The modern street railway is laid with deep and heavy rails (the writer has in mind two pieces of track recently built in which rails weighing 103 and 106 lbs. to the yard, respectively, were used); few steam roads use rails that are heavier than those considered standard for street railways. The weights, per wheel, however, are quite different on the two roads; on street railways the normal weight per wheel is from 4,000 to 5,000 lbs., while on steam roads the weight per wheel is as high as 20,000 lbs. for locomotives, and as high as 12,000 lbs. for coaches; in addition

a long wheel base was considered necessary to make room for the motors between the bolster transoms and the axles, and then there was trouble because on curves the trucks would strike the sills of the closed cars or the steps of the open ones. When the wheel base was shortened the motors came under the bolster and the latter had to be raised, raising the car body and requiring two steps.

The Brill Company has placed three pivotal trucks on the market in which these objections have been overcome. They are intended for the three branches of street railway work which are: Heavy city traffic with its many stops and moderate speeds; a low car body and great adhesion for the truck are desirable. Mixed city and suburban service with frequent stops in the city and high speed in the country; for this the cars must be low and the trucks interchangeable between closed and open cars. Suburban and interurban service, where the highest practicable speeds must be reached on the main lines, and yet the cars must come into the heart of the city over tram roads.

The Eureka maximum traction truck is filling the require-

EUREKA MAXIMUM TRACTION TRUCK.

there are the increased rail pressures due to the presence of the counterbalances in the driving wheels, which at high speeds bring the maximum pressure on the rail to up fully 75 per cent above the normal. The speed on the steam road is 50 miles per hour; on other than interurban electric roads it is nearer 15.

Now, what are the results so far as the track is concerned? The mechanical engineers of the steam roads are on record as saying that their tracks are never injured by well-designed locomotives run at the speeds for which they were intended. On the other hand the street railway managers complain that the track is torn to pieces by the electric cars. There is only one reason for this, and that is the rolling and plunging cars mounted on four-wheeled trucks pound the track, loosen the joints and shake the car to pieces; the car pitches forwards and backwards so that often the entire weight is on a single pair of wheels and racks both truck and body.

Until recently there seemed to be no adequate remedy because the use of two pivotal trucks of the ordinary pattern was open to several objections. On the early pivotal trucks

of the first service; with this truck the bottom of the car sill is but 27 in. above the head of the rail, and only one step is required to reach the ground. The truck keeps the rail perfectly by aid of the spring compressor device at the trail end of the truck. This device is made in the shape of a double inclined plane, the center of which is on a straight line with the track, and when the car takes a curve it rides on one of the inclines and thereby puts more weight on the small wheels. Eighty per cent of the total weight is made available for traction on straight track. The side bars are solid and are spring-supported over the journal boxes; the whole of the center of the truck is open for the motor.

For the second class of service the newer "universal" truck which was illustrated and described in the REVIEW for September, 1897, page 624, appears to be perfectly adapted.

The "perfect" or No. 27 truck was designed for the peculiar service on interurban roads running into cities at the termini. Within the city limits wheels must be used which will not be destroyed by the pavements and which will not injure the tram rails. In the country where T-rails are used

the type of wheel suitable for the speeds common in the city becomes dangerous except at low speeds, and even then it readily leaves the track. In practice it is found that the motormen are tempted to exceed a safe speed, and many accidents have resulted in this service. For T-rail construction the wheels should have wide treads and comparatively deep flanges; but such wheels can not be used where the street paving is laid close against the rails because it will chip into the treads. Also, the deep flanges cut out the grooves of the tram rails and the rails as well as the wheels are quickly worn out.

A pair of trucks of the "perfect" type were placed under a car on the Buffalo & Niagara Falls electric road in the latter part of 1895 and their action fully demonstrated that the conditions of the service had been appreciated and met in the design. The car took the curves, whether long or short, with ease and at speeds that had theretofore been impossible. The trucks did not leave the rails at any speed though severely tested, and during the two years that these trucks have been in service on this road there has not been a single case of derailment reported.

The reasons for this will be apparent when their construc-

tion with safety, and at 10 miles curves are scarcely perceptible. It is evident that the soft side motion must also reduce the cutting of the rails and guard rails at the entrance to curves.

By giving the swing links a wide spread the transverse stability is greatly increased over that of the ordinary truck, and by spreading them longitudinally great stability is given in that direction also. The hangers are 60 in. apart longitudinally and placed but 12 in. from the centers of the journals; this, of course, diminishes the stresses on the truck sides.

Whether the vertical pull of the brakes has much or little influence on the truck frame has a great deal to do with the comfort of the passenger; in this truck the brakes may be applied very quickly and yet there is no canting of the frame.

### FRANCHISE TAX WINS IN KENTUCKY.

Kentucky and the City of Louisville have been trying to enforce a franchise tax, and the Louisville Railway Company has resisted in the courts. The state won its case, and the road will have \$27,000 to pay; but the city will in

BRILL NO. 27—THE "PERFECT" PASSENGER TRUCK.

tion is examined. The radical departures from the former practice consisted in suspending the equalizers from spring links, and in making the equalizers a part of the swing motion by securing them to the spring plank. The load comes upon the equalizer at its center with springs at the ends, thus distributing the load in a more perfect manner than in the standard M. C. B. truck. As will be seen in the illustration there are three sets of springs; elliptic springs to transmit the weight of the car body to the equalizers, coils to transmit it from the equalizers to the truck sides, and, finally, coil springs placed between the truck sides and the journal boxes. The springs in the swing links soften the side motion, whether on tangents or curves, and this is why the trucks stick to the rails; the trucks, of course, must change the direction of their motion more or less suddenly, but the car body follows slowly and is cushioned, so that no shock can be brought upon the wheels such as would cause them to jump the track. And this also is the reason why the motion of the car is easy; no shocks are transmitted to the body, whatever may be motion of the truck. The cars so equipped have made 60 miles per hour

all probability lose as the contract between it and the company provides for the payment of 2½ per cent of gross receipts in lieu of all city taxes. The latter case, however, will yet have to be finally settled by the court. The state franchise tax applies to all the street railways in the state.

### NEW CARS AT BIRMINGHAM.

Under the direction of G. H. Harris, electrician of the Birmingham (Ala.) Railway & Electric Company, 10 new cars have been wired and equipped for the Ensley line, which commenced operation September 1, with electricity for motive power. Five of the cars have been in service for a short time, but the others are entirely new and unequipped by any now on the system. General Manager McClary states that a 20-minute service will be given on the Ensley line, each train consisting of a motor car and trailer.

T. H. Conderman, president of the Wheeling (W. Va.) Railway Company has returned from an extended European trip.

### AMERICAN MUTUAL INDEMNITY COMPANY.

Newton Jackson, who has been very successful in insurance work, and who has made a specialty of street railway risks of various kinds, both fire and personal damage, has become general superintendent of agencies of the above named company, whose headquarters are located in Scranton, Pa., the directors being wealthy capitalists of that city. The company writes liability insurance only, such as employer's liability, boiler insurance, elevator insurance, etc.

A street railway department gives attention to handling the claim department of street railways, for which special facilities have been provided. The company has been very successful in settling such claims out of court, and always prefers to do so where possible. Roads which wish to be relieved of the annoyance and expense of this department, and desire to limit the expense for this item to a definite sum per year, find many advantages in this insurance, which covers all losses from this source.

### THE MONARCH TRACK CLEANER.

The illustration herewith shows the Monarch track cleaner which is manufactured by the Monarch Stove & Manufacturing Company of Mansfield, O. There are a number of points of superiority about this cleaner that will commend it to street railway managers, especially in those parts of the country where the snow problem is an ever-recurring one. There has been a considerable reduction in weight as compared with other devices for this purpose now on the market. It can be adapted to all kinds of platforms and cars without any special changes or fittings. Its greater strength enables it to remove the

heaviest snows without straining or breaking. A steel shoe is attached to the bottom of the blade and scrapes the track without wearing the blade, and as the shoe can be renewed at trifling expense this feature can not fail to prove a valuable one. To these points must be added the fact of high-class workmanship and finish in every part of the mechanism.

The cleaner will be on exhibition at the Niagara Falls convention, and its inventor, Mr. Hurst, will be present to show up its good points. Mr. Hurst is a practical man who has been engaged in this class of work for a number of years.

### AMERICAN FUEL ECONOMIZER.

The value of a fuel economizer in utilizing the heat of flue gases that would otherwise be lost, in purifying the water, and reducing the boiler repairs, is so well known that it is unnecessary to dwell upon these points in connection with the economizer here illustrated.

The American differs materially in detail from the older types: All the joints are taper joints, metal to metal, and the use of either steel or wrought iron has been avoided in the construction because of the rapid deterioration of those metals when in contact with water at varying temperatures.

AMERICAN FUEL ECONOMIZER.

All pipes, headers, wall boxes and parts subjected to water pressure, are manufactured from a special mixture of fine-grained strong irons, producing a metal of high tensile strength. The pipes are cast on end in dry sand moulds, and are of even thickness, smooth and free from blow holes. Sections and pipes are tested by hydraulic pressure to 300 lbs. per sq. in. in the shops.

The tubes may be easily removed and replaced, it being only necessary to take off the cap, when the tube may be drawn out vertically. For keeping the exterior of the tubes free from soot, scrapers are arranged as shown in the illustration.

The American is manufactured under patents by Broomell Schmidt & Co., Ltd., York, Pa.

### CORPORATIONS CANNOT COMMIT HOMICIDE.

It has been discovered that the penal code of New York defines homicide as the "killing of one human being by the act, procurement or omission of another," and does not appear that there is any provision to make corporations liable for this crime. Two New York City roads have had indictments for manslaughter returned against them, but the cases have never come to trial.

### MOTORMAN'S PROTECTOR.

The devices which have been evolved for front platform vestibules have been many, and some have proved excellent, but until now no one seems to have stopped short of an entire front to the car. This involves no small expense to construct, and costs quite a little to put on and remove when the seasons change. Many managers have very good reasons for objecting to the front vestibule.

The problem seems now to have been satisfactorily solved by some of the street railway men of Bridgeport, Conn., and a company has been formed and the manufacture commenced of this device, by the Motorman's Protector Company, of that city. Our illustration readily conveys a very good idea of the plan and device which is brought out to meet the demand and requirements of a vestibule without the expense and loss of room which a vestibule necessitates.

The protector is constructed of a waterproof strip, provided with a sheet of glass, a self-winding roller upon which the strip may be wound, and a frame in which the roller is

THE MOTORMAN'S PROTECTOR.

journalled and means for attaching the frame to a car. This frame consists of side plates connected by cross rods and provided with hook-shaped arms, adapted to engage the hood of a car, and set screws by which the protector is clamped in place.

But one protector is required for each car, as it is adjustable and can be changed to either end at terminals as may be necessary, without delay.

The officers of the Bridgeport Traction Company highly recommend the device.

### SUED FOR DAMAGES AFTER SIGNING RELEASE.

At the September term of court held at Ovid, Seneca County, N. Y., Judge Nash presiding, in the case of Jeanette D. Kist vs. the Geneva, Waterloo, Seneca Falls & Cayuga Lake Traction Company, a non-suit was granted under circumstances that render the case of peculiar interest to railway men.

On February 25, 1897, an accident occurred to one of the defendant company's cars, in which the plaintiff was more or less seriously injured. The Electric Mutual Casualty Asso-

ciation of Philadelphia, insurer of the Traction Company, was immediately notified of the accident, and sent its adjuster, Dr. H. B. Rockwell, to make an investigation. He arrived at the scene about 12 hours after the accident occurred, and succeeded in effecting a settlement with Mrs. Kist, one of the injured parties, and plaintiff in this action, to whom he paid \$100 and secured her release, together with that of her husband. Three or four days after the releases were signed, Mrs. Kist was visited by a "runner" from a law firm in Rochester, and was so influenced by visions of heavy damages, that she was persuaded to institute a suit against the traction company for \$10,000. The "runner" then inveigled her into paying him the \$100 consideration that had been paid her in the previous settlement, and the money was tendered to the general manager of the Traction Company, W. C. Gray, who, of course, refused to receive it. It was then deposited in a bank of Waterloo, New York, to the credit of the Traction Company.

The suit was brought to set aside the release on the ground that it had been obtained by coercion, and that the woman was incompetent as a result of her injuries to sign such a paper. The company was ably defended by Hawley, Nicholas & Hoskins of Geneva, who proved that the woman was not only entirely competent to give a release, but that she was perfectly satisfied with the settlement, until she had been approached by the enterprising law firm from Rochester. Mr. Hawley in his opening address to the jury, alluded in a very pointed manner to a certain class of "ambulance attorneys," that were becoming quite numerous, and who made it their business to prey upon corporations and follow in the wake of the ambulance, ready to pounce upon any victim who may be so unfortunate as to fall into their clutches.

Judge Nash, after hearing the testimony in the case, rendered a non-suit, giving as his reason for so doing, that the only evidence presented by the prosecution that would tend in any way to impair the validity of the release, was given by the plaintiff herself, she having testified that she was in a "dazed condition" and only "dimly remembered signing the papers." The judge further stated that "it is a very remarkable and significant circumstance that both the husband and the mother of the plaintiff should have been present at the signing of the document, and yet neither have been summoned to the witness stand."

It afterward developed that the husband, after hearing his wife swear to what he believed to be falsehoods, whispered to his counsel that he had better not call him to the stand to testify as to his wife's mental condition at the time of signing the release, for he had made up his mind to "tell the truth."

The vigorous manner in which Judge Nash disposed of this case cannot fail to have its influence in cases of similar import.

A rather amusing sequel to this case is that the Casualty Company has both the release and the \$100 paid in consideration of the same, while the plaintiff is compelled to pay the costs of action.

The Eckington & Soldiers Home Railway of Washington is still pursuing its search for a suitable air motor for traction purposes. Engineer McFarland went to New York to examine the experimental air motors on the street railways there.

### ONE HUNDRED DOLLARS DAMAGES FOR IMPROPERLY ISSUED TRANSFER.

Damages to the amount of \$100 were awarded in a suit against the Cortland & Homer (N. Y.) Traction Company. Suit was first brought one year ago, and final decision reached two months ago.

Briefly, the circumstances were as follows: The line running from Cortland to Homer is, within the corporate limits of the former place, divided for transfer purposes, that part of the line north of a certain point being called North Main, and on the opposite side South Main. The issuing of a transfer from North to South Main or vice versa which would, in effect, serve as a stop over ticket is, for obvious reasons, prohibited. The plaintiffs, one Ray and wife, boarded the car in Homer, paying their fare through to Cortland and wishing to stop off at a point somewhat more than midway between the two villages to transact some business, as they alleged, asked the conductor to issue them transfers, which would allow them to do this. The conductor, a comparatively new man, although he knew he was violating a rule of the company, issued the transfers as requested. The couple boarded the following car and presented the transfers to the conductor, who refused to accept them. The man then requested that the car be stopped, stating that he would make a test case of it. They then left the car about a mile from their residence and immediately placed the case with a local firm of lawyers. Shortly afterward an action in the supreme court was brought in the woman's name for \$500 damages. The case was tried the September following, motion for nonsuit being denied, and was sent to the jury, which returned a verdict of \$100 for the plaintiff. The company then carried the case to the appellate division, which affirmed the verdict of the lower court.

The company regards the verdict as excessive, inasmuch as no claim was made of damage to the health or business of the plaintiffs, nor of assault on the part of conductor or other employe, and the payment of 10 cents would have secured passage to destination.

### EMERGENCY TROLLEY WIRE SPLICER.

The Ohio Brass Company of Mansfield, O., has designed a trolley wire splicer for emergency cases. The splicer is made of seamless brass tubing in two duplicate parts, joined at the center by a hollow threaded coupling piece. In this is a coiled spring which forces two steel caps holding the

ends of the wire against the tapered sides of the tubing. In making a splice the ends of the trolley wire are first rounded off slightly with a file and are forced into the splicer with enough force to seat the caps on them their full length. By means of this device a strong compact joint is made with good electrical connection.

A workman in the station of the San Antonio, Texas road, who was raking cinders in the car house touched the overhead wire with his hoe which was solid iron, and falling struck his head on a rail and was killed.

### THE AMERICAN ELECTRICAL WORKS.

It is always interesting to note the growth of a great business concern, and few have had a more successful career than the American Electrical Works, of Providence, R. I. whose president, Eugene F. Phillips, started in business in 1870. Under his management steady progress has been made, until at the present time this company is the largest concern engaged in the making of wire exclusively for electrical purposes. The factories are located at Phillipsdale, R. I., the grounds and buildings comprising about 35 acres, adjacent to the Seekonk river, which is a part of Narragansett bay. The Canadian branch of the American Electrical Works is known as the Eugene F. Phillip's Electrical Works, Ltd., and is located at Montreal. This factory has been also very successful in every way, and now does nearly, if not quite, all of the wire business of Canada.

The American Electrical Works makes a specialty of drawing bare copper wire from the ingot, and its product includes bare copper, weatherproof wire and feeder cables, annunciator and magnet wires, office wire, Americanite rubber wire, and, in fact, every kind of wire that is used in the electrical industry. It is an interesting fact that rubber wire has been manufactured by this company since 1872.

This company has executed many of the largest orders for electric railroads in the United States and Canada, and has recently secured two orders, each for 75 miles of 350,000-c. m. bare stranded copper cable for the Buffalo-Niagara Falls transmission line. It might also be stated that the greater part of the bare wire and weatherproof cables supplied the Yerkes interests in Chicago came from this company, besides other large contracts.

It would be quite extraordinary, while speaking of the American Electrical Works, if the annual "clam bake," tendered by Mr. Phillips to the electrical fraternity, were not mentioned. This "clam bake" has become an institution of the electrical business, and has been given by Mr. Phillips for 19 consecutive years, guests coming from all parts of the United States to testify to the generous hospitality of the donor. From a small beginning, this event has constantly grown in size until it is one of the largest electrical gatherings held in the country.

### THE LAKE SHORE & MICHIGAN SOUTHERN TO THE CONVENTION.

The reputation of this well-known and justly popular route between Chicago and the East is such that no comment is necessary here. Those who have traveled over the Lake Shore to previous meetings know that no attention is wanting to make the trip as pleasant and comfortable as possible.

