne in the project are M. J. Degnon, C. W. Collister and J. J. Hogan, of Cleveland.

Hayes & Arthur, agents for electrical supplies, Cleveland, O., have been appointed agents in the territory of New York west of Syracuse, and central and northern Ohio, for the sale of drop forged commutator segments, manufactured by the Van Wagoner & Williams Hardware Company of Cleveland.

Hirsch Bros., Chicago and New York, have taken the \$100,000 bonds of the line now under construction from Holland, Mich., to Macatawa Park, a distance of 7½ miles, which also includes a lighting plant. There is a resident population served of about 15,000 people and the summer visitors increase this number by 20,000.

The Brownell Car Company, St. Louis, reports an increasing number of inquiries for fare boxes, one of the most recent being from Nijmegen, Holland. The increasing number of interurban roads and the necessity of small roads dispensing with conductors, have combined to recall the many excellent advantages of a good fare box.

Hirsch Bros. & Co. have effected a consolidation of four of the five electric lighting companies doing business in the territory south of 39th street, Chicago. Bonds of the new company which are to be issued to meet maturing obligations of the old companies and to provide funds for extensions have been underwritten by an eastern syndicate.

The Partridge Carbon Company, Sandusky, O., in reply to our inquiry advises us its business during the month of June, and to date, is better than for two years past, with every indication of keeping up right along. Secretary Speer attributes this to the excellent results the Partridge goods are giving and that new customers are constantly finding out their good qualities.

The stockholders of the Consolidated Car Heating Company of Albany, N. Y., at the last meeting re-elected the old board of directors and declared a dividend of 1.5 per cent. The officers are R. C. Pruyne, president; Charles Tracey and D. P. Sewall, vice-presidents; E. A. Groesbeck, secretary; Charles A. Sheldon, general manager and treasurer; J. F. McElroy, consulting engineer.

A successful test of an air motor of the Hoadley-Knight design is reported on the Eckington & Soldiers Home Railway. The car started out with a pressure of 2,050 lbs., 50 passengers aboard and made the circuit including 32 stops within an hour. Stops were made on the grades and curves and there seem to be no difficulty in starting at any point. At the end of the run the pressure in the air reservoir was 350 lbs.

W. P. Woods is now the St. Louis representative of the Simmons Manufacturing Company of Pittsburg. Mr.

Woods has for a long time past been connected with the Missouri Car & Foundry Company, and leaves that concern to enter the railway supply business on his own account. The St. Louis office is at 1013 Chestnut street, where prompt attention will be given to orders for street railway supplies for all systems.

During the past six months some 50 street railways have been added to the long list of roads which have adopted new process raw hide pinions. The use of these pinions for general machinery purposes is also steadily increasing; and not only in this country, but abroad as well. The maker, (the New Process Raw Hide Company, Syracuse, N. Y.) reports shipments to England, Germany, France, Russia, Italy, Sweden, Australia, and South Africa and state that orders by cable are not unusual.

On June 26, J. H. Bass and C. T. Strawbridge were appointed receivers for the Bass Foundry & Machine Works of Ft. Wayne, Ind. The works will be operated without interruption by the receivers under the same management as heretofore and all orders given to or contracts made with the Works or with the receivers will be promptly and faithfully executed. The receivership is only temporary as the assets are greatly in excess of the liabilities; none of the other concerns in which Mr. Bass is interested are affected.

The Clayton Air Compressor Works, 26 Cortlandt street, New York, has a new catalog (No. 9) which is one of the most complete ever attempted. In addition to the illustrated description of the features of the Clayton compressor, and data regarding the Clayton air lift pumping system there is a descriptive article on the use of compressed air, showing the various applications which have been made of it and giving cuts and descriptions of compressed air tools. The catalog is issued for gratuitous distribution and will be sent on application.

The Detroit Steel & Spring Company states that there is a gradual improvement in its general business. However buyers are making their purchases very carefully. As an indication of this, the first six months of this year show an increase of from 15 to 18 per cent as compared with the same period last year yet the tonnage of the sales for this year is not as great as it was last. This will be more than offset by a comparison of the coming six months as it is safe to say that the business will be double what it was during the last six months of last year.

The R. D. Nuttall Company of Allegheny, Pa., has appointed new representatives for its northern states sales department, in the persons of Messrs. Hayes & Arthur, 302 Cuyahoga building, Cleveland, O. Mr. Hayes needs no introduction to many of our readers, being already well known in the electrical line, in which he has acquired considerable experience and made many friends. While not so well known, Mr. Arthur brings into the business an untiring energy and a pleasant personality that will commend him to all with whom he will come into contact.

The National Association of Manufacturers of the United States has secured a building in Caracas, Venezuela, which is to serve as a sample warehouse for American goods. The warehouse is intended for the display of American

goods with a view of bringing them before the public under favorable circumstances for both buyer and seller. It is designed to make the charges for space as low as possible and pay the necessary expenses. Applications for space or further information should be addressed to the National Association of Manufacturers, 1751 North 4th street, Philadelphia.

The American Institute Fair will be opened September 20 and continue until November 4 at Madison Square Garden, New York. Everything pertaining to railways and transportation by land and water will be included in the exposition. The institute has a system of awards for meritorious inventions and improvements which include the gold medal of honor, the special medal of silver, the medal of taste, bronze medals of excellence and merit, diplomas and special awards, which are of value in advertising and selling any article thus honored. Dr. P. H. Murphy is the chairman of the board of managers.

The extensive works of the Ball Engine Company, Erie, Pa., we are glad to learn, are full of work. This company is one of the pioneer builders of automatic engines for electric purposes, having been building the Ball automatic engine for 15 years. Under the present management the engine has reached a high degree of perfection, and is a strictly high grade automatic engine. These engines can be found in a large number of the electric light and electric railway central station plants in this country, and there are a great number of them that have been running from eight to 15 years that are today in constant and satisfactory use.

The Warrenton Woolen Company, manufacturers of high grade cloths for uniforms, is making very gratifying progress in introducing its goods to street railways, and the number of roads now adopting these woollens for exclusive use, is constantly increasing. Among the roads where a certain cloth is "stipulated" and which have named these goods, may be mentioned the Chicago City Railway, the North Chicago Street Railroad and some of the Brooklyn lines. Theo. A. H. Weinz, 57 Leonard street, New York, is the sole agent, and is an experienced uniform man, who has devoted many years to a study of the requirements of that special work.

The Albert & J. M. Anderson Manufacturing Company, 289 to 293 A street, Boston, has just circulated a neat catalog on switches, switch-boards and lightning arresters. A partial list of switch-boards, including those of the Buffalo Street Railway, Metropolitan Street Railway, the Union Traction and other street railway companies, made by this firm, is given. The Ajax car arrester is also illustrated and described. The company reports that the switch department is handling a large amount of work on storage battery switches for large plants. A new brass foundry, lately built and equipped, enables the company to manufacture copper castings of a high grade and every variety of switch and switch-board.

Frank J. Sprague, who received the contract for equipping the electric rolling stock of the Alley "L," Chicago, subject to the satisfactory operation of a six-car train has let contracts for the equipment of the six experimental cars, and a series of tests with the train will be made at Schenectady the latter part of July. The General Electric Company is

to furnish 12 motors; the McGuire Manufacturing Company, 12 trucks; the Standard Air Brake Company, six sets of independent electric motor air-brake equipments. Other contracts have also been let. Green economizers will be used in the power house, Atkinson and Roebbling rail bonds have been specified, copper will be furnished by the Western Electric Company, and the construction work has been let to the Electric Installation Company.

The Central Electric Company of Chicago, is well prepared to furnish all classes of material necessary for repairs and construction. It gives especial attention to the quick shipment of materials, and it has surprised many of its customers to know that their goods were delivered in so short a time after having been ordered. The Central Electric Company appreciates the necessity of quick deliveries, therefore its promptness. It is always abreast of the times, and in possession of the latest specialties, which possess merit. It does not always claim to furnish material at the lowest prices, but its aim is high, and it strives for the best. Quality is the standard, and satisfaction to customers the uppermost motive. The company is constantly inquiring of the trade, as to their needs and soliciting inquiries, and is pleased to be of service to all who desire to investigate its specialties or products.

The H. W. Johns Manufacturing Company, New York reports with gratification that its sales of trolley line and other insulating materials have been greater during the past six months than during any similar period heretofore. Shipments have in several instances been notably large and destined for all parts of the world. The toggle clamp feed wire insulator introduced some months ago, with its automatic, time-saving and economic features, has been quickly recognized as the first practical embodiment of valuable improvements over all other forms of insulators for supporting and insulating heavy cables. There has been some difficulty in keeping up with the orders for the toggle clamp and strain insulators. The company is enlarging its manufacturing facilities in order that there may not be the delay this year in furnishing the H. W. J. electric car heaters occasioned last year by an underestimation of the demand.

The Westinghouse Electric & Manufacturing Company's Chicago branch has during the past two months secured a big share of the electrical contracts let in its territory. In addition to the big equipment of the South Side Elevated Railroad, already noted in these columns, the Westinghouse Company has sold motors and generators to the Indianapolis, Anderson & Marion Electric Railway, Marion, and the Indiana Electric Railway, Goshen; a 150-k.w. generator and several motor equipments to J. C. Hubinger, Keokuk, and eight equipments to the Sioux City Traction Company, Sioux City, Ia.; equipments for the Oakland Railway, Detroit, and a 400-k. w. slow speed direct connected generator to the Dow Chemical Company, Midland, Mich. Among recent contracts for lighting and transmission plants is one with the Apple River Power Company of New Richmond, Wis., where a 6,000-volt inductor type generator will be installed, the first of this type installed by the Westinghouse Company in the western territory.

The first large underground work in St. Louis is now under way, and the Standard Underground Cable Company

of Pittsburg, New York, Chicago and St. Louis, has recently secured from the Bell Telephone Company of Missouri, and the Kinlock Telephone Company, (both of St. Louis) two of the largest contracts ever let in this country (and probably in the world) for telephone cables, these two orders comprising all the underground work in St. Louis yet contracted for, and constituting the complete cable equipment for both telephone companies. Both contracts were secured in the face of the most severe competition, and the well known excellence of the telephone cables manufactured by the Standard Underground Cable Company largely influenced the placing of the order with them, as the prices were exceedingly close. To fill these contracts there will be required more than 650,000 feet of cable, which in turn requires about 100,000,000 feet of No. 19, B. & S., copper wire, and 2,000,000 pounds of lead. To meet this extraordinary demand, the manufacturing facilities of the company in the paper covering department, have recently been doubled, which places it in a position to not only handle this enormous volume of business rapidly and easily, but at the same time to fill without any delay, the large, and constantly increasing orders for telephone cables, electric light and power cables, rubber insulated wire, etc., which are being daily entered. Considerably more than one-half of this cable will be installed by the Cable Company, it having contracted to turn the cable system of the Kinlock Company over to that company complete and ready for service. A large force of expert workmen will be employed for nearly a year in this work under the direct supervision of the St. Louis office.

#### NEW PUBLICATIONS.

A. A. Schantz, general passenger agent of the Detroit & Cleveland Steam Navigation Company, Detroit, has issued a charming little booklet written in verse, describing the lake trip to Mackinac. It is well worth sending for and reading.

"Illustrated Binghamton" is the annual souvenir issued by the Binghamton Railroad Company, of which J. P. E. Clark is the enterprising general manager. It is a book of 36 pages and as its name indicates is profusely illustrated with views of the public and private buildings of the city, and the pleasure resorts and parks which make Binghamton so attractive in summer.

We have just received the report of the fifth annual meeting of the Pennsylvania Street Railway Association held in September, 1896. The papers read at the meeting have been published in the REVIEW, but the verbatim report contains in addition to these the discussions of the subjects, "Street Railway Law" and "Liability Insurance," which are very interesting. In its typography and presswork the report leaves nothing to be desired.

"The Street Railway System of Philadelphia," by Frederick Speirs, Ph. D., is the latest of the Johns Hopkins University studies in historical and political science and an interesting and instructive account of the subject, giving the process through which the different railways of the city have been combined in the hands of the Union Traction Company. Published by the Johns Hopkins Press, Baltimore, Md. Price \$1, bound in cloth.

We acknowledge the receipt of the 1897 edition of American Street Railway Investments, financial supplement of the Street Railway Journal. In addition to the data which has been incorporated in previous editions of the "Red Book" and the review of the year, making mention of the most important events bearing on street railway results, a table has been added in which are compared the gross receipts of 1895 and 1896 of all roads whose gross receipts are in excess of \$25,000 per annum. Companies are arranged according to the magnitude of operations in 1896, making the table convenient for comparing financial results.

## G. E. 52 MOTOR.

The General Electric Company offers a new street railway motor having a capacity of 28 h. p. which is intermediate between the G. E. 1,000 and the G. E. 800. The new motor is to be known as the G. E. 52 and is rated according to the G. E. standard, i. e., a maximum rise of 75° C. in the temperature of the windings after an hour's

NO. 52 MOTOR WITH CASE OPEN.

run at the rated load, the temperature of the air not exceeding 25° C. This motor is designed for ordinary street railway service and will accommodate electric brakes. The frame is of steel, cast in two bowl-shaped pieces and hinged and bolted so as to make it dust and water proof. The motor has four field pieces, each with its own coil. The pole pieces are bolted to the frame. The large bearing surface insures small expense for bearing linings. The armature bearings are designed for the use of both oil and grease. They are constructed on the "outboard" bearing plan and measure on the pinion end,  $7\frac{3}{4} \times 2\frac{3}{4}$  in. and on the commutator end,  $6\frac{3}{8} \times 2\frac{1}{2}$  in. The upper support for the lining is cast with the upper half of the motor frame and the space between the inner end of the lining and the motor frame is occupied by a thrust collar which also acts as an oil guard. The lower support for the lining is a cap bolted to the upper half but not inclosing the lower half of the oil guard. This allows free outlet to the oil and grease and makes it impossible for the lubricant to work into the motor.

The field coils are wound with asbestos-covered wire and are "mummified," each being held in place by a projection of

NO. 52 MOTOR CLOSED.

the pole piece. The connections between the upper and lower fields are made outside the motor and both the field and armature leads are brought out at the front.

The armature is the iron clad, hollow core type, 11 in. in diameter with a spread of 9 in. The laminated core is provided with three ventilating ducts. There are 29 slots on the armature periphery, each containing three coils, connected to 87 commutator bars. The small number of coils minimizes armature repairs and grouping them admits of good insulation. The small weight of the armature is a great advantage in car operation. The standard gear ratio is 4.78 with a taper bore pinion having 14 teeth and a cast iron gear with 67 teeth. The commutator segments are of hard drawn copper,  $1\frac{1}{8}$  in. deep allowing a wearing depth of 1 in. The brush-holders are standard and staggered to prevent wearing of ridges in the center of the commutator. Each holder contains two radial brushes,  $2\frac{1}{4}$  in. long,  $1\frac{1}{4}$  in. wide and  $\frac{1}{2}$  in. thick. The brush-holder yoke is treated with an insulating compound and is rubbed to an enamel finish, preventing the lodgment of carbon dust.

The suspension can be either the nose, the yoke or the sidebar; but the yoke suspension is especially recommended as the weight of the motor is then carried on springs, placed on the side frames of the car trucks. Lugs are cast on the upper half of the motor frame, to which the suspension bar is bolted, the motor being suspended from the top half. This permits easy access for inspection and repairs as the lower half can be swung down into the pit without disturbing the upper half, which remains suspended from the axle and yoke.

When mounted on 33-in wheels the clearance between the

END VIEW OF MOTOR.

bottom of the motor and the top of the rails is 5 $\frac{7}{8}$  in. and between the gear case and the rail it is 4 $\frac{5}{8}$  in. The motor without gear or case weighs 1,460 lbs. and complete with gear and case the weight is 1,725 lbs.

## OBITUARY.

Col. C. W. Frazer, formerly president of the Memphis Street Railway and a prominent lawyer, died July 10. Mr. Frazer was a well known attendant on the conventions of the American Street Railway Association in the ante-electric days, and was the object of much pleasantry from the fact that he was drawn into street railway work through taking an unimportant case for the road of which he afterwards became chief owner and president. He was a bright speaker and a successful manager, and was always one of the conspicuous delegates and warmly welcomed at conventions.

The water pumping station at Chatanooga, Tenn., was shut down for repairs on June 21 and the town was without water. The street railway could not run its cars.

### FAY TENONING MACHINE.

The illustration shows the No. 7 automatic double tenoning machine recently placed on the market by J. A. Fay & Co., 557 to 577 West Front street, Cincinnati. With this machine both ends of the material are cut off to the proper length, and either single or double tenoned; the pieces are fed through the machine on an automatic carriage, producing tenons that are square with each other, with a great saving of the labor and time otherwise necessary. There are

NO. 7 DOUBLE AUTOMATIC TENONING MACHINE—J. A. FAY & CO.

eight tenoning heads, two on each spindle, and each furnished with knives that will cut tenons 6 in. deep; by using two heads on each spindle a tenon 12 in. deep may be cut. The spindles are  $1\frac{1}{4}$  in. in diameter and gibbed to vertical guides where an adjustment of 12 in. may be had. The vertical spindles are of the same size and are fitted with special heads for working double tenons to the depth of 4 in. The capacity of the machine is for timber from 10 in. to 9 ft. between shoulders, and up to 24 in. wide and 8 in. thick; if the ends be first cut to the proper length it will cut tenons on stock 12 in. thick.

### GENERAL ELECTRIC OF CHICAGO MAY USE THE TROLLEY.

It appears that the rumors long current to the effect that the Love conduit system would be installed by the General Electric Railway Company of Chicago as soon as its legal battles were fought, were ill-founded. The city council graciously passed an ordinance permitting that company to use the overhead trolley, but this was vetoed by the mayor. Further action by the council is not to be expected until the factional fight among the promoters is settled.

Gradual improvement in traffic can be noticed on the Brooklyn street railway lines, as may be seen from the report of the Brooklyn Rapid Transit Company. For the month of June, 1895, the gross earnings of the Brooklyn Heights Railroad were \$416,611, and of the Brooklyn, Queens County & Suburban Railroad \$71,595, making a total for the system of \$488,206. In 1896 the receipts decreased on the two lines to \$407,496 and \$65,022, and the total to \$472,519. However an improvement is manifest in this year's figures, which are respectively \$427,312 and \$68,185, a total of \$495,497. For the 12 months ending June 30, the gross earnings amounted to \$5,345,688, an increase of \$206,560 over the last fiscal year.

### SANTA ANA - LOS ANGELES TRANSMISSION LINE.

A contract for the transmission of power from the river running through the Santa Ana cañon to Los Angeles and Pasadena, has been concluded between the Southern California Power Company and the General Electric Company. The amount of power to be transmitted at first is 4,000 h. p. The station will be located in the Santa Ana cañon, 12 miles from Redlands and about 80 miles from the towns in which the electric power will be utilized. The water will be taken from the river through canal, flume and tunnel along the side of the cañon. Here it will be led into a pipe line 2,200 ft. long, giving what will be equivalent to a vertical fall in the water of 750 ft. The wheels will be of the impact type, directly connected to the generators of which there will be four, each of 750 k. w. (1,000 h. p.) capacity. The maximum line potential will be 33,000 volts to which potential the initial voltage will be raised by twelve 250-k w. step-up transformers.

This transmission will be the longest commercial electrical power transmission as yet undertaken, as well as that using the highest voltage. At present the longest is that transmitting the power of the waters of the Ogden cañon in Utah to Salt Lake City, a distance of 36 miles. The Los Angeles transmission will, be over twice that distance, and three times the longest distance yet tried with the power of Niagara which up to the present has only been transmitted to Buffalo, a distance of 26 miles.

### BLACK SAND POOL YELLOWSTONE PARK.

"No person who visits the Upper Geyser Basin should fail to see Black Sand Pool. It lies on the south of the main Upper Basin, and is reached by a road leading past the beautiful Punch Bowl Spring. Black Sand Pool is an oval spring some 40 feet long by 20 or 25 feet wide. The water is of a light blue sapphire or turquoise color—it is not easy to name the precise tint in many instances—extremely beautiful, from whose surface the steam constantly rises. The great peculiarity about it is that the encircling sides, which are in places fifteen feet high or more, are composed of black probably decomposed obsidian, sand."

The above is taken from "Wonderland 97," a new book published by the Northern Pacific Railway. Send six cents to CHAS. S. FEE, Gen'l Pass. Agent, St. Paul, Minn., for it.

### NEW CROSSING LAW IN NEW YORK.

Among the amendments to the general railroad law of New York is the following section applying to the crossings of street with steam railways:

§ 68. All street surface roads hereafter constructed across a steam railroad shall be above, below or at the grade of such steam railroad as the board of railroad commissioners shall determine, and such board shall in such determination fix the proportion of expense of such crossing to be paid by the street surface road.

**THE LOVEJOY TRUCK.**

The Calumet Electric Railway is now experimenting with a new type of non-oscillating truck which was built for the patentee, T. H. Lovejoy, by the Paige Iron Works of Chicago. The construction will readily be seen from the illustration; four levers are pivoted to the rectangular frame which supports the car body and to the upper part of the pedestals; the two levers on each side are connected to

when passing over a low joint, but this arrangement reduces the vibrations that occur with independent springs to a single one, and that one not so violent since the impact of the wheel must lift the whole instead of the half of the car to set up a vibration. The jaws of the bearings in which the supporting levers are mounted permit no lateral motion of the car body, and, as the trial on the Calumet demonstrated, this completely obviates the lateral vibration or "nosing" which is even more disagreeable than pitching.

THE LOVEJOY NON-OSCILLATING MOTOR TRUCK.

each other at the inner ends by the strap passing around a leaf spring which at the ends is connected to the truck side. When the manner in which the connections are made is considered it is evident that the car body and the truck side must be always parallel to each other and that there can be no oscillation of the car except a vertical motion of the whole car which is in itself a very good damper on "pitching." It is of course impossible to keep the car body level

**CONDUCTORLESS CARS AT LANSING.**

Judge Person declined to issue a writ of mandamus to compel the Lansing (Mich.) Street Railway Company to employ conductors on its cars, it being an uncontradicted fact that the company is not making enough money to pay conductors. The judge holds that the discretionary writ of mandamus will not be granted to compel an impossible thing.

## ELECTRIC STATION MANAGERS:

**YOU CAN'T AFFORD TO WASTE YOUR EXHAUST STEAM,** which you are doing, when you can sell it at a large profit. Many Street Railway and Electric Light Companies are making handsome dividends from this source.

**YOUR COAL BILL WILL BE NO HIGHER.**

These are some of the street railway companies that have adopted our systems:

Springfield, (Ill.) Elec. Lt. & St. Ry. Co.  
Terre Haute Electric Railway Co.  
Danville Gas, Elec. Lt. & St. Ry. Co.  
St. Joseph Street Railway Co.  
Ottumwa Electric Railway Co.

If these are not near you, write us and we will send you addresses of users in your vicinity.

Get our New Catalogue containing many letters like this, and full of information.

**AMERICAN DISTRICT STEAM CO., Lockport, N. Y.**

## ONE MANAGER SAYS:

"Have been operating the steam plant five years, warming between four and five million cubic feet of space. Income from steam heat over \$12,000 per annum, all from exhaust steam, except from \$300 to \$500 additional fuel in consequence of steam loss. Carry five to ten pounds back pressure, according to temperature outside, and only need to increase boiler pressure same amount. Have already paid for the entire installation of the steam heating system out of the additional profits since we put it in. We have no trouble or expense from leaky joints, and we do not employ any additional help in operating the plant over what we formerly employed for our lighting and street railway service."

## Directory of Street Railway Associations.

### American Street Railway Association.

President, R. McCULLOCH, St. Louis, Mo.; First Vice-President, C. S. SEROANT, Boston, Mass.; Second Vice-President, D. B. DYER, Augusta, Ga.; Third Vice-President, C. F. HOLMES, Kansas City, Mo.; Secretary and Treasurer, T. C. PENNINGTON, Chicago, Ill. Executive Committee, H. M. LITTELL, New York; H. P. BRADFORD, Cincinnati, O.; C. H. SMITH, Troy, N. Y.; H. SCULLIN, St. Louis, Mo.; G. B. HIPPEE, Des Moines, Ia.  
Next meeting, Niagara, N. Y., third Tuesday in October, 1897.

### The Street Railway Accountant's Association of America.

President, HENRY L. WILSON, Boston, Mass.; First Vice-President, C. M. DUFFY, St. Louis, Mo.; Second Vice-President, J. F. CALDERWOOD, St. Paul, Minn.; Third Vice-President, C. B. REAVIS, Augusta, Ga.; Secretary and Treasurer, W. B. BROCKWAY, Toledo, O.; Executive Committee: The OFFICERS and DANA STEVENS, Washington, D. C.; W. S. DIMMOCK, Council Bluffs, Ia.; W. G. ROSS, Montreal, Can.; E. R. L. THOR, Brooklyn, N. Y.

### New York State Street Railway Association.

President, G. TRACY ROGERS, Binghamton; First Vice-President, W. CARL ELK; Niagara Falls; Second Vice-President, JOHN N. BROKLEY, Rochester; Secretary and Treasurer, H. A. ROBINSON, New York. Executive Committee: H. H. VARELAND, New York City; JOHN W. McNAMARA, Albany; H. M. WATSON, Buffalo, C. L. ROSSITER, Brooklyn.  
Next meeting, Niagara Falls, first Tuesday, September, 1897.

### Ohio State Tramway Association.

President, A. A. ANDERSON, Youngstown; Vice-President, T. R. CATLIN, Canton. Secretary and Treasurer, F. J. SLOAT, Akron; Chairman Executive Committee, W. F. KELLEY, Columbus.  
Next meeting, Columbus, June 8, 1896.

### Pennsylvania State Street Railway Association.

President, JOHN LLOYD, Altoona; First Vice-President, ALBERT JOHNSON, Allentown; Second Vice-President, ROBT. E. WRIGHT, Allentown; Secretary, S. P. LEIGHT, Lebanon; Treasurer, W. H. LANUS, York. Executive Committee, JOHN LLOYD, B. F. MYERS, S. P. LEIGHT, JOHN A. RHOE and E. C. FELTON.  
Next meeting, Allentown, first Wednesday in September, 1897.

### Michigan Street Railway Association.

President, W. L. JENES, Port Huron; Vice-President, W. WORTH BEAN, St. Joseph; Secretary and Treasurer, B. S. HANCOCK, JR., Grand Rapids; Executive Committee, OFFICERS OF THE ASSOCIATION and CHAS. M. SWIFT, Detroit, and E. E. DOWNS, Kalamazoo.

Next meeting, first Wednesday in December, 1897.

### Massachusetts Street Railway Association.

President, PRENTISS CUMMINGS, Boston; First Vice-President, P. F. SULLIVAN, Lowell; Second Vice-President, JOHN R. GRAHAM, Quincy; Secretary, CHAS. S. CLARK, Boston; Treasurer, W. F. POPE, Boston. Executive Committee: E. P. SHAW, Newburyport; E. C. FOSTER, Lynn; CHAS. B. PRATT, Worcester; G. H. CAMPBELL, Lawrence, and S. M. THOMAS, Taunton. Auditing Committee, J. N. AARSMAN, Worcester; C. S. SEROANT, Boston, and ROBERT S. GOFF, Fall River.

Meetings are held every month.

### Connecticut Street Railway Association.

President, H. HOLTON WOOD, Derby; Vice-President, HENRY S. PARMLEE, New Haven; Secretary, E. E. BREED, New Britain; Treasurer, E. S. GOODRICH, New Britain. Executive Committee, A. L. YOUNG, Waterbury; E. ISRAEL KILBY and A. W. DODGE.

### Texas Street Railway Association.

President, CARL F. DRAKE, Austin; Vice-President, A. H. HATWARD, Houston; Secretary and Treasurer, C. L. WAKEFIELD, Dallas. Executive Committee: The OFFICERS and GEO. B. HENDRICKS, Fort Worth, and A. H. HATWARD, Houston.  
Next meeting, San Antonio, third Wednesday in March, 1896.

### The Maine Street Railway Association.

President, W. R. WOOD, Portland; Secretary and Treasurer, E. A. NEWMAN, Portland. Executive Committee, W. R. WOOD, Portland; H. TWITCHELL, Bath; A. F. GERALD, Waterville; J. HAYNES, Augusta; G. E. MACOMBER, Rockland; E. H. BANES, Biddeford; E. K. DAY, Sanford; F. N. LAUGHTON, Bangor; F. W. DANA, Lewiston.

### The California Street Railway Association.

President, CHAS. F. CROOKER, San Francisco; Vice-President, S. B. McLENEGAN, San Francisco; Secretary and Treasurer, J. E. MORRIS, Oakland. Executive Committee, E. P. VINING, San Francisco; F. W. WOOD, Los Angeles; L. WHEELER, Alameda.

## SUBURBAN COMMENCES OPERATION.

The Suburban Railroad of Chicago inaugurated its service between the West 48th street terminus of the Metropolitan elevated and La Grange on July 3. The headway is 20 minutes and the scheduled speed over 20 miles per hour including stops. All the company's cars were equipped with air brakes by the Christensen Engineering Company of Milwaukee, one with a motor-driven and the others with axle-driven compressors. The cars reach a speed of 30 miles and pick up passengers at any point. Both types of brakes have proved very satisfactory, placing the cars under perfect control.

## SUMMER TOURS.

### Rivers, Mountains and Seashore.

#### GRAND TRUNK RAILWAY SYSTEM.

The sale of Summer tourist tickets from Chicago to Eastern Tourist Resorts reached by the Lines of the Grand Trunk Railway System, embracing Niagara Falls, Muskoka Lakes, St. Lawrence River, White Mountains, Portland and Seacoast Resorts, commences June 1st, continuing to September 30th, inclusive.

Seaside and White Mountains Special. "The Finest Train in the World," making weekly trips between Chicago, Portland and Old Orchard Beach. First trip eastbound from Chicago, June 24th. The elegance and comfort of this train, combined with the ever-changing panorama of Nature's grand and beautiful scenery through which it passes, makes it the most desirable train between Chicago and the Sea Shore and Mountain Resorts of the East.

For further particulars, Excursion Folders, Time Tables, Berths in Sleepers, or Tickets, apply to L. R. Morrow, C. P. & T. A., 103 Clark St., Chicago.

## THE BEST ADVERTISERS

Say that one copy of a publication that is paid for, is worth ten sample copies sent to Tom, Dick and Harry.

THE STREET RAILWAY REVIEW is not a sample copy magazine. There are less than one hundred roads in the United States that don't subscribe for it. One road pays for over one hundred copies each month, and several order five or more.

They take extra copies for their men, and we make them a special price when they order five or more at one time. How many does your road get? Don't you think it will pay the Company to have their men read the REVIEW?

There is no doubt that the number of our paid subscribers exceeds the number of papers issued by any other publishers in the same line in the world. Our subscription price is \$2.00 per year.

Old Colony Bldg., Chicago.

## BICYCLE CARS AT PITTSBURG.

The northern portion of Allegheny and the contiguous territory abound in good roads and pleasant resorts for wheelmen but they were almost inaccessible because of the steep hills leading to them. In order to accommodate wheelmen the Second Avenue Traction Company of Pittsburg placed a number of bicycle cars on the Perrysville avenue division. The bicycle cars are closed cars, which would not otherwise be used in summer, with seats at one side removed and racks substituted; the passenger may ride in the same car or in the other cars of the train. The schedule which we have received from J. M. Tate, Jr., general manager of the Northside Division, provides for bicycle cars every 15 or 16 minutes from 1 to 9 p. m. on Saturdays, from 7:30 a. m. to 9:30 p. m. on Sundays and other days from 6:30 to 9 p. m. The fare for wheel and rider is 15 cents.

The Iron Age Manufacturers Index, published as a supplement to the Iron Age of July 1, is an octavo volume of 146 pages, giving the names of manufacturers in the hardware, iron, metal and machinery trades, indexed under their products. For addresses reference is made to the advertising pages of the Iron Age.

## MUST SUE TO RECOVER.

A decision by Judge McAdams, of the Supreme Court of New York, defines the liabilities of street car companies when passengers are transferred without being given tickets, and a second fare is collected. In such a case John A. Stewart sued under the railroad act and secured a judgment against the company for \$50, which is the penalty for receiving more than the lawful rate of fare. The decision of the lower court was reversed, the judge holding that Stewart could have recovered in an action for a breach of contract, and would be entitled to compensation for his loss of time, the additional fare paid and the injury to his feelings, but instead of doing that he brought suit to recover a penalty.

"It is quite manifest that the statute was intended, not to afford a remedy for a breach of contract, but to punish an attempt to exact more than the legal fare from passengers in railroad cars or trains, and that it cannot be extended to cover the case of an attempt to collect what is supposed by the conductor to be the one fare which he is required to receive from a passenger."

## WHERE WILL YOU SPEND THE SUMMER?

It is not too early to begin to think of the best place to spend your summer vacation. Do not leave this matter until the last moment, make up your mind in a hurry and then—regret for the next six months that you did not take more time in making your decision. And while you are thinking of this matter it will pay you to investigate some of the many hundred beautiful resorts situated along the line of the New York Central & Hudson River Railroad. You cannot get a better list to choose from. If you want a gay social time, and can afford it, take the New York Central to Saratoga, Lake George, Lake Champlain, or the Thousand Islands. If you want a quiet, rustic time, you can find it in one of the many small villages scattered through the Adirondacks, the Catskills, or the Berkshire Hills. The New York Central lines will take you into the heart of these famous regions. If you want to spend your vacation in sight seeing, take this same railroad to Boston, Buffalo, Niagara Falls, Montreal, Toronto, Chicago, St. Louis or Cincinnati. In addition to simply taking you to these different places, the New York Central will take you in the best possible manner. It has the fastest and most perfect through train service in the world, with new and elegant sleeping, drawing room and dining cars made by the Wagner Palace Car Company. It has justly been said of this road that, "For the excellence of its tracks, the speed of its trains, the safety and comfort of its patrons, the loveliness and variety of its scenery, the trade and importance of its cities, and the uniformly correct character of its service, the New York Central & Hudson River Railroad is probably not surpassed by any similar institution on either side of the Atlantic."

For further information about any place along this road apply to George H. Daniels, General Passenger Agent, Grand Central Station, New York City.

## A SHORT DESCRIPTION.

A short description of the Lake Shore & Michigan Southern Railway will not be uninteresting to any one who is thinking of taking a business or pleasure trip from New York, Boston or Buffalo to Chicago.

This railroad is the only double track line between Buffalo and Chicago, and in connection with the New York Central and the Boston & Albany railroads, forms the only double track route between Chicago, New York City and Boston. It is the most interesting route between the East and West, traversing the richest and finest portion of the Middle States. In the opinion of those experienced in travel, it has no superior in perfectness of roadbed, punctuality and elegant service and the comfort and care of its patrons.

Leaving Buffalo the line traverses the picturesque south shore of Lake Erie through the Western Reserve, passing on its way a large number of very interesting points until it reaches Elyria, O., a city 25

miles west of Cleveland. Here the tracks diverge; the southern line passing by way of Oberlin, O., and the northern line going by way of Sandusky, O. The two lines meet a few miles east of Toledo, O., but make another divergence about 3 miles west of Toledo. One of the lines runs north through the most pleasing portion of Southern Michigan and the other turns south traversing Ohio and Indiana through northern parts. At Elkhart, Ind., the lines meet again and continue west through a rich farming country past South Bend, La Porte, with its lovely lakes, and traversing the south shore of Lake Michigan, terminate at Chicago.

Wagner vestibule sleeping cars, complete in every detail for comfort, pleasure and safety, are run through between the above mentioned cities. The meals and service of the dining cars are all that can be desired, equalling that at the leading hotels.

Detailed information about the various cars, connections and time tables, will be furnished on application to A. J. Smith, General Passenger and Ticket Agent, Cleveland, O.

#### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

#### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. AUGUST 15, 1897. NO. 8

THE pass question has been almost too effectually solved in Nebraska by the last legislature, and since July 11th any public official, including policemen, who is convicted of riding on a pass or reduced rate may be fined from \$200 to \$500 and have his office declared vacant.

THE Supreme Court of California has declared a forfeiture of the company's rights as to the tracks on Bush street, San Francisco. By reason of consolidation the line furnished practically no business and for some months but one trip per day has been made over the route in question. The company will be requested to remove the unused tracks.

OFFICIAL investigation of the unfortunate wreck on the Soho Hill line in Pittsburg shows conclusively that the accident was the result of overcrowding, which the employes and police did all they could, short of violence, to prevent. It was a rear end collision, in which one passenger was killed and several badly injured. Except in the extent of the results it was very like the Columbia accident a year ago. In both cases the front platform was crowded to such an extent that it was practically impossible for the motorman to work his brake. In both cases it was a pleasure crowd returning from a park entertainment, every person of which seemed imbued with a desperate desire to take the first car. While it may not be a practicable thing to do in either of the places named, it might not be a bad arrangement to load

through heavy turnstiles into inclosed stations, which would enable the starter to control the number who could get through to one or more cars. While the passengers are to blame for the overcrowding, having done so in spite of the efforts of the crew, still so long as people continue to use so little judgment as to their own safety it becomes a question of self-protection to the company to use every means possible to exercise judgment for those who seem utterly devoid of common sense in such matters.

THE consolidated road, Atlanta, has won a signal victory in the United States Circuit Court in defeating an ordinance passed by the city council to take effect last May, providing that passengers shall be carried from any point to any other point on company's lines for one fare. The case reached a hearing in the higher courts with unusual dispatch and this is one of the most important decisions as to transfers yet rendered. The company's franchise calls for one continuous ride for a certain fare, and the essence of the decision may be found in the words, "One continuous ride is one thing and two or more rides with the necessary stoppage and letting passengers off and taking them on is another and entirely different thing."

LAST month we directed attention to the great advisability of increasing revenue by furnishing facilities for the transportation of bicycles. Since then the information has come to us of what has been done in San Francisco. The Market Street road equipped one hill division with dash racks for wheels in February. That month 262 wheels were carried, which meant not only five cents for each wheel, but five cents more for the owner who rode inside the car. This meant \$26.20 for that one division, which otherwise the company could not have earned. The record shows a constant increase, and by May, three months later, the number of wheels carried on this division had increased to 962 for the month.

So promising were the results on the hill division it was decided to equip one of the level lines, which was done in April, carrying in that month 461 wheels. In May the business on that line had increased to 914 wheels, or nearly \$100. The company has now nearly finished equipping all the cars in its big system, placing a rack on both front and rear dash. The rack is easily detachable, weighs only 25 lbs., and when removed leaves no defacement.

We firmly believe almost every road in the country can successfully adopt the same plan to a greater or less extent. We are informed the placing or removing of wheels occupies but a moment and does not materially interfere with schedule time.

ON July 22nd Judge Showalter, sitting in United States Circuit Court for the district of Indiana, rendered his decision in the 3-cent fare case and ruled in favor of the company on all points at issue. It was argued that the Federal Courts must follow the decisions of the State Supreme Court on the constitutionality of State laws, but the judge points out that where in the past a federal question has been involved and the Federal Court ruled in accord with the State Court it was merely because the judges were of the same opinion and not because the Federal Court was in any way subservient to the other. Briefly stated, the reasons for holding the 3-cent fare law unconstitutional are, that in Indiana street railways must be incorporated under general

laws, and that the act of 1897 so altered the act of 1861 that it became special and local in its nature. Jurisdiction was given to the Federal Court both because the plaintiff was a citizen of New York and because the charter contract between the company and the state was involved. The text of the decision will be found on another page and constitutes a most important contribution to street railway legal literature. From the time occupied by the judge in reaching his decision it appears that he has given the case most careful study, and there is every reason to believe, after reading the opinion, that the Federal Supreme Court will sustain it.

Indianapolis has been one of the seats of war which it is the fashion to wage upon all corporations and street railways in particular, and, thanks to the efforts of demagogues and the daily press, it became necessary for all "friends of the people" to join in the attack and forced the republican legislature, for political reasons, to join the democratic city council in the attempt to prescribe 3-cent fares for Indianapolis and thus virtually confiscate the company's property. Political reasons also led the state officials to say a good many rather foolish things and to unnecessarily revile the Federal "interference in state affairs." It is only necessary to compare the arguments, or, for that matter, to read the two opinions, to see that populistic political economy, rather than law, was responsible for the remarkable view taken by the State Supreme Court.

THERE is nothing requiring more care on the part of a street railway electrician than the design of a reliable and efficient feeder system at minimum cost. Thompson's law is frequently quoted and used, but as shown in R. W. Conant's article on the Efficient Transmission of Power to Street Railway Lines, page 431, July REVIEW, its application to feeders is out of place and leads to incorrect results. Those who are designing feeder lines would do well to investigate the curves and formulæ deduced by Mr. Conant, as they are probably the most accurate and scientific published. His work is not purely theoretical, as he has tested every part of it in practice.

There is such a scarcity of data that a general theory has not been deduced, and the electrical engineer depends largely upon his experience and judgment. That there is a great variety in practice may be seen from the article on Feeder Lines in this issue. Some roads have adopted a rather high voltage, as is the case at Minneapolis where the current is generated at 625 volts, and others run the stations at 500 and no more. The latter practice may be justified. There was published in the February REVIEW an article by J. R. Chapman with data to demonstrate the greater economy in operating at 500 than at a higher voltage. The drop in potential generally governs the size of trolley wire and feeders, but as a rule a sectional area of 1,000 c. m. is allowed per ampere of current carried. It is to be remarked that on the system where the highest voltage is used an area of 3,000 c. m. per ampere is allowed. A very liberal allowance in feeder lines may be justified with the view of further extensions. With other companies a small initial cost is imperative, consequently there is a considerable loss in voltage, an inefficient operation of the car motors and a larger generating plant than would otherwise be required. In some instances a road may be operating under unusual conditions, as the City & Suburban at Portland, Ore., where fuel is obtained in greater quantities than desired at a fixed

price. It would not pay this company to make a large investment in feeders, as a considerable loss in transmission would be of no moment.

A careful supervision of the feeder and return circuits will often disclose great leaks. Sometimes the soldered joints become loose, and the contact is very poor. A return circuit with a few defects consumes a large amount of power. On one road in Chicago a copper return was strung direct from the station a few hundred yards to a point where there was some complicated special work, and connections were made to the different tracks branching from this place. The result was that the potentials on all these lines were raised 10 per cent. It often pays for the electrician to test the track joints with a low reading voltmeter and make some apparatus for reading the voltage on the trolley wire and feeders. The data given for the Toronto Railway Company show a marked improvement by connecting the feeders differently without an increase in voltage or of copper lines. This great saving is doubtless due to the fact that a competent electrician studied the system, saw the defects in the first construction and adopted a policy of gradual improvement.

#### STREET RAILWAY ACCOUNTANTS' CONVENTION.

The first annual meeting of the Street Railway Accountants' Association of America, will be held in Niagara Falls upon the same dates as the meeting of the American Street Railway Association. The program is well advanced, and the subjects will be taken from the following:

The Handling and Checking of Transfers from Printer to Furnace.  
The Care and Handling of Fares from Receipt to Bank.  
Materials and Supplies Accounts from Purchase to Use.  
Power House Accounts.  
Pay Rolls: Time Keeping and Method of Paying.  
Car Mileage: How Arrived at and its Use (Street Railway).  
Car Mileage: How Arrived at and its Use (Interurban).  
Statistics: Their Use and Abuse.

In addition to these there will be the report of the committee on standardization and the reports of the officers.

The secretary announces that President McCulloch of the American Street Railway Association has signified his intention of recommending the formal indorsement and approval of this Association by the American and will invite the members of Accountants' in a body to attend the meetings of the American. The president, Mr. Wilson, has been invited to address the American Association, and President McCulloch has accepted an invitation to appear at one of the meetings of the Accountants' Association. The members of the Accountants' Association will be provided with badges the same as those worn by the members of the A. S. R. A. with a designating ribbon added. In addition to the applications for membership which were noted in the REVIEW for June, applications have been received from the Richmond Traction Company, Richmond, Va., and the Campania de Tramvias de Merida, Merida, Mexico.

There is still opportunity to suggest one or two subjects for papers or discussion. Street railway men in the accounting departments who are puzzling their brains in the ineffectual effort to solve some particularly hard problem can undoubtedly get just the light they want by having the association take up the subject, and this can be done by addressing the secretary, W. B. Brockway, Toledo, O.

## DARING FRAUD SCHEME FRUSTRATED.

How William Webb and Wife Tried to Swindle the Memphis Street Railway Out of \$25,000—Clever Work on the Part of Company's Officers—  
Co-conspirators in Jail.

A daring scheme and carefully prepared plot was concocted by two persons giving the names of William Webb and wife, to swindle the Memphis Street Railway (formerly the Citizens) out of \$25,000. So complete were the arrangements, and with physical conditions to bear out the plot, it is a wonder the attempt was not successful. That it was not, redounds greatly to the credit of the officers of the road to whose vigilance the company is indebted for saving the expense of a costly law suit and the almost certain heavy damages. Street railways are constantly the victims of fraud claims; but not in a long time has one been shown up which was more deliberate, or planned with better prospects of success.

Through the courtesy of E. B. Moseley, chief of police of Memphis, we are enabled to publish portraits of the conspirators. They are described as follows: William Webb, carpenter; American, 30 years of age, 6 ft. 1½ in. tall, weight, 210 lbs., well built, sandy complexion, hazel eyes and light hair; one upper front tooth out. Emma Webb; 31 years of age, 5 ft. 1½ in. tall, weight, 145 lbs., heavily built, dark complexion and black hair.

The plot was for Mrs. Webb to board a street car, and when it started fall heavily to the floor, pretend to be seriously injured and subsequently bring suit against the company. As a matter of fact the woman is a sufferer from a disease of the spine, said to have been caused by the brutal treatment of her husband when he was intoxicated. She, of course, was to allege that her spine had been injured by the fall in the car, and a medical examination would establish the fact that injury actually existed.

The Webbs had come to Memphis from Nashville, and from St. Louis to that place. In St. Louis the scheme had been worked on the Lindell road with success, and so well did she play her part there, and so carefully was the affair planned that the company was glad to compromise the suit brought against it, before it reached trial.

The Memphis job was as carefully planned as at St. Louis, but the officers of the Memphis road, through secret sources discovered what was on foot and learned the names of the conspirators. When the information was received Webb and his wife were given no clew which would lead them to believe that their scheme had been discovered. The street car company hired competent detectives to watch the conspirators and one of the company's officers revealed the details of the plot to three of his personal friends. So well did he have the conspirators in hand that he told his friends not only the names and place of residence of the schemers, but he told them the day on which the woman was to fall in the car and the car line on which the job was to be done.

Thirteen will hereafter stand as an unlucky number in the Webb family; for it was upon the afternoon of that day in July that Mrs. Webb, accompanied by another woman, who was to be used by her as a witness, left the house. As they turned onto the sidewalk a man and woman followed close behind them; these were the witnesses for the company. All four boarded the same car on the Jackson Mound line, but for some reason the conditions did not suit and no backs were broken here. After riding a short distance the four left the

car and walked to the Main street line, a car of which was boarded. The car in question is one of the long cars, and also one of the smoothest riding on the road; nevertheless as the car started while Mrs. Webb was yet in the aisle, she fell heavily backward to the floor as if thrown from her feet. She was lifted to the seat, where the sympathy of the passengers was secured by a series of groans and cries which were simply heart rending. In response to the conductor's offer of help she managed to ask for a carriage, but as none was available at that point, she was carried in the car until

WILLIAM WEBB.

EMMA WEBB.

transferred to the first meeting car, going toward the city. It required the services of four men to make the transfer, during which operation she gave evidence of the most intense agony by continued cries and groans and indications of fainting.

From the car she was taken into a grocery store where a carriage was summoned and removal made to her home. When advised of the accident, her husband who was at work, flew into a great rage and declared if any of the company's men dared to come near him with an attempt to compromise the case he would kill them. His feelings so overcame him that he almost wept in speaking of the sufferings of his wife.

The woman had proved a fine actor, and when the company's surgeon was called in consultation with Webb's family physician, it was admitted that there was a spinal difficulty, and everything seemed to be working to perfection. From this on every move of the conspirators was watched, the police were let into the secret, the company's attorneys advised, and the foreman of the grand jury informed of the facts. Still the company did not have a case.

On July 18, three days after the "accident" the following advertisement appeared in the daily papers:

PERSONAL—Will young man or ladies who witnessed fleshy lady fall, Main st. car, near Market, last Tuesday, p. m., address Mr. Webb, 79 Linden st., immediately, and oblige?

All that now remained was for the Webbs to bring suit. This was done on July 27, claiming damages in the sum of \$25,000. As soon as the papers were filed the matter was laid before the grand jury, witnesses heard, and an indictment returned in two hours. One hour later the chief of police and a sheriff arrested Webb at the office of his attorney. Mrs. Webb was then gathered into the toils, complaining bitterly and refusing to be moved until accompanied by her physician and going to jail in a carriage.

Two days after their arrest the Webbs pleaded guilty and were each fined \$100 and sentenced to imprisonment in

the work house for 11 months and 29 days; this is the maximum sentence allowed. The sentence was suspended in the case of the woman, as Webb claimed he coerced her.

The St. Louis case referred to appears to have been one of the early operations of the Webbs, for they did not work it very hard, and while they claimed a good round sum, did not hesitate to settle out of court for a small fraction of the claim. In fact the company settled for about one-fifth what it would have cost to defend if it had allowed proceedings to be brought. The company was deceived into paying this amount by the statement of the Webb's physician, who was supposed to be reliable, and in fact through whom the settlement was effected. They evidently were hard up or timid for the release cost less probably than the expense of tracing them up, although the case seemed so plain there was nothing to indicate fraud.

At Nashville no attempt was made on the street railways, but the Memphis scheme was well planned, and carried out in such a business like and methodical manner, they evidently had every confidence in the success of their plans.

**ROLLER FOR STREET RAILWAY WORK.**

The many extensions recently made and contemplated by the Springfield Street Railway Company of Springfield, Mass., into the outlying sections where macadam is used for road material induced the general manager of the company, Austin E. Smith, to make a special study of the construction of this class of work with a view of substituting machine hardening for the hand rammer commonly used. He had built for this purpose the machine shown in the accompany-

ROLLER FOR SPRINGFIELD STREET RAILWAY.

ing illustration, on the principle of the steam roller simplified, and adapted to track work.

It consists of a very strong wood-frame, four-wheel truck, carrying in the center a heavy iron roll 33 in. in diameter by 4 ft. 7 in. long. This roll is built up in sections so as to leave the road with the necessary crown. The several sections are pressed onto a 4½-in. steel axle. The ends are carried in self-oiling boxes, which are raised and lowered by means of screws; these are arranged so that the roll can be raised to a height of 4 in. above the top of the rail when the roller is transported on its own wheels over roads already built, or can be lowered 4 in. below top of rail, or held at any

intermediate point. However, if the roll meets with any obstruction means are provided by which the roll will pass over without lifting the truck wheels from the track. The total weight of the machine as shown is 11,000 lbs. Directly over the roll and connected with it by means of iron posts is a strong box designed to be filled with iron so as to give additional weight, if desirable.

The ends of the roll can be raised independently of each other so that the shape of the ground line can be varied. Should it be desirable to roll the bed outside the rails the adjustable screws will lift the four flanged wheels entirely from the rails, thus permitting the roller to go where guided.

The truck will be coupled to and receive its motive power from the construction motor car, and affords ample room for transporting men and tools to and from the place of work.

The roller is the work of the Wason Manufacturing Company of Springfield.

**EUROPEAN ELECTRIC RAILWAYS.**

The following table gives data concerning the electric railways now in operation in Europe. It is apparent that Germany is far ahead of any other European country both in the number and mileage of its lines.

|                           | Total Length of Lines in Miles. | Total Power in K. W. | Number of Motor Cars. | Lines with Str. Cond. | Lines with Undergr. Cond. | Lines with Centr. Rail. | Lines with Accum. | Total No. of Lines. |
|---------------------------|---------------------------------|----------------------|-----------------------|-----------------------|---------------------------|-------------------------|-------------------|---------------------|
| Germany . . . . .         | 642.69                          | 18,963               | 1,631                 | 45                    | 2                         |                         | 4                 | 51                  |
| England . . . . .         | 109.42                          | 4,670                | 168                   | 10                    | 1                         | 6                       | 1                 | 18                  |
| Austria-Hungary . . . . . | 83.89                           | 2,589                | 194                   | 7                     | 2                         |                         | 1                 | 10                  |
| Belgium . . . . .         | 34.90                           | 1,220                | 73                    | 4                     | 1                         |                         |                   | 5                   |
| Bosnia . . . . .          | 5.60                            | 75                   | 6                     | 1                     |                           |                         |                   | 1                   |
| Spain . . . . .           | 47.00                           | 600                  | 40                    | 3                     |                           |                         |                   | 3                   |
| France . . . . .          | 279.36                          | 8,756                | 432                   | 19                    | 1                         | 1                       | 5                 | 26                  |
| Holland . . . . .         | 3.20                            | 320                  | 14                    |                       |                           |                         |                   | 1                   |
| Ireland . . . . .         | 18.00                           | 486                  | 32                    | 1                     | 1                         |                         |                   | 2                   |

**A GOOD COMPROMISE.**

In the fall of 1896 the city council of Punxsutawney, Pa., passed an ordinance imposing upon the street railway company the cost of paving between its tracks as is done in larger towns, but which in smaller towns is usually more than the road can bear. L. C. Meyers, superintendent of the company, advises us that after laying the matter before the citizens and explaining what the effect would be upon the road a new ordinance was secured, according to which the company, for the new paving to be laid this year, is to purchase new ties, spikes, etc., and in addition pay the difference in the cost of laying the pavement due to the presence of the track. This amounted to \$60, a saving to the company of about \$1,500. The city had laid 1,600 feet of new pavement before this new ordinance was passed, but the company hopes to secure a compromise as to that also.

THE UNION LOOP, CHICAGO.

The Union Elevated Railroad Company was incorporated in November, 1894, for the purpose of building a loop in the business heart of Chicago. It is capitalized for \$5,000,000 and has \$3,500,000 of bonds outstanding. The officers of the company are L. W. Perce, president; C. D. Hotchkiss, vice-president; Howard Abel, secretary and treasurer. The company agreed to pay the city from its receipts, after deducting \$250,000 per year for interest on its bonds, 5 per cent per annum during the five years from 1897 to 1901, inclusive; 10 per cent during the next five years; 15 per cent during the next 10 years; 20 per cent during the next 15 years; and 25 per cent during the remainder of the term, approximately 15 years.

The line is under lease to the four elevated roads which it is to connect; the lease provides that they shall have the exclusive use of the loop and pay therefor the cost of maintenance, operation and repair, all taxes levied against it and 1/2 cent per passenger carried on any part of their lines; the minimum revenue, however, is fixed at \$62,500 per annum.

The opposition of the abutting property owners to the construction of the loop was very bitter and involved the company in extensive litigation. The original franchise provided that the south side of the loop be built in Harrison street, and in order to effect the change to Van Buren street, which was desired, it was necessary to organize a new company known as the Union Consolidated Railway Company, which extended its proposed route as far west as Halsted street, and by securing the consent of nearly all the property owners on the West Side placed those east of the river in the minority. Suits were brought to enjoin construction, but the supreme court of Illinois decided that after an ordinance had been obtained, the property owners must wait

until the completion of the line, and if injured, sue for damages. The connection between the loop proper and the Metropolitan is a portion of the Union Consolidated.

Heretofore the three elevated roads now operating have been placed at a great disadvantage in competing with the surface lines because of the unfavorable location of their down town termini. With the loop completed any point north of Polk street and between the river and the lake is

FIG. 2.—STATION AT VAN BUREN AND DEARBORN STREETS.

within three squares of an elevated station. What the effect of the improved terminal facilities upon the traffic will be can only be estimated at the present time. In October, 1896, the Lake Street road began running south on Wabash avenue as far as Adams street, but no official statements have been made regarding the increase in traffic. During 1896 the average number of passengers carried daily was 30,200; it has been stated unofficially that the increase after running to Adams street was 4,000 per day.

The Union loop is a double track structure, 11,150 ft. in length, located as shown in Fig. 1, in which the 11 stations, the special work and the signal towers and levers are indicated. Work was begun in the winter of 1895, and with the exception of a few of the stations it is now completed. The loop will be worked left-handed, the inner track being used by the Metropolitan and Alley roads and the outer track by the Lake Street and Northwestern. Only two of these are now operating by electricity, and until the completion of the Union Loop power house each of these roads will furnish power from its own station. Feeders are led from the Metropolitan power station to supply the inner track and from the Hawthorne avenue power house of the North Chicago Street Railroad Company for the outer track. These connections are permanent and will be used for operating the loop at night and in the case of emergencies. The plans of the Union Loop station were published in the REVIEW for January, page 55.

The third or conductor rail is placed between the track, and the wooden box along the center of the structure in which the feeders are carried. The feeder box is covered and serves as a footpath for employees. The method of supporting and insulating the conductor rails and feeders does not differ from that employed on the Lake Street which was fully illustrated and described in the REVIEW, March, 1896, page 133. The insulators were made by the

FIG. 1.—MAP OF UNION LOOP, CHICAGO.

Albert & J. M. Anderson Company of Boston, after the design of J. R. Chapman, the electrical engineer of the loop, who designed the electrical equipment. For feeding purposes the loop is divided into four sections, the north and west and the east and south sides of each track constituting the sections. There are 11 feeders carried from the power house to the structure through a conduit laid in Market street. Each of these feeders is of stranded copper and has an area of 1,500,000 c. m. At stations and special work the bare cables are replaced by insulated cables carried under the structure. While the feeder system in general outline is very simple, the detail drawings showing connections to the conductor rails at special work resemble geometrical puzzles. In spacing the contact rails at cross-overs and switches, the method of making the car bridge the two connections was adopted.

About 1,100 32-c. p. lamps are required for lighting purposes, and they are all on the same circuit, the cables being carried in the feeder box. A 30-pair telephone cable is carried around the structure and connected to switchboards in all the stations and signal towers.

Fig. 2 is a view of the station at Van Buren and Dearborn streets, showing the arrangement of entrance and exit stairways and the passageway connecting the landings on opposite sides of the street which permits passengers to cross from one platform to the other without descending to the street. Two roads are to use each platform, and trains on each of these two will stop at different ends of the platform; no tickets will be used, the passenger paying his fare when admitted to the end of the platform from which his train leaves.

In view of the large number of trains to be run on the loop, and the fact that each line crosses the other track of

torpedo machine with the same respect that he would have for a derail.

The special track work has all been made by the Paige Iron Works of Chicago. The most complicated portion of this is where the four tracks of the Metropolitan at present

FIG. 4—Y AT VAN BUREN AND WABASH.

entering the Franklin street terminal (which will be abandoned) converge to two. This is, however, not yet completed. Fig. 3 is a view looking east from the new Franklin street station (this station will be used by the Metropolitan only) and shows the crossover at this point and the connections with the west side of the loop. The interlocking tower is at the right. In the foreground are seen the feeder box and the bare cables.

Fig. 4 shows the Y at the southeast corner of the loop; the track at the right runs south on Wabash avenue to connect with the Alley L in Harrison street. In the foreground is very clearly shown the guard rail construction which the Paige Iron Works have used throughout this work. It is a 50-lb. rail turned on its side, which arrangement imparts greater stiffness laterally and raises it from the ties so that clips for the switch may pass under it.

#### COLLEGEVILLE (PA.) ELECTRIC RAILWAY.

The citizens Passenger Railway, leased and operated by the Schuylkill Valley Traction Company, obtained franchises in Collegeville, Pa., and vicinity. The Philadelphia & Reading Railroad Company enjoined the railway company from crossing its tracks at Collegeville. It was contended that the right of way must be secured through all the territory mentioned in the charter before any part could be constructed. The railway company decided to abandon the franchises and grants, but the supervisors in Lower Providence demanded \$25,000 for a relinquishment. To circumvent these difficulties the railway company organized and chartered the Collegeville Electric Railway Company. The town council repealed the old ordinance and granted a franchise to the new company. B. M. Douglass, general manager of the Traction Company, deserves much credit for the able manner in which the matter was handled.

Two of the three men accused of robbing a trolley car in Chicago on July 4, were convicted on August 4 and sentenced to imprisonment in the penitentiary.

FIG. 3—LOOKING EAST FROM FRANKLIN STREET.

the loop in two places, the most complete plans have been made for signal and interlocking plants at all junctions and crossovers. Since it is not practicable to provide physical protection in the shape of a derail or skotch block, the torpedo machine will be installed and worked in the same manner as a derail. The moral effect of this torpedo signal is considered to be very valuable; the operator in charge of the plant is required to keep a complete record of each detonator supplied to him and is not likely to permit an engineer to run past a signal at danger and explode a detonator without reporting him for it, and the engineer on his part knowing that he will be reported will treat the

Melbourne, the "Queen City" of the far south has not only a very extensive system of most excellently operated street railways, but has also the largest cable system in the world.

The Melbourne Tramway & Omnibus Company has been in existence now 11 years and still has 19 years before the property passes into the possession of the municipality. The policy of the company in its operation has been such as to win the good will of the people. On its 87 miles of cable lines there were carried in each of the years 1895 and 1896 over 33,000,000 passengers. During the "boom" times in Australia the company enjoyed a most phenomenal business, paying as high as 72 per cent per annum, while shares, the par value of which was only \$5, sold up to \$45. During the succeeding panic the same shares sold down to as low as \$1.68, but have since largely recovered under the payment of yearly dividends of 5 per cent.

A BAD WRECK.

The officers and heads of departments of the road are as follows:

F. B. Clapp, (American), Managing Director.  
 W. G. Sprigg, (English), Secretary.  
 H. A. Wilcox, (American), Assistant Manager.  
 W. Don, (Scotch), Master Mechanic.  
 J. W. Duncan, (English), Superintendent.  
 S. H. Don, (American), Foreman Painter.  
 J. Rocheforte, (Irish), Foreman of Wood Shop.  
 J. Dahn, (Swede), Foreman in Iron Shop.  
 R. Allen, (Australian), Engineer.  
 P. Fargher, (English), Engineer.  
 F. Cleaverley, (English), Engineer.  
 (There are about 10 more engineers.)  
 J. W. Lynn, (American), Inspector.  
 S. Dorum, (American), Inspector.  
 W. P. Savage, (American), Inspector.

The driving plants include 11 power houses, containing 38 engines rated on an average at 275 h. p., but which indicate 375 h. p. each. Only one-half are in use, the others forming the reserve power. With the exception of four English engines they were built in Australia, and all the driving machinery is of Colonial manufacture. The cables, 25 in number, have an aggregate length of over 477,000 ft., or over 90 miles, the cost of which is \$200 per ton. The ropes and rails are of English make and the coal is nearly all Victorian.

The working time of the power house force is 9 hours per day, while those in the shops work 8 hours, which is the system here; but the law permits the men to work up to 60 hours per week if they so desire.

As already stated many of the chiefs of the departments have had long American experience and some are born Americans. The assistant manager, H. A. Wilcox, (to whose courtesy I am indebted for some of the information in these notes), is a native of Providence, R. I., and W. Don, who was born at Brechin, Forfarshire, Scotland, has had 20 years experience in street railway work in New York, and now 10 years in Melbourne, is much more of the new world than the old world. To this gentleman I am especially indebted for the illustrations here presented and for data.

When the company first started, all inspectors and gripmen were imported from the United States, as men having past experience of the street railways on the cable system. Some of the former have fulfilled their engagements and gone back to the United States. There are now only three American inspectors who still have time to serve before their engagements are finished. Upon sounding some of the imported workers I was informed by all that the company could not have done more for them, and a proof of this is the fact that the Melbourne Tramway Company has not experienced any marked accidents and has been extremely free from strikes.

The number of gripmen is about 500 and there are the same number of conductors, or say 1,000 men on the road; while the combined shops employ 160 men. About a score of women and girls are engaged for counting the checks every morning.

The rolling stock up to the present consists of 442 cars, 428 dummies and 22 pair horse omnibuses, which latter conveyances are now only run in the suburbs to meet the convenience of those living a good way off from the cable lines. The company is not at present adding to its rolling stock, simply repairing and replacing as the cars and dummies wear out. In the company's shops, situated at the north end of Nicholas street, Fitzroy (Melbourne), there has been built a combination electric street car for Brisbane (Queensland), and the Melbourne Street Railway Company expects to build more for the northern capital.

# Street Railway Review

In the Melbourne cable tracks there are some 32,000 pulleys placed at intervals of about 30 ft. The general line pulley is 10½ in. in diameter, 3 in. face, and weighs 12½ lbs., including a ¾-inch spindle that is driven in under 6 tons pressure. By this means the set screws are done away with. The estimated reduction of surplus metal by the adoption of the present pulley made from crucible steel is 120 tons.

The hours of running cars are :

Week days, from 5:30 a. m. until 11:30 p. m.  
 Saturdays, " 5:30 a. m. " 12. p. m.  
 Sundays, " 1:25 p. m. " 11. p. m.

The cars are of uniform size and are thereby interchangeable. They are painted different colors for the various lines and show lights at night to match. The company has not equipped its fine conveyances with a correspondingly good

and boring machines were from J. A. Fay & Co., of Cincinnati, Ohio. A hydraulic lift raises or lowers the cars to various departments. The present U. S. imports are chiefly used in the wood department, as follows : white (bass) wood, perforated seating and rubber springs; in fact all rubber materials came from the United States. The steel gongs and bell punches are from America and also the car wheels.

The paint shop is also on the first floor, being separated from the wood shop by a partition. With ordinary care and re-varnishing at intervals of 18 months, cars will run for six years without repainting. Colors are ground in a steam paint mill, and many of the labor saving devices in car painting are used; for instance all the lettering and decorating are done with the rollers and stencils.

The blacksmith, machine and fitting shops are in the

SHOPS OF THE MELBOURNE TRAMWAY & OMNIBUS COMPANY.

light, the old system of lighting the cars with kerosene lamps being still employed. Each car has two inside lamps, one in a casement at each end of the car; each dummy is fitted with a large size lamp let in the middle of the roof or top, and after sunset carries a large square locomotive headlight. Each car is licensed to carry 34 passengers, 22 inside and 6 on each platform; the dummy holds about twenty persons without crowding.

It is the intention to put trucks under the dummies to keep the grip in a rigid position and to make it easier for passengers patronizing the dummy, as a rush in summer time is generally made for the front seats on the dummy where the riders can have a clear view of the road before them.

The company's shops or car and machine works occupy a space of 83 x 330 ft., consisting of basement and first floor. Most of the machinery in the wood shop, universal wood worker, surface planer, thickening machine, band saw, swing saw, circular saws, turning lathe, morticing, tenoning,

basement. There are 63 machines in these shops and 60 men employed. Among the machines are several of American make; the wheel boring and wheel pressing machines were made in New York and the Bryant metal saws by the Q. & C. Company. There are four pits for repairing the under gear of cars and dummies.

The average weekly wage (for 48 hours work) is as follows :

|                                                 |         |
|-------------------------------------------------|---------|
| Woodworkers .....                               | \$11.00 |
| Ironworkers (smiths, fitters and machinists)... | 12.00   |
| Painters .....                                  | 10.00   |
| Decorators.....                                 | 11.50   |

Most machinery pays an import duty of 10 per cent ad valorem, although some comes in at 5 per cent.

The fares on all lines except one (which is 2 pence) are 3 pence (6 cents). The longest line here is from Melbourne Town Hall to St. Kilda, a distance of some 5 miles, or from Hinders street to Brunswick.

The principal streets in Melbourne proper are one mile in length, 99 ft. wide and run at right angles to each other. The leading thoroughfares are named after prominent Australians—Flinders, Collins, Bourke, Lonsdale and Latrobe, running nearly east and west; and cross streets called Spencer, Kind, Williams, Queen, Elizabeth, Swanson, Russell, Stephen and Spring running nearly north and south. The whole city is well lighted by electricity and well paved with hard native woods. The blocks used in the street railway construction, part of the public causeways, are of Victorian (from Gippsland) red gum, a wood that is considered quite as durable as the Australian iron bark which hardens the more it is under water and the longer in the ground.

The price at which these red gum blocks are cut in the forests and delivered to the Melbourne street railway ranges from \$4 to \$5 per hundred square feet. The broad streets are illuminated by arc lights while the little cross streets are lit by incandescent lamps. In the main streets the arc lamps are on wooden pillars or posts placed in the center of the roadway, but where the street railway lines exist the lamps are suspended from iron brackets attached to the pillars erected on the sidewalks projecting some 8 ft. over the roadway.

Victoria's population in 1896 was 1,177,444

## ECONOMY IN CONTROLLER HANDLING.

BY J. R. CRAVATH.

Some discussion has been aroused lately as to whether a rapid or slow advancement of the controller handle in starting a car is the more economical in practice. In these discussions there has been a strong tendency on the part of those few who favor rapid turning on of current to theorize simply on a few of the factors that enter into the problem and leave out of account a number of elements which influence the results in practice. Thus it is argued that since it takes a given amount of energy to accelerate any body from a state of rest to a given speed it makes no difference whether we apply this energy fast or slow. In other words 50 horse-power applied for 10 seconds in starting a car is equivalent to 100 horse-power applied for 5 seconds. The horse-power-seconds in both cases equal 500, and the acceleration in the second case is accomplished twice as quickly and with twice the maximum horse-power required in the first case, the difference in power being balanced by the saving in time. Now this is a well known law of mechanics and cannot be disputed, but it goes only part way into the practical problem. In applying this power to a car in practice there are several very important processes which must be considered before we can arrive at the best coal pile economy. A manager does not care a rap as to the theory of what ought to take place at the car axle. He wants to know what actually will and does take place at the coal pile and how he can get the best results out of the plant from coal pile to car axle.

The first difficulty we encounter when we tell a motor-man to turn on current fast (there is no need to tell him; he will do it anyway) is that the increased accelerating efficiency that series-parallel control gives, as compared with the old multiple arrangement, is partly thrown away by such rapid handling. When motors are thrown from series to multiple the horizontal effort or torque per ampere of cur-

rent drawn from the line is reduced one-half. Now it is horizontal effort that is useful in accelerating a car. Therefore when the controller is thrown from series to multiple before the full benefit of the efficient acceleration afforded by the series combination has been obtained power is simply thrown away.

A second reason why rapid controller advancement does not give commercial results equal to what it should in theory is that unfortunately feeders and trolley wires must be used to conduct current from power station to motors and the line loss in these conductors as in every other electrical conductor is proportional to the square of the current. The line loss must therefore be greater with a high maximum current used in starting a car than with a lower maximum current used for a proportionately shorter time.

A third reason which sometimes holds why too rapid acceleration should not be attempted if economy of power is any object, is that when a field shunt is used this shunt is liable to be cut in too soon, thereby weakening the fields of the motors and lowering the accelerating efficiency or torque per ampere of the motors.

A fourth reason why rapid crowding on of power is not economical is that the maximum power house load (caused by the starting of a number of cars at once) is increased by so doing and so more generating machinery must be kept running to operate any given number of cars.

A fifth reason against attempts at very rapid acceleration is that when motormen are taught to get up to speed as quickly as possible, the practical result is that they will slip the wheels on nearly every start. That this is wasteful is evident. Many motormen will do this whether they are advised to accelerate as quickly as possible or not. There is no trouble about getting men to turn on current fast enough. The trouble is all in getting them to do it slowly enough.

Again and "sixthly," since the heating of the motors is according to the square of the current, the high maximum current that flows when current is thrown on fast heats the motors more than when the same amount of energy is used with a lower maximum current. The more a motor heats the lower becomes its electrical efficiency, because its resistance is increased. Motors are not usually very much too large for the work they have to perform, and consequently this heating often becomes a serious matter aside from any consideration of repairs, for it lowers the speed of the motors so that they cannot perform the same service that they can when cooler, even were the efficiency not to be considered.

Finally I may add that too rapid controller handling in starting a car is not to be recommended for every day practice, because actual tests and trials show it is not economical and this is perhaps the best argument of all.

The writer has in his possession facts and figures which amply sustain this assertion, and, though there are reasons why it would be out of place to publish them in an article of this kind, I am willing to furnish them to anyone who wants to look into the matter further. I have made no mention of the undoubted economy in repairs with slow acceleration of cars.

There is another way in which a saving can be made at the controller by letting the car drift with current shut off as much as possible, but that will not be discussed in this article, as it is merely my object to call attention to some facts relating to car starting that seem to have been overlooked in recent discussions.

### IT'S "MADAM" IN BOSTON.

The daily papers of the east are greatly exercised as to what term shall be used by conductors in addressing female passengers. This is no new thing, for it has come up every little while in every part of the country, and even invaded the sessions of the American Street Railway Association some years ago. It seemed in a fair way to settlement then until some member came in and rudely shattered the train of thought with the announcement of a new method of treating cracked hoofs of horses; and the question of etiquette never came back.

But now its settled, at least for the Lynn & Boston, for General Manager Foster concluded not to wait another 10 years for a solution and has issued the following bulletin:

On and after this date conductors and motormen in addressing women passengers shall substitute the word "Madam" for "Lady."

In arriving at the conclusion consideration was had of the terms "Lady," "Madam," "Mrs." and "Miss," but as it would have been somewhat perilous for the conductor to always make a straight guess as to the two latter, and as the "madam" seemed on the whole preferable to "lady," from this time on it is "madam."

It is positively necessary in many and much better in most cases, that some term should be used in connection with a remark addressed to a "madam." As a matter of fact, "lady" is now used by nine out of every 10 conductors the country over.

### GEAR CUTTING.

It is the opinion of J. M. Roach, general manager of the North Chicago Street Railroad Company, that gears and pinions can be made at the repair shop of the company at less cost than to purchase them. To carry out this work one machine was altered and another ingenious one designed by V. T. Lynch, superintendent of the repair shop.

The blank gears are purchased from a malleable iron works in the city, split in two, one piece being larger than the other on account of there being an odd number of teeth,

GEAR CUTTING MACHINE.

To provide a machine to cut the teeth the cutter head of a 32x32-in. planer was removed and brackets bolted to the frame to support one driving shaft and two cutter shafts. The four brackets were made from one pattern. A worm and gear were substituted for the regular feeding device so as to get a feed of 2 in. per minute. Each of the cutters revolves at the rate of 65 ft. per minute. As shown in the illustration seven gears are bolted to a shaft with a cut gear which serves as a division plate. Each gear has a face of 4½ in. The stocking cutter first cuts a groove which is enlarged to the proper form for the teeth by the involute gear cutter which is just behind the other. Two gears can

KEY-SEATING MACHINE.

be cut each day. The pinions are cut in the same manner. The machine requires little attention.

The key-seating machine was made entirely from old stock and at very small expense. The frame was made from two old side bars, one casting and some pieces forged in the shop. The gear and rawhide pinion were taken from an old motor and the cutter bars made of broken car axles turned down to proper size. The inside of the gear hub is threaded, three to the inch, and receives the shaft which actuates the cutter shaft. The bar contains holes for ten cutters, each of which is  $\frac{1}{8}$  in. higher than the preceding. One end of the bar is supported by a crosshead and the other passed through the hub of the gear or pinion. When a key seat is to be cut the pinion is bolted in place and the machine started. The counter shaft revolves at 800 r. p. m. and the gear draws the threaded shaft, forcing the cutter bar through the hub of the pinion. It requires 30 seconds to cut a key seat  $\frac{1}{8} \times \frac{3}{4} \times 6\frac{1}{2}$  in. and the same time to withdraw the bar. At present the machine is reversed by hand, but a clip will be bolted on the guide bars to automatically reverse. The work of this machine is perfectly accurate and is satisfactory in every way.

### DEATH OF E. M. G. EDDY.

E. M. G. Eddy, who for the last seven years has been chief commissioner of the New South Wales railways, died at Brisbane on June 21. Mr. Eddy was born 1853 and has all his life been in the railway service. He began his career as a clerk in the superintendent's office on the London & Northwestern and rose to be second in charge to the general superintendent. In 1887 he took a similar position with the Caledonian Railway, which he held for a year, and removed to Australia to accept the office of chief commissioner of railways in New South Wales. Mr. Eddy was familiar with the practice in Europe and America, and his administration of the system in Australia was very successful.

**EMPLOYEES GIVE BONDS.**

The Consolidated Street Railway Company of Grand Rapids, Mich., has for some time required bonds from the conductors, motormen and office employes, to protect the company from loss of money from any cause, and cost of repairs through accidents caused by the negligence or carelessness of any employe. The bonds are furnished by the American Security Company of New York at a reasonable cost to the men. The effect of this plan is to produce more care and watchfulness of the employes in performing their duties and will tend to supply the company with a better class of men than otherwise. The employes, knowing the conditions and the responsibilities upon them, have no occasion for discontent, and feel more secure of their positions. President Johnson is satisfied that this plan will result in better service, greater assurance to the company and work no hardship on the men.

**TROLLEY PARTIES ON THE CALUMET.**

The Calumet Electric Street Railway Company of Chicago owns what is probably the largest suburban system in the world. Its 80 miles of track extend through 27 suburban towns and villages in the southern part of Chicago. The routes pass several picnic grounds, touches Manhattan Beach, a resort on the lake front, and run through some sparsely settled and beautiful country. In every way this railway is suited naturally for pleasure riding. H. M. Sloan, general manager, realized the advantages such patronage would bring and every facility has been improved to handle the traffic.

In addition to this the merits of the road have been extensively advertised. Its cars are painted uniformly and it is now known as the "Yellow Line." Sign boards are placed along the routes connecting it with the center of the city and frequent use is made of illustrated posters. A

A PARTY TRAIN—CALUMET ELECTRIC STREET RAILWAY.

**MASSACHUSETTS STREET RAILWAY ASSOCIATION.**

The meeting of the Massachusetts Street Railway Association was a success socially as well as from a business standpoint. The 120 delegates were treated to a fine outing by the West End and the Quincy & Boston roads. The subway, loop and stations were visited, then they were taken to the Dorchester power house to inspect its superb equipment. At Neponset, the Quincy & Boston Street Railway Company received the delegates in three finely decorated cars and proceeded to the power house at Quincy Point. Dinner was served at Downer's Landing after which Nantasket Beach was visited and a trip taken on the bay. As a souvenir of the delightful outing each delegate received a polished disc of granite upon which was inscribed: "This souvenir was cut and polished from a sleeper used in the construction of the first railway built in America, completed October 7, 1826, leading from the granite quarries of Quincy to the Neponset river. Compliments of the Quincy & Boston Street Railway Company."

handsomely illustrated pamphlet, describing the different points of interest along the lines together with a map of the system, has recently been printed. Over 100,000 of these were distributed. All this is attended to by the advertising agent, E. H. Fox, who makes arrangements for all trolley parties, parks and amusement features.

The company does not rest here but makes its cars attractive and comfortable for its patrons. As may be seen by the illustration, the party cars are especially decorated with rows, clusters and designs of incandescent lamps and with bunting artistically draped inside and outside the cars. These same cars are used for the ordinary traffic and all decorations must be removed, which has been a laborious undertaking, especially when calls for cars would come in a few hours previous to starting and the same ones be required for ordinary service immediately afterward. Through the efforts of W. A. Harding, the master mechanic, the decorating has been brought to a system which involves a minimum amount of trouble.

For the tops of the cars the lamps are screwed into the sockets, 10 of which are fastened to a long board, about 3

## THE SAGINAW BRIDGE ACCIDENT.

The accident which occurred on July 7, when a car on the Inter-Urban Electric Railway plunged through the open draw in the bridge over the Saginaw river below Zilwaukie, was most serious, and when it is considered that it happened in the day time and that the approach is perfectly straight for nearly 1,500 ft., there appears to be no excuse for such gross carelessness.

The car approached the bridge at a high speed and was not brought to a full stop at the signal post, 200 ft. distant, as is required by the state law. The bridge tender was opening the bridge for a sail boat, and states that it had swung through an angle of 20° before the car reached the

at one end; during the trip in one direction the motorman has it under his control, but on the return trip must rely upon the conductor, who frequently turns it off with the result that the motorman sometimes finds himself without air when he wishes to make a stop. In this particular case it is stated that the air was all right, but it is evident from the distance jumped that the brakes were not applied until the car was fairly going off the bridge, when nothing could have stopped it. When the danger was seen the motorman reversed the current suddenly and burned out the fuse, which was the first warning that the passengers had of anything being wrong.

There are conflicting statements as to why the car was not stopped in time, but the most probable explanation

SCENE OF THE BRIDGE ACCIDENT, NEAR SAGINAW, MICH.—DIVERS AT WORK.

draw. On reaching the opening the car shot forward into the river, landing squarely with the forward end 74 ft. 7 in. from the ends of the rails; the car is 42 ft. long, which makes the distance covered 32 ft. 7 in. in the clear. The water at this point is about 20 ft. deep, and the car landing squarely was completely submerged, only the trolley being above the surface as shown in the illustration.

There were 13 persons on board; six were drowned, one was rescued alive, but so severely injured that he died within a few hours, and five of the other six were injured more or less seriously.

The cars are equipped with air brakes, but even if they failed to work at the critical moment, it is no reflection upon the brakes, as the arrangement and management of them could scarcely be more careless than it is on the Inter-Urban. The cars were originally equipped with automatically governed air pumps, but they proved to be too small and an auxiliary pump was placed in each car, being located

which is supported by the testimony of competent witnesses is that the motorman was racing with a train on the Flint & Pere Marquette Railroad and did not see the open draw because he was watching the train. No reason is given for not stopping at the 200-ft. post.

Assuming the figures as to the distance that the car jumped are correct, it is evident that the velocity at the time of leaving the bridge was not less than 20 miles per hour, which is certainly a pretty high speed at which to cross a draw bridge. Such railroading as this is criminal and should be punished as such.

On three occasions lately trolley cars of the West Chicago Railroad have been held up and robbed. As an incentive to bring the highwaymen to justice Vice President and General Manager Roach has offered a reward of \$1,500 for the arrest and conviction of the persons who held up the company's cars on 12th, 16th and 43rd streets.

## FEEDER LINES

It is apparent to a street railway electrician that the feeder lines in most of the cities where extensive trolley systems are operated have been built up to suit the growing needs of the city. The copper in many of the lines represents fortunes expended by the street railway companies. With all this investment it is evident many of the feeder systems do not perform the functions expected of them, and the reason is that they are worked beyond the proper limits of application. When a short electric road is constructed it is not a difficult problem to string a feeder along to supplement the conductivity of the trolley wire and keep the voltage near the extremities of the line within 50 volts of what it is at the power station. But when the line is lengthened for two or three miles and branch lines are constructed to meet the demands of a growing city the difficulties begin to multiply. The old material must be used and after the outlay for track construction, new cars and additional power at the station there is little left to put in the feeder system. The capacity of the feeder system is increased only as absolute necessity demands. Each year additional lines and feeders are added until it is not unusual to see as many as 20 or 30 large cables strung along the streets near the power houses.

The feeder system has passed through the same evolution as have the track and trolley line. At first the trolley wire was of small cross section and the feeder ran along parallel to it and connected at frequent intervals, thus making practically one conductor of double capacity. It was soon demonstrated that this plan would not fulfill the requirements for long lines, for the voltage decreased as the line extended away from the power station and a break in the trolley disabled the whole system. Then the trolley wire was sectioned, which minimized the effects of a break in the trolley or of a short circuit.

Good judgment, based on experience, is needed in designing a feeder system to meet all the varied demands of the whole or a part of an extensive trolley system. The number and headway of the cars, the location of the power station, possible extensions, unusual loads on one or more sections, are some of the points to be considered. Boosters are sometimes employed, but not very extensively, for most of the modern stations are equipped with machines generating current at 550 volts and with direct feeders to outlying sections this voltage is sufficiently high.

Information received from street railways operating under different conditions shows some interesting facts. On the Niagara Falls Park & River Railway, which is a comparatively new road, five feeders, ranging from two to seven miles in length and of stranded wire, weather-proof and insulated, are used. Two power stations are equipped with General Electric multipolar machines generating current at 550 volts. The maximum drop allowed is 5 per cent. The trolley wire is No. 00 B. W. G.

There are 225 miles of trolley which belong to the Twin City Rapid Transit Company of Minneapolis and St. Paul. This company is to have the advantages of alternating current, transmission and cheap water power, as soon as the plant at St. Anthony's Falls is completed. At present three power stations, equipped with Edison and Thomson-Houston machines, furnish the power. There are 60 feeder lines of an average length of three miles and of such cross section as to allow 3,000 circular mils per ampere. Some of the feeders are placed in paper tubes enclosed in a pitch-

box, but this conduit is hardly satisfactory. For the most part the feeders follow the trolley lines and have solid trolley connections. The trolley sections are equalized at the trolley circuit breakers through a No. 12 bare copper fuse 12 in. long. The station voltage is from 600 to 625.

The City & Suburban Railway Company, of Portland, Ore., is very happily situated for the cost of fuel does enter into the calculations of the feeder system as it is supplied with mill refuse at a fixed price and in great abundance. A loss in transmission is consequently of little moment and the problem is to keep the voltage at the proper figure. The system has expanded from a small one to its present size and no attempt has been made to accurately proportion the feeders to the different branches, though the down town portion is so arranged that three sections can be handled by switches in the general office. The power is furnished from one power station having one multipolar and four 60-k. w. bipolar dynamos. The voltage is from 520 to 550. The power factor of the station, or the ratio of the average to maximum load, is about .6. There are six feeders ranging from one to three miles in length, and these are of No. 0000 solid copper insulated wire. The trolley wire is No. 0. The feeders follow the trolley lines, usually fixed on the same poles and connected to the wire by a special feeder ear.

The Union Traction Company, of Philadelphia, has 10 power houses and one sub-station with storage battery equip-

FIG. 1.

ment and for which a booster is used. The voltage varies from 500 to 550 with an average drop of 50 volts on the lines.

The feeders are mostly underground in iron pipes, terra cotta and creosoted wood ducts, and insulated with paper, jute and rubber. In all there are 1,426.35 miles of ducts and 269,236 ft. of conduit. From this it may be seen how extensive the system is. There are three methods of attaching the feeders to the trolley wire as shown in Fig. 1. There are 331 feeders aggregating 698.3 miles in length and besides this, 193.2 miles of return feeders and 153.3 miles of telephone wire. All the overhead feeders are on the same poles as the span wires. The cross sections of the feeders are determined by the drop in voltage with a maximum current carrying capacity of 1,000 amperes per sq. in.

The Union Railroad, of Providence, R. I., has one power station equipped with five multipolar General Electric dynamos which give a voltage of 575. From the station run 35 feeders with a total length of about 90 miles. These are 500,000 and 300,000 circular mil cables with weather proof insulation. The feeders are strung on the poles supporting the trolley wire and are connected to it at intervals of about 500 ft. by a live span of insulated wire.

The Washington Water Power Company, of Spokane, Wash., operates 36 miles of street railway. The current is generated from water-power at the same station where current is furnished for lighting purposes. No. 0 trolley wire is used and is divided into sections which are connected with fuse wire only.

On the Camden (N. J.) & Suburban Railway the cars have a headway of 10 minutes. There are five feeders radiating from the station and these are at a voltage of 535.

No. 0000 B. & S. weather proof insulated wire is used for feeders. A booster is being considered for high potential on some of the lines. The maximum drop in voltage is 20 per cent. There are no ground returns on most of the circuits, thorough rail bonding being sufficient. The trolley wire is No. 00.

The Cass Avenue & Fair Grounds Railway, the St. Louis Railway, the Baden Railway, the Southwestern Railway and the Citizens' Railway of St. Louis, are all under one management and are operated from one power station. General Electric direct connected generators furnish the current. There are 52 feeders, from one-half to seven miles long; the greater number are 500,000 circular mils cross section but some are No. 0000. The voltage at the station is 550 and the allowable drop on the line is 50 volts. In most cases the feeders are on the same poles as the trolley lines.

The Helena (Montana) Light and Power Company has six cars operating on 22 miles of track with an average headway of one hour on each branch. This is the consolidation of two systems, but is operated from one power house, equipped with a Thomson-Houston multipoler and a bipolar generator of the U. S. type. The load on the station varies from 71 to 280 h. p. according to the location of the cars, for there are heavy grades on some of the branches. The trolley wire is No. 0 and No. 2 and is divided up into five sections, being fed from feeders one to three miles in length. These feeders extend from the station to the trolley lines by the shortest route and then follow on the trolley poles and are connected to the wire at every fifth pole. A drop of 10 per cent is allowed, the voltage carried at the station being 500 to 550.

The power station of the New Orleans City & Lake Railroad and the Crescent City Railroad is located on the bank of the river and close to the railroad tracks, convenient to coal and water. Most of the lines are parallel and the station is nearly midway between the extremities. The equipment consists of four 500-k. w., one 800-k. w. and two 200-k. w. machines. The average load is 1,400 c. h. p. with a maximum of 3,600 h. p. although as great a load as 5,000 h. p. has been carried. In the feeder system there are twenty-one 500,000-c. m. cables, five 250,000-c. m. cables, seven No. 0000 wires, two No. 0 and two No. 000 wires for feeders, besides thirteen 500,000-c. m. return cables connected to the rails of several of the lines nearest to the station. The feeder lines were designed for the present needs with a view to indefinite extensions whenever necessary. The feeders follow the trolley lines and are on the line poles except for two or three main trunk lines running from the station to the principal points of distribution. The drop in voltage is less than 10 per cent under four miles and rarely over 20 per cent even where the lines are more than seven miles from the station. The sections of the line are on an average 2,500 ft. long and are joined together by fuses and switches, ordinarily kept closed. As a rule the different lines are separate unless used to help one another, but they can be connected by switches at their junctions if desired. Section boxes are placed every 2,000 to 3,000 ft. and at each box is a pair of feeder span wires that stretch across the track 16 ft. apart. Each feeder span wire is continued down one pole to the box where it passes through the switch and fuse and then the two are joined together at the point where the feeder is tapped by a T connection. The voltage at the station is 550.

The accompanying map and tables give a comprehensive statement of the conditions of the feeder system of the Toronto railway. The generators in the station are by the General Electric, Edison and Siemens-Halske Companies and run at a voltage of 560. The average headway of the cars is four minutes and the average drop on the lines is 8 per cent. The feeders are connected to the trolley lines every 1,000 ft. by soldered feed ears, 15 in. long. Table I gives the sizes and lengths of the feeder lines and Table II the dimensions of the trolley wire. The improvement that has been made in the feeder system in recent years is plainly indicated by the figures in Table III, which gives the drop in potential at different points along the line in 1891 and in 1897.

TABLE I—FEEDER WIRES.

| Section Numbr | Feeder Number. | Size of Feeder, B. & S. | Sectional Area, Circular Mils. | A     | B     | Total Length | Length of Trolley in Section, Feet. |

Chicago Street Railroad consists of copper cables, 17,000,000 c. m. cross section. The capacity of the cable for the return circuit is about 50 per cent of the feeders. These are carried overhead in the same manner as the feeders and attached to the track every 1,000 ft. When the trolley lines run under the elevated roads the track is connected at intervals to the iron structure to which the return circuit cables are also attached. At the expansion joints of the elevated structure leaf bonds are used and in this way a return circuit of very great cross section is available.

One troublesome factor in designing a system of feeders is the extra power required in ascending grades. As a rule ample allowance should be made in the feeders, for the current to be supplied increases very fast as the grades become steeper. This is shown in Fig. 2 by the curves which have been plotted and are used by the Westinghouse Electric & Manufacturing Company. The approximate power of the motors required to operate cars under given conditions of speed and grade may be readily determined. Wherever

The difference in the methods is that in 1894 the feed wire was tapped into the trolley wires at the extreme end of the feed wires, consequently the current working back sometimes a distance of two miles making the resistance much greater than in the method of 1897, where feeders are connected at intermediate points from 800 to 1,000 ft. apart. No additional copper was used, and the voltage at the power house is the same. By referring to the map it will be seen that the feed wires are tapped in at the nearest point of the section to the power house. The trolley wires act as feeders in multiple with the main feeders, giving a uniform distribution of current.

Most of the street railway electricians believe that voltages of 750 on the trolley lines are practical with some alterations in the motors and extra precautions at trolley crossings. If these changes were made there would be a great saving in feeder lines, although it might necessitate a considerable alteration in the apparatus and would likely meet with opposition in the cities.

When the station is of very large capacity little dependence is placed in the track as a return circuit. For instance, the return circuit to the Western avenue station of the West

grades are encountered the motors and feeder system can be somewhat relieved by careful manipulation of the controllers. The handles should be turned slowly enough to give a constant acceleration in speed and some companies instruct the motormen not to use the last notch on either the series or parallel portions of the controller. In Minneapolis, where the grades are from 5 to 6 per cent in places, the management believes it is best to run the motors in parallel to prevent heating; the motors are more efficient at the higher voltage, and fast running time can be made.

### MAIL SERVICE IN MAINE.

The first street railway in Maine to have the U. S. Railway Mail Service extended to its lines, is the Rockland, Thomaston & Camden, an interurban line 15¼ miles long connecting these three towns. The car which has been fitted up for this work is 28 ft. long over all, with a separate compartment for the mail. The car is mounted on a Taylor single truck with 33-in. wheels and a wheel base of 6 ft. 6 in.; it is equipped with two G. E. 1,000 motors. Mail is distributed and collected along the entire line of the road.

The company has recently completed a ¾ mile extension on the Highlands branch; this line runs to the limestone quarries and the roadbed is ballasted with stone chips and gravel.

#### OR WINDING.

of the Cincinnati, Covington and Cincinnati, Covington, recently related some facts concerning an electrical Club which presented to account for the enormous field coils on West-where there were heavy coils of which Mr. Smith is supplied with larger wire. This was No. 7 wire. The same was used in the second case as 100 ampere turns were the result. It was naturally found to have no other effect save to magnetize many field coils. As a result it was found that it increases the resistance hard to account for that it being true, but it has ways. It was first discovered in the first car that was sent to Cincinnati that it maintained a schedule that was very similar, but with the exception of further investigation, it was found that the coils of level double track run side by side. The second was similar except that the coils were wound with No. 7 wire and the number of turns of No. 7 was exactly alike and allowed a point for the 2,000 ft. the No. 6 field coils had this. Another test was made of a mile per hour run at Cincinnati finding the number of rail

amount of good argument that such a change in the resistance with the speed of the motor is not decreased and the difference is very slight. It does not account for the facts, but we have the matter discussed in the following questions or answers to this, which is in dynamo or motor

**ELECTRIC TRACTION IN PARIS.**

The progress so far made in the substitution of mechanical for animal traction in Paris has been confined to experimental lines operating with accumulators, one with surface contacts and several using gas, air and steam motors. The latest is a rapid charging accumulator line described by J. Laffargue in *La Nature*. It was installed by the Tramway Company of Paris and the Department of the Seine, and extends from the Madeleine to the suburbs of Courbevoie,

CAR AT CHARGING STATION.

Courbevoie-Neuilly and Levallois, the lengths of the several sections of the lines being respectively 4.1, 4.2, and 2.9 miles.

The generating station is equipped with three water tube boilers furnishing steam at 220 lbs. pressure to three triple expansion Willans engines, each of which is connected to a 120-k. w. 4-pole Brown dynamo. The speed is 460 r. p. m. The engines may be operated either condensing or non-condensing.

Current is distributed through six mains, one each for the four charging stations and two for the electric pumps and lights at the power station. The conductors to the charging

INTERIOR OF CAR.

stations have an area of 300,000 c. m. They are lead covered and armored and laid in the earth without further protection. The terminal at the charging station is very well shown in the illustration.

The cars are double-decked and seat 52 persons; the motor cars weigh about 31,000 lbs., and each can draw one trailer which weighs one-half as much. There are 200 Tudor cells to the car, placed under the seats in hermetically sealed boxes, which are arranged under the seats in the manner shown in the view of the interior of the car. The charging is done at a constant difference of potential; the mean current is 120 amperes and the time required from 10 to 12 minutes.

The motor cars are equipped with two 25-h. p. motors running at 500 r. p. m. and are lighted by electricity. The speed is limited to 7½ miles per hour within the city and 10 miles in the suburbs.

**A PUZZLE IN MOTOR WINDING.**

G. J. Smith, master mechanic of the Cincinnati, Covington & Newport Street Railway, recently related some facts at a meeting of the Cincinnati Electrical Club which puzzled the many bright electricians present to account for. Owing to the burning out of numerous field coils on Westinghouse No. 3 motors on lines where there were heavy grades, it was decided on the road of which Mr. Smith is master mechanic to rewind the fields with larger wire. This was done, using No. 6 to replace No. 7 wire. The same number of turns of wire were used in the second case as were used in the first, so that the ampere turns were the same as before the fields were rewound. It was naturally supposed that this change would have no other effect save to prevent the burning out of so many field coils. As a matter of fact, however, it has been found that it increases the speed of the car. This is so hard to account for that many have expressed doubts as to it being true, but it has been demonstrated in a variety of ways. It was first discovered by the ease with which the first car that was sent out with the rewound field coils maintained a schedule that was impossible for other cars exactly similar, but with the old fields of No. 7 wire. This led to further investigation. Two cars were taken out on a stretch of level double track 2,000 ft. long, where they could be run side by side. The cars, trucks and motors were exactly similar except that the motors under one car were wound with No. 7 wire and those under the other with the same number of turns of No. 6 wire. The cars were accelerated exactly alike and allowed to run with controllers on the highest point for the 2,000 ft. At the end of that run the car with the No. 6 field coils had beaten the other by three car lengths. Another test was made by estimating the number of miles per hour run at full speed by the two cars by counting the number of rail lengths passed over in a given time.

Such are the simple facts. Any amount of good argument can be brought forward to prove that such a change in winding ought to make no difference with the speed of the motors, since the ampere turns are not decreased and the decrease in the resistance of the motor is very slight. Nevertheless such argument does not account for the facts. The REVIEW would be pleased to have the matter discussed in its columns, and to receive explanations or answers to this electrical puzzle from any one interested in dynamo or motor work.

## NO TAX ON CAPITAL STOCK.

The assessors of New York have strenuously insisted upon assessing the capital stock of street railway companies and other corporations. In the case of the Brooklyn City Railroad Company, Justice Cullen, of the Appellate Division of the Supreme Court, renders an important decision and says in part:

"This controversy proceeds from the struggle that still exists by the boards of assessors of various cities to continue to tax the capital stock of corporations under the method that generally if not uniformly prevailed throughout the state until the decision in the case of the *People ex rel. Union Trust Company v. Coleman* (126 N. Y. 448), and the various cases in the Court of Appeals following the decision. Before the decision of the *Union Trust Company* case, it had been the rule with the assessors, where the shares of the stock of a corporation sold above par, to treat that fact as conclusive evidence that the capital stock had not been impaired, and in assessing the corporation for personality, to deduct only its real estate, the amount of stock held by them in other corporations, and the amount of their stock held by charitable, literary and eleemosynary institutions. The decision cited overthrew this rule and worked a revolution in the method of assessing corporations and the extent of their liability to local taxation. The capitalization of corporations and the market value of their shares of stock depend largely on their earning power. In the *Union Trust Company* case it was held that these were not the subject of consideration in assessing the corporation; but that it was to be assessed only for actual capital or property owned by the corporation. Recently the question has again come before the Court of Appeals, and again the law has been declared that the franchise of a railroad cannot be assessed for taxation. It is, therefore, now settled law that corporations have two classes of property, one subject to local taxation and the other wholly exempt from it. This being the law, there should no longer be any attempt to avoid it or to tax property that is exempt. If the law is just every one should favor it; if it be unjust, the only remedy is by application to the legislature to alter it, for it is unquestionably within the power of the legislature to subject this character of property to the same public burden which other property within the state has to bear, a burden which for over forty years corporations have borne without cavil or complaint, and without suggestion that it was not imposed on them by law.

"The return of the relator and the statement were to the effect that the capital stock of the corporation was \$12,000,000 and was all paid in; that the actual value of all the assets of the corporation was \$8,079,271.82; that the assessed value of its real estate, including its tracks, was \$5,471,570, and that its indebtedness was \$6,925,000. The sum of these last two items, which the relator was entitled to deduct from the value of its assets, is \$12,396,570. The result is that the relator's property stands \$4,317,298.18 below the point at which it would be liable for any assessment for personality. For the market value of the shares of stock, the president of the relator refers to the financial reports of the day. These show that the stock sells above 180. It is insisted that the statement that the company has only \$1,500,000 assets in excess of its liabilities is not to be credited in the face of the fact that the value of the whole stock exceeds \$21,000,000. There is undoubtedly great

force in this argument, and it would be unanswerable were it not borne in mind the distinction between the two kinds of assets. If all the assets of this company were only \$1,150,000 it would be incredible that any amount of business skill or any peculiar use of those assets would make the stock of the company worth in excess of \$20,000,000. But there is another asset of the company which it has not returned to the assessors, and which, as we have already seen, under the authorities, the law does not require it to return, that is the franchise of maintaining and operating railroads on some sixty miles of the streets of the city of Brooklyn. This asset may be of sufficient value to warrant even a greater market price for the stock of the relator than that which now obtains. We are of the opinion, therefore, that the Special Term properly vacated the assessment.

"We think that the order directing a reassessment also was properly made. The relator borrowed \$6,000,000 some few years ago. The assessors asked for the details of the expenditure of that sum. This the witness was unable to give, but referred the assessors to the books of the corporation, which, he stated, he would produce. The books of the company were not in fact produced. These the assessors were entitled to examine, to see how the capital of the corporation and money borrowed by it were expended, because the details of such expenditures might show the existence of personal property not returned to the assessors. The president of the relator is hardly subject to criticism in not producing the books, because there seems to have been no subsequent application for them. The matter seems to have been left inchoate and undetermined. We therefore think it wise that there should be a rehearing before the assessors of which they may probe the returns of the company to any further extent that they may desire and obtain any further evidence as to the assets of the corporation. But the assessment must be laid in accordance with the law, and the fact that the justice or the favor of the statutes of the state, as construed by the courts, renders this relator subject to local taxation on some \$5,000,000 and exempts it from taxation on over \$15,000,000 does not justify an attempt to value the latter class of property as part of the former. The order appealed from should be affirmed without costs to either party."

## THE HOUSTON STRIKE.

A strike of motormen and conductors of the Houston Electric Street Railway Company took place July 4th and continued for nearly two days. It was caused by a refusal of the management to reinstate two men discharged for cause and to recognize the Amalgamated Association of Street Railway Employes of America. It was finally decided by the company withdrawing its opposition to the union and agreeing to leave the cases of the discharged men to an arbitration committee consisting of three well-known business men, who decided in favor of the company, but recommended that the men be granted another trial.

To promote harmony and good feeling the management decided to adopt the recommendation of the committee, and reinstated the men. No further trouble is anticipated.

James C. McSpadden of Pittsburg, has been given the contract to build six miles of the West End, Mt. Washington and Banksville line for the Pittsburg & West End Traction Company.

## THE USE OF ALTERNATING CURRENT.

Rotary Converters in Sub-Stations—Alternating Current Motors—Synchronous and Induction Types—Requirements for Interurban Service—The Bradley System—Use of Alternating Currents on the Swiss Railways—Long Distant Transmission.

## PART III.

If alternating current motors were used on street cars, transformers could be placed in sub-stations and would operate with no other care than daily inspection. But at present one other machine has to be interposed between the transmission line and the application of the current. It is but very recently that rotary converters, or motor-generators as they were first called, have come into practical use. Both street railway service and electro-metallurgical work require direct currents and a very efficient type of machine has been developed for the purpose of converting the alternating to a direct current. A rotary converter has somewhat of the booster effect upon the system as it can be made to maintain a constant voltage or can be overcompounded and give an increased potential with greater loads. This is accomplished by having a weak shunt and a powerful series field. The efficiency of a rotary converter is equal to that of a continuous current dynamo while the output for a given size is from 50 to 60 per cent greater. The armature need only be designed for the larger current which is from the transformer and for the greater voltage which is that of the direct current.

Like all rotary machines they require constant supervision and this necessitates a considerable item for labor at each sub-station where the line must be connected to the feeder. This is an objectionable feature for it brings complications into the system, though in many cases the saving in copper in the transmission lines will more than compensate for the expense of sub-stations.

For many uses and possibly for traction purposes poly-phase motors are preferable to continuous current motors. In street railway service a motor should be capable of carrying large overloads without failure and of running in either direction, should have a high initial torque, the speed should be varied with ease, it should have a high efficiency over a considerable range of load, it should be light, compact and require few repairs. It may be seen from the cut of the polyphase motor how simple and substantial is the construction. There are no commutators and brushes to care for and renew; the armature conductors are massive, well protected and insulated in the slots of the armature. The fields and armature are so compact and strong that there is little chance for injury nor is there danger of burnt-out field or armature coils. The motors can be made very light when need be, 70 lbs. per h. p. is an average with a minimum limit of 30 lbs. per h. p. As for the starting torque, the design of the machine can be so made that it will be four or five times the running torque. The reversal of an induction motor can be accomplished by reversing the connections of any two of the primary wires, thus rotating the field in an opposite direction to the armature and bringing it to rest very quickly.

The alternating current motors are the synchronous and induction types, each having some advantage over the other. Synchronous motors were the first to be developed as they are essentially generators used as motors. This type of

motor can be made by replacing the commutator of a direct current motor with collector rings. When supplied with an alternating current the speed of the armature would correspond to the rate of alternation of the current in order that the poles produced by the armature currents may be maintained in a fixed position with relation to the field poles, or in other words, the motor must run in synchronism. If the armature drops out of synchronism, as might be caused by a considerable overload or in starting, the reaction of the revolving pole on a fixed field would tend in one direction and then in the other, bringing the armature to rest. This type of motor necessitates a direct current for field excitation,

FIG. 10—TESLA MOTOR.

consequently a commutator or auxiliary dynamo. The initial torque is very small and the machine runs at a constant speed. These characteristics make this motor unsuited for street railway work under any conditions.

The next step was to produce a revolving field pole which will keep just ahead of the pole induced in the armature core and thus cause a constant pull in one direction. This is accomplished by a different type of field which is induced by the currents in the armature, similar to the currents induced in the secondary of a transformer. This is the non-synchronous or induction type of motor. The principle of the induction motor is very much like that of the static transformer. It has a primary and a secondary either of which may be the rotor of the motor according to the design. When the rotor is the secondary the currents, with the electromotive forces displaced in phase with each other, are sent through the field circuits. The currents in the rotor are induced, the magnetic flux being produced by the stator circuit. The possibilities of great initial torque in alternating current motors are largely due to the fact that its fields do not approach saturation at the normal load and thus the

magnetization of the fields can be doubled if need be to get a much greater torque. This is in contrast with the direct current motors in which the fields at normal loads are near saturation and increased torque must be obtained by a corresponding increase in the armature current. The speed can be regulated by the introduction of a non-inductive resistance in the secondary circuit and it acts in the same manner as a rheostat in the armature circuit of a series motor. With this arrangement the speed can be accurately governed although the efficiency of the motor is lessened by the use of the resistance.

No commutator or even collector rings are used on the smaller sizes of these motors. At overloads there is a decrease in speed but no greater than with a direct current motor. The induction motor is superior in every way to the synchronous motor except its power factor. For the synchronous motor the power factor is nearly unity; for a 25 or 30-h. p. induction motor the power factor would be about .8 which with an efficiency of 90 per cent would give an efficiency from generator to tractive effort of about 72 per cent over a considerable range of load. Fig. 19 represents a Tesla induction motor without collector rings. The primary, or armature, is stationary and the current is fed to the motor through the terminal blocks on the top of the field. The motor is compact; the moving parts can easily be strongly constructed, and as the induced currents are of low potential, the insulation is such as to make burn-outs and break-downs of rare occurrence. The most essential

FIG. 20. FIG. 21. FIG. 22.

and the least understood, but the simplest feature of this machine is the rotary field. If a permanent magnet be pivoted in the center of the fields, as shown in Fig. 20, and the field coils be commutated so that each pair of poles can be successively excited the action will be as follows. The lines of force will pass from one pole to the other and through the magnet, drawing it in parallel to the field lines. If two pairs of poles be equally excited as in Fig. 21 the permanent magnet will be drawn into the strongest field which will be intermediate between them. If the first pair of poles be then cut out as in Fig. 22, the magnet again seeks the strongest field which is in line between the excited poles. The action on the permanent magnet is a rotary one which continues as the poles are successively excited. An induced field from an alternating current acts in the same manner. The current passing through the primary circuit induces the currents in the secondary or rotor and these produce a magnetic pole in the rotor core which is attracted by a pole of opposite polarity in the primary field and a rotary motion is the result. A succession of such impulses causes the rotor to revolve and work is effected. Curves, plotted from tests of this type of motor, are shown in Fig. 23 and 24. Fig. 23 indicates the speed and efficiency of a 50-h. p. motor. The brake horse-power, the drop in speed from no load to full load, the efficiency curve and the torque

are shown in Fig. 24. It will be noticed that the speed is very nearly constant, there being a drop of only two or three per cent, and the efficiency is very high over a great range of load.

An induction motor is called non-synchronous, yet it has a tendency to keep in synchronism with the generator.

This property will make the use of the alternating current motor desirable over undulating country for it will maintain a nearly constant speed in ascending grades and instead of racing going down hill will act as a generator and return power to the circuit.

FIG. 23.

The greatest objection to the application of alternating currents to street railway work at present is the lack of a specially designed motor for traction purposes. From a theoretical standpoint the system with rotary transformers is very faulty. It is rather awkward to put up a transmission for two phase or three phase currents and then have substations with rotary converters at frequent intervals. At Buffalo and Salt Lake City where steam power can be supplied by the cheaper water power and all machines and apparatus are made for direct currents, that system is undoubtedly preferable.

When a proposed interurban is being planned the system which will contain the least amount of copper, the least number of moving machines, and the fewest number of sub-stations is the most desirable. Overlooking for the time the imperfections of the motor, a single phase, low frequency system, with dynamos generating at high voltages and static transformers placed at suitable intervals along the line, would be an ideal one. Its superiority over the multiphase would be in its only requiring one trolley line whereas two would be necessary in the other case. A single phase induction motor of good efficiency can be constructed but the fatal defect is the low starting torque.

An alteration of this plan as been suggested by C. S. Bradley and that is to transmit a single phase current on the line and instead of having transformers placed at intervals along the road, put a phasing transformer in each motor car. By this plan a single trolley line and polyphase motors

FIG. 24.

could be employed. The transformer reduces the voltage at the same time it changes the single phase to a polyphase current and with all this conversion the transformer has no moving parts. The advantages of this system are quite plain for the transformers need only be equal to the capacity of the motors and are used when actually needed, while with transformers in sub-stations their capacity must be equally to the greatest load likely to be on the section of the line to which they are connected. But one trolley is required

with this arrangement. A condenser must also be carried on each car but this can be of small and convenient size. Fig. 25 shows the connections in each car. M is a mesh winding for an induction motor and its connection to the transformer is shown by the diagram. The function of the condenser is to assist in the phasing and prevent lag on the line which would give a low power factor. One objection to this scheme is that it is difficult to get suitable commercial condensers and another is the high voltage on the trolley line.

The Déri system makes use of the alternating currents on the line but has a combination of storage battery, alternating and direct current motors on the car. Single or poly-phase currents are transmitted, with transformers to reduce the voltage at suitable intervals. The direct current motor is intended to be operated as a dynamo a portion of the time and may be combined with the alternating current motor as a motor-generator. When the car is under headway the tractive power comes from the alternating current motor which also expends all its surplus energy in operating the direct current motor as a dynamo. The storage battery B, with connections as shown in Fig. 26, is charged from the shunt motor. In starting and when the alternating current motor is overtaxed the direct current motor receives current from the battery to actuate the car. The electrical connections without the controlling devices for either the direct or alternating current motor are shown in the figure. The diagram is for a three phase system. The full lines represent the alternating current connections and the dotted lines the continuous current connections.

T, T represent the two trolley lines and the track, M, M the motors, R the regulating resistance and A an automatic regulator. It is needless to say that the system as planned at present is too complicated to be of practical use.

It has remained for the Swiss to develop the first three phase system of electric traction. Three phase currents are used on the Lugano and the Gorner-Grat Railways and will operate the Jungfrau Railway. These lines have only been in operation for a short time and no reliable results can be deduced from their performance as yet. The road at Lugano is only three miles long and is under conditions which would not require the use of alternating currents.

secondary of the transformer connections are made to the two trolley wires, and the rails take the place of a third one. The motors on the cars are single reduction, 24-h. p., 12-pole machines which give a maximum speed of  $9\frac{1}{2}$  miles per hour. The speed is controlled by resistance in series with

FIG. 26—DÉRI SYSTEM.

the rotor. At slow speeds and in starting the motors have to run on the rheostat and arc, therefore, not very efficient where frequent stops and slow speeds are necessary. A polyphase system will hardly find application in the city for the double trolley would make switches and cross-overs very complicated. However it could be used with success on conduit lines where a double trolley is not objectionable. It is said that on the Swiss lines the double trolley does not cause any great inconvenience. Even in this country there has been some experience with the double trolley and it has been in use for years in Cincinnati.

Alternate current apparatus will find application in any vicinity where there is a cheap and abundant source of power whether it be from water falls or steam plants favorably situated. The limit of voltage has not been reached for with every new transmission line a higher potential is suggested. Whereas a few years ago a potential of 3,000 to 5,000 volts was looked upon as a high potential, those of 10,000 to 15,000 are now in service. Contracts have been let for a line from San Bernardino to Los Angeles, 70 miles, which will have a voltage of 33,000. However, there is one feature of long transmission and a central source of power which causes serious questioning. With the excessively high voltages break-downs are liable to be of more frequent occurrence and the long lines will increase the chance of accident. This will have to be carefully guarded for the value of such power depends largely upon its reliability. High grade apparatus, substantial line construction, good insulation and protection from lightning will largely remove these dangers.

### STREET RAILWAY INSPECTORS IN MASSACHUSETTS.

The law which provides that the State Board of Railroad Commissioners of Massachusetts shall have the same jurisdiction over street railways as steam roads is now in effect. The inspectors will, at certain periods, examine the tracks, the rolling stock and appliances and report to the commissioners, who are empowered to force the companies to make such alterations or additions as will add to the convenience and safety of the public.

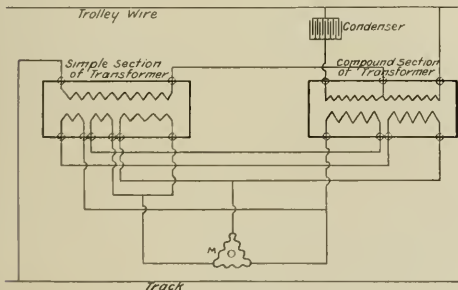

FIG. 25—BRADLEY SYSTEM.

Lugano is  $7\frac{1}{2}$  miles from the water fall which is the source of power and over this distance a three phase alternating current is transmitted at 5,500 volts and with a frequency of 40. The transformer house is centrally located with reference to the lines which have a voltage of 100. From the

## WATER POWER TRANSMISSION AT MINNEAPOLIS AND ST. PAUL.

The Twin City Rapid Transit Company intends ultimately to abandon its steam plants, which are a rather expensive necessity at present owing to the high price of fuel in Minneapolis and St. Paul, and to get all its power from the water power plant now being put in at St. Anthony's Falls about  $1\frac{3}{4}$  miles from its Minneapolis power station. The transmission will be made by means of high voltage 3-phase alternating currents at different pressures according to the distance of transmission. All the transmission wires will be laid in vitrified clay conduits. The cables will be paper insulated. The present steam plants will be used as sub-stations to which the power from the falls will be conducted and transformed into direct current of proper voltage. The shortest transmission will be from the falls to the main power plant in Minneapolis. The voltage for this will be 3,500 and the calculated line loss 3 per cent. At this plant two 600-k. w. rotary transformers will be put in. At the 31st street plant in Minneapolis one 600-k. w. rotary transformer will be installed, the transmission to this plant being at 3,500 volts with 7 per cent loss. To the main plant at St. Paul the transmission will be at 12,000 volts with 5 per cent loss and two 600-k. w. transformers will supply the St. Paul lines.