To take care of delegates, special cars for their exclusive use will be attached to the Lake Shore Limited, and delegates given the benefit of the special rate without extra charge for going on this famous train. The leaving time from Chicago is very convenient, leaving from the Lake Shore Depot at 5:30 p. m. and going through without change to the Falls, reaching there next morning for breakfast. Delegates from the west and south coming to Chicago to take this train can have all arrangements made in advance by writing or wiring C. K. Wilber, A. G. P. A., Chicago, or by calling at the city ticket office, corner Clark and Monroe streets.

## THE VAN DORN COUPLER ABROAD.

The Waterloo & City underground, of London, is another English road that appreciates American devices, and wishing to equip its cars with a perfect automatic coupler placed the order with the W. T. Van Dorn Company, of Chicago. Both the motor and the trail cars have been provided with

these couplers. Our illustration shows the coupler applied to the trailers; it differs from those for the motor cars in that the spring buffer is not attached directly to the car but is bolted to a bar of iron which swivels on the king pin of the truck.

## NEW HAVEN NEW DOUBLE REGISTER.

We illustrate the new double register which the New Haven Car Register Company is to exhibit for the first time at the coming Niagara Falls convention. This register is intended for use on cars operated by two different roads and is so arranged that only one set of rod or cord fixtures is necessary for operating both sides of register.

Each side of the register is complete and is provided with a special lock so that the conductor upon leaving the car locks his side of the register thereby preventing any fares being rung up against him during his absence. The completeness and great convenience of this machine and the superiority of this system of operation over the use of two different registers in a car will be appreciated by

all railway managers. The full operation of the machine will be explained by the company's representatives at the exhibit in Space 47 at the convention.

The New Haven fare registers have a world wide reputation and the production of this new machine will undoubtedly be hailed with much satisfaction by the managers of the large class of roads for which it is intended. The features of these registers are fully protected by patents.

## START TO NIAGARA ON THE BIG FOUR.

The Big Four with its splendid equipment and popular service does not have its own tracks into Niagara but it will run through sleepers from St. Louis and Cincinnati without change, attaching them at Cleveland to the Lake Shore train hauling the special cars from Chicago. Delegates from the territory served by the Big Four are generally selecting this route.

An early reorganization of the Bass Foundry & Machine Works, Fort Wayne, Ind., is in prospect.

## G-2 ASTATIC RECORDING WATTMETER.

During the last three years the demand for recording wattmeters has undergone a great change, and meters which at that time would have been regarded as of enormous capacity are now considered small. Meters of 10,000 amperes are now commonly called for while inquiries have been made for sizes registering as high as 16,000 amperes. Measurements of these heavy currents precluded the use of any form of wound meter field, and the Thomson recording wattmeter had necessarily to be modified. Furthermore, the rapidly growing tendency to set the bus bars closer together and bring the switchboard into the least possible space has rendered it advisable that large meters of this character, where intended for boards of modern construction, should be astatic. While on the majority of switchboards an astatic wattmeter is not necessary, there exist cases in which the best metering results could not be obtained without one; and that total station output meters might be applicable alike to all switchboards, whether within heavy

G-2 ASTATIC RECORDING WATTMETER.

projected fields or not, the G-2 meter has been designed and is manufactured by the General Electric Company in an absolutely astatic form.

In the G-2 meter the field is a single straight bar of forged copper, above and below which are placed two armatures, arranged astatically and having a common commutator. The damping device is also double and astatic, the polarities of the upper and lower group of damping magnets being opposite. The damping mechanism being enclosed within an iron shielding box, any stray leakage lines of an unbalancing character are prevented from entering. The G-2 meter is so independent of local or stray influences that it may be installed directly in front of the very heaviest bus bars without the introduction of any inaccuracy.

The entire meter is held in position upon the switchboard by two studs which form at once the electrical connections and the mechanical support of the instrument. These pass through the board and are bolted to the bus bars by binding nuts with large contact surface.

The cover is of beveled glass set in a polished brass frame fastened to the board.

Sargent & Lundy, Chicago, are interested in a very large amount of work, being either contractors or consulting engineers for construction aggregating \$3,500,000.

The Atmospheric Motor Company has been incorporated at Baltimore, Md., with \$200,000 capital stock, by Sidney S. Frank, H. M. Reinhart and others, of Baltimore.

The Edison-Brown plastic bond is making steady progress not only at home, but across the water. Among the most recent foreign orders are the roads at Blackpool and Dublin.

Breden & Sullivan, of New York, have received the contract to construct the electric road between Nassau and Rensselaer, N. Y., for the Greenbush & Nassau Railway & Power Company.

The Wells & French Company of Chicago is building two 18-ft. closed cars for the Elgin (Ill.) City Railway. These cars are equipped with the Price momentum brake and the standard truck used by the company.

The Southern Street Railway Advertising Company has been incorporated at Baltimore, Md. The capital stock is \$45,000 and the incorporators are Issac E. Emerson, William S. Belding, Charles L. Birmingham, W. Burns Trundle and Parker Cook.

The Electric Third Rail & Signal Company has been incorporated at St. Louis to introduce the invention of B. C. Seaton. The capital stock is \$250,000, and the incorporators are B. C. Seaton, H. H. McElhiney, Benjamin Eiseman and A. M. Sullivan.

The Union Traction Company of Anderson, Ind., has let contracts for 10 double truck motor cars to the Barney & Smith Company, Dayton, O.; for 30 miles of trolley wire to the Western Electric Company, and for rail bonds to J. M. Atkinson & Co., Chicago.

The Safety Third Rail Electric Company has been incorporated at Jersey City, N. J. The capital stock is \$10,000, and the incorporators are William M. Keepers, Newark, N. J.; David F. Halsted, Brooklyn, N. Y., and J. McLeod Murphy, Torrington, Conn.

After a thorough trial of the instrument by the electrical department of the road, the Lindell Railway Company of St. Louis has given an order to the Cravath Manufacturing Company, 825 Monadnock building, Chicago, for Cravath excessive current recorders to equip its Vandeventer avenue line.

The Sargent Company, 675 Old Colony building, Chicago, has issued a pamphlet descriptive of its new "Diamond S" brake shoe. This shoe consists of a number of sheets of expanded steel laid together, into the meshes of which soft cast iron is poured and thus combines the desirable qualities of both metals with great strength added.

The West Chicago Street Railroad has been dissatisfied for some time with its method of lighting cable cars, and recently decided to adopt some good system. After investigation, a contract for equipping 80 cars on the West Madison Street line with the Pintsch system, has been given to the Safety Car Heating & Lighting Company, of New York.

A. L. Ide, of Springfield, Ill., died September 30. As the patentee and manufacturer of the Ide and Ideal engines he gained both fame and fortune. These engines enjoy a deserved popularity for the driving of moderate size electric dynamos and other high-speed machinery, so much so that two shops are maintained to supply the demand, at Springfield and at Harrisburg, Pa.

Mayor & Englund of Philadelphia have secured the contract for all of the overhead material required for the 12.5 miles of the Bucks County Railway, running from Doylestown to Willow Grove, Pa. The contract includes all of the weather proof copper and hard drawn trolley wire, together with the overhead fixtures, flexible horseshoe rail bonds and International fare registers.

The forgings in the engine of the torpedo boat "Rogers" built by the Columbian Iron Works & Dry Dock Company, Baltimore, which broke last week, causing considerable damage to the machinery, are being replaced by forgings from the well known works of the Bethlehem Iron Company at South Bethlehem, Pa. It might be well to remark that the forgings which broke were not made by this concern.

The American District Steam Company, of Lockport, N. Y., has received a contract to install the Holly system of steam heating at Muscatine, Ia., for the Muscatine Electric Railway Company. To utilize the exhaust steam there will be laid 20,000 ft. of 10-in. wrought iron mains, insulated with asbestos paper and incased in a tar-coated wooden log, with variators every 100 ft. to take up expansion and contraction.

The Wells & French Company, Chicago, has issued a small pamphlet describing and illustrating the Price momentum street car brake, which is manufactured by it. This brake was designed by W. G. Price, of the Chicago City Railway. A full description was given at the time of its adoption by this road and will be found in the REVIEW, October, 1896, page 610. The brake is proving very efficient and is earning fine testimonials.

J. Holt Gates & Co., Marquette building, Chicago, have just received the contract to rebuild the entire street railway system of Wichita, Kan. Mr. Gates will lay 20 miles of track, put up 20 miles of overhead work, and equip the power house with 800 h. p. water tube boilers, two 350-h. p. tandem compound condensing engines, three 125-h. p. arc light machines and one 1,500 light incandescent machine. Fifty miles of wire will be required.

The Jamaica government has granted a franchise for electric railways in Kingston and its suburbs to D. B. Chapman of Montreal, Canada. Associated with him are F. S. Pearson, of New York, W. B. Chapman of Montreal, B. F. Pearson of Halifax, N. S., and others, who have sup-

plied \$1,000,000 with which to build the first 25 miles of road. A large power house will be erected for the railway and commercial lighting. Construction will begin very soon and continue all winter.

The H. Channon Company has lately taken orders for Ajax transmission rope manufactured by it to go in the elevator now building at Peoria, Ill.; the new mill of the Texas Star Flour Mill Company at Galveston, Texas; the new elevator for Louisville & Nashville Elevator Company at Pensacola, Fla.; the new elevator for the Kingston Elevator & Transit Company at Kingston, Ont. The drive for the Louisville & Nashville Railroad Company's elevator is probably the largest in the country.

The Canon City & Cripple Creek Construction Company has been incorporated to build 30 miles of electric railway between Cripple Creek and Canon City, Col. This road is the outcome of the excessive charges of the Florence & Cripple Creek Railway for passenger and freight service. Paul E. Hirsch, of Chicago, has entire charge of the construction of the road, and shipments are being made of rails and electric supplies and equipment. The line will cost about \$800,000 and it is stated will be in operation by February 1, 1898.

R. Graham-Woodward has opened offices in the Havemeyer building, New York, and offers his services as expert street railway accountant. Mr. Woodward was auditor for three years of the Oakland, Cal., road and only left it to take up the more extended phases of public accounting and general auditing. His street railway work in this and other roads, with experience in the details of operating departments, fit him for the special work he engages in. He makes a specialty of expert examination of accounts and the arranging of a more simple and economical method of accounting and auditing, with a view to showing where a saving can be effected in the operating department.

The Phoenix Iron Works Company has received a letter through its agent in Japan, Lamar Lyndon, of Kobe, regarding a 75-h. p. tandem compound condensing engine, 7½ and 13½ x 12 in., furnished by it, which is as follows:

"Yokkaichi, Japan, August 28, 1897.

Phoenix Iron Works Co., Meadville Pa.

Dear Sirs:—

We have pleasure to inform you hereby that in the first part of this month we got through with the setting up of the engine which we bought of you, and same was inspected yesterday by the Government officials, and the result was so satisfactory that we thank you for same, and are glad to give you hereby testimonial for the strength and perfectness of the engine which you are selling.

Yours faithfully,

The Yokkaichi Electric Light Co., Ltd."

The E. P. Allis Company of Milwaukee has been doing a very extensive foreign business in large engines for street railway power stations, the contracts aggregating \$500,000. Orders from the foreign trade call for 21 engines averaging 1,200 h. p. each. The six engines for the Central London Railway, the underground electric road building in London, are each 1,500 h. p. Four engines of the same size go to Sidney, Australia, for the increased power required to operate the railways there. Six 500-h. p. engines will be furnished the Dublin Tramways Company. Three engines

of 1,000-h. p. will be required for the street railway lines of Barcelona, Spain, as soon as they are equipped for electric traction. Two duplicate engines will also be shipped to Madrid for tramway service.

A. E. Jones, constructing engineer for the Morrin "Climax" boiler stopped at Chicago on his return from Omaha, a few days ago, where he closed the contract for all the boilers for the Trans-Missouri Exposition. About 3,500 h. p. will be installed, and the order was secured in the face of the usual active competition that is made for exposition work. The progress made by the Morrin people since they entered the field in 1890 has been one continued advance, and the works have not had occasion to lay off a man all through the hard times. At present the works are running full, night and day. These boilers were also installed in the Nashville exposition, and our readers will recall the large battery at the World's Fair where they attracted great attention and made a famous record. The company reports large foreign orders. Among western orders four large units are being installed at Salt Lake City.

George H. Barrus, consulting engineer, of Boston, has recently made an evaporative test on a 200-h. p. Cahall boiler at the Narragansett Mills, Fall River, Mass., from which we quote some of the results and the conclusion of the report as follows:

### HEAT BALANCE.

| Total heat of combustion per lb. of combustible by oxygen calorimeter,                                       | 15,457 B. T. U. |           |
|--------------------------------------------------------------------------------------------------------------|-----------------|-----------|
|                                                                                                              | B. T. U.        | Per cent. |
| Heat observed in useful evaporation, 12,507 × .666 =                                                         | 12,168          | 78.7      |
| Loss by hot gas, 14.4 × 520 × .24 =                                                                          | 1,825           | 11.8      |
| Loss by evaporation of moisture in coal and moisture formed by burning of hydrogen (.043 × 9 + .035 × 128) = | 541             | 3.5       |
| Loss by unconsumed CO <sub>2</sub> , .04 × 10,150 =                                                          | 406             | 2.6       |
| Radiation, carbon in smoke, hydrocarbons, and unaccounted for,                                               | 517             | 3.4       |
|                                                                                                              | 15,457          | 100.0     |

The power developed on the test was 223.4 h. p., or about 10 per cent above the rated capacity of 200 h. p. This was obtained with an average draft of .14 in. water pressure, which is far below the maximum available draft.

The evaporative result was 11,841 pounds of water from and at 212° per pound of dry coal. This exceeds the guarantee of the boilers (10.5 pounds of water from and at 212° per pound of dry coal) 12.8 per cent.

The heat utilized by the boiler was 78.7 per cent of the total heat of combustion of the coal. Of the remaining 21.3 per cent, the gas analyses accounted for 11.8 per cent due to the loss from the waste heat, and 2.6 per cent due to the unconsumed carbonic oxide, all of which is detailed in the table of the "heat balance." The evaporative result is unusually high for a boiler in which the flue gases escaped at the high temperature which was found in this case, but this is not inconsistent, considering the fact that the quantity of gas is unusually small, good combustion having been obtained with a very small amount of excess air.

The boiler steamed freely during the entire run without undue exertion on the part of the fireman, and there was an entire absence of fluctuation in the water line as revealed in the gauge glass. The steam was slightly superheated at a point in the pipe a considerable distance from the boiler.

The British Thomson-Houston Company of London through its representative A. K. Baylor, has just closed an important electric railway contract with the companies op-

rating the tramway system of Dublin, Ireland, and Barcelona and Madrid, Spain. The contract for Dublin includes all steam, as well as the electric generating and motor equipment, and comprises six Allis horizontal engines of 500 h. p. each, six 500-k.w. General Electric generators for direct connection to the engines and complete switchboard and station equipment. The car equipment will consist of 150 complete motor and series parallel controller equipments, the motors to be mounted on Peckham trucks. This contract follows closely that made for the equipment of the Clontarf line, of the Dublin tramway system, which will be opened within the next week or two. The apparatus for this was also supplied by the British Thomson-Houston Company. The contract signed for the Barcelona and Madrid roads covers five 400-k.w. General Electric generators and three of 75 k.w. each, all to be directly connected, while the three latter will be lighting generators, they will also be wound for 500 volts. This contract also includes full station equipment.

Hayes & Arthur, Cuyahoga building, Cleveland, have taken the agency for A. O. Schoonmaker, New York, and will carry in stock a full line of both India and amber mica, and will be able to fill all orders promptly.

The catalog of the Fuel Economizer Company of Matteawan, N. Y., gives some data from tests of Green economizers which show a great saving from their use. There are also numerous diagrams which show the different methods of installation in numerous plants where these economizers are now in service.

The American Air Power Company has been incorporated with a capital stock of \$7,000,000 and will manufacture machinery and apparatus for supplying light, heat and power for railways. It is stated that the Metropolitan Traction Company, of New York, is one of several companies behind this new organization.

The W. T. Van Dorn Company reports orders for its automatic car couplers as follows: Brownell Car Company, 40 couplers; St. Louis Car Company, 40 couplers; Laclede Car Company, 100 couplers. Among recent foreign orders were one for 23 sets for the Waterloo & City underground of London and one for the Glasgow road.

The Albert & J. M. Anderson Manufacturing Company of Boston, has recently issued a new catalog of the electrical and street railway appliances manufactured by it. This company had its electric railway, light and power specialties at the Brussels Exposition, all its goods being placed "hors concours," which is to be translated as "above competition."

This month the Western Electric Company of New York and Chicago sends to the trade the third of its series of handsome engravings. It is a box of strawberries in colors entitled "Full measure and good quality" like electric supplies furnished by the company. On the opposite side of the card is illustrated the Western Electric enclosed arc lamp.

Pantasote, that product of the Pantasote Leather Company which is so extensively used for car curtains, is the material which the Franklin Institute reported, after an

investigation of two years, to be "the best substitute for leather on the market." It is strong, is not injured by heat, is non-inflammable, and does not shrink, stretch, harden, peel or crack.

One of the most enterprising and active concerns in the gear and pinion business is the Catskill Foundry & Machine Works, located at Catskill, N. Y. This company entered the field about four years ago, setting aside a part of the works for the manufacture of gears and pinions exclusively; foundry facilities are superior, and the works equipped in the best manner possible, having entirely new machines of the latest and most improved designs for both steel and cast iron.

The West Shore, Hudson River, and Boston & Albany railroads as well as the Hudson river boats, afford excellent shipping facilities to all points, and saving freight charges to nearby customers. By prompt deliveries and strict attention to all orders they have built up a considerable business, which is constantly growing. The New York office is at 126 Liberty street, managed by J. C. Dolph & Co.

The Ohio Brass Company of Mansfield, Ohio, believes from present indications that this season's sales of the adjustable track brush holders will far exceed all previous ones. During the past month several large foreign shipments of holders and brooms were made, one consignment alone being for 45 sets, and in addition numerous orders have been received from roads operating in the country for both initial and additional equipments of these. Several important changes have been made in the detailed way of manufacturing the holders since they were first placed on the market two years ago, but their operation remains the same.

The Mica Insulator Company of New York, Chicago and London, and Eugene Munsell & Company, miners and importers of "mica" of New York and Chicago, will have a joint exhibit at the Niagara Falls Convention. This exhibit will include the flexible "micanite" plate and the "M. I. C." insulating compound, two new insulating materials which have been introduced during the past year, also the India and amber "mica" in sheet as it comes from the mines, "mica" segments, "micanite" plates for commutator segments, "micanite" and "empire" cloths and papers, several sets of commutator rings and segments for railway generators and motors. Franklin Brooks, vice-president of the Mica-Insulator Company and Chas. E. Coleman, manager of the Chicago branch will be in attendance.

## GRAND TRUNK TO THE FALLS.

The Grand Trunk road has been known as the old time route to Niagara Falls, so long, and by so many thousands, that our readers are already well informed as to its features. The road has been greatly improved and popularized. The Suspension Bridge has been replaced during the present year with a fine steel arch which is one of the best specimens of bridge work in the world. A solid vestibuled Pullman train leaves Chicago daily at 3:02 p. m., and arrives in Niagara Falls at 7:15 a. m. the following day. Tickets and reservations can be had of L. R. Morrow, city ticket agent, 103 Clark street, Chicago, or any ticket agent in the west.

 Business Manager.

#### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

#### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. NOVEMBER 15, 1897. NO. 11

OF all the engineering or technical associations, the American Street Railway might be expected to conduct its finances on a sound business basis. It is, therefore, a matter of pride that the treasurer's report this year shows nearly \$5,000 in the treasury or collectable, as against a deficit of nearly that amount two years ago.

ONE of the most satisfactory results of the convention was the change in by-laws, which places the fixing of the date of succeeding meetings in the hands of the executive committee. This is as it should be, and will be appreciated by every person who attends these annual meetings. The REVIEW has long advocated this departure from the rut in which we have traveled so long, and congratulates the Association on this great improvement. Mr. Kelly, of Columbus, was the one who finally drew up the petition and presented it to the committee, and thus placed the matter in shape to be acted on at the past meeting.

THE Association is turning its path over the course already traveled in its earlier years. Boston was the birth-place of the Association, and Boston will be its host next year. But the Association of 1881 is quite as different from what the Association of 1898 will be, as the Boston of the two dates named. The selection, while somewhat distant for western members, pleases all, and the west will be found with a big representation when the time comes. The city, aside from its ever interesting historical features, presents

as an object lesson one of the best constructed, best equipped and best managed properties in the world, and furnishes plenty to study and copy. Our western brethren may possibly have to dust off their grammars and rhetorics somewhat before they go, but we promise all Boston will be found a good place in which to be.

THOSE who have attended these conventions for ten or more years cannot fail to observe, and with regret, the decreasing number each year of the old guard, those who for many years were always found in attendance. They belonged to the old school it is true, and for the most part were then old enough to be the fathers of the greater number of the present attendants. But they were eminently practical and successful, as a rule the chief owners of the properties they represented, and were a splendid body of men, who have now stepped out of the harness to engage in other pursuits, or retired to enjoy the fruits of their hard earned fortunes. When electricity came in, the most of them went out and while there is the utmost harmony and good will among the rising generation of managers, it is doubtful if the sympathies and warm-hearted interest in each other which characterized the old days, will ever be repeated in like degree.

PRESIDENT McCULLOCH proved one of the best presiding officers that ever filled the chair. He insisted on the convention sticking close to the business before the house, and dispatched that business without a moment's unnecessary delay. At the same time he in no instance tried to turn the channel of what the Association desired, and richly deserves the many compliments he received. His ruling on the question of supply men being allowed the privileges of the floor was eminently correct, and meets with the hearty approval of almost every exhibitor. The limited time of the Association ought not to be granted to the advertisement of anybody's wares, for if once the door is open, in all fairness a whole army should be admitted to the same privilege. And this the supply men realize and appreciate. If some highly radical and absolute departure from existing methods should arise, which involved a great change in operating expenses for example, the matter certainly should be considered by the assembly; but even then it should be made the subject of study and report by some competent committee of actual members.

CONSIDERABLE interest was expressed, not only by supply men, but delegates as well, in the proposition to hold an international street railway convention in Paris, in 1900, during the great exposition. It was believed that street railway men from all parts of the world would be glad of the opportunity to meet in general conference, and the display of exhibits would be of special advantage to the managers of foreign roads. While we Americans naturally feel that we are farther advanced in the science of electric railroading, as in fact we certainly are, and ought to be, on the other hand it is maintained that we may well study to advantage the more durable types of street construction which characterize the track work abroad. The idea is well worth considering, and the convention need not take the place of the annual meeting of the American Association, as the date could be such as to avoid any conflict. There ought to be a sufficient number going over to pretty well fill one vessel, and a continuous convention of

the Americans while en voyage, would occupy the time in a pleasant and profitable manner. We should be glad of an expression from our readers as to the desirability and advisability of the project.

THE outcome of the "dispute in the engineering trades," as the conflict between capital and labor now being waged in England is called, cannot fail to be watched with the greatest interest by the employers of labor in this country. Dispute appears to be a good name for the difficulty which is a combination of a lock-out and a strike. The announcement on the part of the unions that in the event an eight-hour day were not conceded the men would be ordered out was met by the employers deciding to discharge the men in batches of 25 per cent of the total employed; this caused the remainder to go out on a strike. The beginning was in the first week in July and early in October the number of men out was stated to be 59,000, of whom 40,000 were engineers and allied workers.

There are two features about this dispute which are novel in the strikes of late years. The employers for the first time have a federation which really amounts to something and the prospect is that it will hold together. The civil authorities are doing their duty in discouraging "picketing;" this is quite unusual.

The demands of the trade unions have been growing so intolerable that the employers were driven to unite in self-defense and give battle for the purpose of managing their own affairs in their own way, and it is this combination which makes a satisfactory result possible, for heretofore the employers have stood alone. Needless to say this combination or trade union of capital is regarded as a great grievance by the other side, the men being inclined to regard the "sacred right of organization" as peculiar to labor. This time the demand is not "a fair days wage for a fair days work" on the part of the men; but it is for "a fair days work for a fair days wage" on the part of the employers. We at home are union-ridden in many lines—a notable instance of the tyranny of the unions recently occurred in Chicago, where all work on the public school buildings was stopped for weeks until the school board agreed to let contracts only to those who employed union labor—and trust that the day is not far distant when contractors here may succeed in forming a federation sufficiently strong to at least hold the unions down to what is fair and right to both sides.

The effectiveness of "picketing," which in fact consists of abusing non-union men and intimidating them by threats and force, has made it a very common and practically the only serious weapon at the disposal of strikers. Contrary to the usual practice the English magistrates have in this dispute taken to imposing terms of imprisonment at hard labor instead of paltry fines, with the result of greatly discouraging the practice and hence also giving the labor agitators a new grievance.

We have had no street railway strikes of moment since that at Milwaukee in the spring of 1896. That resulted in the complete triumph of the company after a fight against great odds. The city of Milwaukee being chosen as the scene of the strike because it was well known that the patrons of the cars there would lend aid to the strikers, as they did. For a time it was thought that the Chicago City Railway would have a similar experience this year, but the

threatened strike was averted by the firm measures adopted by the company.

When a free born, American citizen is prevented from earning his daily bread by honorable labor, except he do so according to the dictates of a union, it is high time for our Fourth of July orators to fold up the eagle's wings and take some other country as an illustration of the vaunted "land of the free."

THE papers read at the convention are published in full in the succeeding pages and will be found well worthy of a careful reading.

Mr. Sullivan has strong convictions on the subject treated by him, "Municipal Ownership," but relies upon a simple statement of facts and the logical conclusions to be drawn from them, and carefully avoids anything approaching the vituperation that is to be found in so many of the articles written nowadays on this subject. The facts in regard to municipal ownership of railways abroad were given; and also the facts regarding municipal maladministration at home, from which the conclusion is that the powers and duties of municipalities should be abridged rather than enlarged.

Mr. Knox pointed out some of the difficulties experienced in operation, and that many of them were due to the lack of a well defined policy on the part of the management. Frequent changes in the force and useless experiments are a fruitful source of loss.

Mr. Hewitt discussed the use of the storage battery, and the various ways in which it has been applied to street railway work, and gave in detail the experience of the Union Traction Company, of Philadelphia. This subject is one in regard to which data were surprisingly scarce, and the facts given by Mr. Hewitt were greatly appreciated and the discussion of them animated.

Mr. Hoopes treated of the distribution of power to railway lines and drew the conclusion that of the methods at present feasible, direct current distribution will give the best results in the majority of cases, that the three wire system does not show the same economy in railway as in lighting work, and that the field for multiphase transmission is at present quite limited.

Mr. Davis in his paper, which was particularly well and logically arranged, gave the details of the system of discipline of employes as developed by him on the Canal & Claiborne road where it has proved to be very successful in attaining the object sought, that of securing the best men and of identifying them with the interests of the company.

Col. Hest as the pioneer in the development of electricity on steam roads treated of its application to the two lines of the New York, New Haven & Hartford and gave the results in the increase of traffic which surely point to the further adoption of electricity for such service.

Mr. Hield prepared the paper which had been assigned to Mr. Goodrich of Minneapolis and gave a systematic though brief discussion of the principles underlying the settlement of damage claims, and also of the prevention of accidents.

The last vestiges of horse car days are passing away on the Metropolitan Street Railway of Kansas City. The "cannon ball" line has ceased operating by animal traction and the mules are sold. The cars, which are narrow gage, are for sale, and will likely be converted into play houses for some of the small children in the city.

## ALBION E. LANG, PRESIDENT-ELECT, A. S. R. A.

We are once more reminded that Ohio is a state resourceful in presidents and great men, and the Association made a wise and acceptable selection when it called Albion E. Lang, of Toledo, to occupy its chief place of honor for 1898.

Mr. Lang was born in Huntington, Lorain county, Ohio, in the year 1849. His street railway history dates from 1881 when he became the owner of the Monroe & Dorr Street Railroad, in Toledo. At that time there five other roads in

Company, and these two companies control all the street railway and electric lighting properties of Toledo, which is a city of 135,000, and growing rapidly.

Mr. Lang has been a constant attendant upon the meetings of the American Street Railway Association since 1888, having missed but two meetings during that time, and his counsel and judgment have always carried much weight in the deliberations of the body. In 1893 Mr. Lang was president of the Ohio State Tramway Association.

ALBION E. LANG, PRESIDENT-ELECT, A. S. R. A.

that city, which were five more than there should have been, and Mr. Lang set out in a quiet and determined way to bring about a consolidation of them all. In 1885 he succeeded in uniting them under the name of the Toledo Consolidated Street Railway, and became successively the secretary, vice-president and general manager, and eventually the president. Later on the Consolidated acquired two other companies which had come into the field, and a second consolidation occurred in 1895 under the name of the Toledo Traction Company, of which Mr. Lang has been president since its organization.

He is also president of the Toledo Consolidated Electric

Company, and these two companies control all the street railway and electric lighting properties of Toledo, which is a city of 135,000, and growing rapidly.

Mr. Lang is progressive, broad gaged, and far sighted; in manner he is genial and warm-hearted, and has the happy faculty of making friends with all he meets.

He will honor the Association, which has honored him.

In his administration Mr. Lang will have the assistance of an able executive committee. Ex-President McCulloch is a member by reason of being retiring president, and the three vice-presidents, Messrs. Ely, Rigg and Connette, and the other members, Messrs. Wyman of New Orleans, Moore of Trenton, Roach of Chicago and Goff of Fall River, are men whose names are synonymous with successful management in their respective cities.

## THE NIAGARA FALLS CONVENTION.

The Sixteenth Annual Gathering of the A. S. R. A. a Great Success—The Sessions Well Attended—  
Papers Excellent—Exhibits Many and Attractive—Delightful Excursions—Accountants Hold  
Their First Regular Meeting with Good Attendance and Fine Results—  
Next Year, Boston.

The gathering of street railway men in convention at Niagara Falls was a great success; all are agreed on that point. The weather was for the most part fine, with the exception of the smoke from forest fires which clouded the sky and prevented the best views of the Falls, and the rain which came at the close. But it was a jolly, good natured crowd, which did not mind the little eccentricities of late October. The attendance was large, being about the same as at St. Louis, which was a record breaker, and this year a larger number of ladies were present than at any previous meeting.

The attendance upon the business sessions was unusually good, and held up strong to the close. The fact that a warm room was provided for the meetings had largely to do with this.

The exhibits, which are described in detail elsewhere, were fully up to those of a year ago, in point of numbers, careful arrangement, and interest; but suffered greatly from lack of room, the demands for space being such that few were able to display their goods to the best advantage, and the larger exhibitors were positively cramped for room, even after leaving at home much which they would have been glad to bring. The supply men, however, were somewhat compensated by the fact that delegates gave more time than ever before to a study of the display, and more orders were hooked than at any previous meeting in years.

The ladies were nicely taken care of by a large committee of Niagara ladies, who were constantly in attendance, and the excursions were among the most interesting and instructive ever provided. The arrangements by the management of the Association were most excellent, and everything moved along with rapidity and method. In fact it was one constant rush, from arrival to departure, and the extra day did not seem to leave any more spare time, than under the three-day order of affairs. This, however, is but an indication of the steadily growing scope and work of the Association, and points to the no distant time when an entire week will be required to properly take care of the convention work.

The Accountants' Association was a highly gratifying success. The representation was good, the papers carefully prepared, and the report of the committee on a Standard System of Accounts, was the most important advance in this work ever attempted. The warm reception and hearty endorsement and encouragement these young men received at the hands of the "big association" was a graceful compliment which was at once deserved and gratifying, and cannot fail to spur the accountants to better work through the whole year.

The Niagara people did everything in their power to make their visitors welcome, comfortable and happy, and will be long remembered as genial hosts.

The excellent work of President McCulloch and Secretary Penington was evident in the completeness of arrangements, and the absence of much confusion which has marred

some previous meetings. The utmost harmony prevailed throughout, and while there was an active contest for the next place of meeting, it was accepted in good part by the defeated contestants, and the convention next year, at Boston, will certainly exceed in attendance and displays anything ever attempted.

## Tuesday Morning.

The arrival of delegates was somewhat earlier than usual, and promptly at 11 o'clock, Tuesday morning President McCulloch called the meeting to order in the assembly room of the armory. A pleasant feature was the seating upon the platform, in addition to the president and secretary, of ex-presidents H. H. Littell, Henry M. Watson, H. M. Littell and George B. Kerper, and members of the executive committee, Charles S. Sergeant, D. B. Dyer, C. F. Holmes, H. P. Bradford, and Charles H. Smith.

According to custom, an address of welcome by the mayor, Hon. A. C. Hastings, preceded the other business, and after a pleasant introduction by the president, Mayor Hastings spoke as follows:

## ADDRESS OF WELCOME.

Mr. President and Gentlemen of the American Street Railway Association: It hardly seems necessary for me, representing the city of Niagara Falls, to extend a welcome to an association of such a wide reputation that all cities are anxious and happy to entertain you. It seems fitting that we should have you within our gates only long enough to show you the power we generate and send out for manufacturing. We have two large companies; one delivers current to our Buffalo neighbors, some 20 miles distant, and the other runs electric cars 14 miles in another direction.

While the last few years have seen great strides in the commercial use of the great cataract, as long ago as 1725 the French sawed lumber here with power from Niagara river to build old Fort Niagara. From that time forward more or less use has been made of this wonderful fall of water.

With some 200,000 h. p. being developed by the two companies we will have enough power to run a great many factories and we expect that you gentlemen in the near future will be knocking at our doors to obtain power to operate your roads for hundreds of miles about us. The roar of Niagara was heard in New York on a telephone; why not the same energy in larger quantities and commercially? We are generous and trust you will call on us for all you want.

I have this week seen a report of the New York State Railroad Commissioners of 1893 and find that our local road, the Niagara Falls & Suspension Bridge Street Railway Company, was chartered October 20, 1882, this being their 15th anniversary, or crystal wedding, as it were. They have a chance to give thanks that they are alive and healthy. From the same report I find the capital invested in '93 was something over \$100,000,000, with some \$20,000,000 gross income in New York State alone, but I also find your business was not very much better as to net profits than a great many others in that year. From the general air of prosperity as shown in your faces, they must have improved and I trust they will keep on improving until you will not find it necessary to have your men mention about there being more room up front. We will not crowd you while in our beautiful city.

A few words of advice as to how to see the Falls may not be amiss, as you are here for a few days only, and most of your time will be taken up by your business. The park is free to all parts and comprises over one hundred acres that are accessible by walks and road-

ways. The electric car service is such that you can ride for miles with only a change of car from one road to another at two or three different points. The carriage hire is very reasonable—all reports to the contrary—only have it understood when you start, what the rate shall be per hour, which is regulated by ordinance. Don't think because you have driven or walked about for an hour or so you have seen it all. Take time and view the Falls and parks from different points.

We appreciate the honor of your visit and want you to leave with such an impression that the memory will always be pleasant. Remember the latchstring is always out for you and we trust you will come again, individually and collectively. We wish you all success in your deliberations. May your association grow and flourish like a green bay tree. The gates of the city are wide open to you and the only restriction made, is that if you find anything bolted down, please leave it.

Personally, it is a pleasure for me to meet and welcome you and I trust to have that pleasure again. (Applause).

The President: Gentlemen, we are obliged to his Honor, the Mayor, for his words of welcome, and we hope that he will preside at the police court if any of us are unfortunate enough to stray out and be captured.

After the roll call an opportunity was given for new members to join, and the following companies were admitted to membership:

Nassau Electric Railroad Company, Brooklyn, N. Y.  
 Binghamton Railroad Company, Binghamton, N. Y.  
 Buffalo Traction Company, Buffalo, N. Y.  
 Roxborough, Chestnut Hill & Norristown Railway Company, Philadelphia.  
 Chester Traction Company, Chester, Pa.  
 Colorado Springs Rapid Transit Company, Colorado Springs, Col.  
 Southwest Missouri Electric Railway Company, Webb City, Mo.  
 Union Traction Company, Anderson, Ind.  
 Atlanta Railway Company, Atlanta, Ga.  
 Wakefield and Stoneham Street Railway Company, Boston, Mass.  
 Mystic Valley Railway Company, Boston, Mass.