## BUCKEYE COMPOUND ENGINES.

The first compound engine built by the Buckeye Engine Company was built in 1879; the cylinders were 10 and 20 x 18 in. and it was operated at a steam pressure of 80 lbs. per gauge. Careful tests were made and the water rate found to be 19 lbs. per h. p. per hour, a performance which compares very well indeed with more modern constructions. Later designs have been made to keep pace with the increase in steam pressures and the performance of the engines improved in consequence. At the same time it has been

BUCKEYE ENGINE AT CARNEGIE STEEL WORKS.

demonstrated that the Buckeye devices are just as well adapted to the multi-cylinder engine as to the simple one. With tandem engines, automatic cut-off valves are placed on both cylinders and the same may be done with those of

the cross-compound type if desired, though the company recommends the use of a single cut-off placed on to the high pressure cylinder except where the fluctuation of load is very extreme.

The illustrations show two views of one of six engines recently supplied to the Carnegie Steel Company; three of these are installed at the Bessemer plant and three at the

BUCKEYE ENGINE AT CARNEGIE STEEL WORKS.

Duquesne plant of the company. Each is direct connected to a Westinghouse generator, the current from which is used for operating traveling cranes and other machinery.

The nominal capacity of the engines is 500 h. p., the maximum being 750 h. p.; the cylinders are 18 and  $32\frac{1}{2}$  x 33 in.; three of the engines run at 130 and three at 142 r. p. m. Blake condensers are installed with the engines.

## BRUSSELS-TERVUREN RAILWAY.

The exposition at Brussels is not all united in one enclosure as has been the case with the international expositions heretofore; one part is located at the park of the Cinquanteaire in Brussels and the other at the Royal Park in Tervuren; the distance between them is 6 miles. On May 15 an overhead trolley electric railway between the two parks was opened for traffic; the present Brussels terminus is temporary only and the line will be extended farther into the city making the total length 8.3 miles. Cars are run on a 15 minute headway from 7 a. m. to 7 p. m.; the round trip fare is 14 cents for first class and 10 cents for second class places.

The line is double track throughout, of 1 meter gage, and laid with Vignole rails weighing 50 lbs., carried on cross-ties of wood. The trolley wires are of the figure 8 section and carried on iron poles. The power house is located at what will be midway of the line.

Each train consists of a motor car equipped with two 25-h. p. motors and two trail cars. The motor car weighs 16,500 lbs. empty and carries 32 passengers; the trailers are open cars, smaller and lighter, weighing only 5,200 lbs., and have cross benches. The speed is approximately 12 miles per hour.

Charles LeBlanc was the consulting engineer, under whose direction the line was designed and installed.

## REPAINTING OLD CARS.

BY CHARLES KOONS.

PART III.

The proper coloring of the outside body of a street car is not the only difficult feature about repainting. It is a matter just as difficult and of as much importance to secure harmony in the ornamentation, striping and lettering as in the body colors, and it is here that the skill and judgment of the master is seen.

A badly colored car can be made to look all right if there is harmony of colors in the striping; so also can a good color be made to look very common by the style and taste of the ornamentation. Some colors go with others at all times and in all places and are never out of place. Gold harmonizes with any color. It can be used any place in ornamentation, striping and lettering, and looks well. In fact, it stands at the head as the means of beautifying and decorating any color. Its natural richness adds warmth to cold and lightness to heavy coloring, and it is wonderful how a little gold striping and scrolling will change the cumbersome looks of a large street car. It is the painter's best material for decorating, and also the most costly, but it pays well in spite of the extra cost, as it does not wear out or fade. It always looks well and wears until the car is ready to be painted again, which cannot be said of colors, as they all in time grow dingy and gradually fade. Another leaf that has come into common use for street car decorating is aluminum or nickel leaf as it is commonly called. It is very cheap and has superseded silver leaf altogether. Like gold, this harmonizes with all colors, and though not so rich as gold leaf, will last equally as long. It is used mostly for lettering, and looks well when used with gold decorations. Stripes and ornaments of gold and letters of aluminum with the proper shading make a good combination. But where color is used upon color care must be taken to secure harmony. Some colors add coldness, while others add warmth in the way of decoration. There is no fixed rule by which a decorator can judge what is suitable for decorating a color; he must be guided by the looks and the effect when he first started to do his work.

In large factories when striping, ornamenting or lettering is first designed, the designer has the finished work in his mind's eye. He generally is a skilled workman and judges ahead, as when the work is placed upon the car it must pass judgment with experienced mechanics who can tell at a glance if there is anything wrong in regard to harmony of colors, size of lettering, width and kind of striping suitable for certain paneling, and more than anything else the necessary ornaments for certain colored work.

There is such a thing as overdoing this kind of work, and it takes the best judgment possible to pass upon work when it is first begun; no one but a skilled mechanic in this special line is competent to see the finished work; this is the painter's business and he is trained up to see the finish at the start. He has one advantage, however, over any other trade; if his work as he has planned it does not suit he can rule it off and try again, but this does not often happen, for the man in charge has had the matter in mind probably for weeks, and when the work is ready he is ready with suitable colors for striping and ornamenting.

It is often the rule in trade work to be bound by specifi-

cation; in this case somebody else has passed judgment and the same rule holds good. A tailor should never undertake to make a pair of shoes for any one, and the appearance of work should not be spoiled by some one who knows nothing about beauty and taste; if the painter cannot fulfill this part of his work, even if he has to curtail here and there on account of economy, he is not doing his part, and some one else is attending to his work, or trying to do so at least. There are plenty of improvements in the paint shop, as well as in other departments to meet the demands for economical street car painting. Of course, there are not many machines to improve in a well designed paint shop, but there are quick methods of doing parts of the work that aid wonderfully. There are paint journals that will keep any one posted on this score. The painter does not need to be ignorant of any of the new methods of saving money in the painting department, and a dollar or two invested in special magazines will do more towards helping him than a dozen books on the same subject. These monthly issues are full of valuable information and discoveries in the way of improvements, formulas, receipts, newly devised apparatus for paint shop work and everything that is in the line of bettering the work of the painter. In fact a painter is not up to the times without a copy or two of these helps coming to him every month.

A trial of the different improvements soon convinces the most skeptical on the matter of economy. For instance, how much quicker can pumice work be done with Shumacher's rubbing stone than the old way of rubbing with the common pumice, and how much better and quicker will steel wool answer for intricate moldings and carved parts than sand paper, and how could we get along without the Fitch striper for edging stripes, and paint mixers, steam paint mills and dipping troughs of all sizes?

It would surprise some of the painters all over the country to know the price that is being paid for certain kinds of work, but still workmen are making full wages at it. But if it were not for the improvements they could not do it. For instance, with the gilding wheel gold leaf may be laid five times as fast as by hand, and a great saving of material effected. There are scores of things being brought out every year to save time and labor. Patent transfer ornaments and letters are among the greatest of time savers. When the question of cutting down expenses is uppermost in connection with the paint work here is where money can be saved, and still the beauty and ornamentation not be sacrificed. These things the painter should keep in mind, and when the matter of doing cheaper work is broached he should not cut off that which will destroy his part of the work nor sacrifice the quality of it, but he should try and see wherein he can improve his working material so as to bring down the cost. If transfers, gilding wheels, dipping tubs, graining tools, spraying machines or any improvement in the way of brushes, pencils or paint apparatus of any kind will do quicker and cheaper work they should be adopted without delay, and it has surely been proved that these improvements are efficient or they would not be used by the large concerns.

The question of service should always be weighed, however, when adopting a new contrivance, as this is the painter's only hope for his work. When it is sacrificed all is gone. Quality should never be sacrificed for any new improvement, and if the new apparatus will not do as good work as the old way it should not be used. Serviceable

## JUDGE SHOWALTER'S DECISION IN THE INDIANAPOLIS 3-CENT FARE CASE.

The history of the celebrated controversy between the city of Indianapolis and the Citizens' Street Railroad Company has been given in the REVIEW; the text of the act of 1897 prescribing a 3-cent fare in April, page 206; President Mason's report detailing the attempt by the city to confer the rights of the Citizens' company upon the City Railway Company in May, page 290; and the decision of the supreme court of Indiana holding the 3-cent law to be constitutional in June, page 417; the decision of Judge Showalter on the motion to dissolve the preliminary injunction granted by him in April and on the motion of the complainant, the Central Trust Company of New York, to make certain persons who had commenced actions against the company for damages, because a 3-cent fare was refused, parties to the original suit, is here given in full. In accordance with the rule allowing these parties to be made parties to the original suit Judge Woods has granted the decree prayed for.

The present status of the case is that the city is enjoined from enforcing the "law," the company from complying with it, and all parties who have commenced actions for damages from prosecuting the same, which will continue until a higher Federal court can pass upon the case.

The title of the case is Central Trust Company, of New York v. Citizens' Street Railway Company of Indianapolis, the City of Indianapolis and Charles S. Wiltzie, (prosecuting attorney.) The decision of Judge Showalter was handed down on July 22.

On a former hearing a preliminary injunction was granted. A statement of the case is found in the opinion then delivered. 80 Fed. Rep. 218. The defendant, the City of Indianapolis, now demurs to the bill and also moves to dissolve the injunction. It appears that after the hearing on the motion for preliminary injunction the City of Indianapolis brought suit in one of the state courts against one Navin to recover a penalty, under an ordinance of the city for alleged misconduct of Navin in boarding a street car and refusing to pay the fare demanded, namely, 5 cents. This alleged offence by Navin was after the hearing on the motion for the injunction, but before the injunction had been granted. Navin pleaded the act of 1897, called in question by the complainant here, in justification. The cause went by appeal to the supreme court of Indiana and that court on the 11th of June rendered a decision holding the enactment of 1897 valid. Motion to dissolve is made on the strength of that decision. Complainant on its part moves for leave to amend the bill by making defendants thereto certain persons who have brought actions in the state courts for penalties pursuant to said act of 1897.

It is again urged that this suit cannot be maintained against Prosecuting Attorney Wiltzie, because he represents the state of Indiana. If the enactment here in question be valid, then Mr. Wiltzie does represent the state—not the state as a proprietor, however, but the state as a governmental agency. If the enactment be invalid, then he does not represent anything. On the latter hypothesis, he, or any successor to him in office, in attempting to enforce the penalties in the enactment of 1897, would be merely in a wrong-doer. The theory of the bill is that that statute is unconstitutional and void. If the complainant be mistaken in this one proposition, then the bill cannot be sustained as to any defendant. I get the impression from the argument and citations made that a "suit in law or equity" against a state within the sense of the 11th amendment to the constitution of the United States, is a suit affecting in some manner a property right of the state as a municipal corporation. But the discussion on this point seems to me aside from the case at bar. If, as said, the enactment of 1897 be invalid, then Mr. Wiltzie does not here represent the state; if it be valid, he does. But on the latter hypothesis the entire suit must be disposed of before any question special to Mr. Wiltzie can arise. The validity of the amendment, I take it, this court must pass upon. What the rule of decision shall be—whether the opinion of the state court shall be deemed final, or whether this court is charged with the responsibility of investigating the question independently—on any view of that matter, the validity of the amendment, so far as concerns this litigation and apart from any subsequent review by the federal court of appeals or federal supreme court, depends upon the pronouncement of this court. For these reasons I doubt if the discussion concerning the force of the 11th amendment be pertinent.

In *Reagan v. Farmers' Loan & Trust Company*, 154 U. S. 362, the legislature of Texas had on April 3rd, 1891, passed an act establishing a board of three commissioners with authority to fix rates on railroads in that state. Sec. 6, of the act provided that if any railroad company, "or other party at interest," be dissatisfied with a rate as fixed by the board, such "dissatisfied company or party" could

commence a proceeding in a court of competent jurisdiction in Travis County, Texas, against the board and thus determine the question of reasonableness in such rate and from the decision there made either party could "appeal to the appellate court having jurisdiction of said cause." By Sec. 5 of the same law, it was provided, in substance, that the railroad company must carry for the rate fixed by the board and that such rate be "conclusive and deemed . . . reasonable . . . until finally found otherwise" in the direct action provided for in Sec. 6. By Sec. 14 of the same act, if any railroad company, its agent or officer, charged more than the rate fixed by the board, said "company and its said agent and officer" should "forfeit and pay to the state of Texas a sum not less than \$100 nor more \$5,000." Sec. 15 defined unjust discrimination and fixed a penalty of not less than \$500 nor more than \$5,000 upon any railroad company violating any provision of that section. Other penalties were provided recoverable by "the persons injured." By Sec. 19 it was made the duty of the attorney general of the state to prosecute suits in the name of the state for all penalties except those recoverable by individuals. It will now be noticed that by force of Secs. 5 and 14 a railroad company, unless it chose to accept the rates fixed by the board—rates which had not yet been found reasonable by any judicial authority and which in fact might be unreasonable—would be subject to prosecutions at the suit of the state, instituted by the attorney general.

On April 30, 1892, the Farmer's Loan & Trust Company, a New York corporation, being mortgagee of the railroad property of the International & Great Northwestern Railroad Company, a company organized under the law of Texas and having and operating its road entirely within the limits of that state, exhibited its bill in the circuit court of the United States for the western district of Texas, making said railroad company, the three members of the board, and the attorney general, parties defendant. Upon the showing of this bill that the rates fixed by the board were in fact unreasonable, the court issued its writ enjoining the company from adopting such rate, the attorney general from instituting or prosecuting any suit to collect any penalty by reason of the failure of the company to adopt such rate, and the members of the board from any such action by them as would have been appropriate in the aid of prosecutions by the attorney general had Secs. 5 and 14 been valid. This injunction was sustained by the supreme court of the United States. One contention before that court was that by the force of the 11th amendment, the suit could not go against the attorney general, since in the enjoined prosecutions the state would be plaintiff and the attorney general was the state officer and representative in that behalf. Mr. Justice Brewer who delivered the opinion of the supreme court of the United States reviewed the arguments and citations and held that the suit was not against the state within the meaning of the 11th amendment. If Sec. 5 had been valid for any purpose or if Sec. 14 had been valid according to its terms, that is, as applied to any refusal of the company where the rate had not previously been judicially found reasonable as provided in Sec. 6, and was in fact unreasonable, then the attorney general in the inhibited prosecutions would certainly have represented the state. As the case stood and assum-

JOHN W. SHOWALTER,  
United States Circuit Judge.

ing the invalidity of said sections, he represented nothing. His prosecutions would simply have been gross wrongs under the color of void legislative enactments.

The opinion last cited was delivered in May, 1894. The position of Mr. Wiltstie here is the same as that of the attorney general in the Reagan case. If the attorney general had not been specifically named as the officer to carry on the prosecutions under the Texas statute, the duty would have devolved upon some prosecuting attorney in Texas, and such officer in place of the attorney general would have been the defendant. I cannot hold that this suit, as against Mr. Wiltstie, is inhibited by the 11th amendment, without disregarding the law as laid down by the supreme court of the United States. If, in the Reagan case, Secs. 5 and 14 had been deemed valid, the injunction could not have issued or been sustained. Here the injunction is the purpose of the bill. If, as said, the enactment of 1897 be valid, the case fails and the bill must be dismissed as to all defendants; if that enactment be invalid, Mr. Wiltstie, so far as the threatened prosecutions are concerned, does not represent the state in any capacity whatever. So much as preliminary to the matters which arise more particularly on this hearing.

When a federal question is involved the decision of the highest court of the state is not final, but is reviewable by the supreme court of the United States. To this extent, at least, the judicial power of a state is subordinate to that of the United States. But there is no relation of subordination on the part of any federal court to any state court. In certain cases the federal courts of their own motion follow the decision of the state court as determinative of the rights of a litigant. In *Forsyth vs. City of Hammond*, decided April 19, 1897, by the supreme court of the United States, it was ruled that a late decision of the supreme court of Indiana on the validity of proceedings under Indiana statutes enlarging the boundaries of the city of Hammond was law for the parties, especially in view of the circumstance that Mrs. Forsyth herself had taken the appeal which resulted in that decision, and in view of the further circumstance that the state decision was upon essentially the specific controversy afterward, in another form, made the subject of litigation in the case before the supreme court of the United States. But where the controversy concerns a contract and the meaning of the contract depends upon the construction of a state statute, or a provision of a state constitution, a decision on the meaning of said statute, or constitutional provision, by the highest court of a state, made after contract was entered into and rights had vested thereunder, is not conclusive upon a litigant in a federal court. The litigant in such a case is entitled to the independent judgment of the national tribunal.

*Burgess vs. Seligman*, for instance, 107 U. S. 20, involved the construction of a contract between the defendant, a citizen of New York, and a Missouri corporation. The former had received certain shares of stock from the latter. Whether this stock was owned absolutely, or held as the security for another obligation, was the question. The sense of the contract depended on the construction of a statute of Missouri. After the making of the contract, but before the decision in the supreme court of the United States, the supreme court of Missouri ruled in another controversy between the same parties upon the same question that within the sense of the statute the stock was owned and not pledged. Having this decision before it, the supreme court of the United States made a contrary ruling and this in a case where there was no federal question, but only diverse citizenship. If the Missouri decision had been prior to the contract, the federal tribunal would doubtless have said that the contract was made on the meaning of the statute as declared in the state decision and that construction of the statute would doubtless have been followed, as of course. The Missouri statute, be it noticed, was, in a sense, part of a contract—that is, the court could not tell what the contract meant when the parties made it without construing the statute. For a full and clear discussion of the subject and the cases in point, see the opinion of Lurton, circuit judge, in *Louisville Trust Co. vs. City of Cincinnati*, 76 Fed. Rep., 206. If the controversy in a federal court involve a federal question—and all the more if it involve both a contract right, as above explained, and also a federal question—then, of course, that court must decide for itself, treating a state decision with due consideration, but not as foreclosing independent judgment.

Whether the decision in the *Navin* case be conclusive upon the litigants here, depends on the nature of the present controversy, in view of the rules above adverted to.

In the *Dartmouth College* case, 4 *Wheaton*, 519, it was ruled that the charter of a private corporation is a contract between the corpo-

rate body and the state, and that an act of the legislature changing the charter in any respect material to the rights of the corporation is a violation of the provision of the national constitution which inhibits a state from making a law impairing the obligation of a contract. The action was trover, and the parties were citizens of New Hampshire. The appeal went to the supreme court of the United States by reason of the federal question. The case was decided in 1819. This doctrine is still the law—and it applies to the charter of a railroad company. Take, for instance, *Banking Company vs. Smith*, 128 U. S., 74. There the state of Georgia had granted a charter to a railroad company, and the contention was that within the sense of this charter the company was authorized or given the right to charge for carriage of freight as much as 50 cents per hundred weight, or 10 cents per cubic foot, for each hundred miles. The legislature of Georgia had passed a law creating a board with authority to fix rates for common carriers. That board had prescribed rates much less than the 50 cents or the 10 cents mentioned above. The supreme court of the United States ruled that the railroad charter was a contract which the subsequent act could not alter; that if the charter provision upon fair construction had the meaning contended for, then the subsequent enactment could have no application as against it; but upon examination of the words of the charter they were held, when applied to the case before the court, not to have the meaning contended for. The doctrine of the *Dartmouth College* case applies also to a general incorporation law. See, for instance, *Railroad Company vs. Iowa*, 94 U. S., 155. In such a case the sections of the general incorporation law constitute a contract between the state and any corporation organized thereunder. If in a charter it be provided that the corporation may charge rates up to, or within, a specified limit, or that the directors may, subject to certain limitations, themselves fix the rates in their discretion, such provision cannot be annulled or changed by the legislature unless power in that behalf be reserved as part of the charter agreement, and subsequent action by the legislature must be referred to and be within the reservation.

In *Reagan vs. Farmers' Loan & Trust Company*, supra., Mr Justice Brewer says: "If the charter had in terms granted to the corporation power to charge and collect a definite sum per mile for transportation of persons or property, it would not be doubted that that express stipulation formed part of the obligation of the state which it could not repudiate."

In the case at bar it was provided in Sec. 9 of the act of 1861, under which the defendant company was organized, that the directors should have the power to fix the fare on its street railroad; by Sec. 12, that the corporation could not build tracks or operate cars on the streets at all except under conditions which the city would first agree to; and by Sec. 11, that, "This act may be amended or repealed at the discretion of the legislature." The city agreed that the fare charged by the company might be as much as 5 cents. Subject to this, the right to fix the fare was vested in the corporation, and this right cannot be modified otherwise than as provided in the charter contract, namely, by amendment of the act according to the terms of Sec. 11, when read in the light of those restrictions in the Indiana constitution bearing upon the matter of amendment to that act. There is no general authority in the legislature under which the corporate power on the matter of fares can be changed in contravention of the charter contract. Whatever the legislature may do, must be within the sense of Sec. 11 of the act of 1861, that section being itself a term in the charter contract, 11 *Morawetz Priv. Corp.*, Secs. 1, 106, 1, 095.

A railroad corporation chartered, for instance, by some other state, might own or operate a railroad in Indiana. Such a company would have no charter contract with the state of Indiana. The state might provide by law for a board authorized to fix rates, and such rates, if reasonable, might be rates for such foreign company and regulate its charges in Indiana. Such a law would be within the power of the legislature. But the enactment of 1897, here in question, cannot be referred to any such untrammelled power in the legislature, since the charter agreement between the state and the defendant railway company covers the subject of rates. The grant by Sec. 9 of the act of 1861 cannot be taken back, evaded or annulled in any way other than that stipulated, namely, by a law which shall be an amendment to the act of 1861: and valid legislative interference must fall within the scope of Sec. 11 of the act last mentioned, that being part of the agreement. The state and the corporation have agreed that, within the restrictions imposed by the constitution of Indiana on the legislative function touching any law for the formation of business corporations, the legislature may amend the act of 1861, and the ques-

tion is whether or not the act of 1897 is, in view of said restrictions, competent as an amendment to the act of 1861.

These distinctions are made here because, as will presently appear, the supreme court of Indiana rules in the Navin case that the enactment of 1897 is solely by virtue of the general power of the state to legislate on rates. In this way that court clears the subject of constitutional objections. The defendant railway company is treated as though it had no charter agreement with the state of Indiana—as though its charter had been granted, for instance, by Ohio or Illinois. The police power of Indiana on railroad tariffs is thought of as authority, which is in itself unquestionable and all-sufficient for the enactment of 1897. Considered merely as referable to the police power, want of uniformity in operation, it seems to me, might be a valid objection to said enactment. But that question need not be discussed. I think it may be said as a general proposition that no enactment which would be invalid as an exercise of the police power could be valid as an amendment to the act of 1861: but, on the other hand, an enactment proposed as an amendment to the act of 1861 might be unobjectionable as a police law, and yet not be an amendment within the constitutional restrictions which concern a law like that of 1861. To hold such an enactment valid would sanction a breach of the charter agreement. Under a police law the rates must be reasonable; but where there is a charter agreement as to rates that agreement controls. In *Banking Company vs. Smith*, supra, though the rates fixed by the board might have been reasonable, yet if the court had found that the charter gave the corporation power to charge, if it saw fit, 50 cents per hundred weight, or 10 cents per cubic foot for each hundred miles, such could have been the rates, whether reasonable or unreasonable. I may add that a law for the purpose of securing and enforcing fair and reasonable charges by common carriers, is not to be classed with those laws making for the public health and public morals, the power to enact which cannot be contracted away, or parted with, by the state.

It being now understood that the words of Sec. 11 of the act of 1861, "This act may be amended \* \* \* at the discretion of the legislature," constitute in connection with Secs. 9 and 12 an agreement binding upon the state of Indiana, what the sense of this agreement is—whether the enactment of 1897 is an amendment to "this act"—can be determined only by reference to certain provisions in the Indiana constitution bearing upon the question. As the supreme court of the United States in *Burgess v. Seligman*, supra, was obliged to construe the statute of Missouri in order to find the meaning of the contract between Seligman and the corporation, so here the meaning of the contract between the state and the corporation cannot be known without a construction of said constitutional provision. If in the light of constitutional restrictions on the legislative function of corporations, the act of 1897 be not competent as an amendment to the act of 1861, then,—and in breach of the national constitution—the act of 1897 would impair the obligation of the charter agreement as expressed in Secs. 9, 12 and 11, and should be held void.

I take it as clear that no enactment can be competent as an amendment to the act of 1861, which, when read in connection with what would be left of said act, would make the whole an unconstitutional statute. If the enactment of 1897 be valid, then the law for the formation of street railroad corporations in Indiana, as now extant, provides that in the one city which had a population of 100,000 in 1890, namely Indianapolis, such a corporation cannot charge more than 3 cents for each passenger, no matter what its contract with the city may be, and must transfer passengers from one of its lines to another without extra charge, and this under a special code of penalties, involving the forfeiture of its street franchises and divers criminal prosecutions; while in any other city, regardless of population, now or hereafter, the rate agreed on with such city may be charged, the matter of transfers being there left to the company, subject to agreement with the city, and the penal code applicable in the one city identified by the law can have no force. It seems to me that, as to the one city identified in the act, the law, on the hypothesis now under view, would be special and local, since it could never apply to street railroad business by corporations organized under the act of 1861 in any other part of the state; and as to that portion of the state, other than the one city, it would be special and local, since it could not apply to the one city.

Sec. 22 of Art. 4 of the constitution of Indiana reads: "The general assembly shall not pass local or special laws in any of the following enumerated cases, that is to say, regulating the jurisdiction and duties of justices of the peace and of constables, for the punish-

ment of crimes and misdemeanors, and so forth," enumerating fifteen additional subjects. Sec. 23, following in the same article, reads: "In all the cases enumerated in the preceding section, and in all other cases where a general law can be made applicable, all laws shall be general, and of uniform operation throughout the state." Section 13 of Art. 11 reads: "Corporations other than banking, shall not be created by special act, but may be formed under general laws."

From the language of Secs. 22 and 23, when read together, it will appear that a "local or special" law is any law which is not "general;" that it is to say, "of uniform operation," as applied to similar conditions, "throughout the state." Assuming the validity of the enactment of 1897, then the law of which that enactment forms a part is "local or special," since it is not "general and of uniform operation throughout the state." The people of Indiana said in their constitution that "where a general law can be made applicable, all laws shall be general and of uniform operation throughout the state." Also that "corporations other than banking, \* \* \* may be formed under general laws;" in other words, that a general law can be made applicable when the formation of business corporations is the subject matter of legislation. These propositions, when read together, express the meaning that any law for the formation of corporations must be general; that is to say, of uniform operation under like conditions throughout the state. The question whether or not a general law can be made applicable to the matter of corporate organization for enterprises of business and profit is thus foreclosed in the constitution itself. Upon this question no discretion, or power of deciding, is vested in the legislature or the courts of the state. A law for the formation of street railroad corporations must be general; that is to say, of uniform operation under similar conditions throughout the state. Otherwise it is void. If the enactment of 1897 be held valid, then as an amendment it displaces a portion of the act of 1861, and becomes itself part of the law. The effect would be to make the entire law for the formation of street railroad corporations local and special. Therefore the enactment of 1897 is unconstitutional and void.

As to any law on any one of the seventeen subjects mentioned in Sec. 22, of Art. 4, of the constitution, and as to any law for the formation of corporations for business and profit, the question whether such law may be local or special, or must be general, as these terms have already been explained, is settled in the constitution itself. Such law must be general, meaning of uniform application to similar conditions whenever they arise and wherever they exist in the state. A law upon any other subject may be special or local, provided a general law cannot be made applicable to such subject. Concerning this last proposition the supreme court of Indiana long ago ruled that the question whether a general law could be made applicable was a judicial question upon which the judgment of the legislature was not conclusive—and this, I suppose, upon the ground that it was for the courts to construe the constitution. Later, that court reversed this ruling and held that the judgment of the legislature was conclusive. But never, so far as I am advised, until the Navin decision, did that court suggest or intimate that the express declaration by the people of Indiana in their constitution, namely, corporations for business and profit "may be formed under general laws," left the legislature at liberty to decide that such corporations could not be formed under general laws.

In the case at bar the charter agreement between the corporation and the state on the matter of rates, as expressed in Sec. 9 of the act of 1861, subject to the conditions in Secs. 12 and 11, was the chief consideration which induced the acceptance of the charter by the corporators, the expenditures by the corporation in the streets of Indianapolis, and the investment in the railroad property by this complainant, Under Sec. 11 the security, aside from the wisdom and fairness of the legislature, was that an amendment could not be made otherwise than by an enactment which would still leave the law, as a whole, "general and of uniform operation" upon all corporations formed, or to be formed, under it, or at least upon all such corporations formed, or to be formed, as could be associated for legislative purposes by any germane and appropriate classification. No such classification is made by the act of 1897. To the contrary, upon this proposition, I find nothing in the opinion in the Navin case. I may here add that, while the constitutional inhibition is against "local or specific laws," the court rules in the Navin case that it is not material whether the act of 1897 be "local" or not, the decision resting upon grounds entirely distinct from that question.

The charter contract says: "This act may be amended at the dis-

cretion of the legislature." Is the enactment of 1897 an amendment to "this act" within the meaning of the foregoing reservation? This is the question—and it concerns the construction of the charter contract. Whether the act of 1897 is an amendment, and what discretion the legislature is vested with—in other words, whether the act of 1897 would break, or be in accord with, the contract depends upon the sense of certain provisions in the constitution of Indiana. I now call attention more specifically to the state decision in the Navin case. Mr. Justice Monks says in the opinion:

"It is insisted by appellant that the act of 1897 is unconstitutional because it impairs the obligation of a contract. Counsel for appellant do not point out any contract, the obligation of which is impaired by such act.

"If it is the contract under which the street railway company took possession of the streets of Indianapolis and constructed its tracks, it is sufficient to say that the city was not authorized to enter into any contract which would prevent the legislature from legislating upon the subject of fares. It is settled law that the legislature has the power to reasonably regulate the rates of fare for transportation of passengers within the state on street railways."

Here a number of cases are cited; but they are upon the general proposition that where there is no charter contract on the matter of rates, legislation looking to reasonable rates is competent. Not one of the citations concerns any street railroad corporation organized under the act of 1861. The opinion proceeds:

"Besides Sec. 11 of said act of 1861, being Sec. 5,463, R. S., 1894, Sec. 4,153, R. S. 1881, expressly reserves to the legislature the right to amend or repeal said act at its discretion.

"The right of the legislature, however, to regulate the fare upon street railroads organized under the act of 1861, does not depend upon the reservation of the right to amend or repeal the act in Sec. 11 of the act, that power would exist, even if the right to amend or repeal the act had not been reserved."

How can this be? If Sec. 11 were omitted, the legislature could not touch the subject of rates. Note the quotation made above from the Reagan case. Does the supreme court of Indiana mean that where a charter contains no reservation of power to amend, such reservation is implied? or that the vested rights of a corporation, organized under a general corporation law which contained no reservation of power to amend, can be disturbed by any subsequent amendment?

The opinion goes on:

"In order to exempt a common carrier from legislative control over its rates of fare, it must appear that the exemption was made in its charter by clear and unmistakable language, inconsistent with the exercise of such power in the legislature."

If Sec. 11 had been omitted, then, as said, the charter agreement between the corporation and the state would have been that the directors of the corporation could fix the rates, subject to no condition or limitation other than the agreement with the city. As the case stands, the grant to the corporation as to the rate is subject to the condition or limitation other than the agreement with the city and the agreement with the state that the legislature might within the appropriate constitutional restrictions, repeal or amend the act of 1861.

If the learned writer of the opinion means that, in addition to a contract covering the subject of rates, there must also appear in the charter an express exemption from such legislative action as might be competent if there were no contract at all—which would be competent, for instance, as respects a carrier chartered by some other state—I cannot agree with him. The three citations made by Mr. Justice Monks, among which are *Banking Company vs. Smith*, supra, and *The Railway Company v. Iowa*, supra, are to the point, as above stated herein, that if the charter contract cover the matter of rates, legislative interference in that behalf, otherwise than within the terms of the contract, is unauthorized. The state opinion goes on:

"Appellant (meaning the city of Indianapolis) had the power to prescribe the terms upon which and the time for which a street railroad company organized under said act of 1861 should occupy the streets of said city, but such contract when made was subject to the right of the legislature to amend or repeal said act at its discretion, and no contract made by the city with the street railroad company could prevent the exercise of such power by the legislature."

Now follows the conclusion drawn by Mr. Justice Monks from those portions of his opinion herein above quoted:

"It is clear, therefore, that said act of 1897 does not impair the obligation of any valid contract of either the state or the appellant."

If in view of constitutional limitations touching the legislative function as to laws for the formation or creation of corporations, the act of 1897 be not competent as an amendment to the act of 1861, then said act of 1897 certainly does impair the obligation of the charter agreement, as well as the obligation of the contract made with the city—and this in violation of the constitution of the United States.

The learned writer of the state opinion characterizes the enactment of 1897 as "a mere regulation of an existing corporation." In so doing he still has reference to the police power as the untrammelled source of legislative authority for the enactment. But the state contracted that no amendment, which would leave the act as amended a special or local law, should be made. The point is that the enactment of 1897 is not the kind of amendment which it was stipulated in the charter agreement could be made. The long settled doctrine that the twelve sections of the act of 1861 constituted the contract between the state of Indiana and any corporation organized under that act, and the terms of that contract, are ignored in the state opinion. The citations to the proposition that the act of 1897 is "a mere regulation of an existing corporation" concern what may be done when the state is not fettered by its own agreement, upon the face of which the other contracting party has acted and expended his money.

It is said in the state opinion that the legislature, since the adoption of the present constitution in 1851; has occasionally and by some special, specific enactment "enlarged the powers and privileges" of some particular corporation organized by special charter prior to 1851. Surely, the legislature could not diminish the powers and privileges (so as to destroy the vested property right) granted by a special charter to a business corporation—unless by a term in the charter reserving that power. The argument seems to be, however, that in view of the legislative practice referred to touching old corporations under special charters, the grant of an additional power or privilege to an existing corporation is not inhibited by the words in the constitution—"corporations \* \* \* shall not be created by special act." It is thence, apparently, inferred that a special enactment, like that of 1897, destroying the right previously vested in the defendant railway company to fix the fare on its lines at 5 cents, is not unconstitutional. But the scope of the agreement between the state and the defendant company is that any such change on the subject of fares must be by an amendment which, when put into the charter, would still leave that instrument a general law for the formation of street railroad corporations; that is to say, a law uniform in operation under like conditions throughout the state.

If before this defendant company was organized, or, possibly, if before this complainant took its mortgage, the supreme court of Indiana had decided that an enactment taking from the street car companies of one particular city the power to fix rates as agreed upon with that city was, within the terms of the Indiana constitution, an amendment of the act of 1861, the case here would be different. But, as the matter stands, it seems impossible to say that the parties litigant here are not entitled to the opinion of this court, treating the decision of the supreme court of Indiana with respectful and careful consideration, but not as of binding force. Apart from the diverse citizenship of the parties, there is here distinctly the question whether or not the enactment of 1897 impairs the obligation of the charter contract—whether or not the enactment of 1897 does not violate the constitution of the United States. The decision of the Indiana court—assuming that appellant in that case was entitled to and did make upon the record the federal question—is not final, but subject to review by the supreme court of the United States. In *Burgess v. Seligman*, be it noticed, there was no federal question, and the decision of the state supreme court was final and conclusive upon the parties and state courts.

In *Adams Express Company v. Ohio*, 165, U. S., 194, the decision of the supreme court of Ohio upon the question whether the tax law in controversy violated the constitution of Ohio, was held final. But this feature of that case raised no federal question. The state of Ohio has made no contract, the sense of which was to turn on the meaning of the Ohio constitution as authorizing, or not authorizing, such legislation. In deciding merely that the statute in question was not in violation of the constitution of the state, the supreme court of Ohio had no federal question before it. But the construction of the statute apart from its relation to the constitution of Ohio by the Ohio

court was not taken as final by the federal courts. There was no claim made that the law, if valid, would break the obligation of any contract to which the state was or was not a party. But it was contended that the act violated certain other provisions of the national constitution. On this contention the opinion of the supreme court of Ohio was not treated as conclusive. The federal courts followed that court merely because they agreed with it.

The federal question is more distinctly to the front in the case at bar than even in *Reagan vs. Farmers' Loan & Trust Company*. In the latter case it did not appear that the charter contract contained any express provision as to rates. The court inquired whether an engagement by the state to permit reasonable rates was not an implied term in the charter contract, and ruled that this inquiry brought the charter contract into the case for construction. If the charter contract contained such an implied term, then the question would be whether the statute objected to in the case was in violation of that contract. Following is the language of Mr. Justice Brewer:

"Still another matter is worthy of note in this direction. In the famous Dartmouth College case, 4 Wheat, 518, it was held that the charter of a corporation is a contract protected by that clause of the national constitution which prohibits a state from passing any law impairing the obligation of contracts. The International & Great Northwestern Railroad Company is a corporation created by the state of Texas. The charter which created it is a contract whose obligation neither party can repudiate without the consent of the other. All that is within the scope of this contract need not be determined. Obviously one obligation assumed by the corporation was to construct and operate a railroad between the termini named; and, on the other hand, one obligation assumed by the state was that it would not prevent the company from so constructing and operating the road. If the charter had in terms granted to the corporation powers to charge and collect a definite sum per mile for the transportation of persons or of property, it would not be doubted that that express stipulation formed a part of the obligation of the state which it could not repudiate. Whether, in the absence of an express stipulation of that character, there is not implied in the grant of the right to construct and operate, the grant of a right to charge and collect such tolls as will enable the company to successfully operate the road and return some profit to those who have invested their money in the construction, is a question not as yet determined. It is at least a question that arises as to the extent to which the contract goes, and one in which the corporation has the right to invoke the judgment of the courts; and if the corporation, a citizen of the state, has the right to maintain a suit for the determination of that question, clearly a citizen of another state, who has, under authority of the laws of the state of Texas, become pecuniarily interested in, equitably indeed the beneficial owner of, the property of the corporation, may invoke the judgment of the federal courts as to whether the contract rights created by the charter and of which it is thus the beneficial owner, are violated by subsequent acts of the state in limitation of the right to collect tolls. Our conclusion from these considerations is that the objection to the jurisdiction of the circuit court is not tenable."

I may here add, in connection with the matter above quoted, that the *Reagan* case must necessarily be understood as presenting a federal question, and not only a federal question, but a question which concerned "the construction or application of the constitution of the United States," or a question which concerned "the constitution or law of a state" as being in contravention of the constitution of the United States." Otherwise, the *Reagan* case could not have gone, in the first instance, to the supreme court of the United States, but must have gone to the court of appeals of the Fifth circuit. It will be seen from the foregoing quotation from the opinion of Mr. Justice Brewer what one federal question was.

In the case at bar there can be no inquiry as to the reasonableness of the 3-cent rate, or the unreasonableness of the 5-cent rate, unless the enactment of 1897 be, within the terms of Sec. 11, when read in the light of constitutional restrictions, an amendment to "this act," meaning the act of 1861. If the enactment of 1897 be void, then the city and Mr. Wiltzie, in enforcing it, would be mere wrongdoers. The bill avers, in effect, that if no injunction be granted, the railway company will either obey the "law," through fear of the city and defendant Wiltzie, in which case the complainant's security will be diminished in value, or, in defiance of the city and defendant Wiltzie, refuse to obey, in which case the security will be destroyed. Under the circumstances and assuming the act of 1897 invalid, can the defendants, the city and Wiltzie, insist as against this bill that con-

plainant must show that a reduction from 5 cents to 3 cents in the fares would make the income from the mortgaged property insufficient to pay operating expenses and the interest on the mortgage debt? Does it lie in the mouth of a mere wrongdoer, as against a proceeding to stop the wanton destruction, or impairment in value, of a given property, to object that since the complainant holds the property as security for a debt he can have no cause of complaint without a specific showing that there will not be enough value left after the proposed spoilation to satisfy the debt?

The complainant's lien attaches as much to that portion of the property which is to be destroyed as to any other. The general owner whose management of mortgaged property is objected to by a mortgagee may well urge that what he proposes to do with said property will still leave ample security. But what right would a mere wrongdoer have as against even a mortgagee to destroy any portion of the property pledged.

The demurrer is overruled, the motion to dissolve the injunction is denied, and complainant's motion to amend is allowed.

## FT. WORTH CUTS A MELON.

The conditions under which street railways have operated the past three years have not been specially conducive to that delightful operation of "cutting a melon," but the Polytechnic line, at Ft. Worth, Texas, came out with hand bills and posters on July 22 and invited all the world to be present and share in the good time of a "watermelon cutting." While the stock may literally be said to have been watered, as a means of creating travel it was a grand success, and with the interesting program provided, of music and speeches, the event proved an attraction which roads outside the watermelon belt might work with profit. It certainly would be a novelty in the north. Who will be the first to try the scheme?

## STREET CAR BUILDING IN ST. LOUIS.

St. Louis is the greatest street car manufacturing center in the world, there being four large concerns whose entire product goes to street railways. The St. Louis Post Dispatch gave some interesting figures regarding these firms. These four companies, the Brownell Company, the American Car Company, The St. Louis Car Company, and the Laclede Car Company, have a capitalization of \$2,500,000, the annual output exceeds \$4,000,000 and 1,600 men are employed. One very good recommendation is that every line in St. Louis is equipped with cars made in the city and it is often stated that St. Louis has the best equipped street car lines in the world. Last year more than 3,000 cars were built and sold. Among this number were several parlor cars, a dining car and several director's cars, some of these costing as much as \$5,000 apiece. Closely allied to these manufactories is the Missouri Car & Foundry Company which furnishes nearly all the wheels for the street cars. These companies build cars not only for street railway lines in the United States but their reputation has given them access to foreign markets as well, notably Mexico and Central America.

While excavating on a line of the Belt Railway Company, Lexington, Ky., one of the workmen struck what appeared to be a piece of pipe. It proved to be a 64-lb. dynamite cartridge and a terrific explosion followed, killing five of the negro workmen and fatally injuring the sixth. The police are inclined to think the bomb was placed there by someone hostile to the railway company but it might have been accidentally left there by the workmen of the Cincinnati Southern railroad when excavating at that point.

## ELECTRIC TRACTION.

From a paper by M. H. Gerry, Jr., read before the American Institute of Electrical Engineers.

A part of this paper relates especially to the application of electric power to passenger rapid transit on elevated and suburban roads. The conditions for this service differ somewhat from common railway practice. Regular stops are made at frequent intervals; the distance between stations on elevated roads, for example, averaging about 2,000 feet. The interval between trains is small, and the time of stops very short. The traffic is irregular, is heavy at certain hours, and is apt to increase and decrease at a rapid rate. To make the fast running time desired, the speed must increase up to the point where the brakes are applied; thus the maximum of speed is high compared with the mean speed. There is little or no opportunity for maintaining the speed, and the running time depends almost entirely upon the rate of accelerating and of retarding the train.

With a given number of stops per mile, the amount of power required will increase very rapidly with the speed beyond a certain point, and the cost per car-mile will not furnish a reliable basis of comparison for the motive power of different roads unless the conditions are the same. A slight difference in the average speed, or in distance between stations may cause a considerable change in the amount of power required.

There is no longer a question in regard to the ability of properly designed electric motors to operate trains of the heaviest weights in service, and at any speed permissible under practical railroad conditions. In the future, matters of efficiency and general utility must determine the desirability of electric power for any particular railway service.

If traffic is such that a large number of trains must be operated on a division, the electric power will have an advantage in point of economy, over steam locomotives; and if the trains are few, the reverse will be the case. This condition holds good independently of the weight of the trains or of the speed attained. The length of the line is in itself no bar to the successful operation of an electric railway system, as, by using alternating current apparatus, the power stations may be located favorably, and at long distances apart.

For roads operating on their own right of way, there is really no serious objections to the third rail, and all of the difficulties encountered at crossings, switches and in yards can be overcome by methods already in use, or by other devices that have been proposed. The experience already gained also justifies the statement that a reliable

Current is conveyed to the trains by the third rail system, the "trolley rail" being placed 20½ in. outside, and 6½ in. above the running rail. It is of the common T section, bonded with leaf copper bonds, divided into sections to provide for expansion. The insulation for the third rail, on all but a very small section of the road, consists of hardwood blocks, mounted on small iron chairs fastened to the ties. On a recent extension an improved form of insulation made of stoneware has been tried with success. The electric leakage is small at all times. In dry weather it is entirely negligible, and in wet weather is never more than a few amperes. It is greatest after a dry season, when the first shower is washing the accumulated iron dust from the insulating blocks. Steel rails are used for feeders and copper only to make connections. The feeder system is divided into six sections, which are tied together at junction points, through circuit breakers placed in the interlocking tunctions.

The rolling stock consists of motor cars, passenger cars and a few coal and flat cars. The motor cars were furnished by the Barney & Smith Company, and measure 47 ft. in length and weigh about 62,000 lbs. when loaded to their maximum capacity. They are mounted on rigid bolster locomotive type trucks having 33-in. steel tired wheels. The truck centers are 33 ft. 6 in. apart, and the truck wheel base is 5 ft. 6 in. One truck of each motor car is equipped with two motors, each nominally rated at 2,000 lbs. drawbar pull. The motors are operated by series-parallel controllers situated in the cabs at each end of the car. Rheostats of the packed ribbon type, used in connection with the controllers, are placed underneath the car. A circuit breaker placed in each cab is used both as a safety device and as a main switch for opening the circuit between the trolley and the controller. A main fuse box is also provided, but experience has shown that failures of the circuit breaker to act are so rare that the fuse box might well have been omitted. Circuit breakers have proved very satisfactory for this service, as they cost little for maintenance, are reliable as safety devices, and by their quick action reduce to a minimum the damage to apparatus from grounding and short circuiting.

The cars are warmed by electric heaters arranged in three circuits, two of which take about about seven amperes each, and the remaining circuit about four amperes. All of the heaters are required only in the coldest weather, and are turned off and on by the trainmen. By cutting out all or part of the heaters for a short time when the traffic is the heaviest, the peak of the load can be reduced and the heaters used to improve the load factor.

The air-brakes are of the direct or "straight" air type with an additional re-enforce cylinder. The air is compressed to 60 pounds by a vertical pump, driven by a motor of about 3 h. p. The pump motors have automatic control, regulated by the air pressure and also hand control from each end of car. The pump with its motor and automatic controller is placed in one of the cabs.

The passenger cars are 47 ft. in length and of the standard pattern, in use on all elevated roads. They are mounted on swinging bolster trucks, having 30-in. wheels and when loaded to maximum capacity weight about 45,000 lbs. Two, three, and four car, trains are in service at different hours, corresponding with the traffic. About 1,200 trains are handled daily and under very close headway out of Franklin street terminal.

The power house is supplied with water tube boilers, mechanical chain stokers, coal and ash handling machinery, forced draft, automatic oiling system and all modern appliances. The boilers are 14 in number and work at 165 lbs. pressure. There are four vertical cross-compound engines, direct connected to the electric generators. The condensing water is taken from the Chicago river by tunnel, and water for the boilers from the city mains. There are four electric generators, two of 1,500 k. w. and two of 800 k. w. capacity. The switchboard is placed on a gallery and is provided with the usual instruments, including recording wattmeters for each generator. There are six feeder panels corresponding to the divisions of the feeder system.

In an electric railway system the mechanical energy generated is divided into two classes, that utilized in propelling the train and that lost in transmission and conversion. The energy utilized in propelling the train is again divided into that necessary to overcome inertia and accelerate the train, that necessary to overcome grades and that necessary to overcome train resistance, which as here used includes all retarding forces other than the two first mentioned. From experiments on the Metropolitan it was found that the expression  $R = 2 + .19 S$  will give the train resistance with sufficient accuracy, R being

FIG. 1—METROPOLITAN SYSTEM, CHICAGO.

overhead or conduit system for heavy service can be constructed if the conditions favor the use of such methods.

The Metropolitan Elevated Railroad, now in its second year of operation, is the largest road in existence employing exclusively electric power for a heavy passenger service.

The structure has four tracks, from Market street west to Marshfield avenue, at which point three double track lines diverge. The northerly branch divides again near Robey street into two double track branches. From Market street to each of the terminals, the distance is about six miles. (See map, Fig 1).

the resistance in lbs. per ton of 2,000 lbs., and S the speed in miles per hour.

Assuming a 100 ton train run as indicated by the curves in Figs. 2 and 3, which including a stop of 12 seconds give a mean speed of 15 miles an hour the average rate of using power including stops is:

|                                        |             |
|----------------------------------------|-------------|
| On a .5 per cent ascending grade.....  | 106.5 h. p. |
| On a level.....                        | 76.5        |
| On a .5 per cent descending grade..... | 46.5        |

The power may also be divided as follows:

|                                 |          |
|---------------------------------|----------|
| For accelerating the train..... | 60 h. p. |
| For ascending grade.....        | 30       |
| For train resistance.....       | 16.5     |

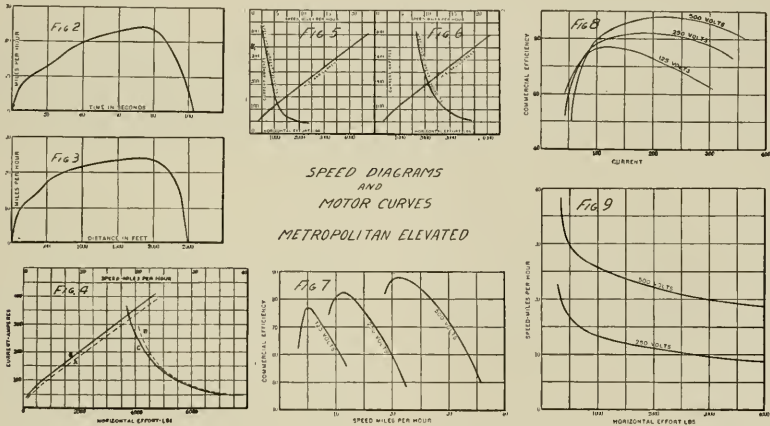

These figures, of course, do not include losses in applying the power.

If the rate of accelerating the train be increased the power required at the axle to move it a given distance in a given time will be reduced since the maximum velocity necessary to make the schedule is reduced.

The train weight may be considered as made up of two parts, the live, or paying load, and the dead load, which includes the weight of rolling stock, motors, etc. As the amount of power required by the train varies almost directly as the weight, it is desirable to have the

zontal effort is shown at A, Fig. 4 and at B the same when running with 500 volts at the terminals and at the speeds shown at C. The horizontal distance between A and B shows the loss in tractive effort due to friction and core losses, and that between C and D the corresponding loss in speed. In Figs. 5 and 6 the relations between current and speed, and horizontal effort for the same motor at 125 and 250 volts are shown. At the lower voltage the running horizontal effort is greater, because the losses affecting it are less at lower speeds but the internal losses are greater and the efficiency at the lower voltage reduced in consequence. Fig. 7 shows the relation of efficiency to speed for various voltages and Fig. 8 the relation of efficiency to current. Fig. 9 shows relation of speed to horizontal effort. The maximum working range of the motor is from 350 to 4,000 lbs. horizontal pull and the total speed variation on this range at 500 volts will be about 14 miles, and at 250 volts about 10 miles. In practice the range of speed at a given voltage is about one-half of this and with 250 and 500 as the pressure at the motor in the series and parallel combination, without further alteration of voltage by putting resistance in circuit, will be about 12 miles over a total range of 34 miles.

The armatures of the Metropolitan motors weigh 1,400 lbs, and are 18½ in. in diameter. At 800 r. p. m. which corresponds to 25 miles per hour the kinetic energy of each motor is 43,000 ft.-lbs; thus there

non-paying or dead load as small as possible. In order that there may be sufficient traction, a separate locomotive must weigh between four and five times the maximum drawbar pull required by the train, all of which is dead load, in addition to that of the cars. It has been stated that a rapid acceleration is desirable if there are many stops, but as each pound of increased maximum drawbar pull from a locomotive must add four or five pounds to the dead weight of the train, a point is soon reached where no further advantage is obtained by increasing weight on the drivers and drawbar pull. The weight admissible on the locomotive driving wheels, on account of track and structure, also limits the amount of traction, hence the drawbar pull and rate of train acceleration. Thus, for a service combining high speed and many stops, there are advantages in a form of motor which may be so placed as to utilize a part of the car weight and live load for purposes of traction. The cars should weigh as little as possible so as to reduce the total dead weight of the train, for it is well known that the ton-miles of paying load form only a small percentage of the total ton-miles moved. On elevated roads it is probably below 6 per cent on the average and on some roads, below 1 per cent.

The requirements of a railway motor are a large output, ability to withstand heavy overloads, freedom from sparking, a low rotative speed, light weight and limited space. The result is the cast-steel multipolar motor, operating with nearly saturated fields and high magnetic densities in the armature. The characteristics of the motors in use on the Metropolitan are introduced instead of a general discussion. The relation between the current flowing and static hori-

zontal effort is shown at A, Fig. 4 and at B the same when running with 500 volts at the terminals and at the speeds shown at C. The horizontal distance between A and B shows the loss in tractive effort due to friction and core losses, and that between C and D the corresponding loss in speed. In Figs. 5 and 6 the relations between current and speed, and horizontal effort for the same motor at 125 and 250 volts are shown. At the lower voltage the running horizontal effort is greater, because the losses affecting it are less at lower speeds but the internal losses are greater and the efficiency at the lower voltage reduced in consequence. Fig. 7 shows the relation of efficiency to speed for various voltages and Fig. 8 the relation of efficiency to current. Fig. 9 shows relation of speed to horizontal effort. The maximum working range of the motor is from 350 to 4,000 lbs. horizontal pull and the total speed variation on this range at 500 volts will be about 14 miles, and at 250 volts about 10 miles. In practice the range of speed at a given voltage is about one-half of this and with 250 and 500 as the pressure at the motor in the series and parallel combination, without further alteration of voltage by putting resistance in circuit, will be about 12 miles over a total range of 34 miles.

The armatures of the Metropolitan motors weigh 1,400 lbs, and are 18½ in. in diameter. At 800 r. p. m. which corresponds to 25 miles per hour the kinetic energy of each motor is 43,000 ft.-lbs; thus there are 86,000 ft.-lbs. of energy dissipated in stopping the two armatures of a motor car at every stop made at this speed; with frequent stops the loss is a very appreciable one.

The average load on the motor is fixed by the permissible increase in temperature. With the air at 60° F. and under average working conditions a Metropolitan motor will radiate heat at the rate of about 650 B. T. U. per minute. This is equal to 15 h. p., corresponding to about 60 b. p. of loading. But these motors will readily withstand for a considerable period of time a loading of three times this amount. Most of the heat produced by this additional loading must be stored in the metal of the armature and frame. A considerable portion of the heat must be generated in the armature, but its thermal capacity is nearly 150 B. T. U. per degree, and a large amount of heat may be stored before the danger point is reached.

The controllers in use on the Metropolitan are two combination series-parallel and have three steps on the rheostat for each voltage. The losses in this apparatus vary from 10 to 20 per cent, depending upon the skill with which it is handled. With care it may be kept down to 10 per cent, making no allowance for the reduced efficiency of the motors at the lower voltages.

Railway generators at the present time are nearly all of a direct current type, but there is reason to believe that in the future two or three phase alternating current machines will be installed. The development of the rotary transformer will be largely responsible for the change in practice. Power stations can be more favorably located in respect to fuel and water supply and through sub-

SPEED AND CURRENT DIAGRAMS,

stations furnish power to large areas. With this change will come also greater economy in the production of power which cannot but have a favorable effect on the development of the electric railway.

The commercial efficiency of railway generators varies from 90 to 95 per cent. Under favorable conditions, the average or "all day" loss for large connected machinery (units over 600 k. w.) is about 7 per cent. Direct connected alternating current generators give about the same efficiency as direct current generators. Commercially, the best results are obtained with a few units of large size. It is unnecessary and poor practice to install many small units for railway work.

The load line of an electric railway is subject to two kinds of fluctuations; first, those sudden changes caused by the starting together of a number of trains, and secondly, the more gradual change due to the variation of traffic at different hours of the day. On roads operating but few cars the fluctuations due to the first cause are of considerable amount, but on the large systems with many cars the changes in loading from starting up of trains are very slightly noticeable in fact—and this is especially the case if feeders are tied together and form a net work. There still exists, however, the change in the load line corresponding to the traffic. A railway load line differs from that of a lighting station in having two nearly equal peaks or points of maxima, one in the morning and one in the evening. These variations are best taken care of by cutting in and out units, while the momentary changes can usually be cared for by a slight overloading of the machinery. Engines and generators for railway purposes have a good efficiency over quite a wide range and generally stand overloads very well. In Fig. 10 are shown seven load curves from the power station of the Metropolitan elevated. The curves correspond to the days of the week and indicate the average power taken, but do not show momentary fluctuations, caused by the movement of trains. The chief characteristics of these curves are the two decided "peaks" occurring daily with great regularity. The peaks vary as to amount and time, with the season of the year, and to some extent with the weather, but are always present in a marked degree.

The load curves of the Metropolitan have proved to be a very sensitive index of the traffic. A delay on the competing cable lines, or increase of travel from any cause is at once noticeable in the power house. The greater station loading is due not so much to the increased weight in passengers carried, as to the longer stops neces-

sary to discharge and to take on passengers, thus requiring a higher speed to keep the trains on time.

The feeder system has an effect upon the form of load curves as well as upon the total amount of energy required. The highest percentage of loss will occur at the moment of greatest loading, but this rarely takes place at the same time on different sections, and an advantage is obtained by connecting the lines together to form a net work as far as possible. Feeders are usually divided into sections as a matter of safety and convenience. The best economy of copper and of power, and the most favorable load lines are obtained when the number of such sections is as few as consistent with the safety and flexibility of the system. When feeder sections are connected, the best practice calls for a fuse or circuit breaker in this circuit. The permissible percentage of loss between the power house and the trains is partly a commercial question, depending on the cost of power and interest on feeder investment. Transformers, rotary converters, boosters, batteries, and similar apparatus forming a part of the feeder system, should be considered with special reference to cost, operating expense, all day efficiency and effect on the load factor of the generating station.

The energy dissipated between the engine and the car axles may be divided into three parts, that lost in the electrical generators, the losses in the transmission lines (including transformers, rotaries, etc.) and the losses in the car controlling apparatus and motors.

The amount of loss in the generators will depend upon their efficiency and average loading. Modern railway generators have good efficiency above half load, and in stations designed with reference to the load line, there is but little difficulty in keeping the machinery above three-quarters at all times.

With machines of good type and size, the all day efficiency ought to be about 92 per cent. A sub-station provided with rotaries and static transformers working under a good average loading, should have an efficiency of about 89 per cent; a loss of 8 per cent in the rotaries and 3 per cent in the transformers. The sub-station apparatus is at its highest efficiency at the time of greatest loading, when the feeder lines are at the lowest efficiency and thus has a favorable effect on the load line.

The losses on railway feeders vary from 10 to 25 per cent. Often there is sufficient copper if rightly distributed and tied together to reduce this at least one-half. Such a change would also improve the load factor and increase the efficiency of the station.

METROPOLITAN ELEVATED RAILROAD.

The data for eight trips are given in the accompanying table and for some of them graphical logs plotted on a speed and time, or a current and time basis. In all of the current curves, it is easy to distinguish by inspection when the motors are in series and when in multiple. The stops on the controller are also distinguishable by the greater peaks on the curves. The smaller peaks and other irregularities are due, principally, to changes in voltage, caused by other trains in the same section, taking more or less current.

Electrical energy can be produced in the vicinity of Chicago, with cheap coal, under the conditions of a railroad load, at less than 5 cent per kilowatt-hour, and in the form of mechanical energy at the car axles, costing about 1 cent per kilowatt-hour, it is several per cent cheaper than it can be generated by steam locomotives. Add to this the actual saving in energy from a more rapid acceleration and from reduced train weight and the total direct advantage

for the electrical system is obtained as far as economy in power is concerned.

While any reduction in the cost of power (not only for fuel, but repairs, labor, water, oil and waste, etc.) is of great importance to railroads, the many other advantages of electricity, representing betterments of the service and greater earning capacity are the chief qualities which will determine its adoption in any case in place of steam locomotives. As a motive power electricity is simple, efficient and wonderfully flexible, and it is hardly wise to predict its limitations.

FIG. 10—STATION LOAD LINES.

## BICYCLE PATH ON THE BROOKLYN L.

President Uhlmann, of the Brooklyn Elevated Railroad, is considering the proposition received from a capitalist to build a superstructure over the elevated lines for a bicycle path. The scheme has been outlined, and as the proportion of the receipts offered to the railroad company is very liberal the officials are disposed to consider it. The residents along the lines are protesting against this proposition as it will add another story to the elevated structure and shut out light and air. The bicycle is a vehicle, and it is claimed that a special act of the legislature is necessary for the building of any pathway or road along a thoroughfare.

### PROGRESS ON METROPOLITAN, N. Y., RECONSTRUCTION.

The underground conduit which the Metropolitan Street Railway Company of New York is now installing was illustrated in the REVIEW for April, page 248, and we here present two views of the Circle at 59th street and 8th avenue showing the work on the cross-town connection between 1st and 10th avenues now building. The four lines on which the conduit will be laid immediately are, on 8th avenue from Harlem river to 59th street, on 6th avenue from 59th street to the Battery and on Madison and 4th avenues from Harlem river to the Post Office. The cross-town connec-

### SAGINAW vs. UNION STREET RAILWAY.

There has been considerable friction between the street railways in Saginaw, Mich., and the city authorities over the question of keeping the railway roadbeds in good condition and the expense of paving the streets. A statement of the case is made by City Attorney Beach as follows:

"The common council by resolution forfeited the rights, privileges and authorities of the Consolidated Street Railway Company in our streets, pursuant to an ordinance of the city which provided that the company was to relay its tracks on Michigan avenue, Hamilton, Cleveland and Madison streets, within a certain time. The company failed to

CURVE AND CROSSINGS AT FIFTY NINTH STREET AND EIGHTH AVENUE.

tion on 59th street will enable passengers to make continuous trips from 8th avenue to 4th avenue and from upper Madison to 6th avenue, and vice versa, without changing cars.

The illustrations for which we are indebted to the Scientific American, are from photographs taken during the building of the conduits and special work at the Circle. In the view looking south, 8th avenue is at the left; in the other, 8th avenue is shown at the right and at the left the commencement of the Boulevard. On the completion of the work at this point the entire Circle will be paved with asphalt.

The West End road of Boston is building an addition to its North Cambridge car barn that will cover over an acre of ground, providing room for 80 cars. In the front part are eight tracks which extend to the street and in the rear ten tracks.

comply with the terms of the ordinance and permitted its tracks to be unsafe and dangerous, and the tracks being in such condition and the cars being operated by electricity the pavement adjoining the tracks was injured and ruined. A bill was then filed by the city in our circuit court for the purpose of enforcing the resolution. An injunction was issued restraining the company from operating its cars over the tracks in the streets above mentioned. The merits of the case will not be disposed of until our September term of court. Action has also been commenced against the Union Street Railway Company operating a line of cars in other streets of the city. The Union Company filed a bill in the circuit court asking for injunction to restrain the city from passing a resolution that had been offered in the council, which resolution forfeited the company's rights and privileges in the streets. It also instructed the chief of police to prevent the company from operating its cars, and instructed the board of public works to tear up the tracks and put

the streets in a reasonably safe condition, fit for travel. This was done under the same resolution, which also provided that the city in the first instance should pave between the tracks at street intersections, the cost for said paving to be paid by the company on demand. The cost for paving between the company's tracks on other parts of the streets was to be paid in five annual payments. Improvements have been made by the city for the company to the amount of over \$35,000. There is now due the city for paving during the years of 1895 and 1896, \$7,250, which the company refuses to pay, and the resolution was offered to forfeit the company's rights, privileges and authorities after it had been given 30 days notice to pay the city the

Three days later the Boston Deposit & Trust Company, which holds the property of the railway company in trust for the bondholders, agreed to pay the claims of the city and asked that receivers for the road be appointed. The court appointed receivers and the sheriff put them in possession on the 24th; at the same time the city was temporarily restrained from tearing up the tracks.

The last move of the company is the most important; an appeal was taken from the decision of the Michigan supreme court to the United States supreme court, which granted a writ of error, citing the circuit judge to appear on October 11th. This may result in tying up the lines until final settlement. Meanwhile the people walk.

THE CIRCLE, FIFTY-NINTH STREET AND EIGHTH AVENUE, LOOKING NORTH.

amount due for paving, and on the failure to pay the same, the city would forfeit its rights, privileges and authorities. The company's bill sets up the fact that it has not paid and cannot pay on account of the financial panic that has existed for the past two years. The city filed its answer and the matter was heard by Byron A. Snow, circuit judge, and the injunction asked for was denied. The company then petitioned the supreme court for a restraining order and also for mandamus to compel the circuit judge to issue the injunction."

The supreme court issued the restraining order, but on July 13 denied the application for mandamus, holding that the insufficient earnings of the company is no legal excuse for its failure to comply with the terms of the contract between it and the city.

On July 16 the city caused the tracks leading from the car barns to be blockaded and stopped the running of all cars,

## RAILWAY ADVERTISING COMPANY SOLD.

The Railway Advertising Company of New York, was formed shortly after street railway advertising came into vogue and grew to be the largest concern of its kind in the country. Ex-Mayor Hugh J. Grant was instrumental in building up the business and has been president of the company. He secured control of the advertising of the Broadway road, the Metropolitan Traction Company, the trolley lines of Jersey City, Newark, Orange, Elizabeth, and other New Jersey towns, also the street railways of Providence, R. I., and contiguous territory. This business ex-Mayor Grant has sold to three of the Winburgh brothers who are engaged in the same vocation in Boston, Baltimore and Washington. The sale is conditional, however, as Mr. Grant holds the title of the concern until the business proves to be as guaranteed.

## NATIONAL ELECTRIC CODE.

The 1897 edition of the rules of the National Board of Fire Underwriters has just been printed, and the uniformity, so much desired in such regulations, is now accomplished. To make this code satisfactory to electrical and industrial men, as well as to the insurance companies, the rules were compiled by the National Conference on Standard Electrical Rules, consisting of one delegate from each of the following organizations: American Street Railway Association, American Society of Mechanical Engineers, American Institute of Electrical Engineers, American Institute of Architects, Underwriters' National Electric Association, National Electric Light Association, National Board of Fire Underwriters, National Association of Fire Engineers and the Factory Mutual Fire Insurance Companies.

Each delegate reports the rules to his association and recommends their approval or adoption. At the meeting of the National Electric Light Association held June 8 at Niagara Falls, the rules met with approval and the other associations will doubtless accept them. Frank R. Ford will present them before the October convention of the A. S. R. A. at Niagara Falls.

The rules having particular reference to street railways are as follows:

**3. Switchboards—**

*a.* Must be so placed as to reduce to a minimum the danger of communicating fire to adjacent combustible material.

Special attention is called to the fact that switchboards should not be built down to the floor, nor up to the ceiling, but a space of at least ten or twelve inches should be left between the floor and the board, and from eighteen to twenty-four inches between the ceiling and the board in order to prevent fire from communicating from the switchboard to the floor or ceiling, and also to prevent the forming of a partially concealed space very liable to be used for storage of rubbish and oily waste.

*b.* Must be made of non-combustible material or of hardwood in skeleton form, filled to prevent absorption or moisture.

*c.* Must be accessible from all sides when the connections are on the back, but may be placed against a brick or stone wall when the wiring is entirely on the face.

*d.* Must be kept free from moisture.

*e.* Bus bars must be equipped in accordance with rules for placing conductors.

**4. Resistance Boxes and Equalizers—**

*a.* Must be placed on a switchboard or, if not thereon, at a distance of a foot from combustible material, or separated therefrom by a non-inflammable, non-absorptive, insulating material.

**5. Lightning Arresters—**

*a.* Must be attached to each side of every overhead circuit connected with the station.

It is recommended to all electric light and power companies that arresters be connected at intervals over systems in such numbers and so located as to prevent ordinary discharges entering (over the wires) buildings connected to the lines.

*b.* Must be located in readily accessible places away from combustible materials, and as near as practicable to the point where the wires enter the building.

Station arresters should generally be placed in plain sight on the switchboard.

In all cases, kinks, coils and sharp bends in the wires between the arresters and the out-door lines must be avoided as far as possible.

*c.* Must be connected with a thoroughly good and permanent ground connection by metallic strips or wires having a conductivity not less than that of a No. 6 B. & S. copper wire, which must be run as nearly in a straight line as possible from the arresters to the earth connection.

Ground wires for lightning arresters must not be attached to gas pipes within the buildings.

It is often desirable to introduce a choke coil in circuit between the arresters and the dynamo. In no case should the ground wire from a lightning arrester be put into iron pipes, as these would tend to impede the discharge.

**6. Care and Attendance—**

*a.* A competent man must be kept on duty where generators are operating.

*b.* Oily waste must be kept in approved metal cans and removed daily.

Approved waste cans shall be made of metal, with legs raising can three inches from the floor, and with self-closing covers.

**9. Railway Power Plants—**

*a.* Must be equipped in each feed wire before they leave the station with an approved automatic circuit breaker (see No. 44) or other device, which will immediately cut off the current in case of a ground. This device must be mounted on a fireproof base, and in full view and reach of the attendant.

**12. Wires—**

## TROLLEY WIRES.

*j.* Must not be smaller than No. 6 B. & S. copper, or No. 4 B. & S. silicon bronze, and must readily stand the strain put upon them when in use.

*k.* Must have a double insulation from the ground. In wooden pole construction, the pole will be considered as one insulation.

*l.* Must be capable of being disconnected at the power plant, or of being divided into sections, so that, in case of fire on the railway route, the current may be shut off from the particular section and not interfere with the work of the firemen. This rule also applies to feeders.

*m.* Must be safely protected against accidental contact where crossed by other conductors.

Guard wires should be insulated from the ground and should be electrically disconnected in sections of not more than 300 ft. in length.

## GROUND RETURN WIRES.

*n.* For the diminution of electrolytic corrosion of underground metal work, ground return wires must be so arranged that the difference of potential between the ground dynamo terminal and any point on the return circuit will not exceed twenty-five volts.

It is suggested that the positive pole of the dynamo be connected to the trolley line, and that whenever pipes or other underground metal work are found to be electrically positive to the rails or surrounding earth, that they be connected by conductors arranged so as to prevent as far as possible current flow from the pipes into the ground.

**34. Car Wiring—**

*a.* Must be always run out of reach of the passengers, and must have an approved rubber insulating covering.

**35. Car Houses—**

*a.* Must have the trolley wires securely supported on insulating hangers.

*b.* Must have the trolley hangers placed at such a distance apart that, in case of a break in the trolley wire, contact can not be made with the floor.

*c.* Must have cut-out switch located at a proper place outside of the building, so that all trolley circuits in the building can be cut out at one point, and line circuit breakers must be installed, so that when the cut-out switch is open the trolley wire will be dead at all points within 100 feet of the building. The current must be cut out of the building whenever the same is not in use or the road not in operation.

*d.* Must have all lamps and stationary motors installed in such a way that one main switch can control the whole of each installation—lighting or power—independently of main feeder-switch. No portable incandescent lamps or twin wire allowed, except that portable incandescent lamps may be used in the pits, connections to be made by two approved rubber-covered flexible wires (see No. 40 *a*), properly protected against mechanical injury; the circuit to be controlled by a switch placed outside of the pit.

*e.* Must have all wiring and apparatus installed in accordance with rules under Class "C" for constant potential systems.

*f.* Must not have any system of feeder distribution centering in the building.

*g.* Must have the rails bonded at each joint with not less than No. 2 B. & S. annealed copper wire; also a supplementary wire to be run for each track.

*h.* Must not have cars left with trolley in electrical connection with the trolley wire.

**36. Lighting and Power from Railway Wires—**

*a.* Must not be permitted, under any pretense, in the same circuit with trolley wires with a ground return, except in electric railway cars, electric car houses, and their power stations, nor shall the same dynamo be used for both purposes.

**40. Wire Insulation—**

*a.* Rubber Covered—The insulating covering must be solid, at least three-sixty-fourths of an inch in thickness and covered with a substantial braid. It must not readily carry fire, must show an insu-

lating resistance of one megohm per mile after two weeks submersion in water at seventy degrees Fahrenheit and three days submersion in lime water, and after three minutes electrification with 550 volts.

#### 44. Cut-outs and Circuit Breakers—

d. Circuit breakers must operate successfully, under the most severe conditions they are liable to meet with in practice, on short circuits when set at fifty per cent above the current, and with a voltage twenty-five per cent above that for which they are designed.

#### 55. Lightning Arresters—

a. Must be mounted on non-combustible bases, and must be so constructed as not to maintain an arc after the discharge has passed, and must have no moving parts.

In justification of rule No. 36, a separate pamphlet has been issued giving the opinions of some of the leading electrical engineers, all of whom are opposed to the practice of using the current from trolley lines for light and power other than street railway work. The electrician of the National Board of Fire Underwriters concludes that there is great danger of fire in an arc of all safeguards and protective devices. The principal reason given for the source of danger is that one side of the circuit is normally grounded—that is, the current depends upon the earth or pipes or wires in the earth for part of its path. This means that but one accidental electrical connection between any part of the wiring of the system and a gas or water pipe or structural iron work or conducting substance of any nature in electrical connection with the earth is necessary, in order to establish current flow and a resulting "burn-out" or fire. In a complete metallic circuit two such connections are necessary, one on each side of the circuit, before current flow can be established, and, therefore, the grounded system is considerably more than twice as hazardous as the metallic.

For those now using power from trolley circuits it is suggested that the street railways put in separate generators and a complete metallic circuit for such service, but if this can not be done the following course is advised: If the foregoing is not possible, and it is not feasible to supplant the electric equipment with some other power machinery, have the entire installation, including motor, resistance box, switch, cut-outs, wire and electrical arrangements of all kinds moved outside of the building and installed in a separate fire-proof structure, entirely cut off from the main building. Power can be communicated from the separate structure to the main building by means of a shaft enclosed in an iron pipe, sealed at the ends. The motor can be started, stopped or regulated from inside the main building by any convenient mechanical means which does not bring about a possibility of communicating fire from one structure to the other. The separate structure should be built of brick, with a noncombustible roof. Not necessarily being larger than simply sufficient to include the motor and its controlling apparatus, this structure can be built at a comparatively small cost, and together with cost for foundations for the motor, would well repay the investment in the increased safety secured in having all power machinery located outside of one's premises. Special attention must be paid to the construction of the structure containing the motor to insure its successfully preventing fire starting in it from communicating with the main building.

A Buffalo syndicate recently purchased the Canandaigua, (N. Y.) Electric Light & Railroad Company and has made arrangements with John Finney, of Rochester, to manage the road. C. J. Purdy is retained as superintendent.

## MOUNTING CAR WHEELS.

The proper gage to which car wheels should be mounted in order that the impingements on the guard rails and frog points may be avoided has in recent years received considerable attention from the Master Car Builder's Association, and several modifications of the rules made. Prior to 1894 the rule was that the distance between the backs of the wheels should be between 4 ft. 5¼ in. and 4 ft. 5½ in. with a further variation of ¼ in. either way from this; the standard thickness of flange was fixed at 1⅜ in. and the minimum at 1 in. In 1894 the standard distance between backs was fixed at 4 ft. 5⅜ in., with a maximum variation either way of ⅜ in. for new wheels; 4 ft. 6¾ in. was adopted as the frog distance dimension (the distance from the protecting side of the guard rail to the gaging line at the frog point); the maximum thickness of flange was made 1 ⅞ in. In 1895 it was recommended that the wheels with flanges less than 1¼ in. should not be remounted and in 1896 that no wheels having a greater difference in the thickness of the flanges than ⅜ in. be mounted on the same axle.

George Tatnall of the Pennsylvania Railroad presented an elaborate discussion of this subject before the New York Railroad Club and deduced as the proper rule: "The distance between inside of flanges shall always be the difference between the constant figure, 4 ft. 6¾ in. and the variable figure, found by measuring the thickness of the thicker flange of the two wheels to be used together;" and that "wheels with a greater difference in thickness of flanges than ⅜ in. shall not be mounted together on one axle;" that "the thickness of flange be measured on a line parallel to the base line, from the gage line of wheel to the plane of the back of the wheel;" that "the maximum thickness of flanges be 1⅝ in., and the minimum to be used in remounting 1 ⅞ in."

At the last M. C. B. convention the committee on mounting wheels recommended changes in the rules and the manner of using the check gage, which if adopted will make the recommended practice identical with the rule as deduced by Mr. Tatnall except that the greatest difference in thickness of flanges of the two wheels mounted together is 1⅞ in., and that the maximum thickness is not changed to 1⅝ in.

W. S. Irvine illustrates in the Railroad Gazette a gage used by him in measuring flanges the thickness of which it is necessary to determine before the rule above given can be applied. The contour of the wheel shown is that of the standard tire. The scale is graduated in 32nds, the center line being at the standard 1⅜ in. and the minimum 1 in.

The lightning arresters on one of the lines of the Staten Island Electric Railroad Company grounded two strokes on the station circuit at New Brighton but the third one went into the armature of the generator, doing considerable damage. The station attendants conducted themselves in a commendable manner, stopping the engine immediately and breaking the ground connection to the dynamo. The power station was left in complete darkness but the connections were changed and the duplicate unit started and within five minutes the cars were running again.

## EMERGENCY WAGON, NEW ORLEANS.

The new emergency wagon of the New Orleans City & Lake Railroad Company was designed by General Superintendent Willard, and has been in service only a few weeks, long enough, however, to demonstrate its great utility and superiority over the old wagons. It is light, compact and very handsome, being painted bright yellow with red wheels and running gear. The platform rests over the front truck of the wagon, and when not elevated forms the driver's seat. The tower is raised by means of a crank, which one man can easily operate. Tools and apparatus of all kinds for repairing the trolley and feed lines are kept in the wagon ready for immediate use.

The wagon is kept ready for service at all times at the station on the corner of Canal and Wells streets, and this being right in the heart of the city enables very quick time to be made to any point of trouble. The stalls, harness and wagon stand are similar to those in a fire engine house, and a span of fine horses have been trained to respond quickly

NEW ORLEANS EMERGENCY WAGON.

when a call comes in. A fire alarm gong has been placed in the emergency station, and in case of a fire on the line from Carrollton to the barracks the wagon responds with hose bridges. The bridges are then laid on the track and the traffic on the line continues without interruption. Besides the large wagon for general repair work shown in the illustration a one horse spring wagon with extension ladder is used for making light repairs, such as bells off, etc., and a third wagon answers calls for appliances to put cars on tracks.

## NEW ROADS IN MASSACHUSETTS.

The proposed suburban line between Mansfield and Easton is making satisfactory progress, the stock having been subscribed and preliminary legal arrangements made. It will come under the same management as the Mansfield, Norton, Taunton and Attleboro system. A special meeting of the subscribers and stockholders of the Norton & Attleboro Street Railway Company was held to authorize the issue of \$40,000 of first mortgage bonds to complete the construction and equipment of the railway. It is thought that the work which begins this fall will be finished in the spring. Work on the electric railway between Foxboro and Mansfield will soon be commenced.

## SERIES-PARALLEL CONTROL AT MINNEAPOLIS.

For some years the Twin City Rapid Transit Company of Minneapolis and St. Paul has led a very independent existence as regards electrical and mechanical repairs and renewals. Instead of buying new motors to replace early types as the majority of roads have done which found themselves with old equipment on their hands this road has rebuilt in its own shops nearly all the older motors purchased by it. As a result it now has a motor equipment which is fairly economical as to repairs. Following out the same policy the method of car control was some time ago changed from rheostatic to series-parallel by building series-parallel controllers in the company's shops from material taken from the old rheostat controllers. The principle of these controllers is very simple. There is no contact drum for changing connections, the change from series to parallel being made by a switch which is operated by the controller handle when the handle is at the point where the connections are to be changed from series to parallel. A rheostat of the old T.-H. type is used for resistance. The first thing done by the controller handle when the current is turned on is to establish a circuit through a few segments of the rheostat and the motors in series. As the handle is advanced the contact arm of the rheostat cuts out the resistance until finally after all the resistance has been cut out the circuit is opened at the contact arm and the handle operates the switch which changes the motor connections from series to parallel. The contact arm then moves on to another set of rheostat segments thereby establishing a circuit with the motors in multiple. As the contact arm advances the rheostat is cut out and the motors are brought up to full speed. The arrangement of the rheostat is roughly shown by the accompanying sketch.

Where the circuit is broken between the series and parallel combinations the contact arm passes over a filling of Portland cement which has been found to be the best material to withstand the arcing and one which is easy to renew when worn out. The whole mechanism is contained in a large wooden box on the platform, and while rather cumbersome is a good home made improvement on rheostat control.

## WHEELS CARRIED BY THE ALLEY L.

It has not been generally advertised that wheels may be carried on the trains of the South Side Elevated, but an order was given to that effect some time since. The order was the result of an accident to a young lady friend of General Manager Hopkins, who was a guest at his house. While riding in the parks her wheel was damaged and she was obliged to walk home, a distance of two miles. The result of this forcibly bringing to the attention of the management the necessity of providing accommodations for cyclists, it was decided to permit wheels in the front car of each train. If it is found that this privilege is not abused and that a reasonable number of wheels are carried the service will be continued indefinitely.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Amount of Change Furnished by Conductor.*

A rule requiring change to the amount of \$2 to be furnished by conductors on street cars to passengers is a reasonable provision for the convenience of the public, and the conductor cannot be required to furnish change for a \$5 bill.

Notice need not be brought home to a street car passenger of a rule reasonably limiting the amount of change which a conductor is required to furnish in order to make the rule operative.

Bartlett, J., delivered the opinion of the court:

This appeal presents a novel question which has not been considered by this court in any case to which our attention has been called.

No opinion was written in the court below.

The defendant corporation operates a horse railroad in the City of New York as a common carrier of passengers.

On the 12th of January, 1889, the plaintiff entered one of the defendant's cars, as a passenger, and when called upon for his fare of 5 cents found that the smallest amount of money in his possession was a \$5 bill.

The plaintiff offered the bill to the conductor, who stated: "I am not supposed to change it; you must get off." To this the plaintiff replied: "I won't get off; you must put me off." The conductor thereupon put the plaintiff off the car.

It is not claimed that he used any more violence than was necessary, or that the plaintiff was actually injured in person or property. The transaction was undoubtedly a technical assault and battery, and the plaintiff seeks in this action to recover his damages therefor. It may be conceded, as was urged by plaintiff's counsel in his very able argument, that if plaintiff was unlawfully ejected from the car, this is a case for substantial damages.

A number of points were discussed at the bar, but in the view we take of this case there is but one question to be considered.

The plaintiff's counsel asked to go to the jury on several questions, and among others the following:

"Whether the \$5 was in this case and under the circumstances testified to, a reasonable amount for the plaintiff to tender the conductor in payment of his fare?"

The complaint was dismissed at the close of the plaintiff's case, and the point is made whether the reasonableness of the tender of \$5 to the conductor is a question of law or a question of fact on the evidence.

It was stipulated at the trial that the defendant has a rule requiring its conductors to be prepared to furnish change to the amount of \$2, and that such rule was not brought to the attention of plaintiff.

It was further stipulated that there was no regulation forbidding the conductors to make change to a greater extent than \$2.

On cross-examination of the plaintiff he testified as follows:

"Q. Why did you say to the conductor, before making any tender, 'I have only got a \$5 bill'?"

"A. Well, because I felt rather apologetic about offering that large amount; because I didn't know whether it might inconvenience him with using up a great deal of his change or not, and, of course, I wouldn't have offered \$5 if I had anything else, and I wanted to explain it."

It thus appears that the plaintiff regarded his offer of the \$5 bill as unusual and requiring explanation.

There is no evidence of a custom on the part of the plaintiff or the public of tendering to defendant \$5 in payment of 5 cent fare and receiving the change, nor of any rule of the defendant imposing upon its conductors the duty of furnishing passengers with change in so large an amount.

The plaintiff swore to the occasion when he had offered a \$5 bill for his fare and had it changed, but it was on the car of another line.

There is no evidence which would have warranted the trial judge in submitting to the jury the question whether the plaintiff's tender of the \$5 bill under the circumstances was unreasonable.

On the evidence, as it stands, the plaintiff's tender of the \$5 bill was unreasonable, as a matter of law, and the undisputed facts are not of such a nature that reasonable men might differ in regard to the inferences proper to be drawn from them.

In this state of the record it is well settled that there is no question for the jury: *Vedder v. Fellows*, 20 N. Y., 126; *Hibbard v. New York & E. R. Co.*, 15 N. Y., 455, 459, 460; *Avery v. New York C. & H. R. R. Co.*, 121 N. Y., 31, 44.

It is quite apparent that a carrier of passengers must make and enforce such reasonable rules as will enable it to discharge its duties to the general public in a proper manner, and if the facts are undisputed and not susceptible of different inferences the question of their reasonableness ought not to be submitted to a jury who might not readily understand the reasons upon which the rule is sought to be founded. If the question is treated as one of law, uniformity is secured, a matter in which the public are interested quite as much as the corporations who are carriers of passengers.

In this case at bar the reasonableness of the rule established by the defendant is obvious. In a large city like New York the round trip of a car of any street line means a very considerable number of fares paid in, and the necessity for the conductor to carry and pay out a large amount of change. When the defendant enacted the rule requiring its conductors to furnish change to a passenger to the amount of \$2 it did all that could reasonably be expected of it in consulting the convenience of the general public, and it would be unreasonable and burdensome to extend the amount to \$5. It would require conductors to carry a large amount of bills and small change on their persons, and greatly impede the rapid collection of fares.

It is not necessary that a common carrier should bring home to each passenger a personal knowledge of any reasonable and just rule which it is seeking to enforce, to so hold would render the enforcement of the rule impracticable.

We have been cited to but one case holding with the plaintiff in this action: *Barrett v. Market Street R. Co.*, 81 Cal., 296, 6 L. R. A., 336.

We agree with the learned supreme court of California, that a passenger upon a street railroad is not bound to tender the exact fare, but must tender a reasonable sum, and the carrier must accept such a tender and furnish change to a reasonable amount; but we cannot assent to the conclusion that a tender of \$5 is a reasonable sum.

It is quite possible that there existed local reasons for the decision in California, as the judge writing the opinion suggested that the \$5 gold piece was practically the lowest gold coin in use in that section of the country.

The plaintiff urges that there are several other questions than the one of reasonableness of amount tendered that should have been submitted to the jury. We have considered these questions in the light of the record as it stands and are of opinion that the dismissal of the complainant was proper.

(Court of Appeals of New York: *Barker v. Central Park, North, East and River Railroad Co.*, 35 Lawyers' Reports, Annotated, 489.)

*Injury to Drunken Man—Excessive Damages—Second Remittitur.*

In February, 1894, the appellee, then in his fifty-sixth year, but with, so far as it appears, mental and physical powers unimpaired by age or disease, left the hotel where he lodged at 5:30 p. m., to go north across Madison street for his supper. In the language of the clerk of the hotel he "was sober enough to walk and drunk enough to be a little noisy," which description of his happy condition is corroborated by the testimony of the proprietor of the hotel.

When he reached the cross-walk a street car of the appellant was standing on the track and in his own version of the affair he stepped over the first rail, and the car struck and threw him down under the car and rolled him for about twenty feet, catching him in the hip. To a man attentive to his surroundings, and in the exercise of ordinary care no such accident could have happened. The home of appellee had been in Chicago nearly all his life. He knew or ought to have known had he given the matter a thought that the car had stopped only momentarily.

Thus far this is my own opinion, but the majority of the court does not agree with the conclusion at which I arrive. In their opinion the question of care by the appellee was for the jury, that in considering it they might take into consideration the usual conduct of ordinary prudent and careful persons in threading their way through the crowds, and across the streets thronged by the multitudes of this great bustling city.

Also, that other testimony presents the manner of the accident more favorably to the appellee than does his own. A policeman stationed at the cross-walk testified that the car was about six feet west of the cross-walk and that as the appellee stepped upon the track the car started forward; appellee made a plunge to get off the track and the car struck him and knocked him against another man and he, appellee, fell under the car.

Paraphrasing the language in *Robinson v. Pioche*, 5 Cal., 461, a drunken man is as much expected to exercise ordinary care as a sober one, and much more is the need of it.

We agree that there is no error in the record if upon the evidence the verdict of the jury was justifiable. The jury awarded \$10,000 after a remittitur of one-quarter of the verdict—the court have entered judgment for the other three-quarters.

It is the judgment of this court that those fractions should be exchanged, and that within ten days after this opinion is filed the appellee enter another remittitur of \$5,000; the judgment is affirmed for \$2,500, otherwise the judgment be reversed and the cause remanded, in either event at the cost of appellee.

(Appellate Court of Illinois, *West Chicago Street Railroad Co. v. Raustedt*, 29 Chicago Legal News, 318.)

*Noise Caused by Electric Car—Liability for Frightening Mule*

The frightening of a mule, caused by the usual noise incident to the running of a street car by electricity, without any unnecessary noise for the purpose of scaring the animal, is held not to make the street railway company liable for the resulting damages.

Supreme Court of North Carolina, *Doster v. Charlotte Street Railroad Co.*, 34 Lawyers' Reports Annotated, 481.

*Agreement of Street Railroad not to Cross at Grade—Control of Chancery over Municipal Corporation as to Use of Street Railroads.*

Each of these parties operates under ordinances of the City of Chicago, lines of street railway in the south part of the city.

In 1892, when they were laying the tracks, they made an agreement by which they both agreed that with the exception of crossings mentioned in the agreement, no crossings at grade or one road over the other should be made.

The appellee thereupon procured from the city an ordinance permitting it to put down tracks on more streets, and in permitting them to do it *vi et armis* made crossings at grade over other places than those the agreement mentioned.

Appellant filed this bill to enjoin the appellee from operating over those crossings, and from making any more grade crossings.

It is further settled in this state that a court of chancery will not control a municipal corporation as to the use of street railroads. *Phillips v. N. W. El. R. R.*, 166 Ill., 131; affirming the same case, 60 Ill. App. 471, is the last reported of the many cases to that effect. And *Doane v. Chicago City Ry. Co.*, 160 Ill., 22; affirming the same case, 51 Ill. App. 353, is a complete answer to all claim of the appellant under the agreement. Not to cross at grade may be—practically probably is—an agreement not to cross at all, and is void against public policy.

(Appellate Court of Illinois, *South Chicago City Railroad Co. v. Calumet Electric Street Railway Co.*, 29 Chicago Legal News, 334.)

---

### IRON FELT.

---

Mr. Monaghan, U. S. Consul at Chemnitz has advised the state department of the invention of a material which is to be known as iron felt. It is made of the best of woolen materials and impregnated with the inventor's patented preparation which gives it a resisting strength of a trifle over 14,300 lbs. per sq. in.; it is not stated whether this is in tension or compression. The article is said to be very useful for railroads of all kinds. Placed between rails and sleepers it deadens sound and prevents shocks. The first experiments were made on one of the Berlin street railways at a point where there were over 360 trains passing daily and the results in reducing wear and noise surpassed the company's most sanguine expectations. It is to be tried on the new road at Leipsic.

---

Pascor & Crilly, contractors, are about to begin work on six miles of trolley line for the South Bethlehem & Hellertown Electric Railway Company of South Bethlehem, Pa.

## ASSESSMENT OF THE TORONTO RAILWAY COMPANY.

The rails, poles, etc., of the Toronto Railway Company were assessed for taxation at \$285,000, but the company took an appeal which was sustained by the courts. The city's case was based on the fact that the pipes, etc., of the gas company are taxed. The court said:

"The Toronto Railway Company has only a street railway privilege for the purposes of the railway, and has neither the same powers nor property in the street as the Consumers' Gas Company has in the lands occupied or used by it for its gas works and pipes. And I do not think that the judgment in the supreme court in the Consumers' Gas Company case governs this appeal.

"It is again argued that the exemption from taxation which I conceive has been conferred upon the company by its agreement with the city is illegal and void. The short answer to this is, that this agreement has been confirmed by an act of the legislature, and has thus been taken out of the ordinary rules which govern such assessments. The city, should I be wrong, has the option of proceeding with

## AIR MOTORS NOT RECOMMENDED.

After a thorough test of the Hoadley-Knight air motor on the Eckington & Soldiers' Home Railway, Engineer Commissioner Black handed a report to the Commissioners, in which all the features of the motor are discussed. He does not anticipate any trouble from explosions. The cars are comfortable, and the machinery operates with little noise. The wheel base, to accommodate the air mechanism, is too long for medium sized curves and the cars are so heavy as to necessitate a reconstruction of the tracks. As the system was planned, trailers could not be used and the power to operate a car was greater by 23 or 24 h. p. than that required for an electric car. While the motor possesses many good qualities yet its development is in such a stage that it would be bad policy to equip such a large system with experimental apparatus.

## Z RAIL AS TRACK RAIL.

Last month we mentioned the work being done for the Market Street road in San Francisco, by the Falk Manufac-

FIG. 1.

FIG. 2.

FIG. 3.

the pending appeal to a higher court. I think the assessment should be struck out and the appeal allowed."

## TROLLEY VICTORY IN PENNSYLVANIA.

The completion of the Philadelphia & Bristol railway is now assured by a recent decision of Judge Yerkes. A permanent injunction against the construction of the road was refused and also a rehearing in the equity suit dissolving the preliminary injunction. The plaintiffs in the case were the Pennsylvania Railroad Company and Henry Gaw, owners of adjacent property on the Bristol turnpike. The court in his opinion stated that considering the apparent disposition of the supreme court to hold that only the want of consent of intervening municipalities shall prevent the building of all or any part of a street railway, this court is not warranted in granting an injunction against the construction of the entire line, at this suit of a private complainant. This will now allow the trolley people to complete the line at Croyden station, which has been open for about 1,000 ft., owing to this litigation. Of course the abutting property owner can maintain an action for damages, but he cannot prevent the completion of the street railway. This decision establishes the principle contended for by the Young bill defeated in the late legislature.

turing Company, in cast-welding cable slot rails, or what is known as Z iron, to enable its use as track rail. We have since secured some views of this work, which are reproduced herewith, and which require little additional description.

Fig. 1 show the chair previously used in construction and a joint exposed for cast-welding. Fig. 2 is of a defective joint which was broken off while hot, a portion of casting remaining on the rail. Fig. 3 shows two finished perfect joints.

The rail is 8 in. in depth and weighs about 80 lbs. to the yard. The joints weigh approximately 175 lbs. each. The rail ends were in very bad shape previous to welding but now the track is perfectly smooth and free from any drop or jar while passing over joints. Not one cast joint has been broken since the work of welding has been completed, and the management does not hesitate to express satisfaction at the results.

The Berkley, Va., street railway was first opened in 1890 and consisted of  $1\frac{1}{4}$  miles of track with two horse cars. Recently it has been lengthened to  $2\frac{1}{2}$  miles and converted into an electric line. The equipment is of the General Electric system throughout. When the line was formally opened invitations were sent to the town officials, members of the press and others interested in the development of Berkley. T. H. Synon is president of the line.

## FARE REGISTERS ALTERED.

One of the conductors of the Staten Island Electric Railroad was arrested for changing the records of the fare registers. The conductor was suspected for some time and a watch was kept. Although his returns did not tally with the count of the passengers on his car yet they always agreed with the register and no one was able to detect the conductor tampering with the register. One evening the detectives noticed the number of fares was less than a short time previous and the conductor was arrested, also another man who had been seen with him many times on the car. Upon being searched a number of small tools and several screws from the registers were found in their pockets. It is suspected that these men are a part of a gang of expert thieves who have worked the fare registers on the Broadway cable, the Brooklyn trolley lines and the New Jersey roads.

## AN AID FOR THE BLACKSMITH SHOP.

C. E. Moore, master mechanic of the Chicago City Railway, who has in years past acquired a very practical acquaintance with the needs of the blacksmith and tool maker, recently devised a very simple little appliance which is meeting with a ready sale, and which is a great time saver when

THE GARDEN CITY ARCH.

it comes to heating iron. It is simply a small arch made of fire brick which is put over the ordinary blacksmith's fire. The inside of the arch becomes white hot almost immediately, so that heat is reflected back from the arch to the iron which is placed inside the arch over the fire. As a consequence the time required to heat the iron is much less than with an open fire, and less fire and therefore less fuel is needed. This arch is being made under the name of the "Garden City."

The charter for the Ingersoll (Ont.) Radial Electric Railway has been granted and arrangements are being made for subscriptions to the stock of the company.

## CORRESPONDENCE.

PENACOOK, N. II., July 19, 1897.

## EDITOR REVIEW:

I noted with interest your article in the current number of the REVIEW entitled "The Telephone in Connection with Wheatstone Bridge for Shop Measurements," and while acknowledging the force of some of your arguments against the laboratory form of Wheatstone bridge for shop practice, it hardly seems as if the advantages offered by the telephone arrangement are bona fide. In the first place, every one who has had occasion to use the bridge form of measurement has found it a tedious and oftentimes vexing matter to balance the arms even when a galvanometer was used and indicated whether the resistance of the unknown arm was plus or minus. With the telephone method there seems to be nothing to indicate from which arm of the bridge the current is flowing, or, in other words, whether the resistance is higher or lower in the unknown arm than in the arm with the variable resistance, and the operator is, therefore, entirely in the dark and at a loss to know whether to increase or decrease the known resistance to strike a balance.

The portable testing set seems to offer the best solution of the problem, although the hitherto high cost has, to a great extent, prohibited its use in shop practice. An instrument of this type, however, accurately adjusted and containing a galvanometer, which would not be more susceptible to outside magnetic influences than any high grade commercial voltmeter, and without batteries (most shops have batteries and therefore do not care to pay for high priced, portable dry cells), at an expense not exceeding \$25, should find a place in every shop where resistance has to be measured. Such an instrument is already on the market.

J. ALBERT MASSIE.

## NO MORE PASSES IN NEBRASKA.

One of the state laws which went into effect July 11 prohibits persons or corporations from furnishing to any officials of cities or towns in Nebraska free light, water, telephone or transportation service, or to charge a less rate than is charged other patrons. If any official violates this law he is fined upon conviction not less than \$200 or more than \$500 and his office is declared vacant. In consideration of this law the Omaha Street Railway sent out the following to those interested:

Our attorney expresses the opinion that, inasmuch as the penalties seem unusually severe, that as a matter of protection to all parties in interest with us, we should, as far as possible, place in the hands of those connected with city affairs who have had transportation, some special notice of the action of the state legislature.

It will be seen that outside of the misdemeanor provisions, with its fines, etc., Sec. 7 declares that upon conviction of any officer for violation under the act that this office shall become vacant and subject to the law governing vacancies.

We regret that we have to place this matter before you, and ask your aid in complying with the law, but we see no other course open to us at present, and on July 11, 1897, our conductors will be instructed to collect from those holding passes by virtue of their connection with any of the city departments.

The police are especially dissatisfied with the operation of the law as their duties often require them to make long and quick trips. Their street car fare will amount to a larger sum than they can afford to pay.

### California.

**OAKLAND, CAL.**—Suit against the East Oakland Street Railway Company and others, to recover on two notes for \$25,000 each, has been brought by the Realty Syndicate Company.

**SAN DIEGO, CAL.**—Affairs of the Citizens Traction Company are still in litigation after five months of negotiation. Recently \$12,000 of receiver's certificates were sold to representatives of Spreckels, owner of the rival street car system, and he will probably ultimately acquire the plant.

### Chicago.

**CHICAGO.**—The Chicago Passenger Railway, controlled by the West Chicago Street Railroad Company, has given a blanket mortgage for \$2,000,000 to the Equitable Trust Company.

**CHICAGO.**—Mayor Harrison's veto of the ordinance granting the General Electric Railway Company right to install the overhead trolley in place of the Love conduit has been sustained.

**CHICAGO.**—On July 31 the Chicago General Railway Company began operating its cars over the 22nd street tracks of the Chicago City Railway between the river and lake. It is proposed that stockholders of the Illinois National Bank purchase the bonds of the Calumet Electric Railway held by the bank.

**CHICAGO.**—Judge Showalter has decreed the sale of the Englewood & Chicago Electric Street Railway. The proceeds will be applied first to pay the \$60,000 of series A receiver's certificates, then \$260,000 of series B certificates, and lastly the bonds. The organization of a new company has already been agreed upon.

**CHICAGO.**—Judge Horton has discharged John A. Roche, receiver of the Suburban Construction Company. New officers have been elected for the Suburban Railway Company. William H. Holcomb is president, J. Charles Moore, treasurer and C. S. Leeds, secretary. From this it would appear that Mr. Leeds has been successful in regaining control, and probably with the assistance of Charles T. Yerkes, J. Charles Moore being president of a line in which Mr. Yerkes is interested.

### Colorado.

**CRIPPLE CREEK, COLO.**—The Cripple Creek District Railway is pushing construction. On July 8 the company ordered 27,000 lbs. of trolley and feeder wire.

**COLORADO SPRINGS, COLO.**—Irvin Howbert, promoter, asks the city council of Colorado Springs for a franchise and water rights for an electric road to be built between that place and Cripple Creek.

**PUEBLO, COLO.**—The Pueblo Electric Street Railway, the Pueblo Gas & Electric Light Company, the Pueblo Light, Heat & Power Company and the Citizens' Light, Heat & Power Company will be consolidated.

**CRIPPLE CREEK, COLO.**—A mortgage has been given by the Cripple Creek District Railway Company to the Central Trust Company of New York to secure an issue of \$500,000 bonds. The proceeds will be employed to build the road as reported in these columns.

**OURAY, COLO.**—Surveys have been made and details arranged for the construction of eight miles of cog wheel electric railway from Ouray to the famous Virginus mine and Revenue tunnel. The enterprise is backed by the Virginus Company, of which A. E. Reynolds of Denver is the head.

**DENVER, COLO.**—The Loretto Heights Railway Company has been incorporated to build a car line two miles long. The cars will be

drawn by horses at first, but if the project proves a success electricity will be installed as a motive power, current being supplied by the Denver Tramway Company. Capital stock, \$15,000; incorporators, Rev. T. H. Malone, Charles M. Ford, Thomas J. Carlin, Mary E. Bindewald and Mary C. Walsh.

**CRIPPLE CREEK, COLO.**—Charles W. Hascall, one of the promoters of the Canon City & Cripple Creek Gold Belt Railroad, says the bonds of the company have been placed in New York. The overhead trolley will be used. Orman Crook & Co., have been awarded the contract for the first five miles of grading. Power houses will be erected at three points along the line, to be supplied with fuel from the company's own mines. At Canon City the company will operate a large reduction works. The estimated cost of construction is \$1,500,000.

### Connecticut.

**HARTFORD, CONN.**—Poles, wire and ties for the proposed extension from Farmington to Plainville have been purchased by the directors of the Hartford & West Hartford Street Railway. Senator Gay, a director says: "We expect to have this road completed and running by the last of September, as there is no hard digging along any portion of the entire route, and we do not anticipate any trouble in securing the right of way."

### Delaware.

**WILMINGTON, DEL.**—The New Castle & Wilmington Electric Railway Company has been doing a large business. F. H. Treat, of Philadelphia, has been elected president; Judge Koch, of Pottstown, vice-president, and C. P. King, of Philadelphia, secretary and treasurer.

### District of Columbia.

**WASHINGTON, D. C.**—An extension of ten miles from Falls Church to Fairfax is contemplated by the Washington, Arlington & Falls Church Electric Railway Company.

**WASHINGTON, D. C.**—Again will the commissioners try to sell the Anacostia Railroad to satisfy certain certificates of indebtedness. It is alleged the company owes the District \$4,000 for repaving.

### Georgia.

**SAVANNAH, GA.**—The City & Suburban Railway Company, it is said, will equip the lines between Sandy and Montgomery with electricity.

**ATLANTA, GA.**—D. H. Livermore has interested northern capital in the Atlanta Electric Railway with a view to its extension to the business part of the city.

### Iowa.

**MASON CITY, IA.**—The Mason City & Clear Lake Traction Company has placed its line in operation.

**DUBUQUE, IA.**—Mayor Dufy has signed the ordinance extending the franchise of the Dubuque Street Railway to 1918.

### Illinois.

**FREERPORT, ILL.**—Citizens offer to aid the Freeport General Electric Company to extend the car line to South Freeport.

**WAUKEGAN, ILL.**—Work has begun on the extension of the Bluff City Electric Street Railway to Evanston. Ground has been broken at Wilmette.

**EAST ST. LOUIS, ILL.**—The East St. Louis Electric Street Railway Company on July 16 petitioned the city council for franchises to build lines running north and east.

**EAST ST. LOUIS, ILL.**—The Belleville & St. Louis Electric Railway Company is buying right of way. The stockholders are Edward Abend, Sr., Paul W. Abt, John A. Day, George J. Kobusch, Judge H. S. Priest, A. M. Meintz and Charles Sutter.

**EAST ST. LOUIS, ILL.**—Within six months the extension of the East St. Louis Electric Street Railway to Gross Park and the city limits will be completed. Surveyors are now at work on this line and when through with it, will survey other lines which will be extended later.

**EAST ST. LOUIS, ILL.**—The East St. Louis & Belleville Electric Railway Company has been incorporated to build between the two cities. Capital stock, \$50,000; incorporators, John A. Day, Belleville; Charles Sutter, St. Louis; Paul W. Abt, Albert M. Meints and E. C. Rhoads, East St. Louis.

**JOLIET, ILL.**—The recently incorporated Kankakee, Wilmington & Morris Electric Railway Company has elected J. A. Henry of Joliet, president, Thomas J. Divens of Chicago, vice-president, and John Hulsizer of Joliet, secretary and treasurer. No time has been set for construction to begin, this depending largely upon the subscriptions of landowners.

**LAKE FOREST, ILL.**—The first 50-year franchise in Illinois was granted July 23 by the Lake Forest council to the Bluff City Electric Street Railway of Waukegan, in which C. E. Loss, the railway builder is interested. The company pays \$10,000 cash or \$15,000 bonds, and will pave the right of way. Immediately the company will build to Highland Park, and next spring to North Evanston, thus giving a continuous ride of 36 miles along the north shore.

### Indiana.

**INDIANAPOLIS, IND.**—The suit of Knight & Jilson to have a receiver appointed for the Indianapolis & Broad Ripple Rapid Transit Company has been dismissed, their claim having been paid.

**CRAWFORDSVILLE, IND.**—It is said several capitalists are interested in a scheme to construct an electric railway from Crawfordsville to the Shades of Death.

**MARION, IND.**—The Indianapolis, Anderson & Marion Electric Railway Company has canceled its contract with Mr. Enricht of Chicago for the construction of the line, and is now considering propositions from other contractors. At a recent meeting in the office of Judge T. L. Sullivan at Indianapolis the following directors were elected. Frank A. Maus, Noah Clodfelter, D. J. Sullivan and Mr. Pearson of Alexandria.

**HAMMOND, IND.**—The council has granted a 30-year franchise for a street railway in the two principal streets, to a number of Chicago and Crown Point capitalists. The line will form part of one 25 miles in length and will connect with Cedar Lake, Crown Point, Griffith and Highlands. Passengers, freight and express packages will be carried on hourly trains. Among those interested are Lamb D. Wold, John Brown, John G. Strabel, Robert P. Bates and Malcom T. Hart.

**INDIANAPOLIS, IND.**—Suit for attachment has been brought against the Indianapolis, Anderson & Marion Electric Railway Company by the F. C. Austin Manufacturing Company of Chicago. Plaintiff sold to Cochran & Ross, who are grading the road, a leveling machine and were given an order on the company for \$1,050, which was accepted by Louis Enricht, the general contractor. It is alleged the account has never been paid and judgment is asked against the railroad company and Mr. Enricht.

### Kansas.

**GALENA, KAN.**—The electric railway people have engaged J. B. Hodgdon to make a survey of their proposed line between Galena and Baxter Springs.

**WICHITA, KAN.**—The Wichita Street Railway & Power Company has transferred its lines to the Wichita Street Railway Company, recently organized by a Boston syndicate headed by William F. Ellis, of Boston.

**LEAVENWORTH, KAN.**—Willard E. Winner, of Lausing, has applied to the county commissioners for a franchise to build an electric road between Lansing and Leavenworth. It is said that Mr. Winner has already obtained the necessary capital.

**LEAVENWORTH, KAN.**—When the matter of granting a right of way to the Winner Electric Railway came up before the county board, Attorneys Kelso and Van Tuyl asked that the matter be postponed until the August meeting stating, that they represented parties who would ask for a franchise to build an electric railway from Kansas City, Mo., through Lansing to Leavenworth, Atchinson and probably St. Joseph.

### Kentucky.

**PADUCAH, KY.**—A consolidation of the People's with the Paducah Street Railway is being negotiated.

**LOUISVILLE, KY.**—The Louisville Street Railway Company's plan to raise \$250,000 by the conversion of 5,000 shares of common into preferred stock has been successful.

### Maine.

**WATERVILLE, ME.**—The reorganization of the Waterville & Fairfield Electric Railway & Light Company is progressing. W. D. Spaulding of Boston, representing bondholders and I. C. Libby of Waterville, will each advance \$20,000 for the contemplated improvements.

**LEWISTON, ME.**—A syndicate of Maine capitalists has purchased a controlling interest in the bonds of the Lewiston & Auburn Railroad Company. The railroad will be reorganized. It is said that 81 miles of extensions will be built with Lewiston as the center, including lines to Brunswick, Bath, Turner and Sabattus.

### Maryland.

**HAGERSTOWN, MD.**—Baltimore capitalists, it is said, will construct an electric road between the various resorts in the vicinity of Penmar. A surveying party is working between Penmar and Waynesboro.

### Massachusetts.

**MILFORD, MASS.**—It is said the Milford Street Railway Company will not build.

**FALL RIVER, MASS.**—The Globe Street Railway petition for an extension in Thompson and Brownell streets was heard July 19.

**WORCESTER, MASS.**—The petition of the Worcester & Clinton Street Railway Company for an extension through Clinton was heard August 4.

**BOSTON, MASS.**—The Boston Elevated Railroad Company has asked the state railroad commissioners to approve an issue of \$15,000,000 capital stock.

**BEVERLY, MASS.**—It is said that President Fergus, of the Gloucester, Essex & Beverly Street Railway plans a branch line four miles in length from Essex to Manchester.

**BROCKTON, MASS.**—The work on the Taunton end of the Taunton & Brockton Street Railway Company's line, which was delayed owing to the non-arrival of rails, has been resumed.

**FRAMINGHAM, MASS.**—The Framingham Union Street Railway, which for ten years has been operated by horse power, has just been equipped in its central division with four electric cars.

**BROCKTON, MASS.**—The state railroad commission has granted the Taunton & Brockton Street Railway Company permission to issue \$100,000 of bonds, and to cross the Consolidated Company's tracks at South Easton.

**BRIDGEWATER, MASS.**—H. Fisher Eldredge, John M. Stetson, N. F. Ryder and others have incorporated the Bridgewater & Middleboro Street Railway Company to build an electric line between the two cities.

FALL RIVER, MASS.—The project to build an electric road from Fall River through Swansea and Warren to connect with the contemplated extension of the Union Street Railway of Providence has been revived.

MANSFIELD, MASS.—E. D. Hewins of Boston is treasurer of the Norton & Attleboro Street Railway Company, recently incorporated to build 5.5 miles of electric road between Norton and Attleboro. Capital stock, \$40,000.

BRAINTREE, MASS.—The railroad commissioners have authorized the purchase of the Randolph Street Railway by the Braintree Company. For this purpose the latter is authorized to issue \$35,000 additional capital stock to be exchanged for stock of the former.

BOSTON, MASS.—The Boston Elevated Railroad Company has been authorized to issue \$10,000,000 of capital stock. Engineer Kimball estimates the cost of constructing ten miles of road at \$3,000,000. His estimates includes 53 motor cars at \$10,000 each and 144 trailers at \$3,000 each.

MANSFIELD, MASS.—A company has been formed to build ten miles of electric road to Easton. The directors are David E. Harding of Mansfield, Lemuel K. Wilbur of Easton, Douglas A. Brooks of Braintree, Edward D. Hewins of Boston, Josiah F. Gaward of North Easton, Franklin Mead of Norton and George H. Swazey of Malden.

WORCESTER, MASS.—The Worcester & Blackstone Street Railroad Company has been formally organized with the election of M. J. Whittall of Boston, as president; Alfred Thomas, vice-president, and Willard E. Ballou, clerk. The officers will operate the road themselves, the talked of consolidation with the Worcester & Suburban being improbable.

PITTSFIELD, MASS.—The Peck Manufacturing Company has had a survey made for an extension of the Pittsfield Street Railway in Peck's road. R. D. Gillette, of the Peck Company, is himself engaged in the street railway business at Westfield, and is so confident that the extension would prove a paying investment that his company will take enough stock in the railroad to build the new line. Rumor has it that other interests are figuring on building an electric road over some of the most important streets in the city.

## Michigan.

JACKSON, MICH.—An electric railway is projected from Jackson to Howell, via Dansville.

ADRIAN, MICH.—The sale of the Adrian Street Railway has been continued for 60 days, the court not approving the ridiculously low bid of \$3,000 made by H. R. Clark.

SAGINAW, MICH.—The receivers of the Union Street Railway have been authorized to issue \$35,000 of certificates, of which \$4,000 will be expended for necessary repairs.

FLINT, MICH.—Flint capitalists have decided to raise \$50,000 to build 16 miles of electric railway to Long Lake and Fenton. George H. Johnson of New York, promises \$150,000 of eastern capital.

PAW PAW, MICH.—Mr. Patterson of Benton Harbor and Mr. Fifield of Chicago are about to purchase the franchises of the proposed S. H. & E. Electric Railway. Citizens have been asked to subscribe \$10,000 toward building the road.

DETROIT, MICH.—Citizens of Utica are enthusiastically in favor of the proposed electric railway from Detroit to Romeo via Center line, Warren, Utica, Disco and Washington, which is being promoted by Fred Blakeley, of Detroit, on behalf of Pack and Everett.

SAGINAW, MICH.—Receivers Loring and Morley, for the bondholders, have taken possession of the Union Street Railway. After standing still a week the cars have been placed in operation. The settlement has been secured by the bondholders paying the \$17,000 due the city.

SAGINAW, MICH.—On receipt of the supreme court decision sustaining the revocation of the Union Street Railway franchise, the city

ran a 20-ton road roller on the track in front of the car house, thus stopping operation. The council then prepared a new franchise to be sold to the highest bidder, but was enjoined from proceeding by the circuit court on petition of the bondholders.

BENTON HARBOR, MICH.—Judge Coolidge has dissolved the injunction issued upon application of Vice-president Deam against other directors of the Benton Harbor Electric Railroad. The decision declares that the 5,500 shares of stock which were divided among the directors were null and void. The court also ordered Deam to at once open the safe of the company, the combination to which he is alleged to have changed and to deliver over to the company's secretary all the books and papers belonging to the company. There are now but 800 shares of stock out, the original amount issued. The stock book shows that they are held 100 shares each by the following eight persons, H. D. Deam, John L. Deam, A. H. Deam, John S. Moats, John W. Hamilton, Charles G. Davies and H. W. Griswold. It is intimated that some of the stock above mentioned has been sold by the original holders and that the defendants in the case now have a majority of the stock of the company. The court also held the 500 shares alleged to have been issued to H. D. Deam for past services were illegally issued and that they were worthless. Arrangements will be made at once to resume work on the road.

## Minnesota.

MANKATO, MINN.—Hankson Taylor of St. Paul is investigating the possibilities of constructing an electric railway in Mankato. Capitalists of St. Paul are interested.

ST. CLOUD, MINN.—Local bondholders, representing \$16,500 have accepted the terms of the eastern bondholders, who now own all the stock. The line will be improved from one end to the other with a view to placing it on a paying basis. It will be taken out of the receiver's hands as soon as necessary arrangements can be made. The eastern bondholders have settled the claim of Receiver C. S. Benson of the Water, Light & Power Company, for \$4,000 for power, also a claim of \$2,500 for personal injury.

## Mississippi.

JACKSON, MISS.—With regard to the new electric railroad Robert E. McKisson, mayor of Cleveland, O., says: "The city council of Jackson granted a franchise to the Jackson Railroad & Light Company, to construct and operate an electric railway over five miles of streets, and to build and operate an electric light and gas plant. The company is capitalized at \$250,000, and C. W. Howard, a wealthy citizen of Chattanooga, Tenn., is the chief holder. I do not own any of the stock, but am interested as a promoter of the enterprise. I went down there to get the matter through the council, and succeeded admirably. The city of Jackson has a lighting contract which expires in 1899, so that we will not have to hurry in establishing our plant, but the street railway has to be commenced right away. The company may sell its rights to some one else after a while."