On motion of Mr. Kelly, the published minutes of the last meeting were approved as printed. President McCulloch then delivered the annual address.

#### PRESIDENT'S ANNUAL ADDRESS.

Gentlemen of the American Street Railway Association: Our convention assembly for the sixteenth annual period is within the sound of nature's greatest wonder, but the wonders that are wrought in our own immediate application and appropriation of nature's resources are even more startling and awe-inspiring than the great Niagara Cataract. If our ancestors of two centuries ago could sit in judgment on our doings of today we would unquestionably be required to involuntarily undertake the feat of the gallant Captain Webb, and if, perchance, we survived the perils of the raging torrent, the bonfires of our aboriginal predecessors would be rekindled on the cliffs below, and a fat-frying would take the place of our discussions and merry making, as there would be no escape on our part from the charge of witchcraft. These great falls were worshipped by our red brother; the venturesome explorer and historian dipped his pen in consecrated fluid as he wrote reverentially of their grandeur; the poet and the maiden everywhere have sung of them in enchanting praise; reverence and poetry and romance have characterized the stories which tell us of them; but the matter-of-fact Yankee of today, casting reverence and poetry and romance to the winds, has harnessed them like an old plow-horse, and compelled them, just as subversively, to do his bidding; they make heat and light and power for all purposes; they revolutionize the processes of the manufacturer and the chemist, and ere we meet here again they will, without doubt, have been saddled with the menial duties of cooking and washing and tilling the soil of all the country around. The enabling element for the utilization of this wasted energy of the past is electricity, in the development and search for uses of which the scientist and manufacturer sleep not, neither do they rest. They furnish us with their best and latest devices and appliances today, and tomorrow these devices and appliances are obsolete. To keep our place in the procession we must join in the cry of "The king is dead, long live the king." We must discard the old and adopt the new, or else be ground

under the wheels of this juggernaut of progress. Unfortunately, if we endeavor to "shun Scylla, we are in danger of being wrecked on Charybdis;" hence we assemble here to counsel together as to how we may best shape our course. To learn more of this revolutionary factor in our business, to discuss this and other kindred subjects, to compare our experiences, to meet and greet each other, to renew old friendships and acquaintance, and to form new ties, to be forced, if need be, to recognize that "there are other pebbles," to find that the American Street Railway Association is filled with men to know whom is both an honor and a pleasure—these, my friends, are some of the things which have brought us together, and it is hoped that a full measure of pleasure and profit will reward all who honor us with their presence.

Our local brethren, with a hospitality as abounding and exhaustless as the never-ceasing flow of their great river, have provided for our physical comfort and entertainment. We beseech them not to seduce us from a proper contemplation of the business before us.

Our noble ally, our helper in all the good work we accomplish, our always alert, jovial and genial friend, the supply man, has contributed, as usual, his share to our entertainment and enlightenment. He is here to show us the best of everything he has. He is not, in one sense, a member of our association; he does not participate in our deliberations; but he stands at our threshold, and the vigilance which he exercises, that none may escape, is worthy of our emulation in the conduct of our business. Let us show our appreciation of his efforts by inspecting his wares, by loading him with orders and by fraternizing with him, that his enjoyment of the occasion may be equal with ours.

We have still another and a new element in our gathering for this year. Whilst we are here engaged in the discussion of questions pertaining to the construction, equipment and operation of the roads and interests in our keeping, there is assembled near by, and also in deliberative convention, an earnest, intelligent, enthusiastic body of mostly younger men than ourselves. They have in view the same objects which bring us together—a betterment in the performance of street railway work. Their duties, whilst distinct and apart from ours, are just as essential, and the requirement is for the same degree of intelligence, industry and integrity. Their organization is young, and they are just starting out in their efforts to enlighten each other by a mutual interchange of information as to methods and ways. I allude to the Street Railway Accountants' Association. Let us not extend to them the right hand, but both hands, and help and encourage them to persevere in their good work. Their interest and efficiency in the performance of their duties is susceptible of the same betterment by convention as ours. If they find it desirable and convenient to meet at the same time with ourselves, and thus extend the acquaintance and good-fellowship between the operating and accounting departments which must result from contact, let that arrangement continue; but if it be considered wiser to have two separate meeting times and places, that may be the plan, but they should have our encouragement and indorsement, and even financial support, if necessary.

Our meetings are always attended by quite a number of persons engaged in the same business as ourselves, but whose companies are not members of the association, and we receive requests for information from the same source, which information is always cheerfully given. We would not like to close our doors against these non-members, but we would be glad to enter their names in our official lists, and their annual dues, which is only a small amount, would fill an aching void in our treasury.

There is still another class who, although members of our association, seldom or never grace our meetings with their presence. Whether this may be from a lack of time, a feeling of exclusiveness or a consciousness of a possession of all the knowledge attainable concerning our business, I know not. But if the first, an effort and sacrifice might be made experimentally; if the second is the cause of their absence, a surprise and discovery is in store for them if they will only develop it. And if the last reason keeps them away, a feeling of charity and good-will for their fellow laborers should impel them to come amongst us and show us how to surmount our perplexing obstacle.

The questions to be discussed in our convention have been selected with reference to newer developments and applications. The gentlemen honored by selection (and the honor should be much coveted) to prepare papers have all been urged to be present and personally present their efforts, thus giving them a force that can only be imparted by the enthusiasm of the author. Time will be given for the presentation and discussion of each paper, and it is hoped the discussions will be free and exhaustive.

I wish that my successor in office may have a secretary and executive committee who so thoroughly realize and faithfully perform their duties as have the secretary and executive committee who have assisted me in the performance of my very pleasant work.

And now, my friends and brethren, thanking you with more earnestness than my language can express for the unexpected honor with which you crowned me a year ago, and promising an impartial ruling on all questions presented, we will proceed with the business of the convention.

The report of the Executive Committee was then read, including the minutes of its meetings held during the year. Deaths during the year were as follows:

W. H. Sinclair, ex-president Galveston City Railroad Co., Galveston, Tex., Jan. 11, 1897.

A. M. Billings, president Memphis Street Railway Co., Memphis, Tenn., Feb. 7, 1897.

John Radall, vice-president Brunswick Traction Co., New Brunswick, N. J., May 9, 1897.

R. Dudley Frazer, ex-president Memphis Street Railway Co., Memphis, Tenn., July 10, 1897.

In the matter of banquet tickets the following action was taken: "That there shall be issued two banquet tickets to each member company of the association, where there are two or more official representatives, and when there is only one such representative only one ticket shall be issued, and where a company is not represented, no banquet ticket shall be issued on account of such company."

The report of Secretary-Treasurer Penington showed a membership of on October 12, 1897, of 163 companies; 15 companies having joined and 12 withdrawn during the year. The receipts during the year were:

|                            |            |
|----------------------------|------------|
| Cash on hand Oct. 15, 1896 | \$1,640.94 |
| Annual dues, 1897          | 3,789.58   |
| Membership fees            | 375.00     |
| Space, exhibit hall, 1896  | 2,146.30   |
| Space, exhibit hall, 1897  | 180.00     |
|                            | \$8,131.82 |

Expenses to October 12, 1897

Leaving cash on hand

The cash on hand with \$1,500 due for exhibit space at Niagara,

and 350 members' dues makes the total assets at date \$4,781.48.

The secretary read letters of regret at their inability to attend the meeting from Thomas Lowry, of Minneapolis, and C. Denmore Wyman, of New Orleans.

H. H. Littell, of Buffalo, then offered the following resolution which was unanimously adopted:

Whereas, The American Street Railway Association, through the report of its president, has been officially informed of the organization of the Street Railway Accountants' Association of America, and

Whereas, The aims and objects of that association are to bring together those engaged in the accounting department of street railways for the interchange of ideas, to promote the adoption of a simple, concise and uniform system of accounts, and to improve the work of the accounting department, and

Whereas, that association is now in convention assembled in this building,

Therefore, be it resolved: That the American Street Railway Association, believing that the attainment of the aims and objects of the Accountants' Association will be of permanent benefit to the street railways of America, heartily endorses and approves of the organization of that Association and pledges to it its cordial encouragement and support.

The President: If there is no further business in connection with the opening exercises of the meeting we will now proceed to the reading of the papers. The first paper is that on "Municipal Ownership

of Street Railways," by P. F. Sullivan, general manager of the Lowell & Suburban Railway Company, Lowell, Mass. This is a subject to which Mr. Sullivan has given considerable personal attention, and he has gone to great trouble and expense to procure information on this subject, and his paper will be very interesting.

#### MUNICIPAL OWNERSHIP AND OPERATION OF STREET RAILWAYS.

By P. F. Sullivan, General Manager, Lowell & Suburban Street Railway Company, Lowell, Mass.

The subject of this paper is one which cannot be treated properly or in other than a limited manner within the time and space permitted. What I shall write, therefore, is intended more to suggest lines along which others may follow, rather than to attempt to treat it exhaustively.

The subject will be considered under the two following heads:

Municipal administration in American cities is so extravagant and unbusiness-like that in the interest of the public, the powers and duties of municipalities should be reduced rather than be enlarged;

Municipal ownership and operation abroad are the exception rather than the rule; and were the reverse true, and such ownership and operation successful from a financial point of view, it does not follow that American cities could or should follow such examples or that if they did so, success would result.

As to whether we should experiment with socialism, particularly under our forms of municipal government while still going through the experimental stage, and as to whether popular government should compete with private enterprises, I leave for other and separate discussion.

#### Municipal Maladministration.

Thoughtful men view with alarm the growth of American cities, and the maladministration of their affairs; some go so far as to believe that both conditions seriously threaten the future of the republic. So alarming have these become that patriotic and thoughtful men, and women, too, have organized in nearly every city in the country with a view of arousing public opinion, of devising ways and means to purify local politics, and to obtain a fair return for money expended.

In nearly every large city in every state in the Union from Maine to California and from Oregon to Florida such organizations exist under one name or another, and in some cities they go so far as to employ counsel and to instruct city governments in their duties. This is true of Boston, Providence, New York, Baltimore, New Orleans, Chicago, San Francisco and other cities. At the present time there are over 60 of such organizations in existence.

Not only are there local organizations, but such organizations also send delegates to national conferences to adopt methods of arousing public opinion, and purifying local politics in every city in the Union. Conferences for good city government were held at Philadelphia in 1894, at Minneapolis and Cleveland in 1895; at Baltimore in 1896; and at Louisville in 1897. To show how general and widespread are municipal maladministration and corruption throughout the country, I quote below extracts from the remarks of a few of the delegates:

#### PHILADELPHIA CONFERENCE, 1894.

"On the other hand, a Chicagoan would have to be in full training, and at his very best, to attempt to do any boasting about his city politics. Indeed, he knows very well that when compared with the government of any but American cities, the government of his city, like that of so many other cities of his country, is simply a deep disgrace to republican institutions and to the great democratic idea."

Franklin McVeagh, Chicago.

"It is no exaggeration of language to say that saloons and gambling houses and brothels are here nurseries for 'statesmen,' that the active hostility of their keepers is, if not fatal, at least, a grave impediment to success in public life; and that men and women who gain their living by habitually breaking the laws have a potent voice in selecting the public servants, who make, interpret and execute those laws!"

Charles J. Bonaparte, Baltimore.

"It must be admitted, however, that there are public servants who are not burning with desire to discharge their whole duty to their employers, and who have no wish to keep the channels of communication open between themselves and the respectable classes. Their tastes and ambitious will lead them in other directions. They have great faith in the power of the corrupt and disorderly elements of the population, and their closest alliances are with those who represent these elements. Under management of officials of this class conditions have been established in many of our municipal governments, which are far from satisfactory. Unbusiness-like methods of administration, have crept in; illicit relations with contractors and plunderers of all sorts have been formed; a thousand subterranean openings into the treasury have been discovered; the guardians of the peace are seen to be on the best terms with several classes of prosperous law-breakers; many officials are using the patronage of their offices with small regard for the interests of the city, but with a constant reference to their own political fortunes. There are honest men in the government, but they find it difficult to resist the rapacious and anarchical tendencies. When any such state of things exists, it is difficult for individuals to bring any effective saving influence to bear upon the city government. The task is one that requires the united and sustained efforts of many good men."

Rev. Washington Gladden, D. D., Columbus, O.

"There is no province where the American people need education more today than in the province of municipal government.

"But the governments of our great cities for the last thirty years have been our despair—Republican Philadelphia as bad as Democratic New York, Baltimore as bad as Chicago. The character of the men at the head of our city governments, our mayors and aldermen and common councils, has startlingly deteriorated. The proudest of American cities must blush when it thinks who the men are in its common council, controlling its high interests, disbursing its millions of money, and representing its corporate life, when compared with the class of citizens who sit in the town councils of Birmingham and Glasgow and the great cities of France and Germany. In almost everything that touches municipal administration we are today behind Europe. We have everything to learn and almost nothing to teach. It is, I say, disgraceful and humiliating."

Edwin D. Mead, Boston.

"First.—That we must keep more constantly before the people the perils to which we are exposed, and the menace to the safety of our free institutions, because of the corrupt governments of most of our large cities. In the light of the present day, was not Wendell Phillips right when he prophesied that the correct solution of the problem of our great cities would test our free institutions more severely than our struggle with human slavery?"

"We all know that the cities are growing out of all proportion to the country districts. It is one of the phenomena of this century the world over. At the present rate of increase the cities will control this nation in 1920. Do we want these great cities as at present governed to hold this power?"

Samuel B. Capen, Boston.

"The officials of our great cities are not elected, nor their affairs managed for the benefit of the members of the corporation, but to reward men for, and to encourage them in, holding or gaining the local votes to swell the majority of one or the other of the great national parties, which have no more interest in or concern with the good government of a city than a mob with the good management of a bank which it loots and plunders for purposes of its own."

John A. Butler, Milwaukee.

CLEVELAND CONFERENCE, 1895.

"The city of Indianapolis has had its share in emphasizing the failure of American municipal government. What with hoodle aldermen, hoodle councilmen and a loose financial system, with police and fire departments worth in votes to the party in control many times the number of employes, with a street department honeycombed with private and party snaps, boss-ridden, party-ridden, and nearly wrecked by its servants, the city had all

the decorations which entitled it to a place in the front rank of civic failures."

Lucius B. Swift, Indianapolis.

"We have our machine; our political bosses; some unworthy men in office; the self-seeking contractor; the dishonest officer of election; the spoil seekers in legion.

"The spoil system is the one great octopus which is strangling virtue, truth and honesty in public life. The weapon of destruction that must be used is the search-light of public opinion, blinding and destroying the evils which follow the creed that to the victor belongs the spoils; that dishonesty is legitimate in politics; that the political party a man belongs to must be his infallible guide in municipal politics; that a public trust is no trust; that the political boss is the boss and that his mandate is the law, the right to the contrary notwithstanding."

Frank N. Hartwell, Louisville, Ky.

"All municipal offices are held by ward bosses or their followers, and their success so intoxicated them that hardly were they well seated before they commenced their carnival of plunder and corruption. The men composing this administration were mainly of small means, and some of the councilmen were dependent upon their daily toil for their support, but notwithstanding their salaries were meagre, or nothing at all, it was not long before they took on an air of general prosperity, ceased to labor at their usual vocations, and waxed mightily in the goods of this world.

"In the department of public works, for instance, at the present time the inspectors and ward foremen almost equal in number the laborers they superintend. To recite the progress of the present administration is but to recount the sacrifice of the city's best interest, and the complete prostitution for personal and political ends by its officers of their official powers. No private individual could obtain the most paltry privilege without being subjected to corrupt demands, and unless he complied his request was promptly refused. The lesson taught the people by this administration has proved a most profitable one, and will, it is hoped, help to bring about the end of boss rule in this city."

Walter B. Spencer, New Orleans.

"The investigations of the Committee of 100 have conclusively demonstrated that the first evil tendency of personal greed as opposed to the public welfare, instead of being sternly checked in this city of Portland, has been actually encouraged by its political managers. If a contractor voted his men aright work was given him liberally and the pay was prompt and excessive. Honest performance of the work itself was, however, a matter of little consequence. Miles upon miles of defective sewers and streets bear eloquent witness to the evil effect of political control in business matters. The contractor and the city officer felt their first duty was to each other's selfish interests, and contractors and officers cannot well serve two masters.

"From the far West we send your greetings. Our city is no worse, is perhaps better, than some of yours, but our cause is a common one, and until our municipalities are honestly and economically managed upon business principles, the war both in the East and in the West should neither falter nor fall."

Thomas N. Strong, Portland.

"The board of public works consists of three members. Under the original charter this was simply a supervisory board, the various branches of the city work being under the charge of separate superintendents. As usual in large cities, this department was for a time the chief center of jobbery and intrigue in the city's affairs; appointments on the board were sought and used for political ends, and its patronage was used to promote the political fortunes of its own members or their political backers."

Edward O. Graves, Seattle.

"It is therefore exceedingly unfortunate that a very large proportion of our office-seekers are unfit or unworthy to fill the places they contend for.

"Men of character and ability are repelled by the conditions imposed on the services expected by those who control the nominations. Men who lead or belong to the vicious or predatory classes are eager and persistent in their efforts to secure the positions which enable them to increase their power, or to de-

fraud or oppress the people by such methods as those which have been so thoroughly exposed by the Lexow Committee in New York."

Charles Richardson, Philadelphia.

BALTIMORE CONFERENCE, 1896.

"In the first place we had everywhere enormous taxation, a taxation which produced a revenue sufficient, if it were honestly and wisely applied, to furnish every city in the land with every possible comfort and convenience, and even to adorn them with the triumphs of architecture and art. But all this was, in great part, misapplied and the consequence was we had very little return for it. Our streets were miserably paved and everywhere in a filthy condition. The schools were poor; the police were corrupt from top to bottom, and in collusion with evil-doers. All departments of government were affected by the demoralization, and the official force, from the mayor down, in our principal cities, was of a character which we could not exhibit in the face of the world without a feeling of disgrace. These were the consequences which flowed from this demoralization."