## Missouri.

JOPLIN, MO.—The city council is asked to grant an electric railway franchise.

ST. LOUIS, MO.—The sale of the Fourth Street & Arsenal Railroad to Albert Arnstein for \$70,050 will be set aside by Judge Flitcraft.

KANSAS CITY, MO.—The Supreme Court has affirmed the ruling of Judge Slover in annulling the franchise of the East Fifth Street Railway Company. The line has not been operated for three years.

ST. LOUIS, MO.—The St. Louis Railroad Company asks the council for right to extend the Broadway cable road to the south, and for permission to install electricity in place of the rope. The Southern Electric road views this proposition with disfavor, as it would be an invasion of its territory.

KANSAS CITY, MO.—The Kansas City & Leavenworth Traction Company has been incorporated to build a great interurban electric railroad. Capital stock, \$250,000; incorporators, F. D. Hutchings, James F. Getty, C. F. Hutchings and Benjamin Schierle, of Kansas City, and W. F. Street, of New York.

ST. LOUIS, Mo.—Receiver Green, of the Fourth Street & Arsenal Railroad, has been discharged by Judge Flitcraft. The sale of the road has been set aside, and the road placed in the same position it was in before the receivership proceedings were brought, excepting that \$5,000, which was put up by the road's backers, was applied to pay debts.

ST. LOUIS, MO.—The North & South Railway Company has been granted a franchise to build 32 miles of electric road in the heart of the city. Construction must begin within six months and be completed within two years. The incorporators of the company are John H. Blessing, John H. Overall, F. F. Barada, John A. Holmes, T. H. Rockwood and G. Becker.

### Nebraska.

LINCOLN, NEB.—M. L. Scudder of New York, and Judge Belcher of New London, Conn., representing bondholders, are in Lincoln to investigate closely the Lincoln Street Railway, with a view to taking the road out of the hands of Receiver B. D. Slaughter, who has made a good record during his two years of management. When reorganized an extension will probably be built to Havelock.

### Nevada.

RENO, NEV.—W. G. Caffrey and associates contemplate constructing an electric railway to carry ore from Olinghouse canyon to the river. Afterward they may put in a line from the Adelaide copper mines to the concentrator at Golconda.

### New Hampshire.

EXETER, N. H.—The new Exeter Electric Street Railway has been placed in operation. The road is 12 miles long.

### New Jersey.

PLAINFIELD, N. J.—The trolley extension up Watchung Mountain has been abandoned owing to the refusal of two property owners to give their consent.

ENGLEWOOD, N. J.—Mayor Currie has signed the ordinance granting the trolley company right of way on Palisade avenue. The company will now apply for the right to cross the Northern Railroad at grade.

HACKENSACK, N. J.—The Hackensack & Passaic Railroad Company has been organized to build from Passaic to Garfield and Lodi to connect with the Union Traction Company's line in Hackensack. Among those interested are W. P. Standish, of Hackensack; J. H. Hertzberger, of New York, and Mr. Smith, of Jersey City.

### New York.

NEW YORK, N. Y.—Rumor has it that a project is on foot to grid-iron the whole of Westchester county with trolley lines.

ALBANY, N. Y.—The new electric railway connecting the Albany Railway and the Cohoes City Railway has been placed in operation.

NEW YORK, N. Y.—Plans for a 3-story power house on 1st avenue have been filed by the Metropolitan Street Railway Company. It will cost \$350,000.

OLEAN, N. Y.—The state railroad commissioners have approved an increase in the capital stock of the Olean Street Railway from \$16,000 to \$300,000.

ONEONTA, N. Y.—The application of the Oneonta Street Railroad for permission to build a line on Maple street has been granted by the state railroad commission.

NEW YORK, N. Y.—The Metropolitan Street Railway sale of \$2,000,000 5 per cent bonds was enormously oversubscribed, investors having offered to buy \$50,000,000.

LONG ISLAND, CITY, N. Y.—Citizens of Whitestone have united in an effort to secure an extension of the Steinway Electric Railway from College Point to their village.

CORTLAND, N. Y.—The judgment for \$298 in favor of Anna V. Ray having been satisfied, the sheriff has released the coal supply and rolling stock of the Cortland & Homer Traction Company.

ONEONTA, N. Y.—The application of the Oneonta Street Railway Company for permission to change its motive power from horse to electricity has been granted by the state railroad commissioners.

OLEAN, N. Y.—A movement is on foot to extend the Olean, Rock City & Bradford Electric Railroad, now running to Rock City, to Duke Centre from Red Rock, or to traverse the old Kendall and Eldred narrow gage route.

BUFFALO, N. Y.—The counsel and president of the Buffalo & Depew Railroad Company have agreed with the village of Depew to accept some minor changes in the franchise. As soon as all consents are obtained construction will begin.

SYRACUSE, N. Y.—Seventeen acres of land has been purchased by the Syracuse & Suburban Railway, on which it is said water power will be developed. The Syracuse Rapid Transit Company has applied for a franchise for ten miles of track.

SYRACUSE, N. Y.—The ordinance granting a franchise to the Onondaga Lake Railroad Company has been signed by Mayor McGuire. Two per cent of the gross receipts must be paid into the city treasury, and the road must be completed before October 1, 1898.

PATHOGUE, N. Y.—No action has been taken by the Patchogue & Port Jefferson Traction Company on the franchise recently granted by the Patchogue village trustees. Its restrictive conditions militate against its acceptance, but nothing will be done until the return of President Bailey from Europe in September.

OSWEGO, N. Y.—C. Sidney Shepard, Robert Maclay and Max B. Richardson have called on the bondholders of the Oswego Street Railway to deposit their bonds before July 27. If a majority of them do so the road will be taken out of Receiver Tiddman's hands, properly equipped and run on business principles.

BUFFALO, N. Y.—The report that a receiver would be asked for the Tonawanda Street Railroad is denied by Treasurer John A. Read. The Buffalo Traction Company has let the contract for the erection of its car house to Henry Rummell, Jr., & Co. Forty carloads of rails were received July 9 by the Traction Company.

PENN YAN, N. Y.—Prospects are that the Savona Valley & Lake Keuka Electric Railroad route will be modified by making Penn Yan the terminus in place of Keuka, as was first proposed. John Zimmerman of Bradford, and Frank Plaisted, of Wayne, are getting right of way over the abandoned Corning and Sodus bay road from Keuka to Penn Yan. An extension from Savona to Bath is also being considered.

CANANDAIGUA, N. Y.—The Canandaigua Electric Light & Street Railroad Company and the Canandaigua Gas Company have been reorganized by the election of new officers. The electric company elected: president, Thomas H. Feary; secretary and treasurer, H. B. Ferguson; general manager, John H. Finney. Directors, Thomas H. Feary, J. H. Pardee, Mr. Root and J. H. Finney. C. S. Purdy was elected superintendent.

NEWBURGH, N. Y.—A consolidation of the Newburgh Electric Railway, Walden & Orange Lake Railroad and Newburgh and Orange Lake Railroad has been closed by the incorporation of the Newburgh Electric Railway Company, under which name the three lines will be operated. Capital stock, \$150,000; directors, Benjamin Norton, of New York; Silas B. Dutcher, William H. Pouch, Alfred J. Pouch, Frederick H. Pouch, Alden S. Swan, William M. Tobias and S. Stewart Whitehouse, of Brooklyn, and Charles N. Finch, of Summit, N. J.

COXSACKIE, N. Y.—T. E. Smith of New York is the principal stockholder in four electric railway companies which have just been incorporated. Other stockholders are W. G. Raines, W. F. Leland, W. F. Smith, M. E. Ingersoll, P. Anderson, E. Richter and Albert A. Lawson of New York, and George C. Spencer of Chicago. These com-

panies will operate in connection with the Greene County Traction Company. The Cossackie & Greenville Traction Company, with \$150,000 capital stock, will build 12 miles of road to Greenville and Durham. The Oak Hill Traction Company, with \$250,000 capital stock, will build 20 miles of road to Oak Hill, Conesville, Cooksburg, Rensselaerville, East Durham and Cairo. The Windham Traction Company, with \$250,000 capital stock, will build 20 miles of road from Durham to Conesville, Manor Hill, Windham, Ashland, Harrisonville and East Windham. The Middletown & Oak Hill Traction Company, with \$300,000 capital stock, will construct 25 miles of line in Greene, Albany and Schoharie Counties, from Rensselaerville through Broome and Middleburg.

## North Carolina.

WILMINGTON, N. C.—The generator of the Wilmington Street Railway was burned out July 11 by a short circuit in the car house. Traffic was stopped for an hour and a half until the reserve machine could be connected.

## Ohio.

MANSFIELD, O.—The proposed line between Mansfield and Shelby is a steam and not an electric road.

CINCINNATI, O.—The Cincinnati & Miami Valley Traction Company has formally placed in operation its line between Middletown and Dayton.

YOUNGSTOWN, O.—R. G. Sykes confirms the report that the Mahoning Valley Street Railway and the Trumbull Electric Railway would be consolidated.

CLEVELAND, O.—Stockholders of the Cleveland & Lorain Electric Railway Company met August 11 to increase the capital stock from \$50,000 to \$1,000,000.

CANTON, O.—Engineer George P. Williams of Pittsburg has been employed by capitalists of that city to survey the proposed Canton Louisville & Alliance Street Railway.

COLUMBUS, O.—The Columbus & Buckeye Lake Traction Company will not build, the promoters alleging that the sale of their bonds was prevented by the influence of steam railroad rivals.

COLUMBUS, O.—Fenders will be attached to its cars by the Columbus Central Street Railway Company, the court having authorized the sale of \$3,000 of receiver's certificates for this purpose.

CLEVELAND, O.—The temporary injunction restraining the Cleveland Electric Railway Company from crossing the tracks of the Cleveland, Canton & Southern Railroad has been dissolved.

TOLEDO, O.—Rumor has it that the Toledo & Maumee Valley Railroad Company will lease and operate the Toledo, Bowling Green & Fremont Electric Railway, and subsequently extend to Waterville and Woodville.

DEFIANCE, O.—Receiver M. R. Fabin of the Defiance Light & Railway Company has been instructed by the court to operate the cars only at such times as receipts cover expenses. Accordingly operation was discontinued July 9.

DELAWARE, O.—The Delaware Electric Street Railway Company contemplates building an extension about one mile in length and will be in the market for track and line material. Quotations should be addressed to F. P. Welch, manager.

CHILLICOTHE, O. J. P. Myers, president of the Electric Street Railway, Light & Power Company, says that as soon as the council settles the matter of right of way the company will begin to lay ties and put in track for the line to Platt street and thence to Arch street. A number of improvements have been made at the power house.

NAPOLEON, O.—The Napoleon & Terrace Park Railroad Company has been incorporated to build a street railway from the main line of the Detroit & Lima Northern Railroad to Napoleon and Terrace Park. Capital stock, \$10,000; incorporators, E. M. Hiner, A. J. Richter, M. Donnelly, James W. Hanna and L. L. Oring.

COLUMBUS, O.—The county commissioners on July 30 hear the petition of the Buckeye Lake Electric Railway Company for a continuance of its franchise. When the franchise was extended last spring it was promised that construction would be in progress by July 1, but nothing has been done. However, it is said that Hon. Thomas J. Keating, attorney for the company, has recently succeeded in interesting outside capital.

DAYTON, O.—Fremont Hill and L. A. Scoville of Chicago have been over the route of the proposed Dayton & Western Traction line together with J. C. Feight, the promoter. The Dayton & Troy Traction Company is being organized to build from Dayton to Troy by way of Harrisburg, Union, West Miller, Ludlow Falls and Pleasant Hill. Among the incorporators are Galen C. Wise, A. G. Feight, W. H. Tomlinson, M. A. Nippen and F. M. Turner.

ASHLAND, O.—The New London & Loudonville Electric Railroad Company, which proposes to build, held a meeting at Ashland recently and elected H. A. Thomas, H. A. Mykrantz, J. R. Swartz, Ashland; G. F. Shelly, Loudonville; S. J. McCready, New London and Bert Hank and E. J. Best, Cleveland, directors. The following officers were elected: H. A. Thomas, president; H. A. Mykrantz, vice president; F. N. Patterson, secretary, and G. A. Ullman, treasurer.

EAST LIVERPOOL, O.—The East Liverpool, Fredericktown & Lisbon Railroad Company has been incorporated to build an electric line between East Liverpool and Lisbon. Capital stock, \$500,000; incorporators, G. A. Steinbrenner, Jonathan Head, S. H. Talles, F. H. Goff and Daniel Moynahan. The latter is a resident of Niles, O., and last spring sold his electric railway for \$90,000 to the Niles & Mineral Ridge Electric Railway Company. James L. Charters of Lisbon has been getting right of way with good success. At Fredericktown the company has bought an option on a site for a power house.

## Pennsylvania.

MCDONALD, PA.—The Carnegie & Cannonsburg Electric Railway Company is meeting with success in getting right of way.

POTTSTOWN, PA.—Engineers are laying out the extension of the Ringing Rocks Electric Railway to New Hanover, a distance of four miles.

TITUSVILLE, PA.—Construction of the Titusville Electric Street Railway is proceeding under the supervision of W. M. Jeffries of Warren.

PITTSBURG, PA.—Permission to extend its lines along Forbes street from Craig street to Joncaire has been granted the Consolidated Traction Company.

CHAMBERSBURG, PA.—Place, Smith & Miller, of the proposed trolley company, have presented a bond to the borough council to guarantee construction.

EASTON, PA.—Surveyors are staking out the route of the new Easton, Palmer & Bethlehem Electric Street Railway, the right of way having been secured.

CONNELLSVILLE, PA.—The Connellsville, New Haven & Leisening Street Railway Company contemplates important extensions to Vanderbilt and Uniontown.

CARLISLE, PA.—The council has passed an ordinance depriving the electric railway company of its franchise in Carlisle, alleging that the company has failed to fulfill its contract with the town.

WEST CLARION, PA.—James Bailey of Brockwayville is president of the West Clarion Railroad Company, just incorporated to build an electric line from Brockwayville to the West Clarion Mines. Capital stock, \$20,000.

READING, PA.—The Mohusville & Adamstown Passenger Railway Company has voted to change its motive power from steam to electricity. The electric current will be supplied by the Reading & Southwestern Railway Company.

BUTLER, PA.—The Butler Traction Company has been incorporated. Capital stock, \$50,000; incorporators, T. B. Clawson and J. D. Woodard, of Warren; M. W. Buvee and George Priestly, of Goodwill Hill, and Lucien Clawson, of Greensburg.

**MCKEESPORT, PA.**—The Allegheny Valley Electric Railway Company asks right of way through the boroughs of Versailles and Christy Park. Most of the right of way for the 18 miles between West Newton and McKeesport has been obtained.

**PHILADELPHIA, PA.**—The Pembroke Electric Railway Company has been incorporated with \$300,000 capital stock. Edward Thompson, of Philadelphia, is president. Other directors are Nathan Spring, Henry C. Ferry, E. D. Wadsworth, W. W. Webster and Henry C. Terry.

**DOYLESTOWN, PA.**—The project to build a trolley line from Doylestown to Willow Grove is dead. The terms exacted by the turnpike company were too hard, and the backers of the trolley company refused to make a cash deposit of \$2,000 as a guarantee that the line would be built within nine months.

**PITTSBURG, PA.**—McKeesport is proceeding against the Second Avenue Traction Company, to compel the adoption of fenders. A big electric railway scheme, with Greensburg as the center, is proposed by Judge Saddler and others. A line will be run from Greensburg to Latrobe, another to Mt. Pleasant, and one in all probability to Delmont, branching off near Manor, through Claridge and Harrison City to Bouquet.

**UNIONTOWN, PA.**—The Uniontown Street Railway, which was recently sold by the sheriff, has been reorganized as the Uniontown Electric Railway Company, with H. L. Robinson as president and R. F. Hopwood as secretary. An extension to Brownfield, three miles distant, at a cost of \$20,000, will be made very soon, R. F. Hopwood, George A. McCormick, Fred S. Chalfant and M. H. Bowman having been appointed a committee to let contracts.

**ALLEGHENY, PA.**—M. K. McMullin and others of Allegheny have incorporated three electric railway companies. One is the Greentree Electric Railway Company, with \$3,000 capital stock, which will build from the junction of Perrysville avenue and East street in Allegheny to the Ross township line. The second is the Northern Electric Railway Company, with \$24,000 capital stock, which will build four miles of road from a point in Ross township to Perrysville. The third is the Ross Electric Street Railway Company, with \$4,500 capital stock, to construct a line on the Perrysville plank road.

### South Carolina.

**CHARLESTON, S. C.**—An extension to Chicora Park is being constructed by the City Railway Company, which has obtained a lease of a part of that resort.

### Tennessee.

**KNOXVILLE, TENN.**—Fenders will be required on all cars after the passage of the ordinance in the council, which has already had a second reading.

### Texas.

**YOAKUM, TEX.**—A franchise to build an electric street railway has been granted to M. G. Ramsey & Co.

**WACO, TEX.**—Application has been made for a new receiver for the Waco Electric Light & Railway Company, the court of appeals having entered an order which, it is claimed, invalidates orders heretofore made respecting the property.

### Vermont.

**BARRE, VT.**—It is expected that cars will be running September 1 on the new Barre & Montpelier Electric Railway. Work is being pushed by the contractors, Ferguson & Richardson of Boston.

### Virginia.

**MANCHESTER, VA.**—John C. Robertson and associates have received a franchise to build an electric road in Manchester to connect with the lines of the Richmond Railway & Electric Company.

### Washington.

**TACOMA, WASH.**—The Tacoma Railway power house was wrecked July 12 by the bursting of a 40-ton flywheel. The breakage of the connecting rod operating the governor caused the engine to race. Traffic was stopped on all but two lines.

**WATERVILLE, WASH.**—It is said that J. W. Mathews and R. S. Steiner are considering the construction of an electric road costing \$250,000, from Waterville to Wenatchee.

### Wisconsin.

**EAU CLAIRE, WIS.**—Attorney T. F. Frawley has accepted the franchise on behalf of the Chippewa Valley Street Railway Company.

**STEVENS POINT, WIS.**—The Stevens Point Lighting Company has given up the proposition to build a street railway, surrendering the franchise.

**APPLETON, WIS.**—The city council of Appleton has passed the ordinance permitting the Fox River Valley Electric Railway Company to build its road through the city.

**RACINE, WIS.**—Receiver Hiram J. Smith sold the Belle City Street Railway July 19, to Frank H. Miller, representing bondholders, who will reorganize the property with Jackson I. Case as manager.

**RACINE, WIS.**—The Belle City Electric Company has been incorporated to carry out the reorganization of the street railway as outlined in these columns. Capital stock, \$200,000; incorporators, Thomas M. Kearney, E. J. Hueffner, G. N. Fratt, Frank J. Miller and Jackson I. Case.

**CHIPPewa FALLS, WIS.**—A franchise has been granted the Chippewa Valley Street Railway Company to build and operate a street car line in the city. This means the construction of an inter-urban line to Eau Claire. Work must be begun within 90 days and cars must be running within a year.

**MILWAUKEE, WIS.**—The Milwaukee Traction Company has been incorporated to build, maintain and operate street railways in Milwaukee. Capital stock, \$2,500,000; incorporators, John W. Wegner, George W. Wilson and Robert O. Betz. The same parties are interested in the Milwaukee & Waukesha Electric Railway project.

**OSHKOSH, WIS.**—The Citizens Traction Company has accepted its additional franchises. J. K. Tillotson says the Citizens Company will build from Neenah to Oshkosh to connect with the line which Henry C. Payne and others are about to build. For the latter enterprise, H. D. Smith of Appleton, has deposited \$1,500 to guarantee the replacing of pavement.

**MILWAUKEE, WIS.**—Another snag looms up before the Milwaukee & Waukesha Electric Railway promoters, in a suit brought by Stutley I. Henderson, a stockholder, who is friendly to the Milwaukee Electric Railway & Light Company, for the appointment of a receiver to wind up the affairs of the company and to restrain the sale of the franchise to the Milwaukee Traction Company.

**MILWAUKEE, WIS.**—The Milwaukee Electric Railway & Light Company closed a deal July 8 whereby it acquired a site for the proposed addition to its power house. This will supply the power required to operate the new line to Waukesha, the line to Whitefish Bay and perhaps the lines to Wauwatosa and North Greenfield. For its line to North Greenfield the company has acquired the right of way held by S. I. Henderson.

**NEENAH, WIS.**—The Fox River Valley Electric Railway Company has been incorporated to build and maintain a line between Menasha, Neenah, Kaukauna and Appleton. Capital stock, \$200,000, which will be given to the contractors. Among those interested are: Henry C. Payne, president; C. W. Collister of Cleveland vice-president; H. D. Smith of Appleton, treasurer; J. J. Hogan of Cleveland, secretary; Henry C. Payne and Charles Pfister of Milwaukee, H. D. Smith of Appleton, M. J. Dregon and C. W. Collister of Cleveland, William Christy, B. K. Miller, Jr., and Frank G. Bigelow.

### Canada

**WINDSOR, ONT.**—Sandwich has finally granted a franchise to the Windsor, Amherstburg & Lake Erie Electric Railway Company. The city of Windsor will be asked to grant right of way.

**WINDSOR, ONT.**—The Windsor, Amherstburg & Lake Erie Railway has brought action against the Sandwich, Windsor & Amherstburg Electric Railway to prevent the extension of the latter to the town limits.

## NO DAMAGES FOR STREET IMPROVEMENT.

The city of Philadelphia has been successful in the suit brought by Ridge Avenue Passenger Railway Company for \$100,000 damages resulting from interruption of traffic while street improvements were being made. The litigation has been in progress for 22 years and all the original counsel in the case are now dead. For a period of four years the improvements of Ridge avenue were being made and the railway company claimed it had suffered great loss during this time.

The supreme court of Pennsylvania sustains the contentions of the city for the most part. A conclusion is reached that much obstruction of public travel by private vehicles and cars had occurred as the result of the work done under the various contracts. The justice was of the opinion that the evidence failed to show any negligence of the city clearly occasioning damage to the company. It was to be inferred, he stated, that the city deemed a long-continued prosecution of the work by many contracts in succession as less injurious

## STREET RAILWAYS IN SYDNEY, N. S. W.

H. McLachlan, secretary of the Board of Railway Commissioners of New South Wales, advises us concerning the street railways of Sydney and Newcastle as follows:

The street tramways in Sydney and Newcastle are under control of the Railway Commissioners. At the present time three systems of traction are in operation, viz., steam, 54 miles; cable, 5 miles and electric (overhead trolley), 3½ miles.

The lines were first equipped with steam power in 1879, and at that time cable or electric traction was practically unknown. Since then, however, lines have been built to be operated by cable and electricity, and the Commissioners are so satisfied with the merits of the overhead electric wire system that it has been decided to build an important line through the principal streets of the city and to work such line by electricity. It has also been decided that the existing city lines which are worked by steam power are to be altered and made suitable for the overhead-wire electric system. The existing cable lines will be continued.

FIG. 1.

FIG. 2.

FIG. 3.

to the public interests than a performance of the entire work at one time. This would have completely stopped travel for a short while. The opinion of the court decides positively that the railway company had no greater rights against interruption in course of highway improvements than any other person, private or corporate, using the road.

It is clear that the city had authority to grade and improve this street. In doing this it had the right to adopt such a method of allotting and carrying out the work as to it seemed best. For the damage resulting to the public, because of the necessary interruption to travel during the progress of the work under the plans adopted, it is not answerable to one of the public, unless the complainant shows a damage different in kind and peculiar to himself. The damage here shown by plaintiff, though probably different in degree than that sustained by any other persons, was of the same kind as suffered by the general public using the street.

## A THIRD RAIL SYSTEM.

The accompanying illustrations show the essential features of a third and fourth rail system which was invented by Benson Bidwell, of Chicago. In Fig. 1 the conductor is between the rails, supported by Z-shaped iron arms which are bolted to the ties at suitable intervals. The conductor is of channel section laid with the flanges down so that sleet and ice will not reach the contact surface. The trolley is supported by a spiral spring inside the vertical pipe and this gives flexibility vertically. The lower part of the trolley arm is pivoted so as to permit a lateral motion. Fig. 2 shows the conductor outside the track. In Fig. 3 the four rail system is represented, which is the same in design as the other except that it provides for a return circuit independent of the track.

The West Chicago road has armed the crews on its "hold-up" lines.

# THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

The Engineering Magazine, in its August review of the British Press, calls attention to an alleged misuse of the expression "transmission of power." The distinction drawn is that a trolley wire or a steam pipe transmits energy, in the one case electrical energy from the central station to the car and in the other heat energy from the boiler to the engine, while a rope drive, a belt or a shaft transmits power. To reach this conclusion power is said to be "work quantitatively expressed in units performed in a specified time," which is a more complicated statement of the technical definition of power as the rate of doing work. It is said: "A trolley wire conveys energy, not power, from the power house to the motor of an electric car. The energy thus conveyed performs no work, except in overcoming the resistance of the wire, till it reaches the motor, wherein it is converted into power, which is expended in the performance of work." In other words it is converted into the rate of doing work (rate is an abstract thing) which is expended in the performance of work." It is not apparent to us why a belt may properly transmit the "rate of doing work" and a trolley wire be denied the same privilege, as is the contention of the Engineering Magazine. If power is used in its general and non-technical sense it is defined as "capacity for action or performance or for producing an effect" and does not differ from energy, "capacity for performing work," if we admit that work is an "effect." As is well said, if we are to agree in thought we must agree upon the symbols of language used to express thought. This is true but we think that there is little use in objecting to the use of power in its popular and non-technical sense when no confusion can arise therefrom.

\* \* \*

Black smoke is annoying but the loss due to the presence of the carbon which makes it black is very slight; a little carbon will discolor a large volume of gas as a single drop of ink discolors a tumbler of water. When much black smoke is produced it is indicative of a loss; but the loss is due to the escape of unburned invisible gasses, hydrocarbons and carbon monoxide. Conditions favorable to the complete combustion of these gasses are also favorable to the production of but little smoke. The best smoke preventer is a good fireman; a poor one will make smoke under any circumstances.

In discussing smoke nuisance before the Franklin Institute, Jay M. Witham states that in order to get good combustion, and hence not to form smoke, it is important to secure:

A grate with 40 to 70 per cent air openings.

A draft strong enough to produce an active combustion, i. e., not a sluggish fire.

A high furnace temperature.

A roomy furnace, so that the gases may linger and have time for burning before traversing much of the heating surface of the boiler.

To feed the fuel regularly, as with a mechanical stoker, or lightly and at short intervals by hand firing.

To thoroughly understand the fuel to be burned.

As to the cost of preventing smoke, he says: It is not necessary to expend a large sum in installation in order to burn fuel with but trifling smoke formation. In hand-firing ordinary furnaces and ordinary boilers, but little smoke will be formed if the furnace be coaled lightly, through alternate doors. In this way but a part of the fire is covered at one time and the gases and air are heated by the remainder. The fire should not be sliced or broken up until the coking is effected. Openings in the front of the furnace, varying with the rate of combustion from  $\frac{1}{2}$  to 2 sq. in. per sq. ft. of grate surface area, are a decided advantage, while but little gain results by the use of a split bridge.

In horizontal tubular boiler settings no special advantage results from the use of a refractory coking arch over the front of the grate, but its presence is desirable for a volatile coal burned under a water tubular boiler. When such an arch is used, of course the coal should be coked in front and then spread, the fires being from 10 to 14 in. thick in front and from 4 to 8 in. thick behind. With mechanical stokers the period of smoke formation need never be long, if they are properly handled. Such devices are, however, costly in installation and repairs, the first cost being from \$25 to \$40 per sq. ft. of grate and the repairs often amounting to from \$5 to \$10 per sq. ft. per annum.

William M. Barr, in the same discussion, which was with special reference to the prevention of smoke in Philadelphia, thinks the thing most to be feared in that city is that changed conditions may bring about a change in the fuel commonly burned. A large number of the boiler plants, and especially the newer ones, have been installed for the use of anthracite coal and the grates are for the most part not more than 24 in. below the boilers, which distance for that coal yields good results but is too small for bituminous coals. Bituminous coals vary in the amount of smoke produced, and the grates may be placed closer to the boiler with the more smokeless ones; 40 in. is recommended as the minimum and a furnace height of 48 in. has been found to give excellent results with unusually smoky coals.

\* \* \*

The cost of steam power depends upon so many conditions and varies to such an extent with them, that any figures as to the average cost must be misleading unless examined with all the limiting conditions in view, and applied to individual cases by one with considerable experience. The tables of costs of which those of Dr. Emery are perhaps the most widely known, are careful estimates for rather large units operating under a nearly constant load. That is to say we already have data sufficient to tell what it should cost to furnish steam power in a given amount; but in commercial plants the power required must also be esti-

mated and provision made for future needs as the business expands, and the result is that the power is not generated under the conditions assumed when making preliminary estimates.

This subject is discussed by Horatio A. Foster in a paper read before the American Institute of Electrical Engineers and data are given from tests upon 22 steam plants of different capacity and operated under widely varying conditions. The rated capacity of the plants tested varied from 40 h. p. to 2,500 h. p., the number of hours per day from 3 to 24, and the cost of fuel from \$1.45 to \$3.35 per short ton. As might have been expected it was found that the costs, even when reduced to a uniform price for coal, varied so greatly that no comparisons could be made except in the case of large compound condensing engines. The cost, including fixed charges, for the four plants of this type tested by Mr. Foster was from .634 to 1.136 cents per h. p. per hour. For three of them, however, the average is .723 cent, the higher cost in the one case being due to the low ratio of output to capacity.

The costs per h. p. for 3,050-hour power generated by compound condensing engines as determined by Mr. Foster and the estimates by various engineers may be summed up as in the table below. All the figures are for coal at \$3 per short ton and include the fixed charges on the plant.

|                                                     |         |
|-----------------------------------------------------|---------|
| Foster—1,346 h. p.....                              | \$37.17 |
| Foster—three plants—926; 1,272 and 1,011 h. p. Av., | 21.78   |
| Emery—556 h. p.....                                 | 23.82   |
| Emery—250 h. p.....                                 | 26.36   |
| Weber—1,050.....                                    | 19.93   |
| Weber—650 h. p.....                                 | 22.46   |
| Hale.....                                           | 16.96   |
| Main—1,000.....                                     | 19.76   |

The three plants reported by Foster were grouped together and the costs averaged because the ratio of output to rated capacity for these was from 84 to 98 per cent and for the other test quoted only 54 per cent. Even eliminating this test the variation between estimates amounts to nearly 50 per cent.

F. P. Sheldon gives in the Engineering Record the cost of power in several textile mills in New England as much below the lowest of these figures. The engines were compound condensing, using steam at about 125 lbs. pressure, and of from 1,000 to 1,200 h. p. The load was steady 10 hours per day for 307 days per year. The costs are stated to be from the accounts kept by the mill owners and include fixed charges. The highest cost per h. p. per annum (3,070 hours) was \$14.85 in a plant using coal at \$3 per long ton, and the lowest \$11.64 in a plant using coal costing \$1.76.

\* \* \*

The most satisfactory unit for rating the performance of a power plant has been much discussed of late and while not always so stated the question is: Is a commercial or an abstract unit preferable?

For an abstract unit the heat units per horse-power-hour or per kilowatt-hour has been proposed. The heat unit basis is called abstract because the statement of performance is in terms of so much useful work for so much heat expended, and the ratio when reduced to similar units is the efficiency of the plant. This is most admirably suited for measuring engine performance especially in an electrical plant, as it is a very easy matter to run the feed water through a meter, take its temperature and read the steam gages and wattme-

ters and therefrom the heat units per unit of work done. When it is attempted to extend this to the boiler plant the question: How many heat units in a pound of coal? presents itself. A coal calorimeter may be used to determine this but cases are on record where independent determinations on the same coal, both made by competent chemists, have differed as much as 15 per cent. The most common way, at the present time, of stating performance is in pounds of coal per unit of work, which leaves much to be desired.

To us it appears that the best basis is what may be termed a purely commercial one of cost per horse-power-hour or per kilowatt-hour, the cost to include fixed charges on the plant. This for the reason that the evaporation per pound of coal or the water rate of the engine ought to be, and in a well managed plant, is a function of the cost of the boiler or engine. To make comparisons on this basis full data as to costs, prices, load line, output and other conditions are necessary, but until such complete data are given but little benefit can be gained from comparisons. When the costs are itemized the inefficient portions of the plant may be readily detected, and when the engine performance or the boiler performance is compared with that of other plants of the same type it can be determined whether the plant is as economically operated as it should be. The objection to the adoption of this basis is the unwillingness of owners and managers to give out data as to costs, being restrained from so doing by the tendency of others to make comparisons without due regard to the conditions.

\* \* \*

The accompanying illustration is from a photograph of the cooling tables installed at the power house of the Chicago Suburban Railroad at Harlem avenue and 22nd st. The details of the construction were described in the

\* \* \*

COOLING TABLES—SUBURBAN RAILROAD COMPANY, CHICAGO.

REVIEW for April, page 210. The reservoir is 100 x 200 ft. and each of the three leaves of the table is 30 x 184 ft., making the total surface from which evaporation may take place 36,560 sq. ft. The intake for the circulating pump is placed at the bottom of the reservoir and being at the end adjacent to the power house is 200 ft. from the point where the water is finally discharged from the tables. The capacity of the reservoir is 150,000 cu. ft. and the water for condensing is always drawn from the coolest part. The water is discharged on to the tables at about 110° F., while the temperature at the intake is about 80° F. This is the second table to be erected in Chicago, the other one being at the plant of the Calumet.

## Fly-Wheel Accident at Tacoma.

On July 11 the power house of the Tacoma (Wash.) Railway & Motor Company was wrecked by the bursting of a fly-wheel. The loss is estimated at \$20,000 and through the accident the greater part of the road was tied up for several days. A detailed description of the accident was contributed to the Engineering News by A. McL. Hawks from which the following is abstracted.

The primary cause of the disaster, which occurred at 1 p. m., Sunday, while the engine was working under a somewhat heavy load, was the breaking of one of the brass arms attached to the sliding collar on the governor, letting the valve stem drop. The engineer, who was in another part of the room, heard the rod snap and, seeing the engine speeding up, hastened to shut the steam off by means of the hand wheel, which was located in a very bad position, as any one operating it had to stand directly in line with the

FIG. 1.—DAMAGED PORTION OF POWER HOUSE.

fly-wheel and beneath the belt by which this wheel drives the counter shafting.

By the time the engineer had partly cut off the steam, this belt was badly frayed and the cable engine, which was "in clutch" on the axle shaft with this engine was giving way on its bed plate. So, when he had the valve half closed, seeing that the speed of the engine was gaining and being disconcerted by the snapping of the frayed edges of the belt, the engineer sought safety in flight. He had scarcely reached a place of safety when the explosion (which sounded like the bursting of a boiler) occurred. The time interval between the first break and the final one was about three minutes. When the dust had cleared away the scene of the accident was as shown by Fig. 1. The bright spot showing through top opening is a break in the roof made by three large pieces which flew straight up and

FIG. 2.—SKETCH SHOWING PATH OF PIECES.

came down through the same hole, landing within a few feet of their starting point. The pieces flying through the front of the building traveled distances ranging from a few feet to 400 ft. The width of their path was very narrow, nothing striking more than 15 ft. out of line, although some pieces bounded erratically and finally stopped some considerable distance from the line.

The sketch, Fig. 2, gives a better idea of the paths of flight of the pieces than can be obtained in any other way. The wheel seems to have burst into three parts, divided somewhat as follows: One arm and about a quarter of the rim flew up through the roof; two arms and a quarter of the rim flew out through the front of the building; four arms and nearly a half of the rim piled up in the back end of the wheel pit. Besides these major divisions several small pieces of the rim flew through the engine room, knocking down a steam pipe, entirely destroying the 4-ft. pulley on the counter shaft, injuring two dynamos, and about half of one arm remained in place. The other arms are broken off close up to the hub plates.

The rim broke into strips varying from 1 ft. to 8 ft. of the length of the circumference and entirely across the face of the wheel. As these pieces show from 250 to over 300 sq. in. of clean fracture in the two faces, some idea of tremendous stress may be gained. The normal speed of the engine was 62 r. p. m. How far this was exceeded is not known owing to the excited condition of the few who were present through only a part of the racing.

The engine was built by the Frick Engine Company of Waynesboro, Pa., and was rated by the builders at 750 h. p. under 80 lbs. of steam. But it had been run under loads estimated as high as 900 h. p. The fly-wheel was built up of two heavy hub-plates keyed to the shaft. Between these plates and bolted through them were the arms, of cruciform shape, 8 x 16 x 2 in. thick. The rim was 2½ in. thick, 4 ft, 8 in. wide, reinforced by two ribs on the back, 2 in. thick by 6 in. high, and also reinforced by heavy shoulder plates at the points where the arms were bolted to the rim. The diameter of the wheel was 25 ft., and the total weight 40 tons. Of the engine, practically the only parts left in place and in good condition are the steam chest and the bed plate. Even the piston rod is bent almost beyond repair.

\* \* \*

Considerable excitement was caused among the passengers on the motor car of one of the Lake Street elevated trains in Chicago on account of the car being set on fire by a melted wire. An excessive current melted the connectors above the motorman and the hot metal dropped on his head causing a severe burn. The fire department, with the assistance of the passengers, put out the fire in the car.

## FOREIGN FACTS.

The electric railway at Port Elizabeth, South Africa, has been placed in operation.

The Portsmouth town council has decided to acquire the street railway at an estimated cost of £100,000.

The Irish Tourist & Development Syndicate is making progress with its electric railway and lighting scheme at Dundalk.

Particulars of the 50-year electric railway concession at Sofia, Bulgaria, will be supplied on application to D. M. Yablanski, mayor.

Novorossjisk (Russia) municipal authorities will receive proposals until November 13th for the construction and operation of an electric railway.

The Brighton-Rottingdean seashore railway is now in operation, the car which was wrecked by the storm last December having been replaced.

Shareholders of the Bristol Tramways & Carriage Company met to approve the construction of a light electric railway to Hanham from St. George.

Opposition to the Teeside Tramways Bill has been withdrawn. The bill grants power to construct electric railways in Middlesbrough, Stockton-on-Tees and Thornaby.

Jassy, Roumania, will receive bids from September 6th to 18th for the construction, maintenance and operation of an electric railway. Bidders will be required to deposit 50,000 fr. cash. Plans and specifications will be forwarded on application to C. Gall, secretary.

Sunderland Tramways Company offers to sell its lines and rolling stock to the city, and to equip for electricity, provided the council will give a lease of the lines for 21 years. No action has been taken by the city, except to approve the change to electricity.

The House of Commons committee has approved the bill of the Swansea Tramways Company to change the motive power from horses to electricity, and to raise additional capital. The bill is opposed by the municipality, which has desired to acquire and operate the lines.

The Calcutta Tramways Company has not been able to install the electrical equipment as arranged in the contract with Crompton & Company, owing to the refusal of the corporation to grant necessary consent. Since January, negotiations have been continually in progress.

For the proposed electric railway the city of Halifax, England, has purchased 630 tons of steel rails at £6 10s. per ton; 30 tons of fish plates at £8 10s. per ton; a Lancashire boiler at £415; 29 sets of switch points at £19 per set, and 100 poles to carry overhead wires, at £1,090.

Birkenhead has appointed a special committee to report to the council: 1. As to the desirability of reconstructing and extending the system of tramways in the borough, and to submit estimates of the same. 2. As to the best system of mechanical haulage to be adopted in the borough. 3. As

to working the same: (a.) Corporation to lay lines and provide power, lessees to provide plant and work same on lease; (b.) The entire system, lines, power, plant, etc., to be provided and worked by the corporation.

The Gesellschaft für Elektrische Hoch-und-Untergrundbahnen has been formed at Berlin, with 12,500,000 marks capital, to acquire certain concessions from Siemens & Halske for the construction of electric railways in the city and suburbs. The Deutsche Bank, Siemens & Halske and others have subscribed the entire capital stock.

The Compressed Air Traction Company has been incorporated at London to enter into an agreement with the American Air Power Company of New York, to acquire and develop inventions and patents relating to mechanical traction, and the production, distribution and use of compressed air and electricity. The capital stock is £125,000.

The street railways of the island of Java comprise the Nederlandsch-Indische Stoomtram Company of Batavia, Samarang-Joana Stoomtram Company of Samarang, Oost Java Stoomtram Company of Sourabaya, Solosche Tramway Company of Solo, Samarang-Cheriban Stoomtram of Samarang, Serajoedal Stoomtram Company of Serajoedal, and Stoomtramweg Djakjakarta-Brosset of Djakjakarta. The last two are in process of construction; the others, except the first, are extending new lines.

## TURN THE GUNS ON THE ENEMY.

E. D. Dubois, manager of the Muncie lines, has an emphatic and radical solution for the bicycle problem. It is, "the way to beat wheels is to go into the business." He undoubtedly voices the almost universal belief when he states that wheels will continue to increase in numbers rather than grow less. The constantly decreasing price places them each year within reach of a larger number of people, and so it goes. His theory, which is being carried into practice with gratifying results, is to make a place specially attractive to cyclists, and locate that place at a point on your lines a sufficient distance out so that the riders will use the cars one or both ways. This of course includes facilities for transporting wheels on your line, either on the dash, or if in sufficient numbers to some initial point like a park, by providing "wheel cars," as has already been done in several cities. For an interurban road he would locate a park midway, and there provide a fine cinder track, divided into three courses, one outside the other. One for scorchers, another for moderate riders and a third for "lazy" wheels. As an adjunct, make it a record track, if possible, as riders will then be more apt to use the cars to save their energies for the track. Some mechanical or other music of a good order and such other entertainment as practicable should be provided.

At this park he would keep wheels to rent by the hour. It may sound like heresy for a street railway to go to buying wheels, but they rent readily at good prices.

In his judgment, for cities of 25,000 to 100,000, where the desirable streets for wheeling are somewhat limited, and where municipal restrictions against fast riding are enforced, the scheme is particularly good. At any rate, says Mr. Dubois, find some way to induce the riders and their wheels to use your cars. And he is right.

## CHICAGO CITY CUTS WAGES.

For years the Chicago City Railway has paid the highest wages of any street railway in the country. There has been considerable newspaper talk of late about changing the cable system to electricity, although several directors have stated no action has been taken by the board, and in any event, a year would be required to build and install the machinery. The present cable conduit is large enough and would require little alteration. It is highly improbable, however, that the present cable driving machinery will be abandoned before it is worn out, as it is useless for any other purpose.

On August 10th, General Manager Bowen sent out the following to all cable car crews:

It is contemplated that all cable lines be electrically equipped. As an expression of preference you will state on this card whether you would prefer to operate an electric car at 21 cents per hour or a cable train at approximately 23 cents per hour for trains.

I prefer to operate.....car.  
Signature.....  
Position.....  
Depot.....

NOTE.—Depot masters will explain any details as to filling out card, etc. Employees, after filling out card, stating preference, name, position, etc., will enclose same in envelope furnished with card, and after sealing hand to clerk of Depot. All cards must be returned before August 14, 1897.

## CHICAGO CITY RAILWAY COMPANY.

If the men reply they would rather take an electric car, at 21 cents, than a cable at 23 cents, it will be an easy matter to shift the present electric men to cable at the price now paid them (21 cents) and put the cable men on electric cars at 21 cents, in accordance with their own written request. Rather than be transferred several miles away to another depot, necessitating moving their families, etc., they would probably accept the cut and remain on cable lines where they now are.

Good cable runs pay as high as \$20 per week and the new rate will reduce this to about \$16.

## TROLLEY PATENT DECISION.

The Circuit Court of Appeals for the Second Circuit of New York on July 21 rendered a decision in the case of the Thomson-Houston Electric Company against the Hoosick Railway Company, which involved the validity of the Van Depoele trolley patent. The opinion was written by Judge Wallace, all the judges concurring, and holds that the five claims under which the Thomson-Houston Company has successfully prosecuted a large number of suits for infringement are invalid, as being anticipated by an earlier patent. The later patent, known as the "broad under-running trolley patent," has always heretofore been held to be the generic patent and the earlier one a special patent covering only the apparatus there illustrated and described.

The court says in part:

This is an appeal from an order granting a preliminary injunction restraining the defendant from making, using or vending the apparatus specified in claims 6, 7, 8, 12 and 16 of Letters Patent No. 495,443, granted April 11, 1893, to the administrators of Charles J. Van Depoele, assignors to the complainant, for "traveling contact for electric railways." The application for the injunction was resisted upon the ground that the patent as to these claims was void because the inventions covered thereby had been previously patented to the same inventor by Letters Patent No. 424,605, granted April 1, 1890, for "suspended switch and traveling contact for electric railways." The validity of the claims, notwithstanding a similar defense, had

been adjudicated at final hearing in the case of this complainant, against the Winchester Avenue Railway Company by the Circuit Court for the District of Connecticut (71 Fed. Rep. 192). In granting the present injunction the court below followed that adjudication without attempting an independent consideration of the validity of the defense.

Both patents originated in the application of Van Depoele, filed in the Patent Office March 12, 1887, and relate to the apparatus of that class of electric railways in which a suspended conductor conveys the working current, and a contact device carried by the car is employed for taking off the current, and more particularly to an improved traveling contact, and an improved arrangement and construction of the switches by which the traveling contact is directed to the proper conductor, and to various details of construction and arrangement of the traveling contact and switches. The application was divided, and while one of the divisional applications was involved in an interference proceeding which delayed the issuance of a patent, the other divisional application culminated in the patent granted April 1, 1890.

The operative parts of the contact device are described in identical language in each patent; and the language of the claims apply describes these parts. While the function of the tension device is stated with more particularity in the earlier patent, the description does not contain a word or hint by which its characteristics can be differentiated from those of the tension device of the later patent. The additional matter is in effect a fuller statement of the advantages of the device.

It is manifest that both patents are intended to and do secure to the patentee the same general inventions as are comprised in the combination of suspended conductor and contact devices, and the combination of suspended conductor, contact device and switching devices, although the earlier patent also covers improvements in the switches, and subordinate combinations between these devices and the elements of the principal combination.

The order granting the preliminary injunction is reversed with costs.

While this decision no doubt disposes of the five claims in controversy, another suit against the same parties is now pending, in which other claims of the patents are involved and the matter if far from being finally settled.

## EXTENSION TO THE YERKES LINES.

Nearly 30 miles of double track will soon be added to the North and West Chicago Street Railroad systems as feeder and connecting lines. The work will be pushed forward with vigor, and already some of the contracts have been let. Superintendent John M. Roach has placed an order with the Johnson Company for 8,000 tons of 85-lb. rails. From 75 to 100 additional cars are required, but bids will not be asked for these until the winter or spring. These lines will be operated from the California avenue, the Cicero & Proviso and the Western avenue power stations. It is likely that one large engine and dynamo will be added to the California avenue station, otherwise the power equipment is ample. To the north side system will be an additional 5 miles on Montrose boulevard from Milwaukee avenue to Evanston avenue; on Robey street  $2\frac{1}{2}$  miles from Lincoln avenue to Rose Hill cemetery; 2 miles on Crawford avenue from Peterson to Elston; 5 miles on Lawrence avenue from Milwaukee to Evanston avenue; the Chicago avenue roadbed will be relaid for  $\frac{3}{4}$  mile from the river to Milwaukee avenue, and the Dearborn street line will be relaid from Monroe for  $\frac{1}{2}$  mile to Polk street. The following lines will be extensions to the west side system: on Robinson avenue from 25th to 35th street, 1 mile; on West 26th street from 40th to Ogden and 48th avenues, 1 mile; on West 12th street from 40th avenue 4 miles to Harlem avenue; on Robey street 1 mile from Milwaukee avenue to Elston; on

California avenue, from Elston  $2\frac{1}{2}$  miles to Division street; and Kedsie avenue 1 mile from Chicago avenue to Madison street. Block pavement, 16 ft. wide, will be constructed along the streets not already paved in that manner. The estimated expenditure will be \$1,500,000.

**THE NEW YORK ASSOCIATION.**

J. P. E. Clark, of the Binghamton Railroad Company, advises the REVIEW that President Rogers of the New York State Street Railway Association is in communication with the local committee at Niagara Falls in regard to the program and entertainment for the convention of September 14 and 15. It promises to be the most interesting and largely attended meeting in the history of the association. From 15 to 20 short, concise papers will be given on practical subjects by some of the leading street railway men in the state. There will also be a large line of exhibits. After the program there will be a general line of entertainment, trolley rides on the lines about Niagara Falls, tours of inspection of power stations and manufacturing plants, etc.

**TRAMWAYS INSTITUTE OF GREAT BRITAIN.**

The annual meeting of the Institute was held on July 22, in London. President John Fell, in his address, reviewed the progress of the year as satisfactory. The official organ of the association had been mailed to all municipal officers in cities having tramways. Officers of tramways owned by municipalities had been made eligible to membership. Officers were elected as follows:

- President—Mr. John Fell, J. P.
- Vice-Presidents—Messrs. J. Carruthers Wain, W. Turton, R. Whittaker (Mayor of Oldham), and W. Mason.
- Council—Messrs. J. Waugh, J. Coomer, W. Stansfield, Graham Harris, J. H. W. Rosenthal, J. E. Waller, E. Pritchard, T. Parker, S. Sellon and E. Garcke.

**NEW PUBLICATIONS.**

The report of the proceedings of the 30th annual convention of the American Railway Master Mechanics' Association, held June 15, 16 and 17 has been issued. Reports from nine committees, which have had technical subjects under consideration, were received at this convention; the most elaborate were those dealing with "Locomotive Grates" and "Ratios of Grate, Heating Surface and Cylinder Volume," the most complete data obtainable being here collected and made available for convenient reference. Copies of the proceedings may be obtained of the secretary, John W. Cloud, 674 Rookery Building, Chicago. Cloth, \$1.50; postage, 15 cents additional.

The Entropy-Temperature Analysis of Steam Engine Efficiencies, with a Blank Diagram arranged for easy application in any concrete case. Prepared by Sidney A. Reeve, M. E. The Progressive Age Publishing Company, 280 Broadway, New York. The discussion of the subject by the author is brief and to the point and the method of defining and illustrating the meaning of the term entropy is a particularly happy one. In order to determine such questions as the commercial economy of re-heaters, jackets, super-heaters, etc., where the gain in efficiency must be balanced against increased cost of construction no method of analyzing steam engine efficiencies is superior to this one, and the principal reason that it has not heretofore been more widely applied is the great labor of preparing the necessary curves; this the author has obviated by doing the work once for all and preparing the blank form which accompanies the book. Price, 75 cents.

**HARAN STREET CAR FENDER.**

The cut of this fender shows a side view of its attachments and a part of the car truck and body. The frame of the fender is made of 1-in. pipe, with a hinge in the angle between the upper and lower parts, so that it can be folded when not in use, or to change from one end to the other of the car. The fender is held about 4 in. from the ground by two chains while a third one is attached to the lever T by which the motorman can raise the fender to clear any obstruction. The fender is hung from one end of lever D

and at the other end is a spring which gives flexibility and saves the lever from being broken should the car tip forward enough to strike the outer end of the lever. Wire netting is used as a covering to the fender. In front are two hollow steel rollers, 3 in. in diameter, which keep the fender from plowing into the roadbed. The merits claimed for this fender are that it can be kept within any desired height above the rail and that it is so constructed that the springs mitigate the force of the blow to persons who may come in contact with it.

**CHANGE IN TRANSFER SYSTEM IN SCRANTON.**

There have been changes in the transfer system of the Scranton Railway Company to prevent abuses of that privilege. It has been the custom of certain clerks living on the opposite sides of the city to exchange transfer tickets, and to break this up two young lady clerks were arrested as a warning to others who had made a practice of getting free rides. The new series of transfers has places for punch marks indicating the line giving and receiving the ticket. These are given only at certain points on the lines and have a time limit of one-half hour. It is imperative that the passenger leave the cars at designated points and board the other car at the same place.

**WOODMAN TICKET PUNCH.**

The No. 2 ticket punch made by the R. Woodman Manufacturing & Supply Company, 63 Oliver street, Boston, was designed for use on transfer tickets on electric and horse railways and is made with an extra long reach, suitable for transfer, commutation and duplex tickets. These punches are sold at low rates but excellence of material and workmanship have not been sacrificed. The company refers to the many roads using this style of punch, among them the West End of Boston, which has 3,500 in use. The Woodman Company is the pioneer in this line of business, having commenced in 1872.

## PERSONAL.

Senator Wellington, of Maryland, has been elected president of the Cumberland Electric Railway Company.

Jos. J. Sullivan has been appointed manager of the Bennington (Vt.) & Woodford Electric Railway Company.

C. A. Murray resigned the management of the Bluff City Street Railway, Waukegan, Ill., and Superintendent Todd now has control.

George B. Morley and Homer Loving on July 24, qualified as receivers for the Union Street Railway Company of Saginaw, Mich.

L. N. Wheelock, superintendent of the Shelburne Falls & Cosrain Electric Railway has resigned to accept a similar position with the Amherst & Sunderland.

E. D. Dubois, superintendent of the Citizens, Muncie, Ind., pleased his REVIEW and other Chicago friends by a call last week. He reports a good and increasing business on his road.

G. J. Smith, master mechanic of the South Covington & Cincinnati Street Railroad, spent a week in Chicago visiting the local plants and calling upon friends, which included the REVIEW office.

I. B. White has resigned his position as superintendent of the Haverhill (Mass.), Georgetown & Danvers Street Railway Company to go to Bradford, Pa. Benj. Bartlett succeeds Mr. White.

Frederick Scullen, son of John Scullen, president of the Union Depot Railway Company, St. Louis, while sojourning in Chicago was overcome by the heat inducing an attack of temporary insanity.

John T. Gordon, who built the first street railway between Oakland and Allegheny City, died at his fruit ranch in El Canjo, Cal. He went from Pittsburg to California ten years ago to become a fruit grower.

C. E. Flynn, general manager of the Carbondale Traction Company recently made a flying trip to Chicago and to Peoria, where it will be remembered he was electrical engineer of the road for several years.

Henry Hubbard resigned his position as general manager of the Pittsburg, Allegheny & Manchester Traction Company and in recognition of his faithful service and popularity the employes presented him with a gold Masonic emblem.

James Rawle, secretary and treasurer of the J. G. Brill Company and vice-president of the Fairmount Park Transportation Company, has been elected to the presidency of the street railway company in place of George S. Grandy, resigned.

At the last meeting of the board of directors of the Wilmington (Del.) City Railway Company the duties of general manager were conferred upon President Lea, and he appointed H. B. Vandergrift to be his assistant. C. F. Hutchings, who has been superintendent, resigned.

C. S. Van Wagoner, president of the Van Wagoner & Williams Hardware Co., of Cleveland, accompanied by Frank X. Cicott were REVIEW callers a few days since. Mr. Cicott sails for Europe on the 20th, where he will represent a number of American street railway supply houses.

James F. Heyward, who has been general manager of the City & Suburban Railway Company of Baltimore, has accepted a position with the United Traction Company of Pittsburg. Before leaving Baltimore the employes under Mr. Heyward presented him with a handsome punch bowl as a token of their good will.

Willis F. Kelly, general manager of the Columbus (O.) Street Railway, called on the REVIEW during a three days' visit to Chicago last week. He predicts a large attendance from Ohio to the Niagara Falls convention in October. He was accompanied by E. N. Stewart, 1st vice-president, and R. E. Sheldon, 2nd vice-president of his road.

Carl K. Mac Fadden, well-known as a writer and expert street railway electrician, spent several days in Chicago. He has literally struck oil in his Indiana wells, and his numerous friends will learn with pleasure of his fine property. While his daily product does not yet rival that of the Standard Oil Company, he says his wells give just as many gallons to the barrel.

Alonzo G. Collins, consulting engineer, who has opened an office at Room 710 Pabst building, Milwaukee, has had an extensive experience in his line of business. For some years he was with the E. P. Allis Company; in 1890 he built the Jones Street station for the new Omaha Thomson-Houston Electric Light Company, and for the last year was chief draughtsman for the Filer-Stowell Company of Milwaukee. At present Mr. Collins is engaged in developing an apparatus for automatically proportioning the materials for making concrete.

W. W. Wheatly has been appointed assistant general superintendent of the Brooklyn Heights Railroad and C. E. Harris has been transferred to the southern division to take Mr. Wheatly's place. R. K. Haldame was placed in charge of the Broadway, Jamaica, Cypress Hills, Reid, Ralph and Sumner avenue lines of the Brooklyn, Queens County and Suburban Railroad.

John S. Bradley, president of the New Haven Register Company has returned from an extended trip to the Pacific coast, during which he traveled nearly 10,000 miles and visited all the railroads west of the mountains. He reports the outlook for business of all kinds as improving as a result of big crops everywhere and better prices. As a side pleasure trip he spent a week in the Yellowstone Park, which is unusually attractive this year owing to the great activity of the geysers.

Jilson J. Coleman, on July 1, became the eastern sales agent for the St. Louis Car Company, and will make his headquarters at Allentown, Pa. Mr. Coleman has had an extended and valuable experience, having been associated with A. L. Johnson, at Cleveland, ten years. He then went with the Steel Motor Company, and built and managed the Allentown road for the Johnsons. When the Johnsons began operations in Brooklyn he was called to the Nassau road, from which he resigned a year ago on account of poor health.

H. F. MacGregor, of Houston, Texas, long and favorably known in street railway circles, on account of his connection with the Houston City Street Railway Company, both while it was operated as a mule line and later by electricity, has purchased a large block of the stock of the reorganized company, and on July 16th assumed the management of the property, succeeding A. H. Hayward, who has managed the road since December, 1895. Mr. Hayward, during his stay in Houston, has carried out many substantial improvements and has made a great many friends, both in a business and social way, and many were the expressions of regret that he is to leave Houston permanently.

F. C. Randall, who for the past three years has had charge of the Chicago office of the J. G. Brill Company, severed his connection with that firm on August 1 to become the eastern representative of the Christian Engineering Works of Milwaukee. His office will be in New York City. Mr. Randall was early engaged in the railroad business in New England and was in the service of the New York & New England, the Boston & Lowell and the Boston & Maine railroads. His experience with street railway apparatus began with the Tripp Manufacturing Company, where he was first foreman and later superintendent. He left this company to take charge of the eastern agency for the J. G. Brill Company. Mr. Randall's long and varied experience in street railway affairs ensures success in his new field.

## SAFETY DEVICES IN MICHIGAN.

The street railway lines of Michigan are being inspected by order of Railroad Commissioner Wesselius and all dangerous crossings at steam roads and drawbridges will be reported, with a view to ordering the construction of derauling and interlocking devices at such points. Undoubtedly the commissioner has authority to require railroad crossings to be properly protected but it is questionable whether his authority extends to bridge crossings.

### THE DULUTH-SUPERIOR BRIDGE.

The great steel drawbridge which joins the twin cities, Duluth, Minn., and Superior, Wis., has been completed and its opening was celebrated in a fitting manner. As may be noted from the illustration the bridge is of noble proportions and it is said to be the third largest drawbridge. Between the piers on the dock lines of Duluth and Superior the bridge is 1,094 ft. and rests on five piers; the draw-span is 491 ft. in length and weighs 1,800 tons. The draw-span rests upon 60 rollers which are arranged in a circle 40 ft. in diameter; it is actuated by electricity. The rollers are of cast steel and weigh 2,000 lbs. each. The motors are connected to the power station by means of submarine cables and also to a set of storage batteries on the pier which can be used in the event of an accident to the cables. The electrical equipment is the most powerful ever placed on a drawbridge as it is designed to turn the bridge inside of two minutes even in the highest wind. Automatic electric brakes and indi-

that "the charges for passage on said road shall not exceed 20 cents for any through line and 10 cents for half lines or short distances." In 1890-1 the Consolidated secured from the legislature a validating act to remove alleged flaws in the charters of the absorbed companies, and as this act contained the clause "be liable for street paving and to other regulations of municipal companies incorporated by separate acts by the law of this state," it was construed that the Consolidated was brought under all regulations passed by legislature in the case of all other street railways in the state. One of these legislature bills allowed the city of Augusta "to regulate fares," and on the strength of this the Atlanta council passed an ordinance to take effect May 1, 1897, by which a passenger was to ride from any point on the company's line to any other point for one 5-cent fare. The effect of this ordinance caused a slump in the company's securities, and bondholders residing in another state took the case into the United States court in New Orleans, where a restraining order was issued May 27.

STEEL DRAWBRIDGE CONNECTING DULUTH, MINN., AND SUPERIOR, WIS.

cators enable the man in the operating cab to tell the exact position of the bridge and manipulate the end locking apparatus with certainty.

The bridge was designed to carry four tons per lineal foot, which together with the weight of the structure makes a load of 10,000 tons. The material is mild open hearth steel furnished by the Pennsylvania Steel Company. Work began in July, 1896, and ended July 3, 1897; the cost exceeded \$1,000,000. It is considered a triumph of engineering skill as it meets the requirements of all kinds of traffic between the cities and does not interfere with the great volume of commerce on the bay. There are two steam railroad tracks, two trolley tracks, two roadways and two side walks.

### ATLANTA CONSOLIDATED WINS THE TRANSFER CASE.

In the United States circuit court sitting in Asheville, N. C., on July 23, a decision was rendered denying the right of the city of Atlanta to pass an ordinance reducing the rate of fare. The Atlanta Street Railway, of which the present Consolidated is the successor, constructed its lines under a city ordinance passed in 1868, which allows

The case came to trial in the circuit court of the United States of the Northern District of Georgia, under the title "The Old Colony Trust Co., trustee, et al., vs. The City of Atlanta and the Atlanta Consolidated Street Railway Co., bill in equity." The case was heard at Asheville, and a decision rendered on July 23. The legislative right of the city to change the existing rate of fare or demand transfers is expressly denied, and the opinion of the court is also that there is grave doubt as to the right to approve rates conferring a right to fix rates.

The court also declares: "One continuous ride is one thing and two or more rides with the necessary stoppage and letting passengers off and taking them on, is another and entirely different thing."

It is a splendid victory for President Joel Hurt; and although the mayor had threatened to appeal in case the city lost, the case may be considered settled.

The Syracuse Rapid Transit Company has elected officers as follows: William M. Brown, New Castle, Pa., president; Willard R. Kimball, vice-president; William P. Gannon, secretary; Austin C. Chase, treasurer. The three latter are all of Syracuse. The executive committee consists of Messrs. Brown, Kimball and Gannon.

## ARION MEETS HIS DEATH.

One of the best known and daring performers at street railway pleasure resorts during the past three years was D. H. McDonnell, or as he was better known, Professor Arion. While he performed a large number of feats in mid air, his principal one was riding a bicycle at night on a live trolley wire suspended 75 to 100 feet from the ground. The wheel and his body were covered with 32-c. p. incandescents taking current through the wheel from the wire on which he rode. A smaller wire overhead completed the circuit. Arion filled a long engagement last summer for the Calumet Electric Railway, of this city, performing several times each day and night at a height of 90 feet and drawing thousands. During this time he was a frequent visitor to the REVIEW office, and by his gentlemanly bearing and

RIDING A LIVE WIRE.

natural modesty made friends of all who knew him. To the writer he said he would never fall unless it was from shock which rendered him insensible. Once during his Chicago engagement he was short circuited and badly burned but succeeded in completing the trip safely. The same accident occurred on the first of this month, at Brooklyn, where he was killed by a fall of 75 feet. The autopsy showed that he evidently had been shocked into insensibility through leakage of the rubber insulating suit he always wore.

He was a man of most exemplary habits, an electrician of no mean ability, and had crossed Niagara 11 times. He formerly lived in Chicago, and his income amounted to \$1,000 per week.

## METROPOLITAN ELECTRIC COMPANY FAILS.

The Metropolitan Electric Co., 188 Fifth avenue, Chicago, dealing in street railway supplies, was closed by the sheriff at noon, July 27, on confessed judgments amounting to about \$35,000, of which \$27,000 is in favor of its president, Wm. H. McKinlock. Capital stock is \$300,000, and assets claimed at \$100,000. Poor business and slow collections are given as the cause.

## CITY LINE LEASED BY THE CHICAGO GENERAL.

E. M. Phelps and F. R. Green, representing the Chicago City Railway Company, and J. T. Witbeck and L. C. Bonney, of the Chicago General Railway Company, have signed a contract for a lease of the 22nd street line of the Chicago City Railway. The stockholders of the Chicago General received the following notice:

"A lease has been executed under which this company secures the right to operate over the East 22nd street tracks of the Chicago City Company from the Chicago river to Lake Michigan.

"This lease is dated July 5, 1897, and runs for a term of 45 years. This company pays to the Chicago City Company 6 per cent per annum on the cost of the physical construction; also the entire expense of maintaining the portions of the street between the river and Wentworth avenue and between Clark street and Wabash avenue and between Indiana avenue and South Park avenue, also one-half of the expense of maintaining the crossings used jointly by the two companies. The expense of maintaining the street from Wentworth avenue to Clark street and from Wabash avenue to Indiana avenue will be paid by the Chicago City Company.

"All litigation between the two companies has been settled and will be dismissed. The settlement is considered extremely advantageous to both companies."

The estimated cost of the leased line is \$45,000. An extension will be made to South Park avenue some time this fall and this will enable the Chicago General to run to the lake. This same company is also negotiating with the West Chicago Street Railroad Company for a line on Throop or Morgan street. A long and bitter fight is thus settled. When, on April 4, 1895, the Chicago General attempted to run a horse car over City Railway tracks, the latter company met it with four wrecking wagons and 200 shop men and reduced the car to kindling wood.

## TAXING FRANCHISES IN DULUTH.

The franchises of the quasi public corporations in Duluth, Minn., were last year assessed for taxation as personal property, and a decision has just been had on the appeal taken by the companies. The judge did not pass on the right to levy the tax but decided that it had not been levied in the proper manner. The case will be carried to the supreme court. The total tax assessed against the different companies was \$9,000. The franchise of the Duluth Street Railway Company was valued at \$75,000.

## STREET RAILWAY TROUBLE AT TAMPA.

There has been a sharp conflict in the management of the Consumers' Electric Light & Street Railway Company of Tampa, Fla. At a recent meeting of the board of directors the Consumers' Company was leased for a term of ninety-nine years to the Tampa Suburban Railroad Company. E. S. Douglas, general manager of the Suburban Company, took charge of the operation of the Consumers' Company. Superintendent Munsing and other of the directors objected to the radical and unexpected changes. Each faction gave orders to the employes which caused great confusion for a time. Mr. Douglas' authority was recognized and a policeman was placed on each car to prevent any interference in the operation of the lines. It was expected that President Chapin, on his arrival from New York, will straighten out this muddle.

**Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.**

The Lake Street "L" of Chicago is endeavoring to get the consent of the holders of its debentures to redeem them at 78 cash.

Tenders for a \$4,000,000 issue of 5 per cent bonds of the United Traction Company of Pittsburg greatly exceeded that amount.

W. H. Patton is trying his new motor on the lines of the Stillwater, Minn., road. It is a combination of gas engine and storage battery.

The Camden (N. J.) & Suburban Railway Company lately distributed \$500 among its employes as rewards of merit, more than 100 motormen and conductors profiting by it.

J. K. Tillotson, who is interested in the street railways of Oskosh, Wis., produced two comedy dramas, Queena and Lindwood, of which he is the author, at the company's pleasure resort.

The fare box system has been adopted on the Northeast line of the Brooklyn Avenue Railway Company, Kansas City, and the directors look with favor upon its installation on the 10th street line.

There seems to be little or no progress in the contemplated change in the motive power of the Manhattan Elevated although it is reported that the third rail system is looked upon with favor.

For the third time the Bridgeton (N. J.) & Millville Traction Company has suffered the loss of a portion of its copper return circuit. Thieves chopped up about 1,900 ft. of wire with axes and carted it away.

It is stated that George S. Grandy has retired from the presidency of the Fairmount Park Transportation Company, and after a period of rest and recreation will devote his attention to some of his other large interests.

An Italian rag peddler stole 900 ft. of live trolley wire from an unused line of the Buffalo, Kenmore & Tonawanda Electric Railroad Company and carted it to Buffalo. He was arrested and turned over to the Tonawanda officials.

The experienced conductors and motormen of the Galesburg (Ill.) Electric Motor & Power Company have had their wages increased to \$11 per week, while those who have been with the company less than a year receive \$10 a week.

The total aggregate of the subscriptions for the \$2,000,000 of 5 per cent gold bonds offered by the Metropolitan of New York amounted to above \$50,000,000. They were sold on the street at 110½. Other securities of the system have advanced sharply.

The vitascope exhibition at Budd Park, Kansas City, has proven a great attraction; every evening 1,500 or more people go out in the trolley cars to watch the moving pictures and listen to the music reproduced by the large phonograph in the park. The exhibition is free.

A verdict of \$16,500 was given to Thomas Leach against the Chicago City Railroad for injuries received in 1893. Leach was then a conductor, and while beneath the car fixing a brake chain another train ran into the rear of the car he was repairing and very seriously injured him.

Frank E. Scovill, superintendent of the Austin (Texas) Rapid Transit Company, informs us that there have been many improvements to the system during the spring and summer. Among other things 8,000 new ties of mountain cedar have been put in place. Traffic has been quite good considering all conditions.

The Lafayette Street Railway Company has extended a line to the Indiana State Soldiers' Home and to Tecumseh's Trail. It passes through some picturesque country and makes a delightful outing for the citizens of Lafayette. The street railway company recently carried in one day 17,000 passengers with an equipment of 19 cars.

Tom L. Johnson, H. A. Everett, Albert Pack, J. C. Hutchins, W. L. Johnson, A. B. Dupont, and A. E. Peters were chosen directors of the Detroit Electric Railway Company. Subsequently the board elected Albert Pack, president; J. C. Hutchins, vice-president and treasurer; A. E. Peters, secretary, and A. B. Dupont, general manager.

The transfer privilege on the lines of the Detroit Electric Railway have been curtailed. Heretofore a passenger could ride on a continuous trip of 28 miles or even all day long by judiciously using the transfers. The recent regulation is to the effect that passengers must ask for transfers when tendering their fares and but one transfer will be issued on one fare.

Wheeler & Boody, contractors for the East Penn Traction Company have commenced suit against the Pennsylvania Railroad Company for \$2,000. The plaintiffs state that their employes were driven from their work by railroad men and some of their tools destroyed. To protect the workmen it was necessary to employ 100 extra men and the damages are designed to cover the wages of these men and the loss of time and tools.

A daughter of one of the directors of the Staten Island Midland Railroad, is spending the summer at one of the hotels on Staten Island and has become quite an expert "motorman" under the tutorship of General Manager Rockwell. The young lady enjoys manipulating the controller handle and has officiated at that post during several trips taken by officials and friends in the directors' car over the lines of the Midland railway.

July 12th was the 38th anniversary of the introduction of street cars in the city of Baltimore. E. H. Hartzell, who still resides in Baltimore, was the driver of one of the two cars first brought to the city. The cars were box-shaped affairs and built to accommodate 12 passengers. When the line was formally opened each car was gayly decorated and

drawn by six horses. The guests, after enjoying the luxury of a street car ride, ended the festivities with a champagne supper.

A syndicate for operating street railways has been formed by C. H. Davis, an electrical engineer of New York City, and B. W. Porter of Derby, Conn., is to be general manager. The ownership and financial interests of the railways are not to be disturbed but the syndicate proposes by buying in large quantities and by scientific management of the roads to lower operating expenses and increase receipts.

The Trenton Passenger Railroad Company brought suit against the Guarantor's Liability Indemnity Company, of Philadelphia, for claims which were presented and payment refused. The lower court decided in favor of the railway company, with the proviso that it should later be established that such insurance is legal. The Supreme Court decided that the contract is valid and deferred action on the amount of damages.

A charter has been granted to the Montreal & Southern Counties Railway by the Senate at Ottawa in spite of strong but unreasonable opposition. This is one of the largest of the proposed railways in Canada, as the lines are expected to serve a territory of 150 sq. mi. connecting with the Montreal Street Railway and passing through the towns of Chambly, St. Johns, Iberville, Bedford, Waterloo, Sherbrooke and intervening places.

The Schuylkill Valley Traction Company has secured a lease on Oak View Park, near Norristown, Pa. Many improvements and attractions will be added to the park. An orchestra has been secured; arrangements are to be made for operatic and dramatic performances, balloon ascensions and other things which will make the park a pleasant resort. The town council gave permission for the company to build a branch line to the park.

The hot weather of July 4th and 5th caused the people of Brooklyn and vicinity to seek the ocean breezes, and the street railways were taxed to the utmost to accommodate the traffic, over 700,000 passengers being carried by the surface roads in one day. The record of the Nassau lines was broken, 275,000 fares being collected on the 5th and 250,000 on the 4th. The Brooklyn Heights Railroad reported 328,999 and 325,000 passengers for the two days.

An ordinance was passed by the council of Pittston, Pa., taxing all street cars entering the city \$10 a piece, but the Scranton & Pittston Traction Company refused to pay this. The city authorities decided to enforce the law and the means employed was to arrest every motorman and conductor in charge of a car coming into the town. This did not last long for the cars discharged the passengers at the city limits and started back over the same route.

The Columbus Street Railway Company has been giving kinoscope entertainments at Olentangy park. The company secured views of Governor Bushnell and staff in the Grant memorial parade and extended an invitation to the governor to be present at the initial presentation. This invitation was accepted and the governor with his staff and their lady friends were taken to the park on the beautiful excursion car, Electra, and enjoyed the entertainment.

On the lines leading to the ocean resorts the Nassau Electric Railroad Company of Brooklyn has had some trouble with disorderly passengers and an example was recently made of such a one. A tailor, named O'Brien, had some words with a conductor and struck him in the face. The police refused to arrest the man and President Johnson was notified. He, with the company's attorney, John M. Ward, of base ball fame, dragged O'Brien from the car and took him to the police station. The obstreperous passenger was fined \$20 for disorderly conduct.

After a decision had been rendered against the Cincinnati Incline Railway by the Superior Court the Board of Administration of the city ordered the company to remove its tracks on Main street, south of Liberty, and a resolution was passed to the effect that no applications for extensions would be received from the same company until it has paid into the city treasury the money due for delinquent licenses. Later the board ordered permits granted to the Cincinnati Street Railway Company to lay track on Main street, previously occupied by the Incline Railway Company.

The report of the receiver of the Metropolitan Elevated of Chicago shows a gain for May over the preceding month. For the time up to and including June the average daily passenger traffic is as follows:

|                                |        |
|--------------------------------|--------|
| January 20 to February 28..... | 44,434 |
| March.....                     | 47,811 |
| April.....                     | 45,546 |
| May.....                       | 40,353 |
| June.....                      | 42,050 |

During the receivership the income and expenditures have been:

|                             | Income—   | Fares.    | Rents.    | Misc.     | Total. |
|-----------------------------|-----------|-----------|-----------|-----------|--------|
| January 20 to February 28.. | \$86,647  | \$1,040   | \$21,406  | \$109,103 |        |
| March.....                  | 74,108    | 2,300     | 359       | 76,767    |        |
| April.....                  | 68,310    | 2,601     | 201       | 71,112    |        |
| May.....                    | 62,546    | 1,051     | 65        | 64,563    |        |
| June.....                   | 63,076    | 3,400     | 48        | 66,533    |        |
| Total.....                  | \$354,606 | \$11,310  | \$22,070  | \$388,080 |        |
|                             | Expenses— | Payrolls. | Supplies. | Gen'l.    | Total. |
| January 20 to February 28.. | \$30,021  | \$13,017  | \$5,050   | \$49,890  |        |
| March.....                  | 26,202    | 11,357    | 454       | 38,104    |        |
| April.....                  | 26,610    | 11,437    | 47,231    | 87,279    |        |
| May.....                    | 27,728    | 13,433    | 3,108     | 44,270    |        |
| June.....                   | 28,334    | 20,665    | 150       | 49,149    |        |
| Total.....                  | \$140,085 | \$70,790  | \$56,902  | \$268,600 |        |

## OBITUARY.

John S. Hoagland, who for many years was connected with the street railway interests of Brooklyn, died at Hempstead, L. I. After being with the Brooklyn City Railroad Company for many years he became superintendent of the Smith street line and guided that line from poverty to prosperity. He accepted the position of superintendent of transportation on the Brooklyn Bridge, which position he held until his retirement a few years ago.

Col. C. F. Crocker, president of the Market Street Railway Company of San Francisco, died at San Mateo, Cal. Besides his street railway interests he was vice-president of the Southern Pacific Railroad, president of the Oriental Steamship Company and was prominent in the many other corporations owned or controlled by the Southern Pacific Railroad. He served on the staff of Governor Perkins and took a prominent part in political affairs. He was president of the California Academy of Sciences, a trustee of the Stanford University, and a member of the Pacific, Bohemian, Union, and University Clubs of San Francisco, and of the Union Club of New York.

### ALLEY L EQUIPMENT.

For several weeks past tests have been in progress on the experimental track of the General Electric Company at Schenectady, N. Y., for the purpose of deciding whether the Sprague system of control is adapted to the conditions of service on the Alley L of Chicago. The tests were under the personal supervision of Frank J. Sprague and were witnessed by President Carter of the South Side Elevated, A. D. Lundy of Sargent & Lundy, consulting engineers for the road, M. G. Hubbard, Jr., of the McGuire Manufacturing Company, of Chicago, which furnished the trucks, and a number of the General Electric engineers.

Six cars were equipped with the Sprague system of control and each car had two 55-h. p. G. E. motors, both on the same truck. Thorough tests were made to determine the rate of acceleration, starting torque, maximum speed, etc.

The construction of the truck is peculiar in that the equalizing bars are extended so as to form a complete lower frame to which the brakes, motor supports, etc., are attached;

aged so that it cannot be operated. In the Sprague system one of these trucks is used on each car, an ordinary trail truck being used at the other end. It is said by parties who witnessed the tests that the motor truck was easier riding than the trail truck.

From two to six cars were run together to determine how the system is affected by different sized trains. It was found that any sized train acted practically in the same manner as one car in tractive effort, acceleration, speed, current consumption, etc. In fact three cars were joined together electrically, but with no drawbars, and so even were the acceleration and speed that they did not pull apart. A maximum speed of 32 miles an hour was attained, but it is intended that the maximum speed shall be sacrificed for greater torque. Some minor alterations will be made in the equipment, although as a whole the tests have proved the system to be very successful. The final tests will be made on the tracks of the elevated company in Chicago sometime in the near future. Already the third rail, which is in 60-ft. lengths and weighs 40 lbs., is being laid. The

M'GUIRE TRUCK FOR SOUTH SIDE ELEVATED, CHICAGO.

this frame is cushioned by springs over the journal boxes. The top frame containing the pedestals and bolster is of cast steel in three pieces. The pedestals set over the boxes and form an additional means of keeping the truck in square and distribute the pulling points from the center plate to the pedestals over each box; the spring supports are entirely on the equalizing bars of the lower frame. This construction is designed to avoid transmitting kicking from the brakes or shocks from the action of the motors to the upper frame, and to make an easy riding truck with a maximum of strength and safety. To meet the ideas of railway men who believe that swing bolsters are indispensable, a second bolster hung on links, is inserted into the main top frame or bolster, the center and side bearings passing up through openings in the fixed bolster and clearing the top surface by about  $\frac{1}{2}$  in. No appreciable deflection can take place except through breakage or some extraordinary strain, in which case the center plate and side bearings would rest upon the rigid bolster and would still be perfectly safe and operative. The truck is constructed so that so long as the wheels and axles are intact there is no danger of the truck being dam-

running rail will be bonded to make a continuous return circuit, and will also be bonded to the structure at frequent intervals. The Roebbling bond is used for the track work and the Atkinson bond on the third rail. Contracts have been let for the engines, dynamos, cooling tower and other apparatus as given previously in the REVIEW. All the bids for the power house construction were considered too high and rejected. Some alterations will be made in the plans and other bids invited.

Since last January there has been in operation between Stuttgart and some neighboring industrial centers, 8 to 10 miles distant, a service of automotor cars equipped with steam engines and Serpollet generators. The cars fitted for service weigh about 37,400 lbs. of which about two-thirds is on the front axle, which is the driving axle. The cars average about 120 miles per day at an average speed of 24 miles per hour. Briquette fuel is used and in the summer the consumption was from 8.9 to 10.6 lbs. per car-mile run. The estimated cost of fuel, oil and waste was 2.8 cents per car-mile, which it is expected will be further reduced.

A. J. Jolly has received the contract to build the Mount Troy & Reserve Township Electric Railway at Pittsburg, Pa.

H. H. Penny & Co., of Charleroi, Pa., have been given the contract to build the Charleroi, Bellevorn & Fayette City Electric Railway.

Mulholland & Elmond have received the contract to lay 1.75 miles of double track for the Metropolitan Street Railway of Kansas City, Mo.

Henry G. Issertel, recently of the firm of Crafts and & Issertel, New York, has withdrawn from the concern to become sales agent for an electrical company.

William D. MacQueston of Mount Vernon has received the contract to complete the extension of the New York, White Plains & Elmsford Railway to Tarrytown, N. Y.

The Goulds Manufacturing Company, Seneca Falls, N. Y., is mailing a new and decidedly interesting illustrated booklet describing many of the plants using its electrically driven pumps.

Pierce & Richardson have incorporated at Chicago to do a general engineering business. The capital stock is \$10,000 and the incorporators are Richard H. Pierce, R. E. Richardson and Charles T. Foster.

George W. Henry, George B. Foster and F. B. Duncan, have associated themselves with J. Holt Gates, 1323 Monadnock building, Chicago, as selling agents for the electrical supplies represented by Mr. Gates.

Among recent orders the American Engine Company, Bound Brook, N. J., has secured an order from the United States Government for a 35-k. w. direct connected plant for the Pension Office in Washington.

One of the most attractive advertisements that we have seen is a 9 x 12-in. card with a photogravure of Niagara Falls; the title is "A Great Source of Supply," Western Electric Company, Chicago, New York.

The National Car Fender Company has been incorporated at New York. The capital stock is \$20,000, and the incorporators are John A. Henneberry, Matthew Baird, Bernard Mahon and others of New York.

The Joseph Dixon Crucible Company, Jersey City, N. J., has recently issued a pamphlet in which the merits of lead paints and graphite paints are compared and some extensively circulated misstatements regarding the former corrected.

The Indianapolis, Anderson & Marion Electric Railway Company has revoked its contract with Louis Enricht of

Chicago and handed the construction over to A. W. Frances, Howard Wilson, E. E. Downs and L. N. Downs of New York.

The Partridge Carbon Company, of Sandusky, O., has established an agency at New Orleans, La., where Schminke & Newman will distribute its self-lubricating motor brush and other well known carbon specialties in the southern territory.

The Crane Company of Chicago will supply the high pressure valves and steam fittings for the power houses of the St. Louis & Kirkwood Railroad, the Memphis Street Railway and the Indianapolis, Anderson & Marion Electric Railway.

George M. Huss, of 218 Clark street, Chicago, has been awarded the contract to build 15 miles of electric railway at Cleveland, O., for the Cleveland, Painesville & Eastern Railway Company. The overhead construction will be done by Christy Bros., of Akron, O.

The Pennsylvania Steel Company has recently opened an office at 413 Western Union Building, Chicago, to look after its business in the western states. W. H. Stearns, for the past three and a half years general sales agent of the Buda Foundry & Manufacturing Company and A. F. Klink are the western agents.

The new catalog of the Buckeye Engine Company, Salem, O., is devoted to compound engines and in addition to the general and detail illustrations contains a good discussion of the theory of the compound engine, the advantages of compounding, results of tests and the considerations leading to the choice of proportions adopted.

Arrangements were recently completed by which the Northern Electric & Manufacturing Company, Ltd., of Montreal, takes the agency for the products of the Ohio Brass Company of Mansfield, O. This company's goods are already well known in Canada, and the combination will no doubt be of advantage to both parties.

W. B. Upton, who is well known as a consulting engineer of several electric railways and power plants in and about Washington, has located his offices in the Washington Loan & Trust Building, corner of 9th and F streets, N. W., Washington, D. C. His specialties are the installation of steam, electric and hydraulic plants and the equipment of power stations and railways.

The Standard Underground Cable Company has issued a circular letter to its customers advising them that it is at all times ready to defend suits brought against the users of its goods for infringement of patents on paper insulated cables and wires. It asks to be promptly notified of such suits that it may be given an opportunity to defend them.

On July 2, the Philadelphia & Reading put on a 60-minute train between Philadelphia and Atlantic City. The train which made the first trip on this schedule ran from Camden to Atlantic City, 55.5 miles, in 48 minutes or at 69.35 miles per hour; the maximum speed was 82.26 miles per hour for

4.8 miles. The entire train was equipped with bearings made by the Ajax Metal Company, 46 to 52 Richmond street, Philadelphia.

A very handsomely illustrated booklet is being circulated by the E. T. Burrowes Company of Portland, Me. The various kinds of curtains and curtain appliances, made by this firm, are fully described and shown by cuts. Detail drawings are also given of the anti-friction swivel device, chains, pulleys and tips, so that the excellence in the design of these fixtures is apparent. The "pinch handle," "climax" and "royal" car curtains are illustrated.

The interurban railway building out of Meadville, Pa., is known as the Meadville Traction Company, and the bond issue of \$250,000 was placed in New York by C. Townsend Blake, of Philadelphia. The contract for constructing the 11½ miles of this road was let to the Walker Construction & Engineering Co., of Philadelphia, which is now pushing the work forward as rapidly as possible and expects to complete it about October 1st.

The Jackson & Sharp Company, of Wilmington, Del., is busily engaged in completing the cars ordered by the Southeastern Railway, London, the sample car which was shipped some weeks since having been approved by the directors of the road. These cars are 55 ft. long with steel underframing, and with the exception of the English style of buffers are the regulation parlor cars of America. They are equipped with Gould vestibules and automatic couplers.

H. B. Coho & Co., St. Paul building, New York, have taken the agency for the well known insulating material manufactured by the Fiberite Company of Mechanicsville, N. Y., and have become associated with Mr. Medbery for the handling of the Warren apparatus. During the past few weeks the firm has closed a contract with the Oyster Bay Electric Light Company and has started a plant of 500 h. p. for the Jones Brothers Tea Company, Brooklyn, the latter is equipped with Eddy apparatus.

The Ohio Brass Company has adopted as a trade mark for its "Genuine Bell Metal Motor Bearings," a cut of a bell on which appear the letters O. B. Co., and hereafter an outlined reproduction of this will be stamped into the metal on each bearing, as a positive means of distinguishing them from those manufactured by other companies. This mark in itself will also serve as an absolute guarantee of the quality of the bearings, for the company stands ready to replace any which do not give perfect satisfaction.

The New England Construction Company has been incorporated at New Haven, Conn., to build and equip street railroads, etc. Its first contract will be the construction of 14 miles of electric railway at Bangor, Me. The capital stock is \$300,000, and the incorporators are ex-governor Thomas M. Waller, of New London; I. A. Kelsey, general manager of the Winchester avenue road; Attorney S. Harrison Wagner, Julius Watterman, Henry L. Mitchell, of Bangor Me.; Charles B. Wellington, of Albion, Me.; Arthur R. Hopkins and a number of other well known Bangor capitalists.

The Bradford Belting Company, Cincinnati, has been appointed agent for that city and vicinity for the sale of

the products of Van Wagoner & Williams Hardware Company of Cleveland. The arrangement gives a good concern good representatives. Hayes & Arthur, Cleveland, are agents for Western New York and Northern Ohio; James Clark, Jr., & Co., Louisville, and Arthur S. Partridge, St. Louis, have been appointed agents for these cities and vicinities. The Van Wagoner copper segments which are made of drop forged pure lake copper are already standard on a large number of roads.

The J. G. Brill Company advises us that its works are running full time with entire complement of men. Business is better than in 1896. During the first half of that year it was very good, but with a rapid falling off after July; now there is more work turned out and very much more on the books. While the prices of glass, paint and other material have advanced the cost of the finished product will not be any higher because of the large building capacity. The outlook is regarded as most favorable because of the fact that the orders received are for new equipment for old lines which have long ago passed the speculative stage.

The Central Union Brass Company of St. Louis has increased its facilities for making electric and railway goods and now has a complete line of overhead material, all new and up to date, designed by M. M. Wood, who is now connected with this company, and whose reputation as an expert in this line is well known. The company will continue making car trimmings and will add from time to time the new patterns and machinery that will be necessary to meet the demands of the trade. It carries a large stock of goods, and can fill orders promptly. This company was established in 1882, and its trade extends over a large territory.

The Mica Insulator Company of New York and Chicago will shortly issue an extensive catalog which, besides a full list of their micanite specialties, contains several pages of useful information for electrical engineers. The catalog includes all the latest types of street railway motors and is thoroughly up to date. The company has excellent reports from its customers to show on the special micanite plates for commutator segments, and that part of the factory in which they are made is very busy. A new specialty outside of the regular mica insulations is an oiled paper, very tough, and made in large sheets, which are one yard wide and two yards long. This is a great improvement upon the small sheets hitherto made. They are able to supply more than double the area of paper for the same price.

The Composite Brake Shoe Company of Boston is represented by the following manufacturers and supply agents, who have the exclusive sale of the "compo" brake shoes for the electric street railway service as follows: Barbour-Stockwell Company, Cambridgeport, Mass., the New England States; Mayer & Englund, Philadelphia, the middle states; Hayes & Arthur, Cleveland, O., the states of Ohio, Michigan, and West Virginia, Western Pennsylvania and Western New York. The shoes will be shipped at present from foundries at Boston and Buffalo, but all purchases and settlements are to be made with the above agents. This arrangement will be an advantage and convenience to parties who wish to use this well known shoe in these sections of the country.

The International Register Company of Chicago reports that its business is much better now than ever before. The factory has been crowded all the spring, but several large orders received lately have made it necessary to increase the number of men considerably, and even with the increased facilities the present orders cannot be filled for several weeks. The company wishes to announce, however, that all orders for registers to be used in open cars this summer will be given immediate attention.

G. B. Coleman, general manager of the Metropolitan railroad, Washington, D. C., has recently completed the Connecticut avenue extension, reaching the Zoological park, one of the most interesting resorts in the city. In making this extension it was necessary to enlarge both power houses which was done by the addition of a new McIntosh & Seymour engine of 750-h. p., and a 500-k. w. General Electric direct connected generator for each station. From the American Car Company were received 50 cars which are now in operation. The new machinery has displaced smaller units, which the railroad company offers for sale. The engine is a compound Corliss, 15 and 26 x 36, with 15-ft. fly wheel of 25 in. face, and heavy double belting. The generator is practically new and is a G. E. multipolar 200-k. w., 525 volts; also switchboard and double heavy belting.

The Consolidated Car Heating Company, Albany, hands us the following: "The United States Circuit Court of Appeals for the Second Circuit, on Thursday, July 22, rendered an elaborate and sweeping decision, reversing the decree of the Circuit Court, which had granted to the Dewey Electric Heating Company an injunction against the Albany Railway Company, to prevent the use of the Consolidated Car Heating Company's temperature regulating switch in connection with an indicating device as being an infringement of the ninth claim of the Dewey patent No. 464,247. The court holds that this claim is entirely void for want of patentable invention, and this decision finally settles the right of the Consolidated Car Heating Company and its customers to use its temperature regulating switches with indicators as the same have been and are now constructed."

"On August 2 Judge Wheeler of the United States Circuit Court for the Second Circuit rendered a decision in favor of the defendant in the case of the Burton Electric Company against the Union Railway of New York, which was defended by the Consolidated Car-Heating Company."

The Western Electric Company, of Chicago, has just issued a very beautiful and complete catalogue of its "E," "EE" and "Q" switches. The different sized switches are described by numbers with their capacity in amperes, and all the dimensions of the switches are given in tables so that it is possible to drill switchboards before the switches are received with the assurance that the switches will fit when they are placed in position. Also a cut and the catalogue number of every switch part are given, which facilitates the ordering of small parts at any future time. Special switches are made for 500 volts, and the Q switches, which represent the quick break type, are made in all sizes from 25 amperes up. There are also shown in the catalogue the latest design of the round type Ellicott voltmeter switch,

the "V" changing switch, and the switch board spring jacks, plugs and cords. A copy will be sent upon application.

The Carnegie Steel Company, Limited, of Pittsburgh, just placed an order for 6,500 h. p. of Cahall vertical boilers for its blast furnaces D and E at the Edgar Thomson Steel Works. This is the fourth order placed for this kind of boilers by the Carnegie Steel Company, making a total of nearly 15,000 h. p. The Cahall people are also building 4,000 h. p. boilers for the Shenango Valley Steel Company of New Castle and 6,000 h. p. for a new sugar refinery. There are now in the shops unfinished orders for upwards of 30,000 h. p., including boilers for the Brooklyn Edison Company, the Union Traction Company of Philadelphia, the Detroit & River St. Claire Electric Railway Company, the Pittsburgh Plate Glass Company, the Buhl Steel Company of Sharon, Pa., the North Hudson Railway Company, and the Hudson Electric Light Company of Hoboken, N. J.

The Central Electric Company, Chicago, which is making a specialty of overhead line material is in receipt of the following letter from a manager of a company which has long been a customer. He says: "I take great pleasure in saying that all the line material which we have purchased from your company has given us the very best of satisfaction. I am using the 15-in. clinch ear altogether, and do not solder and find they work admirably. Your drawn wire trolley splices I have never known to give way. The hangers are first class in every particular. If I can be of service in speaking a word for your line materials, please call on me and I shall be pleased to do so." The Central clincher ear is made in 6, 7, 9, 12, and 15-in. lengths for all sizes of round as well as figure 8 trolley wire, and is growing in popularity, a single recent order being to construct 28 miles of road.

The McGuire Manufacturing Company of this city is very busy and the earlier prediction of a prosperous fall seems about to be realized. The truck department is running full force and an additional order for 50 trucks from the Consolidated Traction Company of Pittsburgh, Pa., has just been received, making 172 trucks which this company has ordered from the McGuire Company in the past six weeks. The company also have quite a number of orders on hand for its combination snowplow and sweeper for fall delivery and has every reason to expect an unprecedented business in this line. Careful managers are already considering methods of car heating for the coming winter and the company already has orders for a great many stoves. It claims the exhaustive tests of coal vs. electricity have resulted in orders being placed with it, almost exclusively for its "Columbia" heaters. The orders for the positive lock ratchet handles continue unabated and the orders for the "Star" grain doors for freight cars are the largest in the past two years.

The Pope motor carriage, of which the technical papers have made frequent mention, successfully covered the distance from Hartford, Conn., to Springfield, Mass., and return. On this trip of 76 miles the storage batteries were recharged several times and the reported cost of energy ranged from 1/2 to 2 cents per mile. The test was considered very satisfactory.

**PENNSYLVANIA STREET RAILWAY ASSOCIATION.**

The sixth annual convention of the Pennsylvania Street Railway Association will be held at Allentown, Pa., September 1 and 2. The Association will convene on Wednesday, September 1, at 11 o'clock a. m. at Manhattan Park, along the line of the Allentown & Lehigh Valley Traction Company. Scientific papers on various subjects of general interest to the members of the Association will be read and discussed and means for the promotion of the general interest of street railways considered. The usual annual business of the Association will also be transacted at this meeting, including the election of officers of the Association for the ensuing year. The second day will be occupied with a series of entertainments provided for the members and visitors of the Association, including an excursion over the lines of the Allentown & Lehigh Valley Traction Company and a banquet at the Manhattan Hotel, Manhattan Park. An interesting programme has been arranged and will in due time be published and mailed to members of the Association and street railway people generally throughout the state. All street railway companies in the State of Pennsylvania are eligible to active membership, and all manufacturers or dealers in street railway supplies are eligible to associate membership in the Association, the membership fee in each case being \$25. Those desiring membership with the Association can acquire the same at once by sending membership fee of \$25 and one year's dues, \$10, to the secretary, S. P. Light, Lebanon, Pa.

Members of the Association are urged to send as many representatives as possible to the convention, and others who have not yet joined the Association are also cordially invited to attend the convention.

S. P. LIGHT, Secretary. JOHN LLOYD, President.

**CITY TAX IN SYRACUSE.**

The city council of Syracuse, N. Y., recently passed an ordinance granting to the Syracuse Rapid Transit Company franchises over an additional 10 miles of streets which was vetoed by the mayor. When returned to the council it was passed over the veto and an amendment added making the franchises conditional upon the company paying to the city after January 1, 1905, one-quarter of a mill for each passenger carried on any lines owned or operated by it within the city. With a 5-cent fare this amounts to a tax of 1/2 per cent of the gross receipts from passengers.

**ENGLEWOOD & CHICAGO SOLD.**

On July 26 Judge Showalter entered a decree for the sale of the Englewood & Chicago Electric Street Railway, the storage battery road, and it is quite probable that the reorganization committee which has financed the receiver's certificates to the amount of \$320,000 and owns all of the uncontested bonds of the company will purchase the property. The proceeds of the sale will be applied to the payment of the expenses of administration, the redemption of the receiver's certificates and the payment of bonds in the order named. The outstanding bonds amount to \$1,178,000, of which \$278,000 are contested by the receiver on the ground that the company received no consideration for them.

**OPENING OF A NEW JERSEY LINE.**

The Rutherford branch of the Union Traction Company is now in operation and forms an important part of the system which is to connect Newark, Jersey City, Arlington, Rutherford, Woodbridge and other New Jersey towns. These lines will also make connection with the street railways of Passaic, Paterson, Hoboken and Newark and will pass through an extensive and populous district. The road has been well constructed and the equipment is first-class. The power station and car barns are located at Rutherford.

INTERURBAN CAR, UNION TRACTION COMPANY.

There are three 300-h. p. engines, three 200-k. w. belt-driven generators and 1,200 h. p. in Stirling water tubular boilers. The cars were built by the Jackson & Sharp Company and are of exceptionally fine design, as shown by the illustration. The length of the car body is 24 ft., over all 33 ft., and is 7 ft. 7 in. in width. The cars are mounted on Peckham double cushion swivel trucks, No. 14. Motors are General Electric 1,000 type.

**ORLEANS BARN IS BURNED.**

The old car barn of the Orleans Railroad Company at New Orleans, La., was partly destroyed by fire at an early hour on the morning of July 22. The flames were discovered first in the car shop, where, fed by paint and other highly inflammable material, they burned furiously and threatened to consume the entire building. While the employees were removing cars and saving other valuable property the city department got the fire under control, but only after the best portion of the barn had been destroyed. The buildings were old and scattered over an entire square. The total loss is \$34,500, of which \$500 is on office furniture, \$2,200 on tools and \$50 on paints in the workshop, and \$17,500 on seven motor cars. The operation of cars was not interrupted. A new and well appointed building with shops will be erected.

The Wichita Street Railway & Power Company has been organized to handle the street railway interests of Wichita, Kan. The corporation has a capital stock of \$300,000 and will soon begin the work of re-equipping the lines and putting them in first-class condition. The directors are William F. Ellis, H. B. Church, and William I. Church, of Boston; A. C. Jones and R. R. Vermilion, of Wichita.

### A TROLLEY LINE ON THE PIER AT ATLANTIC CITY.

The 500-ft. extension to the Ocean Pier at Atlantic City makes it the finest and most complete structure of its kind. The pier has been widened and a fishing platform and several pavilions have been built. The most unique addition is an electric railway which extends the entire length of the pier, about 1,900 ft. into the ocean. The power station is located at the inner end of the pier. The gage is 2 ft. 9 in. and

OCEAN PIER RAILWAY.

at the shore loop the distance between the inner rails is 30 ft., which necessitates a very sharp curve. The loop at the ocean end is broader and permits a curve of 30 ft. radius.

To prevent excessive friction and wear on the wheels the Denney divided axle is used, which permits the wheels to rotate independent of each other. The coupling is of gun metal, in three pieces, which are riveted together after the brasses are in place. The portion of the coupling shown at the right in the cut is shrunk into that half of the axle. The

DENNEY AXLE.

collar at the extreme end of the coned portion of the axle is also shrunk on. A long conical bearing with adjustable brasses is provided as shown. The joints of the coupling are tight so that it may be filled with oil. With this axle little trouble is experienced from the sharp curves. Messrs. Young and McShea were the builders and now operate the line. The illustration shows a train of four cars out on the pier some distance from shore. The pleasant ride and the fine view of the city makes the road a favorite with the summer visitors.

### DOWN TOWN CONNECTION FOR CHICAGO SUBURBAN.

A traffic agreement has been entered into between the Suburban Railroad Company and the Lake Street Elevated Railroad Company and the former will use the line of the latter instead of the Metropolitan, as first planned, to reach the down town district. Reference to the map of the

Suburban Company, published on page 208 of the REVIEW for April, will show how much more favorable is this arrangement to making quick time. The Chicago, Harlem & Batavia division of the Northern Pacific is within two squares of the western terminus of the Lake Street, at West 52nd street, and does not strike the Metropolitan until West 40th street. A large force of men is at work extending the track in West 52nd street north, and cars will be running by August 19. At the junction with the Lake Street passengers will be transferred in the electric elevator.

### EXCELLENT SNOW PLOW WORK.

In these hot days when the manager is letting extra power into his electric fan, or trying to think up some excuse to go and inspect a line in close proximity to some lake or near the sea shore, it might seem unseasonable to talk about snow plows, or the big drifts they went through like a Fourth of July rocket. Nevertheless it will not be so very many months when snow drifts and blockaded tracks will force their unwelcome attention, and it is always well to be too soon rather than too late. The illustration shows a drift nine feet deep, which interested the manager of the Somerset Traction Company, at Skowhegan, Me., last February. The plow which went through this drift

WORK OF TAUNTON SNOW PLOW.

without shoveling was built by the Taunton Locomotive Works, Taunton, Mass. Its purchase was rather unique, for the president of the road had no idea of buying it, when one day he chanced to be in Taunton. Visiting the works when none of the office men were in, he strolled out through the yard and saw this plow. He afterwards was in the market for one, but after inspecting several sent for one just like that he had shown himself. It is the only plow of its special pattern, having a large nose of peculiar shape which rolls the snow out instead of bunting it. The plows are very heavy, and are built and equipped ready for use, with any make of motor specified. As to required power the builders recommend the G. E. 1,000, or Westinghouse 12A, or other motors of corresponding power to these types.

### THE DALE AUTOMATIC BRAKE.

The illustration is from a photograph of a car equipped with the Dale automatic brake. The braking mechanism consists of clutches to engage the rails, and a sliding block with inclined slot, which is so connected with cams engaging the wheels of the car, that by the action of these cams against the wheels the clutches may be raised or lowered; it also actuates wedges that cause the clutches to grasp the rails. The shoes carrying the clutches that bear on the

THE DALE AUTOMATIC BRAKE.

rails are curved upward so that should a rail be loose and project above the other, or out of line at a joint, the clutches will slide over without catching. The brakes are adapted to stop a train going in either direction; both are automatic or under the control of the brakeman, as may be desired, and adjust themselves automatically for a quick or

a gradual stop. Should one end of the car leave the track or run off at the end of a rail, as would be the case with an open draw bridge, the clutches would at once bear and throw the brake into action.

### BLACK SAND POOL, YELLOWSTONE PARK.

"No person who visits the Upper Geyser Basin should fail to see Black Sand Pool. It lies on the south of the main Upper Basin, and is reached by a road leading past the beautiful Punch Bowl Spring. Black Sand Pool is an oval spring some 40 feet long by 20 or 25 feet wide. The water is of a light blue sapphire or turquoise color—it is not easy to name the precise tint in many instances—extremely beautiful, from whose surface the steam constantly rises. The great peculiarity about it is that the encircling sides, which are in places fifteen feet high or more, are composed of black, partially decomposed obsidian, sand."

The above is taken from "Wonderland 97," a new book published by the Northern Pacific Railway. Send six cents to CHAS. S. FEE, Gen'l Pass. Agent, St. Paul, Minn., for it.

Since the article "Chicago City Cuts Wages" on page 542 of this issue was printed, it has been learned that the men on cable runs held a meeting, and almost unanimously, refused to fill out the cards and make the election of working for 21 or 23 cents instead of the present rate 28 cents. The question now is, what will the company do about it?

## ELECTRIC MUTUAL CASUALTY.

W. W. Wharton, secretary of the Electric Mutual Casualty Association, reports that the business and finances of the association are in a satisfactory condition. For the 16 months ending August 1, 1897, the following statement is made:

|                                                          |             |
|----------------------------------------------------------|-------------|
| Gross receipts.....                                      | \$61,426.72 |
| Expenses.....                                            | \$16,583.31 |
| Claims and attorney's fees.....                          | 16,918.40   |

The expenses of the association, for the four months ending August 1, have been \$3,048.52, which is less in proportion than \$13,534.79 for the preceding 12 months, the latter amount includes also the cost of organization. Numerous reports of accidents, which may or may not develop into claims against the members of the association, have been received. A few claims are being contested by the advice of different members, as some accidents have occurred in which there is either no liability on the part of the company or else the claims are for such excessive amounts that adjustment in court is necessary. It is the policy of the association to keep out of the courts whenever reasonable settlement can be made, and for that reason the claims are closely settled to date. There is at present a membership of 45 exceptionally good risks from which the association has an income of \$60,000 and a contingent liability of \$40,000. The different departments are thoroughly organized and are running smoothly, and the association feels that it is offering the best insurance of this kind than can be obtained.

## BROWNELL CAR COMPANY FILES DEED OF TRUST.

The Brownell Car Company on July 23 filed a deed of trust to protect its creditors. The assets, including a large amount of valuable real estate, schedule about \$200,000 more than the liabilities, and the company will undoubtedly straighten out and resume in the near future. Car building has been very light the past year, and as it was impossible to dispose of the real estate except at too great a sacrifice, it was decided best to take this step. The company was one of the oldest in the business, and always prided itself on the superior quality of its product. Mr. Brownell's many friends in street railway and other circles greatly regret this misfortune, even though it be, as there is every reason to expect, only a temporary one, and will wish him a speedy solution of the matter.

## NICKEL-IN-THE-SLOT MACHINE CAUSES TROUBLE.

The Union & Middlesex Traction Company has adopted a unique fare-box and register. It is a glass jar 4x10 in. and registers automatically each nickel as it is put in. The trouble comes in making change, for each coin dropped in, whether a penny or a quarter, indicates one fare. Its supposed utility comes in making it unnecessary for the conductor to handle any money. He passes it around the same

as a contribution basket, but it is forbidden to permit the machine to accept a one cent piece as a fare and the passengers are not disposed to drop in a quarter if a 5 cent piece is not at hand. Two men boarded a car, one tendered five pennies and the other one offered a dime when the conductor presented the fare box. The conductor informed them that they would have to tender exact fare, and this they refused to do. They were then put off and walked to their homes some distance away. Each brought suit for \$5,000 damages.

## THE ELECTRIC FENDER.

The illustration shows the mechanism of the electric fender, invented by Paul Jones, 640 June street, Cincinnati, Ohio. The fender proper, or scoop, which is relied upon to lift the person clear of the track, is suspended under the car as close to the wheels as possible, and is normally held at about six inches above the rails, and dropped when needed. The catch at C which engages the vertical arm and holds the scoop in its normal position may be tripped either by the motorman pressing the trip A, or by action of a magnet

located in the box D. This magnet is energized from the line circuit when contact is made at the circuit closer at B. For the circuit closer to act it is only necessary that the resilient buffer attached to the front of the car be deflected one inch, by striking the body to be picked up. The buffer is of light wire work, and while it is low enough to strike any one prostrate on the track, it is flexible and bends back as it passes over. The buffer having been deflected and made electrical contact at B, the scoop is tripped and drops to the rail where it is locked in position before it reaches the object struck.

## SUMMER TOURS.

## Rivers, Mountains and Seashore.

## GRAND TRUNK RAILWAY SYSTEM.

The sale of Summer tourist tickets from Chicago to Eastern Tourist Resorts reached by the Lines of the Grand Trunk Railway System, embracing Niagara Falls, Muskoka Lakes, St. Lawrence River, White Mountains, Portland and Seacoast Resorts, commences June 1st, continuing to September 30th, inclusive.

Seaside and White Mountains Special. "The Finest Train in the World," making weekly trips between Chicago, Portland and Old Orchard Beach. First trip eastbound from Chicago, June 24th. The elegance and comfort of this train, combined with the ever-changing panorama of Nature's grand and beautiful scenery through which it passes, makes it the most desirable train between Chicago and the Sea Shore and Mountain Resorts of the East.

For further particulars, Excursion Folders, Time Tables, Berths in Sleepers, or Tickets, apply to L. R. Morrow, C. P. & T. A., 103 Clark St., Chicago.

### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. SEPTEMBER 15, 1897. NO. 9

A BROOKLYN conductor who was discharged went and shaved off all his whiskers and came back a new man with a new name. Now he has been found out and wishes he had his whiskers back.

ABOUT two years ago the Cincinnati Street Railway laid some steel ties experimentally, but nothing has been heard of steel ties in a long time. Recent examination of these ties shows such good results the company will now lay a considerable number of them.

NEW JERSEY, in spite of the mosquitoes which are said to cut the trolley wires in summer, maintains 613 miles of road, on which the capital and funded debt is \$74,000,000. The capital stock is nearly \$40,000,000, on which dividends amounting to \$124,000 were paid in 1896.

THE Boston subway, built by the West End road, under the famous Common, and the finest piece of work of its kind in the world, went into service September 1. If some of the staid old fathers of early days, who used to hold tea parties, could awake to see the fine electric equipment emerging from under their blessed Common they would experience several varieties of shocks.

THE Manhattan Elevated, in New York, appears to be still halting between electricity and compressed air. The

one thing of which it seems to be convinced is that steam locomotives as motive power must retire. Trial trips are being made which the air people pronounce very satisfactory, and regarding which the road maintains a profound silence. The railroad commissioners of the District of Columbia have an expert still investigating, which would seem to indicate possibilities for air in Washington in spite of the recent failure there.

Unless compressed air can make some decided and positive advance in the near future in the nature of securing the equipment of some road of standing, it will have to step aside and electricity will have the field practically to itself.

If some men would devote the same energy to securing an honest living that they do to beating a railroad, they would get rich and the manager add to years to his life. The scheme this month described on another page was to remove the screws to the hand rail and then pull the handle off while falling from the car. The man with the pull overlooked one screw and the handle held; but the police got a pull on the man which worked all right, and he went with them to jail.

NOT a month passes but we record the loss of trolley or feeder wire which has been stripped from the hangers and is usually found chopped up into short lengths of a foot or two, suitable for melting into pigs to prevent identification. Some months there are several such reports, the losses ranging all the way from a few dollars to several hundred; and occasionally the damage done causes an expense of one or two thousand. The nuisance is not confined to any state, but is "prevalent all over."

Managers surely are equal to the occasion and will devise some means to discourage this sort of thing. Where current is not carried all night, some one might manage to short circuit the robbers and get a ground with a shot gun; but it's no easy matter to patrol one or two hundred miles at night.

The remedy would seem to lie in suitable legislation which will provide a much more severe penalty on conviction than can at present be enforced in a case of mere theft. This would be another good subject to discuss at the October convention.

THE carrying of your Uncle Samuel's letters is becoming quite important to such roads as are fortunate enough to be posted as mail routes. One road we call to mind earns nearly \$3,000 per annum without any extra expense other than the fuel necessary to pull the extra trailers. The magnitude of the work and its rapid expansion are better understood when we consider the appropriation for the fiscal year is a full quarter of a million of dollars for cable and electric service.

The ruling that compensation should be no more than last year created some apprehension on such lines as are being largely increased as to mail service; but the comptroller of the Treasury gladdens our hearts with the assurance that this applies to the rate paid and not the amount, which is quite a different matter. The department certainly gets as much, if not more value received from its expenditures on street railway mail service, than from the same amount in any other way. If the money contemplated to be spent in the house to house collection were diverted to increasing the street car service, it would yield vastly better returns.

THE executive session at the street railway convention ought to be one of the most valuable features of the meeting, and managers would do well to hand the secretary such subjects as they especially desire taken up at that time. We suggest as one timely topic which has been guardedly spoken of on one previous occasion, viz., the following up and securing conviction of persons caught in making fraud claims for damages. The tendency and temptation, of course, is to follow the lines of least trouble and expense, and the result is that a company seldom follows up an exposure by insisting on the penalty of the law being enforced. As a rule, a manager is satisfied with detecting the fraud and glad to escape being bled. But it seems to us there is a certain moral obligation on all the roads, to prosecute such offenders to the full limit of the law. The expense is not great, as the prosecution is made by the state, but even if it did cost something the results are worth the price paid. If a considerable number of roads would express their determination to seek the punishment of all detected in crooked claims, and the fact was known to the public, the moral effect would be great in discouraging such experiments. Courts resent any effort to use the process of law to secure money through fraud, and juries which are liberal to the plaintiff where real injury exists, are no less severe in rebuking blackmailing efforts, where the facts can be squarely proved. Last month we gave the particulars of the daring attempt to defraud the Memphis road out of \$25,000, and in that case the company was able to produce unquestioned evidence as to the criminal intent and action, and the court promptly inflicted the full penalty of the law, 364 days, which was as little less than the "not to exceed one year" as it could well be.

Companies ought to stand shoulder to shoulder in these things, and one of the chief benefits of the Association lies in the acquaintance thus formed which makes possible a well defined and mutual understanding as to policy, even though no formal agreement is made.

THE general business outlook has taken on a vastly improved aspect since our issue of one month ago. The crop reports continue to improve, and the wheat crop is now known to be assured. Unless an early frost catches the corn in the central and northern corn belt there will be an enormous surplus over home requirements to sell abroad, where, fortunately for us, a shortage in cereals exists. The splendid advance in prices of farm products, both grains and live stock, sets the dollars in motion which will soon roll through all the avenues of trade and manufacture. The settlement of the tariff question, even for such lines as are least affected, is already showing its beneficial effect, for a settled basis is established and the people know exactly how to operate and readily adapt themselves to the settled conditions. The great manufacturing districts of the east are already awakening and ere long will be moving with the old time activity. A spirit of hope and confidence is in the air everywhere, and people who have been guarding their capital most jealously for three years now lend a listening ear to legitimate and promising enterprises. The American people recuperate with a vigor and rapidity not equaled by any other nation, and now the current has fairly turned we may confidently look for the tide which leads to fortune.

The winter business of street railways is never as good as the summer business, but with mills and factories opening

up and thousands of employes once more going and returning from their daily work, there will be a fine increase over last winter's earnings.

The season has not been marked by any considerable new construction. The cities are already well provided for, and in many cases for several years in advance; still there will be some extensions in the towns and a large amount of renewals and reconstruction. The great bulk of new tracks will be found in the many interurbans which will furnish the large part of the new work for the next three years. Of these, there will be hundreds of miles built, and altogether 1898 has every promise of a good year both to operators and manufacturers of materials.

The difficulty in placing bonds which has stalled so many operations planned during the past two years will largely be removed by January 1, giving time to place securities and construct next year. It is to be hoped promoters will confine their efforts to the many really good operations, and not kill the goose as was done four years ago, by foisting a lot of worthless schemes upon a gullible public. However, there is little danger of that, as information on the subject is now general, and investors have a pretty good knowledge of the conditions necessary to success.

#### GOVERNMENT BY INJUNCTION.

THE present coal strike and the mass-convention held under the auspices of the labor unions at St. Louis have served to call attention to the subject of "government by injunction" which first became a grievance during the railroad strike of 1893, and which also appeared in the background as one of the issues of the last presidential campaign. Early in the present strike the state courts of Pennsylvania issued injunctions restraining the strikers from trespassing upon the property of the operators and from intimidating the miners who desired to continue work, and on August 4 Judge Jackson of the circuit court of the United States for the district of West Virginia issued a similar order, which was as follows:

"\* \* \* a temporary restraint order is allowed, restraining and inhibiting the defendants and all others associated or connected with them from in any wise interfering with the management, operation or conducting of said mines, and their owners, or those operating them, either by menace and threats or any character of intimidation used to prevent the employes of said mines from going to or from said mines, or from engaging in the business of mining in said mines.

"And the defendants are further restrained from entering upon the property of the owners of said Monongah Coal & Coke Company for the purposes of interfering with the employes of said company, either by intimidation or the holding of either public or private assemblages upon said property, or in any wise molesting, interfering with or intimidating the employes of the said Monongah Coal & Coke Company so as to induce them to abandon their work in said mines.

"And the defendants are further restrained from assembling in the paths, approaches and roads of said property leading to and from their homes and residences to the mines, along which the employes of the Monongah Coal & Coke Company are compelled to travel to get to them, or in any way interfering with the employes of said company in passing to and from their work, either by threats, menaces or intimidation; and the defendants are further restrained from entering the said mines and interfering with the employes in their mining operations within said mines, or assembling upon said property at or near the entrances of said mines."

As to the effect of this, Mr. Debs, who has been prominent as a leader in the present strike, in the call for the mass-convention of labor unions at St. Louis, says in part:

"The injunction has again done its deadly work. Constitutional liberty has been bludgeoned to death and labor bound and gagged for the perpetual exploitation of corporate capital. There is no relief in the courts. We have tried them all, from the bottom to the top, and they are all against labor. So far as I am concerned, I will appeal to them no more. We will now appeal to the American people. Judges, the creatures of the plutocracy, rule the country by injunction. From justice of the peace to the justice of the supreme court, the injunction has full sway. American citizens are forbidden to open their lips or to walk on the public highway. Sheriffs, marshals and other petty officers issue proclamations and then proceed to shoot and club workmen if they are not as servile and obedient as if they were so many savages off their reservation."

A careful reading of the injunction shows that the strikers have not been restrained from doing anything that they could of right do, and it appears to us that Mr. Debs has permitted his sympathy to prejudice him and his enthusiasm to lead him to make inaccurate statements of fact. No law abiding citizen will claim the right to trespass upon his neighbor's property, to assault his servants, or to interfere with him in the conduct of his business. It would appear that strikers believe that these rights were conferred upon them when they became members of a union; the claim is not made in words, only in deeds.

The writ of injunction is a preventative writ in equity which will issue only where irreparable damage would otherwise ensue, and where there is no plain, adequate and complete remedy at law, and only then when the damage suffered by the complainant is special. Among those who seek to curry favor with the unlawful element, excepting the few that are bare-faced in the advocacy of anarchy, the claim is not made that these injunctions as issued are illegal, because it is too evident that the damage which they seek to prevent would be special and irremediable. But it is said that it is unwise and unjust that a man be restrained from committing an unlawful act, because thereby the brand of criminality is put upon him, and it is urged that nothing should be done until the act is committed, when it may be punished. In other words, a man should stand by and see his business ruined and then have recourse to a prosecution for trespass or assault or malicious mischief or what not, and to a civil action for damages against those who have nothing, a procedure in the nature of trying to get blood out of a turnip.

The efficacy of the injunction lies in the fact that violations of it can be summarily punished. An ounce of prevention is worth a pound of cure, particularly when the cure offered is entirely inadequate as is the case here.

While we sympathize heartily with the strikers in this instance and share the opinion which the leading mine operators do not hesitate to express that the men are underpaid, we think that their leaders are not justified in attacking the courts.

We believe that the danger confronting us is not the prostitution of liberty to "government by injunction," which is in truth no hardship to the law abiding; but that it lies in the attempt to so tie the hands of equity that this "extraordinary" remedy can not be used in the extraordinary circumstances which unfortunately have of late so frequently arisen.

Trolley day at LaFayette, Ind., was not a financial success, the Young Men's Christian Association, which was the beneficiary, receiving but \$160. The conclusion drawn by one of the local papers is that the people are not interested in the Y. M. C. A.

## NEW KIND OF FAKE DAMAGE.

Removes Screws From Hand Rail—Then Tries to Fall and Get Hurt.

In these latter days the life of a manager is being shortened by a multitude of schemes to rob his company and spoil his good record. Last month there was a woman in the case; this month there is a screw loose; if the screw had come out things might have been different as between one Krause and the Joliet, Ill., railway. The scheme is quite a novel one, and out of the multitude of fake claims which are brought to our notice, seems to be the first of its kind and original with Krause.

In some respects the plan was open to detection; in others it would have made a bad case to defend in court, which was evidently part of the program.

It was on the pleasure resort line which runs out to the suburbs, and there is a laying time of several minutes at the

AUGUST KRAUSE, ALIAS JOHN CRAMER, ALIAS JOHN MILLER THE GRAB HANDLE MAN.

park terminus. While the conductor and motorman were talking on the front platform, Krause removed two of the screws which fasten the grab handle to the car, using a screw driver, which he had brought for the purpose. As the hour was late the result of his work did not show.

When the car reached a populous corner near the city the man motioned the conductor to stop. As the car slowed up the man stepped forward, gave a strange pull at the hand rail and rolled off upon the pavement, where he lay in an unconscious condition. Apparently he had been badly injured, and as soon as possible he was removed to St. Joseph's hospital and physicians summoned.

While Superintendent Rush was examining the car he discovered the two screw holes and immediately had search made at the starting point, resulting in finding the steel screw driver in some weeds.

The police were at once advised of the situation and with these facts in their possession hurried to the hospital, determined to place the man under arrest. They found him in a comatose state, surrounded by physicians and nurses, who were endeavoring to revive the apparently unconscious sufferer. When the doctors were informed of the sham they

adopted new methods which soon convinced them the man was not injured at all.

But the fellow was game and during the next few hours astonished everyone with his wonderful exhibition of nerve. Despite the most painful and fear-inspiring tactics of the doctor, the man maintained an appearance of absolute unconsciousness and baffled all attempts to make him admit he was shamming.

The doctors stuck needles into his body, laid operating knives across his flesh and did other terrible things, but the fellow never quivered. Finally, one of the physicians forced open the man's eye and made a motion as though to run a long needle into the optic. This was too much for the imposter, and he dodged. It was then only a matter of a few moments to bring him to his senses, and he finally admitted the suspicions of the authorities were well founded.

The failure of the handle to pull off as he evidently expected was due to another screw which he evidently did not notice in the dark, as it was concealed by paint. His expectation evidently was that the handle would readily yield and the peculiar nature of such an accident would be one a company might naturally settle without much delay. Failing to do so it would make a good jury case. But like the Webbs, last month, his game didn't work, and he gets nothing. He was held on a charge of malicious mischief in bail of \$300. As he made no claim for damages, it will be difficult to secure a conviction, as anybody has a right to jump at his own risk, and there is no law against yanking at grab handles. But the secret is out and every manager will do well to add to his list of doubtful cases those which have any connection with the hand rail.

This man, giving the name of August Krause, at Joliet, is known to have worked the same game in St. Paul, Minn., and in Canton, O., being known in the former city as John Cramer and in the latter as John Miller. The particulars of these cases are as follows:

On September 28, 1895, a man who gave his name as John Cramer and his address as Hastings, Minn., was a passenger upon one of the grip cars of the Twin City Rapid Transit Company in St. Paul. He sat in the rear seat and when he reached Robert street tumbled off into the street with a small brace-handle in his hand. He claimed to be severely injured and was taken to the city hospital and received treatment for some time, his symptoms being mainly subjective. The handle which he held was a small brace running from the seat to the side post, the car being an open one; there was no reason why these should work loose and none have been known to do so either before or since this "accident." The company thought that the case was without merit and at first declined to settle; but as it was unable to secure any evidence that he had removed the screws himself, finally concluded to compromise and settled for \$32.50. Since the Joliet accident John Cramer has been recognized as August Krause.

On March 25, 1897, a man giving his name as John Miller was a passenger on one of the cars of the Canton-Massillon (O.) Electric Railway, and stood on the rear platform. When the conductor left the car at a railroad crossing and the car started to cross the tracks the passenger was thrown to the ground. He claimed that the grab-handle to which he was holding was loose at one end by reason of the nut which fastened it being off. In falling he still held to the handle and continued to do so until it was jerked loose at

the other end also. He claimed to be severely hurt in the hip and back, and was conveyed to the hospital. All the circumstances of the case were such as to excite the suspicions of the officers of the railway company, but they were entirely without evidence (he being the only passenger on the car at the time) and thought it best to settle the case without a lawsuit, and paid his expenses at the hospital and paid him for his lost time. Nothing more was thought of the matter until the company was advised of the case at Joliet. The description of the man and the details of the accident led the officers of the Canton road to think that it was the same man and on receiving a photograph of Krause immediately recognized him as John Miller.

### SYRACUSE RAPID TRANSIT COMPANY.

Since the purchase of the Syracuse Consolidated Street Railway Company under foreclosure sale by a strong company and its consolidation with the Syracuse Street Railway Company to form the Rapid Transit Company, almost the entire system and equipment have been remodeled and many improvements made. The new power station has a capacity of 3,400 h. p.; 2,000 h. p. is furnished by two Allis Corliss cross-compound, condensing engines, 26 and 50 x 48 in., running at 80 r. p. m., and the remainder is from three cross-compound, condensing vertical marine engines, with cylinder dimensions of 16 and 31 x 24 in., and a speed of 150 r. p. m. The Allis engines are direct connected each to one 800-k. w. generator; on the same shaft is a steel plate fly wheel weighing 50 tons. Each of the small engines is belted direct to a 300-k. w. General Electric multipolar generator.

In the boiler room the new equipment consists of six 250-h. p. Stirling water tube boilers and four old return tubular boilers which are 90 in. x 16 ft. There are two main heaters between the condensers and the exhaust of the Allis engines, and one auxiliary heater taking the exhaust from condenser and boiler feed pumps for its heat supply. Also there is one small heater receiving the exhaust from the boiler pumps in the old plant and heating the feed water going to the return tubular boilers. There are no economizers or stokers. A trestle leads directly into the boiler house and the coal is dumped from gondola cars to the floor.

The lines are divided into 12 sections, each controlled from a separate panel on the switch-board. Two types of lightning arresters are in service; the General Electric being placed within the station on the generator panels, and the swinging-ball type suspended outside the building and protecting the feeders to each section.

Single o trolley wire is suspended from span wire with side pole construction. The poles are chiefly of iron, made of 4, 5 and 6-in. extra heavy pipe, 28 ft. over all. For curves, 5, 6 and 7-in. pipe is used. The wooden poles are 7-in. octagonal for straight line and 9-in. top for curves. In the track construction the Johnson half grooved section girder rail, weighing 90 lbs. to the yard and in 60 ft. lengths is the standard. The 36-in., 12-bolt ribbed joint, staggered, is used. The ties are of Georgia pine, 6 x 8 in. x 8 ft., spaced 32 to 60 in. At the joints the spacing is 18 in., so as to give a three tie joint. The sharpest curves on the lines are of 35 ft. radius and the heaviest grade 8.61 per cent. The whole system is thoroughly modernized, and its efficiency and capacity for handling heavy traffic is vastly increased.

## CENTRAL AVENUE STATION, METROPOLITAN STREET RAILWAY, KANSAS CITY, MO.

The new electric power house of the Metropolitan Street Railway Company, at Kansas City, Mo., offers a good example of modern power house construction. The dimensions of the power house are: Boiler room, 144 ft. long, 51 ft. wide; engine room, 144 ft. long, 63 ft. wide, the boiler and engine rooms both being 33 ft. 7 in. from the top of foundation masonry to the under side of the bottom chords of the roof trusses. The unloading shed is 41 ft. long by 20 ft. wide.

The steel frame work construction, in a general way, consists of steel columns supporting steel roof trusses, all rigidly bound together with longitudinal struts and sway rods and transverse lateral bracing, the bracing for this plant being extra heavy to withstand the very high winds peculiar to the locality. The advantages of this construction are: a rigid building capable of withstanding high winds and the vibrations of the engines, and of sustaining heavy loads. The roof covering for both boiler and engine rooms is slate laid upon wood sheathing with heavy builder's felt between, all supported by steel channel purlins.

In the engine room supported by the side columns are longitudinal plate girders carrying a 30-ton electric traveling crane.

In the boiler room, in front of and above the boilers, are located the steel coal hoppers, holding 1,000 tons; two hoppers directly in front of the stack are used as ash receivers. These hoppers are supported on two independent rows of latticed channel columns; the sides and ends of the hoppers forming the longitudinal and cross supporting girders respectively. Each hopper is supplied with a hinged spout containing a cut-off valve, the coal being fed into the boiler stokers by gravity.

The unloading shed is of light steel frame construction, covered on the roof, one side and the gable ends with corrugated iron. This shed is used as a protection during the unloading of coal from the cars.

The economical handling of the fuel supply and of the ashes is deserving of special attention. From the car in the unloading shed the coal is shoveled by hand into the receiv-

ing hoppers; then a conveyor carries it under the boiler room floor to the end elevator, thence to the coal hoppers overhead, where a horizontal conveyor distributes it throughout their length. From the hoppers it is fed by gravity into

CENTRAL AVENUE STATION, KANSAS CITY.

the stoker hoppers. The vertical conveyor also carries the ashes from the ash pits and delivers them into the two center hoppers located in front of the stack, from which they are drawn by gravity directly into the receiving cars in the unloading shed. By this arrangement the fuel and the refuse ashes are handled only once.

The conveyor driving machinery is located in the boiler room roof trusses, the trusses being designed especially heavy to carry this machinery, the conveyor and its load. The floors of the engine room and boiler room are supported on steel beams.

The stack for this plant is a self-supporting steel one, 175 ft. high above the foundations by 10 ft. 6 in. diameter of shell, with a clear flue of 8 ft. 4 in. inside of the brick lining. The stack is located between the boilers in the center of the boiler room.

The entire metal work of this plant, including the structural steel, the coal hoppers and the steel stack, was designed and furnished by the Variety Iron Works Company of Cleveland, Ohio.

The engine-room contains at present one Reynolds-Corliss tandem compound condensing engine with cylinders 30 and 60 x 48 in.; main shaft, 21 in. long by 24 in. diameter in hub fit of armature and fly wheel; main journal 22 in. x 12 in.; fly wheel is 20 ft. 8 in. in diameter and weighs 120,000 lbs., and runs at 80 revolutions per minute. The engine has an automatic stop valve operating by a special governor which is set to operate when engine runs 5 r. p. m. above normal speed. This governor acts and closes the valve shutting of the steam in the main steam pipe, preventing any possibility of the engine running off and wrecking itself as well as the buildings, which has often happened in large power stations. The condensing apparatus consists of a Wheeler surface condenser,

INTERIOR OF BOILER ROOM.

The air pump and circulating pumps are of the Reynolds make and are all well driven by one engine with Corliss valve gear, making a very efficient condensing system. Water is taken from the Kaw river through a 20-in. suction pipe and passed through the condenser and returned to river through a 24-in. pipe. The engine room has provision and space for three more engines and generators of same capacity as the one now in place, making a total of 8,000 h. p.

Provisions are being made for a duplicate of the present unit which the company hopes to have installed and ready for operation before cold weather. In this engine room there is a 30-ton traveling crane with a span of 62 ft. and a travel of 144 ft., the full length of building; it is used in handling the machinery during process of erection and in making repairs. This crane was made by the Brown Hoisting & Conveying Machine Company, of Cleveland, Ohio.

The boiler room contains at present six 250-h. p. water tubular boilers with wrought steel headers, which are designed to carry 200 lbs. steam pressure. These boilers are equipped with chain grate stokers, making the firing almost automatic and smokeless. Provision was made in this room for the installation of 1,600 additional horse-power in boilers. There is also located in this room one Berryman's feed water heater of 3,000 h. p. capacity.

The steam from condenser engine, the large boiler feed pumps and stoke engines is turned into this heater and utilized for heating the boiler feed. In this room there are

1,300-K. W. GENERATOR.

also two large Admiralty boiler feed pumps, made by the I. R. Worthington Company, that are of a pattern especially designed for the navy.

The steam pipe system for this power house consists of one 16-in. header supported on brackets bolted to the steel columns of the building some 12 ft. above the boilers; this header has extra heavy fittings with pipes bent to a large radius connecting it to the drums of the boilers. All flanges are of wrought steel, bored and faced with a corrugated surface and shrunk on the pipe and peened for steam joints. This peculiar arrangement of piping with long sweeps makes it flexible and obviates the use of expansion joints, which are much dreaded by the operating engineers of large stations.

All the valves and piping for this station were furnished by the Crane Company of Chicago. All of the valves are

that company's high pressure gate valves which the company has been using for some time with such success at some of its other stations, carrying 160 lbs. of steam.

The peculiar location of this power station has made it necessary for the company to expend a great deal of money on foundations. The house is situated on the west bank of the Kaw river where the foundation is gumbo and quicksand for a depth of 18 ft., at which depth there is a good, deep stratum of coarse sand. In order to get the floor of the building above high water mark the stone foundation was built 14 ft. high, thus making the foundation machinery and buildings 32 ft. high. This location was chosen on account of its convenience to water, for its good switching facilities and because it is a central point for the distribution of power to the various electric lines which it is intended that this station shall run.

The generator has a capacity of 2,400 amperes at 550 volts, and runs at 80 r. p. m.; it is guaranteed to work at 50 per cent overload for a period of five hours. The armature is 10 ft. 6 in. in diameter and the field has 14 pole pieces.

The switchboard consists of two generator panels, one Wattmeter panel and 20 feeder panels, and was manufactured by the General Electric Company. The feeder panels are supported by a steel gallery in the engine room. This gallery and the stairs leading thereto have an ornamental iron railing, which, together with the switchboard panels, adds to the appearance of the engine room. The frame work of the switchboard and gallery has been erected for two generators and six feeder panels in addition to the above number which provides for increasing the size of the switchboard in the future without increasing the size of the gallery. Sufficient space in the engine room has been allowed for extending the gallery to double its present size. The wattmeter and generator panels are located on the engine room floor under the gallery which supports the feeder panels. The wattmeter panel has one 8,000-ampere Thompson recording wattmeter and the quick break switches for controlling the lights in the power house. The generator panels are equipped with Weston illuminated dial ammeters of 4,000 amperes capacity, automatic circuit breakers of the magnetic blow out type of 8,000 amperes capacity for breaking the circuit in case of an overload, and main switches of the quick break type of corresponding capacity. To the left of the generator panels, supported on a hanging frame, are two Weston illuminated dial voltmeters, which have been calibrated together. One is used for indicating the potential of the line and the other is arranged with plugs for taking the potential of the generator before cutting it in on the line.

The feeder panels are equipped with round pattern Weston ammeters, automatic circuit breakers and quick break switches; also electric bell signals, which give alarm when any of the circuit breakers are open from an overload. The generator is connected to one of the generator panels with three 800,000-c. m. rubber covered cables for the positive connection and three for the negative. The other generator panel is used for receiving the current from the power house, at 9th and Wyoming streets, and delivering it through the wattmeter to the feeder panels. The power house, at 9th and Wyoming streets, with its number of smaller type machines, is maintained to supply current for the "owl" train service and lights during the latter part of the night, also to supply current in case of an accident to the machinery of the new plant. The feeder panels are divided up as follows: Seven panels for the Kansas City Elevated Railway, three for the

Quindaro boulevard line, two for the Armourdale and Argentine line, three for the Southwest boulevard, two for the West Side line, one for the Summit street line and one for a 400-h. p. motor, which drives the cable machinery at the 9th and Washington street power house, and one for the Broadway line, which will be changed from horse car to electric this year.

Arrangements have been made for mounting wattmeters on the feeder panels, one for each road, in order to accurately arrive at the power furnished for each of the lines separately, and the proportion of the cost of operating the power house can be charged against the lines according to the amount of power consumed. On the back of these panels is a long bus bar running the full length of the board, to which eight 800,000-c. m. cables from the main wattmeters are attached. Short bus bars connecting the panels for each road are mounted above the long bus bar, and connections will be made from the long bar through the meters to the short bars. The feeders running from the feeder panel out to the various

is buried 16 ft. below the basement floor on top of the coarse stratum of sand which is from 8 to 10 ft. below low water mark in the river. The plate is not in any manner connected so that the return currents can pass over it to the generator, except at such times as lightning may momentarily cause the generator current to pass over the discharged points of the arrester, thus reducing the action of electric currents on the plate to a minimum, and insuring at all times the proper ground connections for the lightning arresters. This plant is now furnishing current to operate 77 cars daily on 55 miles of electric road and the Summit street cable line with  $4\frac{1}{2}$  miles of track.

On the Summit street cable eight regular trains and two extra trains in the morning and evening are operated daily. Each train consists of grip car and trailer. On the electric lines thirty-one 30-ft. motor cars, four 18-ft. motor cars, fourteen 16-ft. motor cars and eight trailer cars are operated daily.

On July 5, 116 cars, comprising 63 motor cars with 8 trailers and 20 grip cars with 25 trailers were operated during the day, and not a spark of any character was seen on the commutator or at the brushes of the generator, although at times the ammeter indicated 2,700 amperes. The motor operating the cable lines consumed as high as 900 amperes for short periods of time.

The officers of the Metropolitan Street Railway Company are C. F. Morse, president and treasurer; W. H. Holmes, vice-president and general manager; J. A. Harder, auditor; C. F. Holmes, general superintendent; Charles Grover, electrician; D. W. Dozier, chief engineer of power station.

We are indebted to General Manager Holmes for illustrations.

#### A CELEBRATION BY THE AMERICAN ELECTRICAL WORKS.

The nineteenth anniversary of the founding of the American Electrical Works was commemorated by a gathering of the friends and the business associates of the firm at the Pomham Club in Providence, R. I. The day was occupied with base ball, billiards and other amusements. About 300 guests partook of a sumptuous dinner and clambake, the clams for which were grown on the reservation of Eugene F. Phillips, president of the works. Toasts were responded to in a felicitous manner and the remarks were enthusiastically received. Eugene F. Phillips, Mayor McGuinness of Providence, George R. Stetson, vice-president of the National Electric Light Association, H. F. Wood, of the West End Street Railway, Boston, and Hon. J. C. Wyman were among the speakers. Silver headed canes with the inscription, "Souvenir American Electrical Works' Clambake" were presented to the guests. The party then returned to the city in special trolley cars, all feeling that the gathering had been a great success.

The annual reports for the year ending June 30, 1897, of the two operating companies of the Brooklyn Rapid Transit Company, namely, the Brooklyn Heights Railroad Company and the Brooklyn, Queens County & Suburban Railroad Company show that the former company has a surplus of \$112,492 against a deficit of \$13,109 for the previous year, and that the latter reduced the deficit from \$93,727 in 1895 to \$55,116 in 1896.

SWITCHBOARD.

sections on the different lines range from 300,000 c. m. to 1,000,000 c. m. in area, with a total area of 7,786,000 c. m., and all are made sufficiently large to operate 50 per cent more cars in case the travel demands them. The 20 large feeders are carried from the panels to the wall, and thence along the wall on porcelain insulators in a neat and systematic manner, thence through the openings in the wall, where they leave the building and are carried on iron poles to the elevated railway structure, at which point they branch to the various roads. The longest feeder is that carrying current from the power house to the west end of the Armourdale and Argentine line; it transmits power to cars 28,300 ft. from the power house. The negative bus bar, which is 2 in. in diameter, is supported on insulated hangers under the gallery floor about 4 ft. back of the generator panels. Four 1,000,000-c. m. cables are carried from the negative bus bar through brass tubes down to and through the engine room floor into the basement, then through a duct under the street to a column of the elevated railway structure. They are carried up the columns on the structure, then branch in different directions to the several roads. Each feeder and generator panel is provided with lightning arresters, all terminating in one ground plate, which consists of 72 sq. ft. of 16 gauge sheet copper. This ground plate

## BERLIN ELEVATED RAILWAY.

An elevated railway for Berlin was first proposed by the Siemens & Halske Company in 1880, the plan being to support the road on a single line of columns. This plan was approved by the municipality but violently opposed by abutting property owners on several of the streets, who appealed to the Emperor and finally secured the abandonment of the scheme. After ten years, the great increase in the street traffic in Berlin led to the renewal of the project

BERLIN ELEVATED ELECTRIC RAILWAY.

for an elevated road, and this time it met with greater success.

The road will be 4.7 miles in length, extending from the Zoological Garden to Warschauer place, with a branch to Potsdamer place; it is a double track structure throughout. It is to be operated by electricity. Work was begun September 10, 1896, and it is to be completed by March, 1898, under a penalty of \$10,000.

The Siemens & Halske Company received a franchise for

THE UNDERGROUND LINE.

a term of 90 years, beginning March 15, 1896. After four years the company is to pay the city 2 per cent of the total gross receipts, provided they do not exceed \$1,500,000; 2½ per cent if the receipts reach \$1,750,000, etc., the rate on the whole amount being increased ¼ per cent for each \$250,000 increase in the gross income. The minimum is, however, \$5,000. The rate of fare is left to the discretion of the company for the first seven years, after which it is to be fixed by the authorities. Trains are to commence running from both ends at 5:30 a. m. and continue at not less than

5-minute intervals until midnight or half an hour later, depending upon the season.

The illustration shows the type of the structure. The minimum clearance or headway is fixed at 18 ft. The curves have a minimum radius of 900 ft.

From the Potsdamer railroad station an underground line will extend north to the river Spree and thence along the river, in an open gallery just below the pavement, to the Castle bridge. The total length of the underground portion is about two miles.

The second of the illustrations, which are reproduced from the *Zeitschrift für Kleinbahnen*, shows the arrangement very clearly. Where completed through trains will be operated from each terminus to each of the other two termini of this combined overhead and underground electric line.

There are to be 13 stations, the average distance between them being 3,100 ft. The buildings are as simple as possible in design.

## SEVERE STORM IN WASHINGTON, D. C.

We have received from G. B. Coleman, general manager of the Metropolitan Railroad, Washington, D. C., particulars of the severe electrical storm in that city on August 10. It struck Washington about 8 o'clock and lasted 45 minutes, during which an enormous volume of water fell.

From 4½ street and Maine avenue to 9th and B streets, a distance of nearly a mile, the conduits were entirely flooded. Along Missouri avenue and near the Baltimore & Potomac Depot the water in some places was between 3 and 4 ft. deep, making it utterly impossible for even a vehicle drawn by horses to pass along. In addition to this, along Connecticut avenue, on the F street branch of the Metropolitan, the water rushed like a river, and in Georgetown at 32nd street the water was 2 ft. deep along the streets. In passing from Dupont Circle down P street the Metropolitan tracks cross what is known as the R street bridge over Rock creek. At this point the water rushed as if the heavens had opened the flood gates; the bridge was entirely submerged and the tracks covered to a depth of over 3 ft. It was not alone the underground road that was stopped for a few minutes, but every suburban road leading from the city was disabled; even the cable cars that cross at 7th and B streets were stopped by the tremendous flow of water at that point. The storm was a most unusual one and the water fell so rapidly and the streets filled so quickly that before one of the Metropolitan cars could get out of danger the entire street was flooded, covering the car motors and causing them to burn out. In this connection Mr. Coleman says: "I must say that this road fared much better than the others, as we had but one motor burned out, whereas I am told that many of the suburban motors were destroyed. After the storm ceased it was but a few minutes before our entire schedule was in operation as with the exception noted none of the cars were injured."

Within a brief period the Calumet Electric Railway Company of Chicago lost 3,000 ft. of trolley wire from unused portions of its lines. The Suburban and other companies on the south and west sides have suffered similar losses. Martin Chermavich and Vincent Novac had in their possession 75 lbs. of trolley wire cut in foot lengths when arrested by the police. It is thought they are a part of an organized gang of wire thieves.

## COST OF TRACK CONSTRUCTION.

When the Denver Consolidated Tramway Company decided upon the reconstruction of its tracks, the consulting engineer for the company, John A. Beeler, prepared specifications for a number of methods of construction which, with the estimates of the cost, were submitted to the directors. Of the 11 sections which we publish, some are better than others; section M is considered the most durable and practicable, and therefore the most economical, though sections A, F and H are all first-class.

The estimates of cost are per mile of single track including pavement 7 ft. 6 in. wide.

Section A. 72-lb. rail—plastic bonds—hewn red spruce ties, 24 in. center to center—hydraulic cement concrete foundation 6 in. deep under ties and between ties—basalt block pavement . . . . . \$26,940

Section B. 72-lb. rail—plastic bonds—hewn red spruce ties—gravel foundation 9 in. deep under ties—hydraulic cement concrete 6 in. deep under blocks, between ties, and at ends of ties—basalt block pavement . . . . . \$23,000

Same section with gravel under and between ties and hydraulic cement concrete under blocks at ends of ties only . . . . . \$21,570

Section BB. 72-lb. rail—plastic bonds—creosoted ties, 4 in. x 8 in. x 6 ft., 24 in. center to center—gravel 9 in. deep under ties and between ties—hydraulic cement concrete

foundation for pavement 6 in. deep beyond ends of ties—basalt block pavement . . . . . \$21,500

Similar to Section D. 72-lb. rail—plastic bonds—hewn red spruce ties, 24 in. center to center—hydraulic cement concrete 6 in. deep under ties—asphalt pavement with basalt block tothing (instead of steel flange as shown) . . . \$24,700

Section F. 72-lb. rail—plastic bonds—creosoted ties 4 in. x 8 in. x 6 ft., 24 in. center to center—hydraulic cement concrete foundation under ties and at ends of ties—1-in. sand cushion tamped under ties—gravel between ties—basalt block pavement . . . . . \$24,130.

Section G. 72-lb. rail—plastic bonds—four creosoted ties, 5 in. x 8 in. x 5 ft. 6 in., and four tie rods to each rail—Portland cement concrete under rails—asphalt pavement with stone tothing . . . . . \$25,360.

Section H. 72-lb. rail—plastic bonds—creosoted ties, 4 in. x 8 in. x 5 ft. 6 in., 24 in. center to center—hydraulic cement

concrete 6 in. deep under ties—*asphalt pavement with stone tothing*.....\$23,950.

Section J. 72-lb. rail—*plastic bonds—all concrete construction—Portland cement concrete stringers under rails—tie rods 5 ft. apart—*asphalt pavement with stone block tothing**.....\$25,750

Section K. 72-lb. rail—*plastic bonds—four creosoted ties, 4 in. x 8 in. x 6 ft., and four tie rods to each rail—Portland cement concrete strips under rails—*asphalt pavement with stone block tothing**.....\$23,300

Section L. 72-lb. rail—*plastic bonds—hewn red spruce ties, 6 in. x 8 in. x 7 ft., 36 in. center to center—tie rods 6 ft. apart—*hydraulic cement concrete foundations 6 in. deep under ties—Portland cement concrete under rail between ties—*asphalt pavement with stone block tothing***..\$25,340

Section M. 72-lb. rail—*plastic bonds—creosoted ties, 5 in. x 8 in. x 5 ft. 6 in., 24 in. center to center—*hydraulic**

*concrete foundation 6 in. deep under ties and under pavement beyond ends of ties—*concrete between ties—1-in. sand cushion tamped under ties—*basalt block pavement,***.....\$26,280

## CHEAP FARES AT SAGINAW.

Since the Union Railway Company of Saginaw, Mich., went into the hands of a receiver the fare has been uniformly 5 cents. The question of rates of fare was brought up before Judge Snow of the circuit court at Saginaw. Then Receivers Loring and Morley presented a petition asking permission to issue regular tickets at the rate of six for 25 cents, and if this plan worked well labor and school children's tickets would be sold at reduced rates.

The court said he had been doing considerable corresponding of late relative to street car fares and had made up his mind that cheap fares were best both for the people and the company as the extra patronage on account of the cheap fares would increase the receipts. The court believed in educating the people to use the cars. He said it was no inducement for a poor man to invest 25 cents for six tickets. He then ordered that the receivers have tickets printed at once, the regular price to be seven for 25 cents; labor tickets, good for manual laborers only, until 8 o'clock in the morning and from 5 to 6:30 in the afternoon, to be sold at the rate of nine for 25 cents, and school children's tickets, nine for 25 cents. The fare to Riverside park will be straight 5 cents. It was embodied into the court's order that tickets should be placed on sale at prominent business places at the east, west and south sides. Conductors may handle them but that matter has not been decided.

The sale of labor tickets will be limited to actual wage earners not receiving more than \$2 a day, the name of the purchaser, his employer and the wages received shall be written on the cover of the book of tickets. The bond holders feel that the reduced fares will keep the road in a continued state of insolvency and will likely carry the matter to the state supreme court.

## THE TROLLEY DAY FAD.

"Trolley Day" was the invention of a bright Syracuse woman, as a novelty in the way of charity schemes, and was a great success there, as it has since been in nearly all the cities of the country. "Trolley Days" this year have been numerous, and the novelty of society belles and handsome young matrons collecting fares and ringing the front platform bell does not seem to lose its charm on the susceptible young man or the dignified paterfamilias.

One of the cities in which worthy charitable objects have been thus benefitted during the past month was St. Louis, and the receipts are reported to be highly creditable to the generous citizens of that place. The man who had the temerity to offer a pass or ticket was easily induced to change his fare to a coin of good size by the winning smiles of the young ladies, and no one could fail to decline when asked if he desired any change in return. One of these passengers after offering a pass, and substituting a half dollar net, spent his time the balance of the trip and evolved the following:

Oh, this is the day that the girls take the pay,  
 When you on the street car ride;  
 And passes don't go, but they take the dough,  
 And keep the change beside.

## STREET RAILWAY SERVICE REQUIRED BY THE MUNICIPALITY.

At first the street railway systems of America might have been said to be the direct results of the rapid growth of American cities, but that point was soon passed and the converse became true; street railways today are the cause of the rapid territorial expansion of municipalities. The position they occupy is a very important one, and without doubt must continue to become even more so; human ingenuity has as yet been unable to devise any other method of satisfactorily handling the large passenger traffic of cities with so little delay and inconvenience, and at so low a cost.

No other institution is subjected to the same extent to municipal supervision and control and no other franchise which involves such large interests is so made to depend upon the consent of local authorities; that such is the case is of course due to the fact that the railway and the municipality have each stimulated the growth of the other, but it is none the less unfortunate that street railway operation, a purely business matter, should depend to the extent that it does upon those who administer our municipalities, when that is the most conspicuous failure that we have made in government.

In the absence of constitutional restrictions the state legislature has such control over highways that it can authorize the construction and operation of street railways without the consent of local authorities. Eleven states have, however, constitutional provisions making the granting of franchises subject to the local authorities, and 15 others have enacted statutes to the same effect. The franchise being thus made to depend upon the consent of the city, an opportunity is given for the latter to prescribe all sorts of regulations, and these regulations have in some instances extended to nearly every branch of street railway construction and operation. Such attempts at regulation are natural, but they are not always wise; in fact, very seldom so. The reduction of fares, the paving of streets and the details of track construction are at the present time fruitful sources of trouble.

It is here the intention, however, to speak rather of some details of operation, such as the regulation of the headway, the hours during which cars must run and the rate of speed; that is, as to the service which city regulations prescribe.

The power to make regulations on these subjects is either reserved in and made a condition of the grant of the franchise or the attempt is made to exercise it as a "police power" delegated to the municipality by the state. Such regulations are valid if made in pursuance of statutory authority and not in violation of vested rights. Judge Cooley says: "The limit to the exercise of the police power where charter rights are involved must be this: the regulations must have reference to the comfort, safety or welfare of society; they must not be in conflict with any provision of the charters, and they must not, under pretence of regulating, take from the corporation any of its essential rights and privileges which the charter confers. In short, they must be police regulations in fact and not amendments of the charter in curtailment of the corporate franchise."

As to the attempt to prescribe the headway it was decided by the courts as early as 1863 that "an ordinance passed for the purpose of compelling a company to increase the number of or frequency of its trips daily can not affect either public or private rights under an existing charter or ordi-

nance." And even where the right to prescribe the number and frequency of trips has been expressly reserved the ordinance can not be enforced in case it should prove unreasonable.

Speed is a proper subject for the exercise of the police power, and most cities have passed ordinances; in the absence of action by the city the cars may be run at any safe speed, which they should be permitted to do in all cases.

With the object of ascertaining the extent to which cities attempt to regulate the operation of street railways with regard to speed and headway and the time of running the first and last cars, inquiries were sent to different companies asking for information on these points. The questions asked were:

Is a fixed headway required by franchise or city regulation?

Are there any regulations as to time of first and last car?

Are there any regulations as to night cars?

To what rate, if any, is the speed of cars limited?

Perhaps there is no better way of showing the diversity of the requirements than to give a number of the answers received.

Little Rock, Ark. On a portion of the lines the headway is fixed at 20 minutes; cars are to run from 7 a. m. until midnight; there are no regulations as to night cars or speed.

Nashville, Tenn. On one line of the Nashville Street Railway the headway is fixed at 30 minutes; no regulations as to time of running cars or night cars; the speed is limited to 9 miles per hour in the center of the city and 14 miles in other portions.

Memphis, Tenn. No regulations on these points except that the speed is not to exceed 15 miles per hour in the city limits.

Atlanta, Ga. The Atlanta Consolidated is not restricted on any of these points except as regards speed; a city ordinance provides that the speed shall not exceed 6 miles per hour within a quarter of a mile of the Union Passenger Depot and at street crossings, and aside from this is not to exceed 15 miles per hour.

Charleston, S. C. No regulation as to headway and time of running cars; speed is limited to 6 miles per hour on King street, a narrow crowded street about two miles long, and otherwise to 15 miles.

Wheeling, W. Va. No municipal regulations on these points.

Denver, Col. The Denver Consolidated is subject to no regulations as to headway and night cars, but is limited to a speed of 8½ miles per hour in the business section of the city and to 12 and 15 miles in the outside territory and suburbs.

Salt Lake City, Utah. No mention is made in the franchise of the Salt Lake City Railroad Company of headway or time of running cars; the speed is limited to 12 miles per hour.

New Orleans, La. On most of the lines of the New Orleans Traction Company the headway is fixed by the original franchises at 5 minutes from 5 a. m. to 10:30 p. m.; night cars run from 10:30 p. m. to 5 a. m. on varying headways of from 30 to 60 minutes on about two-thirds of the lines; speed limited to 12 miles per hour.

Kansas City, Mo. In the case of the Metropolitan the headway on most of the lines is fixed by the franchises at 5 minutes or less until after 10 p. m., when it may be 10

minutes; cars must run from 5:30 a. m. to 12:30 a. m.; on different routes the speed varies from 8 to 12 miles per hour.

Butte, Mont. At least four cars each way must be run daily, otherwise no headway or time limits are fixed; the speed is limited to 8 miles per hour.

Omaha, Neb. By the city charter of Omaha it is authorized "to regulate and prescribe the time and manner of running street cars within the city limits," but has not seen fit to exercise this power except by fixing the maximum speed in the business portion of the city at 8 miles per hour; other matters are left to the discretion of the company.

Los Angeles, Cal. The headway is fixed at not less than 15 minutes; cars must run as late as 11 p. m.; the speed is limited to 8 miles per hour.

Spokane, Wash. On some of the lines of the Spokane Street Railway the headway is fixed at 30 minutes, on others it is not fixed; the speed is limited to 8 miles per hour within prescribed limits and to 12 miles otherwise.

Oakland, Cal. On the lines of the Consolidated the headway is fixed at 10 minutes; there are no regulations as to the time of running cars; the maximum speed is fixed at 8 miles per hour by ordinance.

Duluth, Minn. On one line operated by the Duluth Street Railway, the Lakeside line, the headway was formerly 12 minutes, but has been changed to 40 minutes, otherwise no regulation; no time fixed for first and last cars; speed is limited to 12 miles per hour, except for nine blocks in the center of the city where it is 8 miles.

Toledo, O. Cars must be run at intervals of 30 minutes for 16 hours each day, the first to start at 6 a. m.; no regulations as to night cars or speed.

Philadelphia, Pa. The ordinance granting the right to use electricity for motive power provided that cars should be run at intervals of not less than 5 minutes between the hours of 6 and 9 a. m. and 5 and 8 p. m., and at intervals of not less than 10 minutes at all other hours of the day, except from midnight to 5 a. m., when it may be one hour; no limit as to speed.

Washington, D. C. The charter of the Metropolitan provides that during the day cars shall be run as often as every 4 minutes, as often as every half hour until midnight, and as much oftener as public convenience may require; there are no charter requirements as to the time of the last car; the speed is limited to 12 miles per hour within the city, 15 miles outside, and 6 miles at crossings.

Harrisburg, Pa. No city regulations on these points except that the speed is fixed at 8 miles per hour within the city limits.

Albany, N. Y. No regulations on these points except as to speed, which is 8 miles per hour in the center of the city and 12 miles in the outskirts.

St. Louis, Mo. All companies are required by city ordinance "to start one car from the terminus between the hours of midnight and 1 a. m. of each day and every hour and a half thereafter until the time fixed for the starting of cars on regular day trips, and the Broadway line shall run cars so that a car shall pass the Court House going north and south at 1 a. m. each day and every hour and a half thereafter until 5:30 a. m.;" otherwise there are no regulations as to headway; the speed permitted varies on different lines, the rates being 10, 12 and 15 miles per hour.

Quincy, Mass. Headway varies from 8 to 16 minutes on different lines; the last car must leave the city not earlier

than 11:30 p. m.; the speed is limited to that usual in other cities similarly situated.

Manchester, N. H. No regulations on these points.

Boston, Mass. In one or two isolated instances the minimum headway on the lines of the West End road is 30 minutes, and in these cases the cars must run between 6 a. m. and 9 p. m.; the speed is fixed at 7, 9 and 12 miles per hour in different parts of the city.

Holyoke, Mass. No regulations on these points.

New Haven, Conn. No regulations on these points except as to speed, which may not exceed 10 miles per hour within 1 mile of the center of the city and 12 miles elsewhere within the city limits.

Providence, R. I. The speed is limited to from 8 to 14 miles per hour according to the route.

Portland, Me. No regulations on these points except as to speed, which is limited to 10 miles per hour.

Erie, Pa. Headway fixed at 10 minutes; cars must run from 6 a. m. until midnight; no limit as to speed.

Montreal. Headway fixed at 5 minutes from 6 a. m. till 7:30 p. m., and at 10 minutes from then until midnight; may run after midnight and charge double fare; speed limited to 8 miles per hour.

Toronto. Service must be approved by the city engineer; first car at 5:30 a. m., last at midnight; speed, average for round trip, 10 miles; in certain parts of the city, 6 miles.

This may be summarized as follows: On 11 of the roads reported the headway is fixed by the city; on six roads the headway is so fixed for a portion of the lines only; on 15 there are no regulations as to the headway. When the headway is prescribed it is between certain hours of the day which also fixes the time of running the first and last cars. But three of the 32 companies report that they are required to run owl cars; these are in Washington, Philadelphia and New Orleans, and in New Orleans the requirement extends to but 10 out of 15 of the company's lines. The speed is regulated by ordinance on 25 of the 32 roads.

The subject of headway will always be taken care of by the law of supply and demand. When the traffic justifies the running of cars the company is only too glad to run them; when the traffic does not justify it any requirement on the part of the city is apt to be unreasonable.

The same may he said of the night service.

There is no reason to suppose that the street car service in Boston is not as satisfactory to the patrons as that of Philadelphia and New Orleans, though the latter require a short headway, and the former what is practically none at all. The example of Omaha is to be commended; while reserving the right to prescribe regulations it has been found that the best of results are obtained where the matter is left to the discretion of the company.

The Old Colony Trust Company of Boston, brought suit against the Allentown & Bethlehem Rapid Transit Company on a mortgage for \$200,000, which the defendant alleged was fraudulent. John Rupp, as referee, decided that the mortgage is valid.

The two street railway systems and the two lighting companies of Paducah, Ky., have been combined. The Paducah Street Railway Company absorbs the Peoples' and the lighting plants will be operated under the name of the General Electric Company. The consideration for the transaction is \$50,000 cash and \$85,000 in bonds.

G. M.

The heads of departments will fill out this requisition and forward to General Manager for approval.

FORM 8.—REGULAR SIZE, 8 1/2 x 9 1/4 INCHES.

uniform price, at which the manufactured article is credited to the foundry, the idea being to prevent the confusion which would naturally arise from fluctuations either in the price of material or labor. The profit or loss at this price is credited or charged to suspense account until the end of the year.

In securing new material to take the place of that which is out of service, the old material is first returned and inspected by the mechanical department, and then divided into two classes, scrap and second hand material. According to the class in which it falls, credit is allowed on the new material taken out, and new material, such as trolley wheels,

for example, to take the place of old can only be obtained by the return of the old, in whatever shape or condition it may be.

In this mere outline it will be seen that all possible holes for leakage are stopped, while at the same time the system offers every facility for reference, in order that all material may be followed throughout its entire course from the date ordered to the time when put in use. In fact, no material is paid for that is not received, none is paid for twice, and no supplies are delivered from the storeroom that are not accounted for and charged to some account.

**RAILS AND POLES TAXED AT TORONTO.**

Judge McDougal has decided that the Toronto Railway Company must pay the taxes on its rails, poles and wires, as assessed by the city.

The decision was in part: "It is now urged that the question to be determined, viz., the liability of the Toronto Railway Company to an assessment upon its rails, poles and wires, is res adjudicata, it having been decided in an appeal from the assessment in question heard before the Board of County Judges in July last that the railway company is not liable to such assessment. It is true that this is the effect of the judgment pronounced by the judges composing the board; but the question had been already decided by the same two judges in an appeal heard in 1896. But since that date a judgment has been rendered in the supreme court of Canada in the case of the Consumers' Gas Company v. Toronto, affirming the liability of the Gas Company to assessment for its mains; and the chief justice of the court, besides so holding, went on to point out that there was no distinction between gas mains and street rails, and stated expressly that the case of Fleming v. Street Railway Company, decided by the court of appeal, 37 U. C. reports, must now be held to have been wrongly decided. It was largely, though not entirely, upon the strength of this case of Fleming v. Toronto Street Railway Company that the two county judges decided, in 1896, that the rails, poles and wires of the Toronto Railway Company were not liable to assessment. In the later judgments of July last, Judge Dartnell says he expresses no opinion as to the effect of the supreme court decision in the Consumers' Gas cases upon the appeal then being considered, and reaffirms his former judgment on other grounds.

"The appeal will be allowed, and the original assessment made by the assessment department against the rails, poles and wires of the Toronto Railway Company be restored to the roll."

### FAILURE OF COAL POCKET AT PATERSON, N. J.

A very serious and singular accident occurred at the station of the Edison Illuminating Company at Paterson, N. J., on August 14, which compelled a complete shutdown for 31 hours.

This station was recently built and very carefully designed, the endeavor of the management being to make it a model in all respects. It is the only station in Paterson, a city of about 100,000 inhabitants, and therefore particularly important. The output consists of high-tension series arc current, direct current at 230 volts for interior lighting and power current at 500 volts furnished to the street railways.

The station equipment comprises six Stirling boilers, rated at 435-h. p. each, which supply steam at 150 lbs. pressure to nine vertical cross-compound Ball & Wood engines. All but two of the engines are direct connected to Edison multipolar generators. The aggregate capacity of the engines is 5,750-h. p.

A large V-shaped coal pocket was built over the front of the boilers. This pocket was of iron, 32 ft. wide, 20 ft.

SKETCH SHOWING COAL POCKET AND BOILERS.

POCKET PLATING RESTING ON TOP OF BOILERS.

deep and 105 ft. long, with its base 19 ft. above the floor. The sides were tied together with diagonal trusses of angle iron, as shown in the diagram, at intervals of 16 ft. The pocket was supported cantilever fashion on I-beams which rested on columns.

At 4:30 o'clock, August 14 (the pocket being filled with approximately 1,000 tons of buckwheat anthracite coal), the right hand side of the pocket, as seen in the sketch, bulged out and broke, dumping hundreds of tons of coal on the floor below. Almost immediately the entire pocket, relieved of its load on one side, canted to the left and fell on the tops of the boilers. The result was a complete wreck of the main steam supply system.

The 14-in. steam header was ripped out, and a part of it was thrown to the floor below. The nozzle of every boiler was parted, steam drums were driven in, flanges cracked, safety valves wrecked, and the system generally destroyed. In five minutes' time all steam had escaped, making a vent by bursting a section of the roof. A fair idea of the confusion may be obtained from the accompanying illustrations, which

were taken Monday, after two days had been spent in clearing up.

Fifteen minutes after the crash men were at work shoveling away the coal and running a new steam main. At 11:30 p. m. of the following day, the arc lights of the town were re-lighted, one of the end boilers having been put into operation. In another 24 hours a temporary 8-in. header had been erected, and the other end boiler of the battery fired up. These two boilers were obliged to carry the whole load for a week or 10 days, while the intermediate ones, which were more seriously affected, were repaired. During the day, August 16, three of the 650-h. p. engines were running heavily loaded and supplied by the one 435-h. p. Stirling boiler. No trouble was experienced from water in the steam or other causes. The output was over 1,000 amperes on each side of the three-wire system, and approximately 1,200 amperes at 550 volts.

The power station at Rutherford supplied current to the White line of cars and the Paterson & Newark line received a scanty supply from a small station at Nutley.

TOP OF BOILERS AND STEAM HEADER.

## CREATING TRAVEL.

H. Milton Kennedy, who is the resourceful general passenger agent of the Brooklyn Rapid Transit Company, in discussing the necessity of working up excursion business on trolley roads, said:

"On a steam road the company asks its patrons to spend dollars, while on a trolley system we ask them to spend nickels, so how much more will they be open to persuasion? A resort to which a steam road carries passengers costs at least a dollar to reach, and it is an excursion people think about before taking, and they do not take it very often. With a nearby resort, reached by a trolley line, a man will make up his mind on an instant, perhaps, on seeing an advertisement. He can reach there in an hour or less, and

## POWER HOUSE OF THE MARKET STREET RAILWAY, SAN FRANCISCO.

The Market Street Railway Company of San Francisco operates by far the largest system in the far west. It includes twelve transportation companies, which were consolidated under one management in 1893. At the present time the system comprises 190 miles of track, of which 26.9 are operated by horses, 60.5 by cable, 19.7 by steam and 82.9 by electricity. Prior to 1894 none of the lines were electrically operated; the work of changing the motive power began on the Metropolitan in that year and has been extended to the other lines as rapidly as circumstances would permit, until now over 40 per cent of the total mileage is operated by electricity.

FIG. 1—GROUND PLAN, BRYANT STREET STATION, SAN FRANCISCO.

it only costs 5 cents, and with a few more nickels he can spend an enjoyable evening. There are thousands of people who have a quarter, or 50 cents to spend who will go to a nearby resort in the evening if they think they can have a good time, and many of them have families they will take with them. It is my business to tell them where to go and what to do when they get there. For that purpose I keep in touch with all the proprietors of the summer resorts around the city, and just as soon as a novelty is introduced I let the people know of it, either by means of placards on the cars or else I fix up some sort of an attractive circular, always striving to avoid the commonplace."

Torquay held a public meeting recently to consider the electric railway scheme.

The electric power station, known as the Bryant street power house, occupies a block 165x199 ft., bounded by Bryant, Alameda, York and Channel streets. Work was begun in 1893 and one-half of the present building finished in the following year; since then the building has been completed and its capacity quadrupled. With the completion of this station the one on Carl street, formerly used to supply the Metropolitan lines, was abandoned. The location of the station is near the center of the car district and favorably situated for supplying the new districts now being developed.

The building is of brick, one story high. The fire room fronts on Channel street and is alongside the steam railroad track and convenient for coal supply. The engine room is separated from the boiler room by a 24-in. wall, and fronts on Alameda street.

The roof of the engine room is supported on trusses which span the room and leave it clear for the operation of the crane; the boiler room roof is in three sections, the trusses resting on the side walls and two rows of columns.

FIG. 2—CROSS SECTION—GENERAL ELECTRIC END.

When first equipped the capacity of the station was 1,800 h. p. The plant was started early in September, 1894, and was run non-condensing until the following April, awaiting the completion of the pumping station which was to supply the condensing water.

Fig. 1 shows the ground plan of the station, the right hand portion in the cut being that first built. Fig. 2 is a cross section through the General Electric end of the station, and Fig. 3 a cross section through the Siemens-Halske end.

The present boiler equipment comprises 36 boilers of the "elephant" type, arranged in batteries of three; all of them are 64 in. in diameter by 16 ft. long. Nine of these, those first installed, are designed to carry 130 lbs. working pressure and are fitted with the United States rocking grates and operated under natural draft. The other 27 boilers are designed for 160 lbs. steam pressure and are

equipped with the Roney mechanical stoker and operated on the Howden forced draft system.

The engines are eight in number, all built by the Union Iron Works, San Francisco; two vertical compound condensing 300-h. p. engines, cylinders 16 and 28x24 in., speed 160 r. p. m., with cranks 180° apart; two 600-h. p. engines of the same type, cylinders 22½ and 39x24 in., speed 160 r. p. m., with crank 180° apart; and four vertical triple expansion engines, with cylinders 20, 30 and 44x30 in., running at 150 r. p. m.

The compound engines were those first installed. The smaller of these have one and the larger have two fly-wheels, each 9 ft. in diameter and 25 in. across the face and weighing 12,000 lbs. Each fly-wheel is belted to the pulley of its generator by a 24-in. double leather endless belt. Each engine is equipped with independent condenser and air pumps, the circulating water being supplied from the

FIG. 3—CROSS SECTION—SIEMENS-HALSKE END.

pumping station under sufficient head to do away with the necessity of circulating pumps in the central station. Steam is furnished to each engine from a large receiver, the admission to the high pressure cylinder being controlled by a shaft governor of the 1de type; the cut-off on the low-pressure cylinder is fixed. Both cylinders are steam jacketed.

In the triple expansion engines, the receiver from which steam is drawn to the engine, is a part of the high pressure cylinder casting and acts as a jacket for that cylinder. The same method of governing is used for these engines as for the smaller ones; the cut-off on the intermediate and low pressure cylinder is fixed and a shaft governor used for the high pressure.

All cylinders and covers are jacketed and the valves are fitted with balance pistons on continuations of the valve stems. The air pumps for these engines are driven from the intermediate crossheads by rocker arms and the condensers are a part of the bed plates and have the circulating water outside of the tubes in contact with the bed plate. All the bearings and slides are arranged for water circulation, the supply being taken from the injector by a donkey pump, and the discharge from each bearing is in plain view from the back of the engine. The top platforms of these four

FIG. 4—CENTRAL PANELS OF SWITCHBOARD.

engines are connected by flying bridges so that there is a continuous path for the oiler from one engine to another. On these engines the cranks are at  $120^\circ$  and no fly-wheels are used, the Siemens & Halske armatures serving as such.

a ground return with an auxiliary wire so connected at the power house as to be inside the circuit breakers and fused at the pump station so as to be disconnected from the ground and used as a return in event of the main breakers going out.

There are 14 generators in the station all connected to the same bars in multiple, the necessary adjustments being made by shunts across the positive and equalizer wires at the back of the switch board, so that the load is equally distributed among the machines according to the capacity of each. There are six 200-k. w. G. E. compound wound railway generators, 500 to 590 volts, 480 r. p. m., belted to the four small engines, one to each of the 300-h. p. and two to each of the 600-h. p. Eight 400-k. w. Siemens & Halske external armature generators, 500 to 590 volts, are direct connected to the 1,300-h. p. engines, one at each end of the shaft. The leads to the switchboard are taken down through the engine room floor into the large conduits and up the back of the board to the terminals.

The switchboard, which is designed for a maximum out-put of 10,000 amperes, is of white California marble, 2 in. thick. It is 59 ft. long by 8 ft. high, and is set 5 ft. from the wall midway of the length of the engine room. There are 29 panels, 2 ft. wide; the 14 to the right of the center are connected to the generators and those at the left to the feeder circuits. The center panel is fitted with Weston illuminated dial ammeter and voltmeter, the latter on a swinging bracket and the former connected in the bus bar between the generators and feeders. A Thomson recording wattmeter and a log desk complete this panel. Each generator panel has mounted on its face a Weston illuminated dial ammeter, a Westinghouse circuit breaker, a shunt field rheostat, a cut-in voltmeter plug, a triple-pole main switch and a Siemens & Halske carbon shunt field switch, which

FIG. 5—1,300-H. P. UNIT.

The system of lubrication is very economical of oil, but 50 gallons per month being used for the eight engines. Reservoirs are placed about the engines, from which the oil is fed to the bearings by means of wicks, as is the common marine practice. The drip is returned to filters placed alongside the main supply tank, which is under the engine room floor, and when filtered the oil is pumped into the main tank under an air pressure of from 15 to 20 lbs. and thence carried to the reservoirs on the engines.

The water for condensing is drawn from San Francisco bay at a point about 6,000 ft. from the station and delivered through a line of 36-in. cast iron pipe. The pumping station is equipped with two centrifugal pumps, driven by 150-h. p. G. E. motors. These motors receive current from the power house and are controlled by rheostats in the field and armature circuits. Only one motor is used the other being held as a reserve. The water is supplied under a pressure of about 15 lbs., which is controlled by a stand pipe in the pump house.

The discharge from the condensers at the power house is through a system of piping connected to the street sewer. The arrangement is such that the pipes act as siphons and relieve the pumps to some extent. When starting in the morning one of the small engines is run non-condensing to start the pump motor. Salt water is used by the water cars for sprinkling, and the fire system is so arranged that the pump may draw from either the supply or discharge of the circulating pumps. The pumping station is operated on

FIG. 6—GENERAL VIEW OF ENGINE ROOM.

opens the shunt circuit gradually through a pair of carbon points, slowly separated by means of a worm gear and crank. The generators being of different sizes the scales on the ammeters are so graduated that a correct distribution of the load is indicated when the pointers are all in the same angular position.

Each feeder panel is arranged to supply four circuits, each of 400 amperes, and has a round dial Weston ammeter, a Westinghouse circuit breaker, and a single-pole switch for each circuit. The top and ends of the board are finished with teak molding, and the illuminating lamps set along the top molding. The feeder wires lead from the bottom terminals of the switches through the floor and along the conduit underneath to the end of the building, thence up and out.

Figs. 4 and 7 show views of the switchboard. Fig. 5 is from a photograph of one of the 1,300-h. p. units and Fig. 6 a general view of the generating room. Fig. 8 shows the exterior of the station.

At the present time the maximum output of the station reaches 6,000 amperes and the average for 24 hours is 2,200 amperes.

### "WORKING RESULTS ON ELECTRIC TRAMWAYS."

(From the Electrical Review, London.)

It is always interesting to get plain talk from go-ahead tramway men, and the STREET RAILWAY REVIEW therefore does a good deed in setting up a "symposium" on the comparison of electric lines with one another, according to the cost per car-mile or per passenger. The symposium, however, is all one way, a practically unanimous opinion being expressed in favor of adopting the cost per car-mile as

FIG. 7.—GENERAL VIEW OF SWITCHBOARD.

a means of comparison. It is not very easy to see exactly what the contributors to, or the originators of, the symposium are driving at; for all practical value in comparison of lines they might as well take the average house rent paid by the respective motormen, or the comparative number of red-headed conductors. Cost per car-mile is readily arrived at; but where is the fairness of comparing line A, which runs through a scattered district, and has a passenger density of, perhaps, five per car-mile, with another line B, in a populous town carrying an average of 10 or 12 passengers per car-mile all the year round? Yet both may have the same working costs per car-mile, for everyone knows that, proportionally, it requires little, or no more, outlay of energy to run cars with a full load than those that are empty. There is all the difference in receipts and net balance however. This tends to show that it is of no value to take simply one side of the account without regard to other conditions, unless the idea is to limit comparison strictly to cost. Tramway shareholders are naturally anxious to see the costs reduced as low

as possible, but they also like to have the cars well loaded. It is not, however, any fairer to take the comparative number of passengers on different lines as a means of arriving at their prosperity or otherwise. Some of the passengers may be "dummies" or "dead heads," some half-rate; nearly all may be paying different fares according to length of travel; some may be counted twice over, if they pay for a continuation of route. Even adopting the car fare as a unit does not give satisfaction, for most lines have a variety of fares according to distance, and it would be difficult if not impossible to reduce them to a standard or typical fare representing the average passenger. It is, of course, easy to see the object of choosing either the car-mile or the passenger as a basis of comparison. In the first case, it costs a definite amount to run a car for a mile, and the less this amount the better the line; in the second case, increase of passengers means increase of receipts and therefore a better line also. A combination of the two seems advisable, but some difficulty will be found in effecting it.

FIG. 8.—EXTERIOR OF STATION.

Certainly it seems of no use taking the passenger unit, a fairer way to our mind is to average the passenger density per car-mile over the whole year. On English lines this varies from 5 to 12, or even more; and an equitable comparison can only be made between those lines which have approximately the same average annual density. Then the cost per car-mile gives a tolerably fair notion of the respective quality of management and design in any two tramway systems. Taken altogether, and regarded as a form of electricity supply, the operation of electric tramways occupies a very peculiar position. The cars have to be run in more or less complete system whether passengers and payment are forthcoming or not. It is equivalent to the position of an electric lighting company which has to keep alight a certain minimum number of its customer's lamps, which are only paid for when they are actually being used. We wonder what electric light supply engineers would say to such a method of obtaining revenue! If electric tramways were on a level with electric lighting companies, they would only be available to a favored group of season ticket holders who would pay a small regular annual fee, and in addition a reduced fare each time they used the cars. Dick, Tom and Harry in the street would have no chance of jumping on for a penny a ride. All which seems to show that electric tramways are even far greater public boons than electric lighting, also that the Wright maximum demand indicator may, bye and bye, have to be adopted also to purposes of a personal and portable nature in connection with the comparative use of electric trams by individuals!

#### PLEASURE RESORT OF THE NEW ORLEANS TRACTION CO.

Few visitors to New Orleans have not taken that most delightful ride out to the West End, where, surrounded by water on three sides, and with the attractions of the ever interesting Lake Pontchartrain, the New Orleans Traction Company has built one of the finest pleasure resorts in the country.

The program provided for the entertainment of the patrons of the road is surprising, both in the quality and quantity of the bill. There are afternoon and evening performances, the latter commencing at 7 o'clock, and lasting until 11:30, and as a sample, taken at random, the following will give a good idea of what is being furnished free to the citizens of New Orleans:

First, a concert of six selections of popular music by full band, followed by a fine acrobatic performance by a troupe of four people. Then the band plays again, after which six scenes are shown with a cinematograph just brought over from Paris. Six pieces by the band and another high wire and trapeze act in which three people occupy twenty minutes. An Edison vitascope presents six pieces, during and after which the band plays. The same amount of entertainment with different music and fresh views and new acrobatic performances follows for each day of that week, making an evening's entertainment fully equal to that provided by most roof gardens, and quite superior to many, which charge 50 cents admission. And yet this is all free and patronized by thousands of the best people of the city.

In reply to an inquiry as to his experience and the future of this feature of street railroading, C. Densmore Wyman, general manager, whose words and judgment will appeal to all in the business, writes:

"Our West End resort is doing finely. We have often on Sundays 12,000 to 15,000 people, and other evenings, when good weather prevails, our attendance is from 2,000 to 3,000. We have a fine band and other attractions, acrobatic and musical. At no place in the United States that I know of is so remarkable and excellent an entertainment provided absolutely free, except the cost of car fare, which is but 15 cents for a round trip of 12 miles, which the trains make in 40 minutes. The location itself is beautiful, being on the lake, and all the surroundings delightful.

"To an old time railroad manager, I imagine the statement that a street railway company should take upon itself a salary list of \$1,500 a week for music and attractions, to say nothing of the cost of the maintenance of hotels, pavilions and garden, and operation of trains, and rely for income upon nothing but car fare of patrons, who are transported such a distance for the small sum of 15 cents; and the company regard the operation as a good financial scheme; would be, to say the least, surprising and a knockout to his antiquated and conservative notions. The fact of it is my experience this summer in the management of a place like our West End has convinced me that ere long the amusement enterprises of the country, in the summer, will be practically conducted by railway companies, and railway managers will have to make themselves au fait with the business of an impresario and amusement purveyor, in all that pertains to the conduct, advertising, etc., of shows."

#### MORE AIR ON THE MANHATTAN ELEVATED.

A new air motor, the product of the American Air Power Company, is being tested by the officials of the Manhattan Elevated Railway Company. The locomotive, which was described in the REVIEW for May, has been in operation in Rome, N. Y., for some time, and it is reported that its work there, as well as the trial trip on the elevated, was successful. The motor in appearance closely resembles the steam locomotives now in service. The tubes are charged at 2,000 lbs. pressure from the compressor plant on Greenwich street and this charge will run the motor for one hour or long enough to make a round trip. The speed of the motor is about the same as that of the old locomotives and there is little noise in its operation. The officers of the railway company have nothing to say in regard to the merits of the machine.

Sanction for the Brompton & Piccadilly Circus Railway has been given by the select committee of the House of Lords. The line will be laid in a tunnel two miles in length, and will be operated by electricity. At South Kensington it will connect with the District Railway.

The line between Kensington Park and Washington street of the Atlantic Highlands, Red Bank & Long Branch Electric Railway Company was built across lots belonging to the Tradesman's National Bank of New York, without proper authority. Representatives of the bank were instructed to stop the cars from running across the lots, which was done effectively by tearing up the tracks and building a fence around the property of the bank. As the company had a terminus at Kensington Park and regular traffic was soon to begin, a conference was held to adjust the difference.

## SHAFTS.

BY E. DEBUS.

At the recent International Congress of Naval Architects and Marine Engineers, held in London during the Queen's Jubilee, a paper on the subject of "Shafts" was read by G. W. Manuel, and the subject was thoroughly discussed by some of the most prominent engineers of both this country and Europe. It was shown that shafts fail generally from two causes; either from flaws made in them during the process of manufacture, or from fatigue of metal due to the work put upon them in actual service.

It was stated that 26 large steamers in the North Atlantic alone had broken their shafts during the past year, and a great many smaller vessels had suffered similar accidents, of which no record was kept. The fact that during the progress of the meeting three of the large Trans-Atlantic liners broke their shafts gave the subject special interest, and many points of value were brought out in the paper and the ensuing discussion.

This subject of shafts is one of vital interest to the street railway engineer. The breakage of this part of the engine is a common accident, and is looked upon by many who have not considered the subject carefully, as unavoidable. Usually engines are bought in the market from the lowest bidder, the guarantee by the builder of perfect workmanship and high efficiency being all that is required.

When the shaft breaks it can be easily shown by the engine manufacturer that a few more miles of track, and a few more cars have been added, and that the service which the engine was called upon to do at the time of the break was more than was calculated when the engine was supplied, and there the matter rests. There are, however, shafts and shafts, and as there is no service, outside of that required by marine work, that is as trying as street railway work, we quote some extracts from the above mentioned paper, feeling that they will be noted by our readers with interest:

"Iron is now less used, especially for crank shafts; steel is gradually taking its place in ocean-going steamers, except for propeller shafts. Iron shafts are, I may say, made up of thousands of small pieces of selected iron, generally termed scrap, cuttings of old iron boiler plates, good navy ship iron, cuttings off forgings, old bolts, horse shoes, angle iron, all welded together, forged into billets, reheated and rolled into bars, cut into lengths, and formed into slabs of suitable size for welding up into the shaft. Before the use of steel generally, considerable improvement on the old method of faggoting, so-called, had been made, more powerful forging hammers used, along with more suitable furnaces and fuel; still, with all this care, I may say there is not an iron shaft without flaws or defects more or less, and when these flaws became placed during the construction of the shaft in proximity to the greatest strain, and though there was no hot bearing (which no doubt would have made matters worse) they often extended until the shaft became unseaworthy and, after all, the best wrought iron shafts that can be made of the finest scrap from the best qualities of selected brands are 60 per cent inferior in strength to the best mild cast steel made on the open hearth system, cast into ingots, and forged down under the hydraulic hammer or press.

"The term mild steel applied to shafts in a general man-

ner does not in my experience represent the condition of the shaft, for I have found there are very great differences in the value and quality of mild steel, even as much as I found in wrought iron, depending largely on the qualities of the iron used and the chemical and moulding operations of converting it into steel, and also the amount and description of mechanical work applied when being forged into shafts. Mild steel was first used by the P. & O. Company in 1880; the dimensions of the shafts were limited by the same rules as those for wrought iron shafts. The steel was made by the best makers, having a tensile strength of 24 tons per sq. in., it being then considered inadvisable to exceed this limit on account of former experiences with high tensile steel. The shafts made were crank shafts and are still running, having been in use 17 years. Up to the present date no flaws of any description have been seen. The engines have been tripled, using the same shafts and bearings, and the working power increased. The percentage above the Board of Trade and Lloyd's rules, which fix the minimum size, is 24 per cent; a percentage above must be allowed, and has been the experience of all ship owners, varying from their records of mishaps and losses and condemnations of shafts by the Surveyors of the Board of Trade and Lloyd's Registry. Since these shafts were first used the tensile strength of mild steel has been gradually increased, and we are now using it at 32 tons per sq. in., possessing equal, if not more, ductility and toughness, to endure even greater stresses than formerly. This has been arrived at by continued improvement in the manufacture by the makers so that the percentage allowed above the rules is now reduced to only 6 per cent, leaving a very slight margin. I mention this, as there is an opinion that the reason some shafts are so free from mishaps is owing to their dimensions being so much above the rules that regulate those sizes, instead of to the superior quality of the material used."

Although many engineers still adhere to wrought iron as a material for shafts, they are becoming fewer annually, and steel is now acknowledged to be the only material suitable for the purpose by those who are most progressive. The latter take great care to specify the quality of steel that shall enter into their shafts. They also go so far as to require that a prolongation shall be left on one end of each shaft from which a test piece can be cut after the forging is finished. Sometimes the chemical composition desired is specified, and sometimes the physical properties are mentioned instead. It is quite common to see the requirements that the sulphur and phosphorus shall be less than .04 of 1 per cent and that the carbon shall not be less than .50 of 1 per cent. This grade of steel has a high elastic limit and gives a very smooth hard surface.

In order to be sure that the ingot from which the shaft is made has no defects in the nature of blow holes in it, best practice requires that it should be cast under pressure in a mould provided with vents to allow the escape of air and gases. This system is known as the Whitworth process of fluid compression, and "fluid compressed steel" is now acknowledged to be the most reliable material for shafts as far as solidity and homogeneity are concerned.

Mr. Seaton, the well known English engineer, who took part in discussing this paper, is quoted in Kent's Mechanical Engineers' Pocket Book, on page 807, as saying: "For wrought iron, the safe stress per square inch should not exceed 9,000 lbs. and when the shafts are more than 10 in. in diameter, 8,000 lbs. Steel, when made from the ingot

and of good materials will admit of a stress of 12,000 lbs. for small shafts and 10,000 for those above 10 in. The difference in the allowance between large and small shafts is to compensate for the defective material observable in the heart of large shafting owing to the hammer failing to affect it."

An instance of this effect of forging under too light a hammer is shown in the diagram given below.

This diagram was made by Prof. J. B. Johnson of St. Louis, to show a series of tests made at the Watertown Arsenal by the United States Government on a 16-in. shaft. This shaft was made of steel, under a 10-ton hammer, from a 30-in. ingot, which was very nearly the proper size, and after it was in service a short time it broke. In order to find out the cause of the break, test specimens were taken out of the metal at various distances between the surface and the center. Specimens 3787<sub>1-2-3-4</sub> were taken. The form of the specimens is shown. The tests are graphically shown by the curves. The test piece 3787<sub>1</sub>, nearest the surface, showed an elongation of 21.4 per cent, and a reduction of area of 32.8 per cent; 3787<sub>2</sub> showed an elongation of 7.2 per cent and a reduction of 5.5 per cent; 3787<sub>3</sub> showed an elongation of 4.9 per cent, practically 5 per cent, and a reduction of 5.2 per cent; and the one nearest the center, 3787<sub>4</sub>, showed an elongation of 2 per cent and a reduction of 1 per cent. In other words, the elongation varied between the surface and the center from 21.5 per cent to 2 per cent, and the contraction varied from 33 per cent to 1 per cent. It is evident, therefore, that the center metal in this forging was practically unworked. In order to be certain that there was nothing in the metal itself that would give this difference, specimens of a larger size were cut out from the opposite side and forged down until they were of the same size as the first. In other words, work was put into the metal that ought to have been put into it when it was first forged, and as a result an average of 25 per cent elongation and 55 per cent reduction was obtained.

To obviate such defects the hydraulic press is now considered the proper tool with which to forge large steel shafts. The pressure applied in shaping a piece of steel should be sufficient in amount and of such a character as to penetrate to the center and cause flowing throughout the mass. This flowing requires a certain amount of time and the requisite pressure should be maintained throughout a corresponding period. All of this is attained by the use of the hydraulic press.

Undoubtedly the highest type of shaft is the hollow shaft. It is lighter and stronger for the amount of metal than any other type. This is the kind of shaft that has been adopted by the various governments of the world for their respective naval vessels. Shafts of this kind are becoming popular in the merchant marine and for yachts. Stern-wheel steamers on the western rivers are also adopting this type of shaft in order to secure lightness and strength. It is getting into general use for commercial work and many street railways have adopted it.

At the last meeting of the Street Railway Association in St. Louis, a hollow shaft, 28 in. in diameter and 25 ft. long, made of fluid compressed steel, was exhibited by the Bethlehem Iron Company. This shaft was one of a large number furnished to street railways in Chicago for engines built by the E. P. Allis Company, the Corliss Steam Engine Company and William Cramp & Sons Ship & Engine Building Company.

Other street railways have also adopted these shafts, notably at Bridgeport, Conn., and the Consolidated Traction Company, at Pittsburg, Pa. These various street railways and engine builders can undoubtedly give full information regarding high grade shafts, and it will be to the interest of street railway engineers to investigate the subject carefully.

### A KAFFIR STREET RAILWAY.

The only street railway in the entire province of Mozambique, Africa, is located in the town of Beira, writes U. S. Consul, U. Stanley Hollis. This railway is about 2 miles in length, built on a 24-in. gage, and its entire rolling stock consists of one flat hand car capable of seating 1 people. Its motive power is from 2 to 4 stout Kaffirs. The Beira Tramway is owned by the Companhia de Mocambique, of that place. There has been some talk of a tramway at Lorenzo Marques, Delagoa Bay, but as yet nothing has been done.

### RAILWAY LINES DESIRABLE IN GALESBURG.

There is a great deal of agitation at Galesburg, Ill., on account of changes and extensions in the lines of the Galesburg Motor & Power Company. The city let contracts for paving the streets on the line running to Lombard University and then the company requested a franchise to relay its tracks on another street. This was vigorously opposed by the property holders along the line who asserted that the removal of the tracks would be highly detrimental to their interests. The company proposed to abandon the old line if the franchise was refused, and it passed the council. The property owners along the route threaten to begin legal proceedings to compel the company to operate over the old tracks.

## INDIANAPOLIS FILES ITS CROSS-BILL.

Our monthly installment of the serial story entitled "3-Cent Fares in Indianapolis," this month consists of an extract from the cross-bill filed by the city in reply to the supplemental complaint of the Central Trust Company, of New York, and the cross-bill of the Citizens' Street Railroad Company. The other defendants were C. S. Wiltsie, prosecuting attorney; E. E. Dill, Fred Wegener, S. R. Miller, Douglass Mitchell and G. L. Payne, who brought suits for damages against the company. The answers to both the cross-bill and the supplemental bill are alike in substance though differing somewhat in form.

These answers admit the incorporation of the street railway company under the act of 1861, the fixing of the fare at 5 cents and the execution of two mortgages on its property for \$300,000 and \$700,000, respectively. They also admit the passage of the Hugg bill, and that Indianapolis was then the only city in the state having 100,000 population.

The answer to the cross-bill of the street railway company denies that the 3-cent fare act is in violation of article 14 of the amendments of the constitution of the United States, or that such an enactment will deprive the company of its property, without due process of law, or deny to it the equal protection of the law.

The answer, continuing, says: "And said defendant avers and charges that said alleged and pretended mortgage indebtedness of \$300,000, \$700,000 and \$3,000,000, thus amounting in the aggregate to \$4,000,000, does not represent any investment whatever in the plant of said Citizens' Street Railroad Company, or its predecessor; that the total cost of the construction and equipment in every way, including the purchase of cars, the laying of tracks, the building of houses, the changing from animal to electric power, at no time exceeded the sum of \$1,000,000, as representing any sum of money placed or invested in said plant by any person or persons whatever; that the total cost of construction and equipment, including all expenses of every kind, character and description, growing out of or connected with the building, equipment and construction of said plant and its appurtenances, amounted in the aggregate to less than, to-wit, \$1,800,000, of which not more than \$1,000,000 was represented by moneys procured upon said loans, and the residue, to-wit: \$800,000 was paid out of the net receipts of said road, after defraying all operating expenses and making reasonable returns to the stockholders upon the investment in said plant.

"But that to the end that said Citizens' Street Railroad Company and its predecessor might exact from the traveling public unreasonable, unjust and exorbitant sums for the carrying of passengers, said Citizens' Street Railroad Company on or about the first day of May, 1896, executed its mortgages in addition to the two mortgages that had heretofore been executed to secure the payment of \$4,000,000 of bonds, and at the same time increased its capital stock to the sum of \$5,000,000, so that it might appear at all times that there was an outstanding bonded indebtedness of \$4,000,000 (\$1,000,000 of said last-named bonds never having been paid upon a mortgage) upon which the company was compelled to pay the interest, and that there was outstanding \$5,000,000 of stock upon which said company was authorized to declare dividends, but defendant avers that there never was any indebtedness or liability either through

bonds or stock issued in excess of \$1,000,000 on account of construction, operation and equipment, save and except as said company and its predecessor applied of its earnings to-wit: \$800,000 in the extension and increase of its plant."

It is further denied that the statement set forth in the cross-complaint as to the amount of the annual expenditure for the two years ending April 30, 1896, and April 30, 1897, correctly represents the expenditures of the company for those years. It is averred that the sum of \$50,000 mentioned as depreciation, is exorbitant. It is also averred that the sums named for repairs, amounting in the aggregate to \$148,000 for the fiscal year of 1896, and \$156,000 for the year 1897 are misleading, as only a small part, not to exceed \$15,000 of the sum in each year, was properly applicable to the repairs of the plant. The remainder of the amounts, it is averred, consisted of additional equipment and new property. It is averred that the operating expenses of the company for any year, independently of extensions and enlargements, do not and have not exceeded \$450,000.

It is pointed out in the answers that the reduction of fare results in a largely increased use of transportation facilities. It is averred that, wholly independently of any increase which will necessarily come as a result of a reduction in fares, the earnings of the company, upon a minimum fare of 3 cents, will realize an amount in excess of \$550,000, being a sum sufficient to pay all legitimate operating expenses and return 6 per cent interest upon the bona-fide actual investment in the plant.

## JOEL HURT RESIGNS "FOR SURE."

Joel Hurt, president of the Atlanta Consolidated Street Railway, who has been trying to resign for four years, did so on August 18, and was very reluctantly released by the board. He remains as director but retires from any active management. He desires to devote his time to important personal interests.

JOEL HURT.

Mr. Hurt became president in 1891 under the distinct condition he was not to be asked to serve more than two years. During his administration he consolidated six roads and made numerous extensions and improvements. On his invitation the A. S. R. A. held its 1894 convention in Atlanta, and he was made president for the ensuing year.

Mr. Hurt is president of the Trust Company of Georgia and of the East Atlanta Land Company. He is also secretary of the Atlanta Home Insurance Company, and will devote his time to these institutions in which he is largely interested. His many friends in the fraternity will learn with regret of his retirement from active street railway work.

Ernest Woodruff, general manager of the road will act as president until the election, which may not occur before January.

Robert Bolan laid down on one of the belts in the power house of the Citizens road of Memphis, and was caught between the belt and wheel when the machinery was started. Both legs were badly crushed.

## TROLLEYS IN NEW JERSEY.

A supplemental report of the State Board of Assessors, giving advanced statistics regarding the electric and street railroads in the state for the year 1896, shows the total receipts of all the street railroads in the state for the year to be \$5,770,171, against \$5,056,598 in 1895, an increase of \$713,573. The expenditures were \$3,546,168, against \$3,431,931 in 1895, an increase of \$144,236, and dividends paid \$124,220, against \$117,320 in 1895, an increase of \$6,900.

The number of miles of track in the state is 613; capital stock paid in, \$38,235,150; funded debt, \$36,420,493, and other debts, \$4,279,396; total of capital and funded and unfunded debt, \$78,935,039.

The total cost of the railroads, including the equipment and appurtenances, is put at \$80,011,559, an average of \$130,500 per mile of track. The total assessed valuation of all steam railroads in the state, including roadbed, equipment, depots and depot grounds, terminals, bridges, franchises and all other tangible and personal property, is less than \$95,000 per mile.

## AN ELECTRIC-CABLE RAILWAY.

### For Moving Electric Cars Over Steep Grades.

BY M. H. BRONSDON, CHIEF ENGINEER UNION RAILROAD COMPANY, PROVIDENCE, R. I.

The operation of electric cars over grades of more than 6 per cent has always been a source of anxiety to street railway managers during the fall and winter months, and instances of cars sliding on grades of less than 6 per cent are not uncommon; but few serious accidents have, however, resulted. Different mechanical devices have been designed and used, and in fact are being used at the present time; such devices as "inclined planes," "rack-rail systems," counterweight systems and cable railways, each having its advocates.

With a street railway manager, it is not a question of any particular form of device; his object is to find the method which will be the most successful and economical in point of construction and operation. Cable railways have been

ELECTRIC-CABLE ROAD—CONDUIT, GRIP AND CAR WIRING.

The reports of the different companies are uniform in style. The Consolidated Traction Company, which expects eventually to control the Plainfield Street Railway, has a mileage of 175 miles; capital stock, \$15,000,000; funded debt, \$14,515,000, and other debts, \$825,688; total, \$30,370,688. The cost of the road and equipment is put at \$35,582,648, an average per mile of \$202,700, more than half as much again as the average for all the roads in the state. The gross receipts of the Consolidated Traction Company for the year were \$2,800,582 and expenditures \$1,468,440. With the Consolidated Traction Company is included the mileage of the Jersey City & Bergen; Jersey City, Harrison & Kearney; Newark Passenger; Newark Plank Road and New Jersey Traction Companies. These companies have a capital stock and funded debt of \$19,788,000.

The average cost per mile as reported to the State Board of Assessors by the Consolidated Traction Company is \$202,700. The Trenton electric roads have a mileage of 34 miles at a cost of \$75,000 per mile. The Plainfield electric road has a mileage of nine miles at a cost of about \$20,000 per mile. This is the least cost of any of the roads in the State.

the most successful, mechanically, but their cost of operation has been prohibitory, excepting on long lines. It is needless to say that any street railway is better off without the use of mechanical devices on grades, but this article with the accompanying sketches is to describe and illustrate a system suitable for cases where it is thought desirable or necessary to have a safety device, and one which is applicable to any grade regardless of the inclination.

The fact that the cable railway will draw the cars up grades and lower them down at one steady speed without relying on traction, regardless of snow or ice or slippery rails, is what makes it desirable. Therefore, any system that combines the safety features of a cable railway and obviates the necessity of skilled labor and its attendant high cost for its operation, is suitable.

Referring to the sketches: Fig. 1 is a cross section of the track construction, showing 7-in. Z-bar slot rails, 9-in. girder wheel rails, heavy cast iron yokes set in concrete, and creosoted plank sides. This has been found to make a very good and substantial construction, costing about \$7 per lineal foot, aside from paving. It is not necessary, however, to use this form of construction with this system, as the "Electric-Cable Railway" has been designed so that it

can be adapted to any cable railway construction and to take the place of existing cable railways.

Fig. 2 is the gripping device which is entirely automatic in its operation. When nearing the releasing points of the road, the grip automatically raises the releasing pin, which in turn bears against the lever D and automatically releases the grip from the car. The piece A is carried on the truck frame about 2 in. above the track. The cable is made end-less by fastening at the grip in the manner shown, being firmly held by the clamp plate C. When it is found desirable to shorten the cable a tackle is fastened to one of the ends E, after removing the plate C, and the cable drawn tight, when the clamp plate is again tightened up and the cable cut off close to the grip. No attention on the part of the motorman is required to make the grip operate; it opens and closes automatically and positively. Two of these grips have been in operation for the past 22 months, making upward of 300 trips daily, and have given the best of satisfaction.

DRIVING APPARATUS AND GOVERNOR.

Fig. 3 shows the principle of the extra car wiring. The grip car is equipped with a double trolley, one trolley wheel conducting the current down into the car, where its pressure is reduced to the proper voltage, a part of the current shunted to the car motors, just enough being used to rotate the armatures, and whatever current is necessary is sent back through the other trolley wheel to the supplemental wire overhead, which is thus charged and in turn energizes the stationary motor at the top of the incline. This stationary motor being geared to the driving drums, it will readily be seen that the whole system is completely under control of the motorman, who starts and stops at will. By shifting the bipolar switch X into the position shown in dotted lines, the supplemental trolley wheel and fixed resistance are cut out, thus sending all the current to the car motors.

The safety device shown at Fig. 5 is to be set so as to admit of but a fixed speed for descending cars. The pump with its plunger and eccentric is set directly under the armature shaft, operating only on descending cars and after a certain fixed speed is attained. The governor is belted

from one of the driver shafts as shown in Fig. 4. When the limit of speed for descending cars is reached the governor raises, first closing the stop valve *b* and opening valve *a*, which allows the pump to draw fluid from the reservoir and force it into the cylinder, thus pushing out the piston and tightening the band brake. As the speed is reduced, the governor falls, closes the valve *a*, opens valve *b*, and allows the fluid to run back to the reservoir.

The driving machinery shown in Fig. 4 is all placed directly under the track, taking up a space about 6 ft. wide, 7 ft. high and 30 ft. long.

These sketches, it must be understood, are not from the working drawings, but were made simply to illustrate the principle of the system. Its particular advantages are that it requires no skilled labor for its operation, that it may be adapted to existing cable roads without interrupting traffic, and that it is simple, safe, and is placed under the track in the street.

### BRITISH STREET CARS.

William E. Curtis, in a recent letter to the Chicago Record, gives some interesting data regarding the street railway systems in various cities in the United Kingdom, which we give in part below:

There are only 153 street car lines in all Great Britain. In Blackpool, Huddersfield, Hull, Leeds, Plymouth, Sheffield and Glasgow all the street car lines are operated by the city authorities. In 30 other cities, including Birmingham, Liverpool, Manchester, Edinburgh and London, the municipal governments own or operate a part of the lines within their limits. In Cardiff and Southampton steps have been taken to municipalise the street railways, and will be completed during the present year. This leaves only 114 street railways under private control, and in several cities the tracks they use belong to the municipality and are leased for so much a mile—the price varies from \$5,000 to \$25,000 a year, or a percentage of the earnings, usually 6 per cent gross, or both.

Before a street car line can be constructed in any city in England a petition endorsed by the city authorities and a certain number of resident taxpayers must be filed with the board of trade, which makes an investigation, and, when satisfied that the improvement is desirable or necessary, issues a permit, which must be confirmed by Parliament. Ordinarily that is simply a formality, and the judgment of the board of trade is usually final. Charters are granted for 21 years. In some cases the cities named above have acquired roads on the expiration of charters; in other cases they have purchased the property under condemnation proceedings or by arbitration, but usually nothing is allowed for good will. It is assumed that it is exhausted when the charter expires. For example, in 1893 the London County Council confiscated or bought a private street railway four and one half miles long. The company demanded \$3,020,450. The condemnation proceedings allowed the company nothing for good-will and only \$648,740 for its tracks, rolling stock and horses, which was considered a fair apportionment.

In Liverpool, conductors are paid \$6 a week for 103 working hours, an average of 14 $\frac{3}{4}$  hours a day. Drivers are paid \$6.50 a week for similar service. In Edinburgh conductors receive \$4.50 a week and drivers \$4.75 for 10 hours a day, or an average of 56 hours a week. In London

wages are better, and conductors receive \$7.75 a week and drivers \$9.62½ for working an average of 12 hours a day. Conductors do not receive so much pay as drivers because they are supposed to have an easier time of it. They are allowed to sit inside of the cars in stormy weather.

In Glasgow, the municipal government pays \$5.75 a week to conductors and drivers for 10 hours' work a day, or 60 hours a week. The cars do not run on Sunday.

In Manchester, Birmingham and Leeds the rate is a little higher, being \$5.90 a week for conductors and \$7.25 a week for drivers for 12 hours' work a day, or 72 hours a week.

In Sheffield, Huddersfield, Plymouth and other cities boys from 14 to 16 years of age are used for conductors and are paid 10 shillings or \$2.50 a week. They take up a collection with a tin can that has a slot in the top into which each passenger drops his fare after change has been made for him by the conductor. At the end of the route the can is deposited with the cashier, who opens it and counts the money. In this way no conductor can "knock down" fares without collusion with the passengers. In other cities they require the conductor to give each passenger a slip of paper or ticket which he holds until he leaves the car, for an inspector is likely to appear at any moment to make an investigation and passengers who have lost their slips or thrown them away have to pay their fare a second time.

It is customary to charge by distance. There are 1-cent, 2-cent, 4-cent and even 10-cent fares, for which different colored slips are returned.

As a rule fares are lower in all the cities of Great Britain than in the United States, but the accommodations furnished are not very good. A single track, frequent switches, long waits and a maximum speed of four miles an hour is the usual rule. The cars are old-fashioned and go poking along, drawn frequently by a single horse, and wait patiently before the residence of a prominent citizen for him to kiss the children good-by. A friend in Birmingham told me that there had recently been a great improvement in the street car service between his place of residence and his place of business, which was thoroughly appreciated by the people. The cars were now running at intervals of 10 minutes instead of 15 minutes, as formerly, he said. Birmingham has been eulogized by writers on political economy and municipal reform. It is cited as a city that possesses a government that is absolutely honest and never indulged in a "job." The grossest case of corruption that was ever known in Birmingham municipal affairs is told of a member of the common council who interested himself in a speculation in land which was made more valuable by some public improvement. Such a flagrant violation of propriety could not be tolerated, and the offending official resigned his seat in the council at the request of his colleagues.

The Birmingham street cars are great double-decked affairs, which are run by steam at intervals of 10 minutes. They usually haul one or more trailers and accommodate as many as 200 or 250 people. They are regular trains. The locomotives are boxed in so that they do not look like anything else in the heavens above or in the earth beneath or in the waters under the earth. The passenger cars resemble those that are commonly used in other cities, except that they are larger and carry passengers inside and outside. The rate of fare is about 1 cent a mile and varies according to distance. They start late in the morning, stop early in the evening, and run at the rate of four miles an hour. Most of this

precious rolling stock is carefully housed away by 10 o'clock at night, but for the convenience of the public one train is held on each of the roads until the plays are over on theatre nights, and this is the most progressive city of England, with nearly 500,000 inhabitants. The municipal authorities of Birmingham will not permit street car tracks to be laid in the business portion of the city. There is an area about half a mile square in the heart of the city, where the principal wholesale and retail shops, the offices and public buildings, the hotels and amusements, are located, into which the Leviathans are not allowed to enter, so that if a person wishes to go from one end of Birmingham to the other he is compelled to walk or hire a cab to carry him for half a mile or so between the termini of the railways. In different parts of the city there are lines of penny buses, which act as feeders to the street cars, and bring passengers to their nearest stopping place.

At present there is a deadlock between the street railways and the common council of Birmingham over an effort on the part of the latter to modernize and improve the service.

Taking England as a whole, the street transportation system is about 30 years behind the times, but the people say that it is good enough for them. James Dredge, the eminent engineer, who was one of the British commissioners to the World's Fair at Chicago, declares that the British public is perfectly satisfied if it can ride at the rate of four miles an hour.

"We do not move quite so rapidly over here as you do in America," he said, "but we accomplish just as much. It makes very little difference whether I reach my office at 10 o'clock or quarter before 10, or whether I am 15 minutes or 45 minutes on the way. I have newspapers to read, or I can spend the time thinking over business affairs and preparing myself for the work of the day. When I reach my office my mind is in a state of composure, my nerves are not fluttering as they would be after a journey in one of your cable cars, and I am in a much better condition to transact my business than if I were hurried down to my office in a catapult. Rapid transit may be a good thing when people want to wear themselves out and rush through the world to an early grave, but four miles an hour is fast enough for the ordinary human being to travel in a crowded thoroughfare."

#### LIBRARY BOOKS FOR STREET RAILWAY MEN.

Largely through the efforts of Captain Robert McCulloch the employes of the street railways of St. Louis are to be furnished with library books at little inconvenience. The public library of St. Louis has branch depositories in drug stores and other convenient centers of business, but this is the first instance in St. Louis or elsewhere that street railway stations are to be distributing points for library books. This will be a great boon to the street railway employes and their families and be an incentive to study and read a good class of literature.

The Griffin Wheel Company suffered \$1,000 loss August 29 by fire in its Chicago foundry. Sparks from a locomotive ignited five carloads of light kindling wood. The flames communicated to the extensive woodsheds, destroying them and their contents. The foundry proper was not damaged, and the plant is running as usual, filling all orders.

## SERPOLLET MOTOR ON THE NORTHERN RAILROAD OF FRANCE.

The Serpollet motor which was described in the REVIEW, July, 1896, page 417, has proved to be suited to widely varying conditions. This boiler was originally designed for a steam driven tricycle; in 1891 the inventor applied it to an autocar for four persons; in 1894 it was used on a steam tramway, and in April, 1897, some cars equipped with Serpollet generators were put in service for hauling light trains on the Paris, Lyons & Mediterranean Railroad. In June the Northern Railroad of France put in service a combination car called a postal autocar equipped on the Serpollet system. La Nature from which we reproduce the illustrations publishes the following data:

The car is used every night for carrying mail from Creil to Beauvais about 46.5 miles; it leaves Beauvais at 11:30 p. m. and arrives in Creil at 12:40 a. m., leaving on the

5 lbs. of briquette per mile not including that necessary to get up steam, and the water rate 33.3 lbs.

On the return, two trail cars were attached, making the total train weight 83,600 lbs.; the maximum speed was above 37 miles per hour; on grades of .8 and .3 per cent the speeds were 23 and 34 miles per hour respectively, the fuel consumption was 8 lbs. per mile.

The illustrations show a general view of the car and a view of the driver's platform. The car is 17 ft. 5 in. long and 8 ft. 2½ in. wide; the postal compartment communicates with the driver's platform by a glass door. There is also room in this compartment for 10 passengers. When loaded the total weight is 49,600 lbs. The steam generator has a heating surface of 121.8 square ft. and a grate surface of 4.95 sq. ft.; its weight is 6,270 lbs. Steam is furnished to two engines with Stephenson valve gear, which are both connected to the front axle, that one alone being driven. The steam pressure carried is 255 lbs per sq. in.

POSTAL AUTO-CAR, SERPOLLET MOTOR.

DRIVER'S PLATFORM.

return trip at 3:40 a. m. and arriving at 5 a. m. This insures a night postal service to all stations on the line. For some time this car has been drawing two express cars as trailers from Beauvais to Creil, returning with three, making the total train weights of about 74,000 and 92,000 lbs. respectively. This car seems to fulfill the requirements and enables the company to give this necessary but unremunerative service at a small cost.

The time required for getting up steam is 45 minutes and the fuel consumed amounts to from 90 to 100 lbs. For a round trip as scheduled above the fuel required is 418 lbs., distributed as follows: 110 lbs. for getting up steam and consumed prior to the start, 99 lbs. on the trip from to Creil, 77 lbs. during the wait at Creil and 132 lbs. for the return trip. The water rate is between 32 and 35 lbs. per mile run.

On trips between Paris and Beauvais, 49 miles, a speed of between 25 and 30 miles per hour were attained on heavy ascending grades. One of these is 1.1 per cent for 4.4 miles and another 1.3 per cent for 3.1 miles. For the trip to Paris with the motor car alone the average fuel consumption was

## KINETOSCOPE PICTURES AT COLUMBUS.

M. S. Hopkins, electrician of the Columbus Street Railway Company, has been experimenting with and perfecting an apparatus which combines the principal features of the Edison kinoscope together with some ideas of his own. Mr. Hopkins desired to take some pictures of local interest to exhibit at Olentangy Park. His most successful venture was one representing 10 years of progress on the Columbus street railway. An old 12-ft. mule car was passed before the camera, the driver being an employe of mule car days. Two women hailed the car by waving their sun-bonnets at the driver, the whole scene being typical of by-gone days. The car following was one of the latest patterns of closed cars. Then came the Electra, the company's fine party car, filled with a jolly crowd of young people. This series of pictures was received with enthusiasm at the park. Mr. Hopkins contemplates a series of pictures of Buffalo Bill's show and the Franklin Centennial parade. Although there are some imperfections still to be removed, the experiment has proven a success.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Duty of Motorneer when Vehicle is on Track.*

When a motoneer discovers a vehicle on the track a short distance ahead of him, it is his duty to have the power which propels the car under his control and to use it so as to avoid a collision with such vehicle if he can; and the fact that the vehicle can be turned off the track does not relieve the motoneer of the duty to use ordinary care to avoid a collision.

The opinion of the court is as follows: This was an action to recover for personal injuries received by plaintiff, and for damages to his property—the result, it was alleged, of the negligence of one of defendant's motoneers while running a street car operated by electricity on one of its lines in the city of St. Paul. In a trial to a jury, plaintiff secured a verdict, which was set aside by the court upon the ground of inadequacy in amount. By stipulation of the parties the evidence received upon this jury trial was then submitted to the court for a decision upon the merits, and subsequently the court made and filed its findings of fact, on which it ordered judgment in favor of the plaintiff for the sum of \$730. The injuries and damages resulted from a collision on a public street between the car and the plaintiff's hack or carriage, which was being drawn by a pair of horses, plaintiff himself being the driver thereof. The collision occurred about the center of a block, as plaintiff was attempting to cross the rails upon which the car was approaching. It is contended by defendant's counsel that there was no evidence to support a finding, made by the court, that defendant's employe negligently and carelessly projected the car upon and against the hack, and further, if there was, that the uncontradicted facts clearly establish that plaintiff was guilty of contributory negligence which would preclude recovery. We have very carefully examined the evidence upon which the court must have predicated the above mentioned finding. It is not very satisfactory, but we are of the opinion that the claim of defendant's counsel cannot be upheld, and that there was evidence which justified a finding that the motoneer did not exercise such care in the management of his car just prior to the collision as a man of ordinary prudence would have exercised under the same circumstances. When a motoneer discovers a vehicle on the track a short distance ahead of him, it is his duty to have the power which propels the car under his control, and to use it so as to avoid a collision with such vehicle if he can. The fact that the vehicle can be turned in either direction, and that the way is open for it to be turned, does not relieve the motoneer of the duty, to use ordinary care to avoid a collision. It must be remembered that the plaintiff was not a trespasser, but was rightfully upon the street. The testimony tended to show that before he came to the place of collision, the approaching car being about 250 ft. distant, he was compelled to turn to the right and drive partly upon the car track, because a pair of horses and a wagon with a large hay rack upon it had been left standing at that point; that, having passed the obstruction, he could not immediately return to the left side of the track, because of other horses and wagons which were occupying the space; that, all of this time, west-bound cars were moving on the north track about opposite him; and that they prevented for a time his crossing to the way north of the track just mentioned. It also tended to show that, just as soon as

the west bound cars passed ahead and the track was clear, plaintiff attempted to cross the rails to the right, and his hack was immediately struck by the east-bound car. This testimony had a tendency to show that plaintiff had gotten himself into a place of some danger, and was hemmed in by horses and wagons upon the left, and by the west bound cars upon the right. The motoneer, although denying that any part of the hack was upon or dangerously near the rails until plaintiff turned to cross to the north, admitted that he saw him with his horses and hack when about 250 ft. away; that he afterwards applied power, and increased the speed of the car, which was running quite rapidly; and that he made no effort to stop, or even to reduce speed, until the car was within 15 or 20 ft. of the plaintiff, the collision occurring almost immediately. Upon this state of the evidence, we are of the opinion that it was for the court, trying the case without a jury, to determine whether the motoneer exercised ordinary care to avoid a collision which might have been averted by slowing up his car. But, as before stated, it is urged that, conceding defendant's negligence, plaintiff ought not to recover, because he was guilty of contributory negligence. The rule is that, to constitute contributory negligence, there must have been a want of ordinary care, under all of the circumstances of the case, contributing to the injury, as an efficient and proper cause thereof, and that there is no want of ordinary care when, under all of the circumstances and surroundings of the case, the person injured did or omitted nothing which an ordinarily careful and prudent person similarly situated would have done or omitted. Tested by this rule, in view of the fact that plaintiff was lawfully driving upon a public street; that the evidence tended to show that he was compelled, when the car was more than 250 ft. distant, to turn out to avoid an obstruction, which brought the wheels of his hack upon the rails; that when he had passed the obstruction he could not promptly turn to the left and clear the rails, because of the horses and wagons which occupied the way, and was not able to immediately cross the rails on the right because of the cars running westerly in the same direction he was driving; and that there were other circumstances and surroundings which may have had a bearing upon the case—we are not prepared to hold that the plaintiff's contributory negligence was conclusively established. Order affirmed.

(Supreme Court of Winnetka. Flannagan v. St. Paul City Railway Co. 71 Northwestern Reporter 379.)

NOTE.—It is held in Witzell vs. Third Avenue Railway Co., *Street Railway Law*, page 270, 23 N. Y. Supplement 317, that the car companies have not an exclusive right to public highways on which their tracks run; and they are, through their drivers, required to exercise ordinary care and diligence in the management of their cars.

It is negligence in an electric street car company to run its car in a narrow and unlighted alley on a dark night so fast that it cannot be stopped within the distance covered by its own headlight.

(*Gilmore vs. Federal Street & P. D. Passenger Ry. Co.*, *Street Railway Law*, page 191, 25 Atlantic Reporter, 650.)

So long as a common user of streets exists in the public, it is the duty of street railway companies to exercise such watchful care as will prevent accidents or injuries to persons who, without negligence on their own part, may not, at the

moment, be able to get out of the way of the passing car. The degree of care to be exercised must necessarily vary with the circumstances of each case.

(Kestner v. Pittsburg & B. Traction Co., *Street Railway Law*, 315, 27 *Atlantic Reporter*, 1048. Ed.)

*Personal Injury—Liability for Future Loss of Time—Instruction not Supported by Evidence.*

This is an action brought to recover damages for personal injuries, sustained by the appellee while driving upon a public street, by being run into by an electric car operated by the appellant company, in South Chicago, and resulted in a judgment for \$3,500, entered upon a verdict for \$5,000 in favor of the appellee.

The case as made by the evidence was a close one, and demanded the giving of correct instructions to the jury. The third instruction, given at the instance of the appellee was in substance like the fifth instruction approved by the court in *H. & St. J. R. R. Co.*, 111 Ill. 219 at p. 227, and again approved in *City of Chicago v. McLean*, 133 Ill. 148, except the following addition: "And any future loss of time and inability to work, if any, resulting from such injury, which the jury may believe the plaintiff will sustain; and may find for him such sum as in the judgment of the jury under the evidence will be a fair compensation for the injuries, if any, which the jury may believe from the evidence he has sustained."

There is but very little evidence, and that is of uncertain and shadowy character, that appellant will suffer from loss of time or inability to work in the future because of injuries received.

The accident happened nearly three years before the trial took place, and at the trial appellee testified that six weeks after he was hurt he went to work again at his previous employment, and he worked ever since without the loss of a single day.

In the face of such evidence, and with no certain evidence that appellee had not entirely recovered from his injuries, it was error of a seriously prejudicial kind to instruct the jury that they might give the appellee compensation for such further loss of time and inability to work, as they might believe (without regard to evidence) he will sustain.

(Appellate Court of Illinois, *South Chicago City Railway Co. v. Walters*, 29 *Chicago Legal News* 334.

*Contributory Negligence—Any Degree of, Bars Recovery.*

This suit was for personal injuries, which resulted in a verdict and judgment for \$25,000.

The assignment of error which seems to us most serious, is for giving the second instruction for appellee. The part complained of is as follows: "In cases of this character there can be no recovery by the plaintiff, unless two things appear from a fair preponderance of the evidence:

"First, that the injury was occasioned through the negligence or want of ordinary care and caution by the defendant, as set out in the plaintiff's declaration.

"Second, that the plaintiff was not guilty of negligence on his own part, materially contributing to the injury."

The proposition of law embodied in this instruction is at least inferentially bad. It says by inference that if the negligence of plaintiff contributed to the injury in a degree which might be regarded by the jury as not "material," the plaintiff might, notwithstanding, recover. Such is not the law. If plaintiff's negligence contributed in any degree whatever, it barred his recovery.

Nor is the fault of the instruction to be ignored because the proposition is thus inferentially put: *Monongahela City v. Fisher*, 111 Pa., State, 13; also, *Mattimore v. Erie City*, 144 Pa. State, 23; *Artz v. C. R. I. & P. R. R. Co.*, 38 la. 294.

In a case of this nature, involving a sharp conflict upon the merits, it may not be safely presumed that this instruction worked no prejudice to appellant.

The facts as presented are such as must be submitted to another jury.

For the error in giving the second instruction for the appellee the judgment is reversed and the cause remanded.

(Appellate Court of Illinois. *Cicero & Proviso Street Railway Co. v. Snider*, 29 *Chicago Legal News*, 431.

## WILLIAM D. RAY.

Although William D. Ray is but 24 years of age he has had 10 years experience in the electrical business, beginning in 1887 as the junior partner of MacFadden & Ray, engaged in electrical construction at Oak Park, Ill. In 1889 he was with the Cicero Water, Gas & Electric Light Company of the same place as electrician's assistant. In 1890 and for two years thereafter Mr. Ray was electrician in charge of the 5,000-lamp lighting plant of the Chicago & Northern

Pacific at the Grand Central Station, Chicago; in connection with this he had charge of four miles of electric and pneumatic block signals and two interlocking signal towers. Later he was with the C. & C. Electric Motor Company installing motors and dynamos. In 1892 he was with the Chicago & Northwestern Railway as electric light inspector, having supervision of the steam and electrical apparatus at Milwaukee, Clinton, Chicago, West Chicago and Escanaba.

WILLIAM D. RAY.

In 1893 he was with the electrical department of the World's Fair as troubleman, inspector and foreman, and the following year with the Standard Electric Company, of Chicago, as assistant consulting electrician. In November, 1894, Mr. Ray was engaged by the Everett (Wash.) Railway & Electric Company as superintendent, and in the following May was promoted to the office of general manager, which position he resigned but a few weeks since.

Mr. Ray is the inventor of an electric arc lamp, which he patented March, 1896, and the author of "Practical Applications of Dynamo Electric Machinery," written in collaboration with C. K. MacFadden in 1893, of which 3,000 copies were sold. Since 1892 he has been an associate member of the American Institute of Electrical Engineers; in 1894 he was vice-president of the Chicago Electrical Association.

During the past summer Mr. Ray took an outing in the mountains and made the ascent and descent of Mt. Ranier, 14,525 ft. high, in one day, which is a record breaker, as the trip is usually counted a three days one. The trip is one of great danger, and one of the party lost his life.

**ELECTRIC RAILWAY IN ST. PETERSBURG.**

The management of the Soci t  des Tramways, St. Petersburg, Russia, intends to abandon animal traction and equip the lines on Liteinaya street electrically during the coming year, and requests bids at as early a date as possible. Propositions will be received for three systems, viz.: overhead trolley, underground conduit, and accumulators. From one extremity of the line to the other is 2.9 miles; there are 2.04 miles of double track and 1.50 miles of single track, one route being used going and another returning, making the total, 5.58 miles of single track. The line is level

2. For the line, including poles which must be of iron, or the conduit.
  3. For a system of ground return, the rails being bonded to the rails of the other track and to a copper conductor.
  4. For 40 motor cars.
- In addition to this, annual and daily estimates are requested:
1. Power station; wages, fuel, oil, etc.
  2. Repairs to line or conduit.
  3. Repairs to electrical equipment of cars.

Also the terms of payment, as this will be considered in letting the contracts. Address: Liteinaya street, No. 35.

THE STREET RAILWAY SYSTEM OF ZANESVILLE, O.

except for 280 ft. which is on a grade of 3 per cent; there are four curves, two of 70 ft., one of 175 ft. and one of 280 ft. radius. The power house is situated 2 miles from one end of the line measured along the track. The maximum number of cars on the line at one time is 36 motor and 36 trail cars; all are double deck cars accommodating about 60 persons. The headway is fixed at 1½ minutes and the hours of running are to be from 7:30 a. m. to midnight.

With the proposition there must be submitted plans and estimates:

1. For the power station equipment the building itself being ready; i. e., boilers, engines, generators, etc.

**ZANESVILLE RAILWAY & ELECTRIC COMPANY.**

The Zanesville Railway & Electric Company is the result of a reorganization of former companies for the purpose of consolidating the street railway and electric lighting interests. The electric railway is an old one having been in continuous operation since 1890. Being divided by two rivers as Zanesville is, the problem of planning a street railway to give the most satisfactory service to patrons with the least track mileage has been a difficult one. The company has studied the matter well and is still improving the routes as

POWER STATION, ZANESVILLE, O.

the necessity of rebuilding the track affords opportunity. The lines cross three bridges, one of them being the famous "Y" bridge at the junction of the Licking and Muskingum rivers. Two of the bridges are covered, with only 14 ft. headroom, so that the trolley pole is bent down nearly parallel to the car roof when passing through. In these bridges the trolley wire is replaced by an iron plate.

With a view to encouraging traffic, the company acquired Gant park, one of the finest in that part of Ohio, and during last winter it was open as a winter resort, having a Casino with bowling alleys, skating park, theatre, etc. This proved to be an important source of revenue in the dull months and extensive preparations were made to provide attractions

CROSSING THE VIADUCT.

which should make it even more popular as a resort during the summer, with equally gratifying results.

The electric lighting plant is in a healthy condition, there being a steady increase of business together with reduced

operating expenses, the result of consolidation. In the early part of the year the lighting plant was improved by installing \$15,000 worth of modern machinery.

The railway service as well has been improved by the new management, new cars put in service, and improved track and overhead construction put in at many points. The power house now contains eight Griffith & Wedge boilers, supplying steam to four engines aggregating 600 h. p. The generators are all belt driven and comprise five direct current Western Electric—three 100-ampere and two 80-ampere—machines. There are now 1,500 incandescent and 325 arc lamps in service.

The railway consists of 10 miles of single track of 5 ft. 2½ in. gage. The rails are 48-lb. girder and 48-lb. T-rails laid in 4½-in. steel bulb chairs on 5 by 7-in. ties 7½ ft. long. Brick pavement is used. The joints are 4-bolt with straight fish plates and bonded with No. 0 copper wire. The trolley wire is of No. 0000 copper and the feeders of No. 000 copper.

The car barn is of wood and iron, 75 by 170 ft. Four

INTERIOR OF POWER STATION.

tracks lead into it from the main line and there are two pits each 90 ft. long. The rolling stock consists of 20 motor cars, 9 open and 11 closed, and 11 trail cars, 7 open and 4 closed, of Stephenson make, one snow plow and one Trenton tower wagon. There are 11 complete car equipments of Sprague motors. The shops comprise an armature winding room and carpenter and blacksmith shops, and the company rebuilds its cars and makes all general repairs.

During 1896 the total number of passengers carried was, in round numbers, 1,250,000, the average per car-mile being 1.1; the car-miles per day averaged 100; and the operating expenses 12 cents per car-mile of which the motive power (leased) cost 2 cents.

The officers of the company are: John Hoge, president; W. Batemann, vice-president; K. B. Conger, secretary; H. B. Westcott, general manager.

The power house of the Union Depot Street Railway Company at Ferry and 20th streets, St. Louis, has been fitted with fire doors and windows. General Manager Scullin wished to take every precaution to prevent the spread of fire at this station, as it supplies current to several of the branch roads of the company.

## SIXTH PENNSYLVANIA CONVENTION.

The sixth annual convention of the Pennsylvania Street Railway Association was held at Allentown, Pa., September 1 and 2. The convention was called to order in the parlors of the Hotel Allen by Robert E. Wright, second vice-president, and after roll-call adjourned for dinner. When called to order in the afternoon a short address of welcome was made by F. E. Lewis, mayor of Allentown, and responded to by Mr. Wright.

Papers were presented as follows: "Relationship between Claim and Operating Departments of Electric Railways," by Richard W. Day; "Trolley Service in the Future," by R. M. Douglass; "Street Railway Legislation in Pennsylvania," by Dallas Sanders. The subject for general discussion was "Street Railway Taxation."

The officers elected for the following year were: President, Robert E. Wright, of the Allentown & Lehigh Valley Traction Company, Allentown; first vice-president, Frank Silliman, of the Scranton Traction Company, Scranton; second vice-president, Dallas Sanders, of the Schuylkill Traction Company, Girardville; secretary, S. P. Light, of the Lebanon & Annville Street Railway Company, Lebanon; treasurer, W. H. Lanius, of the York Street Railway Company, York; executive committee, Robert E. Wright, B. F. Meyers, S. P. Light, E. C. Felton, John A. Rigg.

The next meeting will held at Scranton.

The entertainments provided for the guests were a concert at Central Park on the evening of the first day and an excursion over the lines of the Allentown & Lehigh Valley Traction Company, followed by a banquet at the Manhattan Hotel, Manhattan Park.

### DELEGATES PRESENT.

- Robert E. Wright, A. F. Walters, James Uhl, Allentown & Lehigh Valley Traction Company.
- C. E. Flynn, Carbondale Traction Company.
- A. Markle, Clearfield Traction Company.
- F. H. Alleman, Harrisburg & Mechanicsburg Electric Railway Company.
- S. P. Light, C. H. Smith, Lebanon & Annville Street Railway Company.
- E. C. Felton, F. B. Musser, Middletown, Highspire & Steelton Railway Company. Harrisburg Traction Company.
- C. A. Bragg, Pennsylvania Traction Company.
- John A. Rigg, Norman M. Jones, I. C. Retter, James A. O'Reilly, United Traction Company, Reading.
- J. C. Lugar, Roxborough, Chestnut Hill & Norristown Railway Company.
- Frank Silliman, Jr., Scranton Railway Company.
- Dallas Sanders, E. W. Ash, Schuylkill Traction Company.
- R. M. Douglass, Schuylkill Valley Traction Company.
- John Graham, Col. W. J. Harvey, Wilkes-Barre & Wyoming Valley Traction Company.
- E. H. Davis, W. H. Lanius, C. H. Mayer, Williamsport Passenger Street Railway Company.
- D. K. Trimmer, York Street Railway Company.

### ASSOCIATE MEMBERS REPRESENTED.

- J. C. Brill Company, Wm. H. Heuhlings, Jr.
- Consolidated Car Heating Company, W. H. Ransom.
- F. W. Darlington.
- General Electric Company, R. E. Moore, H. J. Crowley.
- Peckham Motor Truck & Wheel Company, E. G. Long.
- Pennsylvania Steel Company, M. D. Pratt.
- John A. Roeblings Sons Company, R. W. Welsh, W. L. Doyle.
- Lobdell Car Wheel Company, F. A. Lex.
- Westinghouse Electric & Manufacturing Company, C. A. Bragg.

- Taunton Locomotive Manufacturing Company, Jacob Wendell, Jr.
- Rochester Car Wheel Works.
- Western Gear Company.
- Wm. Wharton, Jr. & Company, R. K. Polk.
- Globe Ticket Company, W. C. Pope.
- Municipal Record & Advertiser, F. S. Beattie.
- STREET RAILWAY REVIEW, Fred S. Kenfield.

### Relationship Between Claim and Operating Departments of Electric Railways—The Prevention of Accidents and Disposition of Claims.

Paper read before the Pennsylvania Street Railway Association by Richard W. Day, General Claim Agent Wilkes-Barre & Wyoming Valley Traction Company.