James C. Carter, New York City.

"I cannot here attempt to describe at any length the rise and rule of the despotic oligarchy which for 20 years dominated political life in this city and state, ground down our people, endeavored to crush out independence, cheated us of our suffrage and ate up our substance."

Charles Morris Howard, Baltimore.

"Our municipal condition however, is far from satisfactory. Our administration is neither judicious nor economical. Questions of appropriation do not receive mature deliberation, results in nearly all departments are not the best of their kind, and the disposition of the council has been, and now is, to exceed annually the current revenues of the city."

Virginus Newton, Richmond, Va.

"The interests of the people must be conducted by those who are entrusted to manage them, with the same wise, careful and conservative judgment that a competent business man should use in the transaction of his own affairs."

A. V. S. Lindsey, Nashville, Tenn.

"The abuses of administration were retrenched by law; the heads of departments had just been re-elected for four years, the ring organization was perfect in every detail; its members were held together by the cohesive force of public plunder, and its managers had ample sources on which to draw for all the money which might be needed for any purpose, and had the influence which flows from the absolute power to distribute the public patronage, franchises and improvements; and it was supported by thousands of voters who were dependent on city work and knew that active, willing and efficient service was the price they must pay for the opportunity to earn a living for themselves and family."

George W. Guthrie, Pittsburg.

"The development of an active, intelligent, civic spirit, the practical exclusion of the most ignorant and purchasable classes from the lists of voters, and the absence of political influences in the matter of appointments, in foreign cities, are in brilliant contrast with our deficiencies in these respects."

Charles Richardson, Philadelphia.

Under the conditions disclosed by the foregoing extracts—extracts, too, from American citizens, is it not strange that men will be found who will advocate enlarging the opportunities and powers of our city governments? Surely no business man would advocate it. On the contrary, he would have our municipalities conduct the business in hand in the same manner as the same business could be conducted by private enterprise before he would approve enlarging their powers and opportunities.

But the theorist says, enlarge the responsibilities of the government, and you will improve it. Acting upon that theory the doors of every house of correction and penitentiary in the land should be opened and every evil-doer therein sent back to the community whence he came. He should then be restored to his former position in the community, and instead of looking after his conduct and affairs more closely, he should be given carte blanche to do as he may wish.

Ownership and Operation Abroad.

According to the returns of street and road tramways to Parliament July, 1896, there were 153 distinct street railway undertakings in Great Britain and Ireland, subdivided as follows:

|                                                                                                         |     |
|---------------------------------------------------------------------------------------------------------|-----|
| Number of companies owned and operated by private capital.                                              | 116 |
| Number of undertakings where tracks are constructed by the municipalities and leased to private parties | 31  |
| Number of undertakings owned and operated by the municipalities                                         | 6   |

153

The six cities are as follows:

|                     | Popula-<br>tion. | Miles of<br>Track. |
|---------------------|------------------|--------------------|
| Glasgow and suburbs | 840,000          | 73                 |
| Leeds               | 400,000          | 27                 |
| Sheffield           | 380,000          | 19                 |
| Huddersfield        | 100,000          | 21                 |
| Plymouth            | 90,000           | 5                  |
| Blackpool           | 35,000           | 5                  |

GLASGOW.

Of the above cities Glasgow is the only one wherein the undertaking may fairly be called successful. And with reasonable economy it could not well be otherwise than financially successful. For a population of over 800,000 Glasgow has only 73 miles of tracks, whereas St. Louis, with a population of less than 700,000 has over 335 miles of tracks. It does not follow therefore, that if the government of St. Louis were conducted equally as well as the government of Glasgow, that it could also operate the street railway system of that city successfully financially.

It is well to remember, however, that Glasgow boasts of a "continuity of existence of over nine centuries." We may therefore safely place it within the limits of possibility that when our American cities survive a "continuity of over nine centuries," that they may be so far advanced in methods and morals that they, too, may be intrusted with additional power and responsibilities.

LEEDS.

The city of Leeds had operated its street car system for nearly three years. The first year showed net earnings of approximately \$15,000, less than 1 per cent upon the capital invested, whereas private capital earned and paid 7 per cent the previous year. The second year showed net profit of \$35,000, not quite the interest upon the sinking fund. And such results, too, with a population of nearly 15,000 per mile of track.

SHEFFIELD.

Previous to the acquisition of the street railway by the municipality, July, 1896, private capital received from 5 to 8 per cent dividends from the operation of the property. Under municipal management there was a loss the first year, not even earning the interest upon the capital invested. And such results in a city which has over 17,000 persons per mile of track!

HUDDERSFIELD.

This is the first city in England to attempt the operation of its street railway, and for the 14 years which it has operated the property there is a loss of \$311,000, varying from \$3,300 to \$83,000 in a single year.

This loss has been met by drawing \$105,000 from depreciation account and the balance by taxation, varying from 1-9 of a penny to 5 pence per pound. It may seem strange that the municipality should thus continue to operate under such conditions. The fact is that Huddersfield is a manufacturing city and the non-property-owning and small tax-paying voters are in a majority.

PLYMOUTH.

In the last fiscal year there was a loss of \$5,430. This city did not acquire the property voluntarily. On the contrary, the operating company intentionally forfeited its charter and abandoned the operation of cars.

BLACKPOOL.

This operation shows a net profit for four years of \$992 after paying interest and charging off to depreciation.

And yet in Plymouth, Huddersfield, Sheffield and other cities in England, boys of from 14 to 16 years of age, receiving \$2.50 per week are employed as conductors. Notwithstanding such conditions some of those cities have not earned the interest upon

the capital invested. Does anyone suppose that American cities if operating street railways could employ such conductors at such rate of wages?

In Germany there are only three cities which own and operate their street railway systems, and two which own the tracks and lease them to operating companies. In France, none.

The facts as they are before us are, that there are few cities abroad which own and operate their street railway systems with more or less indifferent results, and only one of which, viz.: Glasgow, which can properly be called a financial success; and yet there are those who would have American cities regardless of differences of conditions and institutions, plunge blindly into the acquisition and operation of 15,000 miles of street railway tracks because Glasgow operates 73 miles successfully.

It seems to me that those who honestly advocate the acquisition and operation of street railways by municipalities do not look below the surface. The find that an occasional city abroad does such things and they immediately jump to the conclusion that we should do likewise. They do not study the conditions with respect to accommodations furnished abroad as compared with those in this country; the methods of administration there compared with these here, and the civil service abroad compared with ours.

### DIFFERENCE IN CONDITIONS.

In a previous paragraph, I showed the difference between St. Louis and Glasgow. Below will be found a comparison of other

### COMPARISON OF ADMINISTRATION.

(City Government in the U. S., by Alfred R. Conkling.)

"The Right Honorable Joseph Chamberlain, in an article on 'Municipal Institutions in America and England,' in the Forum for November, 1892, makes an interesting comparison between Birmingham (his residence) and Boston. He says the total annual municipal expenditure (excepting the appropriation for schools and almshouses) of Birmingham is but \$1,665,000, while that of Boston is \$10,194,000, or more than six times greater than the expenditures of Birmingham. The two cities have much in common. They have about the same population and are both large manufacturing towns.

"The public works of American cities are perhaps the field of more swindling than any other department of the municipality. Brooklyn furnished us with an object lesson. For example, the commissioner of city works finds nearly 50 sinecures in his department, and he has begun by abolishing these offices, at a saving of \$50,000 a year to the city. The result is that he has that additional sum to expend upon actual work for the welfare of the public. Fifty other idlers in his department are marked for early discharge and the commissioner of public parks has also dismissed 75 men whose only occupation was drawing a salary!

"The comparative cost of municipal government in Europe and America is easy to understand. Any person who inspects the annual budget of the chief cities of the old and the new world will

### FINANCIAL STATEMENTS OF REPRESENTATIVE CITIES.

Compare any one of the above foreign cities with an American city of the same population and you will find that the area of the latter is greater and the street railway accommodations greater in proportion than the former. The English cities average over 15,000 persons, and the American cities, over 2,000 per mile of track. And yet there are those who would state that because Leeds could operate 27 miles of track successfully that Cleveland with nearly the same population and area could also operate 205 miles of track, nearly 9 times as many miles of track, also successfully. If, therefore, the methods of civil service and administration were the same in both cities, Leeds could be eminently successful and Cleveland a monumental failure.

he started at the economy of the one and the extravagance of the other.

The average per capita expenditure of the foreign cities above mentioned was \$14.79; of the American cities, \$30.54.

"The new Mayor of Chicago (1894) has said that the greatest danger of cities is that of being robbed by their own officials, in the sense of being burdened with expensive and superfluous office holders. In one month he directed the city treasurer to reduce his salary 10 per cent and transfer it to the general fund.

"A law was passed in 1883 to build a new aqueduct from the Croton river watershed to the city of New York. This stupendous public work became a harvest for politicians; large sums of money have been squandered upon it, and much of the work had to be done over. The defective work, was, in part, owing to corrupt inspectors and engineers, who approved work that was not only contrary to specifications, but done in a most scandalous manner.

"The public works of American cities are, perhaps, the field of more swindling than any other department of the municipality. Mr. White in his suggestive article in the Forum for December, 1890, says 'The city halls ... are the acknowledged centers of the vilest corruption.' In that connection this remark applied chiefly to the aldermen, and, occasionally, to the mayor. But the public works that are controlled by the officials in the city halls of the larger towns are generally as badly and corruptly done as the proceedings of the city legislature. I could give many examples, but I shall simply remind the reader of the "Tweed" courthouse in the city of New York, which cost untold millions, and the new city hall of Philadelphia. The visitor to the Quaker City is at once struck with the prominence of this public building. The gigantic tower is a monument to the extravagance and corruption that formerly existed in the city government.

"Unfortunately, the inspectors of public works in large cities are often political appointees 'out of a job.' They must be taken

care of by the ring, and are put upon the pay-rolls to the detriment of the citizens. Their salaries are so low, and their 'assessments' or contributions to the ring so large, that they are often forced to approve of defective public work, or blackmail the contractors of private dwellings in order to support themselves and their families. These inspectors learn from their superiors lessons in the practice of blackmail. Their political employer or overseer has probably extorted money from the contractors on public and private buildings, so that he is not surprised when his clerks and underlings in turn pursue the same practice. These inspectors show discretion in levying tribute on citizens.

"In the cities of Europe millions have been spent on the quays and docks. Take, for example, the magnificent Victoria Embankment on the Thames at London, the quays of the Seine at Paris and the embankment on the Neva at St. Petersburg. Few American cities have been willing to improve the water-fronts properly. If our water-fronts were improved, economically and carefully, it would meet with the general approval of the intelligent citizen, but so many large cities are cursed with ring rule that the suggestion of a general system of stone embankments and docks (either on bays or rivers) arouses universal objection and indignation.

"Several years ago a dishonest contractor was constructing a sewer near Central Park in New York. He was in great haste to obtain his money, and, instead of using pipes, he laid barrels in the ground, for which he received the contract price.

"As I write, municipal officers of all grades in many of the large cities are now under indictment, and many more would be added to the list if it were not for corrupt police magistrates, packed grand juries and negligent attorneys."

(Municipal Reform in the United States, by Thomas C. Devlin.)

"The science of municipal government in this country is crude. Our methods are expensive and our governments inefficient. The burden has become oppressive and nearly every city in the land is making some efforts for reform, and there are no cities where the same are not necessary.

"That there are able and well-meaning men in all those reform movements no one will question, but there are also 'sore-head' politicians who nourish the rancor of defeat, and hotheaded theorists who have never had one practical thought in matters of personal interest.

"In summing up the short-comings of American cities, it has been very easy to make comparisons with European cities and to suggest the adoption of the same principles of government and methods of administration under which those cities have been made models for efficiency and economy. It is, however, the opinion of those who have studied most carefully the municipal problem in the United States that no material aid can be had from the adoption of European methods in matters of city government.

"The matter of franchise is one of the most distinguishing features between American and European city governments, and which in a measure renders the adoption of European methods impractical. All the powers of government in Europe are in the hands of the property-owning class. In Germany, the three-class system of voting, while affording the masses a pretense of power, gives to the wealthier classes absolute control of municipal affairs.

"A study of the franchise in American cities shows that the non-taxpaying voters are a large majority. Taking Boston for instance, the registered vote of Boston in 1892 was 73,000. There were 32,407 taxpayers, of whom 3,200 were women having no vote, and about 700 aliens or non-residents. Deducting the taxpayers who are non-voters leaves 28,507 as the number of property-holding voters out of a registered vote of 73,000. If every tax-paying voter voted this shows the non-property vote at 46,693 against a property vote of 28,507.

"It is said that the cities are business concerns in which every taxpayer holds an interest, and there is a persistent demand that its affairs shall be conducted on business principles. Then it seems not unfair that representation in the city should be limited, as in a business corporation, to the stockholders, if the same results are desired. If this hypothesis is correct, we must admit that no business would succeed under management similar to the cities.

"It is also true that the ignorant, vagrant and purchasable

element comes almost wholly from the non-taxpaying class, and their only interest in an election, is the price they may receive for their votes. They are an element of especial solicitude to the ward politician, and are often, the decisive power in partisan contests. Indeed, it may be further said, that integrity, honor and ability will never prevail, in city councils particularly, until the candidates may safely disregard the demands of the worst elements of society and know that their election depends upon citizens who hold those virtues to be their chief qualifications.

"Every large city is practically in control of the non-taxpaying element, and from this class the intemperate, vicious and purchasable vote is mostly composed, and it is through his influence with them, and his ability to handle them, that the ward politician secures his own election, and achieves success for, and standing with, his party. He is often one of this party, which he controls, and, if not, affiliates with them, which amounts to the same thing.

"He extends to them so far as he can, the same patronage which he and his colleagues in other wards have received from higher authority. He promises the creation of new offices, clerkships in others, and jobs in parks and streets without number, and thus crowds every department of the public service with incompetency and unworthiness, which would never be tolerated in any private enterprise. Through all the avenues of patronage he looks forward to paying campaign obligations and of maintaining his prestige with the party. Surely the alliance of the business of cities with national politics, and its control by the party machine, is a serious evil. It opens the way for every form of dishonesty and mismanagement which avarice and ambition can suggest.

"The power of the legislature to meddle in city affairs is corrupting both to the legislature and the city. The city 'professionals' will be in attendance at each session of the legislature and when the city charter is acted upon, or special acts concerning the city is passed, they will be marked by their cunning and avarice. The Hon. Seth Low tells us that in every year of his term of office he was compelled to oppose at Albany, the seat of the state legislature, legislation seeking an increase in the pay of policemen and firemen, without any reference to the financial ability of the city or the other demands upon the city for the expenditure of money. . . . New and useless offices were sought to be created and the mayor found that not the least important of his duties, as mayor, was to protect the city from unwise and adverse legislation on the part of the state.

"Edward W. Bemis, writing in Public Opinion, says: 'A recent chief of the Chicago sanitary department assured the writer, that there were not six of his 100 subordinates whom he could trust. It was useless to dismiss any one, for the chief must take in his place whomsoever some alderman may desire.' Not infrequently new offices with chiefs and many deputies are created for no real purpose other than the positions they offer. The pay is often out of all reason for the service rendered, but it is expecting too much of human nature to hope for any change while the system which makes it possible prevails. To cut off the salaries or positions of one's friends who labored during the long siege of an election campaign, requires a degree of courage and ingratitude not attainable by the average councilman.

"Francis G. Peabody, in comparing municipal service in the United States with service in the cities of Germany, says: 'With us municipal offices are the spoils of successful politicians; in Germany they are the prize of experts. It seems to a German as incredible to hear of a city governed by men who are just pausing on their way to some higher place, as it would to hear of a railroad or of a cotton-mill thus superintended. Good city administration with us is an accident.'"

The advocates of municipal ownership point with pride to the postal service of the United States, and would have us infer that in all things the national and municipal governments could do likewise. In this they speak as partisans, yet we should not deny them such comfort as they may get. They do not refer to the annual pension appropriation now \$150,000,000 per annum, nor to the fact that the late General Grant and the late General Garfield, both good authorities, stated that \$40,000,000 would be amply sufficient. They do not refer to the river and harbor appropriations, of which the late President Arthur wrote in one of his veto messages, "as the measure (River and Harbor Bill)

became more objectionable it would secure more support." They do not refer to the National Government's experience in the Union Pacific or to the experience of the state of New York in the Erie Canal.

#### State Ownership of Railroads.

The experience of France and Brazil with government ownership of railroads is not encouraging to the advocates of the idea that railroads should belong to the people at large, and should be operated by officers appointed by the government. The South American republic has determined to abandon state ownership of railroads, after a thorough test of the theory, and is now negotiating with European capitalists for a lease of the entire system, comprising 14,000 miles of track. When Brazil took charge of the Central Railroad, that corporation had paid as high as 9 per cent dividends, but under government control it has not only failed to earn its expenses but has cost the people \$2,000,000 or \$3,000,000 a year above its receipts.

The experiment of state ownership of railroads has been tried longer in France than in Brazil, and under more favorable conditions. The model road there runs through well-populated districts, with large cities as terminals, but the results in France are discouraging. Eighteen years ago a railroad system was constructed, which was to furnish cheap rates for passengers, cheap freight for shippers, and abundant profit for the state. It has done none of these things. At first the advocates of the enterprise insisted that only time was required to prove the wisdom of the project. Eighteen years have passed and the results may be briefly summarized: Theoretic methods have been abandoned, and the railroad is now managed substantially as are those in the hands of private capitalists except its tariff of rates is a little higher, and its cost of operation is considerably larger. The last report shows that the net return on the whole capital expended is 1.35 per cent, and even the state cannot borrow money for less than 3 per cent. The government has every year a considerable deficiency to settle, and the people who use the line pay somewhat more than they would have done if the enterprise had been left to private capital.

Canada has had an experience of state ownership also, but upon a more limited extent. There the government owns about 10 per cent of the whole, upon which it loses about \$500,000 annually.