Since the organization of the Pennsylvania Street Railway Association in 1892, the members have met in convention five times. At each of these meetings the following subjects, viz., Franchises, Right of Way, Construction, Operation and Maintenance have been fully discussed, and by the exchanging of views on the part of representatives of the different railways, valuable information has been given and knowledge gained. The evidence of this fact is noticeable in the improvement of our street railway systems throughout the state since that time. Having noticed the attention given to the above mentioned departments, it has many times occurred to the writer as strange that so important a matter as that of the Accident Department has received but little or no attention at these meetings. This failure to notice a matter of such interest to street railway companies is hard to understand, as it appears no mention of the cause or effect of accidents has been made in the reports furnished by the Association. The fact of this omission is hard to conceive, as one would think the accident department would be worthy of consideration as its cost is unknown to us, and we are thereby forced to constantly deal in unknown quantities. Consequently, no reasonable estimate can be made of the cost of accidents growing out of the operation of street railways. For comparison between the cost of the accident department and any other departments belonging to a railway corporation, the following statement is made to show the various differences: The actual cost of construction can be figured to a nicety, and the cost of operation can be so closely estimated that little or no difference in the amount is liable to arise, and, from past experience, the companies know just about what amount to set aside for the maintenance in the proper condition of the roadbed, overhead construction and rolling stock. The change from horse power to electricity having increased the different hazards to such an extent, we today find new liabilities arising caused by the power of electricity, and as we have every reason to expect, new elements of danger will arise in the future which are naturally unknown to us today. We are, therefore, confronted by the problem of how to best prevent, and in the event of occurring, dispose of the losses growing out of accidents.

To state that a certain company will lay aside a certain sum of money for contingent losses is well enough in itself, but at best it is purely a matter of guess work, for the reason that we have no precedent to govern us and no way of knowing what our future losses will amount to. As far back as we wish to trace history we learn of casualties having occurred which have resulted in the loss of life, injuries to persons and damage to property, and we have every reason to believe that just such will continue to happen in the future. Realizing this fact, our only hope to hold our losses down to a minimum is, first, to regulate our system so as to prevent accidents. This can only be accomplished by a close relationship between the management, the operating department and the claim department.

While it is not the intention of the writer to offer suggestions regarding the management of different roads, yet for the accomplishment of good results on the part of the claim department certain suggestions are herein offered which, if carried out by the operating department, will considerably reduce the number of accidents and the liabilities against the railway corporations. For the success of all roads, the different departments should work in harmony. This fact can be easily understood, for where contention and petty jealousy exist between operating and claim departments, the effect of any carelessness or misunderstanding on the part of one department naturally falls upon the other. It is well understood that where the roadbed, overhead construction and rolling stock are in good condition, the cars manned by competent motormen and conductors, an accident which shows liability on the part of the railway company is an unusual occurrence. But it must be remembered that as long as we are dependent upon human agencies to conduct our various operations, accidents will happen. Admitting that fact to be true, we are then confronted with the different elements which lead up to the cause of accidents, and afterwards devise a means to dispose of claims growing out of them when liability exists.

The cause of our most serious accidents on street railways is owing largely to the failure of the employes to first acquaint themselves with and carry out the instructions given by their employers. Whether this is the fault of the management or the employes is a question which can only be determined by the individual corporation. Where the management is good, such accidents as collisions between cars, cars jumping the track, cars jumping switches, cars colliding with steam trains at crossing, are in most cases owing to carelessness on the part of either motorman or conductor. In such cases the liability of the company is beyond question, and it then devolves upon the claim department to make settlement with those, if any one has been injured, or in the event of failure of that department to do so, it then usually rests with juries to assess the damages with results only too well known to us all.

Experience has taught the writer that care should be given to the construction and special care to the maintenance of overhead wires, as serious accidents have occurred caused by the failure to keep said wires in proper condition. There is a certain class of accidents which occur upon all railroads, such as passengers jumping on and off moving cars, unnecessarily standing upon the running board, standing on the front and back platforms when there is room inside of the cars, running into horses and wagons which unexpectedly turned directly in front of cars; persons walking upon the roadbed many times where it is the private property of the company. Such accidents are generally considered void of liability on the part of the company. But just this class of accidents require almost as much time and attention on the part of the claim department as accidents for which the company is legally liable, for the reason that claims are frequently made in such cases and the facts so tortured by the claimants into apparent liability that it is necessary for the adjuster to fortify himself with all the obtainable evidence to prove non-liability on the part of his company.

To adjust a loss where there is conceded liability is practically an easy matter for the adjuster, as he will first post himself as to the character of the injuries sustained, and following it up by learning the earning capacity of the injured one, and with the assistance of the examining surgeon approximate the length of time of disability. Having obtained such information, he is then in a proper position to decide upon a basis for compensation. But quite the contrary is the case when handling a claim growing out of an accident in which a person is injured or property damaged and the question of liability in doubt. It is in properly disposing of a case of the latter class that the judgment of the adjuster is shown.

The majority of deaths caused by the operation of the electric cars are brought about by contributory negligence on the part of the deceased. Notwithstanding this fact, a claim is usually made and the adjuster is confronted by a husband or wife, a father or mother, or a guardian in case of a minor, and they appeal to the company through him for assistance. Again, it is necessary for the adjuster to exercise good judgment and to bring about an understanding with the before mentioned representatives which will prove satisfactory to all concerned. Just whether to allow a payment or not in such cases is a matter which must naturally be governed by the local situation and surrounding circumstances. To explain how an accident case should be investigated and the losses growing out of it adjusted, is an impossibility, as no two accidents occur alike, and the

matter then solely depends upon the humor of the person or persons injured, together with the all around ability of the adjuster who undertakes the mission. The success of the operation of a claim department largely depends upon the man or men employed, and the secret of their success is regulated to a large extent by their past experience in this work, ability to correctly judge human nature and to maintain perfect control of their temper. For a man to properly handle a claim department, he should be placed in charge unrestricted, for if handicapped by restrictions from the management, his identity becomes insignificant, and the courage and nerve which govern him in a close quarter are lessened to such a degree that his general usefulness is impaired.

Following the suggestion already given for the prevention of accidents, it may be well here to say that the official in charge of operating department has it in his power to increase or decrease the number of accidents more than any other officer in connection with the company. It is within his power to enforce the rules and regulations formed by the management, he having the selection of the motormen and conductors, and the proper manning of the cars depends entirely upon his judgment. The inspection from time to time of the roadbed, overhead construction and rolling stock also being under his supervision, it can readily be seen what a factor this official becomes in the prevention of accidents. The selection of proper men to fill the positions of conductors and motormen should not be overlooked, as the management of the cars with which they are entrusted is solely in their hands from the time they start out on their run until they return to the car house. It is the firm belief of the writer that passengers should be excluded from the front platform of the cars; first, that the position of a motorman is such a responsible one that he should have sufficient room to operate his motor, brake, and bell, without interference of passengers crowding against him; secondly, by the absence of other persons from the platform with him, his sole attention is given to the streets before him and the crossings as he approaches them.

Many accidents have been occasioned through the attention of the motormen having been attracted by a passenger standing by him, and companies have paid large sums of money simply for such little acts of courtesy on the part of the motorman to passengers. The conductors and motormen should also be carefully instructed regarding the furnishing to the company of an intelligent narrative of any accident that occurs to any person upon or by their car. They should also be taught the necessity of furnishing the company with the names and addresses of all witnesses which they may be able to secure, as this is very important in assisting the claim department to get down to the bottom of all the facts which led up to the accident. Such a rule is generally enforced on all roads to a certain degree, but usually a conductor reports an accident simply because he feels he is compelled to do so, and any kind of a report will answer the purpose. These are some of the errors that should be corrected. To prevent discharged employes from becoming valuable witnesses for the plaintiffs in damage cases, the writer has for years pursued the following, which has proven a bar against them from testifying against their employers. An affidavit has been taken, or in the case of a removal, the deposition of any employe who has been in any way connected with an accident on the road. This method has been adopted for the reason that the largest amounts ever recovered in damage cases have been awarded by juries who have listened to detrimental statements made by discharged employes against their former employers.

Regarding the question of feigned injuries which have become so prevalent within the last few years, the writer has found it to his advantage to have associated with his company the most able physicians and surgeons in the locality, so that they may, by their learning, experience and upright character, overshadow the shyster element in the medical fraternity which usually follows up persons who have been injured, keeping them incapacitated so as to prolong their disability, thereby increasing their fees accordingly.

There is no doubt but this Association has been the means of strengthening railway companies in weak places and instilling confidence in the stockholders; and as this Association is the representative body of such a large amount of capital it would not seem to be unreasonable to expect that it should be instrumental in bringing about a change in some of our laws regulating the question of corporation liability, especially so as to the statute of limitation, which as it stands today is one year in the case of death and two years in the case of injury.

In conclusion, the prevention of accidents can only be brought about by a thorough understanding between all the departments of a railway and the settlement of losses growing out of them by the prompt attention of the railway adjuster.

### Street Railway Legislation in Pennsylvania.

Paper read before the Pennsylvania Street Railway Association by Dallas Sanders of the Schuylkill Traction Company.

In 1831 there was probably formed in Philadelphia what was called the first bus or omnibus line. That was the mode of transportation of passengers in that city at that time. This mode of conveyance which was called "Boxall" was started by James Boxall, December 7, 1831. James Boxall was an innkeeper at the Upper Ferry bridge (Callowhill street), and his "stage-coach" was like a chariot. It had about four or six seats running from side to side, and was set well up on its wheels, showing a broad back. It was painted a rich dark green color, and access into it was obtained by iron steps at the side. It was called 'Boxall's Accommodation,' and bore upon the back the words, in gilt letters, 'Fairmount Observatory,' in allusion to a request from the American Philosophical Society, which at that time proposed to erect at Fairmount an astronomical observatory. "Boxall's Accommodation" had a short life. Other omnibus lines in Philadelphia were afterwards established. Such was the means of street passenger transportation until 1857.

In 1857 street passenger railway companies began first to be incorporated. This was done by special acts of assembly giving the companies the right to the use of certain streets in certain cities, and authorizing them to have a certain capital and giving them corporate powers. Probably the first two passenger railway companies that were incorporated were the West Philadelphia Passenger Railway Company on Market street in Philadelphia, incorporated on May 14, 1857, and the Frankford & Southward City Passenger Railway Company, incorporated June 10, 1857, both in the city of Philadelphia, although there was another company incorporated as a steam railroad company earlier than that, which was afterwards given the rights of a street passenger railway company. Street passenger railway companies were incorporated from 1857 down to the adoption of the new constitution, in 1874, by special acts for each passenger railway company, giving it the right to the use of certain streets in certain cities throughout Pennsylvania. Some 65 of such corporations were incorporated during that time.

There was in 1857 opposition to street passenger railways by some of the citizens for reasons which at this day seem to be absurd, but at that time created great contentions and deep-seated feeling among the citizens in many of the cities. The first contest of a legal character arose probably when bills of equity were filed, asking for an injunction restraining the laying of rails on the streets, as it was alleged this would be a nuisance. When the companies endeavored to start Sunday travel in 1859 further litigation ensued. In 1866 a bill in equity was filed before Justice Strong of the supreme court at nisi prius, asking for a preliminary injunction to prevent the running of cars on Sunday, which he granted, but when the case came up before the supreme court in banc, in November, 1867, the injunction was dissolved and the cars were allowed to run on Sunday, and have done so ever since.

Another contest that the passenger railways had, was the admission of colored people to the street cars. This matter was carried on for a long time, until on March 22, 1867, an act was passed admitting colored people to the street cars on equal terms with their white neighbors.

The objection to allowing colored people to ride in the cars that was made so strenuously and fought for so bitterly for such a time in Philadelphia seems to us at the present day also absurd, and we can not see any reason why they should have ever been excluded.

The new constitution adopted in 1871 in Art. 17, Sec. 9, provides that "no street passenger railway shall be constructed within the limits of any city, borough or township without the consent of its local authorities." This was a proper provision, giving the local municipality the power to consent or not to consent to a street passenger railway company being authorized by the legislature in every locality.

From the year 1874, when the new constitution was adopted, there were no street passenger railways incorporated until the act of 1889 was passed. However, on May 23, 1878, the legislature passed a

street passenger railway act entitled "An act to provide for the incorporation and government of street railway companies in cities of the third, fourth and fifth classes, and in the boroughs and townships in this commonwealth."

On March 10, 1879, the legislature passed an act entitled "An act to provide for the incorporation and for the government and regulation of street railway companies now incorporated, or which may hereafter be incorporated in cities of the second and third class in this commonwealth."

The supreme court, in the case of Weinman v. the Wilkesburg & East Liberty Passenger Railway Company, 118 Pa. St., 102, decided in 1888, held this legislation unconstitutional and void under the provisions of Art. III, Sec. 7 of the constitution, prohibiting local and special legislation.

On May 14, 1880, the legislature passed a general act providing for the incorporation of street railway companies in Pennsylvania, by which any number of persons—not less than five—may incorporate a street passenger railway company and have the general powers of a corporation, which railway, however, can not be built without the consent of the local authorities.

Prior to that time, in 1887 and in 1883, motor companies for the construction and operation of motors and cable or other machinery for supplying motive power to passenger railways, had been authorized to be incorporated and they were given authority to invest their funds in the purchase of shares of stock and bonds of any corporation whose rails, railway motors or other property are leased, operated or constructed by them, and they were authorized to lease the property and franchises of passenger railway companies which they may desire to operate, and to operate said railways.

New street passenger railways have been numerous incorporated under the general street passenger railway law of 1889 and others under what are called the motor power or traction law of 1887.

The new system of locomotion by which electricity became generally used in 1892 added a new power by which the passenger cars were moved with great convenience and comfort to the public, giving them larger and cleaner cars, open cars in the summer, heated cars in the winter, and a rapid transit throughout the large cities, connecting smaller cities together and enabling the people at a moderate rate of fare to move from one place to the other with comfort and convenience, and also in the summer opening up many places, like public parks and sources of amusement which hitherto had not been within the purses of many people at which to visit or amuse themselves.

Like all other improvements in street passenger traffic, this met with earnest opposition from some citizens. Public meetings were held, showing the supposed danger of the electrical power, bills in equity were filed in the courts of common pleas in Philadelphia and taken on appeal to the supreme court, where, however, the right to use such a new and novel mode of transportation was upheld. Legal proceedings were taken also in other parts of the state.

This new inanimate power, placed upon the streets of the cities and boroughs and upon the highways of the townships what was practically almost a steam railroad in the rapidity with which it moved, brought about, until the people began to learn that it was not the old horse car, many accidents to people traveling on these roads or crossing them, but as the people have learned that the passengers desire rapid transit and that they must be more careful in crossing tracks of these roads, the accidents have become fewer and fewer. The supreme court of the state has applied to these trolley roads the well-known doctrine of "Stop, look and listen." This doctrine was first applied by the supreme court to steam railroads and was the subject of some criticism in some of the other states of the Union, but it is now being applied as a correct exposition of the law of negligence in many of the other states and is applied in Pennsylvania with limitations to the electric or trolley roads as a proper precaution for persons approaching one of these tracks, and adds to the safety of the many passengers who are carried in these cars, for a collision with a large beer wagon may be as dangerous to the occupants of the trolley cars as to the man who is driving the beer wagon.

By the act of May 21, 1895, street passenger railway companies were given the power to contract for and to regularly gather, carry and distribute the mails of the United States. This distribution of the mail by trolley cars had already been done in some of the other states of the Union and it was found a great convenience to the people. It has been enlarged, and Congress at its last session appropriated \$250,000 for electric and cable car service in the United States.

The second assistant postmaster general in his report for this service up to July 1, 1896, shows that there were 145 different routes throughout the Union, going over 353 miles of track. Since then this traffic has largely increased, and the appropriation made at the last session of Congress was for \$250,000—\$100,000 more than the previous year.

The legislation in Pennsylvania has been of a consistent character, but has been of a different character naturally for steam railroads, incline plane roads and lateral railroads, in connection with the steam railroads and for street passenger railways. The difficulty that the street passenger railways met when they first adopted the electrical or trolley system was, as I have said before, that the people did not realize the rapidity with which they were required to run and did not approach and cross the streets with such care as the supreme court properly decided should be used in such cases, and these roads have suffered from what are known as accident cases, by which endeavors have often been made to nullify them in large amount of damages when there was no reason for such suits.

Justice Dean of our supreme court, in an interesting address delivered last winter before the Law Academy of Philadelphia on "Jury Trials," gives a history of some of these accident cases.

"To sustain my proposition as to the growing tendency of juries in the teeth of evidence, to take from him who hath and give to him who hath not, it is hardly necessary to cite proofs within the knowledge of every judge and lawyer and many laymen. As just one instance, take the case of one private corporation in this city, the street railway companies. In 1886, when the cars were moved by horses, the verdicts in negligence cases were four, aggregating \$16,150. In 1892, before the change had been made to electric power, there were twelve cases, and the verdicts aggregated \$30,608. In 1886, when they paid \$16,150 damages, they carried 137,957,012 passengers, counting single fares. In six years, while still running cars by horse power, the damages almost doubled, increased nearly 100 per cent; the increase in passengers was, in round numbers, from 137,000,000 to 187,000,000, an increase of about 40 per cent. Then the new motive power was put on, and in 1896 the verdicts in negligence cases reached \$345,410.50, the number of cases being 118. The passenger fares increased, however, from 187,000,000 in 1892 to over 261,000,000 in 1896. The increase in travel was again about 40 per cent, in verdicts about 1,000 per cent. As to this last astounding increase, it may be fairly assumed that much of it is due to the fact that the more powerful motor is the more dangerous one, and that a higher degree of care is required on the part of those using it than was exacted in the use of horses. But, assuming that there was an absence of care according to the circumstances in many more cases when the new power came into use than in moving the cars by horses, there was, in any fair view, it seems to me, an increase in verdicts out of proportion to increase of passengers. The figures given I obtained from the department of internal affairs at Harrisburg, from the court records and from the officers of the railway companies. I have no reason to believe they are incorrect.

"As I have said, trial by jury, if it be a fair and impartial trial of disputes on evidence, must from its very nature strengthen the administration of justice and add to the stability of free institutions, but if it be perverted from its object, the ascertainment of truth, into a means of promoting a redistribution of property without regard to legal right, then eventually there comes revolution under legal forms and the institution will be abolished, thereby placing the administration of justice farther from the people and consequently weakening their attachment to its forms, a result to be deplored by every friend of government by the people."

The legislature in 1893 passed an act limiting for two years the right of action for any alleged injury, and they have required where the husband and wife have a suit for injuries to the wife only that the action shall be consolidated in one suit, and at the last session of the legislature in 1897, that an action for an injury to a child and for the father's right of action for such injury shall be consolidated in one suit.

An endeavor has been made in Indianapolis, Milwaukee and some of the southern cities to control the rates of fare when no such condition was placed in the charter, when no constitutional right could be found for such legislative action, but the populistic cry against corporations was the only motive that could have impelled or caused such action. However, the courts in these localities have taken these questions up and have determined them with a due regard to the obligation of contracts and to prohibit and prevent their violation. These instances were probably only caused by a temporary aberration

of the popular mind; but the courts wisely and sternly prevented any great wrong being done to invested capital, invested under the laws granted by these very states. In Atlanta the attempt was to compel a company which operated two distinct lines to give a free transfer instead of exchange ticket. The court said that when the fare was fixed it meant a fare on one route and not on two.

As the years roll by the people realize that they are given greater facilities by the street passenger railways, especially since the electrical system has been applied, where the cars can with ease run up and down grades and with rapidity, connecting places that had been heretofore almost inaccessible to each other and allowing the people freely to mingle at a moderate cost among their friends, neighbors and relatives. True it is, that on many highways of the state these roads have been allowed to run, but the advantage of prompt, convenient and frequent inter-communication is a satisfactory answer to the state allowing the use of its highways for this purpose.

In a report of the Ohio Road Commission, filed December 21, 1893, it is shown that the cost of transportation by horse power is the most expensive and covers the shortest distance; that is, it is shown that by horse power the cost of transportation per ton for 5 miles is \$1.25, while by electric power for the same cost a ton will be carried 25 miles, arguing thereby that the state would be wise in allowing its highways to be freely used by electric trolleys, as they would be a benefit to the farmers and those residing along the roads by cheapening transportation.

The following extracts from the report of the secretary of internal affairs for the year ending June 30, 1896, show the extent of the street passenger railways in Pennsylvania: "The total mileage of street railways reporting for the year ending June 30, 1896, was 1,561.89. These figures may not be absolutely correct, but they are as nearly so as it is possible to make them from the returns received.

"The extent of the street railway service in Pennsylvania is shown in the great number of passengers carried during the year, 376,502,551. These figures are approximately correct, although several companies have failed to report the number of passengers carried."

The Street Passenger Railway Act of 1889 authorizes such railways in their construction "to cross at grade diagonally or transversely any railroad operated by steam or otherwise now or hereafter built."

This apparent authority to cross at grade steam railroads made some persons imagine that it gave a general arbitrary power of crossing at grade whenever and wherever they pleased, but the supreme court of the state wisely determined that under the act of 1871 it had the authority as a court in equity to restrain crossing at grades where it was possible at a moderate additional expenditure of money to cross underneath or overhead. Although the able and careful Secretary of Internal Affairs recommends that grade crossings should be abolished entirely outside of the streets of cities or boroughs, it seems to me that under the wise construction of the supreme court it is better to leave this legislation and the decisions the way they at present stand and not attempt additional legislation on these questions.

The acts of May 15, 1895, and May 21, 1895, enlarge the rights of street passenger railways so that now they are authorized to sell or lease to traction or motor companies and contract for their construction, specify the manner of payments in bonds and mortgages and also authorize the traction or motor car companies to lease or sell to other companies.

The question of giving to street passenger railways the right of eminent domain and also the right of carrying freight is a question still in abeyance in Pennsylvania and will be left for further due consideration, as our legislature does not again meet until 1899. I have not found in this state, as far as I personally have had anything to do with trolley roads, that supposed antagonism between the steam railroads and the trolley roads, except where trolley roads attempt to cross the steam railroads at grade, where it was possible by the expenditure of a little more money to cross overhead or underneath.

Nearly all the litigation, and there is a great deal of it, unfortunately, which has arisen between the steam railroads and the trolley railways in this state is due to the obstinate determination of the parties on the one side that they should cross at grade and on the other side that they should not; but as I have said before, the supreme court has wisely determined this, and in some cases where it was impossible to make an overhead or an underground crossing have allowed grade crossings, and in the instances of other kinds, have properly refused grade crossings.

Any person who can remember what the discomforts of the omnibus

ride were in days gone by, any person who will remember the small, badly ventilated and slow horse street car, often drawn by mules although called a horse car, cannot but turn with pleasure and must appreciate the large improved, well-ventilated and well-lighted trolley car moving promptly and rapidly, and especially the open trolley car that gives fresh and cool air to all who ride in the summer months, so girls and boys, men and women do not want to go back to the old system, but are pleased and proud of Pennsylvania's improvements in having her people rapidly and comfortably carried on her streets and highways.

### UNIFORMS BY THOUSANDS.

Managers, employes and the public all unite in one expression as to the great improvement in the appearance of street railway car crews in these latter days, as compared with the garb which was passed without criticism when bob tail cars and horses were abroad in the land. Probably no one thing

has had more to do with the improved appearance of the men and the maintenance of a good discipline than the general order requiring the men to wear the company's regulation uniform while on duty.

The writer remembers well when the men raised all kinds of objections to getting the first brass button suit, but he has not forgotten that a year or two later, the new men when "turned in", were just as anxious to get their regulation suits at the earliest possible moment, so that the friendly

C. F. ORR.

garb might help conceal from the public the fact that they were green at the business.

The manufacture of street railway uniforms has grown to be a large industry, but the price secured for the men by the companies working through competition has been such that none but such concerns as have the facilities for operating the business on a very extensive scale are able to long continue in it. Such a survival of the fittest, is the concern of C. F. Orr & Co., Chicago, which undoubtedly makes more street railway uniforms than any other house in the world. And every garment is made individually to order from measure taken each time, and the same process of making, fitting and finishing is applied to every uniform that is given to a hundred dollar suit. The street railway uniform as made by them is fully equal to what the merchant tailor would have to charge at least ten dollars more for. During the past 15 years in which this house has been engaged in the manufacture of uniforms it has had competitors by the dozen, but in spite of cut prices which proved to result in poor work, it has kept steadily to the front until now it has the business of all the large roads in this city and nearly all the lines for several hundred miles in each direction. The steadfast rule has been that no man should be allowed to wear a uniform which did not fit, and which was not perfectly made, and the natural result has been that the business has grown until now it has assumed large proportions. The Chicago City Railway, which has divided its work among several concerns for years, has just closed an exclusive contract with Orr & Co., for all its uniforms.

### NEW GOVERNOR OF BALL ENGINE COMPANY.

The illustration shows the new governor recently designed by the Ball Engine Company, Erie, Pa., to fulfill the exacting requirements of electric lighting in the modern office building, where it is demanded that there shall be only the minutest variation in speed under widely varying loads and changing pressures. It is an adaptation of the Rites governor, and very simple in its construction. The entire governor comprises but one moving piece which is pivoted at a single point, thus doing away with the multiplicity of connections and joints (often but poorly lubricated) and making

a mechanism which not only regulates with the highest degree of accuracy but does so with extraordinary rapidity and without surging.

Technically stated, the centrifugal element upon which the degree of refinement of regulation in all governors depends is combined with an inertia element, relatively so great that instant and extreme changes of load are immediately provided for without waiting for the otherwise necessary manifestation of centrifugal force.

The suspension pin is made of hardened crucible steel and the suspension pin eye is of phosphor bronze. The little lubrication required is secured by forcing grease from a compression grease cup into a number of recesses in the bore of the bushing.

### ART IN ADVERTISING.

The Western Electric Company of Chicago is sending to its friends a series of half-tone illustrations of classic pictures with appropriate quotations. This month the picture is entitled "The Battle of Competition" and is from a famous painting, the Rape of the Sabines. It is a handsome half-tone; 8 x 11 in., and will prove an ornament to any office.

It is reported that another trolley line is to be built between Bethlehem and Allentown, Pa., being a continuation of the Easton line.

W. O. HANDS RESIGNS.

The directors of the Northeast Electric Railway Company of Kansas City, Mo., on August 19 accepted the resignation of W. O. Hands as superintendent and purchasing agent, to take effect October 1. Strenuous but unavailing efforts were made to have Mr. Hands reconsider his determination to leave. W. C. Weaver, auditor of the Northeast Electric Company, has been appointed superintendent temporarily and C. G. Adney, assistant superintendent and purchasing agent.

W. O. HANDS.

Mr. Hands has long been identified with electrical and street railway interests. From 1887 to 1890 he worked in the various departments of the Brush Electrical shops of Cleveland and was then employed by the Short Electrical Company. For the next two years he supervised or assisted in the installation of railways in Muskegon, Mich., Rochester, N. Y., Baltimore and Washington. After serving as electrician and superintendent of the Braddock (Pa.) Street Railway Company, Mr. Hands accepted similar positions at Beaver Falls. In 1894 he went to Kansas City to take up the duties of the offices he now holds. As an evidence of good will the company presented Mr. Hands \$100 and a memorial was given by the employees. Mr. Hands has accepted the position of construction engineer with the East Side Electric Company of Kansas City, which is soon to commence work on a new road.

STORAGE BATTERIES FOR TRAMWAYS.

The application of storage batteries to the street railway lines of Zürich and Remscheid was described in a paper before the Elektrotechnischer Verein by Ludwig Schröder. The experiment of connecting the storage battery directly across the terminals of the dynamo without using an automatic cell switch was tried on the Zürich-Hirslanden lines with success. Fig 1 shows the manner in which the 270 cells are connected in the railway circuit. The ammeter A

FIG. 1—CONNECTIONS FOR STORAGE BATTERIES.

reads either side of the zero mark so as to indicate whether the cells are charging or discharging.

The current and voltage curves are shown in Fig. 2, the

FIG. 2—CURRENT AND VOLTAGE CURVES—ZÜRICH.

shaded portion indicating the discharge of the batteries and the heavy line represents the current output of the generators. As may be seen the variation is only between 72 and 102 amperes in the dynamo circuit while the line fluctuates from 20 to 210 amperes. The voltage on the line circuit is quite constant, the maximum variation being between 535 and 560. The curves are plotted for 24 minutes, the time required for the cars to make a complete trip. The battery described has been in service for the past 2½ years, nine months of which it has been connected directly to the dynamo terminals, and as yet there is no trace of wear

FIG. 3—CURRENT AND VOLTAGE CURVES—REMSCHIED.

reported. The coal consumption has decreased to 3.9 lbs. per car-mile, which is low considering the small installation, a 90-h. p. engine, and the hilly roadbed.

On the Remscheid Electric Tramway lines there are some heavy grades, in one place there being a difference of level of 350 ft. in 1½ miles with a maximum gradient of 10.6 per cent. The railway is 6.8 miles long and of this but 180 ft. is on level roadbed. Motors in 40 manufacturing establishments are also connected to the line circuits.

The power station equipment consists of three boilers working at 120 lbs. pressure, four McIntosh-Seymour 160-h. p. engines and four 100-k-w. generators. On account of the grades and the nature of the service the fluctuations in the current demand were enormous; on week days the railway service and the workshops required from 100 to 400 amperes and on Sundays from 0 to 450 amperes. The average demand for the railway service was 135 amperes and including the factories, 232 amperes. The increased demand for power for the factories required an enlargement

of the plant, but for average loads it was ample in capacity. A storage battery was installed, consisting of 250 Hagen cells, having a capacity of 648 ampere-hours with a rate of discharge of 216 amperes. The four compounded dynamos were connected as shunt machines in parallel with the battery, and a booster designed to give 600 amperes at 100 volts was placed in series with it.

The current and voltage curves taken on Sunday when the railway alone is operating are shown in Fig. 3. In the dynamo circuit the variation is between 115 and 150 while on the line circuit it increases from 0 to over 400. The voltage remains very nearly constant, 495 and 515 being the limits. In Remscheid there has been a saving of 11 tons of coal per week since the battery was installed and 200 h. p. of the dynamo output is also saved. The battery complete costs only half as much as the machines which are now available for any further increase in the load.

### THE INDIANAPOLIS, ANDERSON & MARION RAILWAY.

Plans have been matured by several railway promoters, principally Noah Clodfelter, for connecting by electric lines the industrial cities in the natural gas belt in central Indiana. The Indianapolis, Anderson & Marion Railway is the first interurban line upon which actual construction has commenced. The route runs from Marion to Anderson, 39 miles, by way of the Soldiers' Home, through Gas City, Jonesborough, Fairmount, Summitville, Prosperity, Alexandria, Linwood and North Anderson; later an extension of 35 miles will be made to Indianapolis. In construction and equipment this line was designed to equal any interurban in the country.

One power station is built at Alexandria and another at Fairmount, where the fuel, which is natural gas, has been guaranteed free for 15 years. The equipment of each station will consist of two 250-h. p. automatic, high speed engines belted to two 150-k. w. Westinghouse generators, and five 100-h. p. tubular boilers. The trolley wire is figure 8, No. 0000, the contract being placed with John A. Roebbing Sons.

In conception and design the road is an exceptionally fine one, but the greatest difficulty is in the lack of proper financial backing. Last May the company entered into a contract with Louis Enricht, of Chicago, for the entire construction of the railway, including roadbed, track, power stations and equipment, and all electrical appliances; everything was to be complete for operation, and the contractor was placed under \$20,000 bonds for the fulfillment of his agreement. Mr. Enricht let contracts for labor and materials, including rails, engines and electrical equipment. The contract stated that the company was to pay Mr. Enricht a certain amount of cash each month and notes of the company secured by gold bonds. No cash payments were made, but \$16,000 in bonds were turned over to the contractor. On account of some misunderstanding the company wished to cancel the contract and recover the bonds, but this Mr. Enricht refused to permit. Charges were filed and Governor Mount, of Indiana, was requested to begin extradition proceedings to bring Enricht to Indiana for justice. Governor Tanner investigated the case and refused to honor the requisition. Mr. Enricht states that he has complied with his contract so far and is ready to continue to do so and will insist on

carrying it out. He has made an offer, backed by Chicago capitalists, to take the issue of bonds at 90 and complete the road, provided the present company turns over 51 per cent of the stock. The capital stock is \$500,000 and there is a \$500,000 bond issue.

### VICTORY FOR THE AURORA & GENEVA.

As described in the REVIEW for January, 1897, there are two interurban roads connecting the towns along the Fox river in northern Illinois. One of these runs from Carpentersville through Elgin with the southern terminus at Geneva, and the other, the Aurora & Geneva, had at that time completed its line from Aurora as far north as Batavia, two and one-half miles south of Geneva. The intention was to build this short piece of track early last spring, thus permitting a through service from Carpentersville to Aurora.

In order to avoid the heavy grades and surface crossings with steam roads, which would have been encountered by following the highway from Batavia to Geneva, the company wished to secure a private right of way through this district. There were 13 property owners in the district and the company was able to settle with but three of them; after vain endeavors to secure consents condemnation proceedings were instituted in May last. The case came to trial in the circuit court of Kane county and after a hard contest for three weeks was decided August 27.

The property owners claimed heavy damages, but the company was permitted to show benefits as an offset. The aggregate damages to adjacent property claimed amounted to \$53,000; the jury awarded \$4,533, which is considered by disinterested parties to be fair to both sides. The railway company had offered considerably more in settlement of the claims and is in consequence well satisfied.

The property owners propose to appeal the case to the supreme court on the ground that a street railway organized under the "Horse and Dummy Act" has not the power to condemn private property and must confine itself to the highway throughout its entire route. Unless a supersedeas is granted by the supreme court the company will pay the amount of the verdict and proceed with construction at once, taking its chances of an adverse decision by the higher court.

### BICYCLES CARRIED AT ATLANTA.

The Atlanta (Ga.) Consolidated Street Railway Company has decided to permit bicycles to be carried on its cars. This is in the nature of an experiment and no permanent arrangements have been made and no special hangers applied to the cars. Only a very small revenue was expected from carrying wheels, the service being an accommodation to the public. The order to conductors is as follows:

This will be your authority to allow bicycles (not more than two at any time) carried on your car, if in your judgment the car is not too crowded, the bicycles to be hung on the brake handle over the rear dash or held by the owner in that position. You will be required to collect ten cents for each bicycle carried. Do not register such collections but make a special report on your trip sheet, giving the time of day such collections are made.

H. F. Pabish, general electrician of the Union Depot Street Railroad Company has fitted up a complete gymnasium in the power station of the Bellefontaine road.

### Alabama.

BIRMINGHAM, ALA.—The Birmingham Traction Company has been organized with \$50,000 capital stock to operate the East Birmingham & Gate City Dummy Line.

### Arizona.

FLAGSTAFF, ARIZ.—The Santa Fe & Grand Canyon Railway Company will build an electric road from Flagstaff to Williams. Charles E. Potter is treasurer; and the backers are Lombard, Goode & Co., of Chicago.

### California.

PASADENA, CAL.—Tracklaying has begun on all streets upon which the Pasadena & Los Angeles Electric Company holds franchises.

LOS ANGELES, CAL.—The Los Angeles Street Railway Company has contracted with the Southern California Electric Light & Power Company for power to operate its lines for 20 years.

OAKLAND, CAL.—F. C. Havens, representing the Realty Syndicate, bought the East Oakland Street Railway August 16 for \$60,500 at sheriff's sale. The syndicate controls a number of other local roads.

SANTA ANA, CAL.—The Santa Ana & Newport Railway Company has been incorporated to build a line. Capital stock, \$500,000; incorporators, Joseph McFadden, R. McFadden, M. M. Crookshank, W. H. Spurgeon and E. M. Smiley.

### Chicago.

CHICAGO.—A permit to erect a one-story brick power house, 199 x 112 ft. has been granted the South Side Elevated Railroad Company. It is to cost \$65,000.

CHICAGO.—During the next two months the street railway companies controlled by Charles T. Yerkes will expend \$1,500,000 in building new and relaying old lines. Nearly 30 miles of double track will be built. Five miles will be laid in Montrose boulevard, five miles in Lawrence avenue, 2.5 miles in Robey street, two miles in Crawford avenue, 2.5 miles in California avenue and four miles in West 12th street.

CHICAGO.—Work has begun on the stock yards line of the Chicago General Railway. The franchise for the building of the line to the stock yards on Throop and Morgan streets was obtained by the West Chicago Street Railroad Company and under an agreement turned over to the Chicago General, which, with the City Railway, will build the line, the whole to be operated by the Chicago General, independently of the other two companies.

### Colorado.

CANON CITY, COL.—The Canon City & Cripple Creek Electric Railroad Company has been incorporated to build a line. Capital stock, \$1,000,000; incorporators, James J. Cone, Lyman Robison, and Thomas S. Wells.

DENVER, COL.—Orman & Cook, contractors, of Pueblo, promise to have 25 miles of the Cripple Creek District Railway finished in less than five months. At Canon City the company will build a 4,000-h. p. electric plant to furnish light and power to the city as well as to the road. Another of the plants will be located at Marigold. At both of these places the company controls cyanide gold extracting mills. The route is almost an air line with a continuous grade. The Willow Creek Toll Road Company has been incorporated to build roads and electric railways. The main line will extend from the lower end of the Holy Moses tramway to the summit of the divide. Capital stock, \$500,000; incorporators, Henry C. Rowley, M. E. Chapman and L. C. Chapman. The El Paso Electric Railway &

Tunnel Company has been incorporated to build lines in El Paso county. Capital stock, \$1,000,000; directors, Charles Neff, Harry Gertig and D. A. Chapin. The Air Line Electric Railroad Company has been incorporated to construct an interurban electric railway from the suburbs of Denver north through Arapahoe, Boulder, Weld and Larimer counties. Capital stock, \$600,000; president, E. M. Hall.

### Connecticut.

SOUTHINGTON, CONN.—The street railway generator in the light and railway plant of the Southington & Plantsville Tramway was burned out recently and has not been replaced owing to the absence of General Manager L. V. Walkley on his vacation in Canada.

NEW HAVEN, CONN.—The Milford Street Railway Company has obtained practically all the right of way required for its ten miles of road. The whole plant is expected to be in operation before cold weather sets in. They will give a continuous ride from New Haven to Bridgeport. The president of the company is ex-Sheriff Charles A. Tomlinson, and one of the directors is S. Harrison Wagner, the New Haven attorney.

### Florida.

TAMPA, FLA.—Another company to compete with the consumers Street Railroad will be organized, it is said, by F. A. Solomonson, George T. Chamberlain and Edward Manrara.

PENSACOLA, FLA.—The Pensacola Electric & Terminal Company has been incorporated to build and operate an electric railway. Capital stock, \$200,000; president, W. H. Northrup.

GAINESVILLE, FLA.—H. E. Taylor, of the First National Bank, advises us that arrangements have been made for the installation of the proposed electric lighting plant, and that the railway may be put in later.

### Illinois.

WAUKEGAN, ILL.—Lightning ran into the Bluff City Electric Railway power house August 14 and burned out a generator. Until the afternoon car service was paralyzed.

ELGIN, ILL.—The Elgin, Carpentersville & Aurora Railway Company has been incorporated to purchase the Elgin City Railway and lighting plant, and the lines to Carpentersville and Geneva. It is proposed to extend to Lake Geneva, Wis. Capital stock, \$500,000; incorporators, William Grote, George P. Lord, David B. Sherwood, James B. Lane, F. Dunbar Waldron, George M. Peck and Alfred B. Church.

### Indiana.

JEFFERSONVILLE, IND.—Capt. E. K. Howard, of Jeffersonville visited Louisville recently in an endeavor to make a deal for the control of the City Railway of Jeffersonville, consisting of five miles of track, 11 cars and 35 miles.

MARION, IND.—Suit has been brought by the Indianapolis, Anderson & Marion Electric Railway Company against the Fidelity & Deposit Company of Maryland and Louis Enrich to recover \$40,000 for failure to carry out the contract to build 40 miles of road.

INDIANAPOLIS, IND.—The appointment of James L. Bradford as receiver of the Indianapolis, Anderson & Marion Electric Railway on August 30, by Judge Brownlee, at Marion, adds another chapter to the checkered career of Noah Clodfelter's railway enterprise. This receiver was appointed on the application of Ansel B. Smith, Thomas J. and Charles F. Haworth. Judge Baker of Indianapolis has taken no action on the application of Michael Malone of Chicago for a

receiver. The railway company's attempt to have Louis Enricht, the general contractor, tried on the charge of embezzlement has failed, owing to the refusal of Governor Tanner of Illinois to honor the requisition of the Indiana state executive.

## Kentucky.

PADUCAH, KY.—The People's Light, Power & Railway Company has been incorporated. Capital stock, \$50,000; chief incorporators, G. C. Wallace and W. F. Paxton. The new company will operate the reorganized and consolidated lighting and railway plants as reported in the BULLETIN.

## Louisiana.

NEW ORLEANS, LA.—The Orleans Street Railroad Company asks permission to erect a temporary barn. Plans have been drawn for a fine building to replace the one burned.

NEW ORLEANS, LA.—Compressed air traction is being investigated by Robert R. Zell, engineer of the proposed Orleans & Jefferson Railroad, which is to be built out Napoleon avenue through the territory of the new land company. Mr. Zell is visiting Washington and New York to inspect the operation of the systems exploited by the American Air Power Company and the Compressed Air Power Company. Contracts will be closed this fall for all the material necessary to complete the road before spring.

## Maine.

SACO, ME.—Permission to lay track through North and Elm streets has been granted a new corporation, the Saco River Electric Railroad Company. Oliver Downing, of Boston, who has taken \$100,000 of stock in the new road, says that if nothing prevents the cars will be running between Biddeford and Bonny Eagle before snow flies.

SKOWHEGAN, ME.—A syndicate composed of R. W. Brown, E. P. Page, J. P. Clark and A. H. Weston has bought the Norridgewock & Skowhegan Electric Railroad from the bondholders, paying \$15,000 therefor. The road cost, when constructed four years ago, \$55,000. It is proposed by the new syndicate to improve the line and to build a hotel in Norridgewock and a pleasure pavilion at the pines, about half-way between the two villages. It is expected that the improvements to be made will cost about \$40,000.

## Maryland.

BALTIMORE, MD.—The Baltimore, North Point & Bear Creek Railway Company has been incorporated to construct five miles of double track trolley line from East avenue and Monument Street in Baltimore to Bear Creek in Baltimore county. Preliminary surveys have been made. Work is to begin about September 18 and be completed within 90 days. Capital stock, \$300,000; incorporators, Daniel Teller, president; Robert H. Carr, Jr., secretary and treasurer; Samuel Greenwald, Sr., general manager, and H. Y. Bready, chief engineer.

## Massachusetts.

NEWBURYPORT, MASS.—The People's Street Railway Company has filed a \$10,000 bond to guarantee the completion of the road within 60 days.

NEWTON, MASS.—A line paralleling the Newton Street Railway from West Newton to Newton Corner will be built by the Wellesley & Boston Street Railway Company.

NEWTON, MASS.—The Newton Street Railway Company will ask for franchises to build a line from Waltham to Waverley and Belmont, with a view to ultimately extending to Cambridge, where a connection will be had with the West End Street Railway of Boston. Right of way for a line from Waltham to Lexington also is desired.

Haverhill, Mass.—A line from Haverhill to Salem Depot and Canobie Lake, N. H., is to be built by the Haverhill & Salem Electric Railway Company, recently organized with \$60,000 capital stock, by W. B. Ferguson of Malden; Frank E. Lowe of Greenfield; C. E. Barnes of Plymouth; T. C. White of Methuen; W. B. Robinson, Charles Burnham and E. B. Fuller of Haverhill. A franchise will be applied for.

SPRINGFIELD, MASS.—The Springfield & Southwestern Electric Railway Company, which has a charter to build a line from Springfield through Agawam, Suffield and East Granby to Rainbow, is showing signs of activity. It is said the line will be completed this year. Grading has been completed from the state line to Suffield Centre. Two power houses will be built. Horace T. Ford of Suffield, Conn., is president.

LEXINGTON, MASS.—An electric railway company will be incorporated to build a line from North Lexington to Arlington Heights to connect there with the West End Street Railway of Boston. It is also proposed to run branches to Woburn and Waltham, making a total of 15 miles. The probable directors are L. A. Saville and Alfred Pierce, of Lexington; C. E. Dresser, of Leominster; Charles Cummings, of Woburn; R. B. Tabor, of Cambridge; O. M. Gove, of Waltham, and N. H. Peirce, of Arlington.

## Michigan.

SAGINAW, MICH.—Homer Loring and George B. Morley, acting receivers of the Union Street Railway, were August 27 appointed receivers of the Consolidated Street Railway.

HOLLAND, MICH.—Work on the Holland & Lake Michigan Electric Railway has been stopped temporarily owing to a refusal of the Chicago & West Michigan Railroad to deliver more freight until a draft for \$300 for charges is paid.

BENTON HARBOR, MICH.—The Benton Harbor & Eastman Springs Street Railway Company has been incorporated with \$25,000 capital stock to operate the line being built by contractors Forester & Westcott. The incorporators are Seely McCord, Elbert C. Hurd and J. Stanley Morton.

## Minnesota.

BRainerd, MINN.—Operation of the Brainerd Electric Railway has ceased. The line has been losing money from the start.

BRainerd, MINN.—C. N. Parker offers to extend his street car line to East Brainerd and run it for at least one year more if the business men of the city raise a bonus of \$2,000. The committee has secured \$1,500.

STILLWATER, MINN.—The city has begun proceedings to annul the franchise of the Stillwater Street Railway and compel Flint & Scott to tear up the rails. The latter have sold the poles and wire to the Stillwater Gas & Electric Light Company and will be pleased to remove the track, which they purchased as junk.

## Missouri.

ST. JOSEPH, MO.—Material is being placed on the ground for the Union Line extension. While in New York recently Manager Van Brunt purchased a 750-h. p. engine. A new boiler is being set in the power house.

CARTHAGE, MO.—Directors of the Southwest Missouri Electric Railway have decided to put in a telephone system with instruments at each switch. A signal station will be placed in charge of a dispatcher. A steel bridge will be thrown over Turkey creek.

KANSAS CITY, MO.—The East Fifth Street Electric Railway Company has been incorporated to build and operate a line on Fifth street to Heim's brewery. The capital is nominally fixed at \$2,000. The incorporators are Joseph Heim, Ferdinand Heim, M. G. Heim and Clarence Palmer.

ST. LOUIS, MO.—The House of Delegates has placed the General Traction Company's bill on file, where it will probably slumber forever. President Meier has declined to sign the North & South Railway bill. The promoters of the bill plan to reintroduce and pass it in a regular manner.

ST. JOSEPH, MO.—Ferd Heim, a wealthy brewer of Kansas City, is said to be interested in a project to build several miles of electric railway from Lake Contrary to the stockyards at St. George, and by a circuitous route through the city to Krug Park. It is said St. Joseph capitalists will subscribe \$150,000.

KANSAS CITY, MO.—The Kansas City & Eastern Railroad Company has been incorporated to operate a new suburban electric line from Westport to Leeds, a distance of five miles. The company will run two cars at first. These will be of the combination type adapted to carry the produce of market gardeners to the city. Coal will also be transported from the mines at Brush Creek, where the company's power house is located. Capital stock, \$50,000, incorporators, George Hoffman, Charles B. Adams, John Hoffman, Henry Pfeiffer and B. F. Robinson. The chief backer is the Schaefer estate, represented by Pfeiffer and Hoffman.

### Montana.

MISSOULA, MONT.—An electric railway through the National Park to Cook City is proposed. D. B. May is interested.

BUTTE, MONT.—John R. Wharton, superintendent, was August 16 appointed receiver of the Butte Consolidated Railway Company on petition of the Massachusetts Loan & Trust Company, in behalf of bondholders.

### Nebraska.

OMAHA, NEB.—The city has granted the Omaha & Council Bluffs Railway & Bridge Company an extension of its franchise for fifty years to enable the company to raise money with which to carry out desired improvements, as well as to discharge the floating debt.

### New Hampshire.

PORTSMOUTH, N. H.—The Portsmouth, York & Kittery Electric Railway went into operation August 11.

EXETER, N. H.—To provide funds for the construction of three miles of track, the purchase of three more cars and the erection of a car barn in Exeter, the Exeter Street Railway Company has resolved to ask the state railroad commissioners for permission to issue \$25,000 bonds and \$25,000 stock.

### New Jersey.

JERSEY CITY, N. J.—The city authorities will require the Consolidated Traction Company to conform to the law requiring all cars to have vestibuled platforms.

ASBURY PARK, N. J.—Henry S. Terhune of Long Branch has been appointed receiver of the Asbury Park & Belmar Street Railway, to succeed William H. Dayton, who died July 28.

BRIGANTINE, N. J.—Stockholders of the Brigantine Transit Company have voted to make improvements, and have elected new directors.

JERSEY CITY, N. J.—The Columbia Company has been incorporated under the laws of New Jersey to build and operate street railways, electric lighting, water and gas works in Jamaica. Capital stock, \$80,000; \$14,000 paid up; incorporators, Elisha B. Hopkins, Wellfleet, Mass.; Warren F. Wiley and John J. Mulvaney, Jersey City, N. J.

NEW BRUNSWICK, N. J.—Right to lay tracks over the Albany street bridge has been given by the Brunswick Traction Company by the Middlesex county freeholders. The Piscataway township council has granted the company a franchise to the limits of Bound Brook. This system will connect with the Metuchen and New Brunswick route. Secretary Edward Radel says work will be prosecuted vigorously so that the new lines will be in operation by October 1.

### New York.

BALLSTON, N. Y.—A receiver is asked for the Ballston Terminal Railroad Company.

BUFFALO, N. Y.—The village board of Hamburg voted August 18 to grant a franchise to the Buffalo, Hamburg & East Aurora Electric Railway Company upon the commencement of work by the company on the proposed line.

FLUSHING, N. Y.—The Flushing & College Point Electric Railway Company has been notified by the village trustees that unless the improvement of the roadbed is begun within 48 hours the franchise will be annulled.

NEW PALTZ, N. Y.—The new trolley line is in operation between Lloyd and New Paltz. Considerable work remains to be done on other portions of the line, and the crossing of the West Shore Railroad has not been arranged.

LITTLE FALLS, N. Y.—An extension of time in which to construct the road is asked by John V. Quackenbush, of Mohawk, president of the Little Falls & Herkimer Electric Railway Company. The present franchise is about to expire.

STATEN ISLAND, N. Y.—The Staten Island Midland Railroad Company has obtained a favorable decision from the Supreme Court on the necessity of laying tracks through South street in order to get a station at the St. George ferry house.

LIBERTY, N. Y.—Five miles of the Liberty-Jeffersonville Electric Railway has been graded. Oliver Hofer, engineer in charge, says that the materials for construction are ready for shipment, and that the line will be in operation next summer.

NEW YORK, N. Y.—The state railroad commission has granted the applications of the Second Avenue Railroad Company and the Forty-Second Street, Manhattanville & St. Nicholas Railroad Company for permission to change their motive power to the conduit electric system.

NIAGARA FALLS, N. Y.—The Niagara Falls Park & River Railway Company will install more electrical machinery to generate the current for sale to power users. Until the Canadian Power Company has completed its Canadian works it will use a portion of the railway company's present surplus.

GLOVERSVILLE, N. Y.—The contract for grading the Mountain Lake Electric Railroad has been awarded to Alfred Keith of Oldtown, Me., a director of the company. No contracts have been let for cars or rails, and probably will not be until next year, when construction will be pushed so as to have cars running by June 1.

OLEAN, N. Y.—The Olean Terminal Railway Company has been incorporated to build 7,500 ft. of electric road in Olean, to connect with the Olean-Bradford Interurban. Capital stock, \$25,000; directors, F. N. Love, Greenfield, Mass.; Henry S. Sartwell, James W. O'Brien, George Forbes, Joseph L. Page, Fred D. Forbes, William L. Frazee and George Van Campen, of Olean.

NEW YORK, N. Y.—The New York and Brooklyn Bridge trustees have accepted the plans and contracts for the operation of elevated railway and trolley cars across the bridge. The Brooklyn Rapid Transit Company is allowed six months in which to make changes. The Kings County Elevated is given sixty days to begin and one year to complete work, and the Brooklyn Elevated is allowed ten months. A bond of \$100,000 is required from each company.

ONEONTA, N. Y.—The Oneonta Street Railway Company has consolidated with the Oneonta & Otsego Valley Railroad Company, which was incorporated two months ago, and which recently was granted permission by the state commission to build its proposed line. The directors are: Frank Gould, A. C. Moody, A. C. Lewis, Parker Wilson, A. D. Getman, C. Van B. Pruyn, H. H. Getman, Squire B. Gardner and D. W. Miller, all of Oneonta.

### Ohio.

NEWARK, O.—Receiver J. F. Lingafelter of the Newark & Granville Electric Street Railway is making extensive repairs to the roadbed. New switches will be put in.

TOLEDO, O.—The Toledo & Michigan Traction Company, recently incorporated by Detroit capitalists, has applied for a franchise to build. Surveyors are laying out the proposed route.

TOLEDO, O.—It is said that Leopold Freud and Hyacinth C. Burt have sold some of the bonds of the proposed electric railway between Toledo and Detroit. Engineer Mason L. Brown of Detroit is surveying the route.

**WARREN, O.**—The franchise of the Trumbull Electric Railway Company between Warren and Niles was extended recently by the county commissioners from 20 to 50 years, in consideration of \$2,500 worth of road work for the county.

**LIMA, O.**—Right of way for the electric road from Lima to Bellefontaine has been obtained for almost the entire distance between New Hampshire and the Logan County Infirmary. Farmers are deeply interested and \$41,000 of local capital is promised.

**BOWLING GREEN, O.**—Zeph Waltz of Tontogany is getting right of way for an electric road to be built from Bowling Green to Napoleon by way of Weston and Grand Rapids, by the Bowling Green, Weston & Napoleon Electric Railway & Power Company.

**CANAL DOVER, O.**—Control of the Tuscarawas Electric Company has passed from Tom L. Johnson by the transfer of \$50,000 of stock to L. P. Wentz of Sutton, Neb., Theodore Wentz, cashier of the First National Bank, and David King, a retired merchant. The road, which connects Canal Dover and New Philadelphia, never made any money. At times the line has been superintended by Robert Johnson and Tom J. Johnson. John B. Hoefgen, Tom L's confidential man, will be manager.

## Pennsylvania.

**CLEARFIELD, PA.**—Kittanning men have purchased at sheriff's sale the DuBois Traction Passenger Railway and the DuBois Electric Light Plant.

**CHAMBERSBURG, PA.**—Fremont Wilson, chief engineer of the defunct Chambersburg Electric Railway Company, says he has a company that will push the enterprise.

**PITTSBURG, PA.**—Electric motor street sprinklers will be placed on the lines of the Consolidated Traction Company. If possible all lines will be supplied with them this fall.

**PITTSBURG, PA.**—A franchise has been granted by the Braddock borough council to the Corey Avenue Street Railway Company, which is a branch of the Second Avenue Traction Company of Pittsburg.

**COLLEGEVILLE, PA.**—The Collegeville Electric Street Railway Company has been incorporated to build two miles of road in Collegeville. It is expected the line will be sold or leased to the Schuylkill Valley Traction Company.

**GREENSBURG, PA.**—The Greensburg & Mount Pleasant Street Railway Company has been incorporated to build nine miles of electric railway from South Greensburg to Mount Pleasant. Capital stock, \$75,000. W. F. Sadler of Carlisle, president.

**PITTSBURG, PA.**—The McKeesport, Duquesne & Wilmerding Street Railway was purchased August 4 at receiver's sale by Horace Crosby, assistant general manager of the National Tube Works, for \$175,000. Mr. Crosby is a heavy stockholder in the street railway.

**PITTSBURG, PA.**—The Pittsburg & Mount Washington Street Railway Company has accepted the contract with the city by which it agrees to pay 15 cents per car for each round trip over the Smithfield street bridge. The contract for the construction of the entire line has been let to Booth & Flinn, who begin work in September and finish by January 1.

**PITTSBURG, PA.**—The Second Avenue Traction Company has about closed a deal for the purchase of the line operated by the Versailles Traction Company between McKeesport and Versailles borough. The Versailles line will be operated in connection with the road which the Second Avenue Traction Company contemplates building to West Newton.

## South Dakota.

**STURGIS, S. D.**—Manager Wells of the Sturgis Light & Railway Company has received notice that the application of the company to build an electric railway on the Fort Meade military reservation has been granted by the war department. A franchise will be asked for a commercial lighting system.

## Texas.

**CUERO, TEX.**—R. A. Pleasants and others have been granted a franchise for a street car line. The line must be built within 12 months.

**SAN ANTONIO, TEX.**—W. H. Weiss, president, writes that the San Antonio Street Railway Company is in the market for a 5 or 6-ton road roller, operated by steam or gasoline engine. Give description and price.

**GALVESTON, TEX.**—The Galveston & Houston Electric Railway Company has been granted franchises on condition of selling one avenue. The grants have been accepted by the company. W. J. Hamlett is secretary of the company, Judge Norman G. Kittrell, of Houston, attorney, and R. E. Richardson, of Chicago, consulting engineer.

## Vermont.

**BARRE, VT.**—The city has accepted the \$10,000 guarantee bond of the Barre & Montpelier Traction & Power Company.

**ST. JOHNSBURY, VT.**—The St. Johnsbury Electric Railroad Company will begin work on the extension to Lyndon and Lyndonville as soon as the work on the Montpelier road is completed.

## West Virginia.

**CHARLESTON, W. VA.**—The city street car line, which has been in the hands of the court for two years, has been sold for \$21,000 to Cleveland, O., parties.

## Wisconsin.

**WAUKESHA, WIS.**—Stockholders of the Waukesha Beach Electric Railway have decided to issue 100 shares of preferred stock.

**RACINE, WIS.**—Judge Fish has confirmed the sale of the Belle City Street Railway and fixed the compensation of Receiver Smith at \$1,750.

**OSHKOSH, WIS.**—It is now said that negotiations for a consolidation of the electric and horse lines have failed, and that the Oshkosh Horse Car Company will independently equip with electricity.

**RACINE, WIS.**—The reorganized Belle City Electric Railway Company has selected Joseph Miller, president; H. M. Wallis, vice president; Jackson I. Case, secretary, and Frank J. Miller, treasurer.

**MILWAUKEE, WIS.**—The Milwaukee Electric Railway & Light Company has purchased the franchises, track and all interests of C. R. Gether in the Whitefish Bay Street Railway, and will proceed at once to connect the line with the Oakland avenue extension, with the intention of having both in operation by June 1, 1898.

**MILWAUKEE, WIS.**—While the officers of the Milwaukee Electric Railway & Light Company have taken charge of the Milwaukee & Wauwatosa Motor Road, the company has not acquired the line, and its officers are managing the property for its owners who are stockholders of the Milwaukee Electric Railway & Light Company.

**WAUKESHA, WIS.**—Stockholders of the Waukesha Beach Electric Railway held a special meeting to consider a sale of their property to the Milwaukee Electric Railway & Light Company. A committee was appointed to investigate the whole subject. The prospective purchasers offer \$62,500, and desire an option until September.

## Canada

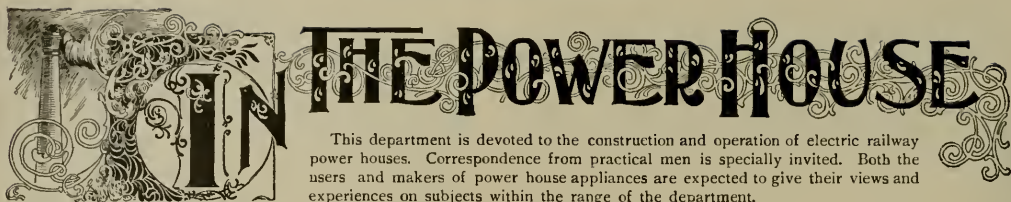

**LONDON, ONT.**—It is proposed to extend the London Street Railway to Pottersburg, and to connect the city with Lucan.

**CORNWALL, ONT.**—An extension 1.5 miles in length is to be constructed by the Cornwall Electric Street Railway Company.

**NIAGARA FALLS SOUTH, ONT.**—The council has granted a franchise over certain streets to the Lundy's Lane Electric Railway Company.

**EXETER, ONT.**—Local capitalists are promoting an electric railway from Grand Bend to St. Mary's, with a scheme for power distribution in connection.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

## A Possible Cause for Fly-Wheel Accidents.

In a paper on "Fly-Wheels and Why They Burst" read before the Electric Club of Cleveland and published in the REVIEW for January, 1896, page 17, Prof. C. H. Benjamin makes the following statement:

"A careful study of the fly-wheel accidents in power stations, as described in the technical journals for the last two or three years, will show that the blocking of the governor was a feature of nearly all of them; that the breaking of the generator pulley has been in several cases the direct cause of the bursting of the wheel and that the sudden shocks caused during a short circuit by throwing the load on and off are probably responsible for several more accidents. Racing of an engine caused by its generator changing into a motor is still a disputed subject, and as this paper is written from a mechanical standpoint I will not enter into the discussion."

While the latest fly-wheel accident, that at Tacoma, appears to have been due to the failure of the governor of the engine, we desire at this time to place on record a recent experience of the engineer of a large street railway plant. The fly-wheel, fortunately, proved equal to the stresses of an abnormally high rim speed and failed in its usual office of so completely wrecking the engine and building as to leave very little ground for the defence of that much maligned though ever consistent servant, the governor. Fortunately the damage, although slight, was so complete and evident that it left no cause for doubt as to the origin of the trouble.

In this particular power station there are four direct connected units, two of 500 k. w. and two of 800 k. w., all operated in multiple. The pressure at the bus bars is 570 volts. The normal speed is 100-r. p. m. The generators are compound wound.

On this occasion there were running two 500-k. w. and one 800-k. w. generators, carrying about 3,200 amperes collectively. Suddenly one of the 500-k. w. generators began to sing and spark at the brushes, the pitch of the screech becoming rapidly higher as the engine increased in speed. For an instant the engine seemed to be merely racing, the indications being the same as though the machine circuit breaker had opened the circuit. The action of the governor was perfect, and as soon as the engineer saw that the governor had completely shut off steam and that the speed continued to increase he realized that the fault lay with the dynamo, and signaled the operator to pull the switches. The engine had attained a speed of about 175 r. p. m. Just before going to the switchboard the operator heard a slight explosion and saw a flash beneath the engine room floor, where all the wires connecting the dynamos and switchboard are located. Immediately afterward the dynamo commenced to screech and spark. Upon reaching the switchboard he found the ammeter indicated 900 amperes, but dropped

steadily, and with the increase of speed just before the circuit breaker and switches were opened the ammeter registered 600 amperes. Upon the machine circuit breaker being pulled the engine immediately slowed down, proving conclusively that the machine was running as a motor. No damage ensued.

Investigation showed that the shunt field wire, running from the rheostat at the switchboard to the negative terminal at the dynamo, had grounded on the positive main machine cable, running from positive brush holders to switchboard, and the shunt field wire being practically a negative at the point of contact was quickly burned off, thereby opening the shunt field circuit. The shunt field coils thus becoming ineffective caused the electro motive force of the dynamo to fall at least 200 volts below that of the bus bars. Then the load on the dynamo, minus the shunt field, almost instantly fell from a load of 850 amperes to zero and still lower, to a point where it quickly changed from a compound dynamo supplying power to a series motor, the field being maintained by the heavy series winding. The friction of the engine and dynamo being the only load resistance opposed, and the potential at the brushes being unchanged, the motoring dynamo must have started to race with at least 1,200 amperes, which was gradually cut down owing to the ever increasing counter electro motive force induced by the phenomenal increase in speed. This falling off of the current was noted, as before stated, by the attendant at the switchboard.

Taking 700 amperes at 550 volts, about 500 h. p., as a conservative estimate of the average power consumed in speeding up the set, and remembering that the accelerating forces were applied almost instantaneously it is not at all remarkable that such a speed should be attained in such an incredibly short space of time. The average flow of current through the shunt field conductors is nine amperes, and as No. 8 wire is used the conductivity is ample.

As soon as the cause of the erratic behavior of the engine was ascertained the fault was remedied beyond all possibility of recurrence. As now arranged any leakage from the positive to the shunt field circuit would readily be discovered before starting the dynamo, by closing the field switch and throwing the equalizer in. Any leakage from the positive would be indicated by the voltmeter used in throwing the dynamo upon the bus bars. Of course it is to be conceded that a heavy ground would immediately burn itself out, but a slight leakage due to poor insulation or moisture would readily be discovered in the manner mentioned. The writer knows of a case where two shunt field circuits were thus affected, out of a total of five, and this was wholly due to poor insulation and a leaky steam pipe. By the discovery of a fall of potential of only 30 volts, with the machine at rest, and placing the cables and wires upon better porcelain insulators, all future trouble in that direction was avoided.

This should direct attention to a source of danger which we believe has heretofore been generally overlooked. There is a possibility of an accident from this cause in the great majority of street railway stations.

Generators with compound windings are universally used in this country for railway work and the best station economy demands that where more than one machine is used they shall be connected in multiple. There is no doubt that if the engine had been wrecked the true cause of it would never have been known and it would have been charged to the engine, the governor having failed to operate properly for "some unknown reason."

### Why Economizers Are Economical.

On July 21 W. F. Gasche presented a paper before the Western Society of Engineers on the "Causes of the Variable Efficiency of Steam Boilers and Their Influence on Tests," in which were brought out several facts of great interest to those who have to do with steam boilers, either operating or testing.

In the course of an extensive experience in boiler testing Mr. Gasche has verified experimentally the formula deduced by Rankine in 1859. As usually stated this formula is  $E' = \frac{E}{S + AF}$  where  $E'$  is the actual evaporative value (from and at 212° F.) of 1 lb. of fuel,  $E$  the theoretical evaporative value,  $S$  the heating surface of the boiler, and  $F$  the number of pounds of fuel burned per hour. The constants

If we put the ratio of the fuel burned per hour to the heating surface equal to  $R$  we get  $\frac{E'}{B} = \frac{E}{1 + AR}$ ; since in a

given boiler the ratio of the heating surface to the grate surface is constant, and also for a given fuel the product  $EB$  may be taken as a constant, we may express the actual equivalent evaporation as  $E' = C \div (1 + ar)$ , where  $r$  is the fuel burned per sq. ft. of grate per hour. Fig. 1 shows the results obtained by Mr. Gasche with four kinds of coal burned under a battery of two return tubular boilers having the following dimensions:

|                                         |                     |
|-----------------------------------------|---------------------|
| Diameter of shell outside.....          | 6 ft. ¾ in.         |
| Length of shell outside.....            | 19 ft. 11 in.       |
| Number of flues.....                    | 50.                 |
| Diameter of flues.....                  | 4½ in.              |
| Length of flues.....                    | 19 ft.              |
| Diameter of stack.....                  | 54 in.              |
| Height of stack.....                    | 60 ft. above grate. |
| Diameter of steam pipe.....             | 8 in.               |
| Total heating surface.....              | 1,352 sq. ft. each. |
| Length of grate.....                    | 6 ft.               |
| Width of grate.....                     | 5 ft. 6 in.         |
| Total grate surface.....                | 33 sq. ft. each.    |
| Ratio of heating and grate surface..... | 41 to 1.            |

Having determined the rate of evaporation of each coal for the four rates of combustion, and assuming the curve showing the variation to have an equation of the form  $E = C \div (1 + ar)$ , the values of  $C$  and  $a$  were computed by the method of least squares and the curves themselves plotted as shown in Fig. 1. The 16 tests used to get the four curves were selected at random from 160 tests made on the same boilers, all of which gave consistent results. Below the lower limit, that is, where the supply of air is excessive, rational results can not be expected and the dotted portions of the curves are merely to indicate possible locations for them at low rates of combustion.

From this the conclusion is drawn that the performance of a boiler should be determined from a series of trials, in which the distinguishing feature is a deliberate variation of the rate of combustion for the successive tests. A few isolated trials will give no conclusive evidence of the evaporative value of a given fuel under a given boiler or the value of other quantities to determine which trials are made. While the formula as given above has been shown to be correct, it must be borne in mind that the use of the same coal under boilers varying widely in type or size will generally produce a different curve of evaporation, because such a change will involve important alterations in both amount and distribution of heating surface.

The next point made by Mr. Gasche is that regenerative devices such as feed water heaters or economizers effect a compound saving, which may be divided into two parts:

The heat actually recovered which has a fuel equivalent. If  $H$  denote the total (heat above 32° F.) of 1 lb. of steam at boiler pressure,  $q$  the "heat of the liquid" of the water at the initial, and  $Q$  the heat of the liquid at the final temperature of the feed water, the saving in per cent by raising the temperature of the feed is  $100(Q - q) \div (H - q)$ .

A further saving is effected, because to generate the same amount of steam after the attachment of the feed water heater less heat is required and the coal is burned at a lower rate of combustion, thus increasing the actual evaporative value of the fuel.

Let  $F$  equal the total fuel fired per hour and  $G$  equal the area of the grate.

FIG. 1.

A and B are to make the formula applicable to different conditions. After studying the results of numerous boiler trials Rankine assigned various values to A and B which were to be used for different types of boilers. This formula is based upon two propositions: From experiments upon boilers the rate of heat transmission has been found to be directly as the square of the difference in temperature between the gases and the water in the boiler. The ratio  $E' \div E$  is largely dependent upon the efficiency of the heating surface, which is defined to be "the proportion borne by the quantity of heat transmitted to the whole quantity of heat which the hotter body must lose to reduce it to the temperature of the colder." Rankine states that the formula "was framed on the supposition that the admission of air and the management of the fire are such that no appreciable loss occurs, either from imperfect combustion or excess of air, the construction of the furnace and the mode of using it being the best possible for each kind of boiler."

Before the attachment of the feed water heater the steam evaporated (from and at 212°) is  $FE' = FC \div (1 + ar)$ .

The fuel equivalent of the heat returned to the boiler by the heater is  $F(Q - q) \div (H - q)$ .

The reduction in the rate of burning the fuel is,  $r(Q - q) \div (H - q)$ .

The formula for the evaporative value of the fuel at the reduced rate is  $E'' = \frac{C}{1 + ar [1 - (Q - q) \div (H - q)]}$ .

Were the same amount of fuel to be burned at this new rate the increased steam output would be  $F(E'' - E')$ , which has a fuel equivalent of  $F(E'' - E') \div E''$ . This reduces to  $Far(Q - q) \div (1 + ar)(H - q)$ .

When this is added to the fuel equivalent of the heat returned to the boiler we have as the total saving in pounds,

$$F \frac{(Q - q)(1 + 2ar)}{(H - q)(1 + ar)} \text{ or in per cent, } 100 \frac{(Q - q)(1 + 2ar)}{(H - q)(1 + ar)}$$

In the event that the equation of the curve of evaporation is of the form  $E' = C \div (ar - 1)$ , the saving in fuel is

$$F \frac{(Q - q)(2ar - 1)}{(H - q)(ar - 1)}$$

The correctness of this reasoning is verified in a series of tests made on a battery of three Stirling boilers with a Green

surface alone. From 1, 2a, 3a and 4a the equation of the curve was computed.

Tests 1 and 2 were made under as nearly as may be the same conditions, except that the economizer was not used in 1; the boiler pressure and the initial temperature of the feed were nearly the same in both and the total equivalent evaporation per hour differed by less than 3 per cent. The coal to evaporate 1,000 lbs. of water from and at 212° F. was 193.4 lbs. in No. 1 and 159.5 lbs. in No. 2, a gain of 17.5 per cent. The gain due to the heat saved by the economizer would be  $100(172.1 - 39.3) \div (1181.8 - 39.3) = 11.6$  per cent.

Comparing tests 5 and 6, it is seen that the saving by the use of the economizer is 21.2 per cent; the rate of combustion was practically the same in both, being 13 lbs. of dry coal per sq. ft. of grate in 5 and 12.3 lbs. in 6. The gain here is due to another cause. The rate of combustion was so low as to take the tests out of the range to which the formula is applicable, there being loss through excess of air, and consistent results can not be expected; but there is a reason why an economizer should prove more valuable under these conditions. An excess of air reduces the initial temperature of the furnace gases, and, assuming the temperature when leaving the boiler to be the same in both cases, the heat taken up in the economizer will be a greater per cent of the total.

The lower the initial temperature of the furnace gases the less will be difference in the heat transmitted by successive unit areas of heating surface, and if we imagine the abnormal condition where each square foot is equally efficient in transmitting heat, it becomes apparent that with the apparatus under consideration the economizer would transmit over one third of the total.

Another point not mentioned in the paper is the fact that it is more economical to have additional heating surface in the economizer than in the boiler itself even if the cost be the same. The circulation is such in a well designed boiler that the temperature of the contents may be said to be practically the same while in the economizer the circulation is slower and always in one direction so that the gases as they become cooled are always meeting tubes with colder water giving the ideal arrangement for transmitting heat.

FIG. 2.

fuel economizer attached. The grate surface and the heating surface were as follows:

|                                   |               |
|-----------------------------------|---------------|
| Grate surface of 3 boilers.....   | 270 sq. ft.   |
| Heating surface of 3 boilers..... | 9,543 sq. ft. |
| Ratio G. S. to H. S.....          | 1:34.2.       |
| Number of economizer tubes.....   | 448           |
| Heating surface 1 tube.....       | 10.69 sq. ft. |
| Heating surface 448 tubes.....    | 4,749 sq. ft. |

The plant had been in operation about two weeks at the time the tests were made, yet it was subject to considerable losses from air leakage, and the departure of the observed results from the curve of evaporation for Ardmoor coal under a Stirling boiler of this size and type are attributed to this cause more than any other.

Fig. 2 shows the evaporation per lb. and the rate of combustion for the six tests which were made. Nos. 1 and 6 were made without the economizer in use, Nos. 2, 3, 4 and 5 with the economizer. The points in Fig. 2 which are marked 2a, 3a, 4a and 5a show the boiler performance alone for tests 2, 3, 4 and 5; that is, they show the equivalent evaporation due to the heat taken up by the boiler heating

\* \* \*

In the introduction to this paper Mr. Gasche criticises the "standard" method of conducting boiler trials and shows that serious errors in the evaporation per pound of coal result from following the recommended practice of the American Society of Mechanical Engineers. The errors result from drawing the fires at the start and letting them burn out at the stop, being in both cases such as to decrease the true rate of evaporation.

The idea in drawing the fire and rekindling it at the start is to ascertain the weight of fuel burned with greater exactness than can be done by measuring or estimating the thickness of the fire at the commencement and bringing it as nearly as may be to the same thickness at the close.

It is stated that in point of fact the heat lost by the boiler during the rekindling far exceeds the heat equivalent of the difference of the two estimates made in taking a "flying start."

When the fire is permitted to burn out at the close there is of necessity a decrease in the evaporation at that time and the apparent average rate of evaporation is lower than

the actual rate during the greater portion of the trial. The rate of firing is also reduced, but in a less degree, so that the evaporation per pound of coal computed for the whole test is lower than the actual performance.

### Cost of Power House Operation.

With this issue we commence the publication of monthly reports of power house performance with the object of putting on record, so as to be easily available for reference and comparison, data as to the cost of operation. The value of such data regularly collected will be readily appreciated and we have received the assurance of their hearty coöperation from several general managers who have heretofore made a practice of exchanging such reports with each other.

The value of the data will be the greater as the number of stations included in the table increases and we ask each manager who is interested in such a comparison to contribute his share by sending us the report of his station.

#### COST OF POWER FOR ELECTRIC RAILWAYS.

\*Oil used for fuel.

### LARGE CROWDS AT NIAGARA.

During the national encampment of the Grand Army of the Republic in Buffalo last month the trolley car service both in that city and at Niagara Falls was very much appreciated, as was evinced by the thousands of extra passengers. All who attended the encampment quite naturally desired to see the Falls, and the steam roads and trolley line to that city were all well patronized. Never before in its history

ment of the road that this enormous number of people was carried without accident.

The gorge road at the Falls also did a big business, and it was forced to borrow cars from the Niagara Falls & Suspension Bridge line to accommodate travel.

### CHICAGO SUBURBAN NOW A YERKES LINE.

It will be remembered that when undertaking the construction of the Suburban Railroad, Chicago, the line which embraces the suburban tracks of the Chicago & Northern Pacific Railroad and a short length of the Wisconsin Central main line, Naugle, Holcomb & Co. also contracted to operate the line for the period of two years if the Suburban Company so desired. On August 17, the contract as regards operation was terminated. The Suburban Company is controlled by Mr. Yerkes, J. M. Roach, vice-president of the West Chicago being the receiver.

It is quite probable that the power house of the company at 22nd street and Harlem avenue will be shut down for the present and power supplied from the Cicero & Proviso station, until such time as the increase in traffic shall make the use of the other necessary.

A moonlight excursion was given under the auspices of the conductors and motormen of the Chester (Pa.) Traction Company to Washington Park, September 2.

G. A. R. VISITORS AT NIAGARA FALLS.

### A NEW BRAKE SHOE.

The requirements for the ideal brake shoe may be stated as follows: It shall give a high coefficient of friction, in order that the train may be quickly stopped. The coefficient of friction shall be uniform throughout the entire application in order that the wheels be not skidded. It shall not roughen the wheel tread. It shall not wear rapidly. It shall be noiseless.

The latest and most complete data upon brake shoes are the result of the extensive shop tests made by a committee of the Master Car Builders' Association, at the shops of the Westinghouse Air Brake Company during the years 1894, 5 and 6; these results show that none of the metal shoes (there were 14 different kinds tested) fulfill the specifications for the ideal. Soft cast iron gives a high coefficient and a quick stop, but the coefficient rises rapidly as the speed decreases and unless the braking pressure be reduced toward the end of the stop there is great danger of skidding the wheel. In fact with all metal shoes there is a great increase in the coefficient of friction near the end of the stop. A cast iron shoe on a steel wheel roughens the wheel tread less, and on a cast iron wheel roughens the tread more than do the other shoes. Soft cast iron shoes wear very rapidly.

Steel or wrought iron shoes smooth the tread of cast iron wheels, but score steel tires badly; the harder the shoe the worse the cutting. They wear longer than cast iron shoes but have lower coefficients of friction. Shoes of cast iron with steel or wrought iron insets, and malleable iron shoes have lower coefficients than the cast iron shoes, and in general may be said to lie between cast iron shoes and steel shoes, the good and bad qualities of both being somewhat toned down.

The chilled iron shoes wear a long time but have a very low coefficient of friction and screech most abominably.

In the spring of 1896 a composition shoe, known as shoe "P" in the published reports, consisting of a cast iron shell filled with a mixture of which iron turnings, sawdust and plumbago are prominent ingredients, was tested and found to have a higher coefficient of friction than soft cast iron; further, the coefficient was practically constant throughout the application, the effect of the shoe was to give the wheel tread a high polish both on cast iron and steel wheels, and it was perfectly noiseless. In fact so far as a shop test could determine it was the ideal shoe.

Road tests of this shoe have since been made and it is reported that after a short time in service the composition filling the shell disintegrates and falls out, leaving only the edges of the shell bearing, so that notwithstanding the fact that this shoe has a high and uniform coefficient of friction, polishes the wheel and does not screech, its failure to stand up under service has prevented its extensive use, and for this reason our readers are probably not familiar with it, and do not appreciate the merits of composition shoes.

The most recent composition shoe is one which has been developed by A. J. Allen and J. F. Morrison, of the South Side Elevated Railroad, Chicago. It consists of a cast iron shell filled with a mixture of iron turnings and mineral cement put in under pressure. This mixture is comparatively soft; pieces of it may be dug out, but when replaced they are as much a part of the shoe as in the beginning. Shoes in which the filling was originally  $1\frac{1}{2}$  in. deep, after running 18,000 miles in this particularly severe service ( $2\frac{1}{2}$  stops to

the mile) wore down until the filling was only  $\frac{1}{8}$  in. deep but it shows no signs of disintegrating and falling out. A set of shoes put in service May 21, after running 16,066 miles showed wear of from 1 in. to  $1\frac{1}{8}$  in. each. The reduction in the wheel diameter in this time was  $\frac{1}{16}$  in. Aside from the good wearing qualities, which equal or excel those of the chilled shoes formerly in use on the Alley "L," they have a high and a uniform coefficient of friction, are noiseless in action and give the wheel tread a high polish. Further, the cost of the materials forming the composition is not great and the shoe can be sold at the same or even a lower price than many of the metal brake shoes now on the market.

The Allen-Morrison shoe was developed, not because of any desire on the part of the inventors to make a "new brake shoe", but as the result of an effort to find a shoe suited to the needs of the South Side Elevated Railroad, and its adoption by the company after making the service tests described calls attention to the merits of composition shoes.

We believe that this subject deserves the careful consideration of street railway managers. The higher speeds made possible by the adoption of mechanical motive power and the fact of operation in crowded streets require that cars be under the best possible control, that is, the brake shoes used should be capable of stopping the car quickly. The frequent stops make it desirable for the comfort of passengers that the brake shoes should be noiseless and smooth in action. Both of these qualities as well as the equally desirable one, from a financial standpoint, of a long life appear to be embodied in this brake shoe.

### MILLER-KNOBLOCK WILL MAKE ELECTRICAL SUPPLIES.

The Miller-Knoblock Company, South Bend, Ind., whose electric street sprinkling cars are well known, is adding to its already large business, an electrical department, which will be under the direct supervision of A. W. Morrell, an experienced electrical engineer and constructor, who has had years of experience in street railway motor work. It is the intention of the company to manufacture and carry in stock, ready to ship at a moments notice, Morrell's improved assembled motor commutators for street railway motors. The fact that street railway men can procure assembled commutators for any and all standard street railway motors will be appreciated. It will also carry in stock armature coils for all the standard motors. A complete equipment for the rewinding of armatures has been put in.

Mr. Morrell, who has charge of the electrical department has had long experience in electric street railway work and is well known at St. Louis, Minneapolis, Indianapolis and Cleveland, where he has had charge at different times of important works.

A young couple sought notoriety by being married on a trolley car in Hoboken, N. J. The ceremony was performed by a justice of the peace and the conductor acted as best man.

An ordinance has been passed imposing a tax of \$25 a year on each car operated by the street railway companies in Denver. This more than doubles the city's revenue from this source, as heretofore the license has been on the whole train.

HOLLOW FORGED SHAFT FOR UNION ELEVATED RAILWAY, CHICAGO.

This shaft is one of three built by the Bethlehem Iron Company of South Bethlehem, Pa., for the three 1,500-k. w. direct connected units now being installed in the power house of the Union Elevated Railroad of Chicago. The dimensions are: Diameter of fly-wheel hub, 28 in.; diameter of bearings, 22 in.; diameter of axial hole, 9 in.; length, 21 ft. 9½ in. The weight is 30,200 lb.

Three shafts similar to this were made at the same time for engines in the power house of the Chicago City Railway and four for engines built by the E. P. Allis Company of Milwaukee for the Northwestern Elevated of Chicago.

We regret that the photograph from which this illustration was made was received too late for us to place it with the article on page 578 of this issue.

#### WESTERN GEAR COMPANY OF MILWAUKEE.

The Western Gear Company of Milwaukee has been incorporated and has purchased the plant and business of the co-partnership which formerly existed under the same style. Herman W. Falk, who is so well known in the street railway world as president of the Falk Manufacturing Company, has purchased a large interest in the business and is president of the company. The other officers are Adolph Quentin, vice-president and treasurer, and Charles L. Jones, secretary.

The plant has been greatly increased and the company has now facilities for handling business and which will permit it to fill large orders promptly. Its specialty is the manufacture of gears and pinions for street railway motors. These are made by the new process, which is patented, the patents being the exclusive property of this company; the special machinery used is also patented. This process differs radically from those employed by other gear makers in that the teeth of the gears are formed in the casting before being cut, and are not cut from a solid blank or rim. The effect of this is to give a uniform and close-grained metal in the teeth, and, consequently, the gears have greater strength and a longer life. That such is the fact has been proved by tests of gears made by the ordinary process and by this method.

It is reported that a continuation of the Easton line is to be built between Bethlehem and Allentown, Pa.

#### WEST END ROAD, BOSTON, LEASED.

The West End Street Railway Company which owns 28½ miles of track in the city of Boston has leased its property to the Boston Elevated Railroad Company. The directors of the two companies have ratified the lease, a synopsis of the terms of which is given below:

On or before January 1, 1898, at least \$5,000,000 in cash shall have been paid in upon the capital stock of the Boston Elevated. Until such payment the West End is to remain in possession. The lease is not to be valid until the Board of Railroad Commissioners have given their approval of it.

The elevated company is to pay all expenses of the West End of every kind, including the maintenance of the corporation; also \$3,750 each six months, and 8 per cent on the West End common and preferred stocks. The West End turns over to the elevated everything, including cash on hand and the subway contract. The lease runs for 99 years. The elevated pays all West End indebtedness, except the schedule indebtedness, and all taxes and all expenses in connection with transfer or registration of West End stock.

In the case of any disagreement under the lease, or anything growing out of it, the issue shall be determined by arbitrators, each side selecting one, and they choosing a third. In case of failure to appoint an arbitrator or agree upon a third, the railroad commissioners or chief justice of the supreme court may appoint the same.

Three years ago the lighting company of Stevens Point, Wis., received a franchise for a street railway which was to be built within three years under a forfeit of \$2,000. Hard times and the use of bicycles made prospects very poor and the lines were not constructed. The city made a compromise with the company and accepted \$500 to cancel the franchise.

C. M. Boyce, for five years superintendent of the Hornellsville (N. Y.) Electric Railway, has resigned.

John Robinson has resigned the superintendency of the Bennington (Vt.) & Woodford Electric Railroad Company.

A. J. Cassatt has been elected a director of the Union Traction Company, Philadelphia, to succeed Caleb F. Fox, who resigned.

E. T. Birdsall of New York has been engaged as consulting electrical engineer for the proposed Springfield & Southwestern Street Railway, Springfield, Mass.

Charles R. Bishop, secretary of the American District Steam Company, Lockport, N. Y., made a pleasant call at the REVIEW office while in Chicago last week.

W. J. Hart, who has been general manager of the Union Street Railway, has accepted a flattering offer to manage the fine Inter-Urban Railway of Saginaw, Mich.

G. B. Lindsay, president of the Chester (Pa.) Traction Company, has sailed from New York on the Lucania to spend a vacation in Europe. He will return during the present month.

Geo. E. Randolph, general manager and superintendent of the Denver City Railroad Company, has resigned that position to accept the Denver agency of the State Mutual Insurance Company of Worcester, Mass.

David T. Bound, who was roadmaster of the Wilkesbarre (Pa.) & Wyoming Valley Traction Company has been appointed superintendent of the Wilkesbarre & Northern Railway to succeed A. A. Holbrook, resigned.

R. M. Douglass, general manager and purchasing agent of the Schuylkill Valley Traction Company, Norristown, Pa., has been chosen secretary and treasurer of the company, vice W. F. Kling of the West End Trust Company of Philadelphia, resigned.

It is stated that A. J. Cassatt, of the Pennsylvania Railroad Company, has decided to become identified with the Union Traction Company of Philadelphia and will serve on the board of directors, filling the vacancy caused by the resignation of C. S. Fox.

E. J. Wessels, general manager of the Standard Air-Brake Company, after a three months business trip in Europe, returned on the "Lucania," arriving in New York on August 27. While abroad Mr. Wessels attended the street railway convention in Hamburg.

P. A. B. Widener, of Philadelphia, who is largely interested in the street railways of that city and Pittsburg, is announced as a candidate for the gubernatorial nomination. He is said to be Senator Quay's favorite for the nomination, which means much in Pennsylvania.

Joseph Shabeck, division superintendent of the West Chicago Street Railroad Company, has received an appointment from Governor Tanner of Illinois. The motormen and conductors of his station presented him with a gold watch as a token of their friendship and esteem.

Edward A. Meysenburg and Francis B. Badt have associated themselves under the style Meysenburg & Badt, Incorporated, as brokers, contractors and engineers, making a specialty of consulting engineering and expert work in patent causes. Their office is 1522 Monadnock building, Chicago.

W. P. Buckner, superintendent of the 12th street division of the Metropolitan Street Railway Company of Kansas City, has resigned to accept a more lucrative position with the Kansas City Railroad. He has been an employe of the company for 11 years and no one has yet been named to fill his place.

C. F. Orthwein, who was chosen president of the Southern Electric Railway Company of St. Louis last March, has resigned to take a much needed rest and later a trip to Europe. He still retains his financial interest in the company and has consented to nominally act as first vice-president. Corwin H. Spencer, ex-president of the Merchants' Exchange and vice-president of the Southern company, was elected president. The other officials remain the same as before.

## NEW PUBLICATIONS.

Vol. 30 of the Proceedings of the Master Car Builders' Association, being a verbatim report of the Convention at Old Point Comfort in June last, has been issued and copies may be obtained of the Secretary, John W. Cloud, 974 Rookery Building, Chicago. Price to others than members of the Association, \$1.50, postage 20 cents additional.

The Money Question, by Henry V. Poor, H. V. & H. W. Poor, publishers. Octavo, paper, 202 pages. Price, 50 cents, postpaid.

The author states that all of our money other than gold is bad and advocates the funding of the entire national debt and the re-establishment of the National Bank. The name of the author is a guarantee that in this work on money, facts are not perverted.

Johnston's "Electrical and Street Railway Directory" for 1897. Containing lists of Electric Light Central Stations, Isolated Plants, Mining Plants, Street Railways (electric, horse and cable), Telegraph Companies, District Messenger Companies, Telephone Companies, Manufacturers and Dealers in Electrical and Street Railway Apparatus, Machinery and Supplies: The W. J. Johnston Company., New York. 752 pages, cloth. Price, \$5.00.

In preparing this directory the aim has been to secure reliable data as to street railway, electrical and other interests and classify it so that it is convenient for reference. The work has been brought up to date, and includes the United States, Canada, Mexico and Cuba. For street railway companies, the capital stock, names of officers, including manager, superintendent, electrician and purchasing agent, and mileage are given.

Poor's Manual, 1897. H. V. & H. W. Poor, publishers, 44 Broad street, New York; A. C. McClurg & Co., 117-121 Wabash avenue, Chicago. Price, \$7.50.

This is the 30th annual edition of Poor's Manual, the accepted authority on the railroads of the United States and allied interests. In the present edition, in pursuance of the policy of revising railway histories, there are given exhaustive reviews of the Erie, Illinois Central and Southern railroads. For the better comprehension of the mileage and ramifications of the larger systems the work contains a series of officially revised maps. The tables descriptive of the funded debts of the several companies are as complete as in former editions. The data concerning electric and other tramways first introduced in Poor's Directory of Railway Officials and Manual of American Street Railways is now incorporated in the "Manual of Railroads," 120 pages being devoted to street railways in all cities in the United States having a population of 25,000 or more. These statements show the history, mileage, equipment, operations, income and capital accounts, directors, officers, etc., and are as complete as for the steam roads.

## OBITUARY.

Thomas Startzell, an employe of the Buffalo Traction Company, was killed by an electric shock while stringing wires. He had the wire across his shoulder and with the assistance of another wireman was drawing it taut. The wire came in contact with a lighting circuit and killed Startzell but did not injure his companion.

Robert C. Shelmerdine, general receiver of the Union Traction Company, Philadelphia, died suddenly from heart disease at his summer home near Abington, Pa.

Charles H. Murray, who was interested in the street railway, electric light and water works companies of Larchmont, N. Y., died at the age of 80. He was a man of great wealth and many charitable institutions profited by his generosity.

## ALLOTMENT OF EXHIBIT SPACE AT NIAGARA FALLS CONVENTION.

At this writing the construction of the annex to the Armory in which the exhibits will be displayed, is progressing nicely, and Secretary Penington reports that about 2,500 sq. ft. in addition to what was expected, will be available. This extra space however, with what was first planned has all been taken, and it has been found necessary again this year to cut down the applications in making the allotment in order to have enough to go around. Fully 2,500 sq. ft. more space could have been sold if it had been available, and this in view of the fact that everything which can go out doors on tracks will be placed there. One or two are now contemplating the erection of large tents for such exhibits as require a great deal of floor space. The local committee promised to have the building ready for occupancy by October 1, and expects certainly to be ready 10 days in advance, at the latest.

From the list of exhibitors published herewith it will be seen that the display this year will be both large and interesting, and as in past years a credit to the association and the big feature of the convention.

The railroads have laid a side track into the building, and heavy shipments can be switched directly into the unloading place. The Adams Express Company promises a local office in the building.

Chairman Beardsley, Niagara Falls, of the local committee on exhibits, states he has made contracts for carpenter and similar work, by which exhibitors will not be overcharged, and also with local teaming companies.

To insure prompt delivery, all charges should be prepaid, and direct shipments made in care of H. W. Beardsley, Convention Hall, Niagara Falls, N. Y. All exhibits must be in place not later than Monday night, October 18 so that the building will be in order by Tuesday morning. Access may be had to the hall Monday, October 14, and the exhibits and building will be guarded so that nothing will be lost or stolen.

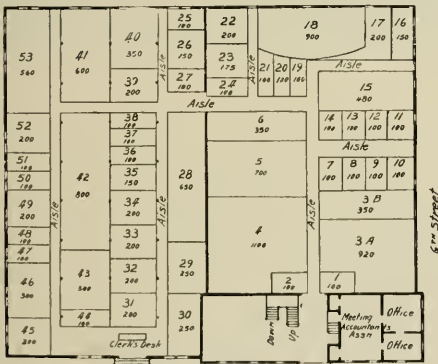

| No. of Space. | Exhibitor.                                               | Sq. Ft. |
|---------------|----------------------------------------------------------|---------|
| 3b            | Barney & Smith Car Company, Dayton, Ohio                 | 350     |
| 4             | General Electric Company, Schenectady                    | 1,100   |
| 5             | Walker Company, Cleveland                                | 700     |

## LOW FARES IN CLEVELAND.

The question of cheap fares is agitating the council and the Cleveland City Railway Company; in consequence an investigation has been made to ascertain what is the exact cost of carrying a passenger. A special accountant was employed to report the result of his investigations to a committee from the city council. It was reported that it cost on an average 3¼ cents to carry a passenger. Some members of the council desire to pass a low fare ordinance and watch the results. The expense of such an experiment would have to be borne by the stockholders of the railway company, but this carries little weight with the city council.

## ACCIDENT ON CHICAGO SUBURBAN.

On the morning of September 14, at 6:45 o'clock there was a collision between two cars on the Chicago Suburban Railroad at a point about 400 ft. north of the switch on 16th street leading into the yards and directly east of the Harlem race track. There was a very heavy fog which obscured the view and made the accident possible. According to the usual morning schedule the south-bound car was to be at the switch, on the side track, leaving a clear road for the north-bound car to pass over the three-quarters of a mile of single track.

The south-bound car had, however, been detained up the line by a derailed car, and was not on the side track. Standing near the switch and on the side track was a car that was being examined by a motor inspector. As the north-bound car approached the meeting point the motorman glanced at the side track and saw this car which he supposed to be the one he was to meet, and turned on the current to get over the stretch of single track as rapidly as possible.

Almost as soon as the switch was passed the south-bound

## WANT THE CONVENTION IN 1898.

The skirmishing to secure the convention of the American Street Railway Association for next year has already begun, and two active candidates are working hard for it.

Detroit was first in the race having put in its request last year at St. Louis, and having again followed it up in the spring when there was some prospect that Niagara might not conclude to carry out the plans there for an exhibit building which it proposed to erect. That matter was solved by securing the old armory in which, with the new annex, the convention will be held and the exhibits displayed.

Detroit offers many attractions and inducements, and the Convention League of that city has joined with the street railway companies in extending the invitation. The hotels are all that could be wished, the rates are reasonable, and good place for exhibits is offered in the large brick, steam heated building used for concerts, etc. It is on the ground floor and close to hotels. The local roads and natural attractions at Detroit would certainly make it an ideal place in which to meet.

AFTER THE COLLISION ON THE CHICAGO SUBURBAN.

car was seen approaching at full speed to make up for lost time. Both motormen shut off the current and applied the air brakes; the rails, however, were wet from the mist and caused the wheels to slide.

Almost before the motormen had realized their danger the cars met, breaking in the front ends, as shown in the illustration. Nearly all the passengers on the cars were bruised by being thrown against the seats or cut by broken glass, 21 being so injured, some quite seriously but none fatally. The two motormen were seriously hurt, and it is astonishing that neither was killed.

When the car bodies struck, the trucks were thrown forward, breaking or bending the center pins, brake rods, etc.; the trucks and motors were apparently little damaged. The total damage to the cars is estimated at \$500. That the accident was not more serious is due to the effective action of the Christensen air-brakes with which the cars are equipped. The fog was so dense that one could not see more than 20 feet.

Cincinnati is also after the meeting and sends out a warm invitation to come there. The meeting and exhibits would be held in the big Exposition building, which would afford more space for exhibits than has been available at any time in the history of the association. What the Cincinnati people can do is forcibly brought to the mind of all who were present at the meeting of the association in that city in 1886, on which occasion the entertainment fairly rivalled that of St. Louis, at which the previous meeting was held.

## SUMMER VESTIBULES IN NEW JERSEY.

A law was passed by the last legislature of New Jersey that all street cars in the state should be provided with vestibules from May 1 to November 1, the dates being evidently transposed. The police commissioners of Jersey City adopted resolutions to the effect that the law should be enforced and the Consolidated Traction Company is endeavoring to prove in the courts that the law is invalid.

CORRESPONDENCE

WHAT ONE SEES IN SHOPS.

EDITOR STREET RAILWAY REVIEW:

During the past month I have visited shops of seven of the largest street railway systems in the west outside of St. Louis, and think that your readers may be interested in learning of some of the things that came under my observation.

In the first shop, which I consider the best equipped street railway shop that I have ever seen, two men were at work putting a commutator on an armature with a 12-lb. sledge, while not 50 ft. away was a hydraulic press of the latest design. At the armature room I learned from the

man in charge that there had been considerable trouble due to broken wires; on walking to the other side of the room where they were making machine wound coils, I found that instead of using a weight or spring coil with a band in the grooves of the reel for putting the proper tension on the wire, it was drawn around a number of porcelain knobs, as shown in the sketch. Trouble from broken wires!

At the next shop, also very complete in its appointments, I watched the operation of changing armatures. The workman was very careful to place a cushion under it to prevent injury, but when it came to removing the pinion preferred to use a 14-lb. sledge instead of the clamp made especially for that purpose. I also saw a new bearing fitted to an armature shaft; the bore of the bearing was a trifle tight, and instead of being reamed to size, it was driven on with the sledge and then eased up by a few blows struck on the sides. At this shop I was told that with good luck a new pair of wheels could be fitted to an axle in four or five hours.

The third shop was a revelation. There all the latest labor saving devices were installed and used in an intelligent manner, so that they really saved labor.

In the shops of a very large system I found men in the paint shop graining with hand tools instead of by the roller process, which does the work in one-fourth the time. In the winding room the method employed when taking off the jam nuts from an armature was for one man to hug the core and keep it from turning while another slowly drove off the nut with a hammer and cold chisel. It might be suggested that a spanner and a clamp to hold the core would be better for this work.

I wonder how many street railways employ this class of mechanics, and whether they find that the saving in the pay roll is sufficient to pay for the effects of the poor work done by incompetent men. I venture the assertion that no road ever had trouble from broken wires in the armatures unless it came from a loose commutator, and that usually results from a sledge-hammer fit, or from a method of winding

similar to that described as obtaining in the first shop mentioned. In this same shop I learned that they had trouble from the hinge pins on the motors becoming loose and letting the pole pieces nose back and forth, injuring the armature. This is caused by the failure to tighten up the hinge bolt. As yet on my own road there has not been a case of this kind, though 90 of the motors have been in use for six years. S. J. G.

MOTOR WINDINGS AND GRATES.

EDITOR STREET RAILWAY REVIEW:

My weakness for trying to solve puzzles in electrical and mechanical fields leads me to offer the following as a possible solution of the puzzle in motor winding, propounded in the last REVIEW. Substituting the larger size wire brings the outer layers or coils farther from the core, thus decreasing the strength of the fields and reducing the counter electro motive force at full speed, permitting more current to pass through the motor. This has the same effect as cutting out a part of the field winding as practiced a few years ago by the Thomson-Houston Company on its railway motors, usually styled "running on the loop." I think that if ammeters and voltmeters were placed in the circuits it would be found that the motors with No. 6 wire use more current than can be accounted for because of the slightly smaller resistance in the field windings.

I am interested in the remarks, credited to W. M. Barr, concerning the proper height above the grates at which to set return tubular boiler and should be pleased to hear from some one who has made careful tests with a view to showing the difference in economy with the height above the grates varied from 28 to 48 in.

And in connection with grates I note that Professor Whitham states that the air space should be 40 to 70 per cent of the total; a professor in the Michigan School of Mines states in Engineering Magazine for July, from 25 to 30 per cent is more than sufficient. "You pays your money and takes your choice;" I wonder how much longer it will be before we shall get facts. R. B. HOLBROOK.

WHO USE ANIMATED PICTURE MACHINES?

KINGSTON, ONT.

EDITOR REVIEW:

We purchased an animated picture machine for use in our park this season and it has proved the best attraction we have yet put on. We have found, however, that exchanging films frequently has proved very expensive, and as there may be other companies who own machines some plan might be adopted such as an exchange bureau and thus a change of views might be effected at small expense. We would be glad to hear from any who own machines their opinion of the plan suggested.

Kingston, Portsmouth & Catarqui Electric Ry.

(We shall be very glad to publish the names of any companies using machines of this character, and the suggestion seems a most excellent one. There is no reason why such an exchange cannot be arranged, and by establishing a circuit a large range of views secured for the season at much less expense than under the present method. In sending names of companies it will be well to state the make of machine used, size, etc. EDITOR.)

## POWER HOUSE ACCIDENT IN PITTSBURG.

On Aug. 28 traffic was suspended for a time on three important electric lines of Pittsburg and the local press stated that the interruption was caused by the bursting of a fly wheel in the power house of the Pittsburg & West End Passenger Railway. The true state of affairs was briefly as follows: On Tuesday Aug. 24 a 110" x 21" pulley weighing 400 lbs. mounted on a jack shaft driven at 140 r. p. m suddenly burst and was thrown to the end of the engine room opposite to the pull of the belt. This did no damage but threw one generator out of operation. The remaining five generators continued to supply current for the lines until the following Thursday when a similar pulley mounted on the other side of the room gave way and was thrown in the direction opposite to that taken by the first pulley. The switchboard was partially demolished and slices cut from the pulleys on the generators upon either side of the path. With the aid of feeder lines from the power house of the Allegheny-Manchester Railway the operation of the road was continued. On Saturday it was found that so much current was being carried through these feeders that the insulation was gradually burning and dropping off causing such a loss that it became necessary to suspend until other feed lines could be laid. Fortunately no one was hurt in either accident.

## STREET RAILWAY ACCOUNTANTS' ASSOCIATION.

The arrangements for the program of the coming convention have been completed; those assigned to papers have all accepted and everything is promising for a very enthusiastic meeting. The success of the association is assured and it will undoubtedly be of much benefit to all street railways as well as the companies represented.

There have been added to the membership since the last issue of the REVIEW the Lindell Railway Company and the Missouri Railroad Company of St. Louis.

The papers to be read are as follows:

"The Care and Handling of Fares from Passenger to Bank"; C. L. Wight, auditor, Toledo Traction Company, Toledo.

"The Handling and Checking of Transfers from Printer to Furnace"; J. F. Calderwood, auditor, Twin City Rapid Transit Company, Minneapolis.

"Pay Rolls—Time Keeping and Method of Paying"; Frank R. Henry, secretary, Missouri Railroad Company, St. Louis.

"Material and Supplies Accounts from Purchase to Use"; W. G. Ross, comptroller, Montreal Street Railway Company, Montreal.

"Car Mileage—How Arrived at and its Use"; H. J. Davies, assistant secretary, Cleveland Electric Railway Company, Cleveland.

"Statistics—Their Use and Abuse"; E. D. Hibbs, auditor, Consolidated Traction Company, Jersey City.

C. N. Duffy, J. F. Calderwood and W. F. Ham constitute the committee on standardization of accounts and will present an elaborate report.

The official programme and circular will soon be issued and will give full particulars of the program and details of the meeting.

Any company which for any reason does not receive the circular will be supplied by addressing the secretary, W. B. Brockway, Toledo, O.

The Traffic Association has authorized the sale of tickets at the rate of one and one-third fares for the round trip on the certificate plan. When buying tickets ask for the American Street Railway Convention certificates; these certificates must be presented to the railroad agent at the convention building October 19 in order to secure the one-third rate for the return.

## PROGRESS ON THE ALLEY L.

The contracts for building the power station of the Alley L of Chicago have been let and the site at the corner of State and 40th streets is being prepared for the foundations. Rapid progress is being made in putting down the third rail and bonding the track. In boring the rails a Stow drill is used to advantage, power for operating the motor coming from the lines of the City railway. The whole apparatus is portable and can easily be moved out of the way of passing trains.

INSULATOR FOR ALLEY L.

The illustration shows a cross section of the third rail insulators. The stand and cap are of cast iron and the insulating portion is close grained porcelain with coarse threads and fastened with the best quality of imported cement. The General Electric Company designed the insulators especially for this road and is to deliver 20,000 at the rate of 2,500 a week.

The Detroit & St. Clair River Electric Railway Company has let contracts for rails and spikes to W. H. Doyle, Detroit; rail joints, American Rail Joint Company, Cleveland; overhead material, Ohio Brass Company, Mansfield, O.; engines, Russell Engine Company, Massillon, O.; pumps and condensers, Laidlaw-Dunn-Gordon Company, Cincinnati, and cars, Wells-French Company, Chicago. The road is to be 47 miles in length. F. T. Ranney is president, T. N. Fordyce, secretary, and C. H. Lawrence, superintendent.

**NEW YORK STATE CONVENTION**

**Fifteenth Annual Convention Held at Niagara Falls—Large Attendance—Excellent Papers Read—Numerous Excursions.**

The fifteenth annual meeting of the Street Railway Association of the State of New York was held in the International hotel, Niagara Falls, N. Y., on Tuesday and Wednesday, September 14 and 15. As of the former meetings of this association, it can be said this was the best both in attendance and interest in the history of the organization.

The president, G. Tracy Rogers, president of the Binghamton Railroad Company, presided, and opened the program with the annual address. This was followed by reading of minutes and report of the executive committee read by Secretary Robinson. The treasurer's report shows:

|               |             |
|---------------|-------------|
| Receipts..... | \$ 7,687 62 |
| Expenses..... | 6,326 24    |
| Balance.....  | \$1,361 38  |

**President's Annual Address.**

The president announced the presence of a delegation of prominent tramway officials from abroad, welcomed them in the name of the association, and extended an invitation to participate in the discussions. The program was then taken up.

In behalf of the Street Railway Association of the state of New York, it is my privilege to extend to you all a cordial welcome to this, our Fifteenth Annual Convention. It seems most fitting that we should meet here at Niagara, if for nothing more than to observe the object lesson which nature unfolds before us. The power exhibited here in Nature's workshop is awe-inspiring and could it be utilized would propel every street car in our state.

This year, which encloses a decade of electrical traction, has been one of steady advancement on old lines; while no startling developments have been obtained during the year, it seems almost impossible that the next to years should witness so many radical changes of benefit and advantage to us and the public. The past year will long be remembered by those connected with street railroads, in many cases, as one of the most discouraging since the adoption of rapid transit. Trade and commerce have, we hope, reached their lowest ebb. The bicycle is now our too successful competitor. It operates without franchise or track, and pays no taxes. On the contrary, cinder paths are constructed, pavements laid down and in many cases pavements changed for its benefit. As a means of locomotion the bicycle has come to stay, but as a novelty it is being overdone and will share the fate of other novelties, and I believe has reached its zenith.

It has taken an almost superhuman effort during the past year on the part of a manager to keep the receipts of his road up and the operating expenses at a minimum. The populist element in our midst has attacked us on every line and it seems as if the accident lawyer has been more vigilant than ever before, if that were possible.

But the dawn of good times is here and we have reason to believe we shall receive our share of the good things to come. It is evident that investors believe in the future of street railroads, for during the past year there have been expended over one million dollars, in Brooklyn alone, in extensions, new equipment and track. There have been 1,000 miles of electric railroads built, and 5,000 motor cars added to the equipment in the United States, amounting to an investment of \$35,000,000. Many new roads are being built in our state, connecting towns and villages with cities. Notable improvements have been made recently in motors and car construction, especially for the suburban and interurban roads. Cars, with all the comforts and conveniences of a steam passenger coach, are now in operation on some lines.

The legislature and New York City officials have been dawdling with the question of rapid transit for a number of years, but whatever

results have been accomplished in this direction may be attributed to the enterprise of the railroad companies. They have recently obtained the consent of the state Board of Railroad Commissioners to

G. T. ROGERS.

adopt electricity, instead of horse power, over a distance covering 110 miles of track. This change involves an expenditure of \$12,000,000, and I am informed that contracts have already been made for a large portion of the work. Contracts have recently been closed between the Brooklyn Bridge Trustees and the Brooklyn surface roads by which the trolley roads of Brooklyn will extend their lines across the bridge. They propose to carry a passenger for a single 5 cent fare from New York City to any portion of Brooklyn reached by their lines, thereby saving the passenger

the usual 3 cent bridge charge and the annoyance of changing cars. This great improvement will cost the Brooklyn roads half a million dollars. These improvements, costing millions of dollars, now about to be made in rapid transit for Greater New York cannot help but meet the approval of the public and the advantages to be derived therefrom by the people of the metropolis are incalculable.

Nothing has been done within the past ten years which has insured more to the benefit of the people of our state than the adoption of rapid transit and the consolidation of street railroads in cities, both large and small. Consolidation, which was at one time regarded as a menace to public welfare, is now universally recognized as redounding to its advantage. Since the development of rapid transit the areas of our cities have extended to a marvelous extent. This rapid growth could have not been attained but for our street railroad systems and the adoption of electricity, furnishing a cheap, flexible and easily controlled motive power. It is far within the bounds of truth to say that for every dollar invested in a street railway, another dollar has been given to the people through the resulting increase in property values alone. The street railways have handsomely repaid the public for their franchises.

The populist element, with its plans for obtaining cheap fares and its ideas of municipal ownership, together with high taxation of railroads, if allowed to be successful, will materially cripple street railways. Such dangerous methods, if adhered to, will wreck the property of investors in street railroads, and turn over to duly appointed receivers the street railroads' properties of our state. It will paralyze the splendid suburban growth, which is the munificent payment being daily made to the people by the street railroads for whatever benefits they may have received. The American system of uniform fares is intended to stimulate this growth and to put the whole municipal area and its environs on an equality. It secures to the common people freedom from the tenement and a basis of calculation in changing of homes or places of labor. Free transfers and numerous other advantages have been given to the people by the street railroads without compulsion by the legislature, or municipalities. The free transfer system has been so liberally adopted in this state and the margin of profit is already so small that any legal reduction in fares, however little, would compel a complete abandonment of the far sighted policy which is building up the cities of our state. Our street railroads are earning less per mile than they earned under the horse car period. This is due to several causes, the generous building for the future in suburbs, the increase of interurban traffic and the generosity of the street railroad management in giving the people a better car service by increase in car speed or greater frequency of cars.

Vested right is the last remedy we should seek in order to protect our franchise rights, but in many instances such measures must be resorted to in order to protect us against the clamor of the socialistic element. A number of decisions have been made of late which should be very gratifying to us. Millions of dollars of street railroad securities are held by the masses, and the legislature and municipality cannot afford to allow this vested right or earning power to be interfered with. Our securities rank higher each year in the financial world and are more acceptable as collateral for loans or investments.

It has been my experience that the majority of people appreciate and are ready to reciprocate any improvement or benefit extended to them. The roads with which I am connected have enjoyed the hearty co-operation of the public, the press and officials of our city and it is an obvious fact that the nearer we can consistently conform to the wants of the people, the less trouble we shall have in getting what we ask of them.

More bills affecting street railroads were introduced in the legislature last year than ever before; no doubt, a majority of them at the request of constituents. Had they become laws and been put in operation, the public, as well as ourselves, would have suffered. We found the members ready to listen to our arguments and anxious to enact such laws as would be of service to the public good.

During the past year there has been organized an association of street railroad accountants. This association should have a cordial and hearty support. Next to the manager of a road I consider the accountant the most important official; in fact, the successful manager must rely upon him largely as a guide in the management of the road. The manager and the accountant must act in harmony in conducting the policy of the road, and in order to make any street railroad a success, all heads of departments must be interested and act in unison.

An important advance made by the street railroads since the adoption of rapid transit is the improvement in the character of employees. Better discipline is now maintained and more courtesy shown in catering to the public. As our business grows in technical and scientific requirements, it naturally attracts a class of men to whom there was formerly no call or inducement to enter its service. Those are facts to be considered in selecting our employees. The street railroad companies of this state are taking great interest in their employees. Nearly every road has a mutual benefit or employees' club connected with it. Each has a plan agreeable to the ideas of the employees, and in nearly all instances the management has not only endorsed, but become a part of these societies. A number of roads have furnished club rooms and other substantial assistance for them. We can not take too much interest in the men connected with the operation of our roads.

The organization of Mutual Indemnity Insurance Companies for electric railways has been suggested as a protective measure against the prohibitive rates we are now charged. For years, insurance companies have been experimenting with insurance upon street railroads. From the results obtained I should judge the business was not satisfactory. The insurance companies have either refused to write this class of risk or have established, in many instances, prohibitive rates. In a measure, this may be the fault of the street railroad manager, who feeling the responsibility in part removed may have been more careless in the handling of his road. A number of roads still have low rate policies, but they are based upon the record of the roads' casualties. Not long since, the rate for fire insurance was almost prohibitive, but I am pleased to state that we are now being insured at a fair rate, as compared with other business risks. Owing to the insurance regulations we are now debarred from the sale of power, which, in many cases, would be a large source of revenue, and under the present restrictions commercial lighting from the electric railway circuit will have to be confined to out of doors.

The rapid increase in the number and size of parks and pleasure resorts owned by street railroad companies and operated by them as traffic promoters has been one of the striking developments which has accompanied the introduction of electricity as a motive power on street railroads. The general opinion of street railroad managers, who have had experience in this direction, is that such pleasure resorts properly conducted, with a judicious selection of amusements and entertainments, tend to increase the ordinary traffic of a road. But in some cases, where the character and class of people to be served has not been studied, parks owned and operated by street railroad companies have not been successful adjuncts to the road. An amusement league for the interior cities of the state have

been suggested. The idea is worthy of consideration and, if properly handled, should be a saving and convenience to the roads in such cities.

The experiment of carrying U. S. mails has proved a success, and the postal car service on our roads is appreciated by the public and accepted by the Government. New freight and express routes are being established, which operate not only as a convenience to the people but as feeders to the steam roads.

The application of electricity to the existing steam roads is, today, a question of great importance to the practical railroad man. They are still in search of Aladdin's lamp, but they do not seem to have made any decided advance during the past year. We have, no doubt, made inroads into their local passenger receipts and probably will continue to do so. Our roads are so situated that in most instances we are at an advantage. We can operate at a much less cost than they and our depots are at our patrons' door steps. The convenience and cheapness of our transportation recommends itself. I believe there is room for us both, and, in a measure, the electric roads are a feeder to the steam roads and the more closely they are allied the better for both.

Considerable progress has already been made in the utilization of the different water powers in which the state abounds, notable the Falls of Niagara, the St. Lawrence river, the Hudson river at Mechanicsville, Oriskany Falls near Utica, and several others which are worthy of mention. It has been suggested that the latent power now contained in the large culm piles of Northern Pennsylvania be also made available. The increased facilities resulting from new class of machinery and inventions for power transmission, the development of the alternating current, the multiphase system and the creation of the induction motor have become actual facts and practical long distance power transmission is within our reach.

It is still a question as to whether the storage battery is becoming a practical factor in the operation of our roads, and whether at the present cost we can use it to advantage in our central stations and at the ends of our feeders, thereby assisting in maintaining the potential on the trolley lines. Compressed air and the many other powers now being tried may have some surprises in store for us. The results of these experiments and inventions may be the beginning of a new era in the street railroad world.

I congratulate you upon the financial and physical conditions of your roads, for notwithstanding that the past year has been the most depressing in our history, it is the first year for some time during which a receiver has not been asked to take charge of some road of our state. Many of the improvements I have referred to have been very materially promoted by the intelligent discussions they have had at the meetings of our association. I am a believer in the importance and good results that can be accomplished by united action. I know from personal experience for the past two years that this association has been a tower of strength in protecting the legitimate rights of the street railway interests of this state and I hope that the same earnest and energetic support it received during that time will continue to be given it by all persons charged with the duty of looking after such properties.