The railroads and their equipments and fares of France and Germany operated by the government, cannot be compared with those of England, operated by private capital; and the manufacture of tobacco and cigars by the government of France has produced such vile stuff as to be an object lesson to enthusiasts of government monopoly.

#### Public Ownership and Private Operation.

Some of the advocates of changing the present state of things stop short at the operation of street railways by the municipalities and advocate that the municipalities own the tracks and lease them to private capital. They are aware of the present condition of our administrations, and dare not go to the logical length of the position. If our municipalities are so unbusiness-like and corrupt in their methods as to be incapable of operating a street railway property, then they are also unfit to manage the construction of the property and to make contracts for its use. You cannot stop half way.

The motive for public ownership abroad is twofold. The first has reference to the conditions of the streets and street surface. They have, as a rule, finely constructed and maintained streets, and in their very proper regard for keeping them so, they desire to control all construction and maintenance of tracks. The second has reference to controlling and regulating the methods of operation. That has proved a failure, and can be accomplished better when granting a franchise. In nearly every case in England where the municipality acquires the operation of the property it did so involuntarily.

The city of Toronto, Canada, is the only instance on this continent of public ownership and private operation. The conditions and contract there please the theorists and the street railway company, and all are happy. While I am neither a prophet, nor the son of one, I will state that in my opinion before the con-

tract period shall have expired, Toronto will have cause to regret that it adopted some English methods under almost American conditions. The municipality constructs the concrete bed for the tracks, supplies and does all paving, and removes all plowed snow. The compensation which it receives per mile of track is much less than that paid in some states by one company for running over the tracks of another company. Percentage of receipts, rates of fare, etc., should be looked upon as nothing more nor less than a premium for which the operating company receives a monopoly. Competition and the fear of it are completely shut out. Single fare and transfer carry a passenger only to the suburbs. Those going to and from the suburbs pay extra fares, and as the city grows in population, it will become as congested as foreign cities, or the people will be compelled to pay extra fares to get to and from suburban homes. Such conditions exist nowhere in the United States.

The conditions with respect to Toronto and its suburbs suggest a practical problem in the United States should municipalities desire to acquire street railway properties. Usually broad street railway systems are operated within the limits of the municipality as at Toronto. Should the systems be extended farther additional fares are charged. In the United States, on the contrary, in nearly every instance the street railway system extends beyond the city or town limits and usually only a single fare is charged. Should a city obtain the street railway system within its own jurisdiction an interesting problem is opened with respect to the owner of the balance of the property; and in case the balance of the property should be acquired by the other towns through which the system may be operated, as to divisions of "spoils," profits and losses. It may result as it did in Birmingham, England, in the price of gas. That city provides its own gas and charges suburban towns 50 per cent more than it charges its city consumers.

W. W. Bean, of St. Joseph: I move that a vote of thanks be extended to Mr. Sullivan for his very able paper, and that the same be spread upon the minutes. Carried.

The President: We will now proceed to the next paper "Some of the Difficulties Existing in the Construction and Operation of Electric Street Railways," by G. W. Knox, electrical engineer, Chicago City Railway Company.

Mr. Knox read the paper as follows:

#### SOME OF THE DIFFICULTIES EXISTING IN THE CONSTRUCTION AND OPERATION OF ELECTRIC STREET RAILWAYS.

By G. W. Knox, Electrical Engineer, Chicago City Railway.

With the smaller street railways during the panic period, from which it is to be hoped we are about emerging, it has been a struggle for existence, and a road that has pulled through these times without running behind, may be considered fortunate.

The railway management has often during these times been called upon to make a good showing in dividends, having at the same time a decrease in earnings to contend with; how to do this has been a most perplexing problem for many a street railway manager, and by his not being equal to the emergency, has resulted in there now being a long list of roads in the hands of receivers.

I do not charge up to the stock manipulators or the hard times, all the crime of the necessity for receiverships of these railways. Many an electric road now in the hands of a receiver could be making neat incomes for the investors had a closer study and practice of the economic principles governing the details of construction and operation been made and thereby done away with the many wasteful measures which are sapping the very life out of what might have been paying investments.

The keynote of doing this does not lie altogether in the ability to make any one or two large reductions or savings, but rather in lopping off here and there the many unnecessary extravagances existing in the various departments of the system.

The first and most important step in working out economies is in selecting a corps of operators from the head foreman down to the man sweeping out the depot. If they are interested, and are working for the good of the company, scarcely an hour of the time in

G. W. Knox has been at the head of the electrical department of the Chicago City Railway Company for the past five years. Mr. Knox was graduated from the Northern Illinois College at Fulton, Ill., in 1885, and at once engaged in railroad work, superintending the construction of depots along the lines of the Burlington & Northern Railroad. Two years later he

was connected with a car building concern, and the following year the Thomson-Houston Company sent him with several of the first electrical equipments that were installed west of the Mississippi river. In 1889 he entered the service of the Sprague Electric Railway & Motor Company and was given charge of street railway work in Milwaukee, Minneapolis and St. Paul. When the Edison General Electric Company, Mr. Knox was retained in the railway department and was sent to install equipments in Cincinnati, Springfield, Ill., Columbus, Newark, St. Joseph, Mo., Kansas City, Lincoln, Ill., and other cities. When the Chicago City Railway decided to equip its horse lines for electric traction, Mr. Knox was employed January, 1893. To prepare for the World's Fair traffic it was necessary to work day and night stringing the wires and completing the equipment, but the design and construction were of such high

order that no serious accident or breakdown occurred during that period of arduous service. Mr. Knox planned the feeder system and line apparatus on the City Railway.

G. W. KNOX.

which they are engaged can go by without their effecting little savings which in time swell the item of economies to mammoth proportions.

The examples of how this is done are very numerous. For instance, had a certain motorman been the man for the position and exercised more care in operating his car, he could perhaps, have averted an expensive accident case for his company. In a minor matter an armature winder by being interested and more painstaking in his work, could by insulating an armature coil with perhaps a thirty secondth of an inch more insulation, have saved a burn out and an expense of \$25 or \$30. These are only examples of the many instances where a reduction in expenses is made possible.

In considering the question of our engines and electrical machinery we have reached a state of comparatively high efficiency and economy, and there is not the chance of making the saving on these lines, in either the designing or operation, that there has been in the past.

There is also but little chance, in a broad sense, for argument upon questions,—as to feeder requirements, the necessity of ample and absolute return, cars, motors, etc.,—a general idea of what is required is so well understood that these problems narrow down to a study of how to accommodate the conditions as found, which the man in charge should be fully able to meet.

In the management of railway work, the greatest opportunities for economy will be found in the details of construction and operation.

It is totally out of the question for any one to lay down a code of rules to be followed, owing to the varying conditions. The success attained in both construction and operation depends wholly upon the practicability of the man in charge of the work. What is greatly needed by those directly in charge of the equipment and operation of electric railways, is a better opportunity for meeting each other to discuss matters of detail in construction and operation.

One of the mistakes into which we are most liable to fall is the rut of self satisfaction with our own style of work. Then it is that the manifestations of decay and inefficiency begin. Those who are most satisfied with their own work are often the ones making the poorest showing. It is imperative in order to eliminate the difficulties with which we meet, that we brush up against the other fellow and get his ideas. To be better able to do this, the plan now adopted by the electric railway companies of several states of having state meetings for the discussion of plans for better methods of carrying on the work, should be made general. There are a few of these state organizations for the purposes mentioned, but there are not enough of them. The American Street Railway Association, has, I believe, too much of a national character to afford the time to take up and discuss details, of which the work is principally composed.

To these state meetings, the companies should send the men at the head of the different departments, for which all concerned would be well repaid by the benefits derived therefrom. By keeping a man

isolated, back in some dingy old shop or barn, he cannot be expected to be bristling with the bright ideas that bring forth the efficient service which characterizes the others fellow's road, and makes it a good dividend payer.

Following up the idea—that it is the first wrong step that counts—our whole aim must necessarily be to make as few mistakes in the construction as possible, for it is an easily demonstrated fact that the cost of operation depends largely upon the method of construction.

It is an absolute necessity that we look ahead and plan against all kinds of speculative disaster, ignoring if you please, in this case, the teaching that "we should not cross the bridge until we come to it." A little foresight which results in preventing an accident, will probably mean the saving of the profits for many days' operation. One of the examples being—with ordinary conditions in the installation of overhead work—is the use of but one insulation between positive and negative. For the first year or so, this will be found sufficient, but a little later on the insulation begins to deteriorate and there follow frequent short circuits and burn outs, which stop traffic and entail an expense many times the cost of two additional insulations, which would insure to a reasonable extent against such leakages and burn outs.

It is not fair to the owners of the majority of the electric railway properties to say that they have worked on the retrenchment idea as regards expense in putting in the system; as universally they have been liberal with their money, but where they are to be censured is in the fact that they have not familiarized themselves more fully concerning the methods of installation. They have been inclined to leave the question entirely to the honesty of the contractor or supervising engineer, who was not necessarily dishonest, but a man who knew a good thing when he ran across it, and perhaps slighted the work accordingly.

Among the most important matters to study for economy connected with construction and operation is the supply department. There is an immense sum of money needlessly squandered in supplies and repairs for an electric road in a year. One of the causes of this waste lies in the fact that the roads have not yet arrived at a standard in the design of the apparatus which they use, to which too much importance cannot be attached. Every road should be its own designer of all articles used, for why should the manufacturer be better able to determine than you what is required. You are on your own grounds, you know exactly the conditions to be met and are in constant touch with the difficulties as they arise, and are far better able to devise the remedies than is the manufacturer miles away, who perhaps has only his own experiments and a confusion of theoretical speculations to rely upon.

I mean in no wise to decry the assiduous and most excellent work of the manufacturers of electrical apparatus. It was and is a field of necessary inventive development, and the manufacturers are sparing no effort or expense in their endeavors to supply the trade with the improvements in demand, but the unwary railway man has had an immense amount of experimental claptrap machinery inflicted upon him, all of which has cost dearly, and which is still maintained at a sacrifice. It is a lamentable fact that we have not done more than we have towards correcting this evil.

Along this line another evil for which the railway man in his efforts to save money is in part accountable, is in the shaving of prices on material to the extent that it has resulted in competition being so sharp among the manufacturers of electrical supplies that they have adopted the piece work plan in order that cheapness may be secured, thus turning out upon the market apparatus that was not gotten out for efficiency, but to fill orders. Of course these articles may have been built according to specifications, and stood the shop test, but there is demonstrated an entirely different proposition when this apparatus is put into actual use; it is then that we see the bad effects of the hurried and slighted work of the pieceworkers.

To free ourselves of these troubles we must be more careful in getting out the specifications and checking up the material received. The most carefully prepared specifications in detail should go out for every piece of apparatus used. You will then find that your supplies are coming to you made up in the proper manner, your supply man knowing that should he send out a mixed up and defective lot of material it will be promptly returned to him with charges "Collect."

To be able to get out the specifications needed it requires a certain amount of experimental work, and how far to go with this experimenting is a problem requiring the keenest discretion. Experimental

work should only be encouraged and allowed by a company to the extent of having in view the elimination of an existing money-wasting evil. The testing, making of new designs and patterns, with perhaps the subsequent throwing in the scrap heap of the article gotten out to conform to some pet theory, when kept track of is found to be a tremendous waste of money.

Experimental work should, however, be encouraged as far as it is profitable in the way of stimulating sagaciousness and promoting adaptability on the part of the men handling the work, but all experiments should be allowed only as passed upon by the management of the road, who should be fully competent to determine the probable practicability of the theory proposed.

In making up and buying supply parts, one of the factors of economy lies in the bulk to be used. Of course, the greater the amount purchased, the greater the saving. I would, though, strongly advocate not getting too great a quantity of stock of any kind of material on hand, as the defects developing often require the complete changing of designs, with consequent scrapping of all material in stock.

Another serious difficulty to be considered in connection with operation is the inefficiency of the motormen. I concur with a railway manager who once said: "Motormen, like poets, are born, not made." There are motormen who will operate a car day after day, year in and year out, without the slightest accident or complaint while others are constantly having wrecks and their cars are always being run in the depot out of order.

In the calling of a good motorman, we have a position with more responsibility attached perhaps, than the position of an engineer of a steam railroad. A motorman, of course, has not in trust property that has the value of a steam railway train, but his field of operation lies where there is greater menace to life and property, (for which his employer is responsible in case of injuries) than with a steam railway engineer. A trustworthy motorman should be required to pass a physical examination, possess a cool, collective temperament, judgment in cause and effect of ideas in general, and have a fair amount of mechanical ability. He should be obliged to undergo the most strict examination as to his fitness in these requirements and in addition be thoroughly conversant with the correct methods and rules of how to handle the equipment.

The board of examiners for the fitness of employes on street railways will be able to make a better showing in efficient operation than most other departments, by giving more attention to the examination and instruction of operators, and that there is needed improvement in this particular, is evinced by the magnitude of the accident account which is due mostly to the operators not being properly schooled in the work they are handling.

I do not believe in attempting to educate motormen to any extent in electrical knowledge, as it has been proved that it is a waste of time, and nothing is accomplished by it. Giving them an insight into, and encouraging them in determining the cause and remedy of some electrical trouble with which they may meet on their cars while on the road, you have men with all kinds of theories, wasting the company's time in tearing apart and dissecting the equipment and perhaps not then locating the trouble; at the same time, they are undoubtedly blocking the line, where, had they, after failing with the simpler methods of locating the trouble, called for an emergency crew, or been pushed into the depot, they would have been doing much better service. There are, of course, some cases where it is excusable for men to attempt to locate trouble on their cars, but, as a rule, it is found to be the wrong practice. If they understand the brake mechanism, the proper manner of applying the power into their motors, how to cut out a disabled motor, and the rules as given in the rule books, they will have about all they are able to master.

A good, bright interested motorman, or other operator on the system, upon noticing anything wrong with the equipment should be educated in, and made to feel that it is his first duty to report everything coming under his observation that is working to the detriment of his company, and he should have this so impressed upon him that he will feel uneasy about his position until he does so.

It may be asked, what is to be done with employes in cases of carelessness and consequent losses through their actions. Of course, it is out of the question to always avert accidents or mishaps, and specific rules cannot be laid down defining what is to be done in handling every case, other than by saying, it depends mostly upon the ability to get the right kind of men and to instruct and impress upon them that the burden of preventing such losses rests entirely with them. It

is well to remember in disciplining men for offences or carelessness in their work, that if they have clean records in the way of good intentions, they should be given another chance, as they will in all probability improve as a result of their experience and make valuable employes for the company.

In placing a man in charge of work or a department, he should be given the full responsibility of his position; then he will take an interest in what he is doing, have a little company of his own, so to speak, wherein he tries to save the dollars to the extent that he would were it his own. That is the way he should feel and act, and if he does not, his placed cannot be filled too quickly. A company should, however, be governed with all cautiousness in making changes with heads of departments, also operators in general. A man assuming a new position usually comes loaded down with fertile ideas. They may have fitted perfectly the conditions existing at his former location, and believing that is a poor rule which does not always work, he immediately proceeds to put into effect his ideas. Some of them may be good, but as a whole, by the time he has tried all of them, the company is, in the long run, unless heretofore there existed a deplorable state of affairs, liable to lose money by his practices.

I know of an excellent piece of railway property which should be paying good dividends. The company was born at a time when the experimental stage in electrical apparatus was well under way, thus enabling the selection of a fairly first-class equipment. It spent plenty of money on the installation, but as soon as the road was equipped the practice of changing management every three or six months was adopted. This resulted finally in it having about every style of apparatus. One of the managers came to the conclusion that he could make money by scrapping a style of motor he found on the road, so back in the corner they went. When his six months had expired, and the other fellow came on, he said he would make those motors go all right by changing their windings and otherwise fixing them up, and they were dug out of the scrap pile, the rust scraped off, new windings of field and armature substituted, and the motors are now in operation.

*This practice costs money.* There is nothing at all strange that this road should be struggling along for existence in the hands of a receiver, and I will not believe that overstocking or the hard times had all to do with its being in this position.

As a rule, the general condition of affairs out on the line and in the depots and stations of street railways is in a much shabbier state than exists in other lines of business. This is partially on account of the apparatus used being out in the middle of the street or back, may be, in an old, dark barn, where no one really expects to see good order and cleanliness prevail; but is a most serious mistake to allow this state of affairs to exist. Besides being directly wasteful of itself, it has the effect on every man connected with the company of making him generally careless and neglectful in his work. Out on the line it breeds contempt for the whole system in the public eye, and will act as a barrier to getting further concessions for lines. I can call to mind a repair depot, where the floor of the shop part is as clean as the floor of a Dutch kitchen, the walls and ceilings are neatly white-washed, and there is an individual place for every repair part used, from the cotter pin of the trolley wheel to the truck wheels of the car. Any repair man could be blindfolded in this depot and yet he would be able to go straight to and get any article of repair needed. There is no time lost in pulling out and hauling over material to find what is wanted. The results obtained by reason of those practices are highly profitable and wonderfully gratifying to the management. In point of neatness of cars, a minimum in the number of car trouble reports and amount of material used in repairs, while the car expense per day is no greater, and in most cases less, than that of other depots working under like conditions.

Much valuable time is lost and money thrown away by roads which are keeping so many records on matters pertaining to operation. Where a few records may be gotten out with a view of demonstrating that a leak is going on in some line of the work, or for the purpose of comparison in spurring some of the departments up when they are inclined to be negligent, there is of course money in it, and in fact it is necessary in order that the work may be handled intelligently, but where you have your men spending their time in keeping track of how long a certain armature ran, the length of time it takes to make repairs of a certain part of the motor, etc., which records are rarely referred to, and should one want to use them, it would be necessary to spend as much time as it originally took to get them out in looking them up for use; it is all a waste of time and money.

The man in charge of a department should be able, when called upon, to show exactly what it is costing to perform any part of the work under his charge, but he should be able to have this knowledge without the constant keeping of a lot of records.