The growth of our association and the interest taken in it by nearly all of the roads are subjects of congratulation. It is the desire of the management that the active men connected with our roads take more interest in the association and especially in the convention work. I desire to thank you for the interest you have taken and also for your earnest co-operation in the affairs of the association and the prompt response which I have always been accorded. I sincerely believe in the future of the association, but it will become whatever we make it. Thanking you for your kind attention, I wish you, one and all, a large share of the prosperity, which I believe is in store for you.

#### How Can We Increase the Efficiency of Our Employees?

W. W. WHEATLEY, BROOKLYN.

The term "efficiency" implies the existence of a standard of excellence. To speak of increasing the efficiency is only another way of speaking of a nearer approach to that standard. Briefly outlined, a high standard of railway service may be described as safe, regular, frequent, rapid, clean and comfortable. Any near approach to that standard will be found to depend largely upon the human element in the service.

In order to divest the subject of any uncertainty and to confine its consideration within definite limits, the writer assumes that it refers principally to those employes who operate cars, in other words, to conductor, motormen or gripmen. They are the employes who come into direct daily contact with the public, and whose bearing and conduct, in the public eye is, to a great extent, the embodiment of the efficiency or inefficiency of the service rendered by the company. Our problem therefore is, how can we manage to secure in the personal and in the conduct of our employes, the nearest possible approach to a higher standard of service, public and private.

For the safe, economical and efficient operation of a railway, there are three essential conditions:

1. A good track and motive power.
2. An attractive and comfortable car equipment.
3. Faithful, capable and well trained employes.

The first and second requisites may be obtained by a reasonable expenditure of money assisted by a high degree of mechanical skill. Money alone cannot buy the third requisite, because character and faithfulness upon which alone conscientious, capable and trained service depends, must be cultivated and developed. Of course it pays to give a good price for brains, but brains alone will not make faithful, capable and well trained employes. Good materials bring a high price and intelligent men are worth more, because they are more likely to become competent than ignorant ones.

A simple and direct solution of our problem may be indicated under two headings:

1. Improve the personnel by the selection of better men.
2. Improve their conduct and increase their faithfulness by a better system of discipline and training.

Let us consider first how we are to obtain better men. The man becomes the employe not entirely upon his own volition, but through the process of selection by one of the company's officials. Whatever official is charged with the duty of selecting conductors, motormen or gripmen bears a heavy weight of responsibility. To a large extent he is responsible for efficient service on the road, for upon him depends the selection of men who in their habits, education and tendencies are fitted for the work. Unfit men once in the service may become very grave factors in the attainment or non-attainment of good results. The very best mechanical and engineering talent is engaged at great expense for the purpose of selecting and testing the materials used in the construction, repairs and maintenance of roadway, power plants and equipment, and watching the results obtained from them. The utmost care is exercised before any device or material is selected for temporary or permanent use, but what methods do we pursue, and how do we assure ourselves of the fitness of the men in whose hands are to be placed expensive property and human lives? Are they not often hurriedly selected to meet some pressing temporary requirement or what is worse, are they not often permitted (without regard to their fitness) to enter the service at the behest of some politician whose friendship may become useful?

The officer who is to select the men should himself be selected with great care, and he should be protected from any influence likely to prevent him from selecting the best material. His field of choice will be limited largely by the wages paid to employes. If only such wages are paid as will suffice to command the service of inferior and therefore incompetent men, he should not be blamed for his frequent failure to select good men. No definite rules can be laid down for the selection of better men except to say that good character and fitness for the work should be the sole requirement for entry into the service. An ignorant, talkative blackguard should under no circumstances be permitted to enter because he is not built right for the business, and by no system of discipline or training can a man of this character be fashioned into a gentlemanly, courteous employe. The writer believes it is best, as a rule, in selecting new and inexperienced men to take those who have had more or less of mechanical training either on the farm or in the workshop, provided, of course, they are suitable in other respects; and preferences should be given to married men beyond the age of 25, because as a rule they are more steady, reliable and more amenable to discipline. Professional floaters who go from place to place, often under assumed names, are always to be avoided. This branch of the subject is too large to be compassed in a few paragraphs. Suffice it to say that success in selecting good men is largely a question of being a good judge of human nature, aided by careful methods of looking up the antecedents of applicants.

To improve the conduct and increase the faithfulness of our

employes, a better system of discipline and training is demanded. It is the policy of railroad managers to bring their equipment, track and power up to the highest state of efficiency, but do they know that their men have a clear and practical knowledge of their rules and of the proper operation of their equipment?

Do they know that their rules are habitually observed and that their equipment is operated in the manner prescribed?

Experience has taught the leaders of military organizations that it is one thing to make a rule or give an order, but quite another thing to know that it is enforced. They have learned that efficiency of discipline can be obtained only by close inspection, and it is so in railway service. Inspection should be made not by secret service detectives, but by trained inspectors, as is done in military organizations. In discipline, as in some other things, an ounce of prevention is worth a pound of cure.

Discipline consists not merely in administering punishment for offenses, but in a broader sense it consists in educating and training the men, so that it will not often be necessary to administer punishment. We may have the best roadway and equipment, but unless we are able to properly control and guide the intelligent human machines through whose agency results are to be accomplished, we may never have a higher standard of efficiency.

Efficiency of service comes only as the result of long and persistent training, education and experience, and is therefore incompatible with short tenure of position. Is it not a conspicuous fact in street railway operation, that there is a comparatively short tenure of service of conductors, motormen or gripmen? Are we not continually discharging one set of men and employing new and inexperienced men to take their places, and if so what is the underlying cause and what the remedy? Passing hurriedly over these very suggestive and interesting questions regarding tenure of position, it may be profitable to briefly review our present methods and opportunities of training new and inexperienced men.

In steam railroad practice, before a man is permitted to act as conductor or engineer in charge of a train with valuable property and human lives, he is subject to several years of education and training in one or more subordinate positions. Opportunity is thus afforded to study his character and temperament, observe his methods and measure his fitness for promotion, but in street railway practice there are, as a rule, no subordinate positions in which men are required to serve before being placed in charge of a car. New and inexperienced men are inducted into the service in large numbers, and after being schooled for a few days are given exclusive, absolute and independent control of a car running through crowded city thoroughfares and populous suburbs. Is it to be wondered at that costly accidents are the result?

It will be generally conceded that the position of motorman or gripman is vastly more important and responsible position than that of conductor, as it concerns safety in operation. Why then should not all motormen or gripmen be required to serve an apprenticeship of three to six months in the shops, or as conductors, during which time they could become perfectly familiar with the roadway, equipment and the rules and regulations, and during which time the officers could become better acquainted with them? After having served such an apprenticeship would they not naturally be better qualified for the more responsible position? Men often blunder because they know no better. Some know they are ignorant and try to learn, while others do not try to learn. Some know they are ignorant and try to learn, but they do not know how, while there are still others who think they know it all and are entirely unconscious of their ignorance. In either case the officers of a road are more or less culpable if they do not take the measure of the men, and not only give them the opportunity to become competent, but insist upon their becoming so before being placed in positions of responsibility.

But after all has been said about obtaining better men and training them to become more proficient in their duties, it still remains to make them faithful and attach them to the service. This point needs no emphasis when we remember the exactions of the service and the influences that are continually at work to degrade and mislead them, and prevent the proper and faithful discharge of their duties. There is no other calling which makes heavier demands upon the mental and physical endurance of men, and they should not be surrounded by demoralizing conditions which unfit them for the best service. Every company should take some interest in the social surroundings of its employes. They should be given some opportunities of enjoyment as well as self improvement. We must remember

that the chief end of their existence is not work, and when their work for the day is done we should offer them some counter attraction to the street corner, the saloon or the gambling den. We should try to lead the men to feel that the company takes an interest in their welfare, and wishes to improve their social condition. By so doing we shall more surely attach them to the service, and make them more faithful and efficient.

Minor mistakes and blunders there will always be, but men do not as a rule make serious blunders with deliberate intent. In order to avoid blunders some incentive should be held out to make the men more careful. It is indeed questionable whether the fear of punishment is always the best incentive to offer, and yet how many of us offer anything else? The disgrace of suspension and the loss of wages may often be a deterrent, but what kind of an impression does it leave on the man's mind after it has been inflicted, especially so when it comes after a long term of faithful service? Well may we raise the question whether our system of discipline is not wrong, when we hold out no other incentive to efficient faithful service than the fear of punishment.

Many of the principal steam railroads throughout the country are making a distinct advance in their system of discipline, which is more in keeping with the progressive enlightened spirit of the age. They are trying to abandon the "Master and Man" idea and are seeking to attach men to their service by treating them "Like Men," and by giving some recognition and credit for varying terms of faithful efficient service. Instead of fines and suspensions, which often beget a sullen, revengeful spirit, many roads are adopting what is widely known as the "Brown system of discipline, without suspension," which consists in keeping a debit and credit account with each man and advising him personally as the entries are made. Suspensions are made only nominally—that is, they are entered against the man's record, but are not actually enforced. Geo. R. Brown, general superintendent of the Fall Brook Railway, who first inaugurated this system, says concerning it in substance as follows:

"Penalties are imposed for two purposes:

"First, to uphold the law and prevent its further violation; and second, to reform the violator. Punishment inflicted indirectly benefits many who do not violate the law as well as to the one who does. It often occurs that the disgrace and injury occasioned by a strict enforcement of a sentence does more to ruin the guilty than anything else, and a wise provision has been made, allowing courts to use their judgment as to carrying out punishments; this is known as 'suspending sentence.' If the same time offender does better and is not guilty of the same or other offenses, the judge conveniently forgets the sentence hanging over him, but should be go on committing one misdemeanor after another his 'record' rises up to condemn him. I believe in the practice of suspending sentence with railroad employes."

Under this system a man's position depends on his "record," and a long term of faithful service entered to his credit counts for something every time the account is balanced. That is undoubtedly the correct principle which teaches the employe that he will as surely receive credit for his good work as that he will be charged with his errors and faults, and he will certainly become a better man when he learns that his final success depends solely upon the "record" that he makes. The writer suggests that it may be possible to embody into practical methods adapted to street railway service the principle herein briefly outlined, but it should be undertaken only by those who are in sympathy with it, and whose experience in dealing with men has fully convinced them that harshness is less powerful than kindness, and that just, humane treatment of men will bring about a closer relationship and more perfect confidence between employer and employe.

J. B. Cahoon: I agree most heartily with all that Mr. Wheatley has said, but I do not think he has carried the matter far enough; not as far as we have carried it on our road in Elmira. We not only go into the subject of a thorough examination of the man as to his personal character and habits, etc., but as far as possible have conformed to the law of the state and placed him in the power house and given him a thorough training there, and followed that up with a course in the machine shop and car house, and endeavored in that way and through careful training on the cars to put him in a position to understand what his duties are. Of course we have a small road, but we have the good fortune to retain our employes for longer terms of service than is usual. A man in starting in goes on as an extra man and remains an extra man, as we find by experience, for about a year and a half. He only runs on the lines of smallest travel. In

this way by the time he gets a regular run he is pretty thoroughly educated in his duties, and we can see whether our judgment has been right in regard to the man and whether he is a competent employe or not.

We have also taken up the social side of the life of the conductors and motormen and established a club room for them with the daily papers, electrical papers, prominent magazines and various games and things to amuse them when off duty. This is located at a very convenient point where all our cars meet, and we hire a room for that purpose solely, on one of the principal streets of the city. In addition to that we have taken the men into our confidence, so to speak, and when there has been a falling off in the earnings we have talked with the men in a general way and explained to them how our daily receipts depended upon them; how if they are not polite to ladies and do not help them on and off the cars and answer inquiries politely and promptly they are hurting the road, and not only the road, but themselves; because if our earnings decrease it means we have to decrease our operating expenses and be compelled to economize, taking cars off and putting the men back on the extra list where they will get less pay. We have also adopted the service stripe system. We give a man for each five years of service a gold stripe on his sleeve, with an increase in pay of 5 cents a day, which is not much, but it serves as an incentive to the men and shows that they are considered, and that we are trying to do what is right by them. I have told them that if our earnings pick up so that we can do better than that we will be glad to do it. We have some 14 men who wear the five years service stripe and four or five who wear two stripes on their sleeve, indicating 10 years of service, and who get an increase of 10 cents a day. We have found that by taking this personal supervision of each man and looking after his comfort, etc., that our earnings are picking up, that the men are more attentive to their duties and more careful of the property of the company and work with the management of the road in operating it on an economic basis.

The President: Can we not hear from some other roads, giving their experience? Will Mr. Murphy or one of our friends from across the water tell us what they do there?

Mr. Murphy: Mr. President and gentlemen: I thank you for the opportunity given to me of saying a few words. As a tramway manager for 20 years I have had some experience in this line and fully approve with the sentiments expressed in the paper which has been read, in fact it is quite in accordance with my own views. We have a rather different class of people in Dublin from what you have in this country; the men are apt to keep their positions longer. We have many men in our company who have been with us a great many years and a service stripe for 10 or 15 years would be quite common. We look after the comfort of the men as far as we possibly can and increase our efforts each year. We have a road 45 miles long, with 1,600 horses. We are about to adopt the electric system, and it is with that object in view that the committee has come over here, consisting of two directors and myself.

The next paper was entitled "A Decade of Electric Railway Development," by W. J. Clark, General Electric Company, New York.

Adjournment was then taken to 2:30 p. m.

#### Tuesday Afternoon.

The afternoon session opened with the reading of the following paper:

#### The Influence of Accurate Measurements Upon Economic Operation.

BY CARYL D. HASKINS, BOSTON.

In no branch of commerce, save perhaps in some of the industries dependent upon the generation of electrical energy, is it considered sufficient to know only what raw material is used and what revenue is received. Nor is this information actually regarded as sufficient even in these industries.

Until very recently, however, there has been no satisfactory method of actually determining how much electrical energy has been produced during any given period.

Many generating stations in the early days followed a system of frequent readings of ammeters and voltmeters, basing their assump-

tions as to actual output on the product of coincident readings multiplied of course by the time factor, thus obtaining an approximation of the kilowatt hours output per day and therefore the approximate cost of generation per k. w. hour.

Many, however, abandoned these frequent readings of instruments, feeling that the approximations of true output measurement were too unreliable to be of real value, because of the constant fluctuation of load between readings.

The conditions just described are in reality those of yesterday rather than today, and they existed only up to that time when it became possible to obtain output meters of sufficient capacity to measure in an accurate and proper manner the true output.

Such meters as these to which I refer are now readily obtainable and are being rapidly adopted, not only by street railway companies but by lighting companies also.

Electrical engineering skill has responded to the needs of the industries to which it is tributary, and standard designs now exist up to capacities as high as 8,000 amperes. Whilst special instruments have been designed large enough for 16,000 amperes.

These total output meters are accurate to a high degree, not only upon steady and normal loads but upon rapidly fluctuating loads as well, giving a true account of all energy output through them on loads ranging from 5 or 6 per cent of their rated capacity up to about 15 per cent above their rated capacity. The reliability of the record being unaffected with the rapidity of fluctuation of current between these points.

It is doubtless needless for me to emphasize the real economic value of the reliable data which can be obtained by the use of these total output meters.

Knowing the efficiency which is to be expected from the generator, engine, and boiler equipments, it is a simple matter to determine just how much coal and water should have been expended for the run of any given day to generate the indicated k. w. hours output.

Thus it not only becomes possible to determine just what it is costing to generate a k. w. hour, but it also becomes possible to check the inefficiency of the equipment and to locate trivial faults which might otherwise have escaped notice.

For example, should the indicated output fall 10 per cent below what ought reasonably to be expected from the known input of coal and water, an effort would at once be made to determine where the trouble lay. Whether in uneven firing of the boilers, ill-set valves on the engine or some minor fault in the generator.

In no other way known to me can this positive means of check upon a generating system be maintained than by the use of total output meters.

Important as is the measurement of the total station output there is yet another application of positive measurements, which, whilst it has been long appreciated by many, has not been applied in practice at all up to the present time, simply because the necessary meter was not available. I refer to the measurement of the energy used daily to operate each car.

Every street railway management realizes that a quite large proportion of the total energy generated is wasted by the careless and improper use of the controller and the brake, and where the old rheostat method of control is used the opportunity for waste on the part of the motorman is yet greater.

Almost every street railway superintendent makes a different estimate of the percentage of power wasted upon the system under his charge, for there can be no positive knowledge upon the subject nor can the conditions be regarded as at all stable.

An average drawn from the opinions which have been expressed to me would, however, indicate that not less than 20 per cent of the total energy generated is wasted by improper manipulation of the handles upon the part of the motor man. This improper manipulation being due to some extent to ignorance, but more generally to carelessness.

A meter has now been designed which will, I believe, change all of these wasteful conditions. This meter is intended for permanent installation upon the car, and its indications show accurately the consumption of energy in k. w. hours for any desired time.

Grave difficulties surrounded the designing of a satisfactory meter for this purpose, and the perfecting of the device has only been accomplished by sustained effort extending over a long period. It was necessary not only that the meter should be accurate under the extremely unfavorable conditions of heavy vibration and shock to which it has to be exposed, but also that its construction should be of

such a character as to endure these rough conditions for long periods without damage to the mechanism and without the impairment of accuracy.

Such a meter as that which I have described is now obtainable and has been successfully operated in actual service over an extremely rough piece of track for many months.

With a street car meter permanently installed on every car the street railway management at once has the same means of checking the motorman as is provided by the cash register for checking the conductor.

Assuming that the energy wasted is actually 20 per cent of the total, as I believe it to be, it is, I think, fair to expect a saving of at least half the present waste, or 10 per cent of the whole amount of energy generated as a result of the knowledge on the part of the motorman that the management has absolute means of ascertaining how much power he uses per run, or per passenger, or per mile. For under this system he cannot fail to realize that the management has in its possession adequate and reliable data upon which to base promotions or encouragement, reprimand, or discharge.

Many steam railroads have long made a practice of offering annual prizes to the engine crew doing the most work with the least coal and water, and I anticipate that a similar system of reward may be found advantageous and profitable in street railway practice.

Cutting down the waste of energy 50 per cent means saving 10 per cent of the total output, and it therefore means to the street railway management either the saving of 10 per cent of the coal and water which is being used today, or the ability to operate 10 per cent more cars with the same central station capacity. In which ever way the matter may be viewed—whether in the light of a saving of raw material, or an increase in service without increase in expense at the station—the economy accomplished is very great, and you will all, I am sure, agree with me when I venture to assert, that the influence of accurate measurement upon economic operation is of the first importance, provided proper use is made of the data thus obtained.

In reply to a question Mr. Haskins stated the meters had not yet been placed upon the market, but soon would be.

Mr. Nichols stated that the paper he was about to read had been prepared by his mileage clerk, Charles J. Ingalls, to whom any credit which might attach to the paper, was due.

Then followed a paper "The Advantages of a Car Mileage Record."

Mr. Cole: My system is similar in detail to the one which Mr. Nicholl describes; the motorman turns in a report which is taken off by the starter, and in all its details it is similar to the Rochester system.

Mr. Cole, of Elmira, who read the next paper, prefaced it with the remark: "In the preparation of my paper I have been guided, to a great extent, by the nature of articles which have appeared in the public press. The public are being educated in the belief that the nickles taken in by street railroads are by some miraculous process being turned to gold and the gold is used in the corruption of public men. Such assertions are an obstruction to the liberal policy of a street railroad and binders its good service; and at the same time it is an insult to public men. I believe public officials and railroad men should educate the people as to the facts and dissolve the fancies."

#### Facts and Fancies Concerning Street Railroads.

W. W. COLE, ELMIRA.

Today, if you pick up the Review of Reviews, the Forum, or any of the leading magazines or daily papers, you are confronted by writings as significant as the writings on the wall. Everywhere we read articles on municipal ownership and state government of railroads, committees of investigation, and the introduction of restrictive laws. These articles are nearly all of a socialistic tendency, and conceived in fancy dreams, and like Pygmalion's Galatea, the Statue of Liberty becomes charged with magnetic life and lightens and carries the world—for love and 3 cent fares. In the many discussions of the distribution and gifts of franchises it may be well to define that a franchise is the right bestowed upon some party or parties to do something; that something to be of benefit to the general public, and

it is always understood that if the parties obtaining the franchise have made intelligent calculations, and conduct with experienced and economical management, that they are entitled to remuneration, for first their service to the public, second for the intelligent application of their services and money.

The municipality is a public business corporation; the railroad a private business corporation; but both are in the service of the public with this distinction—if the municipality makes mistakes in its management, the public must pay; if the railroad company is mis-managed, the individuals pay, and the public is still carried for the same price. Now, if any large manufacturing corporation should approach the Board of Trade of any city in the United States, and make a proposition to locate interests that would increase the comfort and possibilities of usefulness of many citizens, make suburban homes available, and values of real estate higher, make houses rent more readily and for greater values, and homes in the city to become more desirable, and homes in the country of easy access, increase the trade of the various business interests, and to open up parks and furnish free amusements to the public, to guarantee that they would employ a certain number of men at wages generally higher than paid by the local mercantile interests, and that they would give constant and permanent employment at all times to a large number of men, to such a concern the business men of any city in the country would offer a bonus in cash, land for a site, and concessions in taxes; and should such an industry meet with reverses, it would be the common interest to give it general aid. Yet all these things have been done by the average railroad company; but when a railroad is once located and established, it cannot move its interests to a more favorable community, and thereby hangs the tale!

I will now quote from a current number of a magazine:

"Every legislator who, during the past winter, voted to give the enormously valuable street franchises of the cities of Chicago and Boston to private syndicates and corporations committed a crime against the living and oncoming generations. Massachusetts gave the special privileges of the city of Boston away for a quarter of a century, and the state of Illinois gave to a millionaire street car magnate the privileges of the city of Chicago for half a century. The city of Glasgow, Scotland, gives street car service for less than half the amount our citizens have to pay, and yet last year that city netted over \$400,000 above her expenses. The street franchises belong to the citizens, to the society which makes the life of the city, and the giving of those franchises to private individuals is plundering the people of their own to enrich a few multi-millionaires. Our prisons are thronged with people who have been incarcerated for deeds essentially less criminal in nature and essence than those of many men who are now placid Honorable before their names."

It hardly seems possible that such an article can be written in good faith, for if such conditions really exist, what benefit would really accrue from municipal ownership of street railroads, when these city officials whom we are led to believe are more criminal than the inmates of our state prisons would be the very men to guide and manage the public corporation. Under such specious argument it is not surprising that it is further asserted "that corruption can be removed by doing away with franchises, or that when no valuable privileges are to be had, there will be no powerful organizations to corrupt the city, and that no good reason exists why the railroad should not be as well managed under public as private ownership of railroads."

If such statements are the facts and not fancies, is it possible, that in spite of inefficiency and corruption, that the net financial result would be more favorable than any which could be obtained from franchises? I would suggest to writers of such articles that they reform the cities first, and the railroads next, as corruption is a disease that cannot be cured by scattering it or driving it in.

The Citizens Committee of Boston in its report states:

"Public ownership enjoys the benefits arising from the increased efficiency of contented, well paid labor, the economies of combination with other public departments, and the diminished cost per unit that accompanies the enlargement of business, consequent upon lower rates and the larger interest and patronage extended by the people to an undertaking of their own. Combination of the street railways with the gas and electric light plants would lead to large economies, and further co-ordination with highway, police and fire departments would increase the efficiency, safety and economy of all the services involved."

I believe this has been the experience of all trusts, whether formed

by public or private business corporations, and like any other labor saving machine, a combination of effort well directed and guided must lead to success, whether conducted by public or private corporations; but why should a railroad controlled by a municipality receive greater co-operation from police and fire departments more than the private corporation? As tax payers we are entitled to all the protection and assistance to serve the public interests that could be rendered the public corporation.

Again this committee states: "The change from private to public ownership of a great monopoly means a change of purpose from dividends for a few to service for all. This change of purpose is the source of the improvement under public ownership in respect to cheaper transportation, a better paid and more contented ownership, a fairer diffusion of wealth and power, etc. This change of purpose will accompany the change to public ownership here as well as in Europe or Australia, and therefore public ownership of the railways here will cause a movement in the same general direction as in Glasgow."

We will compare Glasgow with Boston. In Glasgow motormen and conductors are paid from 85 cents to \$1.12 for a day of 10 hours; in Boston they are paid \$2.25 for a day of 9 hours; and if Glasgow had brought the employes to the same state of contented citizenship, and made a fairer diffusion of wealth as they already obtain in Boston, the vaunted \$400,000 net would have been "nit."

The value of franchises, the possibility of lower fares or better service, the advisability of city ownership, and all such problems can only be answered intelligently by the results already obtained. In Huddersfield, England, the financial statement does not indicate any great diffusion of wealth from municipal ownership of street railroads. The operation of the lines for the year ending March 31, 1895, resulted in a deficiency of £2,473. Each year of the 14 years of its history this tramway has run at a loss varying from £671 to £16,626 in 1893, involving a total loss of £62,220. This has been met by transferring £20,982 from depreciation account, leaving only £340 to represent the depreciation of 14 years. The remainder of the deficit has been made up by special taxes ranging annually from ½ of a penny to 5 pence in the pound, and costing the rate payers £41,238.

In Leeds the enterprise cost £131,305. For year ending March 25, 1895, tramways show a profit of £133 7s. 5d., after paying expenses, which include interest and sinking fund.

In Plymouth the enterprise cost £50,000. After providing for interest and sinking fund, the tramway in the last fiscal year lost £1,086. In December, 1896, the system had only just been completed. And the employes of these roads are contented citizens at very low wages. A factor which plays an important part in European schemes of municipal ownership is the low rate of interest which they would have to pay on the money spent in purchasing the railroads. This low rate of interest is the will-o-the-wisp, which will lead these advocates of municipal ownership into financial quagmire. The majority of persons urging the public ownership of railroads are moved by a desire to have the city receive large franchise returns; but these desires will not materialize from the facts. In the cost of labor as an index of the cost of city management, we find a situation that is if possible less promising in the matter of street railway operation than that of other managements. About 70 per cent of the operating expense of a street railroad company goes to pay labor—what could the city pay for the same wages? The general experience has been that policemen and firemen are better paid than the average railroad employe, and in many cities after 20 years of service, they can look forward to the retired list. Under municipal control, the railroad employe would not throw away votes, and as for the value of his services, he should certainly receive as much as a policeman. The management of street railroads requires qualities of the very brightest order, and a deficit in these qualities is generally followed by a deficit in the ledger. Most of our managers have grown up in the service, and have served a long apprenticeship in the various departments before attaining their present positions, and if experience counts for anything, they are professionals.

Our city officials are not professionals, as a rule, in matters pertaining to private corporations, and the committee of investigation is straining after an assumed standard of perfection, defective in theory and practice. The city officials serve a composite personality which recognizes neither gains nor losses. On account of the short time of service of the various officers of a municipality, it is impossible for them to acquire more than a superficial knowledge of

the intricate duties and methods of economical administration in serving the wants of the public.

The Englishmen secure poor service at low cost, and all Europe observes a policy which retards the rapid development that all America demands. In this country the street railroad has made it possible for the workingman to own a cheap, comfortable country home, and he can reach his work within the city in 20 or 30 minutes for 5 cents, with a ride of seven or eight miles. In Europe the workingman for 2 cents is transported perhaps a mile in 10 or 15 minutes from a congested tenement house to his work in a thickly populated district, and with an inherited ox-like patience, he waits until a car comes along that has the prescribed amount of room. There is an impression that railroads are generally over-capitalized, but when a real knowledge of facts is obtained, it is found that all roads constructed in the earlier days spent vast sums in the purchase of apparatus, and again, on the reconstruction which was necessary, to give the public the benefit of rapid improvements. This money was honestly expended, and today the public has the benefit of a liberal policy in the clean, well-kept, up-to-date service generally rendered. And the men who have spent their money and time in perfecting this service are entitled to remuneration for both the service in actual operation and those benefits they have made possible throughout the land.

Today every city has its Board of Trade or Chamber of Commerce, composed of men who have the city's best interests at heart. I think that the relationship between the City Council and the Board of Trade should become close, and in all matters pertaining to investment of the city's funds for a financial return, that a committee be appointed from the Board of Trade to advise with the city officials.

The prevalent desire for improvement in all things pertaining to public service will doubtless bring out many advantages not now clearly apparent. But conclusions cannot be jumped at, nor can the end be reached by the action of any one man, or body of men, as conditions are nowhere the same. Even the wind sent by God, which turn our windmills and carry our laden ships o'er the water, at times do us an evil, yet they are, nevertheless, a public benefit.

#### Advantages of Up-to-date Street Railroad Service. Why the Rate of Fare Should Not be Reduced.

BY C. L. ROSSITER, BROOKLYN.

One has only to recall the wretched transportation facilities of horse car days to appreciate the advantages of an up-to-date street railway. We remember the small dimly lighted horse cars, so cold in winter that straw was placed in them to keep the feet warm, and so poorly lighted that it was impossible to read in them. Insufficient horse power frequently made it necessary for passengers to get out and assist the horses on the steep grades. Today over 80 per cent of the street railways in this country are operated by electricity, and millions of new capital have been expended in constructing the necessary new tracks, cars, electric equipment and expensive power houses, so that to ride in one of the modern cars of an electric railway today is a positive pleasure, and thousands of dollars of the income now received by the roads come from this pleasure riding.

The electric street railway today is essential to every city, not less so than its departments of sewers, water and street lighting, and in fact the railroad in nearly every case is the pioneer in all the improvements and building up of the city. The railroad corporations are very frequently looked upon as being antagonistic to the city's interests and both the public and the city are oftentimes inclined to impose unjust burdens and hardships upon the roads; when in fact the capital to construct the railroads is furnished by banks, trust companies and organizations having in their trust the savings of the people. The purchase of a piece of farm land for building purposes in the suburbs of any of our cities is followed immediately by a request upon the local railway to extend its line, and without such extension it will be found that the city itself will be very slow to make expenditures for the improvement of the streets and sewers, water mains, etc., and next to impossible to get the gas and other companies to extend. In support of this statement some figures in regard to Boston are very instructive showing as they do in the case of Brookline, a suburb of Boston, that in the 30 years from 1855 to 1885 the increase in value was from five and one-half millions to sixteen millions, while in the next five years, with the introduction of the street rail-

way, the values increased to thirty millions. Another case that will illustrate this has occurred in Brooklyn. During the year 1896 one of the roads constructed an extension some three miles in length through an entirely new territory where the streets for blocks had not been cut through and no improvements whatever made to the adjoining property. Today, less than a year since the road was opened, there have been over 500 houses constructed, (nearly all of them being occupied as soon as completed) on the line of this street and adjacent side streets. If it had not been for the railroad extension not one of these houses would have been built, and it can be readily seen that it is not the railroad company which will reap the first advantages but the city, which will have increased its assessment roll not less than \$3,000,000 in the present year and the opportunity given to hundreds of individuals of finding comfortable homes. If the city and the public treat the railroad companies justly and fairly there will be no trouble caused by the policy that the companies pursue, as nothing pays better to the owners of the railroad property or to the city itself than to have a railway, up-to-date in its cars, equipment, tracks and facilities. The roads can be trusted as they continue to be prosperous to give the greater part of every nickel that is taken in, to the public, in the shape of good wages to their employes, thus securing competent and reliable men, and also expending, as it can afford to do so, the necessary money for extensions as required, and for new cars and equipment properly maintained, and the companies will continue this policy so long as the public show appreciation of it by patronizing the cars. On the other hand if the earnings of the road are not sufficient to properly and well maintain the property the spectacle of old cars and equipment and negligent employes will be seen, and while this means loss to those who have invested, it is no less a direct loss to the city and the public which has such a railroad. To secure the needed funds for extensions and improvements of our electric roads there must be a perfect understanding between the city and the owners of these properties. If the city places unnecessary burdens and taxes on the roads that can not be met, then those who are called upon to furnish the capital will refuse to do so and the city will be the loser tenfold over what it could possibly gain in any other way.

I believe the street surface railway to be as necessary to a city as its street, sewer, water and gas systems; and if the railways to-day can maintain friendly relations with the city's representatives and give to them and to the public full information as to the financial and physical condition of the properties a much better understanding will be had and the final result will be to secure the good will of those on whom the success of the railroads depend. An up-to-date street railway service pays the company itself, particularly if it has a competitor who is not up-to-date; it pays the city and the public in the immediate benefits they receive in clean, attractive cars, good service and freedom from accidents, and it pays the employes of such a company to be identified with it and to assist in bringing such a result about as well as in good wages promptly paid.

In regard to the matter of fares and why they should not be reduced I want to say at the outset they have been reduced and today the street railways of this country are carrying passengers a longer distance and at cheaper fares than in any other country in the world. The distances in the 10 largest cities in this country where the public is carried for a single fare of 5 cents range from 9.9 miles to 18 miles; this latter in Brooklyn. In horse car days a ride of five miles for a single fare was a long one and the average was below this. The railways in Glasgow, Berlin and some other foreign cities are frequently referred to as furnishing lower rates of fare. This is not so. On the contrary, they are not only much higher, but have many disadvantages which would not be tolerated in this country. The average and usual rate in England is 2 cents for the first mile and 1 cent for each mile thereafter, and this works injury to the laborer and artisan classes. In this country the average rate is from  $\frac{1}{4}$  to  $\frac{1}{2}$  cent per mile and in many cases less than  $\frac{1}{2}$  cent per mile. Abroad five representative cities average 11,000 population per mile of track. Seven of the largest cities in this country average 2,127 population. This means that the laboring classes and artisans abroad are compelled, on account of the high rates of fares of the suburbs, to live in the crowded quarters of the city, to the menace of their health, and this overcrowding and density of population is causing much concern to the cities; while the railroads in this country with five times the track and facilities to the same population give to those who desire it the opportunity of finding comfortable homes in the suburbs where their families can be properly brought up. In the matter of

wages of conductors and drivers, in England they receive 85 cents to \$1.12 per day of 10 hours. In this country the conductors and motormen receive from \$1.75 to \$2.25 per day of ten hours. Very many trips are run on all our roads for the accommodation of the public, on which the revenue taken in does not equal the wages of the conductors and motormen, and the average street railway, with the luxurious and comfortable electric car well lighted and well heated in winter, gives the cheapest transportation in the world.

It has been said that it would be an ideal condition to have the street railways all confined to some lonely field in the remote country where they could be run on time, never crowded, and quite unobjectionable, but quite useless also; but as crowded thoroughfares are unavoidable in a large city and means of transit indispensable, the problem is, how best to accomplish it to the benefit of all concerned. Complaints are made too often without cause and without reason. The fact is that most of the roads are giving better service to the public than they can afford, the trouble being that the people expect too much for 5 cents.

### The Prevention of Accidents; The Best Method to Accomplish this End.

BY H. S. COOPER, SCHENECTADY, N. Y.

If the cause—or causes—of the majority of accidents on street railways be thoroughly and critically examined and analyzed, it will be found that directly or indirectly the personal, human element very largely predominates among them. From an examination of these causes and from my own experience in the matter of handling employes, I have been led to practice the belief that in this personal element lies most of the danger from accidents, and also the means of their prevention, according as to how it is managed.

I do not mean to say that the remedy lies entirely with the human element unassisted, for no matter how good the workman is, he must have tools—and good tools—before his work can be his best. We must supplement our human nature with the most perfect "safety appliances," moral, mental, and material, if we wish to obtain anything approaching entire immunity from accidents for which we are really responsible, or are held responsible. But we may equip our roads from the bottom of the substructure to the top of our poles with the most approved safety apparatus and still have our "holocausts" (as the lay press so appropriately calls them) if we do not give full consideration to the personal element.

By the personal element I mean the whole personnel of the company; not only the motormen and conductors, not only the starters and switchmen, not only the inspectors and repairers, but every one connected with the company; the foremen, superintendents, managers, clerks, counsel, executive officers, board of directors—and I do not know but what I would include the stock and bondholders.

That may seem far-fetched, but let us look at it. If a company inaugurates or perpetuates a policy by which it hires the "cheapest" kind of men regardless of the duties they are to be made to perform; if it pays them only what is compelled by law, by trades-unions or by the competition of other labor-employers; if it works these men longer hours than human beings can endure and remain well balanced; if it works them in unnecessarily uncomfortable, exposed, or dangerous situations; if it gives them difficult and delicate duties to fulfill, and inefficient means or apparatus to perform them with; if it shirks the use of improved safety appliances or methods, and only installs them when the loss from accidents, the force of public opinion, or the hand of legal authority forces it to do so; if it treats its employes merely as a minor and necessary adjunct of its machinery and apparatus; if it does any, or most, or all of these things do you not suppose that the personal element will be a danger element?

On the other hand, let a company hire men of habits and intelligence suitable to the duties that they will be required to perform; let it take care of them in such manner that they will at all times be in condition to exercise their faculties of mind and body to the fullest advantage of their duties; let it give them the proper means and facilities for performing those duties in a perfect manner; let it give them every tried so-called "safety appliance" before adverse circumstances force it to; and I will guarantee that the personal element will be a safety element.

Why? Because the men are better men? Not all that. Because they are more comfortable in the performance of their duties? Not

all that. Because they feel more secure in their positions and the fulfillment of those duties? Not all that either. While all these points have a bearing (and a great one) on the safety element, the real reason, the soul of the whole matter, lies in the fact that one company does not seem to care for immunity from accidents if that immunity causes more trouble and expense, the other proves that it does not want accidents at any cost. The one shows that it does not care for accidents, the other proves that it does not want them. In the first the employes feel that the company does not "back them up" in any safety efforts, in the second one, they feel that the company is "right behind them" in any efforts that they may make for safety, and, conversely, that it is "right on top of them" for any neglect of safety.

That is the real "safety appliance," the feeling that pervades the company from the highest officer to the lowest employe, that the spirit of the company as evinced by all its actions is for *safety*, first, last and all the time. Let that spirit be shown, that policy carried out, in deeds as well as by words, by those officials who are regarded as "the company" and it will permeate not only every employe but the public as well. It will act not only as a preventative of accidents, but as a corrective of their effects when they do occur. With every possible care taken by the company for the safety of its employes and the public will come a greater care of the employes and the public for the company. For what is "the public"? It is you and I! We are the public to anything we are not directly interested in. Who are "the employes"? Just you and I! We are all employes in anything we are directly concerned in!

Now, as the public, how would we act with respect to these two companies? We would believe everything bad that was said or published about the first one and would add our little mite to its damnation whenever possible; on the streets of its routes we would be obstructive; on its cars we would be kickers, obstinate and subversive of its rules; as tax-payers we would be against any concessions to it; as plaintiffs we would be vindictive; as witnesses we would be biased; as jurymen we would be prejudiced. If we were in the "fake" accident business, either as counsel or client, we would pick it out as a "soft thing". It would be "the public be damned" against "the company be damned" and we all know from past experience which can stand that fire the longer.

As to the other company, we might feel all the above, but the facts would be against us, and our adverse feelings and actions would only rebound on us. As a matter of fact, however, we would not feel that way, for you must remember that the public is you and I and better men than any of us. We will probably feel "anti-corporationy", we think we have had good reason to do so in the past, but we are American citizens (actual or in embryo) and as such have very fair average intelligence, therefore when we get it "rubbed into us" that this company is trying to carry us in safety to ourselves, our walking and driving neighbors and the employes, we will—slowly, and perhaps grudgingly—acknowledge the fact, and act upon it. And the difference will thereupon be very evident, to the company.

Now,—as employes—how will we act towards these two? You must remember that as employes we are apt to gain a knowledge of our employer's affairs and actions, that is, as a whole, pretty correct, and we always discuss them thoroughly among ourselves. If any one thinks we don't and won't he will be badly mistaken. Tom may just have been dismissed for leaking information from the office, Dick may have been suspended for being too "informative" to a passenger and Harry may have been bounced for cussing and discussing the company and its affairs in public, but all the same the information will still leak out and the discussion among us will still go on. And what will we say and do in the case of Company No. 1? We will have borne in upon steadily—and perhaps unconsciously—what I heard a motorman in an up town line in New York City say, a few weeks ago:

"We don't give a damn if the company don't! It isn't such a soft job that a man should kill himself to hold his 'posib.' Mebbe they'll learn some sense when the courts an' legislature sock it to 'em a little more!"

You can see that in a company like that the personal element might be a little adverse to safety.

But with Company No. 2 how would we act. Our feeling would probably be that the company was dead in earnest in regard to its determination to avoid accidents at any cost, and, to quote another remark I heard on a street railway:

"If we want to keep in the procession we'd better be gettin' a

move on us an' fall in line or the ol' man 'll be chasin' us with our last pay envelope."

Needless to say that this was not on the same road as the first remark I quoted.

I have spoken before of equipping with "so-called" safety appliances. Now, what are safety appliances? Do they consist simply of the fenders, brakes, switches, signals, etc? Do they not consist of much more than these? Turn the thing around and look at it! Is not every single article we own and operate a "danger appliance?" Is there anything from the cap of our power station chimney to the bottom of our pole-holes that is not a menace to safety if not of the proper material, properly made, and properly operated? Is there a single article in our power houses, car barns, repair shops, lines, tracks or cars that has not at some time or in some place killed, maimed or injured somebody? And what prevents these articles doing so all the time? What prevents our having "holocausts" at the rate of one a minute for the whole 24 hours? What is it that acts as a safety appliance against this mass of "danger apparatus?"

It is the "personal element," that made, that bought, that erected, and that repairs, renews and operates them with a first, if wholly unconscious, thought of safety. Metaphorically speaking, the "personal element" is a chain—the brake chain which our energetic friends the air-brake men are trying so hard to throw into "innocuous desuetude." Like that chain its strength is measured by that of its weakest link. For that chain you do not buy up a scrap of mixed metals because you can do so at a bargain; you buy the very best metal you can obtain for that purpose. Now why not do so in the human chain? From president clean through all the officers and officials down through the employes to the very wipers, we need the very best of the kind. Therefore the first and most important requisite is good men, men who are sober, industrious and reliable in word and deed. These you can not buy in a scrap heap; they are standard goods and have a market value, so if the price you pay for your labor is below the market, don't hug yourselves with the idea that you have struck a bargain, ten to one it is "scrap" and at the first "emergency stop," bang! will go a link or two!

If lead were selling at a cent a ton would you buy it to make brake chains of? No! Why? Because it is not suitable for the purpose, Make your links of suitable metal; fill your positions with suitable men; don't put round men in square holes, or vice versa. If you want the best results in safety the men must be a good fit in their holes. If you find misfits among good men see if the fault is not in the hole. I have seen holes of such a peculiar shape that nothing short of a jelly fish could fill them, and a jelly fish is invertebrate; it has neither backbone nor brains.

See that your chain is a chain and not a handful of loose links; weld link to link with the fire of self interest and the hammer of discipline; make every link feel not only that its safety is dependent on every other link, but that on its integrity depends the safety of every other link and of the chain as a whole. Lubricate the chain; see that there is no unnecessary friction at any point, and especially between links. Friction between links wears two links and is doubly dangerous. Watch, examine, and overhaul your chain; throw out any links that show any undue wear, defects or weakness; remember that the strength of the whole chain depends on that of its weakest link. Keep it bright, free from rust and dirt. Nothing is more dangerous than these two. The depth of the rust is an unknown quantity; from the outside it may seem only a coating and yet be eating clean through the link, and as for dirt, it hides all sorts of defects.

You all have rule-books and bulletin boards. Now, both of these are good when they are good and when they are bad they are the very devil; and nothing will render them so quickly bad as to have dead rules or orders in them. It is very strange, but there is nothing on earth that smells so badly and so quickly and is so contagious as a dead rule, so, if you and a dead safety rule cut it out as quickly as possible; if you don't it will start rust spots on the links sure. If you find a good rule or order dying—as rules will do—of inanition caused by negligence, rub the links briskly with it; that will clean and brighten the links and resuscitate the rule. See to it that the rules and orders are alive in every part of their being. They are part of your safety appliances and are subject to wear, decay and breakage the same as the other parts. Overhaul them, renew, repair, mend and amend them as you would any other part of your machinery or apparatus. Don't let them either wear or decay unnecessarily.

Put up a big blackboard in every department; put one up in the directors' room and in the officers' offices, and when a

safety rule is being slighted, when it is being overstrained, when it has been re-vamped, changed or repaired put up a big "Notice" on the board and call attention to it.

You can go farther than this; if you are about to have something something extra in traffic or in operating; if your city is to have some event that will greatly increase your traffic; if the winter season is coming on with its attendant snow, sleet and ice; if the summer season is approaching with its increase in traffic—seize the opportunity to put a little blood into some of the anemic rules, give them an outing on the blackboard, rub up the links with them, it will do them both good.

In fact it is wise to go even farther than this. Make it a point to see that the safety rules and orders all get an airing once a season or so. If neither regular traffic nor extraordinary events give you an opportunity to give them exercise, do it anyway. "Out of sight, out of mind," is a wise adage!

Now, lastly, don't overstrain the chain or any links of it. If you were buying the material for an actual chain, one on which your safety would absolutely depend, what would you do? You would ask the manufacturer for a guarantee of strength per square inch, of elastic limit, etc., all with the idea as to how much it would stand, and then you would give it a duty far inside of its limit, for you want a "factor of safety"—and a large one. Now when you deal with the material with which our chain is formed, that most sensitive of all materials, human nature, do you do the same thing? If not, why? Probably because you do not like to go to the manufacturer and will not do so even when you die.

It is true, if we want to build an edifice, a machine, a bridge, a car, anything at all on which profits or people are to depend, we require at the hands of the builder or maker a constant factor of safety, and yet when we put into these articles their souls—the human element which is to repair or operate them, which thus holds in its hands the power of life and death, of ruin or success—we treat it as if it were the ultimate ether, without weight, form or physical properties, infinitely strong and elastic! Else why are the employes often worked regularly, hours longer than nature will stand and be recuperative; why are they often worked in positions so uncomfortable, locations so exposed that they can not use their muscles or their minds to any advantage; why are they paid so poorly that their whole waking thoughts are merely schemes to piece out their wages so that they will cover their needs; why are they often treated so unfairly that they lose interest in their work and in their employer; or so unjustly that their interest changes to ill will?

We instinctively allow a factor of safety to everything else—even to so homely a thing as a camel's back, we give the margin of a "last straw" and yet we deny it to the personal element, which needs it most! Is this done from thoughtlessness, or carelessness, or because we honestly believe that this factor is so infinitely great that we may disregard it in our calculations? If the last is the true reason for our neglect how mistaken we are! For there is nothing so capricious, so sensitive, as the personal element, nothing with which we deal has so small and changeable a factor, and the best results as regards safety will be to the company that carefully keeps it a maximum.

Dropping metaphor, the personal element is the danger element. Ninety-nine one-hundredths of the accidents come—not by some *thing* that failed—but by some *one* that caused it to fail by neglecting at some time his safety duty. It may have been the board of directors who were niggardly in their policy; it may have been the president who knowingly carried that policy into effect; it may have been the purchasing agent who bought because "it was cheap;" it may have been some one in the supply department who failed to properly inspect the goods when received; it may have been the heads of any and every department who were lax in discipline, inspection or correction, it may have been the sub's in these departments who took their tone from their superiors, it may have been the men who repair or renew and who did a "that-will-do" job instead of a "that-is right" job, it may have been one of the "operating" men who "forgot" or "didn't think," but it was some one and not some thing that did it.

Some one once wrote something about the "cussedness of inanimate objects," and I have heard that phrase in various forms given as an excuse for accidents. Don't take any stock in it, it is a bald-headed old fraud! If there is or was cussedness in an inanimate object it was induced by an animate object; the "personal element" was getting in some of its bad work.

Ninety-nine out of every hundred accidents which we have had to father, would not have occurred had not some one failed in his safety duty. We may spend any amount of money on improved sand boxes, controllers, switches, signals and the thousand and one new safety devices now being exploited, and the personal element can render them nugatory at the very minute we need them. We can brand our motormen as butchers and the public as blind idiots by putting a contraption of steel springs, canvas and tarred rope on the front ends of our cars and danger will quietly walk in at the rear end in the shape of some small neglect of safety committed long ago by some one at the other end of the line!

The question is how can we change this personal "danger element" into a personal "safety appliance?" The answer is "with good men, suitable men, well paid, well cared for, well equipped, well watched, well disciplined and permeated, saturated, soaked, with what should be the instinct of every member of the company from the president to the track-greaser—the idea of safety as a first thought in every duty they perform!"

### Electric Street Railway Repair Shops.

BY ROBERT DUNNING, BUFFALO.

The equipment of the repair department of the modern street railway is of necessity governed by the same conditions which will obtain in the various other departments. There is, of course, much in common whether the road be of electric, cable or horse power, but as this paper is limited to the electric railway I will confine my few remarks to what in my experience has proved to be the most practical for the proper maintenance of the repairs of that style of road.

The repairs of the electric road which operates twelve or fifteen cars, are, generally speaking, as varied in character as those of a much larger road, but it would be impossible for the small road to maintain a repair equipment equal to that of the large road, so much of their repair work must of necessity be done outside. But it is of the larger road which I speak. The road which operates from 100 to 400 cars.

In the lists of machinery and tools which I have prepared I have aimed to give only those which are most generally useful as the volume of work increases. Many little conveniences for its quick and easy handling will suggest themselves and can be added to the equipment.

The machine shop with its auxiliaries the blacksmith shop, truck shop, and armature room, naturally takes precedence in repair work. The value of a convenient arrangement of those departments and the proper location in each of work-benches and machinery to give full working space cannot be over-estimated. To find that you cannot operate your speed drill press at times, on account of work in the shaper or planer being in the way, is aggravating and unprofitable. In a factory where new work is being turned out, space may be economized, but in a repair shop you know not what a day may bring in to you. A good rule to observe in this matter is to take as much room as you think you will need and then double it.

A lathe equipment consisting of one 24-in., one 20-in. and one 20-in. speed lathe will meet all ordinary requirements of that class of work. The larger lathes should be provided with gib crane fitted with differential air pressure lifts for the safe handling of heavy work.

Two large drill presses 22-in. and 26-in. and one speed drill press will do the work of that department.

The other machinery may be listed about as follows:

- A good milling machine (not necessarily universal).
- A shaper with 16-in. stroke.
- A hydraulic wheel press.
- A pinion press.
- A vertical wheel boring machine.
- An axle lathe.
- A power shearing machine.
- A power hack saw.
- A power thread cutter, right and left.
- A power punch.
- And the necessary bending and shaping machines for sheet iron and tin work.

The grinding work can be done with one dry and one wet grinder, a fine and coarse emery wheel, and there should also be a set of buffing wheels for finishing car and electric fittings.

A babbling furnace and suitably arranged gas or charcoal stoves

are a necessity. The air for blowing these fires may be provided by a tank and pump, operated from a special pulley on the overhead shafting.

The necessary vises and hand tools must be according to the men and work, but in the matter of wrenches I prefer the solid jaw fitted to standard nuts to the screw or set wrench. A good arrangement with regard to tools is to have a special tool room in charge of a competent tool maker, and a check system for the purpose of making the workmen responsible for tools drawn.

In the armature room, besides the necessary work benches and armature stands, a binding machine, a field winding machine and bake oven are essential. A jib crane or overhead trolley with chain falls are necessary for the proper handling of armatures, and a full outfit for testing work completes the outfit.

Have system in the arrangement of work benches. Keeping the different kinds of work separate you will thus avoid the delay and trouble of hunting for mislaid pieces.

The truck shop, besides the usual assembling tools, should have an overhead hand power crane of from 4 to 6 thousand pounds capacity for the safe handling of motors, etc.

The carpenter shop next claims our attention. The same rules which apply to space and arrangement in the machine shop apply here.

The following outfit of machinery will do for all ordinary work:

- 1 planer.
- 1 resurfacing machine.
- 1 jointer.
- 1 mortiser.
- 1 boring machine.
- 1 shaper.
- 1 wood turning machine.
- 1 band saw.
- 1 emery wheel.
- 1 good grindstone.

A first-class man should be in charge of the machinery, who thoroughly understands the grinding and sharpening of tools, and it should be his work to see that not only the machines were kept in order, but also that tools owned and used by workmen were in proper shape.

In the space devoted to work on car bodies see that there is plenty of room for necessary trestle benches and the convenient handling of work. Pit room for half a dozen cars is a necessity. As a means of moving cars an I trucks between carpenter, machine and truck shops, an electric transfer table will be found most convenient.

The paint shop should be constructed so that it will have good roof light, and the width between the tracks should be sufficient to allow the work to be performed on cars standing parallel and not to crowd the workmen; in other words, the gauge lines of tracks should be between 7 ft. and 8 ft., and should be of such capacity so as to have the cars pass through regularly every 9 or 10 months.

The floor should be of concrete with a smooth surface, so that it would be easily kept clean and free from dirt, and should also be graded to be easily drained.

The power for operating the machinery can generally be best furnished by motors in each shop conveniently located, and so set up as to permit of quick substitution in case of a burn out or break down.

Many small repairs which can be done by hand, such as the replacing of trolley wheels, switches, bell or register cords, etc., can be as well done in the car house proper as in the shops, and result in a considerable saving of time, and I think it well to have tracks set aside for this work and have the conductors of cars instructed to run cars in need of certain repairs on to those tracks when coming into the barn, and to leave a note on file in the barn foreman's office stating repairs needed.

In the whole general scheme of repair work there are minor but yet important parts which go to round out and complete the whole. Among these is the pattern maker, a visit to whose den shows many minute reminders of the transitory state of affairs even in the street railway business, and the draughting room where a look through the drawers and pigeon holes reveals many ideas "born to blush unseen" by the outside world.

The management which has the interests of its road constantly in mind will keep ever closely in touch with the repair department. Do not be afraid of doing too much for it. The fault is generally the other way, for though it works in dirt and as a rubbish producer is

unequaled, it is but performing the vital work of renovation, and removing that which is dead and is acting as a clog to the whole system.

I do not wish to create the impression that repair work is the one great and vital factor in street railway economy, but I do wish to claim a high place for it.

Look well to the repair department.

### Street Car Wheels; Shall They Be Made Heavier?

BY F. D. RUSSELL, ROCHESTER.

It seems to me this might be better handled by some practical street railway man, the user of the wheels, than by the maker, for the one knows from actual experience what is needed, while the other can only get his knowledge second-hand, as it were, from observation and by keeping in touch with what is going on. However, to see what can be done with the subject by the maker, suppose we first glance at the motors, beginning with the earliest, their weight and power, and then at the character of the service, and see what is now required of wheels.

Mr. Sprague's Richmond motor, of the summer of 1888, which I understand is the same as Edison No. 6, had 15 nominal horse-power and could work up to about 23 under favorable conditions. Its weight was about 1,700 lbs. and it required a  $3\frac{1}{4}$ -in. axle. The F. 30, another double reduction motor of 1888, was rated at 20-h. p., could develop 30 and weighed 2,200 lbs. The S. R. G. of 1891 and the W. Ps. 30 and 50 of 1892, as also the G. E. 800 and G. E. 1,000, which brings us to the spring of 1896, together with the Westinghouse motors of corresponding period, are so well known to all of you that I will not go into detail regarding them, further than to say, that by the spring of 1896 we arrived at 35 to 50-h. p. motors, nominal capacity, and weight of 2,100 to 2,400 lbs., using  $3\frac{1}{4}$  or 4-in. axles. I understand the Westinghouse Company has made a special  $6\frac{1}{2}$ -h. p. motor for Pittsburg, using 4-in. axles, and that there is a G. E. 51 rated at 80-h. p., competent to work up to 120, and weighing nearly 4,000 lbs., this uses  $4\frac{1}{4}$ -in. axle. Of course there are larger motors, but this is about the limit at the present time for street car service. I confine myself for purposes of illustration to these two lines of motors, and no neglect is intended toward any other makes.

With the development of the motors the possibilities of electric traction have appeared and been realized, and it is literally beyond the power of anyone to foresee to what extent the electric motor will further revolutionize travel within the next to years. I speak of a period of 10 years to come, because 10 years ago, beyond some cable lines in big cities, storage battery experiments in New York and Philadelphia, and some few overhead lines, the "Hay" motor reigned supreme. At the 1888 Convention of the National Association at Washington, although everybody was on the qui vive on mechanical traction, the principal power was still horse or mule. I well remember how Mr. Sage, of Easton, Pa., amused everybody, and also voiced the general sentiment, when, after listening the better part of two days to papers and discussions on all sorts of mechanical traction, he suddenly came to his feet with the demand for information on what he and others actually had to deal with, viz., the horse and how to use him. Cable, he said, was only for big lines, and electricity for those who could afford to experiment. For himself, he wanted to compare notes about feed, stable, harness, and horse matters in general, whereas he had not heard a word about horses since he arrived, and that was what he came for.

That is nine years ago next month. Now, if you please, just look for the horse railways, and see how many you can find. Outside of New York city, practically all the lines have been changed over, one of the last to reconstruct being Charleston, S. C., this season, and I may add, we furnished the wheels and axles.

In addition to the general change, an entirely new class of road has come into existence. I refer to interurban lines, making fast speed, and competing successfully with the old established steam roads.

While, of course, the motor car required at the outset a different wheel from the horse car, the change would not be so marked if motor cars, as in horse car days, remained within corporate limits, within which it is necessary to run at moderate speed, but now they either lead to suburbs or from town to town, and it is in the outside limits or between places where the speed is made, and the speed a wheel has to make has much to do with the kind of wheel required.

Of course motor wheels have been undergoing during the last nine years a somewhat similar development to that of the motors, trucks and cars, and may be said to have kept pace with what has been required of them. Our first 30-inch motor wheel weighed about 250 or 260 lbs., and our first 33-in. was a 300-lb. wheel, and, I may add, this is a good pattern yet, for moderate sized cars at not over 15 or 18 miles. These photographs show both sides of this wheel. Next we came to 280 lbs. for the 30-in. and 335 lbs. for the 33-in., and then, which was about four years ago, to 300 lbs. and 350 lbs. respectively, and remained at that for a couple of years or so, with the exception, of course, of special lots from time to time. These photographs show the latter.

About a year and a half ago, at the desire of our general sales agent, George G. Morse, of Taunton, Mass., I made with him a tour of discovery through Maine and other parts of New England. Mr Morse was supplying our wheels to practically all that section, and I may say that the visit was a revelation to me as to fast interurban service. Although our wheels were performing the work well and satisfactorily, we added on my return about 30 lbs., to wheels for that kind of service, which brought us to 370 or 380 lbs., and these are photographs of a very competent wheel of that weight. We also brought out a 400-lb. wheel, having eight spokes or arms instead of the usual number of seven, for fast, long runs, also snow plow and snow sweeper and sprinkler service.

These are all 33-in. wheels. On 30-in., we now run about 325 lbs., sometimes to 335 and 350 lbs., but 335 is probably heavy enough for a 30-in. wheel.

I do not wish to be understood that more weight is in any sense desirable. The lighter the wheel, in fact the lighter the whole equipment within limits, the better it is for the roadbed. The service is bad enough for the tracks as it is, without adding any more weight than is absolutely necessary. A comparison of the weights of the motors will show that the increase has been mainly in capacity. Take for example, two Westinghouse motors, viz., the 15-h. p. of 1890, and the 50-h. p. of 1896. These both weighed 2,400 lbs. And so it has been with us to an extent. There is a great deal in the manufacture of a wheel besides the mere question of weight. The question of the pattern, the careful proportionment of all parts to obviate strains in cooling, the mixture, and treatment of the iron, as well as the annealing of the wheels, not to mention any number of minor things, which have to be watched carefully, all these must be combined to produce a thoroughly reliable wheel.

For instance, here is a photograph of a solid plate wheel, weighing 450 lbs, this style of wheel, which is known as a single plate, being preferred in certain quarters. Now I have practiced on plate wheels to my heart's content, and I am satisfied that the pattern shown in this other photograph, viz., our special eight spoke, open-plate wheel, is infinitely stronger and better in every way on 400 lbs. of weight than any form of single plate wheel weighing 50 lbs. more.

To sum up briefly, and taking the 32-in. wheel for a standard, our conclusion is that 380 lbs. to 400 lbs. on  $2\frac{1}{4}$ -in. and  $2\frac{1}{2}$ -in. tread is not any too much for the present service.

There are two factors which try the very withers of cast iron wheels. One is the twist or torsional strain as the motor drives the wheel, and the other is the heating of the periphery of the wheel from the friction generated by high speed, or continued application of the brakes. This latter I firmly believe is the hardest part of the service required of a motor wheel, because it tends to expand the rim, and set up a severe stress where the arms, which remain cool, unite with the rim. All our patterns are designed to resist this strain.

Now, gentlemen, if you will allow me a moment or two longer, I wish to say a few words on the subject of standards, axle standards, I mean, for the wheels, in tread and flange, are gradually approaching as near to a standard as the varying conditions of service will admit.

Perhaps some may think I am going beyond my province in touching upon axles, but let us see.

Lately we purchased about 1,000 bars of steel for axles, partly to protect our present requirements, and partly because the advance agent of prosperity had taken so long to come around that we thought he might actually do so, and run up the steel market for us. We know how you all like to have any of the supply men raise prices, and we know, also, that when you want axles, you want them at once. You do not like to wait a fortnight, or three weeks while we send to the mill for the necessary steel. Hence, we try to anticipate what our friends are likely to want, and, I do assure you, it was

nothing short of a Chinese puzzle to make up a list which would properly cover our needs.

Taking the trucks in order of length of axle, (then no one need object to the order in which he is mentioned,) we have

|                   |      |                                                                                 |
|-------------------|------|---------------------------------------------------------------------------------|
| Taylor            | axle | .....6 ft. 3 in. long.                                                          |
| Peckham           | "    | .....6 " $4\frac{3}{8}$ " long, and he also has a<br>6 " $6\frac{3}{8}$ " axle. |
| Brill             | "    | .....6 " 5 " long.                                                              |
| McGuire           | "    | .....6 " 5 " and also 6 ft. 6 in.                                               |
| Bemis & Baltimore | "    | .....6 " $5\frac{1}{2}$ " long, and                                             |
| Diamond           | "    | .....6 " $5\frac{1}{2}$ " long.                                                 |

I have not at hand the lengths of the Dupont, or Dorner & Dutton, or any other axles not mentioned in above list, but you can depend upon it, they are different.

The foregoing lengths are on standard gauge and usual tread, which means not exceeding  $2\frac{1}{2}$  in. All, I believe, are subject to variation where wheels have tread wider than  $2\frac{1}{2}$ -in., and, of course, far wider and narrower than standard gauge.

My idea in speaking of these varying lengths of axles is to suggest whether you cannot get together and establish a standard axle, and by amicable arrangement with the various truck makers, bring about the adoption of a standard length of axle, a standard journal, a standard brass and a standard box.

The Master Car Builders of the steam railroads long ago took exactly such action, and it is nothing new which I suggest. They have a uniform standard. Their axle is 6 ft.  $11\frac{1}{4}$  in. long, and the journals and boxes and brasses are interchangeable the country over. If they could establish such a standard, why cannot street railways arrange for the same? Instead of interfering with the interests of any truck maker, it seems to me it would benefit, and it certainly would simplify matters enormously for everybody concerned.

#### The Banquet.

The banquet at the International was a very enjoyable affair and the toasts bright and witty. Hon. W. Caryl Ely, of Niagara Falls, presided. The program was as follows:

|                                                      |                                    |
|------------------------------------------------------|------------------------------------|
| Welcome.....                                         | Hon. Arthur C. Hastings.           |
| The Empire State.....                                | Hon. James M. E. O'Grady.          |
| Street Railroads from the Consumers' Standpoint..... | John Kendricks Bangs               |
| Our Hosts.....                                       | Hon. Edmund O'Conner.              |
| The Railroad Commissioners.....                      | Hon. Ashley W. Cole.               |
| Niagara of Today.....                                | Hon. Thomas V. Welch.              |
| Our Trans-Atlantic Visitors.....                     | { William Murphy.<br>J. B. Cannon. |
| The Association.....                                 | John W. McNamara.                  |
| The Railway Press.....                               | J. H. McGraw.                      |
| The Ladies.....                                      | J. H. Stedman.                     |

#### DELEGATES OF STREET RAILWAY COMPANIES.

Boyle, John W., Pres. Utica Belt Line St. R. R., Utica.  
 Brewster, J. C., Supt. N. F. & S. B. R. Co., Niagara Falls.  
 Cahoon, J. R., Geo. Mgr. Elmira & Horseheads Ry. Co., Elmira.  
 Clark, J. P. E., Gen. Mgr. Binghamton Railroad Co., Binghamton.  
 Cooper, H. S., Schenectady Ry. Co., Schenectady.  
 Cole, Wm. W., West Side R. R. Co., Elmira.  
 Cleminshaw, Chas., Pres. Troy City Ry., Troy.  
 Danforth, R. E., Buffalo, Bellevue & Lancaster Ry., Bellevue.  
 Deming, Peter C., Supt. Buffalo Railway Co., Buffalo.  
 Ely, W. Caryl, Pres. N. F. & Buffalo Ry. Co., Niagara Falls.  
 Evans, H. C., Nessen Electric R. R., Brooklyn.  
 Feeley, Thomas H., Buffalo, North Main St. & Tonawanda Ry. Co., Buffalo.  
 Haveon, Wm. E., Supt., Citizens St. Ry. Co.; Fishkill-on-Hudson.  
 Heller, W. A., Lewiston & Youngest Frontier Ry., Lewiston.  
 Hill, Chas. B., Niagara Falls & Susq. Bridge Ry.  
 Johnson, A. L., Pres., Nassau R. R., Brooklyn.  
 Johnson, Henry A., Metropolitan St. Ry. Co., New York City.  
 Morgan, Godfrey, Buffalo St., Main St., & Tonawanda Ry. Co., Tonawanda.  
 Marshall, C. K., N. F. & B. Ry., Niagara Falls.  
 McCabe, Ambrose P., Metropolitan St. Ry. Co., New York.  
 Mooney, F. P., C. & H. Traction Co., Cortland.  
 Maloney, F. G., Electricia, Elmira & Horseheads Ry. Co., Elmira.  
 Maffitt, John H., Rapid Transit Ry. Co., Syracuse.  
 McCormack, J. H., Gen. Supt. Brooklyn Heights Ry. Co., Brooklyn.  
 McNamara, John W., Albany Ry. Co.  
 Newton, Henry S., Syracuse Rapid Transit Ry. Co., Syracuse.  
 O'Connor, Edmund, Att'y of Association, Binghamton.  
 Porter, B. W., Saratoga Traction Co., New York.  
 Porter, Alex. J., Director, N. F. & S. B. R., Niagara Falls.  
 Penington, T. C., Sec'y Am. St. Ry. Assn., Chicago.  
 Rogers, G. T., Pres. Binghamton R. R. Co., Binghamton.

Slifey, Geo. H., Nassau R. R. Co., Brooklyn.  
 Smith, Chas. H., Supt., Troy City Ry., Troy.  
 Stedman, J. H., Rochester Ry. Co., Rochester.  
 Story, C. B., Hoosick Ry. Co., Hoosick Falls.  
 Seixas, E. F., Amsterdam St. Ry. Co., Amsterdam.  
 Van Horn, Hart, N. F. & B. Ry., Niagara Falls.  
 Van Etten, Amos, Kingston City Ry., Rondout, N. Y.  
 Wheelley, W. W., Brooklyn Heights R. R. Co., Brooklyn.  
 Watson, Henry M., Pres. Buffalo Ry. Co., Buffalo.

#### OTHERS PRESENT.

Anderson, Edger P., Dublin United Tramways Co., Dublin, Ire.  
 Beeton, S., Dick, Reese & Co., Hove, Sussex, Eng.  
 Anderson, Wm. Sec'y and Man'g'r Dublin United Tramways Co., Dublin, Ire.  
 Baker, Frank M., R. R. Commissioner, Owego, N. Y.  
 Cole, Ashley W., R. R. Commissioner, Albany, N. Y.  
 Coonan, J. B., Dublin, Southampton, Barcelona & Tramway Union Co., London, Eng.  
 Donn, Geo. W., R. R. Commissioner, Binghamton, N. Y.  
 Dickinson, Alfred, European Tramways, Birmingham, Eng.  
 Flett, George, Managing Director, Dick, Kerr & Co., London.  
 Morphy, J. F., Dublin Tramways, Dublin, Ireland.  
 Murphy, Wm. Martin, Dublin & Belfast Tramway, Dublin, Ireland.  
 Nicholl, T. J., Rochester Ry., Rochester, N. Y.  
 Phillips, W., Niagara Falls Park & River Ry., Niagara Falls, Ont.  
 Read, John A., Tonawanda R. R. Co., North Tonawanda, N. Y.  
 Esteb, F. A., Pres. R. D. Nuttall Co., Allegheny, Pa.  
 Sharp, Edward P., Manufacturer's Agent, Buffalo, N. Y.  
 Smith, Pemberton, N. Y. Car Wheel Works, Buffalo, N. Y.  
 Shippy, H. L., John A. Roebings Sons Co., N. Y.  
 Waite, E. B., Tonawanda R. R. Co., North Tonawanda.  
 Wood, Chas. N., R. D. Nuttall Co., 31 State St., Boston, Mass.

#### REPRESENTATIVES OF MANUFACTURERS.

Allison, Giles S., St. Louis Register Co., 18 Broadway, New York.  
 Aeb, A. E., Pennsylvania Steel Co., 2 Wall St., New York.  
 Adams, H. E., Central Electric Co., Chicago, Ill.  
 Beach, R. H., General Electric Co., No. 41 Broad St., New York.  
 Clark, Wm. J., General Electric Co., New York.  
 Duell, C. H., Vice-Pres., Peckham M. T. & W. Co., New York.  
 Dutton, W. A., Cleveland.  
 Evans, H. C., Johnson Co., New York.  
 Feeley, Thomas H., General Electric Co., Buffalo.  
 Grenger, J. A., New York Car Wheel Works, New York.  
 Hanna, J. A., Peckham M. T. & W. Co., Chicago.  
 Haskell, G. W., J. G. Brill Co., Philadelphia.  
 Hollbrook, Percy, Weber Joint Manufacturing Co., Cotton Exchange, New York.  
 Jackson, Geo. J., Sec'y National Conduit & Cable Co., New York.  
 Lawless, E. J., American Car Co., No. 115 Broadway, N. Y.  
 Long, E. Y., Peckham Motor Truck & Wheel Co., New York.  
 McTigue, J., General Electric Co., New York.  
 Merens, H. T., Gen. Sales Agt. Corning Brake Shoe Co.  
 Morris, Elmer P., McGuire Mfg. Co., No. 35 Cortland St., New York.  
 MacGovern, Frank, Roessler, MacGovern & Co., New York.  
 Morrell, Frank A., Sterling Supply & Mfg. Co., New York.  
 Mason, Geo. T., The Okoite Co., New York.  
 Peckham, E., Pres. Peckham M. T. & W. Co., New York.  
 Potter, D. F., Gen'l Electric Co., Buffalo, N. Y.  
 Pugh, D. W., Stephenson Co., New York.  
 Polk, R. K., Wm. Wharton, Jr., & Mfg. Co., Philadelphia.  
 Racson, H. N., Consolidated Car Htg. Co., Albany, N. Y.  
 Randall, T. C., Eastern Agt. Christensen Eng'ng. Co.  
 Sheble, Franklin, Edison-Brown Rail Road, Philadelphia.  
 Swao, O. W., John A. Roebings Sons Co., New York.  
 Teobroek, Wm. H., Diamond Truck & Car Gear Co., Kingston, N. Y.  
 Vosburgh, A. C., New Process Rawhide Co., Syracuse, N. Y.  
 Vincent, C. A., Vice-Pres. Ball & Wood Co., New York.  
 Walsh, C. N., McIntosh, Seymour & Co., New York.  
 Watson, H. D., Edw. P. Allis Co., Milwaukee.

#### REPRESENTATIVES OF THE PRESS.

STREET RAILWAY REVIEW, F. S. Kenfield.  
 Street Railway Journal, James H. McGraw, W. H. Taylor,  
 Electricity, Charles D. Shain,  
 Electrical Engineer, T. C. Meritt,  
 Electrical Review, Chas. W. Price,  
 Electrical World, L. H. Parker,  
 Western Electrician, J. B. O'Hara,  
 Stenographer, T. E. Croesman.

Wednesday was chiefly spent in inspection of the various electric lines and power plants, the party taking special cars, crossing to the Canadian side and passing down the river returned via the Gorge Route. The cars used on this trip were equipped with Christensen air brakes, and the numerous curves and heavy grades afforded ample opportunity for the excellent demonstration which was made. The trip was a highly enjoyable one, and no effort spared by the local roads and officers in the entertainment furnished their guests.

G. Tracy Rogers was re-elected president; all the other officers were re-elected except that J. T. Dunning, of Rochester, who succeeds Mr. Beckley as second vice-president. The next meeting will be held in Brooklyn.

**\$2,000,000 IN FOREIGN ORDERS.**

American street railway supplies to the value of \$2,000,000 are being purchased for shipment across the water to be installed on the new electric lines at Barcelona and Madrid, Dublin, and other places. The delegation of visiting engineers and tramway officials who are here for that purpose include A. Dickinson, a well known tramway engineer; George Flett, joint managing director, and Walter Rutherford, manager of the electrical traction department of Dick, Kerr & Co., London, and William Anderson, managing director of the Dublin Tramway Company.

Mr. Dickinson is consulting engineer for the Madrid and Barcelona roads, and has already placed several large orders. Among which may be mentioned Brill trucks for both lines; and five 750-h. p. Allis engines. At this writing the order for 160 motors and five 500-k. w. generators has not been closed. Mr. Anderson will do the buying for the Dublin road.

It is significant that these large orders are sent to this country, and is evidence that the constructing engineers across the water are pursuing the wise policy of profiting by the experience of American roads instead of experimenting, and that they are buying here in the full assurance that they are securing apparatus which is true and tried and on the performance of which they can absolutely depend. It is but reasonable that our American builders which have spent hundreds of thousands of dollars perfecting their apparatus, and with thousands of miles of electric lines in operation on which to study conditions and early failures, should have worked out all the weak points, and arrived at a position of par excellence, not possible to foreign manufacturers.

**MORE EXHIBIT SPACE AT NIAGARA.**

As we go to press we learn of the return from Niagara of Secretary Penington, of the American Street Railway Association, where he secured an enlargement of the exhibit building by which 2,400 square feet additional space is made available. Mr. Penington states every inch of it has been taken and that the display will be very large and interesting.

It is stated that the Realty Syndicate, which has consolidated three of the street railway systems of Oakland, Cal., is now negotiating for the Piedmont and Broadway lines.

A heavy wire guy rope of a derrick fell across the trolley wire on one of the lines of the West End Street Railway of Boston and was melted in two by the arc formed.

The Englewood & Chicago Electric Company and the Calumet Railway Company have each issued orders that bicycle riders and their wheels may be carried for one fare at the discretion of the conductor.

The City of Atlanta, Ga. has given notice that application will be made to the state legislature for an amendment to the city charter, so that it will be empowered to regulate transfers and other street railway questions.

E. R. Robinson has filed a bill in the United States circuit court for an injunction restraining the Chicago City Railway Company from using car wheels which he alleges

are similar to the pattern upon which he has applied for a patent. There are 6,500 such wheels in use on the City railway.

New tickets have been issued by the Cleveland City Railway Company as the old tickets were being counterfitted in great numbers. It is supposed that some one had stolen a plate in Chicago where the old tickets were printed.

The Anderson Street Railway Company had a well sunk beside the power station in hopes of striking gas, but salt water was the only product when Trenton rock was reached, and the company abandoned the attempt to secure cheap fuel by drilling.

George B. Pennock, the professional inventor, has turned his attention to street railway lines and with his "voltage distributor" will do about 1,000 times as much work as the ordinary system. We have yet to hear of a company which wishes to effect this great saving.

E. C. Crosby, principal owner of the electric railway at Springfield, Vt., has refused to continue as president of the Battleboro Street Railway but his successor has not been chosen. There is considerable friction between the railway officials and this was the cause of Mr. Crosby's resignation.

A train of six cars of the Zanesville (O.) Railway & Electric Company speeded down the incline from the "Y" bridge and struck an approaching train, injuring five passengers, two of them were fatally hurt. An hour later a car jumped the track maiming two passengers so that they will die and seriously injuring two others.

The Lorain (O.) Street Railway Company is to have some high speed motor cars, equipped with four 50-h. p. motors. A trip was made over the tracks of the Cleveland & Elyria Railway Company by one of the new motor cars and a speed of 40 miles an hour was attained. It is expected that this can be increased to 50 miles per hour.

Six Manayunk, Pa., boys played a joke on the Wissahickon Electric Railway Company by greasing the tracks for a considerable distance but the boys see no humor in the trick now, as they are in jail. One of the cars began to slip backwards on the greased rails and it was with difficulty that a collision with a passenger train was prevented.

The office force of the Twin City Rapid Transit Company took their annual outing, the trip being a trolley ride to Fort Snelling, Como Park, Minnehaha Falls and Lake Harriet. At the latter place the party, numbering about 50, enjoyed a sumptuous repast. Instrumental and vocal music was furnished by the Apollo mandolin trio, and the whole trip was full of enjoyment.

John B. Hoefgen has commenced suit against the East Liverpool & Wellsville Street Railway Company, et al, in the common pleas court at Cleveland, O. He alleges that the interest was not paid on the bonds April 1, 1895 and the stockholders declared the bonds due and foreclosed the mortgage. On 249 \$1,000 bonds Mr. Hoefgen received \$79,630, and having sold the bonds for \$249,000 there is due him the sum of \$169,370 and interest, \$37,350. The plaintiff asks that all stockholders be made responsible for the debt.

## BRILL "UNIVERSAL" TRUCK.

The ordinary four-wheel non-pivotal truck, when used at high speeds under large cars, is destructive to the track and roadbed and uncomfortable for passengers on account of its excessive and violent motion, besides being exceedingly noisy. It is also severe on the car body, which is rapidly shaken to pieces.

The truck illustrated is a new form of the pivotal type, designed to take the place of four-wheel non-pivotal trucks on long car bodies. It is called the "universal," and is a modification of the "perfect," or No. 27, and also has certain features of the maximum traction truck. It is intended for use under cars of all kinds where a pivotal truck is an advantage. The objections to pivotal trucks of the usual patterns are numerous, and, being very difficult to meet, really prohibit their employment in most cases for street railway service.

A long wheel base has been considered necessary in

or closed, without adding to the height of the car, there being ample space to swing on the shortest curves.

A long half-elliptic spring on each side of the truck acts as an equalizing bar, the ends being carried in the spring swinging link cases, which are hung from the frame by ball and socket joints. All the weight except that of the wheels, axles and boxes is carried on the springs on the journal boxes, and this together with the arrangement of the bolster and equalizer makes an easy riding truck.

The braking apparatus has been designed with a view to prevent the kicking up under the action of the brakes which is characteristic of the ordinary equalized swing beam truck. Also, the braking pressures are graduated to the weights on the wheels to prevent skidding the non-driven wheels.

The "universal" truck was first adopted by the Consolidated Traction Company of Jersey City, which ordered 50 trucks at first and soon followed with an order for 100 more.

BRILL NO. 27-D.—THE "UNIVERSAL" TRUCK.

pivotal trucks in order to give the motors space between the axles and the bolster transoms. If the wheel base is made short the motors come under the bolster, and it has to be greatly elevated to obtain proper clearance. These conditions prevent a pivotal truck of the ordinary form being used, because, in the case of the closed car, the swing of the truck brings the wheels against the sills, and with the open car the swing interferes with the steps. Such trucks can, therefore, only be employed when the cars are very wide or when they are placed very high, so as to necessitate the use of two steps. There are but few places where such cars can be used successfully.

Certain valuable features have been taken from the maximum traction truck and combined with others of the No. 27 truck, thus obtaining the great convenience of the first with the easy riding qualities of the latter.

The weight of the car is carried on side bearings, as shown in the engraving. The truck draws from the centre by means of an elevated plate steel bolster. This bolster is so designed that there is ample room for the motors.

Having thus made space for the motor, there is no difficulty in shortening the wheel base to 4 ft. This makes the truck short enough to use upon narrow cars, whether open

## FORECLOSURE SUIT AT BLOOMINGTON.

The Bloomington (Ill.) City Railway was one of the first to adopt electric traction, and was equipped with Westinghouse apparatus in 1892. J. J. Patterson, the president of the company and his son, who is general manager, were instrumental in building the system and supplied most of the money. First mortgage bonds to the extent of \$100,000 were due June 1 and \$73,000 in second mortgage bonds in July. An agreement was made with the bondholders for an extension for six months without any further action, and later they were notified that arrangements has been made with eastern capitalists to supply the money when the bonds came due in December. After this agreement the foreclosure suit, filed September 1, was unexpected by the Pattersons. It is thought that the bonds can be paid off when the fall term of court opens. No delay in traffic and improvements going on will be occasioned by the prospect of the suit.

A steam header in the power house of the Louisville (Ky.) Railway Company exploded on August 10, doing damage to the amount of \$200. No one was injured.

**CAHALL BABCOCK-WILCOX BOILERS  
CHOSEN.**

The Cahall Babcock-Wilcox boilers, made by the Aultman & Taylor Co., are crowding their namesakes in many

SECTIONAL VIEW OF CAHALL BABCOCK & WILCOX BOILER.

places. A recent instance may be cited in the case of the Staten Island Electric Company, which had been using Babcock & Wilcox boilers and did not wish to change the type, but was not averse to getting what it considered

equally as good for less money. In the recent installation the Cahall B.-W. was installed to the extent of 2,500 h. p. The Union Traction Company, Philadelphia, which has 23,000 h. p. of Babcock & Wilcox has just ordered 500-h. p. of the improved Cahall B.-W. boilers. Some people even go farther and insist that the Cahalls are even superior to the B. & W.'s of the same type, as evidenced by the following letter written to the manager of one of the largest roads in the country, in response to an inquiry as to what had been the experience of the writer in using this boiler. The Pittsburg Wire Company wrote as follows:

"During the past five years we have put in at our works, 2,500 h. p. of Babcock & Wilcox boilers, manufactured by the Babcock & Wilcox Company in New York. We have just put in 500 h. p. of Cahall Babcock-Wilcox boilers, manufactured by the Aultman & Taylor Machinery Company of Mansfield, Ohio, for which Thayer & Co. are general eastern agents.

"We have been requested by the manufacturers of the Cahall Babcock-Wilcox to write you, giving our opinion of the comparative merits of the two makes. We wish to state without hesitation that the most careful scrutiny and examination on the part of our engineers and superintendent reveal the fact that the Cahall Babcock-Wilcox boiler is much better built, more carefully made, and is in fact, superior in design, workmanship and material to the boilers that have been furnished us by the other company."

That the Babcock & Wilcox boiler was and is one of the best of its type, there is no question, and the prices received during the past 15 years have made the owners immense fortunes; but the time has come as it comes to all monopolies, when "there are others," and buyers rejoice and get the advantage.

THE  
**Lake Shore & Michigan Southern Railway**

WILL RUN SPECIAL CARS

On its Limited, leaving CHICAGO

at 5:30 P. M., October 18th,

FOR THE BENEFIT OF DELEGATES AND OTHERS ATTENDING THE

Convention of the American Street Railway Association

AT

NIAGARA FALLS, OCTOBER 19TH-22D.

NO EXTRA FARE ON THIS TRAIN.

This Train Arrives at NIAGARA FALLS in time for Breakfast the following morning.

In order that ample accommodations may be provided and proper assignments made, reservations should be made at an early date.

NEW RECORDING INSTRUMENTS.

A SHORT DESCRIPTION.

The Siemens-Halske Company of Berlin has introduced some new types of recording ammeters and voltmeters, which were described in a paper read before the Elektrotechnischer Verein, and reported in the London Electrician. In Fig. 1 an outline is given of the moving parts of the instrument. A represents the armature pivoted between the

FIG. 1.

two poles, the construction and connections being similar to that of the Weston instruments. The recording mechanism is a unique feature. A strip of plotting paper p is unrolled from the drum P by the wheel T. A point S is fixed to the pointer Z, and is normally at a short distance from the paper so that the movements of the pointer are not impeded in any way. Above the pointer is a hammer K which turns about the bearing D. By means of the electromagnet E and a toothed wheel r and the ratchet wheel R on the same spindle the hammer K is allowed to drop for an instant on the pointer once every two seconds. Beneath the paper is an ink ribbon B and when the paper is

A short description of the Lake Shore & Michigan Southern Railway will not be uninteresting to any one who is thinking of taking a business or pleasure trip from New York, Boston or Buffalo, to Chicago.

This railroad is the only double track line between Buffalo and Chicago, and in connection with the New York Central and the Boston & Albany railroads, forms the only double track route between Chicago, New York City and Boston. It is the most interesting route between the East and West, traversing the richest and finest portion of the Middle States. In the opinion of those experienced in travel, it has no superior in perfectness of roadbed, punctuality and elegant service and the comfort and care of its patrons.

Leaving Buffalo the line traverses the picturesque south shore of Lake Erie through the Western Reserve, passing on its way a large number of very interesting points until it reaches Elyria, O., a city 25 miles west of Cleveland. Here the tracks diverge; the southern line passing by way of Oberlin, O., and the northern line going by way of Sandusky, O. The two lines meet a few miles east of Toledo, O., but make another divergence about 3 miles west of Toledo. One of the lines runs north through the most pleasing portion of Southern Michigan, and the other turns south, traversing Ohio and Indiana, through northern parts. At Elkhart, Ind., the lines meet again and continue west through a rich farming country, past South Bend, La Porte, with its lovely lakes, and traversing the south shore of Lake Michigan, terminate at Chicago.

Wagner vestibule sleeping cars, complete in every detail for comfort, pleasure and safety, are run through between the above mentioned cities. The meals and service of the dining cars are all that can be desired, equalling that at the leading hotels.

Detailed information about the various cars, connections and time tables, will be furnished on application to A. J. Smith, General Passenger and Ticket Agent, Cleveland, O.

FIG. 7.

pressed against it by the pointer a mark is made on the inside which is visible from the front as the paper is translucent. The ink ribbon is moved by means of the gearing O. The recording mechanism, including the paper, ribbon and clock work can be drawn out from the rest of the instrument without removing the cover. Fig. 2 shows the instrument with the cover removed.

Fare boxes have been permanently adopted by the Tenth Street Cable and the Northeast Electric Railway of Kansas City, after a 30-days' trial.

**\$9.00 ONLY \$9.00.**  
**EXCURSION TO NIAGARA FALLS, ONT.**

Account of opening of the Grand Trunk New Single Arch Double Track Steel Bridge, September 23, 24 and 25.

Three days free open air entertainment. Illumination of the Bridge and Falls and magnificent pyrotechnical display under direction of Prof. Paine of New York.

Tickets on sale September 22 and 23. Good for return until September 27, 1897.

For information as to reservations, etc., apply to L. R. Morrow, C. P. & T. A., No. 103 Clark street, Chicago.

**KLONDYKE. KLONDYKE. KLONDYKE.**

The latest and most reliable information regarding this remarkable region, gleaned from returned miners and others, can be obtained by forwarding a 2-cent stamp and address, to Chas. S. Fee, general passenger agent Northern Pacific Railway, St. Paul, Minn. There are two routes to this region: one via Dyea and Juneau and over the mountains; the other via ocean steamer to St. Michaels, thence via river steamer up the Yukon river. The sailing ports of the steamers in either case are Seattle, Tacoma and Portland. The Northern Pacific through trains carry first-class and tourist sleeping cars and through dining cars.

The West Chicago Street Railroad Company has been selling 11 tickets for 50 cents or 22 for \$1, the conductors having them on sale on the cars. An order has been issued that these tickets henceforth will only be on sale at the office of the company.

Funkhouser & Coates have received the sub-contract to build four miles of the Riverview Electric Railway at Beaver Falls, Pa.

G. S. W. Brubaker, of Lancaster, has received the contract to build four miles of road for the Newtown Electric Street Railway Company, Newton, Pa.

Thomas Dempsey has been awarded the contract to grade the line of the Michigan Traction Company between Battle Creek, Gull Lake and Kalamazoo.

The Tennis Construction Company, E. A. Tennis, president, has been awarded the contract to build the Montoursville (Pa.) Passenger Railway, five miles in length.

The Union Elektricitäts Gesellschaft, Berlin, has published a small pamphlet, illustrating the exhibit of the company at the Hamburg convention of street railway men.

L. G. Hallock has been awarded the contract to rebuild five miles and electrically equip 15 miles of road for the Wheeling & Elm Grove Railway Company, Wheeling, W. Va.

The Parrish Signal Company has been incorporated with \$100,000 capital stock at Jackson, Mich., to manufacture the Parrish electric railway signal, invented by Homer Parrish.

The new catalog of Gisholt tools recently issued by the Gisholt Machine Company, Madison, Wis., is a handsome book of 40 pages, which will be sent to those interested on application.

Vandergrift & Jacobs, of Philadelphia, have been awarded the contract to build five miles of road at Wilmington, Del. for the Wilmington & Brandywine Springs Electric Railway Company.

Macartney, McElroy & Co., of New York, have received the contract to supply overhead material, rails and all iron work for the Brunswick Traction Company's extensions at Bound Brook and Metuchen, N. J.

Construction will be resumed immediately on the Baltimore & Washington Electric Railway. The receivers of the Baltimore & Catonsville Construction Company have been discharged and the company declared to be solvent.

The Western Electric Company's standard trolley wheel has been meeting with great favor among street railway men owing to its careful design and the superior composition of the metal having exactly the right wearing qualities.

Because of the continued increase in the demand for its cut pinions and gears the R. D. Nuttall Company of Allegheny, Pa., has added to its equipment four more new gear cutters, one of which is a bevel gear planer of the latest type.

The Canon City & Cripple Creek Construction Company has been incorporated at Chicago to build an electric railway between two Colorado cities. The capital stock is \$100,000 and the incorporators are Paul E. Hirsch, Henry Frantzen and Sigmund Zeisler.

The Empire Electrical Traction Company has been incorporated at New York, N. Y., to manufacture street railway appliances. The capital stock is \$100,000, and the directors are William W. Doty, William Reinhart and others of New York.

The American Air Power Company is negotiating with the Compressed Air Power Company for a consolidation of the two, which, by their combined ownership of the Hardie and Hoadley patents, would control the manufacture of air motors for street cars.

The Sherbrooke Electric Street Railway Company, Sherbrooke, Que., has let contracts for generators to the Canadian General Electric Company, for closed cars, to Rhodes, Curry & Co., Amherst, N. S., and for open cars to Ahearn, & Soper, Ottawa, Ont.

Simon Harold has received the contract to build two miles of road for the Riverview Electric Street Railway Company of New Brighton, Pa., a new company organized with E. L. Hutchinson, president; F. W. Walker, secretary, and F. G. Barker, treasurer.

The Automatic Life Saving Car Guard Company has been incorporated at Kingston, N. Y., to manufacture fenders. The capital stock is \$25,000, and the directors are John N. Cordts, A. H. Clark, Daniel R. Gillee and G. D. B. Hasbrouck, all of Kingston.

The Standard Underground Cable Company announces that it has opened an office in rooms No. 1225 and 1226 Betz building, Philadelphia, which will be in charge of T. E. Hughes who was formerly manager of the wire department of the company, in New York.

While abroad General Manager Wessels of the Standard Air-Brake Company closed several important contracts for air-brake outfits for use in Continental cities. Among other recent orders are one for 60 equipments for one of the Colonies and a further order for 15 complete outfits.

The American Air Motor Company has been incorporated at Bayonne, N. J., to purchase and control patents on air, steam and electric motors for street cars. The capital stock is \$75,000 and the incorporators are Lucius T. Gibbs and Robert M. Thompson, of New York, and C. C. Garrison, of Bayonne.

A. H. Englund of Mayer & Englund attended the Allentown convention of the Pennsylvania Street Railway Association, and gave to each of his friends a neat box of lead pencils as a souvenir. These are something novel and neat and the firm will be glad to send them to its friends who will write for them.

The new catalog of the Ball & Wood Company, 120 Liberty street, New York, is a very handsomely illustrated book of 60 pages. The demand for its engines has led the company to build them in all the various forms which are used in general manufacturing work, as well as for railway

and lighting service. They include the simple and compound horizontal engines, both tandem and cross-compound types and vertical engines of all sizes. They are built for belt or rope drives and also for direct connected sets. There are included in the catalog several pages devoted to the details of construction and also a description of the method of testing the governors for regulation.

The Cincinnati Street Railway Company has just placed an order with J. A. Hanna, western agent of the Peckham Motor Truck & Wheel Company, for 100 trucks of the 7D type, Excelsior. Less than a year ago the Peckham Company received an order for 175 trucks, and this makes a total of 350 trucks now running on the Cincinnati Street Railway.

Mayer & Englund, Philadelphia, have obtained for Albert & J. M. Anderson of Boston, a large contract for knife switches from the Union Traction Company of their city. These switches are for the switchboard of the new 13th and Mt. Vernon street station. When completed this board will have nearly 300 switches, of capacities varying from 600 to 3,600 amperes.

The Western Electric Company has removed its New York offices to 57-67 Bethune street. Besides the offices this magnificent building will contain stores for the sale of its manufactures and other electrical supplies. The present store in the Thames street building will be continued. Friends of the company are receiving in their mail a good map of lower New York with the location of the new building clearly indicated.

Additional agents for the Standard Air-Brake Company has been appointed as follows: Dick, Kerr & Co., Ltd., the well-known tramway supply people at 101 Leadenhall street, London, E. C., will hereafter be sole agents for the United Kingdom. E.H. Cadiot & Co., 12 Rue St. Georges, Paris, have the agency for France. The Bergische Stahl-Industrie of Berlin, which represents the Standard on the Continent, has already inaugurated a very good business in air brakes.

After a careful investigation of the question, including personal visits to the factory by the master mechanic of the company, the West End Street Railway Company, of Boston, has placed an order for eight double-track snow plows with the Taunton Locomotive Manufacturing Company, of Taunton, Mass. The Taunton Company reports that the snow plow business has opened up this season in a more promising and satisfactory manner than ever before, it having already sold more plows than during the whole of last season.

F. W. Bunts, formerly assistant secretary and treasurer of the Walker Company, has bought out the Cuyahoga Supply Company, dealer in electric street railway and lighting supplies, and general selling agent for Eugene Munsell & Co. and the Mica Insulator Company in Cleveland and northern Ohio. Mr. Bunts will continue the business under the same title as formerly, occupying the offices at 102 Superior street. Mr. Bunts is a young man who has a large acquaintance in the city of Cleveland and vicinity, and his association with the electrical trade will, no doubt, bring to his company a large business. His leading lines, to which he will devote his special attention, will be the "micanite"

specialties as manufactured by the Mica Insulator Company, of New York, Chicago and London, and Eugene Munsell & Co.'s India and amber mica in all of its various forms. The electrical trade of Cleveland and vicinity will find it to their interest to consult the Cuyahoga Supply Company as to their wants, as a large stock of the above lines will be carried ready for immediate delivery.

F. E. Triacca is now associated with J. C. Dolph, as the representative of several large manufacturers of street railway supplies. The name of the firm is J. C. Dolph & Co. and his offices are located at 126 Liberty street, New York. Mr. Triacca is widely and favorably known among electrical men in New York, and Mr. Dolph's acquaintance among street railway men is wide. The company will sell the rail bonds and commutator bars manufactured by the Forest City Electric Company of Cleveland, O., and will represent the Sterling Varnish Company, the Catskill Foundry & Machine Company and the Standard Gate Company.

E. B. Hatch of Hartford, Conn., representing the H. W. Johns Manufacturing Company, has recently returned from a European trip. While in England, he called upon Bergetheil & Young, 12 Camomile street, London, E.C., the foreign representatives of the Johns Company for vulcabeston, trolley line and other insulating materials, and the "H. W. J." electric street car heaters. During the past year the electrical export business of this company has considerably increased, several large orders having been filled for the insulating materials used in the construction of tramways in South America and in Europe.

The Consolidated Car-Heating Company, Albany, N. Y., hands us the following: "On August 25, Judge Putnam, of the United States Circuit Court for the District of Massachusetts, rendered a decision in favor of the complainant, with an order for an injunction and accounting, in the suit of the Consolidated Car-Heating Company of Albany, N. Y., against the American Electric Heating Corporation and the West End Street Railway Company, of Boston, Mass. This is the suit for the infringement of the patent to James F. McElroy, covering the Consolidated Car-Heating Company's spiral coil construction of electric heaters, which is now used in the majority of street cars operating electric heaters in this country. It is considered a most important victory."

Another company has entered the street railway field and is competing for liability insurance covering street railway risks. The new concern is the American Mutual Indemnity Company of Scranton, Pa. The promoters are wealthy bankers, coal operators and manufacturers of Scranton. The concern will transact a general casualty insurance business and it is said that considerable money has been put into the business. The directors are: C. H. Zehnder, president Dickson Manufacturing Company; Charles Robinson of E. Robinson's Sons, brewers; R. G. Brooks, vice-president West Side Bank and Dime Deposit Discount Bank, also a coal operator; W. W. Watson, vice-president Traders National Bank; Elmer H. Lawall, general superintendent Lehigh & Wilkes-Barre Coal Company; E. P. Kingsbury, director Scranton Savings Bank & Trust Company and secretary and treasurer of the Enterprise Powder Manufacturing Company; Alfred Harvey, silk manufacturer and coal operator; A. C. Fuller, vice-president and treasurer of the

Scranton Stove Works; W. S. Diehl of Watson, Diehl, Hall & Kemmerer, attorneys; F. W. Lange and T. R. Brooks, coal operator. The officers are: W. W. Watson, president; Elmer H. Lawall, vice-president; E. P. Kingsbury, treasurer; T. R. Brooks, secretary; F. W. Lange, medical director, and Newton Jackson, general superintendent of agents.

Wendell & MacDuffie, 26 Cortlandt street, New York, report the following sales of snow plows, manufactured by the Taunton Locomotive Manufacturing Company, of Taunton, Mass.:

|                                                     |   |        |
|-----------------------------------------------------|---|--------|
| Brockton, Bridgewater & Taunton Street Railway..... | 3 | plows. |
| Brockton & East Bridgewater Railway.....            | 1 | "      |
| Bridgewater, Whitman & Rockland Street Railway..    | 2 | "      |
| Worcester Construction Company.....                 | 3 | "      |
| West End Street Railway of Boston.....              | 8 | "      |
| New London Street Railway.....                      | 1 | "      |
| Hingham Street Railway.....                         | 1 | "      |
| Norwich Street Railway.....                         | 1 | "      |
| Buffalo Traction Company.....                       | 1 | "      |

This is evidence of the good standing which the Taunton plow has among street railway people, and before the time snow flies, it is not unlikely that this firm may double this list.

The Hoppes' Manufacturing Company, of Springfield, O., reports quite an improvement in business, within the past few weeks having received orders from the following: Union Traction Company, Philadelphia, three exhaust steam feed water heaters, aggregating 8,000 h. p., for the Mt. Vernon station of this company that was recently destroyed by fire; Henry R. Worthington for the Ridge-wood pumping station, Brooklyn, N. Y., 500-h. p. live steam feed water purifier; Flushing, L. I., 400-h. p. purifier and 400-h. p. exhaust steam feed water heater; East St. Louis (Ill.) Ice & Cold Storage Company, 500-h. p. heater; Kirkhoff Bros., Indianapolis, Ind., 400-h. p. heater; Live Oak (Fla.) Manufacturing Company, 100-h. p. purifier; Argentine (Kan.) Water & Light Company, 150-h.p. heater; Ames Estate Building, St. Louis, Mo., 150-h. p. heater; Miami Valley Railway, Piqua, O., 200-h. p. heater; Bettendorf Metal Wheel Company, Springfield, O., 100-h.p. heater; Excelsior Milling Company, Yankton, S. D., 100-h. p. heater; Taggart & Son, Knoxville, Iowa, 75-h. p. heater.

Recent tests of the plastic bonds that have been in service two or three years at Denver, Col., Newark, N. J., and Richmond, Va., have resulted in several large orders for new work in these cities. The superiority of this bond is further attested by the fact that after long service abroad the bond is specified for the important new lines of the Central London Underground Railway and the Manchester, England, and Sydney, Australia, tramways. Many of the leading American engineers are beginning to realize that an ordinary copper bond fastened mechanically to a steel rail, is more wasteful and unscientific than an overhead line of wire with unsoldered joints. Harold P. Brown of New York who put the plastic rail bond on the market some years ago, reports also a good demand for the E.C.A. bond used to rebond old roads without disturbing the pavement. For roads that wish a reliable copper bond at a low price, he has introduced the Welded Flexible Bond, whose peculiar method of manufacture permits him to sell at more favorable prices than any other type of copper bond with equal conductivity. This bond is quite a novelty in copper work; samples will be sent on application.

C. K. King, secretary of the Ohio Brass Company, Mansfield, O., has just received official notice from the Patent Office, that a patent has been allowed him on a new and improved method of attaching hangers and ears to the trolley wire by the use of rivets or similar means; also on a specific form of a trolley wire splicer. This patent relates particularly to the devices which are adapted for use with figure 8 and similar design of conductors. The Ohio Brass Company has manufactured and sold, under this patent, to electric railways in the United States only, since the first of the year a sufficient quantity of overhead construction devices for figure 8 trolley wire to build 300 miles of single track line. These are giving such universal satisfaction that they are being recognized as a standard by the leading engineers of this country, and are being called for by them in their specifications. This company recently secured through its new Canadian agent, the Northern Electric & Manufacturing Company, Limited, of Montreal, an order for the entire lot of track bonding and overhead construction material, which will be used in the electrification of the Sherbrooke Street Railway Company, Sherbrooke, Que. The other foreign agents of the company are: Edge & Edge, Sydney, N.S.W., Australia; Norsk Elextrisk Aktiebolag, Kristiana, Norway; Scandanavia; E. H. Cadot & Co., Paris, France, France; Naglo Brothers, Berlin, Germany, Germany; Vereingte, Electricitats Actien Gessellschaft, Vienna, Austria, Austria, Roumania & Italy; Sheriff, Swingley & Co., Johannesburg, South Africa, South Africa.

## THE COLUMBIA MACHINE WORKS.

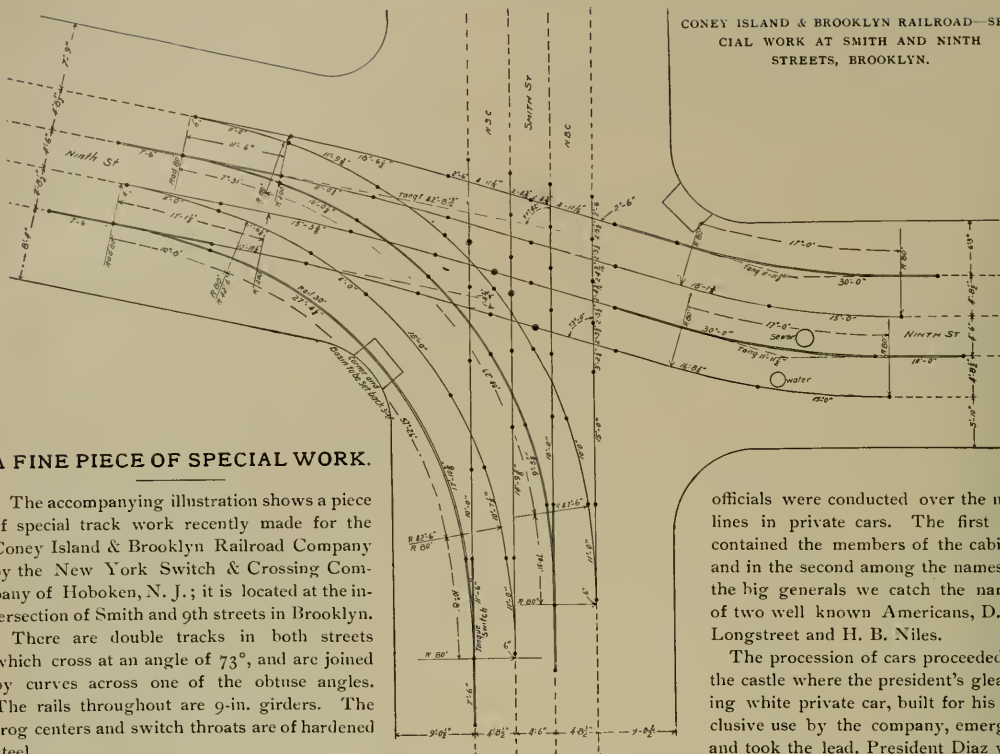

The Columbia Machine Works, Buehler & Platt, of Brooklyn, have taken a new four story building on the corner of Fulton street and Columbia Heights. The machinery formerly belonging to the Scott Electric Lamp Company now out of the business, has been installed here and further additions of new and improved machinery also made. The Columbia Machine Works have thereby removed a com-

COLUMBIA MACHINE WORKS SAND BOX.

petitor and at the same time increased the capacity of their factories. The factory covers an entire block on Doughty street, from Columbia Heights to Furman, and also embraces the numbers 2 to 18 Columbia Heights. The firm manufactures electric railway supplies, which if separated would constitute 12 different lines, all necessary. Among the specialties are commutators, drop forged copper segments, armature windings, trolley wheels, bearings, sand boxes, fuse boxes, switches, brake and controller handles and car trimmings. The office has been removed from 18 Columbia Heights to 18 Fulton street.

CONEY ISLAND & BROOKLYN RAILROAD—SPECIAL WORK AT SMITH AND NINTH STREETS, BROOKLYN.

### A FINE PIECE OF SPECIAL WORK.

The accompanying illustration shows a piece of special track work recently made for the Coney Island & Brooklyn Railroad Company by the New York Switch & Crossing Company of Hoboken, N. J.; it is located at the intersection of Smith and 9th streets in Brooklyn.

There are double tracks in both streets which cross at an angle of  $73^\circ$ , and are joined by curves across one of the obtuse angles. The rails throughout are 9-in. girders. The frog centers and switch throats are of hardened steel.

The "chrome" steel used for this purpose is the best wearing steel known. The fished joints are indicated in the drawing by the solid circles. The four which are marked by double circles are 6-bolt joints 20 in. long.

The method of constructing the work with steel centers is to place the centers and the ends of the rails in sand and pour molten cast iron around them which forms the binder and enables the most complicated pieces of work to be made without bolts.

When the company first began to use chrome steel for centers considerable difficulty was experienced in getting it of the proper temper, so as to be neither too hard nor too soft, but this was soon overcome and the work so made is giving excellent satisfaction. The strong point of the hardened center construction is that the material of greatest resistance is placed where it is most needed.

### PRESIDENT DIAZ INAUGURATES A NEW LINE.

The inauguration of a new street railway line in the city of Mexico is made the occasion of an official and military display which may well fill with envy the heart of an American manager; and judging from the several column account of the event as related in the Mexican Herald, Thos. H. McLean next to the president himself, is about the biggest dignitary in the republic.

The event occurred on Sunday in accordance with the custom of the country, and a large party of military and state

officials were conducted over the new lines in private cars. The first car contained the members of the cabinet and in the second among the names of the big generals we catch the names of two well known Americans, D. F. Longstreet and H. B. Niles.

The procession of cars proceeded to the castle where the president's gleaming white private car, built for his exclusive use by the company, emerged and took the lead. President Diaz was escorted to his car by Mr. McLean,

who with several members of the cabinet entered the president's car. The new line extends several miles out to the suburb of Santa Fe, and during the passage of the excursion cars a good portion of the route was guarded by infantry and cavalry of the regular army. The Herald says:

"The road has very many picturesque features. Yesterday the country looked beautifully green and fresh after the long rains. The view from kilometer 5 is perhaps the most picturesque of any along the entire line. From the windows of the car the passenger commands an immense stretch of country dotted with haciendas, villages and churches and in the far distance, backed by the silver streak of Texcoco, the City of Mexico lifts her diadem of towers. An adventurous feature made this spot still more picturesque yesterday. A party of cavalymen were making a short cut on the hill side and their bright uniforms and gleaming sabres seemed to give just the finishing touch that the eye demanded to the foreground of the picture.

"Each kilometer too has its history for those engaged in the construction of the road. At kilometer 2 Paymaster Smart was bound and robbed in his tent one night by daring miscreants. At kilometer 6 two of the peons fought one morning on coming to work, a step-father and a step-son. The latter hurled a rock at his step-father striking him on the head. The father thereupon ran his step-son through with a maguey leaf, showing the immense strength and penetrating force of that leaf. And so on, Contractor McGavock perhaps and those who worked under him could tell a story about every inch of the road.

"Work was begun on the Santa Fe extension on the 19th of January of this year and was completed on the 20th of July. From Tacubaya to Santa Fe there is a rise of 170 meters. This necessitated in construction a large number of curves or development, as the company was restricted to a  $2\frac{1}{2}$  per cent grade. There are only two level pieces on the entire extension, one of 400 meters and another of 250 meters. The maximum grade as above stated is  $2\frac{1}{2}$  per cent, and the average grade is about 2 per cent. The length of

the line is  $8\frac{1}{2}$  kilometers. The longest cut is 1,260 meters, averaging about 4 meters in depth. The deepest cutting is 6 meters. The longest filling is 600 meters, averaging about 3 meters in depth. The deepest filling is 4 meters. The contractor was W. J. McGavock; Juan Mendoza y Roca, chief engineer; D. A. Fletcher resident engineer; J. W. Rogers, superintendent of construction, and Engineer Mariano Tellez Pizarro government inspector. The rock to be handled was tetepate the whole distance, with the exception of about  $1\frac{1}{2}$  kilometers of hard conglomerate in the neighborhood of kilometer 7, which made the work there very hard.

"The president dismounted at the entrance to the village of Santa Fe, where the houses were all gayly decked and their inhabitants showed their enthusiasm by gathering en masse to catch a glimpse of the president, ringing their church bells and letting off sky-rockets and fire-crackers without a moment's cessation from the time that the president set foot in their town to the moment when he reached the grove where the dinner was to be served. The president was received at Santa Fe by the prefect of Tacubaya, Francisco Martinez, by the mayor of that town, Manuel Palafox, by Major Enrique Mondragon, principal of the powder factory, by Colonel Juan Quintas Arroyo, inspector of the powder factory, by engineer Jose Mondragon, by engineer Toribio Liebana and by others of the local authorities.

"The president walked in the direction of the old church, on one side of which is a steep path leading down to the grove where the banquet was to be served. At one point of the route the artillery band was stationed and as the president approached it struck up the national anthem, which was also sung by the young children of the public schools of Santa Fe, who were drawn up in line. The entrance to the grove was guarded by soldiers of the Battalion de Tiradores. Ahead of the president, secretary Felix Reyes of the Santa Fe town council carried a tricolor banner with two hanging ribbons held by little girls, Anita Cutierrez and Sara Castallo.

"The beautiful grove had been tastefully adorned with bunting and flowers and the table was laid alongside the limpid stream which flows through it. The spot is a delightful one, cool and sequestered,

while the imposing old ruins of the hermitage on the hill-side above, with their legends and associations, give a historical interest to the spot."

A magnificent banquet was served at the destination, during which the artillery band discoursed the choicest Mexican selections, and then followed the speeches. Mr. McLean occupied the head of the table with President Diaz. To his many friends by no means the least interesting feature of the banquet was the toast given by Mr. McLean, in Spanish, which greatly pleased the banqueters and caused President Diaz to shake his hand and congratulate him on his good Spanish. Diaz also spoke at considerable length congratulating the citizens on the enterprise of the company and wishing the latter large returns on its investment.

The town of Santa Fe, now numbering some 30,000 residents was founded in 1531, some of the original buildings still remaining in good repair and use.

#### A RUNAWAY CAR IN SAN FRANCISCO.

The brakes of one of the Mission street cars refused to act when the car was coming down College Hill. The trolley wheel soon left the wire and the motorman had no possible means of controlling the car, which ran with increased velocity at every turn of the wheels. The motorman remained at his post ringing the gong. The car barely missed a freight train on the San Jose railroad tracks and crashed into the rear of a car at the corner of Mission and 17th streets. Of the 12 passengers aboard seven were more or less seriously bruised or cut.

## REMOVING ICE FROM THE THIRD RAIL.

During the severe storms of last winter the elevated railroads operating by electricity experienced difficulty in making schedule time by reason of the third rails becoming coated with ice, and are now making preparations for effectually eliminating delays from this cause.

The illustration shows a track cleaner patented by Millard J. Scott, a railroad man of extensive experience, which is now being given a trial on the Metropolitan Elevated of Chicago. It consists of an arm bolted to the truck side and

SCOTT THIRD RAIL CLEANER.

projecting over the rail. At the end it carries a cutter, consisting of seven steel disks placed quite close together, to break the ice, and just behind this a wire brush to remove particles thus broken. The tension placed upon the cutting disks is regulated by the hand wheel. When it is desired to throw the cleaner out of action the handle, shown dotted in the illustration, is inserted at the rear end of the beam and by moving a cam the tension is removed from the spring, thus lifting the cutters and brush from the track. When out of action it is locked by a wooden plug. The great advantage of this method of handling the cleaner is that the men are protected against all danger of being burned.

## A GOOD PUNCH.

The illustration shows a punch, known as the '98, manufactured by Warren Hill & Co., Hartford, Conn., which is designed for special orders where a long reach is desired; it is made with any reach from 1 in. to 2½ in. and will punch any form of duplex, commutation or transfer ticket. The object which the firm had in view was to produce a punch of an entirely new design and mechanism, and at the same time one adapted to any and all tickets in use, without imitating other makes, and it makes the claims of originality, simplicity, durability and the best workmanship for its goods. The dies are protected by a steel stripper which covers the male die and is arranged so as never to get out of order. The screw at the joint is large and carefully fitted, making a strong fulcrum subject to little wear. Several types of these punches are fitted with magazines for collecting the pieces punched out, thus preventing the by now means uncommon fraud, worked by plugging punched commutation tickets. Any die will be made to order and over 300 designs are carried in stock. John B. Holaday, 174 Pearl street, Hartford, Conn., is the manager to whom inquiries should be addressed.

## EXTENSION OF MADISON, WIS., LINE.

The Madison City Railway of Madison, Wisconsin, has added to its lines an extension of about two miles from the original terminus on University avenue to the cemeteries. The first car was run on the afternoon of August 9, with Superintendent George H. Shaw, acting motorman. Major F. W. Oakley, receiver, and a party of prominent citizens occupied the car, and the round trip was made as smoothly as if a regular run. The line after leaving University avenue, runs across Breeze Terrace and Monroe road to the pretty little suburb of Wingra Park, located on Lake Wingra. Turning here to the north it passes through private right of way to Mineral Point road, crossing the Illinois Central Railroad on a viaduct and thence to the Protestant and Catholic cemeteries, which are located opposite each other on the Mineral Point road. The route is beautiful, present-

VIADUCT, MADISON CITY RAILWAY.

ing as it does at several points charming vistas of Lakes Monona and Mendota, bordered with fine trees, and dotted with sailing yachts and other pleasure craft. The view from the viaduct is especially interesting, showing the city lying between the two lakes, with the white domed state capitol rising grandly in its midst.

The track is laid with 50-lb. T-rail on 6 x 8 in. x 7-ft. cedar ties, with oak ties of the same size under special work and curves. The curves are all long radius transition, and there are five long radius diamond switches. The overhead line is built of No. 0 copper trolley wire with soldered ears.

The entire work, both track and overhead, was built by the Falk Manufacturing Company of Milwaukee, which also built all of the special work, and furnished all materials. The fine construction of this line is in harmony with the excellent equipment of the Madison City Railway, which under the management of Receiver Oakley, and Superintendent Shaw, maintains its plant in unexcelled condition.

## A FISHING TRIP.

"Along the lines of the Chicago, Milwaukee & St. Paul Railway" is the title of a beautifully illustrated pamphlet of 32 pages, the contents of which are devoted to practical methods of fish-catching in nearby lakes and streams.

One copy will be sent to any address on receipt of 2-cent postage stamp. Geo. H. Heafford, General Passenger Agent, 110 Old Colony Building, Chicago, Ill.

## NIAGARA FALLS CONVENTION.

The Cataract and City of its Name—Their Early History and World-Wide Fame—Romantic Legend, All Surpassed Now Quite, By Recent Miracles in Dazzling Light—How the Resistless Current of the Rushing Stream at Last is Harnessed, Takes the Place of Steam: What the Convention People Hope to Do—What They Will See, Where They Will Go—All This and Many Pages More, Our Readers Here Will Find in Store.