One of the most commendable practices employed in the maintenance of a street railway is the regular calling together of the heads of the different departments for consultation on matters pertaining to their respective departments. The details and new complications constantly coming up concerning the work are so varied and numerous, and the men actually handling the work have such an excellent opportunity of observing and dealing successfully with the difficulties arising, that their reports at once place the situation of affairs panoramically before the management for action. Some serious trouble with the equipment or operation may be going on; some one man, perhaps, has a way of remedying the difficulty, which the others had not thought of, and again, practices that are extravagant may come to light during these meetings; so that those who have not tried this plan will find it a most valuable adjunct in methods of operation.

The subjects mentioned are, I know, being constantly thought about and worked upon by all street railway men, and are well understood by them, but there is no denying the fact that there exists with us in our work at times an unjustifiable and inexcusable amount of carelessness which results in the property depreciating as a money earner, to the extent that the holders of street railway securities become disgusted, withdraw their holdings, the receiver is appointed and the road is branded as a failure.

The way of preventing the most of these cases rests with the men who are actually handling the equipment, in assisting the management in keeping down expenses; how far this is accomplished resolves itself into the extent to which we go in getting the most practical men who will be able to adapt themselves to and handle efficiently the conditions existing in their respective lines of work; and there must be constant vigilance on the part of heads of departments in taking advantage of the advancements being made, and in thoroughly and constantly checking every man and his work.

H. H. Littell, of Buffalo: I move that the paper be received, spread upon the minutes, and a vote of thanks returned to Mr. Knox. Carried.

The President: I think Mr. Knox also deserves thanks for being present and presenting his paper. It is my opinion that the selection of a man to present a paper before this Association gives him an opportunity (especially if he is a young man and is not known except in his own city and amongst his own people with whom he is thrown in contact), to become known all over the country and to men who come from every section, and he ought to appreciate it so much that he would take the pains and trouble, recognizing the compliment of the selection, to prepare a paper and come here and read it, and Mr. Knox deserves credit for having taken that trouble and I am glad that he has done so.

H. H. Littell, of Buffalo: I think that the paper just read commends itself to every street railway man, whether he be president, general manager or superintendent of a company, and especially if he is the electrician. The paper should be read carefully and studied carefully as it is very important, and especially in reference to buying the supplies, and not buying in too large quantities; and also the point about calling the heads of departments and employes together. I have been practicing that for a good many years, and we have a school every Monday. We not only talk over matters, but we discuss them, and the practice is attended with a great deal of good. It is certainly a great benefit to our company, and consequently to the public, and I think that this paper should be given a great deal of careful consideration.

On motion, the meeting adjourned until Wednesday morning at 9:30.

#### Wednesday's Session.

President McCulloch called the meeting to order at 10:30 a. m.

The Saginaw Street Railway Company, of Saginaw, Mich., acquired membership in the Association.

The President: The first business this morning will be the report of the auditing committee.

Mr. Sergeant: Mr. President and gentlemen: I beg to say that we have examined the accounts, and we have affixed to the report of

the treasurer the following certificate: "We have examined the cash account of T. C. Pennington, treasurer, and find the same supported by proper vouchers, and find the same correct.

Niagara Falls, October 20, 1897.

C. S. SERGEANT,  
D. B. DYER,  
Auditing Committee."

Mr. Bear: I move that the report be received and spread upon the minutes. Carried.

The President: The first paper this morning will be that on "Application of Storage Battery to Electric Traction," by Charles Hewitt, electrical engineer, Union Traction Company, Philadelphia, Pa.

Mr. Hewitt read the paper, as follows:

#### APPLICATION OF THE STORAGE BATTERY TO ELECTRIC TRACTION.

By Charles Hewitt, Electrical Engineer, Union Traction Company, Philadelphia.

To give a history of the application of the storage battery to electric traction would only be turning over dry bones. The long series of remarkable failures is no doubt familiar to you all. To say that the storage battery has no place in electric traction is an error, and on the other hand to say that it will supplant all other means of applying power to the cars, I believe, only the dream of the enthusiast. We are sufficiently acquainted with the possibilities and limitations of the storage battery of today to be able to make installations whose success will be certain; improvements in manufacture have certainly been made during the past few years, but the cause of past failures has been due quite as much to errors in installing and in manipulation as in manufacture.

In preparing this paper I have made an effort to obtain accurate information from parties in Germany, France and England, but all such attempts have been of no avail. As far, therefore, as the state of the art in Europe is concerned, we must rely upon what we have been able to gather from current literature.

The most important applications of the storage battery to electric traction are:

1. The application of the battery direct to the car or locomotive.
2. The application of the battery at points on the line distant from the generating station.
3. The application of the battery in the power house.

#### The Application of the Battery Direct to Car or Locomotive.

We are led to consider this form of application first, not on account of its successes but rather on account of its conspicuous failures. From our investigation we can see nothing in this form of installation to commend, except for certain local conditions, which are peculiar to the large cities on the continent of Europe.

The first cost is greater than our present overhead form of construction, and the expense of operation is considerably greater; in fact it is doubtful whether the expense of operation can be brought below that of horses. It is less reliable, and more objectionable to passengers on account of the gas given off. But very little reliable data are obtainable from all the various experiments which have been made. Most all such experiments, in this country at least, have been made by the battery manufacturers and the results obtained have been most carefully guarded. Mr. Dawson, in an article, published in Engineering, October 16, 1896, says: "Two principal causes have so far prevented the successful use of the accumulator cars, their great weight and rapid deterioration of plant; owing to these causes, the manufacturers of storage batteries only have seriously taken up accumulator traction, and although they have been working on the problem since 1880, little reliable information has ever reached the public."

In a paper read by the writer before the Engineers' Club of Philadelphia, December 5, 1896, I gave in detail results of a test made by me of a certain battery car. The main results agreed quite closely with data which have come to us through European publications and I

CHARLES HEWITT.

Charles Hewitt was born in Trenton, N. J., January 28, 1861, and his early education was obtained in the state school in that city. In 1879 he entered Princeton University and was graduated by the John C. Green School of Science four years later. In 1887 Mr. Hewitt was instrumental in organizing the Edison Electric Illuminating Company and became general manager. Two years later he entered the employ of the Sprague Electric Railway & Motor Company, and for five years remained with that concern and its successors, the Edison General Electric and the General Electric Company, designing and installing some of the most important roads that were built during that period. In 1894 Mr. Hewitt was employed by the Electric

Traction Company of Philadelphia, and became electrical engineer for the Union Traction Company when the latter absorbed the former.

feel confident in stating that the battery car requires considerably more power to operate than an ordinary trolley car of the same size and under the same conditions, and further, the battery car will require a larger investment in generating machinery. The unreliability of the battery car, and the disadvantages due to the necessity of constantly changing the batteries are familiar to you all, and we have no facts which would warrant us in holding out any hope of improvement in this line. In fact, unless some form of battery be discovered with entirely different characteristics from the lead battery, I should advise leaving such experiments to those who enjoy spending money on this kind of a hobby.

When the action of the battery is thoroughly understood it is not difficult to understand the cause of failure. Every battery has what may be termed a critical rate of discharge. From zero up to the critical rate the working e. m. f. remains practically constant. Above the critical rate the e. m. f. decreases as the rate of discharge increases. On the other hand, the e. m. f. increases with the rate of charge and the length of charge. For any particular battery there is a rate of charge which cannot be exceeded without useless waste of energy. In Fig. 1, I have shown typical curves for charge and discharge at normal or critical rates and the portion between the curves represents lost energy. In Fig. 2 I have shown the discharge curve taken from a traction battery test. With a fairly constant discharge at the average rate used by the car, with rests of one minute every 15 minutes, the fall of e. m. f. is very marked. You will appreciate therefore the remarks of Sir David Salomon, "that it takes power to get current through the battery, and it also takes power to get the current out." These critical rates of charge and discharge seem to be partly due to the time required for the chemical reactions in the battery to take place. The physical limitations of a car require the battery to have a large output for its weight and bulk. To obtain this it is necessary to increase the surface of active material as much as possible and to decrease the inactive supporting grid. In consequence the battery plates become mechanically weak. The conditions seem to prevent the making of plates large

enough to prevent exceeding the critical discharge rate, and which are at the same time light enough and small enough to be carried on a car. The inherent characteristics of the lead battery are such that it is very doubtful whether it will ever be successful in propelling cars unaided by other sources of power. Great results are expected from the experiments now being made in Chicago; but great results have been expected before, and I do not look for results in Chicago much different from those that have preceded. It is claimed that the batteries in use in Chicago will show a much longer life than any that have as yet been tried. But even if the life of the plate were all that could be desired, we would not feel warranted in recommending the system.

There is another phase of this method of application which is used somewhat extensively in Europe. In some of the larger cities on the Continent there is a prescribed area within which overhead lines are not allowed to be erected. To overcome this difficulty the cars are supplied with batteries sufficiently large to propel them at a low rate of speed for a distance of three or four miles from the point where the overhead line ends, into the city and return. While the cars are completing the trip the batteries are charged from the overhead wire. I am sure such an arrangement would not commend itself to any practical railroad manager, except as a makeshift in such government ridden cities as exist in Europe. There are only two cities in this country where such an arrangement might reasonably be considered, and in those cities the slotted conduit has (and I believe wisely) been adopted.

The advantages of this method are apparent. Aside from the lack of overhead lines in the crowded city center, which is purely aesthetic, the most marked advantage is the lack of necessity for changing the batteries for charging. But this advantage is offset by the fact that as the charging is done en route the current for charging must be transmitted over the feed wires in addition to the current necessary for propelling the car with its extra weight of battery, thus increasing the loss due to charging. The power transmitted may be divided as follows:

1. For propelling the car without the battery.
2. For propelling the extra weight of the battery.
3. For charging the battery.

I regret that I have been unable to get accurate data showing the relation of these items to each other. But I feel satisfied that the extra cost of feeder cables due to the extra power transmitted and the decrease in efficiency will more than offset any saving in the cost of linework, while the cost of operation must be, and is acknowledged to be in excess of the less complicated system in common use in this

FIG. 1.—CHARGE AND DISCHARGE CURVES.

country. The fact that overhead lines are in use up to the proscribed limit and that the battery is only used where it is compulsory speaks volumes. It is also significant that the commissions appointed by the larger roads in England and Scotland to investigate the various methods of traction in vogue throughout Europe and America have vetoed any form of battery car.

The following data are taken from the writings of Mr. Dawson and others:

| Comparative data of accumulator cars.                                 |               |         |           |
|-----------------------------------------------------------------------|---------------|---------|-----------|
|                                                                       | Paris.        | Berlin. | Vienna.   |
|                                                                       | Lead.         | Lead.   | Cop. Znc. |

A third phase of the battery car system is the battery locomotive. Aside from special forms such as the Heilmann locomotive, the one most worthy of mention is the experiment on the New York elevated railway, in which the battery is connected in multiple with the motors and charges or discharges according to the demands of the train. When the demand of the motors is sufficient to lower the pressure on the line to or below that of the battery, the battery will then discharge into the motors, thus relieving the feeders. When current is shut off from the motors, the battery will charge. No results of

this experiment have been made public yet, but it is difficult to see how much is to be expected. It has the advantage of maintaining a fairly constant pressure at the motors, but this can be accomplished better in other ways, as I shall show later. It subjects the battery to usage which history has proved to be disastrous to its life and efficiency. In this method the extra weight of the battery has the certain advantage of giving additional adhesion to the rails.

While not wishing to seem pessimistic, I must confess that to me the outlook for the battery car is not bright, and I do not look for much improvement unless some combination of elements be discovered whose characteristics are entirely different from the lead battery

### The Application of Storage Batteries on the Ends of Long Lines.

In such applications the conditions are entirely different. The battery in this case acts essentially as a pressure regulator. The conditions do not restrict the size of the plates, so that the plates can admit of such a size that the current density on discharge can be kept well within the limits of normal discharge; and in consequence of this, the battery is not subject to the great loss of efficiency, due to the fall of e. m. f. on discharge.

Only a few such installations have been made, two of which are on the Isle of Man; one has been installed by the Anaconda Mining Company at Butte, Montana; there is also a small plant at Merrill, Wis. The first installation, however, that has been made for any large city road for its suburban service, I find, is the one installed by the Union Traction Company of Philadelphia, Pa.

FIG. 2.—BATTERY DISCHARGE THROUGH RHEOSTAT.

The road was originally a horse car line which ran as far as the depot at Pelham, a distance of 7.3 miles from the power house. Conduits and cables were installed for operating a number of cars which were supposed to be amply sufficient. The phenomenal increase in the travel, however, necessitated a large increase in the car service. In addition, the success of the line warranted its extension to Chestnut Hill, 2.3 miles farther. More recently the line has been extended down a long grade to Hillcrest avenue, and from Hillcrest avenue to the Wheel Pump on the Bethlehem Pike 1.6 miles farther, making the line 11.2 miles from the power house, with the first extension of the line to Chestnut Hill, the underground cable was also extended, but the drop in pressure over this long line made it impossible to run the requisite number of cars, as the speed of a trolley car is approximately in the direct ratio to the applied e. m. f. The cables for feeding this section consisted of one cable extending to Chestnut Hill, one to Cheltenham avenue and one to Wayne Junction, about five miles from the station; all these cables were 1,000,000 c. m. in area, copper, rubber covered and leaded, laid in terra cotta ducts. The investment in feeders for this line had reached a point considerably above \$100,000 not including the conduits. To have increased the cable system so as to have supplied this section properly would have required about 336,000 ft. of 1,000,000-c. m. cable. At \$1.05 per ft. laid, this would amount to \$352,800; deducting the value of cables which were already laid, and which is estimated at \$79,000 we find

FIG. 3.—VOLT METER CHART TAKEN AT CHESTNUT HILL BEFORE THE BATTERY WAS INSTALLED.

FIG. 4. VOLT METER CHART TAKEN AT BEACH AND GREEN STREET POWER HOUSE.

FIG. 5.—DIAGRAM OF CHESTNUT HILL CABLES.

FIG. 6.—VOLT METER CHART FROM BATTERY HOUSE AFTER THE BATTERY WAS INSTALLED.

FIG. 7.—BOOSTER VOLT METER CHART.

FIG. 8.—CURRENT AND PRESSURE CURVES AT WOONSOCKET BEFORE BATTERY WAS INSTALLED.

that the extra cost for cables without conduits would have been \$273,800; this figure is, of course, prohibitive.

In order that you may appreciate the condition of the line previous to the installation of the battery, I would call your attention to Fig. 3 which shows a recording voltmeter chart taken at Chestnut Hill, and to Fig. 4 which shows the pressure at the station bus bar on the same day; 350 volts was frequently touched; the average was a little over 400 volts with 530 at the bus bar.

It was necessary, therefore, to furnish some means of keeping up the pressure. If a station had been built at that point, it would of necessity have been small and inefficient. From records taken at the main power house, it was found that it would be necessary to provide a station of about 750-k. w. capacity; such a station would have cost about \$85 per h. p., or a total of \$85,000. A battery station on the other hand required but little real estate, and would be inexpensive to operate, its cost would be considerably less than a power station. In the Chestnut Hill plant the entire cost of real estate, battery and building was approximately \$25,000; to this must be added the cost of a booster in the main power house. This required a 200-k. w. generator, which with its engines would cost about \$8,000. The total cost of battery and booster would, therefore, have been \$33,000. In this installation, however, they simply adapted a 300-k. w. generator at their power house to this service, so that they were put to but little extra expense in the power house for adapting it to booster purposes. We find, therefore, that deducting \$33,000 the cost of the battery and booster, from \$85,000, the cost of a station, that the difference in first cost is \$52,000 in favor of the battery. In addition to this, they were put to an expense of a little over \$13,000 for changes in the cable. In the estimates that follow I do not include any cost or interest on the cable, as the investment would have been about the same whether they had built a station or installed a battery. It is very apparent, therefore, from the facts given, that on a score of the first cost, the battery was by far the cheapest installment which they could make. In order that you may better understand the results which I propose to give in reference to the operation of this battery, I beg to describe the plant somewhat more in detail.

You will see by Fig. 5, there are three cables concerned in this work, which are numbered No. 3, No. 4 and No. 7, all of 1,000,000 c. m. in area; the lengths of these cables are shown on the diagram. Cable No. 4 is the only one which supplies the trolley wire direct; or, in other words, all the taps from the underground cable to the trolley wire are tapped on Cable No. 4; this cable runs all the way from the bus bar at the power house to the end of the line on the Reading Pike at Chestnut Hill. It feeds in all about 12 miles of trolley wire. Cable No. 3 runs direct from the power house to the bus bar at the battery house, e, as shown in the diagram. Cable No. 7 simply augments the capacity of cable No. 3.

In ordinary operation the current on cable No. 3 passes through the booster at the power house, by which the initial pressure is raised 150 volts more or less above the ordinary bus bar pressure of 550 volts, Fig. 7. By this means the drop in the cable is overcome, so that the pressure at the battery house can be adjusted to a point where the battery varies but little to either side of the zero point or, in other words, it charges and discharges continually maintaining the

load on cable No. 3 nearly constant, and consequently maintaining a constant e. m. f. where the current passes out from the battery house through cable No. 4, as shown in Fig. 5. This cable (No. 4) is therefore fed from two points, namely, from the power house end at 550 volts and from the Chestnut Hill end at about 515 volts. As a consequence, the distribution along the line from Wayne Junction to the end at Chestnut Hill is comparatively uniform and is now very satisfactory.

At first the battery was allowed to discharge during the day about three times as much as it charged, making up the charge at night between the hours of 1 a. m. to 5 a. m. Later the amount of day discharge was decreased until the charge and discharge were about equal. The first gave a very even voltage of a little over 500. With the present method the voltage is somewhat more irregular, but the average is somewhat higher. By keeping the battery continually up to full charge, the night man has been dispensed with.

Fig. 6 is a copy of an average voltmeter chart after the battery was installed. When the load in the line is low, the current going over the cable No. 3 to the battery house, divides at the bus bar, one part supplying the necessities of the line, the other part charging the battery. When the demand on the line is heavy, the pressure drops a little at the battery house; all the current going over cable No. 3 will pass out over cable No. 4, and in addition, the battery will discharge sufficiently to make up for the extra demand for current. This has the effect, as I have stated above, of keeping an almost constant load on cable No. 3. At times the load on cable No. 3 has become so heavy as to exceed the cable's capacity. At such times by an arrangement of switches at the power house, shown in Fig. 5, cable No. 4 is put on the booster as well as cable No. 3. In doing this, the current through the booster is largely increased, but the pressure can be reduced from about 250 to 125 or 130 volts, (see Fig. 7) and in addition, a better pressure is obtained at the Wayne Junction end of the section.