October 19th is the day; Niagara Falls is the place; and the 16th annual convention of the American Street Railway Association is the event, which will call in council the street railway managers of the land.

An ever increasing army these, with wives, and daughters, and supply men, all of whom no sooner depart from one convention than they turn their eyes in pleasant anticipation of the next. The constantly increasing attendance; the new ideas gained, and old ones exploded; the social features; the magnificent exposition of street railway appliances; and the meeting of old friends and the making of new acquaintances, all combine to augment the value and importance of each succeeding gathering.

All the world has traveled to worship at the shrine of Niagara Falls, that magnificent cataract whose glories ever grow upon the visitor; and it is particularly fitting that in its journeyings about the land the American Association should one year pitch its tents upon the banks of the mighty torrent. Especially so at this time when that torrent has been fairly harnessed, and a little of its power turned into those channels which most interest us. The electric power and railway features of the outside work of the convention, combined with the excellent program prepared, offer unusual attractions to the delegate; and we anticipate a large attendance and a profitable meeting.

In the following pages our readers will find a complete and concise account of what will be done and what will be seen, thus preparing in advance, each delegate for an intelligent and profitable visit to the various points of interest.

### Headquarters.

While there are several other hotels at the Falls, the executive committee has selected the International Hotel as headquarters, and it will be at that house that the majority will be found. The hotel is large, and special arrangements will be made to care for the comfort of guests. A description of the house will be found elsewhere in this issue.

\* \* \*

### Meetings and Exhibits.

The sessions of the convention will be held in Convention Building, now used specially for that purpose, and belonging to the local board of trade. The meeting room is on the second floor, while the entire lower floor will be occupied by exhibits, thus placing everything under one roof. The building is steam heated and well lighted. Wires for power are run into the building from the circuit of the local company. A detailed plan and description of the convention building appears on another page.

\* \* \*

### Accountants' Association.

The first regular meeting of the Street Railway Accountants' Association convenes in Convention Building on the same dates as the American Association. Program and full particulars on another page.

\* \* \*

### Railroads.

The usual special rate has been made by the railroads. Pay full fare going, taking a certificate receipt, presentation of which to the secretary in Niagara will secure return home at one-third fare.

### Excursions.

The natural attractions and the remarkable electrical plants at Niagara present unusual opportunities for pleasure and inspection trips, and the local committee has arranged a series of excursions in special cars which will take the visitors to all the points of interest on both sides of the river, and an opportunity afforded to study both water power stations under the most favorable conditions.

\* \* \*

### Banquet.

The annual banquet will occur at the International Hotel at 7 p. m. Thursday, October 21. Speaking and music will be a feature of the dinner. Tickets, \$7; to be had from Secretary Pennington.

\* \* \*

### The Ladies.

A large number of ladies will accompany delegates this year, and special provision has been made for their entertainment by a local committee of 25 ladies of Niagara. While the gentlemen are in attendance upon the sessions the visiting ladies will be entertained.

\* \* \*

### Register.

As soon as possible after arrival go to the local secretary and register your name, your road and city, and hotel at which you are stopping. You will receive a button, which is the insignia of the Association, and which will be good for transportation on any street car you may wish to use. These buttons will be in four colors: one color for members, one for ladies, another for supplymen, and one for members of the Accountants' Association.

## EARLY HISTORY OF THE FALLS AND CITY.

As early as 1535 the French explorers learned of the existence of a great waterfall at the head of Lake St. Louis, as Ontario was called, and mention of it is made in nearly all the published accounts of voyages to New France; the early maps show a river with the Falls indicated, but its location is only approximate in all of them until Sanson in his map of Canada, published in 1657 correctly locates the great lakes and the Niagara river, which appears under the name of Ongiara. The first white man, however, who is known to have seen Niagara Falls is Father Hennepin, who was a member of La Salle's party in 1678. He describes them as a "vast and prodigious Cadence of Water, which falls down after a surprising and astonishing manner, insomuch that the Universe does not afford a Parallel \* \* The Waters which fall from this horrible Precipice do foam and boyl after the most hideous manner imaginable, making an outrageous Noise, more terrible than that of Thunder; for when the Wind blows out of the South, their dismal roaring may be heard more than 15 leagues off." The sketch which he made of the Falls, the first known picture of them, shows several points of difference from their present state. Father Hennepin was the first to adopt the modern spelling of Niagara, which is said to mean "thunderer of waters."

The territory about the Falls was occupied by the Neuter nation of Indians, so called because the warriors

of the two neighboring nations, the Hurons and the Iroquois, which were tribal enemies of each other, could meet in peace and safety when visiting the Neuter nation. Eventually the neutrality of the Neuters with the neighboring tribes disappeared, and after almost complete annihilation at the hands of the Senecas, the tribe became merged into the Iroquois. The Neuters saw in the Falls their tribal divinity to which they made sacrifices; individuals also made offerings, as they had pressing need of divine assistance.

La Salle saw the military advantages which a command of the territory contiguous to this connection between the great lakes would give and established a trading post on the point of land at the mouth of the river, and at the head of navigation, the site of Lewiston, built a fort or stockade. Carrying cordage, anchors and tools with him up the mountain and through the forest to a point five miles above the Falls, where the town of La Salle now is, he built the Griffon in 1679, which was the first vessel to navigate the upper lakes. The trading post at the mouth of the river was fortified in 1687, and abandoned the following year, but rebuilt in stone by the consent of the Indians in 1725 and afterward maintained, the post being known as Fort Niagara.

The portage around the Falls began at the present site of Lewiston, and had its upper terminus at about one and one-half miles above them. The upper terminus of the road was fortified in 1750, and called Fort de Portage or Fort Little Niagara; this fort was destroyed in 1759 to prevent its falling into the hands of the English, who had already captured Fort Niagara. After the defeat of the French in the short and decisive campaign of 1759, they practically surrendered all their territory to the English, and the latter in 1761 built Fort Schlosser to replace Fort Little Niagara. At the Devil's Hole about three miles below the Falls on the American side, the Seneca Indians in 1773 ambushed a supply train and also the relief party sent to its rescue, only 11 out of the two parties escaping.

The Niagara region was not the scene of any more hostilities until the war of 1812.

The Americans were defeated on Queenston Heights, the battle in which General Brock lost his life. Early in 1813 Fort George, built by the British at the mouth of the river on the Canadian side, was captured by the Americans, and the English abandoned their other posts, Fort Erie at the source of the river and Chippawa just above the Falls. In December, 1813, the British took the offensive, recaptured all the posts taken from them, captured the forts on the American side of the river, and sacked and burned Youngstown, Buffalo and the smaller

Fac-simile of first engraving of Niagara Falls. From Hennepin's "New Discovery," published in 1697.

towns in the vicinity. The turn of the Americans again came in 1814; Fort Erie was recaptured on July 3 and the British defeated in the battle of Chippawa July 5. On July 25, General Scott met the enemy at Lundy's Lane and the fighting was continued until late in the night, by the light of the harvest moon; this was regarded as a substantial victory by the Americans though still annually celebrated as such by the Canadians. Fort Erie was occupied until November, 1814, and blown up by the Americans when they withdrew; it is still in ruins.

Navy Island was at one time the principal rendezvous of the insurgents in the Canadian rebellion of 1837. On the night of December 29 of that year a British force crossed to Schlosser in boats and captured the steamer Caroline, which had been chartered by Buffalo parties for the purpose of carrying excursion parties to visit the camp on Navy Island; the boat was set on fire and forced over the Falls. This was regarded as a breach of international law and was the subject of much correspondence between the two governments.

In 1866 the Fenian invasion of Canada was made at this point and the battle of Ridgeway fought. With these exceptions peace has reigned at Niagara since 1815.

AMERICAN FALLS FROM GOAT ISLAND.

The township of Niagara dates back to 1800. The original village was known as Manchester and was incorporated as the village of Niagara Falls in the early 30's. In 1892 the two villages of Niagara Falls and Suspension Bridge were consolidated and made a city, which then had a population of about 12,000. Because of the power development and the rapid growth of manufacturing enterprises the population of the city has increased to 23,000 as given by the directory census.

☐ One of the prettiest and sweetest legends connected with

the fall, the Indians of the tribe watched its course with eager gaze. Suddenly they were startled by seeing another canoe, propelled by a powerful hand, leap out from the bushes and speed toward the maiden. Onward it darted, and just before her canoe passed over the brink of the precipice the Indian maiden recognized her father. His glance told her that his love for her was uppermost, while those on shore realized that their chief and his daughter would not be separated even in death. He met death by passing over the Falls a few moments after her. This reci-

the Falls of Niagara is that which has to do with the old Indian tradition that it was the custom of the red men of the forest each year to sacrifice the fairest maiden of their tribe to the Great Spirit of the Falls by sending her over the cataract in a white canoe laden with fruits and flowers. The Spirit of the Falls called for unbounded homage, and on one occasion the daughter of the chief of the tribe was selected for the annual sacrifice. To the maiden thus selected it was deemed an honor to be chosen. The old chief loved his daughter, the fairest in the tribe, but he betrayed no feelings of sorrow that his daughter was to be given up to the Great Spirit. As the white canoe, guided by the fair maiden's hand, swept down the rapids toward the brink of

tal is the red man's fact, of the maiden's sacrifice, but the white man has a fancy of the Maiden of the Mist. This fancy portrays the real spirits of the Indian maidens sacrificed to the spirit of Niagara, in days gone by, as idealized into the Maiden of the Mist—a mythical and typical maiden dwelling at the base of the falls, and continually, by day and by night, disporting herself in the ever-rising and never-falling clouds of mist or spray, awaiting and greeting the spirits of those victims who yearly yield up their lives to the "Thunderer of Waters." At the Cataract House are to be seen two large oil paintings by James Francis Brown, of which the cuts used herewith are reproductions.

THE FALLS.

In no place does nature reveal herself in greater majesty than at the Falls of Niagara. The usual observer is spell-bound with awe and wonder at the impressive sight. The effect upon the engineer is the same for a time but he soon begins to marvel at the energy here dissipated. The volume of water passing over the falls is estimated at 275,000 cu. ft. per second and were it utilized would generate 5,800,000 horse-power. These figures in themselves mean little because the mind does not grasp them; to put it in another way, if the potential energy of the waters of Niagara were converted into work, it would probably exceed the sum of the efforts of all mankind, for to replace the water above the falls each man, woman and child would have to carry 1,100 lbs. of water up 165 ft. every 24 hours.

The Niagara river is the outlet for the waters of four of the five Great Lakes, the largest bodies of fresh water on the globe; the total area of these four lakes is about 85,000 square miles and all the overflow finds its way over the Falls where the channel is but about 3,550 ft. in width. The total fall between Erie and Ontario is 333 ft., 55 ft. of this is in the half mile of rapids above the Falls, the Falls themselves are some 165 ft. high, and in seven miles below there is a further fall of 100 ft.

In the early sketches of the Falls a third fall is shown on the Canadian side. This was called the Lateral Fall; it has long since disappeared. Table Rock probably formed the bed of this fall. Large portions of this rock fell in 1818, 1828, 1850 and 1886, and the fragments are still visible scattered on the slope on the Canadian side.

Geologists and other scientists find in the Falls a favorite theme for theorizing. One of the interesting opinions advanced a few weeks ago was by Prof. John Level, of Niagara, who holds that the recession of the Falls is chiefly caused by the breaking of the rock from explosions of air which becomes compressed beneath the falls until it explodes, tearing off fragments of rock.

One or two writers hold that the gorge was originally a crack in the earth violently wrenched apart, and others that it was washed out by ocean tides; but the prevailing opinion is that the gorge was cut out by the river itself and this view is substantiated by so much evidence that Professor C. K. Gilbert of the United States Geological Survey does not deem the others worthy of serious consideration.

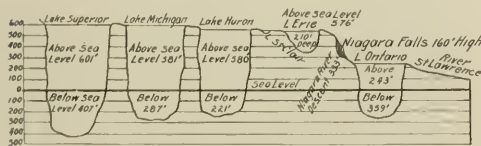

WINTER SCENE FROM GOAT ISLAND.

Niagara Falls. He has determined that there is a change of level taking place in the great lakes, involving an elevating in the northeast and a depressing in the southwest, the eventual result of which will be the lakes emptying into the Mississippi instead of the St. Lawrence. Incidentally Chicago is to be inundated and become a new-world Venice. Our readers need not be alarmed, however, for the REVIEW will have reached its 500th volume before the dire catastrophe takes place.

There has been complaint that the diversion of water for power purposes has already detracted from the beauty of the Falls but as the amount so taken is less than 1 per cent of the total it does not appear that the injury can be serious. When the plan of Government Reservations was first broached it was with the idea that the Falls should be preserved in all their grandeur and free from the spoiling hand of the engineer (another name for vaudin) as a heritage for future generations. In contrast to this view as to what should be the future of Niagara Falls the following remark of Lord Kelvin may be quoted:

"The originators of the work so far carried out and now in progress hold concessions for the development of 450,000 h. p. from the Niagara river. I do not myself believe any such limit will bind the use of this great natural gift and I look forward to the time when the whole water from Lake Erie will find its way to the lower level of Lake Ontario through machinery doing more good for the world than that great benefit which we now possess in the contemplation of the splendid scene which we have presented before us at the present time by the waterfall of Niagara. I wish I could think it possible that I could live to see this grand development."

In answer to a question he added: "No, I do not hope that our children's children will ever see the Niagara Cataract."

CROSS-SECTION OF GREAT LAKES.

The method by which the gorge has been cut away differs from the normal process of erosion, by the rubbing and pounding of rock fragments carried along by the stream; Niagara carries no such rock fragments. Here the lower strata of shale are cut out by the rolling about of large masses of limestone at the base of the precipice allowing the limestone at the crest to break off.

Professor Gilbert predicts the time when there will be no

## INCIDENTS OF INTEREST.

From 1833 to 1873 a tower 45 ft. high, 12 ft. in diameter at the base and 8 ft. in diameter at the top, stood on the rocks at Terrapin Point. It was round in shape, and was built of stone gathered in the vicinity. It was a rough

TERRAPIN TOWER (DESTROYED).

structure quite in harmony with the wildness of its surroundings, and had a lookout gallery at the top. Some of the then owners of Goat Island pretended to feel that it was unsafe, and in respect to the wishes of a majority of them it was blown up in 1873. This work was done by Thomas Conroy, one of the famous Niagara guides, who now has a place in the paid fire department of the city of Niagara Falls. To destroy it he used 75 lbs. of gunpowder. About 6 ft. of the spiral stairway was cut out from the bottom of the tower, and in this space the powder was buried, the place being tightly boxed with 2-in. oak planks. When the powder was exploded the spiral stairway was sent through the top of the tower to a height of about 50 ft., and a good portion of the tower was blown over the precipice, while the

MAID OF THE MIST LANDING.

remaining portions were torn down, thus removing a charming feature of Niagara.

It is related as a matter of history at the Falls that in 1852 a gentleman from West Troy, N. Y., while crossing to the tower fell into the current and was carried to the edge of the fall, from which point of danger he was rescued from apparently inevitable destruction, by life lines passed to him by a party of rescuers. The effect of the shock on his nervous system was so great that he remained speechless for several hours after being taken to his hotel.

The famous Blondin was the first man to cross the Niagara gorge on a tight rope. Blondin was a Frenchman, and made the claim of being the originator of the horizontal tight rope. Blondin's acts at Niagara undoubtedly made him the wonder of the world, but it is a fact that since his

BLONDIN CROSSING NIAGARA.

time others have repeatedly crossed the gorge on wire cables of much smaller dimensions than Blondin's rope cable. It was in the spring of 1859 that Blondin first took steps to erect a cable on which to cross the mighty chasm. This cable was located very close to the spot on which the gorge road car barns now stand in what is known as the old Pleasure Ground. His first trip was made June 30, 1859, and, being a success, won for him much fame. In 1860 Blondin erected his cable farther down stream over the Whirlpool Rapids, just north of where the new steel arch now spans the gorge. He walked this rope with stilts, with baskets on his feet, blindfolded, and also carried a man across on his back. This man was Harry Colcord. Blondin also took a small stove out on the cable and cooked there. His performances drew great crowds. His wheelbarrow act was especially commended. It was in 1860 that Blondin crossed the gorge before the Prince of Wales. The prince and party were located in a shelter at the Canadian end of the cable, and in order to heighten the effect, Blondin put in a few extra feats. When Blondin was presented to the prince his royal highness said, "Thank God it is all over." To this Blondin replied by offering to carry the prince

GRAHAM AND HIS BARREL.

across the rope blindfolded, but the prince declined the invitation. On November 29, 1895, Blondin married Catherine James in the Brantford, Eng., registry office. He has since died, but the story of his wonderful performance at Niagara still lasts. Collections and an entrance fee to an enclosure at either end of his rope is what paid Blondin for his performance.

The first man to attempt to win fame by a trip through the Whirlpool Rapids was when Joel K. Robinson and his two associates, McIntyre and Jones, voluntarily made the trip on the steamer "Maid of the Mist," June 6, 1861. Next came Capt. Matthew Webb, the famous English swimmer, who lost his life in an attempt made July 24, 1883. Webb's only protection was a bathing suit. Three years later Carlisle D. Graham, a cooper, made the trip successfully in a barrel of his own make on July 11, 1886. Graham's feat made him a hero, and he is justly entitled to credit for his act. Undaunted by the perils of the fierce waters he made a second trip on August 19, 1886, this time with his head protruding from the top of the barrel. His third trip was made June 15, 1887, and his fourth on August 25, 1889. On the second trip he stopped at the Whirlpool, and on the fourth trip his barrel was much smaller than the one he first used. Several other people have since made the voyage, but Sadie Allen is the only woman who ever made the trip and lives to tell the tale. She made the journey on November 28, 1886, in company with George Hazlett, who had made the trip in the same barrel in company with William Potts on August 8, 1886. Charles A. Percy has twice

defied the rapids in a boat, but Robert William Flack lost his life while endeavoring to make the passage in a boat of his own construction on July 4, 1888.

Measurements taken by the United States government show that the water under the upper suspension bridge is about 194 ft. deep. The American Fall has a height of 165 ft., and the Horseshoe Fall a height of 158 ft., it will thus be seen that the water in the river before them is deeper than their height.

Despite all stories to the contrary, it may be stated as fact that no human being has ever, so far as recorded, passed over either of the falls of the great cataract and lived to tell the tale. The Falls of Niagara thus remain unconquered.

The danger line above the falls is a little below Port Day. Men have come down the river and made the landing on the head of Goat Island, but this is a dangerous feat. When a boat gets much below Port Day, its occupants realize that the danger of being swept down stream on the current is very great, and when once in the grasp of the current below this point it is almost resistless, and the chances of life are the chances of landing on one of the islands or rocks above the falls and being rescued.

One of the grand sights of Niagara is the wreck of the old Lewiston suspension bridge. This structure was destroyed by a high wind on April 16, 1864. Some days previous to the disaster a big run of ice down the river made it necessary to loosen some of the guys from their fastenings. During the quiet weather which followed, the bridge attendants were unmindful of the danger to which the structure was subjected by the loose guys, and a big wind storm came up and swept the suspended structure away. It was never rebuilt, and all these years the cables have been suspended over the water unused.

Report has it that a few years ago, a desperate criminal having escaped from prison, made his way to the boundary with the intention of getting into Canada. He did not dare to venture on the bridges, and in the darkness of a terrific storm crept across one of the cables and reached the other

OLD BRIDGE AT LEWISTON.

RAPIDS ABOVE FALLS.

side in safety. When our readers come to visit the wrecked bridge they will appreciate the courage of the act, although it is a fact that in daylight men have crossed on the cables from bank to bank. This wreck is soon to be replaced by a new bridge, or rather by the removal of the upper suspension bridge to this site.

One of the very interesting incidents about the Falls of Niagara which has been almost forgotten, was the sending of a vessel loaded with wild animals down the upper rapids and over the great precipice. The vessel did not, as many now suppose belong to the government, but it was a merchant vessel condemned as unfit for service on the upper lakes. She was named the "Michigan," and the trip is evidence of the early day enterprise of the hotel keepers of the Falls to draw a crowd to that resort. One of the most interesting souvenirs of this memorable trip is one of the small handbills, which at the time was sent in all directions from Niagara Falls to draw a crowd by stage. The REVIEW has discovered what is supposed to be the only existing copy of one of these bills, and now presents its text for the perusal of its readers, as follows :

THE PIRATE MICHIGAN,  
with a cargo of ferocious animals, will pass the  
Great Rapids and Falls of  
NIAGARA,

8th of September, 1827, at 3 o'clock.

The first passage of a vessel of the largest class which sails on Erie and the upper lakes, through the great rapids, and over the stu-

pendous precipice at Niagara Falls, it is proposed to effect on the 8th of September next.

The Michigan has long braved the billows of Erie with success as a merchant vessel; but having been condemned by her owners as unfit to sail longer proudly "above," her present proprietors, together with several public spirited friends, have appointed her to convey a cargo of living Animals of the Forests, which surround the upper lakes, through the white tossing and the deep rolling rapids of the Niagara, and down its grand precipice into the basin "below."

The greatest exertions are being made to procure animals of the most ferocious kind, such as panthers, wild cats, bears and wolves; but in lieu of some of these, which it may be impossible to obtain, a few vicious or worthless dogs, such as may possess considerable strength and activity, and perhaps a few of the lesser animals will be added to and compose the cargo.

Capt. James Rough, of Black Rock, the oldest navigator of the upper lakes, has generously volunteered his services to manage this enterprise, in which he will be seconded by Mr. Levi Allen, mate of the steamboat Niagara. The public may rest assured that they will select none but capable assistants. The manager will proceed seasonably with experiments to ascertain the most practicable and eligible point from which to detach the Michigan for the rapids.

It is intended to have the Michigan fitted up in the style in which she is to make her splendid but perilous descent at Black Rock, where she now lies. She will be dressed as a pirate; besides her menagerie of wild animals, and probably some tame ones, it is proposed to place a crew (in effigy) at proper stations on board. The animals will be caged or otherwise secured and placed on board the "condemned vessel" on the morning of the 7th, at the ferry, where the curious can examine her "cargo" during the day at a trifling expense. On the morning of the 8th the Michigan will be towed from her position at Black Rock to the foot of Navy Island by the steamboat Chippewa, from whence she will be conducted by the manager

to her last moorings. Passage can be obtained in the Michigan from Black Rock to Navy Island at half a dollar each.

Should the vessel take her course through the deepest of the rapids it is confidently believed that she will reach the Horse Shoe unbroken; if so she will perform her voyage to the water of the Gulf Basin beneath, which is of great depth and buoyancy entire, but what her fate may be the trial will decide. Should the animals be young and hardy and possessed of great muscular powers, and, joining their fate with that of the vessel, remain on board until she reaches the waters below, there is great probability that many of them will have performed the terrible jaunt unhurt.

Such as may survive and be retaken will be sent to the museums in New York and Montreal, and some perhaps to London.

It may be proper to observe that several steamboats are expected to be in readiness at Buffalo, together with numerous coaches, for the conveyance of passengers down on the morning of the 8th. Coaches will leave Buffalo at 3 o'clock on the afternoon of the 7th for the Falls on both sides of the river, for the convenience of those who may be desirous of securing accommodations at the Falls on the 8th. Ample means for the conveyance of visitors will be provided at Tonawanda, at Lockport, at Lewistown, at Queenston and at Fort George to either side.

As no probable estimate can now be made of the numbers which the proposed exhibition may bring together, great disappointments regarding the extent of our accommodations, may possibly be anticipated by some; in respect to which, we beg leave to assure our respective friends and the publick in general, that in addition to our own, which are large (and will on the occasion be furnished to the utmost limits), there are other publick houses, besides many private ones, at which comfortable entertainment may be had for all who may visit the Falls on the present occasion, an occasion which will for its novelty and the remarkable spectacle it will present be unequalled in the annals of internal navigation.

This bill is signed by P. Whitney, keeper of Eagle Hotel United States Falls, August 2, 1827, and by Wm. Forsyth and John Brown, keepers of the Ontario House and Pavilion, Canada Falls.

One of the most interesting incidents of the Falls is the construction of the basket cable railway. A company to build a bridge for the accommodation of the Great Western Railroad was chartered by New York in April 23, 1846, and in Canada, June, 9, 1846. Charles Ellet, Jr., (afterward General Ellet) of Philadelphia, was the engineer who had the contract for building the bridge and desired first to provide a cable suspended from towers erected on either side of the river and a basket in which men and tools might be

operation of the cage and cable are thus described by Mr. Hulett:

“The first thing to be settled was the size, form and the material of which this cage should be constructed. The engineer proposed that the cage be made of wood, and instead, I suggested iron. The engineer’s objection to iron was its weight. In answer, I suggested that I thought one of iron could be made of less weight and more secure than one of wood. To test this proposition, the engineer made a plan of his wooden cage, and carefully estimated its weight. I then made a plan of a basket made of iron, which was also weighed and found to be 10 pounds lighter than that of wood. ‘We will have it iron’, exclaimed the engineer, provided we can get it made. I assured him that getting it made would present no difficulty, as I would make it with my own hands. The next interrogatory of the engineer was, ‘What shall be its form?’ We both at the time were sitting in rocking chairs of the same pattern. I requested the engineer to arise, and these two rockers were drawn close together, the

CROSSING IN BASKET IN 1848.

engineer exclaiming, ‘That is just what we want and will have.’ Next in order was the construction of the cable upon which the basket was to travel. This cable was to be constructed of 36 strands of No. 10 wire, each strand to be subjected to a uniform stress, and the 36 strands bound into a round form by being wrapped by a transverse wrapping of a small annealed wire at intervals of 8 in.; each wrapping being about 4 in. in length. This cable was formed around an iron yoke or clevis at either end as a means of fastening to the rock. After the detail of making the cable was disposed of, came the question of how to get it over. The engineer suggested offering a premium of \$10 to the first boy who should successfully fly over the Gorge his kite string and fasten its ends to a tree on either side. The premium brought a score of lads into the contest, and a boy by the name of Homan Walsh (who now resides in Lincoln, Neb.) was the successful winner of the prize, which was paid as soon as the kite string was secured on each bank of the stream. The following day a stronger line was drawn over by the kite string, and a rope of sufficient strength to haul over the iron cable was substituted. By means of this rope the iron cable was hauled across the river and its ends secured to the solid rock and placed upon the wooden towers, with a deflection of about

BASKET FOR CABLEWAY.

hauled across, thus saving a journey of 10 miles for each crossing that must be made, the ferry being five miles below the site of the bridge. Mr. Ellet finding it necessary to spend a portion of his time elsewhere, secured the services of Theodore G. Hulett (afterward Judge Hulett), who is still living in Niagara Falls, to superintend the construction and erection of the necessary ironwork. The design and

25 ft. between the towers. I made the iron basket and its attachments with my own hands, and it was placed upon the cable. A strong windlass was made of a wooden drum of about 4 ft. in diameter, and so geared that one man at the crank could haul over any required load. One of these

THEODORE G. HULETT.

windlasses was placed on each bank, the draft rope passing around these drums at one end, and the other attached to the yoke from which the basket was suspended. This yoke was made of iron, with a grooved roller at either end that it ran upon, the flanges astride the cable.

"The first passage of this basket was attempted (March 31, 1848) to be made empty, but when almost across it suddenly stopped and the windlass on the opposite side would not bring it ashore. It could be drawn back, but not forward, and the basket was drawn back to the American shore. Mr. Ellet mounted the car, which was let loose from the tower, and descended the down grade with great velocity until its momentum was arrested by the up grade on the opposite side, when the windlass on the opposite side was set in motion and hauled the basket with its passenger to the point of obstruction, which was found to be a spot in the cable that had been flattened when the cable was being hauled across, and to such extent that it exceeded the width of the groove in the roller, which caused the flange of the forward end of the roller to rise upon the cable and its edge to sink between the expanded strands of the cable. The engineer saw the difficulty at a glance, and he soon remedied it by contracting the width of the cable, and the rollers passed over, and the first passenger landed in safety across the Gorge in this fairy basket. It was found that the groove in the rollers was too shallow and the tread too narrow to prevent undue friction on the transverse wrapping of the cable and new and deeper-grooved rollers were substituted. This change made this mode of transportation complete, and

it was used for that purpose for more than a year, and carried across the Gorge more than 2,000 passengers, there having crossed in one day 125 persons, 90 of them ladies. The round trip fare was one dollar.

"This cable was used until the preliminary bridge structure was completed, and then removed."

Several persons each year lose their lives at the Falls, either through accident or with suicidal intent, the opportunities and certainty of the latter being unequalled. People have even traveled hundreds of miles for the express purpose of throwing themselves into the water at the crest of the falls. To the casual visitor the safeguards and protection provided, especially on the islands, would seem to be almost criminally deficient. While the bridge leading to the islands is always closed before dark, there are places where a horse taking sudden fright might easily precipitate a carriage into the rapids a few rods above the falls, and from which escape would be absolutely impossible. Visitors can not exercise too great care. A particularly sad case a few years ago was the death of a young bride, who stooped to fill a small pail with water and the force of the current was sufficient to overcome her balance and she was swept over the brink before her companions could comprehend what had happened.

As a rule bodies going over the Falls are held down by the pressure of the water, often for several days or weeks, before floating down the river. On a few rare occasions bodies have been recovered which did not show the slightest scratch, one such case having occurred in May of this year, but usually the body is terribly crushed and disfigured by being dashed against the rocks. In August of this year two men and a boy who were crossing the river in a small boat were drawn into the current and in spite of every effort to escape were swept over the brink before the eyes of spectators helpless to render any aid.

WHIRLPOOL RAPIDS FROM BRIDGE.

THE FALLS IN WINTER.

Niagara is ever changeful, and there are those who have lived beside its banks a score of years that insist it never twice presents the same appearance. But by far the most pronounced change is, when the Falls put on their winter garments, and are clad in a solid garb of purest ice and snow, in which the tints range from spotless white to deepest sky blue. The effect is one impossible to imagine in October by those who have never witnessed one of the famous ice bridges. The swift, turbulent current prevents the early formation of ice even in cold seasons, and not until midwinter, or later, with its most intense cold, does the Water King consent to the ice carnival.

The ice floes coming over the precipice are dashed to atoms, and gradually these fragments gather, and are frozen into a solid mass, extending out from either shore until a connection is made in midstream. With this foundation to build upon the snow and spray willingly form an alliance, and steadily night and day, build up fantastic shapes like miniature mountains, while from the rocks depend gigantic icicles, weighing hundreds of tons. The spray bedecks the trees, and shubbery, and bridges on the islands, which in the sunlight present a picture of rarest beauty.

Residents at the Falls hail the cold weather with joy, and the daily press heralds the announcement throughout the land. Excursionists flock from every direction to witness the most wonderful winter scene upon the globe.

### FEATURES OF THE FALLS.

The Falls are on the Niagara river 22 miles from the head in Lake Erie and 14 miles from the mouth in Lake Ontario. The total descent in the 36 miles is 333 ft. For two miles after leaving Lake Erie the current in the river is quite swift, then the channel broadens and is divided by Goat Island, below which it is two and one-half miles wide. Fifteen miles from Lake Erie the channel again narrows and the rapids begin. In the last three-quarters of a mile above the Falls the fall in the river bed is 55 ft. At the brink the channel is divided by Goat Island which occupies about one-fourth of the total width, 4,750 ft. At the Falls the river bends from west to north; on the right of Goat Island is the American Fall, 1,060 ft. wide and 167 ft. high, and on the left the Canadian or Horseshoe Fall, with a contour of 3,010 ft. and a fall of 158 ft. The water is much deeper over the crest of the Canadian Fall so that while only three times as wide as the American Fall, fully nine-tenths of the total water flows over it. One cubic mile per week for the volume flowing over the Falls is sufficiently accurate for general purposes; a more exact figure is 1.13 cubic miles per week. The international boundary line is in the middle of the so-called Canadian Fall. Below the Falls the river is from 1,000 to 1,200 ft. wide, but two miles below narrows to 800 ft. and farther down at the Whirlpool Rapids to 250 ft. Within seven miles below the Falls the

total fall is over 100 ft. The several strata which are exposed in the gorge are gray quartzose sandstone, red shaly sandstone, gray mottled sandstone, green shale, compact gray limestone, soft shale and limestone in the order named. Because of the dip in the land from north to south the water in cutting out the gorge has encountered in succession strata of varying degrees of hardness and the rate of recession of the Falls had varied in consequence. From 1842 to 1890 the average rate of recession was 2.2 ft. per year on the Canadian side and 2½ ft. per year on the American side. At present the rock at the crest is limestone with shale about 90 ft. below. Geologists state that a farther recession of two miles will cut away all the limestone and leave the Falls stationary on sand stone with the height reduced 50 per cent; the fall when the river first took its present route to Lake Ontario was about 300 ft. or twice as much as at the present time.

To properly "do" the Falls one should start from Prospect Park, a part of the New York Reservation. From the "point," which is protected by a stone wall, a fine view is obtained of the American Fall from the very brink; farther to the right is Hennepin view. Near here is the superintendent's office and the inclined railway and stair leading to the dock of the "Maid of the Mist." From the bridge leading to Goat Island there is a fine view of the upper rapids on the American side. Goat Island is about 80 acres in area; near this island is Luna Island, so-called from the lunar rainbows seen from that point of view, which separates the American from the Center Fall. On the American side there are several small islands which takes their names from some incidents or persons prominent in the history of the Falls.

At the lower end of Goat Island one may procure a guide and descend Biddle stairs (built in 1829 by Mr. Biddle, president of the Bank of the United States) to the Cave of the Winds. A path leads over gangways and bridges among the rocks at the foot of the Center Fall to the "Cave" behind it where the choking, blinding and deafening tumult of wind and water defies description. The "cave" is about

100 ft. long, 130 ft. high, and of varying width, there being in places but 3 ft. between the wall of rock on one hand and the water on the other. The trip to the Cave of the Winds cannot be undertaken without a guide and is sufficiently dangerous with one. All members of the party are clad with water proof suits which have only the face exposed and after being roped together, slide along a narrow ledge with the perpendicular wall of rock in front, and the mighty volume of water thundering in the rear. It is the most exciting and pleasurable experience of a visit to the falls.

To the left from the Biddle stairs is Porter's bluff from which one obtains the best view of the Horseshoe Fall from the American side; a tower formerly on Terrapin Rock, a small island at this point, was blown up because deemed unsafe. The path on Goat Island continues along the south side where there is a group of four islands known as the Three Sisters and Little Brother; from here is the best view of the Canadian Rapids.

About 250 yards below the Falls is the suspension bridge crossing to the Canadian Park. Here there are several points of interest, Ramblers Rest, Inspiration Point, Table Rock, Cedar Island and the Burning Spring. From Table Rock there is an indescribably grand view of the Horseshoe Fall. This rock which formerly overhung the cauldron close to the Horseshoe Fall has been greatly reduced in dimensions, by pieces falling and finally by blasting off a large portion because it was unsafe.

In addition to visiting the two parks one should see the Cave of the Winds, the Grand Rapids from the Canadian side, and take a trip on the Maid of the Mist. The first boat of this name was of 170 tons burden, driven by a 100-h. p. engine and followed the same route as her successors do today; she did not pay, however, in the early days and was sold on condition that she be delivered at Lewiston. She was taken through the rapids in 1861 by J. R. Robinson and two assistants and safely delivered at Lewiston thus proving what the courts have since held that Niagara is a navigable stream.

The present suspension bridge just below the Falls was built in 1889 to replace the one carried away by the storm January 10 of that year. The first bridge at this point was completed in November, 1868. The span of the new one is the same as that of the old, 1,268 ft.; the bridge is 190 ft. above the water.

Two miles below Suspension Bridge is Cantilever Bridge built in 1883, and one of the first of its kind. It is of steel, 900 ft. long; the two arms are 395 and 375 ft. long respectively, connected by a central span of 130 ft. This bridge is 245 ft. above the water. One hundred yards below this bridge is the new steel arch bridge built in 1897 to replace the one which was known as the Railway Suspension Bridge, and used by the Grand Trunk road. The suspension bridge at this point was of iron built by John A. Roebling of Trenton, N. J. Work was begun in 1852 and March 8, 1855, the first steam train crossed on it. A carriage way was provided 28 ft. below the railroad tracks. This bridge was rebuilt in steel in 1880 and in 1886 the stone towers were rebuilt in steel. The new bridge has two decks; on the upper are two railway tracks and on the lower a carriage way, two trolley tracks and foot ways.

A short distance below the new bridge, on the Canadian side, is the so-called Rapids Park, which afford the best view of the Whirlpool Rapids. It is reached by an inclined railway. At this point the river channel is less than 300 ft. wide; the surface of the water is from 20 to 30 ft. higher at the center than at the sides. Webb lost his life in an attempt to swim through these rapids in 1883; since then others have passed through safely in barrels. Blondin and others have frequently crossed the gorge on hemp ropes or wires.

LONGITUDINAL SECTION OF NIAGARA GORGE.

Base line is at sea level. It is divided into miles. Water, black; drift, dotted; Niagara line-tone, block pattern; shales, broken lines; F, falls; R, railway bridges; W, whirlpool; Foster, Foster Flats; E, escarpment.

On the American side there are three elevators running down to the water. One mile below the Rapids Park is the Whirlpool. At the Whirlpool the water describes a loop. In the diagram of the Whirlpool (which, together with the sections showing the Falls and river and the outlines of the crest of Horseshoe Fall, are reproduced from a geographic monograph by Prof. G. K. Gilbert, of the U. S. Geological Survey), the direction of the surface currents is shown by arrows. On the north side the Niagara limestone can be traced to A and the Clinton limestone to B. On the south side the Niagara limestone is visible as far as E, the Clinton bed and the quartzose sandstone disappearing under the drift at D and C, respectively. Because of the course of the river making the sharp bend, and because of the incoming current meeting drift instead of stone on the far side, the Whirlpool basin has been hollowed out. The drift contained many boulders, and these were sorted out and accumulated until they formed a sloping wall covering the sand and gravel below the water level, and preventing further encroachment.

At the bottom of the cliff are the double tracks of the "Gorge" electric road which is built on a shelf blasted out of the rock, and only a few feet from the water. The view here, especially when coming up stream, is superb, and affords a comprehension of the magnitude and power of the water not obtained in any other way.

PLAN OF WHIRLPOOL.

Access to points on the water's edge is given by numerous inclined railways and elevators. In the very early days a tramway was constructed at the head of navigation, for the purpose of hauling goods up onto the high bank for portage around the Falls. The cars were lifted by means of a windlass turned by Indian labor. The first mechanically operated inclined way was built just below the Falls in 1844, to connect with a ferry to Canada. The road was 330 ft. long, the inclination being  $31^{\circ}$ ; there were two tracks with a stairway between them. The power was furnished by a water wheel.

BRIDGE, LAGOON AND ROADWAY.

## THE PARKS.

Ever since the discovery of the Falls they have been regarded as, in the apt language of Father Hennepin, without a parallel in the universe, and as the transportation facilities of the country became developed to such an extent that traveling with comfort became possible they have been the Mecca for tourists in America. By the action of the State of New York and the Province of Ontario in establishing reservations the visitor to the Falls has to a great extent been delivered out of the hands of the avaricious hackman who formerly roamed abroad, and can now enjoy the Falls without losing his money and temper.

The first practical step toward the establishment of a state park at the Falls was embodied in a message from Governor Robinson to the legislature, January 9, 1879, recommending that a commission be appointed, although the subject had been much discussed prior to that time. After several attempts to secure legislative action favorable to the project, a bill, was passed and received the approval of Governor Cleveland, April 30, 1883, under which a commission

BRIDGES BETWEEN ISLANDS IN THE STATE RESERVATION.

NEW BRIDGE TO LUNA ISLAND.

was appointed to select lands for a state reservation. The commissioners selected some 107 acres in the vicinity of the Falls, the land taken embracing all of Goat Island and the adjacent islands, Prospect Park, from the brink of the cataract to the new suspension bridge, also a strip of land running from Prospect Park to Port Day, bordering the river and containing the buildings which marred the beauty of the natural scenery. The property condemned was valued at \$1,433,429.50; the legislature in 1885 made the necessary appropriation and the reservation was opened to the public with imposing ceremonies on July 15, 1885. The buildings along the river bank above the Falls have been removed, leaving the view of the rapids and cataract unobstructed.

In 1885 and 1886 the reservation was maintained by the receipts from the inclined railway, the rental of buildings and the sale of old material. Since 1887 the receipts of every kind are required to be paid into the state treasury, and annual appropriations of from \$20,000 or \$25,000 have been made for the care and maintenance of the park. The receipts range from one-third to one-half of the state appropriation. When the property was taken in hand the numerous bridges and buildings were greatly in need of repair and large portions of the annual appropriations have been so spent.

The reservation is visited by about half a million people annually, about one-half of whom are residents of New York. The tolls formerly charged on the grounds (Prospect Park, 25 cents; Goat Island, 50 cents, and the inclined railway, 25 cents) aggregated one dollar for each person, so that since 1885 there has been saved to the public more than the cost of the park to the state.

The state commissioners are Andrew H. Green, president, New York; John M. Bowers, New York; Robert L. Fryer, Buffalo; William Hamilton, Caledonia, and George Raines, Rochester. The Reservation is in charge of Thomas V. Welch, superintendent.

When governor-general of Canada Lord Dufferin made urgent recommendations to the Dominion Government look-

ing to the establishment of a park on the Canadian side of the Falls. No action was taken on this, however, and the provincial legislature of Ontario finally decided to assume the responsibility, and March 30, 1885, passed an act similar to that of New York. The territory marked out by the commissioners of the province is described in the report of the park authorities as follows: From the Clifton House southwards, following the general direction of the river, and at a distance of about 300 yards from the edge of the rocky wall of the gorge there is a beautifully wooded escarpment rising 100 ft. above the general level of the plateau immediately adjacent to the gorge and leading to the general level of the table land between the two lakes. This escarpment is clearly defined up to and beyond the head of the rapids, and it was decided that a better boundary could not be chosen to delimit the territory reserved for a park. The intention of the commissioners was at first to select a line embracing the whole of the escarpment, but it was found that the adjoining proprietors put a very high value upon the land forming the very edge of the bluff, and in consequence a line a little below the top of the escarpment was chosen; thus securing to the park the slope with its wealth of foliage, while at the same time all commanding views from the table land above were retained by the owners and their demands for compensation for the portion taken below the table land made less onerous. The lands thus selected comprised a total area of some 154 acres and embraced all the land from the escarpment described to the river, including Cedar Island, the Dufferin group of islands, the talus under the cliff from the Clifton House southwards to the margin of the Horseshoe Fall.

The value of the lands so chosen was determined by arbitration, the awards and expenses amounting to \$136,813.24.

In 1887 the "Commissioners for the Queen Victoria Niagara Falls Park" were constituted a corporation and authorized to issue bonds for the purchase of the park lands. This park was formally opened May 21, 1888.

STONE BRIDGE OVER THE OLD MILL RACE.

Other property, including the Military Reserve at Queenston, has been placed under the control of the commissioners, so that the Canadian park system comprises the following: Queen Victoria Park at Niagara Falls (the park proper)... 151 acres. Chain reservation along the river from Chippawa to Fort Erie..... 106 acres. Accretions at Fort Erie..... 70.75 " Chain reserve and land on top of the high bank of the river northerly from the park to the Military Reserve at Queenston..... 70 " Talus and lands below the cliff from the park to Queenston..... 255.75 " Lands at Queenston, including portion of the Military Reserve..... 35 " Reserve along water's edge from Queenston to Military Reserve at Niagara-on-the-Lake..... 43.5 " Total, not including lands under water..... 675 "

The cost of the lands which were purchased was \$154,104.71. The cost of maintenance and the interest charges on the bonds issued is derived from moderate tolls levied upon visitors under the falls and carriages over the islands.

The present commissioners are John W. Langmuir, chairman, Toronto; George H. Wilkes, Brantford; Benjamin E. Charlton, Hamilton, and James Bampfield, Niagara Falls. The superintendent of the park is James Wilson.

## CONVENTION PROGRAM.

Following is the program of the four days meeting :

### Tuesday, October 19.

10 a. m. Meeting called to order by Robert McCulloch, President. Address of Welcome.—Hon. A. C. Hastings, Mayor. Calling of the Roll. Invitation extended to join the Association. Address of the President. Report of the Executive Committee. Report of the Secretary and Treasurer. Reading of Paper.—Municipal Ownership of Street Railways; P. F. Sullivan, General Manager, Lowell & Suburban Railway Company, Lowell, Mass. Reading of Paper.—Some of the Difficulties Existing in the Construction and Operation of Electric Street Railways; G. W. Knox Electrical Engineer, Chicago City Railway Company, Chicago, Ill.

### ENTERTAINMENT.

2:30 p. m. A visit will be made to the power house of the Niagara Falls Hydraulic Power & Manufacturing Company, after which the cars of the N. F. & S. B. Railway Company will convey the party to the power house of the Niagara Falls Power Company, and the factories of the Niagara Falls Paper Company and the Carborundum Company.

Pleasant entertainment will be provided in the evening at the hotels—music, dancing, etc., and if weather is pleasant, trolley party excursions to visit the Rapids, etc.

### Wednesday, October 20.

Convene at 9:30 a. m. Reading of Paper.—Application of Storage Battery to Electric Traction; Charles Hewett, Electrical Engineer, Union Traction Company, Philadelphia, Pa.

Reading of Paper.—Power Distribution and Use of Multiphase Current Transmission for Ordinary Street Railways; Maurice Hoopes, Electrical Engineer, Lynn & Boston Railroad Company, Lynn, Mass.

Appointment of Committee on Nomination of Officers and Next Place of Meeting.

2:30 p. m. Party will walk across the upper Suspension Bridge to the Canadian side, where the cars of the Niagara Falls, Park & River Railway will convey party to Chippewa and Queenston, where the steam ferry of the Niagara Falls Navigation Company will be taken to Lewiston, thence by the Niagara Falls & Lewiston Railway Company (Great Gorge Route) through the Gorge to Niagara Falls.

The committee will provide pleasant entertainment in the evening.

### Thursday, October 21.

Convene at 9:30 a. m.

Reading of Paper.—Discipline of Employees; Geo. H. Davis, Superintendent Canal & Claiborne Railroad Company, New Orleans, La.

Reading of Paper.—Application of Electricity to Railroads now Operated by Steam Power; H. N. Heft, President Meridan Electric Railroad Company, Meridan, Conn.

Reading of Paper.—Best Method of Settling Damage Cases and Prevention of Accidents by Use of Fenders or Otherwise; C. G. Goodrich, Vice-president and General Manager Twin City Rapid Transit Company, Minneapolis, Minn.

Election of Officers.

9:30 a. m.—A trip will be arranged for the ladies to Youngstown and Fort Niagara over the Great Gorge Route and the Frontier Railroad, in charge of Ladies' Reception Committee assisted by gentlemen of the Reception Committee.

7 p. m.—Annual Dinner at the International Hotel.

### Friday, October 22.

Convene at 9:30 a. m.

Unfinished Business.

Installation of Officers.

Adjournment.

### Local Committees.

#### GENERAL.

Hon. A. C. Hastings, Mayor, Chairman.

Hon. W. C. Ely, President Buffalo & Niagara Falls Electric Railway Company.

Charles B. Hill, Treasurer N. F. & S. B. Railway Company.

Capt. John M. Briaker, President Niagara Falls & Lewiston Railway Company.

W. A. Heller, Superintendent Lewiston Frontier Railroad Company.

John Foy, General Manager Niagara Navigation Company.

Col. Henry M. Watson, President Buffalo Railway Company.

H. H. Littell, President Crosstown Street Railway Company, Buffalo.

J. M. Bostwick, Treasurer Niagara Falls & Clifton Suspension Bridge Company.

W. Phillips, Superintendent Niagara Falls, Park & River Railway.

Burt Van Horn, General Manager Buffalo & Niagara Falls Railway Company.

Frank LeBlond, Manager Maid of the Mist Steamboat Company.

Hon. Thomas V. Welch, Superintendent State Reservation.

James Wilson, Superintendent Queen Victoria Niagara Falls Park.

Hon. Arthur Schoellkopf, Secretary and Treasurer, Niagara Falls Hydraulic Power & Manufacturing Company.

W. A. Brackenbridge, Engineer Niagara Falls Power Company.

Joseph P. Devine,

L. W. Pettibone,

Hon. James Low,

A. H. G. Hardwicke,

Wm. Richmond,

Benj. F. Thurston,

Wm. S. Humbert,

W. H. Barnes,

Walter McCulloch,

Eugene Cary,

Thomas McDowell,

D. Isaacs,

Gen. Benj. Flagler,

Supplement Street Railway Review.

## CONVENTION BUILDING.

Again this year the association is fortunate in having the meeting place and the exhibits under one roof, and the announcement that the building is steam and electrically heated will be hailed with joy. When the invitation was extended the local committee expected to erect a structure for the use of the convention, but the problem was solved by the purchase of an armory by the Board of Trade, for convention purposes. The committee enlarged this by the addition of a one-story annex, 77 x 126 ft., which gives a total floor space of nearly 20,000 sq. ft. The assembly room for the American Street Railway Association is on the second floor, where a commodious room, seated with chairs is sufficiently removed from the exhibits to secure quiet, and yet make them accessible. The Accountants' Association will meet in the smaller parlor on the first floor. Both meeting rooms can be reached only by passing through the exhibit hall.

The building is at the corner of Walnut and 6th streets, on the line of the city road, which will run special cars between the International and the hall. The ride occupies but six minutes; or the distance makes a pleasant walk of about 12 minutes.

There will be a practically unlimited amount of power; two circuits will be run from the station of the Niagara Falls Hydraulic Power & Manufacturing Company, one supplying alternating currents at 104 volts and 125 cycles per second for light, and a direct current of 500 volts for the use of exhibitors. A track 300 ft. long has been constructed in front of the hall, where cars and other large exhibits will be accommodated. Railroad connections have been made direct to the convention building, so that heavy shipments can be unloaded from the cars into the building. Where

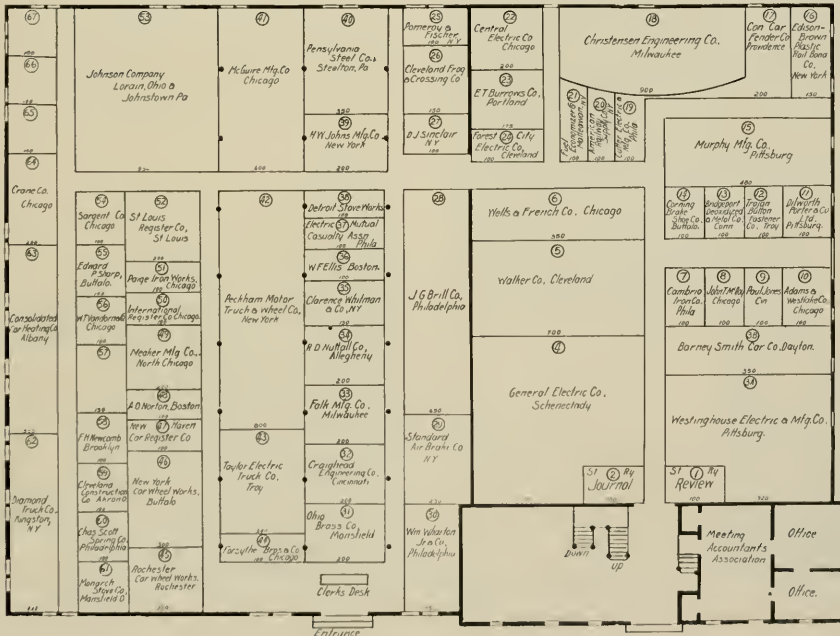

CONVENTION AND EXHIBIT HALL AT NIAGARA FALLS.

teaming is required special rates have been secured, as well as for carpenter and other necessary work of installing exhibits. The building will be open to receive shipments 10 days in advance of the meeting, and exhibitors are urged to have everything complete by the morning of the 19th.

Cars, sweepers and other large equipments suitable to go outside, will be placed in front of the building on a special track. Such exhibits will be arranged in the order of their arrival. Track space has been taken by the following:

- J. G. Brill & Co., Philadelphia.
- Peckham Motor Truck & Wheel Company, Kingstong, N. Y.
- McGuire Manufacturing Company, Chicago.
- Taunton Locomotive Manufacturing Company, Taunton, Mass.
- Taylor Electric Truck Company, Troy, N. Y.
- American Car Company, St. Louis.
- G. C. Kuhlman Company, Cleveland.
- Dupont Car Company, Boston.

# Street Railways of Niagara

Few places are as favorably situated for the construction and operation of electric railways as the two cities of the same name. A resident population of goodly size, with the thousands of visitors, combine to make a steady business throughout the year for the roads, which have almost entirely displaced the old-time and avaricious hackman. Not only can the visitor reach the desired points of interest without any loss of time, but is transported in comfort and rides farther for a nickel than he formerly could travel for a dollar. The production of power by the great water plants has also greatly simplified construction, obviating the time and money necessary to erect stations, and reducing that feature to a simple question of monthly rental.

On the American side are five roads, and on the Canadian two. These lines have 127 miles of track upon which are operated 166 cars. The line to Buffalo has very largely diverted the passenger traffic from the steam roads, the frequent service and delightful ride making the trip enjoyable.

The various electric lines on both sides the river are creditable examples, both in construction and operation, and will be found highly interesting to the railway visitor. All the roads are operated from current generated by water power, the only road having its own station being that of the Park Railway on the Canadian side. During the convention visitors will be conducted over the whole or portions of all these lines.

### Niagara Falls & Suspension Bridge Railway.

The growth and progress of the city of Niagara Falls during the last seven years are in no way better illustrated than by the development of the Niagara Falls & Suspension Bridge Railway and its connections. In the year 1890 the system consisted of 15.8 miles of single track, connecting the business centers of what were then the villages of Niagara Falls and Suspension Bridge. The rail weighed 38 lbs. to the yard and was the old fashioned center bearing strap rail, and the equipment consisted of four 12-ft. bobtail cars, each drawn by one horse, supplemented in the summer season by a few open cars.

CHARLES E. HILL.

This answered the requirements of the locality at that time, but simultaneously with the embarkation of outside capital in the scheme of utilizing, on a large scale, the water power of Niagara Falls, the stock of this railroad was purchased by parties residing at Niagara Falls and Buffalo, who saw the importance of the promised development. From that time, in order to keep pace with the progress of the city, the company has

constantly extended and improved the system, until now it claims to give to the city of Niagara Falls better street railroad facilities than are enjoyed by any city of the same population in the country. In 1891 the main line above mentioned was entirely rebuilt and double-tracked, using a 63-lb. girder rail with Samson joints, and newly equipped with 18-ft. and 22-ft. cars of the best pattern, made by the J. G. Brill Company. At this time the road was also electrically equipped, a temporary power house being installed in anticipation of the company subsequently procuring its supply of power from one of the two large companies. In 1892 the road was extended two miles up the river to what is now the beautiful settlement called "Echota" on the lands of the Niagara Falls Power Company. In 1893 a five mile extension was added, covering Pine street, Sugar street and Ontario avenue. In 1895 the line to "Echota" was rebuilt and double-tracked with 72-lb. girder rails, and extended one mile to the city line for the purpose of accommodating the cars of the Buffalo & Niagara Falls Electric Railway, which use these tracks of the local road, and bring into the city annually 350,000 passengers; and in 1896, an arrangement was made with the Niagara Falls & Lewiston Railway Company, known as the "Great Gorge Route", under which the cars of that company are brought into Prospect Park over part of the main line. The total length of the road is about 10 miles and of track 17 miles. This company was one of the pioneers in heating its cars by electricity, having used the electric heating system ever since the road was electrically equipped.

W. B. RANKINE.

The development of the system may perhaps be better gathered from the statement of the number of passengers carried each year since the present management acquired the road, which is shown in the following table:

|                             |           |
|-----------------------------|-----------|
| 1890.....                   | 426,025   |
| 1891.....                   | 444,045   |
| 1892.....                   | 785,454   |
| 1893.....                   | 1,237,405 |
| 1894.....                   | 1,234,978 |
| 1895.....                   | 1,539,317 |
| 1896.....                   | 2,135,740 |
| 1897..... (6 mo. estimated) | 2,400,000 |

In the year 1896 the company abandoned its power house and began taking its supply of power from the Niagara Falls Power Company. This power is part of the product of a 5,000-h. p. dynamo which is operated by means of a 5,000-h. p. water turbine. The turbine is 140 ft. below the

floor of the power house of the Niagara Falls Power Company, the generator being located on the floor and connected with the turbine by a shaft 130 ft. long in the clear. An alternating current is taken from the dynamo at a voltage of 2,200 and passed through a transformer which converts

it into a direct current of 550 volts. This current is carried to the feeder system of the railroad, which passes the power house, the switchboard apparatus being located inside the power house. An interesting feature of the installation is a device invented by Paul M. Lincoln, electrical superintendent of the Power Company, which was improvised to meet the conditions of the agreement upon which the power is supplied, viz.: that the railway company shall not exceed a certain specified consumption for a greater space of time than two hours each day for a given number of consecutive days in any calendar month. The meter provided by Mr. Lincoln is so arranged that the excess of power used over the limit agreed upon, is registered each day by an ordinary clock, so that at the end of the day the space of time during which the over-use has been indulged in by the railway is accurately shown upon the dial of this timepiece. To insure regularity in the supply, the transforming machinery is in duplicate, so that in the event of the breakdown of one machine the other can instantly be put into use. The officers of the company state that the continuity and regularity of the supply of power is all that could be desired, and the advantage of such a connection, doing away entirely with a power house, will be instantly appreciated by all railroad managers.

J. C. BREWSTER.

The officers of the company are: president, J. T. Jones, Buffalo; vice-president, Wm. B. Rankine, New York; secretary and treasurer, Charles B. Hill, Buffalo; superintendent, John C. Brewster, Niagara Falls, N. Y.

LOOKING UP FALLS STREET, NIAGARA FALLS, N. Y.

## The Niagara Falls & Lewiston Railway.

The Niagara Falls & Lewiston Railway, better known as the Gorge Road, is one of the most beautiful routes that can be imagined, passing as it does along the very edge of the Whirlpool Rapids and through the wild scenery of the Gorge. The engineering difficulties to be overcome were unique if

WHIRLPOOL BEND, GORGE ROAD.

exception be made of some of the railroad construction in the Rocky Mountains, and its cost per mile probably exceeded that of any electric line.

What is perhaps the best view of the cataract is obtained from the steel tower built and owned by the Niagara Falls & Lewiston road. This tower is 300 ft. high and is located on the high bank opposite the State Reservation Park.

Starting at the Tower Hotel in Niagara Falls the line runs through Falls street to 3rd and down 3rd, which has a grade of 5 per cent, for 1,600 ft. From this point there is a cut through the solid rock for 300 ft. until the New York

FALLS FROM THE GORGE ROAD.

Central tracks are reached; this cut is on a grade of 9 per cent and is 50 ft. deep at the lower end; it is 22 ft. wide at the bottom and the walls have a slope of .2 in. per foot. From here the line descends to and down the face of the cliff to the foot of the cantilever bridge; the grades are, first, a short one of 2 per cent, then 6 per cent for 1,000 ft., 84 per cent for 2,500 ft., and 5 per cent for 500 ft. From here to Lewiston the track is along the water's edge and from 20 to 30 ft. above it.

Work was begun April 10, 1895, and a construction train was run to the Buttery elevator, 5 miles and 700 ft. 84 days later. This point was the southern terminus for over a year. The line is seven miles long. The track is laid with 60-lb. T-rails on white oak ties, 6 x 8 in. x 8 ft. At curves the inner rail is protected by a guard rail and a stringer 6 x 8 in. is laid outside of the outside rail for the entire distance that the route is along the river. The most interesting section of the track from a constructive point of view is that between

the bridges and the Tower Hotel. At the Michigan Central cantilever bridge the piers are located on rocks projecting from the talus, the most southerly one being but 15 ft. from the shore; there are also large boulders along the talus. Blasting was prohibited by the bridge company for fear that the structure might be injured. The method adopted was to

TOWER OWNED BY GORGE ROAD.

build three piers which carry two plate girder trusses, one 54 ft. and the other 72 ft. long, over which the tracks are laid. The north pier is on the bank, but the footing courses of the other two are under water, being laid on bags of hydraulic cement carefully placed and rammed into the crevices between the boulders. The center pier is protected by riprapping and the south one by a heavy sea wall, which in turn is pro-

CURVE AT BRINKER PARK.

LITTLE ROCK, GORGE ROAD.

tected by riprapping. Iron rods also were drifted into the rock and built into the piers, and on the shore side of the sea wall tie walls were built into the bank for 20 ft.

At the Grand Trunk bridge the railway company was not permitted to remove the badly weathered sandstone and shale covering the limestone, the only solid stone in the neighborhood, and accordingly built two walls. The upper one prevents the earth from above from falling upon the electric tracks and the lower one prevents the earth under the roadbed from sliding into the river.

On the ascent up the talus, the slope of the debris was increased by filling in with rock. Here the 6 x 8-in. guard stringer is some 4 ft. from outside edge of the slope and a further guard is provided near the edge. This latter is a stringer made up of logs 14 in. in diameter and 16 ft. long, which are laid on posts 14 in. high set at intervals of 10 ft.

The overhead line is of No. 00 wire with Billings & Spencer hangers, divided into sections of 1,000 ft. Power is furnished by the Hydraulic Power Company.

UNDER THE CANTILEVER BRIDGE.

The road operates 30 cars of the 14 bench open type, 31 ft. over all. The cars were furnished by the Brill Company, which also furnished the maximum traction tracks. Each car is equipped with two 50-h. p. Westinghouse motors and provided with Standard air-brakes. Bars are provided on the water side, and heavy curtains for the shore side for inclement weather.

The officers of the company are: J. M. Brinker, president; F. C. M. Lantz, vice-president; H. P. Bissel, secretary; R. W. Jones, treasurer; J. K. Brooks, superintendent; G. A. Ricker, chief engineer; D. B. Worthington, general passenger agent.

#### Lewiston & Youngstown Frontier Railroad.

This road passes through the Niagara fruit region and connects the villages of Youngstown and Lewiston. Local capitalists were interested in building a road through this region and a company was organized in the summer of 1895. Franchises were secured to lay tracks in Lewiston from the New York Central station to the town limits and in Youngstown along Church and Main streets to Fort Niagara, and it was decided better to purchase a private right of way between the villages rather than build along the River road. A strip of land, 30 ft. wide was purchased some 400 yds. east of the River road and fenced in. It is a single track railway of standard gage with five turnouts and end switches, also a branch in Lewiston to the New York Central freight depot and one in Youngstown to the docks. As the country is very level there were no difficult fillings, only a few wooden box culverts, and one trestle 18 ft. long and 9 ft. high to construct. The entire length of the road is 10 miles. The construction of the line commenced in the spring of 1896, the contract for the roadbed, overhead work and fencing being \$63,500 and was completed in August of the same year. All the fences and poles are painted olive green. In the two towns the track is laid with girder rails, 67 and 87-lb. and in the country 56-lb. T-rails are in use. The power

SCENES ON THE LEWISTON &amp; YOUNGSTOWN FRONTIER RAILROAD.

comes from the Niagara Falls Hydraulic Power & Manufacturing Company whose station is  $7\frac{1}{4}$  miles from Lewiston which gives a maximum distance of transmission 16 miles. The current is conducted over a 500,000-c. m. stranded copper wire strung on the poles of the "Gorge Road" and connected to the feeders and trolley wire at Lewiston. The current from one of the 1,000-h. p. generators is raised to 750 volts by means of a booster for the long transmission. The equipment is for freight and light baggage as well as passenger service. There are four open cars and two closed combination baggage and passenger cars made by the J. G. Brill Company and these are equipped with G. E. 1,000 motors. During the past summer a large freight traffic has been handled, consisting chiefly of peaches, grapes, apples and other fruit, in refrigerator cars; formerly this has all been

Falls, via Tonawanda and North Tonawanda; the greater portion of the right of way is along the highways—the old military roads. The line was an expensive one to build because the company accepted onerous conditions as to the paving in Tonawanda and North Tonawanda, and constructed several steel highway bridges, and a viaduct over the New York Central and Erie railroads to avoid a dangerous grade crossing near North Tonawanda. This viaduct has three spans, one of 42, one of 78 and another of 182 ft., with approaches 500 and 600 feet long respectively; the clear space above the steam tracks is 35 ft.

While as stated the company has but 14.5 miles of double track, it has traffic agreements with the Buffalo Railway Company and the Niagara Falls & Suspension Bridge Railway Company, by which it is enabled to run its cars from the center of one city to the center of the other, making a route of 23 miles. Under these agreements the company also issues transfers good over the local lines. The Buffalo agreement is for 50 years, and that at Niagara Falls for 35 years.

The track work is of the best; 73-lb., 7-in. girder rails of a special section rolled by the Cambria Iron Works, in 60 ft. lengths, are laid on oak ties 6 x 9 in. x 8 ft., spaced 2 ft. between centers, and the line is ballasted with crushed stone, top dressed with gravel rolled hard. The rails are bonded with Chicago bonds. The overhead work is carried on octagonal Norway pine poles. The line is divided into three sections, two of 4 miles and one of 8, and there are some 52 miles of No. 0000 feeders, and 14 miles of 500,000-c. m. wire, which was furnished by Washburn & Moen and John A. Roebbling's Sons Company.

The road is operated by power furnished by the Niagara Falls Power Company, and the company has also a power station of its own, at North Tonawanda, which was built when the road was first constructed—before the transmission line was built. This is used at present when heavy traffic demands it, particularly in the summer. The company expects to place transformers in the power house at North Tonawanda, in the near future, and discontinue the use of the steam plant.

The company owns 35 motor cars, which are 28 ft. inside, and 30 ft. over all, on double trucks having 33 in. wheels. Both cars and trucks were furnished by the J. G. Brill Company. The car-barn is located near the center of the line and is an exceptionally fine building of its class;

FORT NIAGARA.

teamed to Lewiston. On account of the rich country through which it runs and the power facilities this road is a very prosperous one. The officers are: L. D. Runsey, president; H. C. Howard, vice-president; K. Evans, secretary; G. R. Teller, treasurer and R. B. Goodman, superintendent and engineer.

#### Buffalo & Niagara Falls Electric Railway.

The Buffalo & Niagara Falls Electric Railway corporation was formed in 1892, and the right of way secured, but because of the panic in the following year work was not begun until the spring of 1895. The contract was awarded to the White-Crosby Company in May of that year, and the work was completed in the following September.

The road comprises 14.5 miles of double track, extending from the city limits of Buffalo to the city limits of Niagara

W. CARL ELY.

BURT VAN HORN.

C. K. MARSHALL.

the dimensions are 78 x 390 ft., including office and repair shops. The fare from Niagara Falls to Buffalo and return is 50 cents, one way 35 cents. During the day the regular cars run every 15 minutes, and oftener when the traffic demands it; during the week of the Grand Army encampment there was a continuous service at 5-minute intervals from Buffalo to Niagara Falls, during the entire week.

The service afforded is appreciated by the citizens of Buffalo and tourists, as the number of passengers carried indicates. From the opening of the road, (September 22, 1895),

to July 1, 1896, the number of passengers carried was 662,435; from July 1, 1896 to July 1, 1897, there were 1,125,351 passengers carried over the line.

The officers of the company are Hon. W. Caryl Ely, president; H. H. Littell, vice-president; Burt Van Horn, secretary, treasurer and general manager, and C. K. Marshall, superintendent.

The directors are, W. Caryl Ely, H. H. Littell, H. M. Watson, Henry J. Pierce, John J. McWilliams, George H. Dunbar, Robert L. Fryer, Burt Van Horn and Joseph T. Jones.

BUFFALO & NIAGARA FALLS ELECTRIC RAILWAY.

## Buffalo Railway Company.

The intimate connection existing between Buffalo and Niagara Falls, since the completion of the electric railway and the power transmission line, would make an article on the street railways of Niagara Falls incomplete unless mention were made of the street railway system of Buffalo, and

much more so since these interests owe so much to the officials of the Buffalo Railway Company.

Buffalo is particularly well located for the development of a street railway system; it is the trans-shipping point for the greater part of the lake commerce, and this fact has concentrated the business interests in a small area on the lake front, from which the city spreads out fanwise to the north and east, with an area of 40 square miles. The manu-

facturing interests are large and will continue to grow as more use is made of the cheap power from Niagara.

The Buffalo Railway Company operates 150 miles of track, of which it owns 77 miles, all of which is within the city limits. This company was organized in 1890 and chartered for 999 years, and it is particularly fortunate in having franchises for the same term, of which but 30 years have elapsed. The capital stock of the company is \$6,000,000, of which some 10 per cent is carried in the treasury, and its funded debt is \$5,170,000, the greater part of which being the bonds of the constituent companies, and the bond issue of the Crosstown road.

All lines are operated by electricity; the change from horse to electric traction began six years ago, about the time the present management took charge of the road, and the last car was run November 10, 1894, at which time the company operated about 140 miles of track. Since that time but slight extensions have been made to the line; the increase in the number of cars however in these three years was from 345 to 500 at the present time. The importance of the system and the value of the property is shown by the traffic returns: in 1896 the gross receipts of the company were

\$1,867,000, being exceeded by but 12 other companies in the United States.

There are in the territory contiguous to Buffalo seven interurban lines, having in the aggregate 79 miles of track, which are valuable as feeders for the Buffalo system. All these lines terminate at the city limits.

The officers of the Buffalo Railway Company are Henry M. Watson, president; H. H. Littell, vice-president and general manager; Joseph S. Baecher, secretary and treasurer; Peter C. Deming, superintendent.

Mr. Watson is well known to street railway men, having been president of the American Association in 1890-91. He was at that time president of two of the street railways of Buffalo. It was through his efforts that the roads of that city were brought into a single system.

Mr. Littell was the first president of the American Association, being at that time general manager of the Louisville City Railway Company, thus giving to the Buffalo Railway Company the honor of having two past-presidents among its officers. Mr. Littell became vice-president and general manager of the company just as the lines were being changed to electricity, and to his experience and executive ability the efficient operation of the company is largely due. To him also is due much of the credit for the construction of the power transmission line to Buffalo, the Buffalo Railway Company being the first to contract for power, and urging upon the Power Company the necessity for rapid work until the line was completed.

Few delegates to the convention will be satisfied to return home before they have inspected the Buffalo lines, which will be found splendid examples of the best practice in modern street railroading.

## "The Canadian Route."

The Niagara Falls, Park & River Railway, or as it is more quickly termed, "The Canadian Route," is an extremely interesting road. When Father Hennepin made

H. M. WATSON.

H. H. LITTELL.

POWER HOUSE OF THE NIAGARA FALLS, PARK &amp; RIVER RAILWAY.

his famous journey in 1678 he followed identically the same route from Queenston to Chippewa which is now traversed by this road, and could he return to earth it is probable he would be no less astonished at this modern system

tion cars are used, with three tiers of longitudinal seats, so arranged that each passenger secures an uninterrupted view. The special scenes of interest include the historic Queenston, Brock's Monument, the battleground of Queenston

Overlooking Queenston

Whirlpool and Lower River

of travel than he was when his eyes gazed for the first time on one of Nature's greatest pictures.

The road is 13½ miles long, double tracked on rock ballast, and affords the finest views to be had from the Canadian side; in fact, to properly appreciate the American Fall one must view it from the Queen's dominion. In the construction of the road no expense was spared to secure a perfect roadway. The bridges are of steel, resting on pedestals of finest masonry; the curves are protected with guard rails and rail braces, permitting a high rate of speed where desired. Specially designed observa-

American Fall, winter.

Heights, the ruins of two forts, after which the road skirts the gorge until the Whirlpool is reached. The Whirlpool Ravine is crossed on a splendid steel structure 500 ft. long and 135 ft. high. Here, also, the company has an incline railway, operated by gravity, water being used for counterbalance, and which takes the tourist down 200 ft. to the water's edge. Resuming the journey, the road passes through the city of Niagara Falls, Canada, and crosses the Dufferin islands, which afford splendid views of the Rapids and Falls. A steel bridge 100 ft. long carries the road from the islands to the mainland,

GRAND TRUNK SUSPENSION BRIDGE REPLACED BY STEEL ARCH BRIDGE IN 1897.

where the line skirts the river for a mile and a half to Chippewa, where connection is made with steamers for Buffalo.

The company built its own power house, a substantial structure of stone, in which are installed three American turbines of 45 in. diameter, working under a head of 62 ft. and delivering 1,000 h. p. each.

The water is taken from the rapids just above the Falls by a flume 200 ft. long to the gates; here it plunges a depth of 62 ft. on the turbines below, and is then carried away by a tunnel 600 ft. long, discharging underneath the Falls. The power is conveyed by the proper shafting and belting to the dynamos, in such a manner that any required number of these machines may be used as necessity demands.

The generators are General Electric multipolar 200-k. w. Forty-one cars are in operation, equipped with G. E., W. P. 50 motors. There are seven feeders ranging in size from No. 0 to No. 000,000. Another incline at the Maid of the Mist landing is owned by the company, this incline being worked by electricity.

The "Canadian Route" commenced operation the year of the World's Fair and during the short season available, carried 420,000 passengers.

In addition to the popularity of the route with loyal Canadians, thousands of Americans come over to make the trip.

The officers are E. B. Osler, Toronto, president; Wm. Hendrie, Hamilton, vice-president; R. A. Smith, Toronto, secretary; W. Phillips, manager; J. C. Rothery, superintendent, and J. E. Stephenson, general passenger and ticket agent, Niagara Falls.

## BRIDGES ACROSS THE NIAGARA.

Members of the American Street Railway Association who attend the Niagara convention will witness the early stages of a work that is destined to result in the erection of a second great steel arch across the gorge and the passing away of the last of the famous suspension bridges between the Falls and Whirlpool Rapids. In the construction of these new arches connecting the Dominion of Canada with the United States, it is interesting to note the provision made for the passage of electric cars over them, thus defining quite clearly the recognition the trolley is receiving in New Niagara. The demands of the locality about the Falls are such that, in order to accommodate the pleasure travel, it is easy to be seen that electricity has played an important part in the innovation in bridge building to be found there.

The old railway suspension bridge is but a memory now, it having been removed during the past summer. As originally built this structure

was of wood with stone towers. The first train crossed it March 8, 1855. The first connection between the cliffs was made by a kite string as described elsewhere. In 1880 the suspended structure of this bridge was renewed in steel, and in 1886 the stone towers were replaced by steel ones. The suspension bridge was a single track structure on its upper deck, and the demands of the time were for better facilities for crossing the gorge, and so the new arch was built with double tracks on its upper deck, and a trolley track on the lower floor.

The second steel arch now building will replace the upper suspension bridge, and it will be the fourth

BRIDGE TO BE REMOVED TO LEWISTON.

bridge erected on this site. The first bridge here was in 1868, connection between the cliffs having been made by carrying a cord across on an ice bridge, and previous to that time the method of crossing was by a ferry. The bridge was opened on January 2, 1869. It was a wooden structure, which in 1887-8, gave way to a bridge of steel. During a violent wind storm on the night of January 10, 1889, this structure was torn from the suspenders and dropped into the gorge, a large portion of it still being hidden beneath the waters of the river. The bridge was at once rebuilt, and it is this structure, less than 10 years old, that is to be replaced by the second arch. It will have a double trolley track, carriageways and walks.

When taken down the suspension bridge will be rebuilt on the site of the old Lewiston bridge, seven miles below the Falls, which was destroyed by wind April 16, 1864, and never rebuilt. In the spring of 1864 a big ice jam piled up

about the guys of the old bridge at Lewiston, and in order that the ice should do them no damage, they were loosened. During the pleasant weather that followed the bridge attendants overlooked the loose guys,

and when the high wind came up, the bridge fell an easy prey to its force, and it has ever since stood a wreck marking man's forgetfulness. It is understood a trolley track will also be laid on the bridge to be built at Lewiston, and, if so, it will result in several trolley loops about the gorge, for crossing by trolley will then be possible at three points.

The opening of the new steel bridge was made the occasion of a three days carnival in the latter part of September. The bridge had been open for traffic for some weeks but a

popular entertainment was designed to attract visitors to the Falls. A feature of the three days celebration was that the lower deck of the bridge was thrown open and no tolls charged.

SKETCH OF PROPOSED BRIDGE.

GRAND TRUNK DOUBLE DECKED STEEL-ARCH BRIDGE DURING CONSTRUCTION, 1897.

## THE FALLS HARNESSSED.

Niagara Falls now has the right to lay claim to being the "Power City" of America. That this idea was in the minds of those who settled the district about the Falls is shown in the name given to the first village, Manchester. Ever since the first saw-mill, built in 1725 and operated by water power from the Falls, men had been endeavoring to perfect plans whereby at least a portion of the great power there might be diverted to industrial purposes. While the probable future of the Falls was indicated, before the practical difficulties could be overcome, such improvements had been made in the steam engine and the cost of steam power so

There are now two power companies at the Falls, the Niagara Falls Power Company and the Niagara Falls Hydraulic Power & Manufacturing Company.

## The Niagara Falls Power Company.

In 1885 Thomas Evershed, division engineer of the New York State Canals, was called upon to devise a plan for the more extensive utilization of the power of Niagara, and the idea as developed by him was to do so in such a manner as to preserve the natural beauty of the Falls. During a long

INTERIOR OF STATION—NIAGARA FALLS POWER COMPANY.

reduced, that water powers were not sought out and developed as before. At Niagara a few small plants were built but nothing of magnitude was done.

In the early 40's Augustus Porter, who was one of the large proprietors at Niagara, proposed an extension to the system of canals and races then in use and in connection with others arrangements were made for the building of a canal. Many delays, however, ensued, and it was not until 1861 that the plan was carried out. In that year Horace H. Day, the successor to the original company, completed a canal 35 ft. wide, 8 ft. deep and 4,400 ft. long through which water was brought from the river above the Falls to a basin on the bluff of the lower river. Various mills were established on the margin of this basin; the wheels installed drew water from the basin and discharged it through short tunnels terminating in the face of the bluff. This afterward was acquired by the Niagara Falls Hydraulic Power & Manufacturing Company.

carcer as an engineer Mr. Evershed had been engaged upon work in the Niagara River district and he was at this time laying out the New York State Reservation.

Charles B. Gaskell, who was the oldest user of water power at Niagara, after consultation with Mr. Evershed associated himself with seven other gentlemen of Niagara Falls and obtained a charter from the state of New York March 31, 1886, which was afterward amended and enlarged by several successive acts. Mr. Evershed issued his plan and estimate July 1, 1886, and it was at once demonstrated, as was the case when ocean-going steamers were first proposed, that the scheme was impossible, and further, that if it were possible, no one would make use of the power. It required three years for the promoters to convince capitalists that the undertaking would be a commercial success.

The Cataract Construction Company was organized in 1889. Those interested in this company were William B.

Rankine, Francis Lynde Stetson, J. Pierpont Morgan, Hamilton McK. Twombly, Edward A. Wickes, Morris K. Jesup, D. O. Mills, Charles F. Clark, Edward D. Adams, Charles Lanier, A. J. Forbes-Leith, Walter Howe, John Crosby Brown, F. W. Whitridge, W. K. Vanderbilt, George S. Bowdoin, Joseph Larocque, Charles A. Sweet of Buffalo, and John Jacob Astor. Mr. Adams was chosen president of the company; Dr. Coleman Sellers, of Philadelphia, was retained as general consulting engineer, and Clemens Herschel, formerly of Holyoke, as hydraulic engineer.

Mr. Evershed's plan was adopted with some modifications, and after thus fixing upon the general arrangement,

Taking up first the general plan of the installation. Water is drawn from the river at a point a mile and a quarter above the Falls, and conducted to the power house through a canal which extends inwardly 1,700 ft. This canal is 250 ft. wide at its mouth, which is 600 ft. from the shore line. The walls are of solid masonry, 17 ft. high, 3 ft. thick at the top and 8 ft. thick at the base, laid up in American cement mortar. The power house is along the side of the canal, and the walls of the latter are pierced by 10 inlets, guarded by gates which permit the delivery of water to the wheel pit in the power house.

The wheel pit is an elongated shaft, 140 ft. long, 18 ft. wide and 178 ft. deep. This pit is lined on the bottom with

INTERIOR OF STATION—NIAGARA FALLS POWER COMPANY.

attention was given to two important features, the turbines and the methods of transmission. For the purpose of securing the latest data from engineers and manufacturers, Mr. Adams while abroad established the International Niagara Commission in London, in June, 1890. This commission consisted of Sir William Thomson (Lord Kelvin), chairman, Dr. Sellers, Lt.-Col. Theodore Turretini, of Geneva, Switzerland, Prof. E. Mascart, of the College of France, and Prof. W. C. Unwin. The commission examined into the methods of power development and transmission, and received competitive plans from some 20 different engineers and manufacturers, and awarded \$22,000 in prizes. The selection of Faesch & Piccard to design the turbines of 5,000 h. p. capacity and the adoption of electricity for transmission in preference to ropes, hydraulic pipes, or compressed air are well known.

16 in. of brick, the top course being of the best quality paving brick, and on the sides, to the height of 30 ft. above the top of the invert, with from 2 to 2½ ft. of brick masonry. The walls are capped with a single course of limestone 30 in. thick, and on this are the girders carrying the weight of the penstocks and turbines.

The wheel pit is connected by a lateral tunnel with the main tunnel serving the purpose of a tail-race, and carrying the water from the turbines to the point of discharge just below the suspension bridge. The length of the main tunnel is 7,000 ft.; in addition there are the tunnel connection to the wheel pit and a short tunnel circular in shape and 10 ft. in diameter which was provided with a view to the possible development of lands owned by the company on the north side of the tunnel.

The average slope of the main tunnel is 6 ft. in 1,000; it

was deemed best to lower the portal so that a considerable portion of the discharge might be under water, and 90 ft. from the portal the grade is changed to an ogee, dropping 11 ft. in that distance. The slope gives a velocity of  $26\frac{1}{2}$  ft. per second or about 20 miles per hour when running at full capacity. The maximum height of the tunnel is 21 ft. and the maximum width 18 ft. 10 in.; the net section is 386 sq. ft. It is lined throughout with at least four rings of the best hard-burned brick, making the wall 16 in. in thickness. At points where from the nature of the surrounding material it was thought best to increase the thickness of the wall there are six and eight rings of brick.

EXTENSION TO WHEEL PIT.

Work on the tunnel was prosecuted from three points, two shafts and the portal, and over 1,000 men were engaged continuously for more than three years. Some 300,000 tons of rock were removed and 16,000,000 bricks used for the lining. The shafts were started late in September, 1890, and 6,700 ft. of the tunnel completed in January, 1893; but the whole was not finished till 1894. The rock excavated was used for filling in the lands under water which were owned by the company, and at the present time the greater portion of the plant of the Niagara Falls Paper Mill is on land so filled in.

Aside from the business of generating power in its own plants the company rents the privilege of discharging into its

tunnel as a tail-race, the Niagara Falls Paper Company having such a lease and discharging into the main tunnel by a branch tail-race 7 ft. in diameter. This installation is unique in that it is the capacity of the tail-race and not the supply of water that is limited.

The penstocks are built up of steel and are 7 ft. 6 in. in diameter, tapering down from an elliptical section having the major axis about half again as long.

The three turbines first installed were built by the I. P. Morris Company of Philadelphia, after the designs of Faesch & Piccard of Geneva, Switzerland. They each consist of two Fourneyron turbines, one being inverted and set over the other so as to neutralize the weight on the bearing. Each of the twin wheels is made three stories high and the speed gate is a cylinder which moves up and down on the outside of the turbines. The water from the penstock is allowed to pass through the disk of the upper guide-wheels and to act vertically upward upon the disk of the upper turbine; the disk of the lower guide wheel is solid and the pressure of the water upon it is carried by rods extending through the wheel casing.

The turbine wheels are made of bronze, the rim and buckets in a single casting. The guide wheel has 36 and the turbine wheel 32 buckets. The wheels discharge 430 cu. ft. per second and under the available head, 136 ft. from the surface of the water down to the center of the pair of wheels, will make 250 r. p. m.; at 75 per cent efficiency the output is 5,000 h. p. The shaft is of steel and hollow, 38 in. outside diameter, and  $\frac{3}{4}$  in. thick, except at the journals where it is 11 in. in diameter and solid. A thrust bearing is placed near the upper end of the shaft. It should be mentioned that the upward pressure of the water on the shaft is slightly in excess of weight of the shaft and dynamo fields. The speed-gate is operated by the governor and the speed regulated by its movements. For shutting down entirely the head-gates leading to the penstock are used.

The dynamos are perhaps the most interesting machines of their class that have yet been installed, and were built by the Westinghouse Electric & Manufacturing Company after the designs of Prof. George Forbes. They are of the umbrella type, the field revolving and the armature being stationary. The field ring serves as a fly-wheel for the turbine.

Each generator is 11 ft. 6 in. high from the bottom of the bedplate to the floor of the bridge, which extends over them, for the purpose of giving access to the brushes bearing upon the collecting rings at the top of the shafts. The diameter of the revolving field ring is 11 ft.  $7\frac{1}{8}$  in.; these rings are of nickel steel, forged in a single piece by the Bethlehem Iron Company. Each generator delivers 5,000 electrical horsepower and requires about 5,150 h. p. to be delivered through the turbine shaft, when at full load. The total weight is 170,000 lbs., about 79,000 lbs. being revolving weight. There are six pairs of poles and the generators deliver a two phase alternating current at 2,200 volts.

The governors are after the design of Faesch & Piccard. An interesting feature of the governing is that only one is effective. The alternators are run in multiple so that they must run in synchronism and the speed be that of the fastest governor. In practice it is impossible to set all the governors for the same speed and only the one set for the highest speed does the work.

The power station which houses the generators and covers the wheel pit is a handsome building of Queenston

limestone in the Moorish style of architecture and is along the side of the canal. A bridge connects it with the transformer house. The machinery hall is a plain pitch-roof structure that can readily be extended to cover the new

renting power. In this connection should be mentioned the facilities for switching which are afforded by the Niagara Junction Railway Company (an allied company) whereby any occupant of a mill-site may receive cars from and

wheel pit without marring its symmetry. Three of the 10 units contemplated were first installed and during the last summer work has been progressing on the new wheel pit which when completed will provide for the other seven units.

The Niagara Power Company owns 1,072 acres of land about its station, and leases it to manufacturing concerns

deliver them directly to any of the railroads entering the Buffalo-Niagara Falls district.

The first to use power from this plant was the Pittsburg Reduction Company which has a contract for 3,500 h. p. The current is by means of static and rotary transformers converted to a direct current at 160 volts. This conversion is in two parts; first in static transformers to a two-phase

alternating current at 115 volts; second, in rotary converters to a direct current at 160 volts. This company is engaged in the manufacture of pure aluminum from an oxide of the metal by smelting it in retorts, the mass being melted and the aluminum reduced by means of an electric current.

The Carborundum Company takes 1,000 h. p. from the

WESTINGHOUSE ARMATURE.

Niagara Power Company and this is received in a single static transformer built by the General Electric Company which reduces the voltage from 2,200 to 250; a reactive coil is employed to control this from the maximum down to as low a voltage as 90.

Carborundum is a silicate of carbon made by subjecting the constituents to an intense heat in an electric furnace. The furnace is filled about half full of salt, sawdust and glass sand and on this is laid a core of coke about 21 in. in

diameter and 14 ft. long; contact is made at the ends by packing the coke tightly about bunches of carbon rods which constitute the electric terminals. The furnace is then filled with salt, sawdust and sand. The current heats the core to incandescence and after 24 hours the process is complete, the carborundum being removed in crystals. This is broken up, sorted to size and moulded with a binding material, into wheels, etc., for grinding and polishing.

The Acetylene Light, Heat & Power Company was using 1,000 h. p., the current being transformed to 100 volts, but because of the increase in the demand for calcium carbide has recently increased its plant and now takes 5,000 h. p. In order to display the illuminating power of acetylene the company has placed search lights along the river and at the Falls; they give a beautiful effect and are greatly appreciated by visitors, as heretofore the Falls have been in darkness at night.

The Niagara Electro-Chemical Company has a capacity of about 1,000 h. p., but until recently was using only 400 h. p. It receives current at 2,200 volts and reduces the voltage to 115 in static transformers; this is then changed to direct current at 160 volts by rotary converters, of which the company has three of 250 k. w. each. In this plant the current is used almost exclusively for the manufacture of sodium, decomposing the caustic soda of commerce.

The Central Power & Conduit Company uses some 1,000 h. p. which is transformed to a pressure of 11,000 volts and transmitted to Buffalo. At the Falls end there are two transformers located in the transformer house across the canal from the power house. Each has a capacity of 935 k. w. They are 94 in. high on a base 56x64 in., and weigh 25,000 lbs. each; they are cooled by a blast of air driven up through the core and cells. At the Buffalo end there are three transformers which step down the current from 10,700 volts (the line loss being 300) to 370 volts. This current is carried to two 500-h. p. rotary converters which feed the railway bus bars at 500 volts. This equipment was furnished by the General Electric Company.

The transmission line to Buffalo was built by the Niagara Falls Power Company at great expense. The line is 26 miles long, and for 18 miles a strip of land 30 ft. wide was purchased outright; for five miles the line is along the Erie Canal. The line was constructed by the White-Crosby Company of Baltimore.

SAMPLES OF LINE CONSTRUCTION—NIAGARA FALLS-BUFFALO TRANSMISSION.

Cedar poles, 18 in. at the butt, 8 in. at the top and from 35 to 65 ft. long were planted 75 ft. apart. These poles carry three cables, each of 19 strands, having a total cross-section of 350,000 c. m. For the last 1,200 ft. the cables are laid in vitrified tile ducts. One of the greatest difficulties in the construction of the line was in securing insulators which would stand a high voltage test. By co-operation with the manufacturers great improvements were made in the insulators. That adopted was a double petticoated one of porcelain, made by the Imperial Porcelain Works of Trenton, N. J. All of the feeder cables for this line—two order for 75 miles each, 150 miles of 350,000-c.m. cable—were furnished by the American Electrical Works of Providence, R. I.

Recent tests have shown the insulation resistance of the line to be 300,000 ohms on wet days and 1,000,000 on dry days. The actual working efficiency of the line is very

Hygeia Ice Company, using 50 h. p. For this service General Electric and Westinghouse rotary converters are used, being located in the power house of the Niagara Falls Power Company.

In addition the Niagara Falls & Suspension Bridge and the Buffalo & Niagara Falls Electric Railway each take 250 h. p. for their lines.

Prospective users of power are the Mathiesen Alkali Works, 2,000 h. p.; the Chemical Construction Company, 500 h. p.; and the Albright Wilson Company, 200 h. p.; and about 500 h. p. is to be used in the grain elevators of Buffalo.

#### The Niagara Falls Hydraulic Power & Manufacturing Company.

This company is a powerful rival of the Niagara Power Company and though comparatively little has been written in description, it is well worthy of attention, because of the contrast between the two. In the case of the Niagara

POWER HOUSE AND TRANSFORMER HOUSE, NIAGARA FALLS POWER COMPANY

high, being 79.6 per cent between the generators and the railway circuit, including the losses of the step-up transformers, line, step-down transformers and rotary converters. This high efficiency indicates that it is practical and economical to transmit current 25 miles at 11,000 volts. The transformers, the insulation and the line are all designed for a potential of 22,000 volts. This will bring the losses lower and make the efficiency still higher. At Buffalo, rotary converters change the alternating to a direct current at 500 volts. Connections are then made to the feeders and trolley lines of the Buffalo Railway Company, requiring no alterations in that system. Since last November there have been but two interruptions, and these of very short duration, so that it is demonstrated beyond peradventure that the transmission is thoroughly reliable. Transmission is now only a question of higher voltage for more distant points. Many sanguine predictions are made about the distances this power can be transmitted, but the problem is gradually but surely being worked out from experience.

Other companies taking power from this plant are the Buffalo & Niagara Falls Electric Light & Power Company, using 500 h. p. of alternating current and 150 h. p. of direct current for lighting Niagara Falls; the Niagara Falls Waterworks Company, using 15 h. p. at 500 volts, and the

Power Company the power house is on top of the bluff the wheels located in pits 178 ft. deep, excavated in the rock, and the tail-race a tunnel 7,000 ft. long, constructed at great expense. The Hydraulic Company conducts the water to the top of the bluff below the Falls in an open canal, thence down to the bottom in penstocks along the face of the cliff and generates power at the bottom, utilizing the same fall (with smaller units, however,) with an amount of capital invested that is almost insignificant in comparison with the other; and it might be added that the turbines are of American design in this plant.

The enterprise was the outgrowth of the first scheme to make use of any considerable part of the power of Niagara. Jacob F. Schoellkopf and Abram Chesbrough, organized the company of the present name in 1879, and infused new life into the hydraulic canal. As already mentioned this canal was some 1,400 ft. long, terminating in a basin near the edge of the cliff. The company was unable to make use of the entire fall because it did not own the slope at the water's edge, having merely the right to discharge the water over it. In 1886 the company acquired these sloping lands and the full head of 215 ft. became available.

The capacity of the old canal was about 13,000 h. p. had

the fall of 215 ft. been used, and was fully taxed by the 6,000 h. p. of wheels installed at the time the sloping lands were bought.

The Cliff Paper Company in 1892 erected its plant at the foot of the bluff, carrying water down through an inclined tunnel in the upper part of the bank, and a penstock along the surface of the slope, and was the first to make use of the full fall.

In the same year the Hydraulic Power & Manufacturing Company began work, increasing the capacity of its canal, widening and deepening it to the present dimensions, and completed it in 1894.

The installation of the power plant at the bottom of the gorge soon followed, being completed in 1896. It is rec-

of the right of way is 100 ft., the canal proper is but about 70 ft. its average depth being 11 ft. At its lower end, running parallel with the high bank there is a basin 400 ft. long and 70 ft. wide. For this installation a canal 275 ft. long, 16 ft. wide and 20 ft. deep, in which the water runs at a depth of 16 ft., leads to a forebay 180 ft. long, 30 ft. wide and 22 ft. deep. This forebay is located between the canal basin and the edge of the high bank, the south end being closed with a wooden dam the idea being to extend the forebay at some future time, when another connection will be made with the canal basin. It is over this forebay that the gatehouse is built which covers the gates by which the water is let into the penstocks, previously passing through racks for screening out all floating substances likely to endanger the wheels

NIAGARA FALLS HYDRAULIC POWER & MANUFACTURING COMPANY—INTERIOR OF POWER HOUSE.

ognized as one of the recent great works in the city, so rich in power facilities and development. The method of development is plain and simple, and the installation is winning much praise from engineers for its efficiency. To all interested in power for trolley lines the plan has several features which will attract attention, especially as a portion of the power operates a trolley road 15 miles distant from the power station. The erection of the plant was under the immediate supervision of Wallace C. Johnson, who is chief engineer of the company.

The hydraulic canal takes water from the upper Niagara river at about the lowest practical point, there being a descent of about 50 ft. from the entrance to the canal to the Falls. The canal is about 4,400 ft. long, and while the width

in the power house below. Under the gate house there is also a gate by which the canal can be cleaned at any time desired. This waste gate consists of two gates, each 20 ft. deep and 8 ft. wide. It is in the apparatus for handling these gates that Mr. Johnson takes especial pride, for it is constructed after his designs, and works most efficiently. In front of each pair of gates stand two cast iron cylinders, each about 8 ft. high, and containing a piston. The tops and bottoms of these cylinders are connected to a pump, run by an electric motor, by which oil can be forced into the top or bottom of the cylinders as desired. The piston rods of the two cylinders are connected at the top by an iron beam carrying four heavy iron hoops, which take hold on pins in the gates, and by simply running the pump and adjusting the

valves the gates may be raised or closed at pleasure, one or both gates being handled at a time. By means of this apparatus a pressure of 100,000 lbs. can be exerted on the gates if necessary. The gate house itself is an iron framed structure covered with corrugated iron 180 x 16 ft. The penstock that takes water from the forchbay to the wheels is 8 ft. in diameter, and for 25 ft. it proceeds in a horizontal direction to clear the edge of the high bank, when it descends in a vertical direction 135 ft. to a solid foundation on the lower stratum of Niagara limestone. From this point it extends, on an angle of 45°, to the power house building, under the floor of which it runs about 70 ft., being 10 ft. in diameter for this distance. The penstock is made of the best quality

of lifting 26 tons. The crane was built by the Buffalo Structural Steel Works. Immediately on entering the power house one is impressed by the beauty and simplicity of the installation. Every part of the machines is before the attendant's eye. If an accident occurs, the cause can be instantly determined. The four water wheels of the plant was made by James Leffel & Co. of Springfield, Ohio. They rest on the floor and take their water supply from the penstock through five-foot openings, each wheel having an individual supply. The inlet pipes to the wheels can be closed by valves operated by hydraulic pressure. The valves are 60-in. and made after Mr. Johnson's plans by R. D. Wood & Co., of Philadelphia.

NIAGARA FALLS HYDRAULIC POWER & MANUFACTURING COMPANY.

of steel plate, each piece of which was rolled to special order and tested and inspected before going into the work. It is  $\frac{3}{8}$  in. thick at the top and  $\frac{1}{4}$  at the bottom. Ritter & Conley of Pittsburg did the work on it. At the lower end this penstock has 100 lbs. pressure to the sq. in. Beneath the power house floor there is a tail-race formed by two masonry walls 17 ft. 6 in. apart and extending from a point 6 ft. below the water in the river back to a point 20 ft. above, or to the floor of the power house. In this tail-race the entire lower portion of the penstock with its enormous weight hangs suspended on iron supports.

The power house is built of stone quarried on the site. The completed section is 100 ft. wide and 60 ft. long, to be extended until it is 180 ft. long, the work now being in progress. It is a one story building, 30 ft. from the floor to the eaves. The roof is supported by iron trusses, leaving the floor free from posts. All parts of the interior are reached by a traveling crane, operated by hand and capable

The details of the wheels were designed by James Leffel & Co.'s engineer, A. F. Sparks, and the entire weight of each one is about 50 tons. They stand on very strong, heavy, double steel beams, placed upon solid foundations of stone, the whole being of a most substantial character. These steel beams span the tail-race, and from the same frame work the horizontal portion of the penstock is supported by means of 48 iron rods, each  $1\frac{1}{2}$  in. square. The wheels are known as James Leffel & Co.'s Niagara type, which is their double discharge turbine in form, and detail especially adapted to the requirements of the Niagara development. This type of wheel consists of a large, flattened, vertical, circular casing containing the guide case of the wheel proper. It is into this exterior casing that the water is admitted from the supply pipes underneath, flowing upwards and surrounding the guide case, being admitted to the runner through a series of oscillating guides, which constitute also the gates. From the sides of this casing project the discharge pipes,

laterally and then downward by a gradual curve, to which draft tubes 20 ft. in length are attached, thus utilizing in part the atmospheric pressure. The heads of the large casing are of curved form to secure strength. They are made of cast iron  $3\frac{1}{2}$  in. thick, and a circular band of steel plates  $\frac{3}{4}$  in. thick, double riveted to the cast heads, constitutes the straight or cylindrical portion of the case. It is within this casing and the guide casing that the runner or wheel proper is located upon a horizontal shaft, supported by adjustable ball and socket oil bearings, upon heavy arched iron bridge-trees exterior to the outer casing. The runners of the wheels are 74 in. in diameter, and made of bronze and iron, very substantially built. The shell comprising the buckets proper, which receive the water by a sharp dividing diaphragm or ridge, is made of bronze, the central portion, upon which the shell is rigidly fastened, being of iron. The wheels discharge the water laterally into the receiving or discharge pipes, and owing to the peculiarity of the design, there is no uncompensated pressure upon any part of the wheel, and therefore no end thrust or pressure endwise on the shaft, but the whole is perfectly balanced wherever it comes in contact with the water. The gates are of the James Leffel pattern, made of the best of steel, and are operated by the double ring arrangement which is easily within the control of a hand wheel operated by one person. To the hand wheel shaft the automatic mechanical governor is readily attached, and in this plant the Lombard governor, made by the Lombard Water Wheel Governor Company of Boston, is in use. The head of water is about 210 ft.

The greater part of the power from this new plant is transmitted on aluminum cables, two in number, each containing 250 wires, to the top of the high bank to the new aluminum factory of the Pittsburg Reduction Company which has two plants at the Falls; the other one has been mentioned. To supply this power the Westinghouse Electric & Manufacturing Company built and installed six 560-k. w. electrolytic generators. These machines were installed under the personal supervision of W. K. Dunlap, the representative of the Westinghouse company at the Falls and are directly connected by flexible couplings to the shafts of the turbines. Each of the turbines nearest the high bank operates two of these generators, and each machine generates 2,000 amperes at 280 volts operating at 250 r. p. m.

The six of these machines are all exactly alike; the field of each consists of eight laminated steel pole pieces, which are cast into a circular yoke or frame. The armature core is composed of punched steel disks, carefully annealed, while the core is built upon an iron spider, which also carries the commutator. The periphery of the armature is slotted to receive the winding, which is composed of copper bars held in slots by means of retaining wedges of hard fibre. These wedges are driven into the notches near the top of the slot, longitudinal with the armature. Should it become necessary to remove any armature coils, they can be pressed out at will. Ventilating spaces through the spider and armature core are so arranged to allow constant circulation of air through the commutator and windings when the machine is running. The commutators are constructed from the very best hard rolled copper obtainable, the segments being spaced by prepared mica of such corresponding hardness that an extremely even wearing surface is presented to the brushes. The brush holders are supported by a casting which is secured to the bearing. Carbon brushes are used.

The fourth turbine is used to operate two generators

built by the General Electric Company. These generators are of 750 h. p. each, their capacity being 1,000 amperes at 550 volts. They are rigidly connected to the water wheel, and are run at a speed of 300 r. p. m. They are compound wound for railway service, and are to be run in multiple. Since the completion of this installation, the Niagara Falls Hydraulic Power & Manufacturing Company has supplied the Niagara Falls & Lewiston Railroad, better known as the Gorge road, with electric power for operating its cars, and also the Lewiston & Youngstown trolley line. For this latter service a second generator, made by the General Electric Company, is used as a "booster." It stands on the power house floor directly in front of the first two generators and their connected water wheel. The service it gives is very good, and the voltage at Lewistown is about 580, and that at Youngstown, about 15 miles distant, is about 507. The current for the operation of the Gorge road comes from the same generators in the power house, but it is taken from a different panel of the switchboard so that it does not pass through the "booster" before being used. The booster was tried at the start, but the current was found too strong for the Gorge road. That portion of the installation furnished by the General Electric Company was installed under the supervision of I. R. Edmonds, the Niagara Falls representative of the company.

It should not be overlooked that any one turbine in this new power house can be operated separately. The superintendent of the Niagara Falls Hydraulic Power & Manufacturing Company's plant, as well as that of the Buffalo-Niagara Falls Electric Light & Power Company, is F. G. Lott, who is an electrician of wide experience. Mr. Lott is highly pleased with the efficiency of the "booster" for trolley line work, and takes pleasure in explaining its workings to visitors.

The business head of the Niagara Falls Hydraulic Power & Manufacturing Company is Arthur Schoellkopf, ex-mayor of Niagara Falls. Mr. Schoellkopf is a man not unknown in street railway circles, as he was for years president of the Niagara Falls & Suspension Bridge Street Railway Company. He is a man of extended means, and one who has done much in developing the power resources of Niagara.

Work is progressing on the extension of this power house, and five more turbines, of 2,000 h. p. each, will soon be in operation.

In conclusion attention may be called to the success of Niagara as a power center, as evidenced by the fact that the two great supply companies are both engaged at the present time in increasing their plants.

## THE PAN-AMERICAN CONGRESS.

The Pan-American Congress has already begun to dawn on the horizon of events, and the location of this promising exposition has been chosen. It is midway between Buffalo and Niagara Falls, directly on the line of the Niagara Falls & Buffalo Electric Railway, and well served by steam roads. Some of the most prominent men in the state of New York are on the board of managers and the grounds are in every way desirable and well suited to the purpose. It would be difficult to select a better site, for while the object of the Congress is to make the delegates familiar with the material resources and products of the Americas, no visitor from abroad is satisfied without a glimpse of Niagara.

**OFFICERS OF THE AMERICAN STREET RAILWAY ASSOCIATION.**

The convention of 1897 will be the sixteenth in the history of the association; a history full of interest, and recording an evolution as wonderful as it has been beneficial to the people. The importance of the organization which represents so stupendous an industry can not be overestimated, and it is a matter of pride that its history is a pleasant one to recall and that its proceedings have yet to record dissension, bitterness or strife. The A. S. R. A. was never as strong as it is today; it never had a greater field of usefulness than now; its future was never brighter or so full of promise.

As in the case of the smallest member company, the secret of success lies in good management. The selections for officers and managing board have always been well made, and the official roster this year has never been excelled. Every member is a worker; each enjoys a long experience

THOMAS C. PENINGTON, SECRETARY A. S. R. A.

in railway work; and their management of the affairs of the association has been conscientious and praiseworthy.

The officers this year are: President, Capt. Robert McCulloch, St. Louis; first vice-president, C. S. Sergeant, Boston; second vice-president, Col. D. B. Dyer, Augusta, Ga.; third vice-president, C. F. Holmes, Kansas City; secretary-treasurer, T. C. Penington, Chicago.

The executive committee includes the above and H. M. Littell, New York; H. P. Bradford, Cincinnati; C. H. Smith, Troy; H. Scullin, St. Louis; G. B. Hippee, Des Moines.

The list of meeting places, with president for the year, is as follows:

| Place.         | President.        | Year. |
|----------------|-------------------|-------|
| Niagara Falls. | Robert McCulloch. | 1897  |
| St. Louis.     | H. M. Littell.    | 1896  |
| Montreal.      | Joel Hurt.        | 1895  |
| Atlanta.       | Henry C. Payne.   | 1894  |
| Milwaukee.     | D. F. Longstreet. | 1893  |
| Cleveland.     | John G. Holmes.   | 1892  |
| Pittsburg.     | Henry M. Watson.  | 1891  |
| Buffalo.       | Thomas Lowry.     | 1890  |
| Minneapolis.   | George B. Kerper. | 1889  |
| Washington.    | Chas. B. Holmes.  | 1888  |

|                                                                       |                      |      |
|-----------------------------------------------------------------------|----------------------|------|
| Philadelphia.                                                         | *Thomas W. Ackley.   | 1887 |
| Cincinnati.                                                           | Julius S. Walsh.     | 1886 |
| St. Louis.                                                            | *Calvin S. Richards. | 1885 |
| New York.                                                             | William H. Hazzard.  | 1884 |
| Chicago.                                                              | H. H. Littell.       | 1883 |
| Boston, organization meeting, Moody Merrill, chairman, Dec. 12, 1882. |                      |      |
| *Deceased.                                                            |                      |      |

**THESE WANT THE NEXT CONVENTION.**

One of the most interesting questions at each convention is "Where will the next meeting be held?" and this year the association will not be embarrassed for want of invitations. There will not only be requests in abundance, but they are coming from desirable cities, any one of which would be good, and each will urge its own special advantages and attractions with vigor.

Detroit was first in the field, having put in its request last year and has been following it up energetically ever since. In addition to the street railway companies' invitation, the Detroit Convention League, an association which secured over 80 meetings for that city this year, has taken an active hand. The Association has never been to Detroit, and that city certainly would make a very desirable place in every way.

Cincinnati thinks it about time the street railway men came there again, now they have been to St. Louis a second time. They emphasize their exposition building as an ideal place to show exhibits, and are making an active canvass among delegates in advance of the Niagara meeting. Like Detroit, it is centrally located, with abundant railroad connections and good hotels.

Omaha has been constantly in the papers of late on account of the Trans-Missouri Exposition which will be held in that city in 1898. The exposition buildings are already under way and will be pushed to rapid completion. Our Omaha friends promise that the show will surpass both Atlanta's Cotton Exposition and the Nashville Centennial. The Government has made a generous appropriation and many states as well, and everything points to a magnificent affair.

Louisville has a citizens' committee at work raising funds and making plans to secure the convention, and will come prepared to paint in glowing colors the desirability of meeting there and the interesting southern features which were so pleasing at Atlanta. There are one or two other cities which will in all probability put in their invitations; so among them all the nominating committee will have no easy task to select one from so many, and all desirable.

Still another strong candidate for convention honors is the city of Richmond, Va. Many of the delegates to the Washington meeting in 1888 made the trip to Richmond and had a most enjoyable time. The electric road there at that time was in its infancy and working out its own salvation, being one of the earliest in the country.

**REVIEW HEADQUARTERS.**

The STREET RAILWAY REVIEW will have two offices during the convention; space No. 1 at convention hall will be found immediately to the left of the entrance to the session room; the other at the International hotel is on the office floor directly opposite the clerk's desk. We shall be pleased to have our friends make themselves at home in both places.

# STREET RAILWAY ACCOUNTANTS ASSOCIATION OF AMERICA

The Street Railway Accountants' Association of America was organized "to bring together those engaged in the accounting department of the street and interurban railway companies, for the interchange of ideas, to promote the adoption of a uniform system of accounts, and to improve the work of the accounting department." This association has undertaken a work far reaching and no less essential than the matters which call for an exchange of the best ideas and widest experiences of the brightest men engaged in the operating departments of the same companies. The need of such an organization has been the natural outgrowth of the marvelous expansion in the street railway business, which has inevitably carried its many increased ramifications into the accounts. This effort on the part of the street railway accountants to improve methods and introduce economies, has already commended itself to the Executive Committee of the American Street Railway Association, and a large number of presidents and directors, and deserves and should receive the hearty encouragement and support of every street railway company in America.

The association was organized in Cleveland, on March 24, 1897, at the close of a two-days meeting at which some most excellent papers were read and discussed. Nearly 50 representatives of street railways were present, coming from points near and remote in the United States and Canada.

Their work occasioned the warmest commendation for the thorough and systematic manner in which it was conducted and above all for the earnestness and dispatch with which the very large amount of business was transacted. The good results of this meeting have been heard from on every side. M. W. Hall, secretary of the Camden & Suburban Railway, Camden, N. J., was the presiding officer at the organization meeting, and permanent officers were elected as follows:

President, Henry L. Wilson; Auditor, West End Street Railway, Boston.

First Vice-President, C. M. Duffy; Secretary, Citizens Street Railway, St. Louis.

Second Vice-President, J. F. Calderwood; Auditor, Twin City Rapid Transit Co., Minneapolis-St. Paul.

Third Vice-President, C. B. Reavis; Secretary, Augusta Railway Co., Augusta, Ga.

Secretary and Treasurer, W. B. Brockway; Auditor, Toledo, Bowling Green & Fremont Ry., Toledo, O.

Executive Committee, the above and

Dana Stevens; Accountant, Belt Railway Co., Washington, D. C.  
W. S. Dinmock; General Manager, Omaha & Council Bluffs Railway & Bridge Co., Council Bluffs, Ia.

W. G. Ross; Comptroller, Montreal Street Railway, Montreal.

E. R. L. Tighe; Accountant, Brooklyn Rapid Transit Co., Brooklyn.

The very practical and suggestive character of the papers read at the Cleveland meeting will be seen from the subjects presented, which were: "From Horse to Electric Accounts", H. L. Wilson, Boston; "Suggestions for a Standard System of Accounts", C. N. Duffy, St. Louis; "Transfers," Frank R. Greene, Chicago; "Monthly Closing of Accounts," Dana Stevens, Washington; "The Relation of Accountants to Managers and Employees," P. V. Burlington, Columbus; "A Simple System of Interurban Accounting," W. B. Brockway, Toledo; "Naming and Standardizing Apparatus," J. P. E. Clark, Binghamton; "Depreciation," H. C. McJilton, Baltimore. The papers were all excellent, showing careful preparation and much study, and constituted the largest and best contribution to the literature of this department ever made. The discussions were thorough and afforded fully as much information and data as the papers. The exhibits in connection with the papers

and discussions were a very valuable addition to the work of the association, and the blanks and forms were found to be so important and numerous that a committee was appointed early in the convention to arrange and classify the forms so that they could be more satisfactorily studied. For this purpose a special room with long tables was provided, and when delegates were not in session these exhibits were constantly thronged. The opportunity for gaining

new ideas, and learning of economies in conducting the accounting department was highly appreciated. It may be mentioned here that these forms were all in blank and not for the purpose of showing actual figures.

A committee was appointed to gather forms and blanks, and arrange same at the meeting at Niagara, and companies are urged to respond promptly if they have not already done so, in order that this feature of the meeting may be as valuable and complete as possible.

The program for the coming meeting will commend itself to every accountant as treating of subjects of vital interest to him in his work, and with the discussions, which are always as valuable and interesting as the papers, will constitute a veritable post-graduate course in accounting. There is scarcely a road in the country that can afford to miss the benefits of this meeting by not sending some delegate from its accounting department, for the information gained will be carried home and put into actual use in improving the character of the work, and what is equally desirable, doing it in a more economical manner. In a single instance of which we have personal knowledge, one delegate to the Cleveland meeting effected a saving to his company of \$25 per month, as the direct result of one new idea gained.

H. L. WILSON,  
President.

W. B. BROCKWAY,  
Secretary.

C. N. DUFFY,

J. F. CALDERWOOD.

C. B. REAVIS.

F. E. SMITH.

President Robert McCulloch, of the American Street Railway Association, has accepted an invitation to appear at one of the meetings of the Accountants' Association; and President Wilson has been invited to address a few remarks to the larger association.

New members recently added are:

- St. Louis & Suburban Railway, St. Louis.
- The Peoples Railway, St. Louis.
- Lowell, Lawrence & Haverhill Railway, Lawrence, Mass.
- New Orleans Traction Company, New Orleans.
- Richmond Traction Company, Richmond, Va.
- Campania de Tranvias de Merida, Yucatan.
- Elmira & Horseheads Railroad, Elmira, N. Y.
- Worcester Consolidated Street Railway, Worcester, Mass.
- Birmingham Railway & Electric Company, Birmingham, Ala.

Acceptances have been received from nearly 100 roads, stating their intention to send delegates to this meeting, and a large attendance is thus assured.

Following is the program:

**Monday, October 18.**

7:30 p. m. Meeting of the Executive Committee at the International Hotel.

**Tuesday, October 19.**

10 a. m. President's annual address.  
Report of executive committee, routine business and appointment of convention committees.

Paper.—"The Care and Handling of Fares from Passenger to Bank." C. L. Wight, Auditor The Toledo Traction Company, Toledo, Ohio.

**Wednesday, October 20.**

9 a. m. Paper. "The Handling and Checking of Transfers from Printer to Furnace." J. F. Calderwood, Auditor Twin City Rapid Transit Co., Minneapolis, Minn.

Paper.—"Pay Rolls—Time Keeping and Methods of Paying."

Frank R. Henry, Secretary Missouri Railroad Company, St. Louis, Missouri.

Paper.—"Materials and Supplies Accounts from Purchase to Use." W. G. Ross, Comptroller Montreal Street Railway Co., Montreal.

**Thursday, October 21.**

9 a. m. Report of a committee appointed at Cleveland, Ohio, March 21, 1897, on "A Standard System of Street Railway Accounting, Covering the Classification of Operating Expenses, Classification of Construction and Equipment Accounts and Form of Annual Report." Chairmen, C. N. Duffy, Secretary Citizens Railway Co., St. Louis; J. F. Calderwood, Auditor Twin City Rapid Transit Co., Minneapolis; W. F. Ham, Secretary Nassau Electric Railway Co., Brooklyn.

2:30 p. m. Report continued.

**Friday, October 22.**

9 a. m. Paper. "Car Mileage—How Arrived at and Its Use." [Street Railway.] H. J. Davies, Assistant Secretary Cleveland Electric Railway Co., Cleveland.

Paper.—"Statistics—Their Use and Abuse." E. D. Hibbs, Auditor Consolidated Traction Co., Jersey City.

- Election of officers.
- Appointment of committees.
- Adjournment.

All papers will be followed by an open discussion upon the subject in question.

A rate of one and a third fares on railroads has been secured. Pay full fare going, taking a "certificate receipt" on presentation of which to proper officer at Niagara an order to purchase return ticket at one-third will be issued. The members of this association are included in all the entertainments arranged for the American Street Railway Association, and are invited to attend its annual dinner which occurs at the International, Thursday evening, October 21, at 7:30 p. m.; the tickets are \$7—the actual cost to the association.

W. S. DIMMOCK.

W. G. ROSS.

DANA STEVENS.

E. R. L. TIGHE.

## HEADQUARTERS AT THE INTERNATIONAL.

There is a certain interest which always centers in the headquarters hotel, and which is different from that to be found among the exhibits or in the session room. It is at headquarters that the social life of the convention is found, and by no means the least valuable part of the gathering is that derived from the quiet, confidential talks, where little groups of acquaintances gather after meals or in the evening, and exchange confidences and experiences. It is here the officers sojourn; here receptions are held, and here the annual banquet is spread. In selecting the International for all these, the executive committee found its task an easy one, and no one will question the wisdom of the choice.

The management is in splendid hands, S. A. Greenwood being one of the best hotel men in the country; and one who has had a long experience in handling conventions and knows just what to do and how to do it. The International is not only the leading hotel at the Falls, but is the largest, is situated on the principal business street, and looks out over the State Park Reservation to a commanding view of the Falls and river. And it may be observed that on the site of International was the first hotel at the Falls; it was the Eagle Tavern, built about 1804 and destroyed by the Indians and British in the War of 1812.

THE INTERNATIONAL.

In fact, from the windows on three sides of the building may be seen the river, rapids and islands. The hotel has, also, a park of its own into which the dining room extends. The building is of brick and Niagara limestone, with the kitchen and laundry in separate buildings.

The International with its accommodations for 600 guests' is filled all through the summer season, which extends from the first of May to October, and attracts the best class of visitors. The convention comes at a date when the house is in better condition than at any other time in the year to take care of it. A rate of \$3.50 to \$4.50 per day has been made for delegates. Our illustrations give several glimpses of the hotel.

THE LOGGIA—INTERNATIONAL.

The Albany Railway Company was sued by the administratrix of John Piehl, who was killed by being struck by a piece of the fly-wheel which burst at the company's power house a year or so ago, and a verdict for the plaintiff was secured in the lower court. On appeal the case was reversed, it not having appeared that the engineer of the plant was negligent so as to charge the company.

The Riverview Street Railway is now under construction at Beaver Falls, Pa., and will be two miles long. The contracts so far involve \$30,000. John M. Hughes is the moving spirit in the company.

#### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

#### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. OCTOBER 15, 1897. NO. 10

A PECULIAR case has been made the subject of litigation at Oakland, Cal., several passengers bringing claims for damages for \$200.05 each on account of having to walk where they expected to ride. It seems the company made a change in the leaving time of its last car on one of its transfer lines in the suburbs, without, as plaintiffs claim, having given public notice of the fact, hence when they transferred it was to foot power instead of electricity. The state statute contains a section which requires street railways to give notice in advance of contemplated changes in schedule.

In selecting the place for next year's convention, no decision should be reached until it is definitely settled what amount of suitable exhibit space can be provided for the display of appliances. The demand, and absolute necessity, for floor space has increased each year until now it requires a building of large proportions. At least 25,000 square feet should be insisted upon as a minimum and twice that amount would not be too much. This year, not only have many exhibitors had their applications cut down nearly one-half, thus preventing the exhibition of much which they would have been glad to bring, but the Association is thereby deprived of just so much revenue it would otherwise have earned. With restricted space, too, it forces exhibitors to condense and crowd what they do bring until it neither shows nor can be approached with advantage. Twice the space available this year could have been sold, with the

result that accepted exhibitors could have done better, and some who applied too late to get any space, would have been taken care of.

The convention has grown to large proportions and its requirements both for hotels and exposition purposes are now correspondingly large.

EVERYTHING points to a large attendance at the Niagara convention. The West certainly will send a big representation, and the location of the meeting place being so convenient to those in the East, it is fair to anticipate an unusually large number from that territory. The program is a most excellent one, and the committees appointed well selected. Many questions have come up during the year which managers will wish to discuss, and the natural attractions at the Falls certainly leave nothing to be desired in that respect. The exhibit space was all taken early in the season, and that feature alone is well worth the time and expense of making the trip. The time has been extended to four days, which will permit of taking things a little more comfortably than in previous years, when it has necessarily been one continuous rush from arrival to time of departure. There is not a company but can profitably send one or more delegates to this convention. The attendance of ladies will be larger than ever, and special provision for their entertainment is promised.

DELEGATES to the convention should plan to spend as much time as possible in the exhibit hall. The temptation always is to devote so much time to the excursions and local features of interest that many leave the display to the last and then find they must hurry away. The exposition of railway appliances is alike a credit to the supply men, who spend thousands of dollars to make a creditable display, as it is to the Association which calls it into existence. We feel that the exhibitors are justly entitled to a reasonable portion of the time of those in attendance, and the inspection should be considered quite as much one of the things to receive attention as the reading of a paper or the election of officers. Aside from the courtesy due exhibitors the display is really a grand opportunity to study the various supplies, and is the one occasion in the whole year on which the manager may actually compare one with another. The benefit in the line of a thorough understanding of the machinery, from inspection and explanation is invaluable, not only in itself but for the suggestions and new ideas to be obtained. Very few of the appliances to be shown at Niagara can in the nature of things be brought to the manager's office to show him there, and it is only the large attendance which makes possible the expense incurred to bring from all directions the vast collection which is to be seen at these meetings. We do not know of another association at the convention of which there is anything like, in value, number or size, the exhibits to be seen at the conventions of the American Street Railway Association, and the delegate who fails to spend a good many hours in the exhibit hall loses more than he may realize.

THE Association has been repeatedly put to no small inconvenience by the arbitrary restriction in its constitution as to the date upon which its regular annual meeting shall be held. The REVIEW has long urged the necessary change which will enable the executive committee to exercise that discretion which it most assuredly should have conferred

upon it. If the meetings were always held in one city there would be less reason for it, but moving about this great country it frequently happens that the middle of October is accompanied by cold and unpleasant weather, especially in the northern tier of states. At Montreal we had snow; a month earlier the weather was ideal. By all means the executive committee should have the power to fix the date, as it now has to change the place if emergency should require.

The matter will come up for action at this meeting, as Mr. Kelly, of Columbus, presented to the committee at its meeting in February, a petition with the required number of signatures, and the committee will present it with favorable recommendation in the annual report. If accepted by the Association it must lie on the table one year, and can be called up for final vote in 1898.

Change the date to a month earlier, or better, give the executive committee authority to set the date, and if it ever takes the convention to the Arctic regions in December, the members can make it hot for the committee.

### WE HAVE BEEN HERE BEFORE.

While this is the first time the Association has met at the Falls, it has visited Niagara in a body before. It was in 1890 when the convention met in Buffalo, and after Henry M. Watson, president of the Buffalo lines, had royally entertained his guests with the good things of that city, he chartered a special train and we all took a day off and visited the Falls. The special left Buffalo at 11 o'clock and ran to Niagara, where it crossed on the suspension bridge. After viewing the sights on the Canadian side the party recrossed on foot and were met with carriages for a drive about the islands and to other points. After lunch another special of observation cars was taken for the trip down the river along the Gorge to Lewiston. Mr. Ely, now president of the Buffalo & Niagara Falls road, was then treasurer of one of the incline lines on the American side and tendered its courtesies to the delegates.

There will be not a few present this year who will recall with pleasure that delightful excursion. The great changes which the few intervening years have wrought are emphasized in the fact that where the 100 miles of excursion then was furnished by steam cars, now the same trip will be made under vastly better conditions for seeing the sights in electric cars exclusively.

### THE BUFFALO CONVENTION OF 1890.

The convention of 1890 was the ninth annual meeting, and like so many others was one of the best ever held; it certainly was a most pleasant and successful one.

Thomas Lowry, of Minnesota (then only of Minneapolis), was president that year, and at the outset of the meeting horrified a good many of the old timers by declaring in his official address that, "I believe that this is the last convention that will ever seriously consider horses for the operation of street railways," and his prediction was true, for while the program that year included "A Perfect Street Railway Horse," the horse has never been to a convention since.

It was that year the mechanical system battled for supremacy. There were representatives of eight systems

of electric roads, including storage battery and underground and each was given 10 minutes, and used 20, to tell how the method he represented was the best.

It was at that meeting Albion E. Lang, of Toledo, extended an invitation for all to visit his city, where experimental tests were to be made in 60 days with compressed air motors. The cable men were still strong at this convention, and many a manager went home more undecided than ever as to which he wanted, storage, overhead, underground, compressed air or cable; and sensibly at that time, concluded to stick to his horses one more year.

Another program feature was B. F. Owen's paper on created travel and park resorts under the title of "Novel Schemes for the Development of Street Railways;" and Hon. G. Milton Scribner's second installment of his splendid contributions, which have never been equaled in convention papers, "Public and State Treatment of Corporations.

It was at this meeting that electricity really was accepted by any considerable number of delegates as the coming motive power and as much time was given the subject as all the other topics combined.

The banquet was given at the Iriquois hotel with the genial C. Densmore Wyman as toastmaster.

### AN INTERESTING RELIC.

On the desk of the editor of the REVIEW, doing duty as a paper weight, is a section of rail, which has an interesting history, and which dates back to the early 60's. The accompanying sketch will serve to illustrate this form of wrought iron rail, which was rolled and laid at Providence, R. I., in 1864.

Chief Engineer Bronsdon has looked up the matter and kindly hands us the following information:

Between 25 and 30 miles of track were laid on 3 x 5-in.

chestnut stringers and ties. The stringers were cut to fit the under side of the rail, as shown in the illustration. The spikes with countersunk heads were placed in the center of the rail and directly in the path of the wheel tread. The rails were of varying lengths, 22 ft., 25 ft., and 29 ft., and no splice bar was used at the joint, excepting a short piece of cast iron about 6 in. in length formed to fit the under side of the rail.

This casting served to carry the ends of the rails and prevent them from sinking into the stringer. The rail weighed about 22 lbs. to the yard.

In speaking of this rail, General Manager Potter, who was then starting on his railway career, and was connected with this same company, states that this rail has done as good, if not better work in its day, than our present girder and heavy T-rails are now doing under electric service. Of course the cars were small and light and speed was not then desired.

After the stringers had rotted away and it was found necessary to make repairs, it was customary to simply lay a

10-ft. piece of the chestnut stringer at the joints and drive spikes along the rail into the dirt or decayed stringer, which ever was left, under the rest of the rail. When this rail was considered worn out, it was snapped up by dealers in second hand rail and again sold and relaid to do good service. In fact it has been laid and relaid, exchanging to different roads several times.

Some of this iron is still in use for transferring coal at a coal pocket in the Providence power house; is doing good work today and to all appearances will wear another generation.

It is one of the first forms of wrought iron rail which was rolled to take the place of cast iron rails for street railway purposes.

### TRANSPORTATION ON THE SOMO.

Ten years ago a primeval forest of stately pines occupied what is now the site of the interesting city of Tomahawk, Wis., which with its excellent water works, electric lights, broad regularly laid out streets, and one of the finest hotels

boats are patterned after street car bodies on scows, drawing about 18 in. of water.

The motive power is a small tug to which the boat cars are coupled up like any other train, and so closely that a person may step from one to the next without difficulty.

The trip up the Somo river is one never to be forgotten, the train winding around sharp bends with the tug and last cars moving in opposite directions, and taking "curves" of seemingly impossible radius.

The train is run every Sunday for the entertainment of the owner's friends, and where desired for long trips of two or three weeks, a nominal charge is then made for the pay of the crew and for stocking the boat.

The scenery is entertaining, and the route covers a trip which may justly claim the title of being a strictly pleasure resort line.

Some of our readers who have old and useless horse car bodies, might do well to consider offering them for this purpose, or where they have suitable water at their own resorts, to transform some into house boats. In fact this has already been done at Kansas City, where an old car of the Broad-

TRANSPORTATION ON THE SOMO.

in the country, is a revelation to the dusty traveler in the wilderness.

The town and pretty nearly all its belongings, are the property of a millionaire lumberman, of Milwaukee, W. H. Bradley, and he has provided with a liberal hand, churches, school houses and modern improvements of all kinds.

While Tomahawk has not yet aspired to the dignity of a street car line, Mr. Bradley has done the next best thing, and taking advantage of the miles of water travel made possible by the three rivers, the Tomahawk, the Wisconsin and the Somo, has inaugurated a system of transportation at once as enjoyable as it is unique. By no means the least attractive feature of this monopoly lies in the fact that it is conducted without money and without price so far as the passengers are concerned, and Mr. Bradley, in this as in several other directions, receives his return in the thanks of appreciative guests.

The train of house boats illustrated consists of seven in all, one being fitted as a kitchen and another as dining room, for use on long trips into the interior. Two more are fitted with berths with good beds, and the rest are parlors. The

way line was launched on the hulk of a flatboat. A carpenter quickly made it secure and it floated away quite a trim and attractive craft.

### THE INDIANAPOLIS 3-CENT FARE CASE.

The city of Indianapolis has determined to take the initiative in the controversy that is expected to arise with the Citizens' Street Railroad Company over the surrender of the streets under the law declaring all street railway franchises void after 1901, the object of the city being to have all question as to the validity of the act settled before that date.

Regarding the present status of the 3-cent fare case, on the call of the case before the United States Circuit Court of Appeals the announcement was made that the railway company would move to dismiss on the ground of want of jurisdiction, the company contending that the appeal should have been to the Supreme Court of the United States. It would appear that the city was ill advised when the appeal now pending was taken.

## THREE TRUE TALES.

The editor was recently being shown over one of the best managed roads on the Atlantic seaboard, and coming out of the power house his attention was attracted by the handsome stack which constitutes one of the landmarks of the city. After expressing his admiration for its beauty from an architectural standpoint, he ventured to guess its height, and suggested 175 feet as about right.

The manager smiled as he gazed thoughtfully at the stack and replied:

"No, it is exactly 225 feet to the capstone, but there was one day when I thought it was a mile high."

"How was that?" we inquired, anxious for a solution of the puzzle.

"Well, it is not a very long story, but I wouldn't repeat the experience for the power house and the whole road thrown in. The day the boys were setting the cap, the president of the road and myself happened out, and stood some little distance away watching the men working at the finishing touches. There was no scaffold except the little staking of a floor at the top.

"Ever been up there?" inquired the president.

"Well, no," I replied, "been pretty busy you know and there really was no occasion for me to go up."

"View up there must be fine," said he, "you won't have a chance after to-day," and I could not but feel that he was rather pleased at the idea that I had not been attracted to this method of transportation. So I bluffed back with the remark that I had only been waiting for the right kind of company when I made the ascent, something like a president or director. That threw the burden of proof back on to him, and not to be outdone he said he wouldn't mind a little thing like that, and would just as soon go up as not; rather thought it would be a nice trip up in the air. At that I plucked up and assured him I was more than anxious to go, and would be both pleased and honored at his company. Matters had now reached a pass

where neither one of us could gracefully retreat, so the president tried to look indifferent and said he positively must make the ascent. At the same time as his eyes slowly followed up the long line of masonry he didn't look re-enthusiastic, in spite of his words.

"Well, come on," said I, starting for the stack; and not to be behind the procession he forged ahead of me and reached the base first.

The rigging consisted of an ordinary single wheel wooden block pulley, which hung about three feet out from the top from a piece of 6x8-in. timber, and a hemp rope, one end of which was attached to the winding drum of the donkey engine on the ground, and the other to the bucket in which the brick and mortar had been raised. Now, this bucket was nothing more than half an oil barrel which had been sawed in two and suspended by a rope handle like a letter A. The bucket came down empty just as we reached the place. We got in, the president sitting on one side with his feet in the tub and his hands grasping the main rope. I occupied the side opposite and did the same. I sat facing the engineer, and the smile on his face which I caught as the word was given to start was anything but reassuring. As

the rope began to tighten and the bucket left the ground the president called out, "Let her go up slow." We began to rise, and as we did so the rope commenced to untwist and the bucket to spin slowly round and round. To add to our distress, the president is a man weighing 200 while I am satisfied with 120 pounds, and he so overbalanced the tub that his side was away down while mine was away up. And so we were going up, whirling round and round, and the rope squeaking through the wheel far above us. I took one upward glance and that was enough. Then I looked down about 80 or 90 feet, and it seemed as if we were set on a flagpole. Then I looked at my companion and the sweat was running down his face in streams, and he was hanging to that rope as a drowning man would. The ridiculousness of the fool trip struck me and I began to brace up. I urged him to look toward the east where the view stretched out for miles, and to the south, where the church spires, in another state, were visible. "Shut up and hang on," was the response, and, in fact, I found my time pretty well occupied with my part of the rope. The slightest move changed the balance of the bucket as it spun round and threatened to pitch us out. Meanwhile we were steadily but gradually, oh so gradually, rising. My hands and wrists were already numb with the tension of the grasp on the rope. I began to wonder if we ever should reach the top, and to commend myself as a consummate idiot for ever having started. Then I began to estimate the factor of safety in that rope, and for the first time realized how small it was and the responsibility that was vested in that little piece of hemp. Come to examine it, it didn't look much bigger than a clothes line, and the longer I looked the smaller it seemed. And what if there was a weak spot. It had been in use for many days hauling hundreds of tons to build that stack, and altogether I was in any but a cheerful state of mind; and suppose the engine should fail to stop hoisting in time—

"Must be 'most there," puffed the president, breaking the silence; and so we were, almost to the top. You can well imagine the look of surprise on the faces of the boys when they discovered the nature of the load, and they hastened to swing the bucket in to the platform.

We got out and tried to stand erect, but the strain of the ride and the cramped position combined to make us feel as though we had ridden all night in a day-coach.

But once in a place of safety the president recovered his spirits and chaffed me about looking pale around the gills, and that I was no sort of company for a man going up in a balloon. He told me next time he should not bring me along, and I mumbled a sincere 'amen'; and swore I would lead a better life, at least until I again reached the ground. The president expatiated on the grandeur of the landscape, which was indeed an inspiring sight, and not content with naming the several points of interest, began narrating the history of each one after another. In this way we spent fully half an hour. Finally I suggested we had better put on our things and go home. The president looked at me with a grieved sort of expression on his face, stepped cautiously to the edge, took one look over into space, and pointing to the south remarked confidently:

"I should say Cuba lies in about that direction; and think the Klondike must be just beyond that clump of trees." Then he resumed his account of the Indian war which happened ages ago.

But all things have an end, and finally all the Indians had been slain, and the whites had been nicely settled, and the

several towns had grown into cities, and history was exhausted.

The bucket came up empty and I started toward it.

"Hold on there," said he, "I get in first;" so I waited for him to embark on the aerial craft. The bucket was on a level with the platform, and when he jumped in with his 200 pounds the slack in the rope let it suddenly drop five or six feet before the rope became taut. My heart was in my mouth, for I thought he had gone straight to the bottom. But he didn't, and when I slid down the rope into the bucket he was hanging in space with the tub standing on edge in mid-air. We made a quicker trip down than we had coming up, and soon were safely on solid earth once more. The president mumbled something about a parcel of fools, and without any regrets at leaving, we drove home.

But the most remarkable thing of all was when, the next day, the men had taken down the rigging, and I picked up the pulley through which the rope had run which raised us. The shaft was worn down to less than a quarter of an inch in diameter, by actual measurement. Next time when I go up stacks I shall first examine the pulley and then stay on the ground.

\* \* \*

"I will tell you a gong story," said a manager the other day, "and it was one on me. We have a down town loop, where the street is very narrow, and we have a close squeeze to get through even with a single track. We were having so many collisions with wagons I put up a bulletin calling special attention to having the gongs sounded, everywhere and at pretty much all times. Still the boys kept forgetting to ring the bell. Then I stuck up another notice a good deal more stringent, but still they didn't seem to rise to the emergency, and finally I had to make an example of two of them. Then the gongs woke up with a vengeance. I was delighted, but a day or two later I managed to sprain my ankle, and had to stay in the house four days.

"The main line, which also carries several branch lines, is directly in front of my house. The first morning I thought the cars must be in one continuous blockade by the way the gongs sounded, but after crawling to the window two or three times only to find the street deserted, I abandoned the painful operation of looking out. And they kept it up. They all seemed to know I was where I couldn't get away and they serenaded me. All day and until after midnight; and the next day, and the next. They evidently intended the old man should get enough. By the fourth day I was satisfied, and a new bulletin went on the board."

Motor-men will sound gongs only at street crossings and when approaching vehicles or pedestrians; and will use discretion and not sound gongs unnecessarily.

\* \* \*

"Speaking of gongs reminds me of a story," said a superintendent who was standing in the group. "One of our lines passes a lodge room, used by several organizations, so there is something nearly every night. It is down in the business district, and the cars and teams are thick and naturally the gongs are going most of the time. The line in question was a loop extension opened after cold weather set in, so the societies did not notice it until spring. Then it grew warm, and when they opened their windows the noise

from the bells came in. One of the leading citizens, and an officer of the lodge, came to me with the request that the men be instructed to draw the gongs as mildly as possible on lodge nights, as it was very annoying to have the clatter right in the middle of the most impressive portion of a charge. I told him I would look into it, and thanked the gentleman for calling my attention to the matter. Then I went off and forgot all about it. The next week he stopped his carriage in the middle of the street, got out, and came to where I was standing on the curb. I thought I was in for it sure, and was about to offer an apology for the neglect when he said:

"I want to thank you personally, and on behalf of our members, for having abated that gong nuisance. You don't know what a difference it has made, and we are all very grateful. It is such things that the public appreciate, and which go to make a road popular."

"Very pleased to do it, I assure you," I replied; "always glad to have my attention called to these things"; but a notice went up within 15 minutes about ringing gongs in front of the Masonic building on lodge nights."

#### ATTEMPTED STRIKE ON THE CHICAGO CITY RAILWAY A FIZZLE.

A few discharged employes of the Chicago City Railway took advantage of the spare time thus provided to try to work up a strike. W. D. Mahon, the professional agitator scented the battle from Detroit, and hastened here to direct matters. Meeting after meeting was held in the hours between midnight and dawn, and the company was notified through the daily papers that the men were to be taken back, and the union recognized or there would be a strike. General Manager Bowen came out most emphatically from the very first and stated there would be no union men in his employ, even if it should be necessary to discharge the entire force. Repeated efforts to secure any further statement from him proved ineffectual, and when the mayor tried to get his hand in to "arbitrate" he was told there was nothing to arbitrate and that the company would continue to conduct its own business at the old stand. The directors absolutely refused to be drawn into the matter, and announced the whole thing was in the hands of the manager so far as the company was concerned and that he would backed up in whatever course he saw fit to take. After 10 days of agitation the whole thing has quieted down and not a car missed a single trip. Mr. Bowen is certainly to be commended for the positive and fearless stand he took and the company is better for it today. The question of wages, which are the highest in the country, was not involved; it was simply a question of turning over the discharge of employes to the whims of a union. This adds one more to the list of failures of Agitator Mahon, who fell down quite as lamentably at Boston, Philadelphia and Milwaukee.

Charles H. McCann brought suit against the Consolidated Traction Company at Newark, N. J., for \$10,000 for injuries alleged to have been sustained when thrown from his horse which shied at one of the company's sprinklers. It was stated that his injuries prevented him from wearing a stiff hat, but the company's counsel called attention to the fact that Mr. McCann wore a flat topped derby into the court room. The verdict was in favor of the railway company.

### GRANVILLE C. CUNNINGHAM.

Granville C. Cunningham and J. Ross of the Montreal Street Railway Company made a trip to England recently to complete the negotiations by which the Birmingham street railways passed into the hands of Canadian capitalists, and now the announcement is made that Mr. Cunningham

has been appointed manager of the Birmingham system. Mr. Cunningham was a member of the executive committee of the American Street Railway Association and has long been prominent in its councils. After receiving an education in civil engineering in Edinburgh he went to Honduras, Central America, and was engaged on a railroad project there. In 1872 he went

to Canada, and for the next 17 years was connected with various railroad interests. Previous to the introduction of the electric system in Toronto Mr. Cunningham visited the principal cities in the United States; his report and recommendations were accepted by the Toronto city council. In 1892 he was appointed chief engineer of the Montreal Street Railway Company, and its equipment for electric traction was carried out under his direction. He is a member of the Institute of Civil Engineers of London and the Canadian Society of Civil Engineers. In appreciation of his many good qualities his employes presented him with a fine silver tea and coffee set. Mr. Cunningham's successor is F. L. Wanklyn, general manager of the Toronto Railway Company.

### FINE RECORD OF THE FALK COMPANY FOR 1897.

The Falk Manufacturing Company, which is the owner of patents covering the cast-welded rail joint, and is also builder of special work, reports a large business during the past year. Early in the spring cast-welding was introduced on the Pacific coast by the welding of the Pasadena & Pacific Railway Company's tracks at Los Angeles, Cal., and has been continued at Oakland and San Francisco. In the latter city the welding of the unique "Z" bar track rail of the Market Street Railway line has been eminently successful. Some other large contracts have been with the Cleveland Electric Railway and the Cleveland City Railway Company, of Cleveland, Ohio; the Toledo Traction Company, of Toledo, Ohio; the Mahoning Valley Railway Company, Youngstown, Ohio; the Milwaukee Electric Railway & Light Company, the Nassau Electric Railroad Company, the Brooklyn Heights Railroad Company, of Brooklyn, N. Y., and the Elgin City Railway Company, Elgin, Ill., etc.

The company has during the year completed and put into operation several valuable improvements, which have brought the joint to the highest standard of perfection. The joint has also attracted increased attention abroad, being now in use in some of the largest roads of France, and contracts have recently been closed for its adoption in Germany and England. The additional test of the past winter and the wide range of its success justify the prediction that the cast-

welded joint would prove an invention of the greatest importance in track construction, made by the REVIEW when it was first brought out.

The special work department, which was established last year, has been crowded with orders to its utmost capacity, and has been working overtime almost continuously. Shipments have been as far east as Brooklyn and south to New Orleans. The company is also taking contracts for the complete equipment of roads as to track and overhead, furnishing all materials.

### MONTREAL INTERURBAN.

The Montreal & Southern Counties Railway is projected to afford transportation facilities for a large section of country about Montreal. One branch will run to St. Johns through Chambly and the water power at the latter place will be utilized. From St. Johns it is proposed to extend the line through Ste. Alexandre, Notre Dame de Stanbridge, Mystic, Bedford, East Stanbridge, Dunham, Cowansville, Sweetburg and Knowlton. From the latter town the road will pass through Bolton Pass to Bolton Springs and Bolton Centre, thence to Eastman, Magog, over the Hatley Mountains to North Hatley and Sherbrooke by way of Capelton and Lennoxville.

A. J. Corriveau has recently made a tour over the proposed route and was very favorably impressed by the opportunities for large traffic and the lack of engineering difficulties in constructing the road. He anticipates that building will commence early next spring.

### WINTER PROGRAM OF THE CHICAGO ELECTRICAL ASSOCIATION.

The fall and winter program of the Chicago Electrical Association is as follows: "Economy in Electric Car Control," by J. R. Cravath; "Evolution of the Isolated Electric Plant," by Harold Almert; "The Safe Current Capacity of Electric Conductors," by C. H. Sewall; "Daily Mathematical Conveniences," by S. G. McMeen; "Heavy Electric Traction," by Cloyd Marshall; "Electricity in Ship Building," by C. C. Mattison; "Electrical Shop Transmission," by H. G. Dimmick; "The Art of Constructing Telephone Apparatus," by H. P. Clausen. The meetings are held the first and third Fridays of each month at 1737 Monadnock building.

### NEW CONDUIT TESTED AT HAMBURG.

At Hamburg, Germany, a piece of track 525 ft. long has been built to test a new form of electric railway conduit. It is an inverted U-shaped metal trough made in sections of convenient length and shielding the conductor which is mounted on suitable insulators. The purpose of this form of conduit is to prevent the conductor being submerged in water and it acts on the principal of the diving bell. The imprisoned air in the U conduit holds the water away from the conductor. In one of the recent tests the leakage of current, with the tracks and conduit flooded, was between .2 and .3 ampere. It is stated that the conduit is not expensive in its construction.

## CABLE LINE OPERATED BY ELECTRIC MOTOR.

BY CHARLES GROVER.

That it may be economical to operate a cable railway with an electric motor power has been fully demonstrated by the Metropolitan Street Railway Company, Kansas City, Mo.

The cable machinery in the power house at 9th and Washington streets, which has been driven by a 24 x 28-in. Wright engine for the past eight years, is now operated by a 300-k. w., 4-pole electric motor. The Summit street cable line, which has 2.17 miles of double track with grades as heavy as 10 per cent is operated by this motor. During the 19 hours daily run an average of 208 trips made over this line by six cable trains of a grip car and trailer each.

Extra trains are run morning and evening during the periods of heavy travel. On July 5, the motor pulled 20 grip cars with 25 trailers for a few hours during the day. It has been observed by the passengers as well as by the officials of the road, that the speed of cable is more uniform

shaft on the winding gear of the cable machinery was lengthened out 13 ft. and a belt wheel 24 ft. in diameter with 37-in. face was mounted on this shaft.

The motor is mounted on a concrete foundation with a wood platform for insulating the motor frame from the foundation. A double leather belt 36 in. wide is used for transmitting the power from the motor to the cable machinery. This belt passes over a 34-in. pulley on the motor shaft to the 24-ft. pulley on the cable machinery with a distance of 36 ft. between centers of the shafts carrying the pulleys. The stretch of the belt is taken up by an adjustable pulley mounted on an iron frame.

The motor runs at a speed of 380 r. p. m. when up to speed, and with the use of the specially arranged starting rheostat described below, the motor can be operated at any desired speed from 10 revolutions to 380 revolutions. The demand for the wide variation in speed is at such times as it is necessary to repair the cable or put in a new one.

The switchboard is made of slate 2 in. thick, has a front surface of 48 sq. ft., and is supported on a frame made of angle and T-iron. It was designed and built in the com-

MOTOR DRIVEN CABLE PLANT—KANSAS CITY, MO.

and that there is less jerk to the cars than when operated by the engine. The current for operating the motor is obtained from a 1,300-k. w. generator at the Central avenue power house, which also supplies current for the electric lines in the western portion of the city. The current is carried for a distance of 8,855 ft. over a triple braided weatherproof insulated copper cable of 1,000,000 c. m. area for the positive conductor. The return conductor consists of 1,670 ft. of both insulated and bare copper cable of 1,000,000 c. m. area, and is tapped to the iron structure of the Kansas City Elevated Railway, which forms the remaining 7,185 ft. of the negative conductor. The iron structure was heavily bonded at all its joints with No. 0000 flexible copper bonds.

The motor was originally a General Electric Company's standard 300-k. w., 4-pole generator with a speed 480 r. p. m. and 500 to 625 volts when run as a generator. It was used four years ago as one of the generators which operated the Kansas City Elevated Railway, but since that time it has been idle, until it was taken into the Metropolitan Street Railway Company's shops, and remodeled for a motor.

The arrangement for attaching the motor to the cable machinery is shown in the photographs. The intermediate

pany's shops, and is mounted with a Form K automatic circuit breaker, of 1,000 amperes capacity, manufactured by the General Electric Company, a voltmeter of 600 volts capacity, a Weston ammeter of 1,000 amperes capacity, a positive and negative switch, a double pole double throw reversing switch and 48 small switches for the rheostat.

A small electro magnet is mounted to one side of the circuit breaker, with its coils connected as a shunt to the motor circuit and provided with mechanism to open the circuit breaker, when the potential on the line falls below 100 volts. With this arrangement the automatic circuit breaker will automatically open the circuit from an excessive amount of current or from the failure in the supply on the lines.

The starting rheostat consists of 12 separate boxes made of white pine, each box contains 680 ft. of No. 9 galvanized iron wire, wound in spirals 2 in. in diameter, and placed in a zigzag shape with glass partitions between them. Water is piped to each box and a continuous stream is passed through and around the coils to keep the iron wire cool during the time the rheostat is used in operating the motor at very low speed. The glass partitions between the coils prevent the electrolytic action from destroying the iron

wire. Each box has four points of resistance in series which are connected to quick break switches on the switch-board, and the twelve boxes are connected in parallel. The arrangement of the resistance coils gives from 50 to 1,080 amperes at 500 volts for any desired length of time. The rheostat is connected in on the negative side of the motor to prevent a leakage of current through water connections.

The operation of a cable line, especially one which contains numerous long and heavy grades, is one of the most severe tasks that can be put on a motor. The change of load to which the motor is subjected on this cable line ranges from 20 h. p. acting as a generator to over 650 h. p. as a motor. The average horse-power required to operate the road estimated from the total during the month of July was 146 h. p.; that required to drive the cable including the friction of the machinery and motor without the cars is 117 h. p. The wide variation of load does not take place at all times during the day, but usually during the morning and evening when the cars are heavily loaded and the extra trains are out. The trains, at times, become blocked from various reasons, and if this occurs at or near the foot of a heavy grade the motor has from six to eight heavily loaded trains to pull up the grade. After they pass over the top of the hill, and are descending they pull the cable above speed and cause the motor to generate a current which is delivered back to the Central avenue power house, and from there to the electric lines. The extreme maximum and minimum loads do not continue long, therefore the heating effect on the motor from the excessive current which reaches 900 amperes at times, does not alter its temperature perceptibly. The sparking at the brushes and the armature reaction due to the extreme overloads were the principal difficulties to overcome. If a larger motor had been used so the peak of the load would be approximately the rated power of the motor, if a properly designed shunt motor, it would run sparkless. Such a motor would, however, not only run with poor efficiency, due to the small average load required, but would greatly increase the investment over what is really necessary. The interest on the larger investment together with poor efficiency would increase the cost of operating.

The most interesting feature to the financial man, is the cost of operating as compared with the steam plant. The items of operating expense given below, are those which have been affected by the change of power from steam to electricity. Under the head of steam plant the items are taken as an average per month during the year 1896; those under the head of electric motor are taken for the month of July, 1897:

#### OPERATING WITH STEAM PLANT.

|                                      |            |
|--------------------------------------|------------|
| Engineers, firemen and oilers.....   | \$ 205 00  |
| Repairs on engine and machinery..... | 58 00      |
| Oil and waste.....                   | 21 45      |
| Coal.....                            | 604 55     |
| Water.....                           | 46 52      |
| Total.....                           | \$1,025 52 |

#### OPERATING WITH ELECTRIC MOTOR.

|                                                                                                     |           |
|-----------------------------------------------------------------------------------------------------|-----------|
| 64,458 kilowatt-hours consumed during the month of July, 1897, at \$0.048647 per kilowatt-hour..... | \$ 313 57 |
| Motorman.....                                                                                       | 50 00     |
| Oil and waste.....                                                                                  | 2 00      |
| Water for rheostat and workroom.....                                                                | 2 50      |
| Total.....                                                                                          | \$ 368 07 |

The foregoing figures show that \$657.45 was saved during the month of July, 1897, as compared with the average cost per month of operating the steam plant during the year of 1896.

The men that repair and splice the cable attend the motor also, and one-half of their salary has been charged above as motorman.

The cost of producing a kilowatt per hour as given above was taken from the actual cost of operating the Central avenue power house during the month of July, but does not include the interest on the investment, or the allowance made for depreciation in the value of the machinery and building.

### A FINE TRIBUTE.

One of the happiest testimonials we have ever seen, was posted on the boards of the New Orleans Traction Company, on September 20, and is evidence of that spirit which most firmly binds the employe to the manager in the mutual interests both serve. The bulletin reads as follows:

#### NOTICE.

To Employes:—

It is with the greatest regret that the management announce the resignations of Messrs. B. Willard, general superintendent, W. Nelson Smith, chief electrician, and Ben Johnson, assistant superintendent and claim adjuster. These gentlemen, finding it to their advantage to accept positions elsewhere, were perforce of necessity obliged to relinquish their duties with our company, and we were obliged with reluctance and regret to bid them good-bye. They have all distinguished themselves in their respective departments of construction and operation, and to their skill, energy and loyalty, the company is largely indebted for its present status of excellence. They will be greatly missed in our councils and our work, and I am sure that all the employes will join with those of us who were immediately associated with them in an official capacity, in regret at their leaving, and will follow them with us, with the heartiest of good wishes for their further success in the new fields to which they go.

Obligated thus to do without the help of such faithful and intelligent workers, it is ours, both officers and employes, to exhibit in larger measure, our devotion to the interests of the company, and especially at this time, and under present discouragements, to fail in nothing that shall tend to improve the service and general operation of the road. We may have the utmost faith in the splendid future awaiting our great system, and we may anticipate this by bringing to bear forethought, care, accuracy and courage in the performance of every duty falling to our respective positions.

C. D. WYMAN.

General Manager.

### FREIGHT LINE AT BALLSTON SPA.

Considerable interest is being manifested in the completion of the Ballston Terminal Railroad, at Ballston Spa, N. Y. This road has been contemplated for some time, and within the last three months, under the energetic management of J. C. Stanton, gives evidence of early completion.

The power house, which is a commodious and substantial structure, of modern ideas, is now completed. The selection of Hamilton-Corliss engines, Westinghouse electrical apparatus, Brill cars, and Mayer & Englund overhead material, indicates the excellence of the work, which will be completed this month.

The road is largely a freight line, which will be handled by electrical locomotives designed especially for the Ballston Terminal Railroad, and are now being erected at the works of the J. G. Brill Company, in Philadelphia. The passenger service will be taken care of by the ordinary passenger cars.

# CROSSINGS OF STEAM RAILROADS AND STREET RAILWAYS.

The decision of the supreme court of Pennsylvania, rendered in May last, whereby the Scranton & Pittston Traction Company (acting as contractor for the Lackawanna Street Railway Company) was permanently enjoined from crossing at grade a steam railroad operated by the Delaware & Hudson Canal Company suggested the desirability of collecting data upon the subject of crossings and the examination of the regulations prescribed by statute and by municipalities.

Street railways are those which are constructed in streets, whether on, below or above the surface is immaterial, along and over which cars are propelled as common carriers for the accommodation of the people living on and near the highways, and to facilitate the transportation of passengers. They may be constructed within or without the limits of municipalities and when laid for the purpose of facilitating the use of the street by the public are street railways, independent of the motive power that may be used. When some of the first steam roads were chartered the idea prevailed that the tracks laid by them would be admirable for wagon traffic, but it was soon abandoned, and at present it is the purpose of "facilitating the use of the highway by the public" that serves in a great measure to distinguish the street railway from its elder brother. While this distinction is as sharp as ever, the street railways have in many instances proved to be successful competitors of railroads. Most electric interurbans carry express and light freight as well as passengers, and this competition is perhaps one reason why the steam roads have made such strenuous efforts to prevent electric lines crossing their tracks at grade. To prevent grade crossings means in a majority of cases such increased cost as to prohibit the construction of the electric road.

Railroads were essentially interurban roads in their conception and have remained so except in the large cities, where there is a suburban business. In the beginning street railways were distinctly urban; the street car was evolved from the omnibus and for convenience provided with a track to run upon; next the cars were provided with trucks; then came cars with mechanical motive power, which made increased size possible and led to double truck cars. All these vehicles were for urban traffic and entitled to the use of the streets and also to cross steam railroad tracks without being subject to more restrictions than would a carriage or omnibus. Extensions of street railways to run between different towns could not be predicted, but bearing in mind that they are for the same purpose, it is not apparent why the interurban car should not have the same privilege of crossing railroad tracks as did the stage coach.

The status of street railways and of railroads and their rights in the streets is very clearly set forth in the decision of the supreme court of Indiana in the case of the Chicago & Calumet Terminal Railway Company against the Whiting, Hammond & East Chicago Street Railway Company, decided in 1891. The law regarding crossings as there

stated is that which obtains in most of the states in the absence of special statutes providing for the interlocking of grade crossings or placing the subject in the hands of the railroad commissioners. (Indiana has such a statute passed in 1897, which will be referred to later).

In this case the street railway company had secured franchises and licenses from the cities of Hammond and East Chicago and from the county commissioners, permitting the building and operation of an electric railway which would cross the tracks of the railroad company at grade at five different points, at all of which the railroad was crossed by streets or highways. The street railway had completed its lines with the exception of the crossings, and was ready to construct "jump crossings" at its own expense. The railroad company refused to permit the construction of any crossings except upon the conditions that the street railway would agree to certain requirements, covering the expense of maintaining gates and flagmen at these points and the future construction at its own expense of interlocking switches as may be demanded. The street railway applied for an injunction to prevent the railroad from interfering with it in constructing the crossings, which was granted; the railroad appealed to the supreme court, which sustained the injunction.

The court said in part:

"It is the settled law of this state that the public takes only an easement in the streets of a city or town, and if a steam railway company lays its tracks upon such streets, the abutting owner of the fee whose title extends to the center of the street is entitled to recover damages. (T. H. & I. R. Co. v. Scott, et al., 71 Ind., 29; Eichels v. Evansville St. Ry. Co., 78 Ind., 261; Cox v. Louisville, etc., R. R. Co., 18 Ind., 178; Sharpe v. St. Louis, etc., Ry. Co., 19 Ind., 296; Ross v. Faust, 51 Ind., 171; Nelson v. Fleming, 56 Ind., 310; Anderson, etc., R. R. Co. v. Kernodle, 54 Ind., 310; Roelker v. St. Louis, etc., Ry. Co., 50 Ind., 127).

"The basis upon which this rule rests is that the appropriation of the soil over which a street passes for the construction, operation and maintenance of a steam railway is a new or additional appropriation to that of the easement granted to the public, which entitles the abutting owner to such damage as he may sustain thereby. (Cox v. R. R. Co., supra).

"It follows from this that the steam railway which obtains a right of way over a street and constructs its railway thereon obtains something more than an easement; it obtains property rights in such right of way subject only to the right of the public to travel over the streets. And the question here presented by challenging the sufficiency of the complaint is whether the same rule applies to street railways; that is, whether the appropriation of a street to the use of a street railway is a new and additional appropriation, a new and additional burden to that of the easement of the public generally. It is conceded by the appellant (the rail-

road company) that a street railway is not an additional burden upon the fee in the street, although appellant claims that strong reasons exist against the doctrine. It is conceded, however, that the courts have quite generally held such use of a street is not an additional burden; that it is simply an extended use of the right which the public acquired in the first instance. This concession we think admits that appellant has no cause to complain of the action of the circuit court. The writer of this opinion (Judge McCabe) seriously doubts the soundness of the rule thus conceded by the appellant. It is true that street railway corporations have a right to the use of the public streets of a city or town for the purpose of ordinary travel over them in the same way that any other portion of the general public may enjoy that right. But when they obtain a right of way over such streets to lay down their tracks on such streets, they obtain and secure a right and an interest in the street that the general public does not and cannot have and enjoy. They obtain to all intents and purposes as much a property right in their right of way in the streets attached to the soil as does the steam railroad laid in such streets. This is so because such companies are authorized to mortgage their corporate property and franchises to secure the payment of loans of money to the corporation. Such power necessarily carries with it power to sell such property and franchises at sheriff's sale to make the money. (2 Burns' R. S., 1894, Sec. 5, 473; New Orleans, etc., R. R. Co. v. Delaware, et al., 114 U. S., 501.)

"How such a right can constitute nothing more than the easement has in the street it is difficult to understand. If the location and operation of a street railway on a public street is no new nor additional burden on the soil, but rests on the easement the public has in the street, then it would seem to the writer the company need not obtain any license, permit or franchise from the municipal authorities to construct its tracks in the public streets of a city. And yet it is the settled law in this and other states that a street railway cannot be laid upon the streets of a town or city without a grant of a license or franchise therefor either by the municipality or the legislature. (Indianapolis Cable St. Ry. Co. v. Citizens' St. Ry. Co., 127 Ind., 369; 23 Am. & Eng. Ency. Law, 946-947, and authorities there cited.)

"No other part of the public is required to obtain a license or franchise to use or enjoy the easement of the street. The very fact that a franchise is required to authorize and justify a street railway company to lay down its tracks on a public street seems to the writer a sufficient reason for saying that such was not one of the uses in contemplation when the street was opened and dedicated. Besides, it is settled law that the street railway company, when once its track is constructed on a street, has rights over that part of the street where its track is located superior to those of the public who enjoy only the easement in the street. For instance, the public must turn off of the street railway track when met by the street railway cars. (23 Am. & Eng. Enc. Law, 990-991, and authorities there cited.)

"But the overwhelming weight of authority seems to settle the law both in this state and elsewhere that a street railway is not an additional burden to that of the general easement in the street and that the owners of the fee are not entitled to damages on account of the construction thereof on a public street. (Eichels, et al. v. Evansville, etc., Co. et al., supra; Indianapolis Cable Co. v. Citizens' Co., supra; Elliott v. Fair Haven, etc., R. R. Co., 32 Conn., 575; Hinch-

mann v. Paterson Horse R. R. Co., 17 N. J. Eq., 75; Jersey City, etc., R. R. Co. v. Jersey City, etc., Horse R. R. Co., 20 N. J. Eq.; Cincinnati, etc., St. Ry. Co. v. Cumminsville, 14 Ohio St., 523; Hobart v. Milwaukee City R. R. Co., 27 Wis., 194; Attorney General v. Metropolitan R. R. Co., 125 Mass., 515; Brown v. Duplesses, 14 La. Ann., 842; Savannah & Thunderbolt R. R. Co. v. Mayor, etc., 45 Ga., 602; Pedicord v. Baltimore, etc., Ry. Co., 34 Md., 463; 23 Am. & Eng. Enc. Law, 954, 955, 956 and 957, and authorities there cited.)

"These authorities and others that might be cited so firmly settle the rule that it could not now be departed from without serious disturbances of vested property rights. The use of the street by the appellant (the railroad company) is subject to the easement in the public and the burden of keeping the street crossing over its tracks in such a condition as not to impede or obstruct the public easement and use of the street by the public generally is a burden already resting on the appellant. This burden is in no way to be added to or increased by the crossings appellee (the street railway company) proposes to construct. So long, therefore, as it is the settled law of this state that a street railway is not an additional burden to that of the easement the general public has in the street, and that the street railway company's right to use the street is founded on that easement, that long it must be held that the right of such street railway to cross over the tracks of a steam railway laid on such street is subject to no conditions other than those to which the general public is subject in traveling over such streets. When the steam railway company obtains its right of way over and along a public street, it does so subject to the right of the general public to use that street and the street crossings over its tracks, and it is generally incumbent on such steam railway companies to make such crossings as passable for the general public as they were before the construction of their tracks thereon. The duty therefore is incumbent on the steam railway company only to make the crossing as passable as it was before the construction of its tracks thereon for the public generally, or as nearly so as practicable. That does not impose the burden of providing cross rails and tracks for the street railway to make the crossing. But the street railway is proposing to furnish all that itself and to be to all the expense of making the crossing and connection. Appellant contends that this will be a burden and a hindrance to the free and unobstructed use of the appellant's steam railway which it is claimed is a taking of private property without just compensation in violation of the Constitution. True, it is a hindrance and an obstruction to the use of appellant's steam railway. But having obtained its right of way subject to the burden of the easement in the public generally, and the street railway being entitled to the use of that easement, all the rights appellant obtained in the street for its steam railway were subject to the right of the street railway to use the street. In short, the appellant's rights obtained in the use of the streets for its steam railway were subject to the burden of the appellee's use thereof in the ordinary and proper manner for its street railway. The complaint shows that appellee was only proposing to use the streets at the crossings in the ordinary and in a proper manner for the construction of street railway crossings, and that it had been hindered and obstructed therein by the appellant in the use of force. It would therefore not be a tak-

ing of private property without just compensation, because it does not propose to take from appellant anything it ever owned. It never owned its right of way over and across the streets named free from the burden of the public easement, a part of which belongs to the appellee, the street railway. The conclusion we reach is not in conflict with the case of the Indianapolis, etc., Gravel Road Co. v. Belt Railway Co., 110 Ind., 5, cited and relied on by the appellant. In that case the gravel road company was a private corporation and the owner of the gravel road before the construction of the Belt Railway. The property of the gravel road company was not acquired subject to any easement in the public or anyone else to construct a railroad across its gravel road. It was there held very properly that while the statute confers upon railroad companies the power to cross highways and to do so without the payment of compensation so far as the public is concerned, yet that a gravel road owning its road owns it as anybody else owns his property, and that private property cannot be taken by anyone without just compensation, nor, except in case of the state, without

for its street railway. (2 R. S., 1894, Secs. 5165 to 5168; R. S. 1881, Secs. 4155 to 4158.)

"The right to pass over a highway by a steam railway is subject to the easement of the public, a part of which is owned and enjoyed by the street railway."

### ELECTRICITY FOR MERIDA, YUCATAN.

The excellent system of horse, or rather mule railway, at Merida, Yucatan, will be converted to electric. The work of changing several of the principal routes is already under way, and it is hoped soon to bring the entire system up to date. This road is one of the most progressive of the Central American properties, and the energetic young manager, N. Escalante y Peon, some time since laid out a fine pleasure resort which has proved a great success.

Our illustrations show street scenes in Merida, the view at the left being that of the Plaza de la Independencia, and the one at the right a street scene on 60th street, Merida.

PLAZA DE LA INDEPENDENCIA—MERIDA, YUCATAN—SIXTIETH STREET.

such compensation first assessed and tendered. (Art. 1, Sec. 21, Constitution of Indiana.)

"And it was there further held that the building of a railroad across such gravel road would be a taking of private property within the meaning of the section of constitution referred to, on the ground that it was an incumbrance on the property. Manifestly that case has no application here because the gravel road company acquired its property in the gravel road, not subject to, but free from any easement or incumbrance of any kind whatever. Not so with the appellant, the steam railroad company, in the case now before us. As we have already seen, it acquired its rights subject to the easement and incumbrance against which it admits by its assignment of error it has made forcible resistance.

"The same principle applies to the crossing over appellant's tracks where they cross Indiana Boulevard, a public highway of the county. The statute provides that the county board may grant the right of privilege to a street railway company to use any public highway of the county

### CONSOLIDATION AT BIRMINGHAM, ALA.

The Birmingham, Powderly & Bessemer Railway Company, operating 13 miles of steam dummy road, has been absorbed by the Birmingham Railway & Electric Company. The property transferred includes the 13 miles of track, three locomotives, 14 passenger and freight cars, all tools and 350 acres of land between Cleveland and Bessemer. This line will soon be equipped for electric traction and will complete a circuit of trolley roads taking in Bessemer and the whole Birmingham mineral district that far. General Manager McClary contemplates using a voltage of 750 on this line.

The Birmingham (Ala.) Railway & Electric Company has provided a special car for conveying the pupils of the Athenaeum at East Lake to and from the city. Each morning the car leaves the Morris Hotel in charge of one of the teachers and returns in the evening. Only the school children are accepted as passengers.

## AN OVERHEAD ELECTRIC SYSTEM WITHOUT THE TROLLEY.

In a paper read before the British Association for the Advancement of Science at its meeting in Toronto, J. G. W. Aldridge reviewed at some length the present conditions of electric traction in England. He stated that there are 103.5 miles of tramway line operated by the trolley, 15.75 miles by the third rail, 6 miles by storage batteries and 4 miles by the conduit system. The relative costs for construction and equipment per mile of single track are £5,500 for the trolley, £10,000 for the open conduit system and £7,000 for the closed conduit. After mentioning that for economy and sound financial success the trolley system has proved itself to be the best all around device for tramway operation he said that there are and will be instances where overhead wires will be absolutely prohibited in certain cities.

The open conduit system is so expensive in its construction as to be out of the question for most localities and no closed conduit system has shown sufficient merit to justify its serious consideration. The author then introduces a new system of his own design which is intended to do away with the overhead contact wires. The general plan is to have two supports at the extreme ends of the car and a wire stretched between them as shown in the cut. Poles of the ordinary pattern are planted at intervals of 50 ft. or within the length of the span of wire on top the car. From the pole there extends a horizontal arm over the track and to this is pivoted a support for a rod, ribbon or roller, which is connected to the feeder line. When the wire on top the car strikes this contact the springs of the pivoted arm permit it to lift and swing slightly in the direction in which the

car is going yet hold it with sufficient rigidity to give good contact. Before the collecting wire passes from under it another contact is reached so that at all times the electrical apparatus in the car is in circuit.

If at any place it is impractical to set the poles at the required distance, a surface contact plate can be put in the track midway between the poles, and can be regulated by electro-magnets just as a closed conduit system is to avoid keeping the contact always alive. A contact shoe is fixed under the car in this case.

The advantages claimed for this system are: Fixed overhead wires are avoided; the poles are considerably shorter than generally used for such purposes; the stay wires and anchor poles at curves are absent; the poles are at regular intervals and can be used for lighting. The cost of such a system would be about 25 per cent more than the trolley but much less than the conduit systems.

## ACCELERATION TESTS AT SCHENECTADY.

Among the many events connected with the visit of Lord Kelvin to the works of the General Electric Company at Schenectady, N. Y., none possessed more interest to the electrical railway engineer than the acceleration test made upon the experimental track which runs along the heel path of the Erie canal for a distance of nearly two miles.

The car used was one of the familiar American elevated railway type provided with four 50-h. p., 500-volt 90-ampere motors, known as the G. E. 57, mounted two on each of the trucks. On each armature shaft was a 33 tooth pinion meshing into a 52 tooth gear fixed to the axle. The total weight of the loaded car was 25 tons, including trucks, motors and passengers.

At present, owing to the long distance which must be covered by elevated railways and the frequent stops and starts resulting from the nearness of stations, the question of quick starting and stopping has become a serious matter. Quick stopping, is, however, well taken care of by both air and electric brakes leaving rapid acceleration as the point needing attention. Realizing this the General Electric Company has been experimenting for the past several months, with the idea of determining at what rate of acceleration the passengers would be annoyed.

As a starting requirement, W. B. Potter, chief engineer of the railway department, assumed that an increase in speed of three miles per hour each second would not be unpleasant and the car was equipped as already explained to prove or disprove the assumption. The only departure from ordinary practice was to reduce the gear ratio and use a controller which would admit sufficient current to give the required starting torque. In some of the previous runs the car had attained a speed of 28 miles per hour at the end of 10 seconds, while on the test under consideration the car was moving at the rate of 30 miles per hour, at the end of 10 seconds. On this particular run, 5 seconds after the controller handle was moved the car had attained a speed of 19 miles per hour; at the end of 10 seconds, 30 miles per hour; 15 seconds, 35 miles; 20 seconds 38 miles; and in 25 seconds a speed of 40.5 miles had been attained.

These figures convey no real idea of the rapidity of the start. However, a comparison with acceleration on steam roads may serve to bring out this point. An ordinary train seldom exceeds a speed of 10 miles per hour at the end of 10 seconds; just  $1\frac{1}{3}$  the speed attained in the same time by the test car. In a similar test of a regular elevated train at the end of 20 seconds the speed was only 13.5 miles per hour during which time 196 ft. had been covered as against 38 miles and 356 ft. in the case of the electric car.

The sensation due to the rapid starts was not unpleasant, and as the starting was perfectly smooth those standing were inconvenienced no more than is now the case with the elevated trains drawn by the slower steam locomotives.

The Brooklyn Rapid Transit Company has distributed some handsomely illustrated pamphlets advertising the special car service for theater, Sunday school and social parties. One circular explains the advantages of Brooklyn as a residence district, and with this was sent a pass for a complimentary trip over the routes of the company. H. Milton Kennedy is the general passenger agent and attends to all the special traffic.

## NEW WATER POWER STATION AT TAMPA.

Florida is usually considered a low, flat country and the statement that a water power of considerable magnitude has been developed will occasion surprise to many engineers. The Consumers' Electric Light & Street Railway Company, of Tampa, has built a dam across the Hillsborough river and a fine power station at a cost of \$200,000. The city of Tampa has increased very rapidly in population in recent years; it is now claimed that there are 25,000 inhabitants. The Consumers' Company has built up a railway system which is well suited to serve the present and future needs of the city. There are about 30 miles of track upon which 27 motor and three trail cars operate. Until the first of this year the electricity was generated at a steam plant which was the largest in the state.

Realizing the advantages of cheap power, water rights were secured and a dam and station, shown in Fig. 1, built on the Hillsborough river six miles from Tampa. The dam and flume are constructed of concrete masonry composed of the best Portland cement and flint rock taken from the bed of the river on the shoals at the dam, over 6,000 cu. yds. being used. The flumes occupy a space 110 ft. long by 24 ft. wide and 30 ft. high from the base, and to these flumes is joined the weir which is 132 ft. long and 19 ft. 6 in. high. At the end of this, is a waste gate 14 ft. wide, making the total length including retaining walls, 162 ft. At either end of this masonry are wings composed of dirt.

Parallel with the flumes and dam is located the power house, 150x50 ft. under which the water discharges upon leaving the wheels. In the masonry flumes are installed, four pairs of 36-in. McCormick horizontal water wheels arranged to operate separately or together. The machinery in the station is used not only for street railway service but also lighting and power. These departments are run separately, two pairs of wheels driving each, being belted to jack shafts located in the power house and 35 ft. from the turbine shafting. These jack shafts are driven by four 33-in. belts. At either end the jack shafts are coupled to the generators by clutch pulleys; the one to two 300-k.w. alternators for

the lighting, and the other to two 200-k.w. General Electric railway generators. The shafting and standards are mounted on heavy I-beams which rest on the masonry. The bearings throughout are of the ring self-oiling type.

On the opposite side of the station, 30 ft. from the main

FIG. 1.—DAM AND POWER HOUSE.

shaft, as shown in Fig. 2, is a 500-h. p. engine, belted to the jack shaft to which the water wheels are connected. The engine is installed as an auxiliary to be run in unison with the water wheels in case of low water. Under the boiler house, which is located opposite the station, is a large cistern where all the water for the boilers is filtered and treated when using steam. The steam machinery was that in service before the water power was developed.

At high water the river has a maximum power of 4,000 h. p. and the minimum is 800 h. p.; the four pairs of wheels now installed develop 1,500 h. p. One of the lines runs from the city to the station which is eight miles from the center of distribution. This road is laid with 56-lb. T-rails; the bonds, consisting of lead and scrap copper, are of Superintendent Munsing's design.

FIG. 2. INTERIOR OF POWER HOUSE, TAMPA, FLA.

## THE OLDEST STREET RAILWAY AIR-BRAKE COMPANY.

NCE more the Standard Air-Brake Company, of New York, exhibits at the convention of the American Street Railway Association, and as in years past its display will not be only interesting and instructive, but will illustrate the progress of the year in this work. Our pages have steadily chronicled the achievements of this enterprising concern until

in the brake it offers today one would not recognize the original. These changes have been made at the expense of great outlay and untiring study, until the perfected brake now offered and in service, would seem to leave no further improvement to be desired.

As is well known, it is the pioneer in street railway air braking and is to be commended for the determination shown in making the business the success it has become. Starting as it did in 1891, the company has seen the remarkable changes which have occurred in street railway practice. E. J. Wessels, the managing director, has shown very keen foresight in preparing to meet problems which he felt were certain to arise as street railroading became more and more an exact science. With commendable prudence several years ago he began the development of a motor compressor, by means of which it would be possible to equip any electric car or train without requiring any part of the car axle on which to mount such apparatus. The company has not been satisfied with apparatus that merely met requirements. Its ambition has always been to make its apparatus exactly what its corporate title implies, "standard." In order that this end might be secured, the company has spent a large amount of money and years of patient labor in solving the problem. Difficulties which would have daunted ordinary individuals have apparently not terrified it. Many varieties of apparatus have been tested and the wheat sifted out from the chaff. It is generally known that the company has been doing a very large business and that most of its apparatus at present in use has been in constant operation on the different roads for from two to three years. Mr. Wessels reports that the company's business thus far in 1897 has been a record breaker. Sales have exceeded those of any previous period. Collections have been very satisfactory. Since last convention the motor compressor has been installed in a large way on special roads. Various sizes are now furnished, ranging from 1 h. p. to 5 h. p. One of its best points is the ease with which the armature can be withdrawn by removing the front head of the motor. The motor is securely protected against dust and moisture by being iron clad. It is of the slow speed series, multipolar type. The frame being of steel, gives lightness with maximum capacity. The insulation is such as to guard against possible grounding or breaking down. There are some interesting devices for preventing the the ingress of oil from the bearings and compressor. The motor compressor runs at 600 r. p. m. and does not require to be in operation much of the time, as it very quickly replaces air which has been drawn from the storage reservoir comprised in the Standard air-brake system, when making stops.

The Standard Air-Brake Company's axle driven compressors have been making a phenomenal record and have given great satisfaction wherever installed. Since last convention

the company has sold hundreds of these outfits, and "repeat" orders have come, not only from the Continent of Europe but from Australia, where a large number of different types of Standard outfits are in service. The single acting compressor Type A furnishes sufficient air to supply enough pressure for heavy cars, even though they are operated at slow speed. The Duplex double acting compressor, which was installed a number of years ago, is still in service, notably on the Buffalo railway, where 30 outfits are completing their third year of hard service. Although the air-braking apparatus has had to contend with slush, ice, dirt and changes in temperature, there has been little difficulty experienced in its operation. The interlocking controlling handle with which all Standard outfits have been supplied since last convention, has proved a great success and in no instance has there been a failure to accomplish the end sought, that is, the prevention of tampering with the apparatus on the part of careless or malicious parties. The company furnishes its own type of brake rigging and is prepared to equip a car with everything in the brake line down to the brake shoes. In fact, it prefers to do this, so that all parts of the brake rigging may be properly adapted for use with the Standard system. Within the past few months the company has greatly increased its capital stock and it is well known that all its purchases are made on a spot cash basis. By reason of its financial ability the company has always been able to buy to advantage and can therefore supply air-brakes at reasonable prices. Associated with Managing Director Wessels are some of the most noted international bankers in the world, making a strong combination, which gives railway managers a sure guarantee that whatever the company undertakes will be faithfully performed. E. H. Dewson, Jr., the company's chief engineer, is well known to the fraternity by reason of his experience east and west. H. P. Merriam, one of the company's engineers, is at present in Europe supervising the installation of a large number of air-brake equipments for which General Manager Wessels secured contracts. The company has been most fortunate in its selection of foreign representatives. They stand in the very front rank and include such names as Dick, Kerr & Co., Limited, London; Bergische Stahl-Industrie, of Berlin, Germany, and Noyes Brothers, Sydney and Melbourne, Australia.

## FUEL OIL ON THIRD AVENUE ELEVATED.

Experiments were recently made with crude oil as fuel for a train on the Third Avenue elevated, New York. The oil was carried in barrels in the coal bunk and sprayed on the fire with pumps. The result was far from satisfactory, the steam pressure falling to 45 lbs., and clouds of offensive smoke poured into the cars.

In many respects oil would seem to be an ideal fuel, but in spite of frequent trials on many steam roads it has failed to secure a footing. Recently a very thorough test was made on one of the suburban trains of a leading steam road in this city, but the expense was found to be nearly twice that of coal fuel, and after a continued effort to make a success of the experiment it was abandoned.

The Camden & Suburban Railway Company, on September 21, provided a street car collision as an attraction at Knight Park. Two cars were set on fire and started towards each other at a high speed, resulting in a realistic smash-up.

### NEW ELECTRICAL FEATURES ON THE LINDELL RAILWAY, ST. LOUIS.

Various temporary arrangements for testing the electrical conductivity of track joints have been devised and put in use from time to time, but it is doubtful whether there is anywhere in use a more completely equipped car for testing and maintaining bonding than that in use on the Lindell Railway of St. Louis, designed by Samuel Barnes, the electrical engineer.

It is an old horse car propelled by two old double reduction motors. Under each corner of the car is a shoe, making two contacts with the rail for testing the drop of potential across the rail joints, as shown in the engraving of the

nections of the testing circuits. It will be noticed that in addition to the voltmeter wires leading from each pair of shoes there is another set connected to a few battery cells and an electric bell circuit. This is for purposes of testing, to be sure that the shoes make contact, for if they do not make contact there can be no voltmeter deflection, and if one of the shoes should be raised or the circuit broken, considerable testing might be done with the operator under the impression that everything was all right because he got no deflections, when really the truth would be that the circuit was open. By using a few cells of dry battery and an electric bell it can be found in an instant whether the circuit is all right. The voltmeters used have the zero point in the middle of the scale and deflect to

TEST AND DRILL CAR OF THE LINDELL RAILWAY, ST. LOUIS.

car herewith. From the two contacts on each shoe, wires lead up to the low reading voltmeter terminals, and also to a test circuit explained later. Two voltmeters are used, one for each side of the track. The object in having contact shoes on each end of the car is to make it always possible to take the readings on joints between the car and the power station. The car is usually sent out during the night, when nothing but owl cars are running. Consequently the current taken by the test car plays an important part in the drop of potential at any one joint. Therefore, when the car is approaching the power station, or a negative feeder running to it, the shoes on the front end of the car are used, and when the car is going away from such a feeder those on the rear end are used. The voltmeters employed read to twelve-thousandths of a volt. Whenever a deflection of five-hundredths of a volt is obtained the joint is marked as bad and is rebonded. The accompanying diagram shows the con-

right or left according to the direction of the current. Thus there is no trouble with reversing the voltmeter terminals and no danger of mistaking a reversal for a zero deflection. The testing is done very rapidly and 90 miles of track have been tested in 27 hours. The crew consists of a motorman, a trolley boy and two men to read voltmeters. The car is not only used for locating faults but for remedying them. Under the center of the car on each side is a track drill for use in rebonding defective joints. These drills are driven by one of the motors. A belt is run from the commutator end of one motor as shown, to the horizontal shaft which operates both drills. When drilling is to be done the pinion is taken off of the motor so that it is free to drive the drill. The drill belt is kept tight with an idler pulley. It is not necessary to disconnect the drill machinery when the car is running as there is no harm in letting it revolve. The other motor propels the car when

the drill motor is disconnected for use with the drill. In order to get the car exactly in the position desired for drilling, the armature journal on the motor which propels the car is extended out each way, so that a man sitting in front of a

INTERIOR BOND TESTING CAR OF LINDELL RAILWAY.

drill between the wheels can attach a hand crank and move the car a little one way or the other. This makes a very convenient arrangement.

The main object of this kind of testing is, of course, to give the comparative condition of the bonds, so that repairs can be made on the joints that need attention without tearing up the pavement and rebonding all the track. There is no way to tell, unless it be by the melting of the snow around a joint in winter, whether one bond is in any worse condition than any others along the line, except by going over the whole track with a voltmeter and this test car affords a means of doing this rapidly. In the car, small double pole switches are used to manipulate the testing circuits.

As a substitute for the car, to test joints during hours of heavy traffic on the road, the company has a voltmeter case or stand, in which the low reading voltmeter is placed and the legs of the stand are arranged to make contact with the rail on each side of the joint. The legs fit the shape of the rail head and two sharp steel points on the legs insure a good contact on the head of the rail. A third leg or pointer shown in the drawing keeps it from tipping over. All that is necessary to do to take a reading is to set the device down on the rail with one

PORTABLE VOLTMETER STAND FOR JOINT TESTS.

leg on one side of a joint and the other leg on the other, — the voltmeter terminals being connected to the metallic contacts on the legs. It can be carried around in one hand and is very convenient, as a glance at the engraving will show.

The test car is also used for testing the insulation of the strain insulators in the span wires along the overhead lines. To do this one terminal of a voltmeter is connected to the trolley pole and the other terminal to a wire which is run up beside the trolley pole and which makes contact with each span wire a few inches from the trolley hanger. The deflection noted will then be due to whatever current flows to ground through the voltmeter and strain insulators on that span wire and the insulation resistance of the strain insulators can be determined by the usual formula

$$X = \frac{E R}{V} \text{ -- R}$$

where R = resistance of voltmeter,

E = full voltage between the trolley and the ground,

V = voltage as indicated by the testing voltmeter,

X = insulation resistance of insulators.

By connecting one terminal of the voltmeter to the ground and the other to the test wire which makes contact with the trolley the insulation resistance of the trolley wire hanger is measured. Thus the complete overhead and track electrical work can be tested with this car with a minimum of labor. The car is made of scrap materials and cost little save the expense of putting it together.

#### MACKENBEUREN-TETTANG RAILWAY.

The electric railway between Mackenbeuren and Tettang, Wurtemberg, was built for passenger and freight service. It is a single track line, nearly three miles in length, with 15 turnouts. The track is standard gage and laid with 44-lb. rails. Current is generated at a water power station on the Schussen river where there is a fall of 8½ ft.; there are two turbines of 45 and 75 h. p. capacity, respectively. There is also a reserve steam plant with a 60-h. p. engine and boiler. The larger generator is of the four pole type and gives a voltage of 700 for the trolley line, while the other machine is a 2,100-volt alternator for lighting and power purposes. The trolley line is supplemented by a feeder and the two are joined together at intervals of 220 yds. Two motor cars are in service, each equipped with two 25-h. p. motors and have compartments for mail and small baggage. The motors are connected in series with rheostatic control.

**SOME METHODS OF MAKING EFFICIENCY TESTS OF STREET RAILWAY MOTORS.**

FRANK B. PORTER.

It becomes many times advisable, even necessary, in street railway practice to make an efficiency test of the car motor, as, for instance, on the equipment of a newly constructed system or upon the proposed purchase of new motors for a system in operation. Probably each manufacturer upon application will readily supply a prospective purchaser with data and plotted curves of speed, torque, horse-power and efficiency for various amperes used, but it is a business proposition that the buyer should examine somewhat for himself and make comparative tests under like conditions of the different motors before a contract is closed. Again, when it becomes desirable to make a change in the winding of armature or field coils of the motor, which is sometimes done in street railway practice to meet some special condition of service, it is well to make an efficiency test after rewinding, as a check on the accuracy of the calculations made previously.

It is the object of this article to describe with some detail a simple method of efficiency test in use in many electrical manufacturing shops which will give good results when applied to the street railway motor in the repair shop. With care, these results should be quite accurate, and data from comparative tests under like conditions of various types of railway motors would prove most instructive.

Take an axle shaft and fit to it a pulley, having deep double flanges, both external and internal, as shown at

A and B in the cross section. Also fix to this axle a gear such as is used in service to engage with the armature pinion, and a collar to take up end play; there should be no end play, the motor fitting exactly between axle gear and collar, but not wedged so as to produce excessive friction. Place the axle shaft when equipped as above, into the motor axle bearings as though it were the car axle with the motor in place. Construct a hard-wood beam of cross section sufficient to fit easily in between the two flanges of the pulley, say of about 1 in. in width. Cut out a portion of the beam so as to fit the periphery of the pulley for an arc of a few inches, or about 75° as at C, Fig. 1.

Bore the beam on each side equidistant from the center of the surface of contact with the pulley, and in these holes place the eye bolts D with nuts on top to enable them to be tightened at will; have several strands of 3/4 in. cotton rope spliced into each eye bolt around the under side of the pulley as at E, so that by screwing down the nuts the amount of friction can be regulated and the motor load consequently varied. Notch the end of the wooden beam at F, as a bearing for the edge G. Move up an ordinary platform scale, such as is used in the shop for weighing material, and place upon it four car spring rubbers; on these rubbers rest

a block having a triangular section, so as to offer an edge to the beam, and allow an exact measurement of distance between the center of the pulley and this knife edge, to be made. Place a cut-out, a fuse, a variable resistance and an ammeter in series with the motor with a volt meter in shunt as in Fig. 2.

After turning on the current and starting the motor, any desired load can be obtained by tightening the nuts of the eye bolts, that is, by increasing the friction between beam and pulley. If the horizontal distance from the center of the pulley to the bearing point of the beam on the scale platform were equal to the radius of the car wheel the pounds indicated upon the scale would be the pull at the periphery of the car wheel for the current passing; if this distance were equal to four times the radius of the car wheel, the scale reading should be multiplied by four to obtain the pull at the car wheel. By placing a tachometer against the end of the axle, a speed reading, usually in revolutions per minute, at any load may also be obtained. To calculate the horse-power developed by the motor for any given amount of current passed, proceed as follows: Multiply the horizontal distance, in feet and decimal parts, from the centre of the pulley to the bearing, on the scale by two, and this result by  $\pi$  (3.1416), this gives the circumference of the sweep of the beam, were it free to move; multiply this result by the revolutions per minute, as read from the tachometer, and the result is the speed in feet and decimal parts per minute. As the voltage is not apt to be constant, and it is necessary to assume a constant standard of voltage in comparing speeds in different tests, or in taking many different readings as data from which to plot curves, it will be well to assume a constant of 500 volts as a standard, and correct each speed reading to conform to this. To do so, divide 500 by the reading of the voltmeter, taken at each speed reading, and multiply the observed speed by the result. Multiplying this calculated speed by the pressure on the scale in pounds and dividing the result by 33,000 gives the horse-power that would be exerted by the motor at 500 volts and the amount of current used as noted when readings were taken.

Multiplying the voltage (500) by the indicated amperes and dividing this result by 716 gives the horse-power supplied to the motor were the voltage 500, and dividing the horse-power exerted by the horse-power supplied gives the efficiency of the motor. Expressing the above process in algebraic formula, as perhaps presenting the operation more clearly to those familiar with their use:

- D Distance from horizontal center of axle to bearing on scale in feet and decimal parts,
- $\pi$  3.1416,
- R Revolutions per minute as recorded by tachometer,
- E Indicated voltage as read from the voltmeter,
- I Amperes,

$$T = \text{Force applied to scale measured in pounds,}$$

$$\frac{2 \pi D R T}{33,000} = \text{Brake horse-power actually exerted.}$$

$$\frac{(2 \pi D R \times \frac{500}{E}) T}{33,000} = \text{Brake horse-power exerted by motor if voltage had been 500,}$$

$$\frac{E I}{746} = \text{Actual horse-power supplied to motor,}$$

$$\frac{500 I}{746} = \text{Horse-power supplied to motor at 500 volts,}$$

$$\frac{2 \pi D R T}{\frac{33,000}{E I}} \text{ or } \frac{(2 \pi D R \times \frac{500}{E}) T}{\frac{33,000}{500 \times I}} = \text{Efficiency of motor.}$$

When the motor is started in making a test, water should be poured into the pulley between the flanges of the inner circumference to prevent overheating, also the face of the pulley should be lubricated to insure an even friction, and a constant pressure on the scale, without which no accurate reading can be taken; more important is this in regard to the speed reading. Many experimenters think it advisable to use a separate means of load when taking this reading, and rigidly couple the armature shaft of the motor being tested to another, which it drives as a dynamo, delivering current back to the line, and use a variable field shunt as a means of regulating the load. If this latter method is followed in taking speed readings they should be used in connection with the scale readings taken when the motor was passing the same amount of current (amperes).

If the beam be constructed so that the horizontal distance from the center of the pulley to the bearing on the scale equal the radius of a circle 33 ft. in circumference, it will simplify the calculations considerably, and, besides, a beam of this length should be of about the right design for an ordinary platform scale; the use of a shorter one perhaps causing an overload when the heavier currents are passing. The scale should of course be balanced with the weight of the beam, block, rubbers, etc., when in position, before the motor is started and the test commenced.

By placing the pulley and beam first on the armature shaft and obtaining the horse-power exerted for a given amount of current used, and then changing to the axle and making a test at the same load, the horse-power lost in the friction of the gears and axle bearings can be determined.

If the motors are already under the car, and it is wished to make a test without removing them, place a screw jack under each side of an end of the car and raise it until there is a very slight amount of friction between the wheel and the rail. A bell crank lever may be designed, as in Fig. 3, and securely fastened to a pivot at A, so that when the drawbar is coupled to it at B, and the current turned on, (the motor at the other end of the car being cut out) the pull exerted at B will be transmitted to C and may be measured on a scale as

before. The load can be varied, and consequently the amount of amperes passed, by lowering gradually on the jacks, increasing the friction between wheel and rail. The speed at any load may be obtained by taking off a journal box cover and applying the tachometer to the end of the shaft and a calculation made of the horse-power exerted at the drawbar for any given amount of current used. To do this multiply the the indication on the scale by the quotient obtained from dividing the long arm of the lever by the short one. Multiply this result by the speed in feet per minute, and divide the product by 33,000. The algebraic formula in this case is:

$$D = \text{Diameter of car wheel in feet and decimal parts,}$$

$$\pi = 3.1416,$$

$$T = \text{Scale reading in pounds,}$$

$$L = \text{Length of long arm of lever,}$$

$$L' = \text{Length of short arm of lever.}$$

$$S = \text{Speed in revolutions per minute,}$$

$$h. p. = \text{Horse-power.}$$

$$\frac{T \frac{L}{L'} D \pi S}{33,000} = h. p.$$

In making this test, care must be taken to see that the lever is securely pivoted at A; for if not, as the friction increases between the wheel and the rail, with starting resistance cut out at the controller, a runaway car may result and a general mix up of the lever, jacks, etc., take place. Again, whatever this pivot is fastened to should be securely anchored. It would not be good practice to use any part of the car house construction, as a beam or sill, for this purpose, for unless it were especially strong we might have a nineteenth century illustration of Sampson and the Philistines. By taking two posts, as shown in Fig. 3, about 14 in. in diameter, with the pivot between them, and sinking them some 7 ft. in the ground, a safe and suitable structure can be easily prepared. The friction of the lever upon this pivot should be made as small as possible, having a smooth bearing with lubricant applied.

It must also be observed that there are no depressions in the rail where the car wheels revolve or a loss in energy would result in the form of a blocked wheel and not appear as pull at the drawbar. Some lubrication of the rail under the wheel may be necessary, a little powdered soapstone will probably be found sufficient; also clean wheels and a clean and smooth rail under the wheel. The lever should be provided with a brace rod and turn buckle, as shown at F in Fig. 3, in order that it may keep its shape under stress and be adjustable should the angle vary somewhat by shrinkage.

The horse-power of both motors acting together in either series or multiple may be found for any given amount of current used by noting the pull at the drawbar, using the same lever as in the preceding test and obtaining the speed in an actual run by means of a Boyer speed recorder or a tachometer, belted to the axle, the motor using the same amount of current in each case. In this last method, however, the horse-power developed in overcoming the friction in the gears and axle bearings would not be included in the result, as the drawbar pull would be made with the car resting on the rail, and the wheels consequently not revolving unless they should slip as the starting resistance is cut out at the controller and large amounts of currents passed.

In conclusion it should be reiterated that care must be exercised in the preparations for a test, and absolutely like conditions must prevail in comparative tests in order to make the results valuable.

## RECORDING WATTMETERS FOR STREET CARS.

The advantage of exact measurement of station output has long been recognized, and the requisite meters provided, but to record the ever varying energy used on a car traveling over all conditions of road, involves difficulties almost unsurmountable. The new meter which has been placed upon the market after a number of years of experimental work, is intended for installation in the car, like a cash register. It records the actual energy used by the car. A few trials determine the proper energy consumption per car per trip under various conditions of track and traffic. Subsequent readings of the meter determine at once if energy is carelessly wasted, and thus serve as an effectual check on the motorman and condition of the motors.

Well authenticated data prove that meters on lighting circuits increase the lighting capacity of the station by nearly 30 per cent. Many railway managers agree that the average waste due to carelessness of the motorman, amounts to not less than 20 per cent of all the energy generated. The economy, therefore, which will be induced by the use of street car meters will mean a saving of half of the average waste or 10 per cent of the total energy generated. The profit from such economy is two fold: It saves, first, the cost of coal and water necessary to generate one-tenth of the total energy output of the station; and second it increases the receipts by increasing the car capacity without enlarging the station, or in other words enables the station manager to operate 10 per cent more cars without increase in the station equipment.

Car meters used in connection with station meters supply a beautiful system by which the detailed and combined efficiencies of a station are directly obtained and an account given of the energy developed by every pound of coal con-

FIG. 1.—METER IN CASE.

sumed in the station. The adoption of such a system will, by necessity, increase the efficiency of any station under intelligent management, since it reveals and locates with unflinching accuracy any causes of wasted energy.

The simple motor construction of the car meter, as shown in the accompanying illustration, is similar to that of the other forms of Thomson recording wattmeter, but new

FIG. 2.—THOMSON RECORDING STREET CAR METER.

conditions imposed by the rough service have been met by the careful design of the rotating parts. The unavoidable vibration, due to rough tracks, demands a low drop in the armature in order that contacts may not be injured by sparking. High torque is also a requirement so that heavy brush pressure insuring perfect contact can be used. The sudden and wide variation of current requires a meter that will start quickly and slow down as soon as the current diminishes. The General Electric Company, claims high accuracy for its new car meter and also that it has the ability to withstand severe and continued use on the roughest tracks. The meter is now made for 500-volt circuits in sizes for 25 or 50 amperes with a liberal provision for overloading.

## THE ELECTRICAL EXPOSITION FOR 1898.

Ever since the electrical show held in New York City during May 1896 there has been a feeling in the trade that it should not be the last. Its splendid success in the way of bringing trade to exhibitors has led to a very general demand that it be repeated.

A company has been formed and incorporated with \$20,000 capital, and a live up-to-date board of directors to conduct such an exhibition in 1898. The officers and directors are Cyrus O. Baker, Jr., president; Ferd. W. Roebing, vice-president, and George F. Porter, secretary and treasurer. These officers, with Leonard F. Requa, Chas. A. Lieb, J. W. Godfrey, and H. H. Harrison, constitute the board of directors. Executive committee, C. O. Baker, Jr., Leonard F. Requa, and H. H. Harrison. Marcus Nathan has been selected as general manager.

This insures a first-class exhibition. The new electrical inventions and improvements developed since the last show will be an important factor. The interest and coöperation of many manufacturers already assured will count for much towards making this a more complete demonstration of all the applications of electricity and its branches than was possible in the first exhibition in 1896.

E. T. Birdsall of New York has been engaged as consulting electrical engineer for the proposed Springfield & Southwestern Street Railway, Springfield, Mass.

## TROLLEY CARS AT DOVER.

Dover is the first city in England where the street railway system has been designed and constructed for electric traction. The work has been completed and the lines were recently opened for traffic. The equipment is largely of American manufacture and is of the best and most substantial design.

The Electrical Engineer of London has this to say: "The rails are of the girder type, weighing 87 lbs. to the yard, 30 ft. long, and laid on a continuous block of Portland cement concrete, 12 in. wide and 8 in. deep. Two motors on each car are of the G. E. Soo type, each capable of a nominal output of 25 h. p., and mounted on a Peckham truck. The motors are regulated by one or the other of two K2 series-parallel

## EXCESSIVE DAMAGES NOT ALLOWED.

A year ago the four year old son of Loren Fox was killed by an electric car of the Oakland Consolidated Street Railway Company and a verdict of \$6,000 was given to the father by the superior court. The railway company appealed to the supreme court and the verdict was set aside. The father of the boy is a poor plumber and in reference to the damages sustained by him on account of the loss of his son, Judge Van Fleet said:

"We think it quite manifest upon its face that the verdict was actuated by something other than a consideration of the evidence. When we regard the probable number of years to be taken in his schooling comparatively little valuable time would be left to be devoted to the service of the parent. And

CORNER FOURTH AND ADAMS STREETS, MARION, IND.

controllers, placed one at each end of the car. Eight of these motor cars have already been equipped and four trailers. The Peckham trucks appear to carry all before them in this country, as every electric tramway now running is using them. The car bodies, which are supplied by the Brush Electrical Engineering Company, are very comfortably fitted. They hold 20 passengers inside and 24 outside. Another feature of the car equipment is the placing of a meter on each car to measure the energy taken by the motors. In this way a check on the driver will be kept, so that any undue waste by careless use of the controllers may be prevented. The power plant consists of two McIntosh & Seymour engines, direct coupled to two 100-k. w. dynamos of the General Electric type. The switchboard is built up of two standard G. E. panels with additional panels for meters."

The Metropolitan road of Kansas City hauled 135,000 passengers Sunday, August 15. This is the best record for 1897, the average Sunday traffic being 110,000

while in no sense conclusive, we have the right, and it is most reasonable in judging of the probable character of occupation the deceased would have pursued, to regard, with the other circumstances surrounding him, the calling of his father, since experience teaches that children do frequently pursue the same general class of business as that of their parents."

## THE MARION CITY RAILWAY.

The street railway system of Marion, Ind., dates back to 1889 and unlike many roads built at that time was not built to sell. The original promoter of the enterprise was W. C. McWhinney, who associated himself with three other gentlemen and organized the Marion Street Railway Company. After operating a short time as a horse road the lines were rebuilt and equipped for electricity, the electric road being opened July 4, 1891. One of the stockholders withdrew and the company was reorganized in 1892 as the Marion City Railway Company. The officers are Eli Halderman,

president; C. W. Halderman, vice-president, and W. C. McWhinney, superintendent and general manager.

The road comprises 25.5 miles measured as single track, there being six miles of double track. There are four routes: The main line extends from City Park, 2½ miles north of the public square to Jonesboro, 7½ miles to the south; the double track is on this route from the square to the Soldiers' Home, 3 miles. There is a branch a mile long to the Normal College and also one from Jonesboro to Gas City, a mile distant. Route No. 2 is two miles long extending to the cemetery southeast of Marion. Nos. 3 and 4 are the lines to West Marion and York, respectively. The franchises for these lines were obtained at different times and are for from 30 to 50 years.

W. C. McWHINNEY.

The track is now laid with 60-lb. T-rails in 30-ft. lengths, on white oak ties 5 x 7 in. x 7 ft., spaced 2 ft. between centers. Wheeler rail joints are used, and the track is bonded with No. 0 wire. The sharpest curve is of 50 ft. radius and the steepest grade 5.75 per cent; there are but three grades. The lines cross the tracks of three steam railroads, one of them in two places, at grade. The special work at these points is of 87-lb. T-rails and was all furnished by the Paige Iron Works, Chicago. No. 0 trolley wire is used; it is strung on cedar poles 30 ft. long and 7 in. in diameter at the top, spaced 100 ft. apart; the cars, hangers, insulators, etc., were furnished by the Ohio Brass Company. There are four feeders, one 2 miles, one 3 miles and two 5 miles long; they are of No. 00 wire.

The power house which is one of the most modern and finest looking plants in the country, is located at Home avenue and 30th street. It is constructed entirely of stone, brick, iron and slate, excepting the floor which is of wood, and is completely fireproof. The front part of the building containing the engine and dynamo room is 52 x 87 ft., and the boiler room which adjoins it at the rear is 45 x 56 ft. In the building and foundations there are some 600,000 bricks. The roof is of fireproof tile covered with slate. In the boiler room the floor is brick; in the engine room it is of

mill construction, supported on 10 x 12-in. sills; on these is laid 3 ½-in. pine flooring and on top of that 1 ¼-in. white maple, oiled and polished. There is a large ornamental fire place in the side wall which is not shown in the illustration.

The engine equipment consists of two Buckeye compound

POWER HOUSE—MARION CITY RAILWAY.

engines with cylinders 17½ and 33 x 33½ in. Each is direct connected to a 350-k. w. Siemens & Halske generator, run at 118 r. p. m. and wound for 500 to 550 volts. A 12-ton fly-wheel, 12 ft. in diameter with 16-in. face, is mounted on each shaft. The engines are operated non-condensing.

The switchboard is of white marble, 2 in. thick, and divided into four panels, one of which is used for the lighting circuits. Weston instruments are mounted on the board.

In the boiler room are two water tube boilers rated at 750 h. p. each. In each are 131 1-in. tubes 18 ft. long, and on top three drums 38 in. in diameter and 18 ft. long. The pressure carried is 125 lbs. at the present time which will soon be increased to 150 lbs. Natural gas is used for fuel being burned with Claybourne burners. Crude oil is fed into the boilers to prevent the formation of hard scale and an automatic feeder supplies it at the rate of one quart per day. The Crane Company of Chicago furnished the valves and piping. Stratton separators are used on the steam lines and all the exhaust returns to a heater which raises the feed to about 200°F. City water is used.

INTERIOR OF ENGINE ROOM—MARION CITY RAILWAY.

The stack is of brick, 75 ft. high, and 13 ft. square at the base. The flue inside is 7 ft. The connection from the boilers to the stack consists of three underground conduits arched over.

The road employs 50 men and operates 32 cars, eight of which are open. The closed cars are of 16 and 18 ft. body and the open cars have a seating capacity of 45. The cars and trucks were manufactured by the J. G. Brill Company and the Barney & Smith Company, and are equipped with G. E. 800 and S. R. G. motors. The company has two car barns, one with three tracks 150 ft. long and one with two tracks 200 ft. long. At one of the barns is also located the repair shop.

Cars are run at speeds varying from 9 miles per hour in the center of the city to 25 miles; the headway is 10 minutes on the route No. 1 and 20 minutes on all other lines. Marion has a population of 22,000, Jonesboro has 2,500 and Gas City 5,000 and in addition there are some 3,000 at the Soldiers' Home, giving a total population served by the

BOILER ROOM—MARION CITY EAILWAY.

company of nearly 35,000. The Union Traction Company which will build a road from Anderson to Marion has already completed 9 miles of track to Alexandria, and in the near future will open a line from Jonesboro to Fairmount, leaving only 10 miles to be built in the spring. This line will connect with the Marion City Railway at Jonesboro and cannot fail to prove a benefit to the latter.

The general manager, Mr. McWhinney, is another example of a railway man who entered that field after a successful career in other lines. Mr. McWhinney was born in Preble county, Ohio, in 1848, and after engaging in various mercantile enterprises removed to Marion in 1889 and soon organized the street railway which has been in every way a success.

### THE GENERAL ELECTRIC 57 MOTOR.

The new G. E. 57 street railway motor has been introduced by the company in response to the demand for a motor of greater capacity. It is similar in design to the G. E. 1,000; while still as compact, it has an output of 50 h. p. at 500 volts. The frame is dust and waterproof and is of steel, cast in two bowl-shaped pieces with a hand hole in the lower half for cleaning. There are four laminated poles, each having a separate coil which is wound on a cast spool, thoroughly insulated with asbestos. There is a cover-

ing of heavy duck drawn over the spool to protect the winding from injury.

The armature is similar to that of the G. E. 52 and is 14 in. in diameter with a spread of 12 in. It is iron clad, the core being built up of annealed laminated disks, and in assembling these, three sets of spacing blocks are used, pro-

GENERAL ELECTRIC 57 RAILWAY MOTOR.

viding three ventilating ducts. There are 33 triple coils, each composed of three separate coils, and these are wound with either two or three turns per coil. The three-turn winding is the standard for ordinary service. This method of winding insures few repairs and admits of thorough insulation. The armature is as light as possible.

The commutator has 99 segments of hard drawn copper 2 in. deep, giving a wearing depth of 1 in. The brush-holders are staggered to prevent the wearing of ridges on the commutator, and each holder contains two radial brushes, 2 1/4 in. long, 1 3/4 in. wide and 5/8 in. thick.

The bearings are of ample size, the pinion end being

WITH FRAME DROPPED.

3 1/4 x 8 3/4 in.; the commutator end 2 7/8 x 6 3/8 in. There is a combination thrust collar and oil guard which the lower half of the case does not cover, thus allowing the lubricant free egress and preventing it from working into the motor frame. Either oil or grease may be used. The lower oil wells are provided with felt wicks which wipe the shaft through holes cut in the linings. The motor is adapted for either nose or yoke suspension, and with a slight modification of the frame can be fitted for side bar suspension.

For inspection or repairs the lower half of the motor can be swung down into the pit without disturbing the upper half. When mounted on 33-in. wheels the clearance between the bottom of the motor and the rail is 3 1/4 in. With the 67-tooth gear and case the weight complete is 2,972 lbs.

A BIG FIRE AT WASHINGTON.

CHICAGO UNION LOOP IN USE.

Fire entirely destroyed the central power station of the Capital Traction Company of Washington, D. C., the night of Wednesday, September 29, and the loss aggregates \$1,000,000. The building occupied a block bounded by D, E, 13<sup>1</sup>/<sub>2</sub> and 14th streets, and was six stories in height; the ground floor and a part of the second were occupied by the company for the cable plant and offices, and the rest of the building was let for offices and manufacturing purposes.

It was of "mill" or "slow burning" construction and was completed for occupancy June, 1893. In spite of its construction the building burned with remarkable rapidity. The engines driving the cables continued running until a large piece of iron fell from the floor above into the wheels. The engines were of the E. P. Allis make with 36 x 72-in. cylinders and rated at 750 h. p. The boilers consisted of a battery of eight 184-h. p. water tubular boilers.

After a long season of parlay all the leases for the use of the Union Loop have been signed, Leslie Carter, president of the South Side Elevated Railroad, being the last to agree to the terms of the lease. All the differences were settled in a conference held October 2 and on the following morning the trains of the Lake Street Elevated Railroad ran around the loop without any previous announcement. The Metropolitan West Side Elevated began operation around the loop October 11. The South Side Elevated Railroad Company has yet to complete the connection on Harrison street, a half square between its structure and the

Loop. All the supplies are at hand and the work is progressing rapidly and will be finished by October 25. The Alley L trains will be drawn around the loop by the locomotives now in use until its cars are equipped for electric traction. Some progress is being made in this work

WRECKING WALLS WITH DYNAMITE.

THE FIRE, 11:45 P. M.

RUINS NEXT MORNING.

The entire plant was designed and furnished by Robert Poole & Son Company, Baltimore. The cars of the company are stored in the sheds at either end of the line. Horses were procured at once and 50 cars, the cable trailers, were put in service on the lines. The Metropolitan Railroad Company tendered the use of 25 horse cars. Plans were made at once for erecting a temporary structure and installing machinery to drive the cables. The station of the Washington, Alexandria & Mt. Vernon Electric Railroad on 13<sup>1</sup>/<sub>2</sub> street was also seriously damaged.

The photograph of the fire from which our illustration was reproduced was taken at 11:45 p. m., 30 minutes after the fire started; it was taken by E. R. Myers, and is quite a rarity in the art. The other two views show the ruins, one of them being taken as a charge of dynamite was exploded under the front wall the following day.

Since the above was put in type the directors have decided to adopt the underground electric system, and will build electric stations instead of restoring the cable plant. The present cable conduits will be used.

Mrs. S. G. Milliken, of Augusta, Me., has been chosen a member of the board of directors of the Bangor, Oronto & Oldtown Railway Company. She is the first woman to be elected to such office in the state.

as the new motors and trucks are being placed under the cars and the vestibules built by the Wells & French Co., of Chicago. Frank J. Spague is in Chicago supervising the work preparatory to installing his system.

It requires from 17 to 18 minutes for the trains to make the circuit, on which there are 12 stations in the two miles.

TERRE HAUTE HAS AN OBJECT LESSON.

A spasm of legislating struck the Terre Haute city council, and for want of something better to do an ordinance was introduced cutting the speed of electric cars down to about one-third the previous rate; requiring stops to receive and discharge passengers to be made at the near crossing; and cars to come nearly to a standstill before crossing any street, regardless of whether any passengers wished to get off or on.

President Harrison was equal to the emergency and instead of camping at the city hall, published a notice that if that was the kind of service the people wanted they need not wait for an ordinance to get it, and put the entire system on the proposed schedule for three days. Before the three days were over the whole town was in arms, and raised such a cry that the council was glad to retreat by deferring action on the ordinance. It will probably not come to life again.

## MODERN COMPRESSORS FOR AIR-BRAKING.

BY E. J. WESSELS.

Although compressed air was known in Aristotle's day and has long been used for a variety of work, its application in the field of electric traction remained in an undeveloped state until recent years. So long as horse cars were the order of the day, no necessity existed for its use in braking surface cars. Shortly after the first electric car was put into service, the company of which I have the honor to be managing director, met the need which arose by furnishing an air-braking system, operated by a single or double acting compressor, for controlling electric and cable cars.

As electric traction developed, increased demands were made upon us for apparatus of higher efficiency than had sufficed in the dawn of street railroading. As a result not only had existing conditions to be confronted and met but what was fully as important, a system had to be evolved which would successfully meet the radical changes which became necessary. The air-brake system really had to be ready before the need for it had become fully apparent. No time was granted for experimenting, after the high efficiency car motors were in place.

With these special needs in view, an electric compressor embodying radical changes had to be designed. Many experiments were made with the initial outfits and large outlays were necessarily incurred, without always being followed by satisfactory results. It may be admitted with perfect frankness that the first apparatus left much to be desired. We had to rely upon the reports and friendly criticisms of railway managers in order that defects might be cured and that each installation might be an improvement upon its predecessor. Some of our friends realized that their interests and ours were very closely allied and through them we obtained important help.

The problem of braking by air, high speed, heavy cars running in trains, is not as simple as might appear at first blush to the uninitiated. It becomes more complicated when the factors of heavy grades, frequent stops and numerous

crossings are involved. A motor compressor which answered in 1895 falls short of the requirements of 1897. With a full appreciation of this fact our company's aim has been ever to keep in the van. The illustrations accompanying this article are not "manufactured" but taken from real life, and represent the interior and exterior of our latest ma-

THE STANDARD MOTOR COMPRESSOR.

chine as actually photographed. Reference to some of its features may be timely and it will be seen wherein this type of air compressor differs from all others. The  $1\frac{1}{2}$  h. p. type is illustrated. The motor compressor is very compact, being but  $26\frac{1}{2}$  in. long by 15 in. wide by  $18\frac{1}{2}$  in. high. The complete weight is 400 lbs. The motor is of the iron clad, multipolar, slow speed, series type. It was found after repeated experiments that the use of gears necessitated a much bulkier machine and that the noise arising from a geared machine was very much greater than from the other type. This noise was intensified after the gears showed wear. For this and other reasons the geared type was abandoned.

While our motor is absolutely rain and dust proof, nevertheless the construction is such as to make the brushes readily accessible. It will be noticed that the commutator is of very generous proportions, as are also the brushes. Special brush holders are provided, which are exceedingly convenient. Their long springs insure even tension of the brushes and require only infrequent adjustment. The wide insulating surfaces prevent leakage through "creeping." In this motor extraordinary precautions have been observed throughout for obtaining the strongest and most durable insulation.

While the armature is of the slotted drum type (such as is used in the best sort of street railway motors) the winding is special, being of the well known Hochhausen type. It should be stated that ours is the only company which is authorized to use the Hochhausen patents in air-compressor work. Damaged sections can be renewed (in case of injury) as is common in car motor armatures. The machine is thoroughly protected against ingress of oil from bearings and compressor.

The compressor is of the single acting type, with double cylinders which are placed vertically, with trunk piston connecting directly to eccentrics in crank case. The pistons are carefully balanced to insure a minimum of noise and freedom from vibration. The eccentrics are effectively lubricated by revolving in a closed chamber partly filled with oil,

THE STANDARD MOTOR COMPRESSOR.

which is kept at such height as always to be in contact with the sliding surfaces. The compressor is bolted to the end of the motor and the shaft is a prolongation of the armature shaft, although it does not form a part of it. The compressor has a capacity of 11 cu. ft. of free air per minute when working under a gage pressure of 60 lbs. per sq. in. It is capable of operating with great economy even at 100 lbs. pressure, although in straight air work the maximum pressure required by the Standard system is 60 lbs. The remarkably high efficiency of the compressor is largely due to the design of the valves. These combine ease of access with a minimum loss arising from clearance. Being made of steel, they are very light and are practically indestructible. The air supply is drawn from a chamber which, although dust proof, has so large a filtering surface that the work of drawing the air through the same is inappreciable.

This modern motor compressor has been in operation for a number of months, and has been mounted on a number of cars with very satisfactory results. The operation is completely governed by the automatic current controller, which relieves the motorman of responsibility by starting the motor compressor when necessary to replenish the air supply, and by cutting out as soon as the needed supply has been obtained.

In view of the recent advent of the third rail and Sprague systems, he indeed would be a bold prophet who would undertake to predict what the next five years may have in store for the traveling public, but it is safe to assert that, no matter what form of electric construction may become the recognized standard of the future, the modern air compressor will be found doing its work of maintaining a sufficient air supply (in connection with an air-brake system) to curb the speed of what would often otherwise prove "wild" trains or cars. For such work it is singularly well adapted and its place is not likely to be usurped by any other forms of braking apparatus, with their pronounced weaknesses and limitations.

### SERVICE TEST OF ALLEN-MORRISON BRAKE SHOE.

When describing the Allen-Morrison composition brake shoe in the REVIEW for September, page 604, mention was made of the mileage run by car No. 24 on the South Side Elevated of Chicago, which was equipped with these shoes for the purpose of testing them. At that time the shoes had run 16,666 miles.

On September 9 the mileage was 21,011 miles, and four of the eight shoes were removed; the average loss in weight of these four was between 11 and 11½ lbs. each. On September 23 the other four were removed, after making 23,373 miles; the loss in weight for the second four was 12½ lbs. each. The reduction in thickness of the shoes was 1¾ in. and the reduction of the diameter of the wheel (steel tire) 1/16 in. The thickness of the composition in one of these shoes which we have examined is less than 1/16 in., but shows not the slightest evidence of any tendency to break loose from the iron shell.

In the same service chilled iron shoes run 16,000 miles and soft cast iron shoes between 1,000 and 5,000 miles.

Wages of trainmen on the Denver City Cable Railway have been increased from 18 to 20 cents per hour.

### THE RED MAN AND THE WHITE.

(With apologies to Lord Kelvin, who, while visiting the Falls, a few weeks ago, said:—"No, I do not hope that our children's children will ever see the Niagara cataract.")

In the early days when the world was new,  
And woods, and sky and prairie were unsoiled with use;  
A dusky warrior wearied with the chase  
Came to a river's brink and paused to rest.  
He quaffed the waters pure and sweet,  
Drawn from the depths of the great inland seas;  
And resting in the shade beside the stream  
The queen of slumber closed his eyes with sleep.  
When he awoke the sun was in the west,  
And from the distance came a mighty roar,  
Like constant thunder rumbling o'er the hills;  
And to the voice thus calling he arose,  
And hastened on to find the cause unknown.  
Nearer and nearer came the awful roar,—  
As if the Titans battled for their life,—  
Until he saw the cloud of conflict rise  
Above the struggle of the waters wild.  
Upon the earth he prostrate flung himself,  
Nor dared to stand in presence so austere,  
But gaining courage knelt and slowly crept  
Until his eyes looked down into abysmal depths.  
No human face had ever turned its glance  
Into that chasm wild and fierce;  
No human hand had e'er been raised  
In homage to the god of endless storm;  
No human lips had ever kissed  
The sweet faced Maiden of the Mist.  
Then in his ear a whispered word,  
"Return unto your tribe" it said;  
"Nor ever dare again to tread  
"The borders of this sacred land."  
In fear and trembling he retraced  
The pathless track which he had come,  
And to the chief he told the tale  
Of all which he had seen and heard.  
The wise men sat in council grave,  
And when at last the pipes went out,  
The brave was taken hence and slain.

\* \* \*

Years passed. One day the white man came,  
And marveled much at what he saw,  
Then went away to come again,  
With harness for the waterfall.  
He dug a ditch, the water turned  
From out the path it long had known;  
He forced it through a turbine wheel,  
Direct connection was the song.  
No longer free this water god,  
Now he must work by night and day,  
His arms are bound, free-willed no more;  
Where once he bounded o'er the rocks at play,  
Now he must draw great cars, on tracks;  
The sparks he scattered in a million drops  
Are now collected in an arc;  
His breath that filled a cave with wind,  
Is fastened with a copper band,  
And ere its freedom it may take  
Must even turn an electric fan.

### FINE RECORD AT GIRARDVILLE.

E. W. Ash, general manager of the Schuylkill Traction Company, Girardville, Pa., reports an excellent record for his road. During the year ending July 1897, over 2,000,000 passengers were carried on the 22 miles of track and the personal injury account amounted to only \$10. One of the main lines has a grade one mile long, a considerable portion of which is 8½ per cent, and in running this mile cars made an average of 10 stops each trip.

## DETROIT FUNERAL CAR.

The accompanying illustrations show exterior and interior views of the special car which the Detroit Citizens' Street Railway Company has provided for the use of funeral parties. The interior of the car is handsomely upholstered

DETROIT FUNERAL CAR.

and carpeted and draped in black. In the front is a space for placing the casket, with seats at the sides; the rear portion of the car is provided with cross seats, making places for about 30 persons in the car. The charge made by the company for the use of this car is \$15. The advantages of

INTERIOR OF CAR.

such a service in a city, and particularly one so well provided with street railways as Detroit, will be readily appreciated, and it is rather surprising that funeral cars are not more common in our large cities.

The Southern California Electric Light & Power Company of Redlands, has contracted to supply the Los Angeles Street Railway Company with power for the period of 20 years. The minimum payment is fixed at \$50,000 per annum,

## FENDERS FOR CHICAGO.

On September 27 the Chicago city council passed an ordinance which provides that within 60 days all the street railways shall equip their motor and grip cars with fenders, and shall equip all open cars with wire or other suitable guards on the side towards the inner rail, and also place such a device on the side of the cars to protect passengers from falling under the wheels. The fenders "not to be more than 4 in. above the top of the rails, and shall be of such design as to effectually form a guard for the wheels of the cars, subject to the approval of the mayor and the commissioner of public works." The mayor signed the ordinance October 2.

## FORSYTHE'S CAR CURTAIN FIXTURES.

During the fall of 1895 Forsythe Brothers & Co. introduced to the trade their patent roller tip curtain fixtures. This curtain was entirely new both in principle of operation and in form of construction, and was the first fixture to show a working or tilting head having friction surfaces of divers holding power whereby the shade is made self-righting. It had the ordinary tube with spring actuated rods, these latter at their outer end tips being provided with anti-friction rollers. This construction makes the fixture right itself and remain level and within the grooves. It can be operated either by grasping the finger pieces or the curtain anywhere along the bottom. The fixtures are exceedingly simple and very durable. While remaining in the grooves when in use they can still be readily removed therefrom, for cleaning, repairing or washing of the curtain or window. These curtains met with immediate favor and have been adopted and extensively used by nearly all the leading railroads and many street car companies. Although this concern has but recently sought after the traction company trade, they are able to report to us that this department has grown rapidly and they are forced to work at night to fill orders. They have lately filled orders for the Metropolitan Traction Company of Washington, their second order, the third order from the Fort Pitt Traction Company of Pittsburg, the Detroit Citizens Street Railway Company, the new cars for the Chicago City Railway Company.

W. H. Patterson, president of the Bloomington (Ill.) Street Railway Company and Senator J. J. Patterson have succeeded in making satisfactory arrangements with creditors and the company will continue operations under the present management; there is now no probability of the appointment of a receiver being asked, as was for some time expected.

About 225 Italians at work on the Oxford (Me.) Central Railroad, struck on account of not receiving their pay on time. They captured the contractors, Albert Davis and L. B. Wilson, and held them as hostages. Their position was precarious and Albert P. Bassett, a state detective, went to the rescue. The prisoners made a dash for liberty and reached the wagons which had been provided for them. The Italians then turned furiously upon Bassett, who made a most courageous fight. He was severely beaten about the head and received a bullet wound but made his escape after shooting six of the strikers.

## COST OF POWER FOR ELECTRIC RAILWAYS.

| STATION.                           | MONTH. | Output Measured by | Monthly Output, Kilowatt-Hours. | Cost of Electrical Output per Kilowatt-Hour—Cents. |        |                            |        |           | Gals. ### LATEST CONVERTIBLE CAR.

### THE SMALLEST ROAD.

Many managers are still looking for a convertible car which shall be equally adapted to summer and winter use, and which can be changed from one to the other without going into the shop. In fact, on some roads doing a big summer traffic, where sudden storms bring extreme changes of temperature in a few minutes, such a car is really a necessity.

The car we illustrate is called the "Duplex," and was built at the Jackson &

We have repeatedly printed descriptions of big roads, with thousands of cars, carrying millions of passengers, and earning enormous sums of money. Here is what might well be termed the "minimum road," and the owner writes us of it as below. The road is in California, and in response to our mild suggestion that all well regulated lines found it profitable to subscribe for and read the REVIEW, he relates the story of his woes. Under the circumstances we hardly have the audacity to expect an entire day's earnings for one year's sub-

THE DUPLEX CONVERTIBLE CAR.

Sharp works, Wilmington, Del., and is one of an order for several which were built for the Duplex Car Company this summer and sold to the Bergen County Traction Company. One of these cars will be exhibited at the Niagara convention, and will be found on the special track directly in front of the convention hall. The inventor of the car is John A. Lovell, a Boston capitalist.

The passenger receipts of the Brooklyn Rapid Transit Company for the month of September were \$30,921 more than for the same month last year.

scription. He says: "Our road is literally a one-horse concern, not averaging \$2 a day receipts; so I hardly deem it advisable to subscribe for your paper. Being 71 years of age, and with bicycles, competition from livery stables, etc., and business rather falling off, there is little prospect of my ever seeing an electric line here."

It is stated that the Westinghouse Electric & Manufacturing Company has purchased the Gibley's Electric Company of Milwaukee and the plant will be closed as soon as the important contracts on hand have been completed.

## CENTRAL ELECTRIC NEW OVERHEAD SPECIALTIES.

The Central Electric Company, Chicago, is constantly adding to its line of railway specialties, and we illustrate some of the most recent. The bracket hanger is arranged to fit many types of bracket arms, as well as the special angle brackets. The bridge, or barn hanger, is made especially for places where the ceiling or roof is very close to the ground and is made short so that the wire is held close to the ceiling. These hangers, where specified, are furnished with special clincher bolts which will hold in rock, making

it unnecessary to fasten timbers. The company claims the distinction of originating another useful feature which can be applied to all its overhead materials of the West End type. It is a very small device which fits the stud just above the ear and absolutely prevents the ear from working loose from the stud. Various other methods have been employed to overcome this difficulty, one of which the Central Electric has employed in all of its West End hangers for some time, viz., the self-locking features of the cap;

but this method of locking the stud to the ear is something radically new, and has never before been used in railway overhead materials.

The conductor signal bells are nicely finished and furnished complete with 6-in. gongs. In addition to the various hood gongs a full line of foot gongs is carried.

The mechanical strain ear is desirable on account of its strength and quick application. It is impossible to move it on the wire after it is placed in position. These ears are made for No. 0, No. 00, or figure 8 wire. The company has made a careful study of overhead parts, and reports that where samples of these goods are sent, orders almost invariably follow.

## PERSONAL.

L. M. Erb has resigned as general manager of the Leavenworth Electric, and will go into construction work.

G. A. Cooke, assistant to the general manager of the Toledo Traction Company, was a caller on the REVIEW, September 18.

Col. C.F. Morse, president of the Metropolitan Street Railway Company has returned to Kansas City after a two months' vacation.

F. H. Chamberlain leaves the United States Electric Company, of Washington, to become electrician for the Metropolitan Railroad of that city, succeeding W. A. Heindle.

Fred Mundes has received the appointment of general road master of the lines of the Houston Electric Railway Company. Mr. Mundes has been in the service of the company for many years and is a capable and experienced railway man.

C. W. Smith, president of the Pasadena & Los Angeles Electric Railway Company, was severely injured by being thrown from a mule while descending the Mt. Wilson trail. Although cut and bruised about the face the injuries will not result seriously.

W. C. Gotshall, who resigned his position with the Union Depot Railroad Company, of St. Louis, to take charge of the underground construction work on the lines of the Metropolitan Traction Company, New York, was married to the Countess Von Rathgen, of Hamburg, Germany, at the home of Dr. Heidenfeld in the Catskills.

Ben Willard, who has been engaged the past three years in charge of the installation and construction on the New Orleans Traction Company, having completed the work has resigned to become assistant engineer for the General Electric, and will make headquarters at Schenectady. Mr. Willard's work is of a high order and his friends will continue to watch his future with interest.

S. L. Nelson, secretary and general manager of the Springfield, (O.) Railway Company, attended, on Wednesday, September 22, the 55th wedding anniversary of his father and mother. There were seven children in attendance, of which Mr. Nelson was one, he being the baby of the family. There were 10 grandchildren and one great-grandchild. There has not been a death in the family for 50 years. His father and mother are both very hale and hearty, his father being 79 years old and his mother 70.

## OBITUARY.

Thomas W. Fowler, well known to street railway men as for many years superintendent of the Lewis & Fowler Car Company, died in Brooklyn, on September 30. Mr. Fowler was 77 years of age.

Allen D. Norman, receiver for the Citizens' Traction Company of San Diego, Cal., died after suffering several weeks from nervous prostration. Mr. Norman was a native of Illinois and during his residence of 10 years in San Diego had become prominent in business and social circles.

Charles A. White, president of the Bibber-White Company of Boston, died at his home in Malden, Mass., September 16. He was prominent in manufacturing and electrical interests and was largely instrumental in building up a large business in feed and insulated wires of all kinds. At the time of his death he was president of the Malden Council.

Albert L. Ide, the well known maker of high speed engines which bear his name, died at Chetek, Wis., where he had gone in search of health. He went to Springfield, Ill., in 1855 and has made that city his home ever since. He was two years in the army, and at the close of the war built and became president of one of the street railway lines in Springfield. He began manufacturing in 1870 and built up a large works. He was also president of the National Electric Company, at Eau Claire, Wis.

**BICYCLE HANGER FOR STREET CARS.**

Street cars will carry bicycles, or at least the progressive roads will do so, and every manager who desires to increase his receipts will have to make some kind of provision for this service. Contrary to first impressions it is found that it is not on hilly lines alone that cyclists are glad to avail

APPLIED TO DASH.

themselves of a "lift," but that when tired, or accompanied by ladies, it is very acceptable to use the cars, especially against a strong wind.

The hanger illustrated is made by the Champion Bicycle Hanger Company. The hangers may be attached to both dashes and the closed side of open, and both sides of closed cars. On open cars the pedal does not protrude beyond the width of the foot board, and wheels are hung high enough so as not to interfere with pedestrians.

The dash holders are riveted to a portable wrought iron frame in a series of three, four or more as may be desired, and are placed about 18 in. apart, allowing ample room for the handle bars; from the back of each holder are books made solid with the frame and shaped to fit the rail of the dash-board, and made to be put on, or taken off with ease. Where the rear wheel comes in contact with the car, are iron prongs that engage the tire and keep the wheel from

CHAMPION BICYCLE HOLDER.

swinging when turning curves. The wheel when in the holder is from 12 to 15 in. from the ground. There is positively no danger of scratching the enamel or straining the wheel. A special device is supplied where folding fenders are used.

**THE INTERNATIONAL DOUBLE REGISTER.**

The increasing necessity for better methods of registering fares where a large proportion of transfers are used has resulted in the adoption of double registers on many of the largest systems. The register here illustrated is, with the exception of trifling improvements, the same as shown by the International Register Company at the St. Louis convention. This machine has not been advertised during the year as the company had orders for quite a number, and preferred to demonstrate in actual hard service that the register had passed the experimental stage, before pushing its sale.

This machine has several novel features which add much to its efficiency. The first and most important is the fare indicator, located in the center of the dial, where it is most likely to attract attention. This always indicates the kind of fare last registered in large plain letters, the background being bright red for cash and white for transfers. Two of the new International totalizers keep separate records of the two classes of fares. These totalizers show the readings in much larger figures than heretofore used in a double register, and the manufacturer lays stress on the claim that these are the only register totalizers that are tamper-proof in themselves. In addition to this all the registers of this company are protected by a glass signature seal. A solid drawn case fits closely over an iron rim on the bed plate and is secured by a spring lock covered by the seal. The mechanism cannot be reached in any way by wires while the glass dial and seal remain unbroken.

The totalizers of some registers are accessible to any one who can handle a screwdriver and the facility with which they can be opened and set back is hardly appreciated by most street railway managers, but those who have given the subject their attention will not fail to commend the double protection offered in this as well as the other machines made by this company.

**CITY REGULATION OF SPEED.**

A judgment rendered in favor of the Nassau Electric Railroad Company of Brooklyn in an action brought by the city for the violation of an ordinance limiting the speed to six and eight miles an hour has been reversed. The company claimed that the consent of the city to the building of a road to be operated at a rate of speed not exceeding to miles per hour constituted a contract, but the court held that the regulation of the speed of street cars is to be exercised under the police power of the state, and when the power is delegated to a municipality it can not be alienated by the latter, as would have been the case had the consent been held to be a contract.

## DOUBLE TRUCKS FOR ELECTRIC RAILWAYS.

BY T. L. HARRIS.

The thoughtful engineer or manager who has given some consideration to the modern practice in track building for steam and electric roads and to the conditions that obtain in the two classes of service has not failed to observe certain facts which when examined seem quite remarkable.