#### COST OF OPERATING.

For volt and ampere meter readings taken from the power house in October, 1896, we find that 136,576,919 watt-hours were delivered to the line at the battery house. These figures I may explain do not

FIG. 9.—CURRENT AND PRESSURE CURVES AFTER BATTERY WAS INSTALLED AT WOONSOCKET.

include the watt-hours generated by the booster, since we have assumed that this entire amount is lost in transmission. As a matter of fact, this is not strictly correct; but if a station were operated at Chestnut Hill, it would be run at a bus bar pressure a little above the battery pressure, and therefore for our present purposes the assumption is correct. From our experience in operating power houses of various capacities we find that a power house operated at Chestnut Hill under conditions which I have described would cost about 1.5 cents per kilowatt-hour. We therefore got the following as the cost of generating the number of k. w. h. required by the Chestnut Hill

branch during the month of October, 1896, if furnished by a station at Chestnut Hill:

|                                                               |            |
|---------------------------------------------------------------|------------|
| 134,848 k. w. h. at 1.5 cents.....                            | \$2,022 73 |
| Interest on \$85,000 at 5 per cent per annum.....             | 354 17     |
| Depreciation on machinery, etc., at 5 per cent per annum..... | 354 17     |
| Insurance, taxes, etc.....                                    | 200 00     |

Total cost of operation for the month by direct methods..... \$2,931 07

Actual cost of operating the battery and booster.

|                                                     |             |
|-----------------------------------------------------|-------------|
| Watt-hours delivered to cable No. 3 by bus bar..... | 136,576,919 |
| Watt-hours generated by booster.....                | 31,234,648  |

Total watt-hours delivered to cable No. 3..... 170,811,567

The cost of operating the power house for the month of October, exclusive of interest and depreciation, was 7 mills per k. w. h.; therefore, we obtain the following:

|                                                      |            |
|------------------------------------------------------|------------|
| 170,811,567 k. w. h. at 0.7 cent.....                | \$1,195 68 |
| Cost of labor and supplies at battery house.....     | 179 73     |
| Total.....                                           | \$1,375 41 |
| Depreciation of battery at 5 per cent per annum..... | 83 33      |
| Interest at 5 per cent per annum on \$39,000.....    | 137 50     |
| Taxes, insurance, etc.....                           | 32 00      |
| Total cost of operation.....                         | \$1,625 24 |

Deducting this from the cost of operating by a station at Chestnut Hill, we find the difference in favor of the battery for the month would be, \$1,302.83.

Since October 1, 1896, the method of operating has been somewhat changed and by installing wattmeters more accurate data have been obtained.

During the month of May, 1897, there was delivered

|                                  |                         |
|----------------------------------|-------------------------|
| To cable No. 3 at 550 volts..... | 101,750,000 watt-hours. |
| To cable by booster.....         | 28,969,280 " "          |

Total at station..... 130,719,280 " "

|                                       |                 |

Total output at battery house to line..... 103,043,448 " "

|                                                      |            |
|------------------------------------------------------|------------|
| 103,053,348 watt-hours at 1.5 cents per k. w. h..... | \$1,545 80 |
| Interest on \$85,000 at 5 per cent per annum.....    | 354 17     |
| Depreciation at 5 per cent per annum.....            | 354 17     |
| Insurance, taxes and miscellaneous.....              | 200 00     |

Total cost for May, 1897, by direct method..... \$2,454 14

|                                                    |           |
|----------------------------------------------------|-----------|
| Actual cost of operating battery:                  |           |
| 130,719,280 watt-hours at .6 cent per k. w. h..... | \$ 784 26 |
| Cost of labor and supplies.....                    | 163 67    |

Total..... \$ 947 93

|                                                      |        |
|------------------------------------------------------|--------|
| Depreciation of battery at 5 per cent per annum..... | 83 33  |
| Interest at 5 per cent per annum on \$39,000.....    | 137 50 |
| Taxes, insurance and miscellaneous.....              | 32 00  |

Total cost of operation..... \$1,100 76

NOTE: Cost of operating power house for May, 1897, was 6 mills per k. w. h.; 5 per cent depreciation of battery is the amount guaranteed by the makers.

Deducting \$1,100.76 the actual cost of operating battery for May, 1897, from \$2,454.14, the cost if station had been built at Chestnut Hill, we find a saving of \$1,353.38 in favor of the battery.

We may safely say, therefore, that the saving by using the battery is about \$1,350.00 per month or about \$16,200.00 per year.

### RECAPITULATION.

Saving in cost of installing battery over a new power station for Chestnut Hill..... \$52,000 00

Saving in operation per annum..... 16,200 00

These results speak for themselves, and need no further comment. The following data may also be of interest:

| Average " " " 12 p. m.....              | 1.188 |

At a specific gravity of 1.16 the battery would be about empty; so that we find at no time was the battery more than half discharged.

At the end of 15 months of continuous operations, we have only had to repair two leaky tanks at an expense of about \$25. The positive plates look as good as when first installed, and show no depreciation whatever; the negatives on the other hand have contracted somewhat and some of the plugs have cracked, but this in no way impairs their usefulness.

This method of power distribution cannot be considered economical per se, but where the conditions are such as we have described, there is no question as to the economy in favor of the battery.

### Application of Battery to Power House.

This form of installation has not become very generally appreciated in this country, and but few installations have been made. As its advantages become better known, I feel confident the practice will become more general.

The wide fluctuations in load in railway power houses are now well known. The average daily load varies from 50 per cent of the maximum in small stations to 70 per cent of maximum in the largest stations. From a very large number of observations in all parts of the country I find that in the majority of stations the average load is very close to two-thirds of the maximum load. Now it is also a well known fact that the maximum economy of the steam engine exists for a very small range of load, and that on each side of the point of maximum economy the efficiency falls off; rapidly on the overload, somewhat less rapidly on the underload. The result is apparent.

FIG. 10.—HEAVY LINE SHOWS OUTPUT OF FOUR GENERATORS WITHOUT BATTERY. LIGHT LINE SHOWS OUTPUT OF THREE GENERATORS WITH BATTERY. EASTON TRANSIT CO., EASTON, PA.

In most stations the engines at the best have an average load of only two-thirds their most efficient load, and as a consequence consume over 4.5 lbs. of coal per kilowatt-hour.

With badly regulated engines, and especially with water power plants, the changes in load are accompanied by variations in speed and consequently in voltage. These troubles may be entirely corrected by installing a battery.

The battery in this case becomes distinctly a load regulator. Figs. 8 and 9 show results obtained at Woonsocket, which is a water power plant. In Fig. 8 the load is carried entirely by the generators, and as is to be expected, the potential curve is very irregular, varying almost 100 volts, while the current varies from 0 to 250 amperes. The action of the battery is shown in Fig. 9, where the generator load varies about 50 amperes and the potential curve is most regular. Fig. 10 shows the results obtained at Easton, Pa. In this case the battery is quite small and the advantage is not quite so marked as it would be if a larger battery were used. Instead of using four generators, however, they are able now to operate the same number of cars with three engines. No cost figures for these plants are made public, but the increased efficiency is made apparent.

It is necessary that the capacity of the battery should bear a larger ratio to the output of the station than is necessary for potential regulation as described in the previous section of this paper. In potential regulation a comparatively small battery is necessary, since by changing the potential of booster from time to time during the

day the charge and discharge can be kept very low. In the case described a battery rated at 120 amperes has successfully regulated for a total output of 1,400 amperes. For load regulation, however, the battery should have a capacity equal to one-third the maximum output of the station. The average load of the station may then be made the maximum load of the engines, the battery taking care of the fluctuations.

As in the previous case there are no physical limitations to be placed on the size of the plates to be used, and the charge and discharge may be kept well within the normal rates. Under such conditions the efficiency of the battery is high, 85 to 90 per cent, and the deterioration very low. In most cases no additional labor will be required.

The President: Gentlemen, you have heard Mr. Hewitt's paper. We would like to have it fully discussed.

Mr. McCormack, of Brooklyn: Mr. Hewitt, I understood, stated that there were two cities in the United States where a car storage battery would be applicable. I would ask to what cities he refers.

Mr. Hewitt: I have in mind the cities of New York and Washington. There may be other cities which would like to have that system, but these are the only two which are seriously considering the matter.

Mr. McFadden, of Chester: Do you recommend the storage battery in conjunction with the booster in smaller stations, or the booster itself, say with a capacity of 900 amperes?

Mr. Hewitt: From my observation I believe that all small stations would be benefited in a large measure in their economy, if they had a storage battery. Of course, the question of investment must be considered in all these cases; but as a general principle, the operation of the station would be economized, if the battery can be used as an auxiliary.

Mr. MacFadden: What is the difference in cost per k. w. h. between the output of the booster, independent of the battery?

Mr. Hewitt: The only case in which I have had personal experience is the one in Philadelphia. I assume the output of the booster to be the same as the general output of the station. We do not keep separate records of the cost of it, and it would be impossible to do so. The steam furnished for the battery engines is from the same source as the steam furnished for the other engines, and we could not separate them; but I have taken the cost of the station for the months described, and assumed that was the pro rata cost of the k. w. h. generated by the booster.

Mr. Harrington, of Camden: Ask Mr. Hewitt if the manufacturers of the battery installation have guaranteed the depreciation, and if so, what the guarantee is?

Mr. Hewitt: The storage battery people will guarantee the depreciation, and they have guaranteed the depreciation in our case. I believe it is for five or 10 years, and at a certain rate pro rata to the cost of the battery. I do not feel at liberty to say just what the figure is. I do not think, however, that there is any special secret about it. Any man who wants to purchase a battery will get the information from a battery company.

Mr. Patterson, of Salt Lake City: I am very much interested in Mr. Hewitt's paper. It brings out some things that I have been thinking of along this same line. We in Salt Lake City have a steam plant as well as a water power plant, and we are now running our system by water power 18 miles from the city. We have occasionally, not often, been caused to shut down; once from a snow slide, which swept away the channel which we had around the mountain, and once from losing a bucket off the wheel. We still have our steam plant kept in good running order, but it takes from an hour to an hour and a half to steam up when these things occur. I was thinking when listening to the paper, that it might be possible to operate a storage battery in connection with our plants. I would like to ask Mr. Hewitt if, in his opinion, if we can have a storage battery, and if it would be a plausible scheme to turn the current after shutting down (we are at present, on average days, not counting the big days, running from 300 to 500 amperes), and run the plant by a battery; and if so, at which end of the plant would it be best to put the battery? I presume, of course, at the transformer end.

Mr. Hewitt: I think I am right in saying that the transmission referred to us by the gentlemen is an alternating current transmission; and there are difficulties in working a storage battery in conjunction with an alternating current. For that reason, it would be

impracticable to put the battery at the generating end. To put it at the steam plant end, which, I presume, is in the city, is simply a question of dollars and cents. A battery can be bought large enough to run any road in the United States, if you want to pay for it. It takes a pretty large battery to run the road, independent of all other sources, but it is simply a question of dollars and cents entirely. In using the battery, in conjunction with other sources of power, as I have explained in the paper, you take up simply the fluctuations, and let the station do the main work; but to have a battery installation large enough to do the entire work, and make up the fluctuations as well, you would find it necessary to have a pretty large battery for any ordinary road, but it can be done, if you want to buy it.

Mr. MacFadden: Would you consider it economical to have a booster and storage battery combined, as a booster line, where you would only want the power at certain times, during heavy loads and on heavy grades. The reason I ask is that we have a booster and only use it as required, and we have very good results, using it without any storage battery at all. I do not know about the economy. Would it be better to have the battery in conjunction with the booster, for such work, or turn the generator into a booster? We can use it either way, as required. If we do not use it as a booster, we can run it as a generator.

Mr. Hewitt: In the case referred to at Chester, I do not think the battery would add to their economy. The battery, as a potential regulator on the end of a long line, becomes useful when the variations are so great that in case of a sudden stopping of the cars, the potential would go so high as to do damage. For instance, at Chestnut Hill, on our plant there, we at times have the booster as high as 250 volts, above the usual 550 volts, making 800 volts in all. If the cars should be stopped or blocked at any point, the potential would go very high, and become dangerous and blow out the lights in the lamps and cause damage to controllers and other consequences would be sure to follow. The battery prevents the pressure going up in such cases. In the case the gentleman has mentioned, where the potential does not have to be boosted as high as to be dangerous, and is only boosted at times of heavy load, when the potential on the end of the line is within safe limits, I do not think it would be economical to use a battery. The local conditions of every case must be considered in all such installations.

Mr. Mundy, of Louisville: I desire to ask about the application of the battery, particularly in suburban work, such for instance, as race track travel, without the use of the booster. If the battery were mounted in cars, would it be practicable to run these cars out in cases of special loads to the end of the route, when you will have the load, and then, during the race or anything of that sort, the battery would be charged from your line, and at the instant of starting of the cars, pulling off at the same time the battery, and discharging back into the line, to carry you over the heavy peak? What do you think of the application of that? You could use that same battery, in times of long waits of that kind, by having a side-track at the station, and run it in to act as an auxiliary at the stations.

Mr. Hewitt: That is one of the variations of the scheme used abroad, which is perfectly possible. It is a matter, of course, on which an opinion could hardly be given in an off-hand way such as this. It would have to be considered entirely with a view to the local conditions. The cost of the battery would have to be considered against the cost of putting up the necessary line work, and running cars under these conditions and the cost of maintaining the batteries would have to be considered as against the cost of running the cars in the other way. It might in some cases prove valuable, and it might in other cases prove very costly. I could not give an opinion or estimate at the present time.

Mr. Mundy: Which do you consider would be the most economical? The use of the battery or the use of the booster.

Mr. Hewitt: I am hardly prepared to give a judgment in an off-hand way in a case like that.

H. H. Littell, of Buffalo: This is the most important question, as far as dollars and cents are concerned, that has been brought before this meeting—the question of saving money. The gentleman talks of a saving of \$33,000. It has been shown to us that we can save \$75,000 yearly in our operation by the use of the storage battery, and I am almost led to believe that we can do it, but we have not made any contracts yet. I believe we ought to hear from all of the storage battery men. They have not asked me to make this request, and I have not talked with them on the subject. I believe we should give them an opportunity to say what they have to say. I ask that

unanimous consent be given to the various representatives of the storage batteries to state the merits of their respective batteries.

President McCulloch put the question asking unanimous consent to have the representatives of the storage battery companies address the meeting; but as objection was raised by some of the members that the time of the convention could not permit this, the matter was not acted upon affirmatively.

Mr. Mundy: I ask the question if it is practicable to construct these batteries so that you could handle them on cars without drawing the liquid from the cells?

H. H. Littell: That shows the necessity of hearing from the battery men. The battery Mr. Hewitt described does not go on the cars, and is not supposed to be put on the cars. It is an accumulator.

Mr. Mundy: I mean with reference to what I said a few minutes since, using it at the end of the line, if it could be handled in a car of that kind, to stand jolting without spilling the cells?

Mr. Wilson, of Sioux City: During the last few years a number of the smaller plants throughout the country—those which are operating a load from 300 to 1,000 amperes—have installed direct connected units, a great many of them using compound engines. As Mr. Hewitt stated these engines run at their highest efficiency only through a small range of the load. Now, in these smaller plants these engines run at very light load the most of the time. Mr. Hewitt spoke briefly, I thought, of the application of storage batteries to stations for load regulation. I would ask him if he can say anything further on that point and give some idea of what saving could be effected in stations of the size I have mentioned.

Mr. Hewitt: I spoke briefly on that subject, because there has been so little done in that line. If I had gone any further, it would have been in the line of argument only, and I wanted to keep as close to the facts as possible. In the case of Easton, it required four engines to run their cars. At the present time they run with three engines. That of itself shows that these three engines will run more economically than the four in the previous case; the number of cars remaining the same. The difference will be between the economy of an engine running at approximately its maximum economy and an engine running at a lower economy. Just what the difference is at Easton, I do not know, because I was unable to get the exact data; but it would probably be a difference of 25 per cent in the coal. If an engine is running at a low economy, with five or six pounds of coal, at a low average load, and you increase the load to its maximum economy, you can probably reduce the coal per horse-power-hour output 20 or 25 per cent; but, in addition to that, you must deduct the loss in the battery itself, so that the net saving would possibly be 20 per cent or thereabouts. I do not wish to quote that as an authority, because I have not the facts.

Mr. Harrington, of Camden: I would inquire if there is any person present who has had experience in the question which has been raised, as to the matter of percentage of efficiency between running with or without the storage battery. It has been raised in our particular case, and just that one question is the hinge point, I think, more than anything else, to decide the question with us—just what saving would be effected, what the percentage would be. Mr. Hewitt thinks it would be about 20 per cent. If any of the Easton people are here, they would probably know.

The President: Is there any gentleman here who has had experience so that he can answer this question?

Mr. Ely, of Niagara Falls: I agree with Mr. Littell that this is probably the most important question coming before us, as it means, if successful, the saving of thousands of dollars, to say nothing of the cents. We are taking power for the Buffalo & Niagara Falls Railway, and other street railways of Buffalo as well, from these large generating companies, the Niagara Falls Power Company, and the Niagara Falls Hydraulic Power & Manufacturing Company. They generate the power and sell it to the street railway companies at so much per electrical h. p. per annum. You will see at a glance that the street railway company has to pay for that power, whether it is used or not, and for eight hours of the day, on an average, but a small quantity of the power will be used, and for a certain number of hours, on our line particularly, four or five hours, no power whatever is being used; but we are paying all the time the fixed rate for the entire amount of power. If the accumulator could be used to store the current, and we could use it at times when we might not take it from the power companies direct, it would be a saving to our companies of thousands of dollars per annum. In Mr. Littell's case it would be great saving. His company is taking 1,000 h. p. from this

transmission line, and they are going to take more. Mr. Hewitt, in your judgment, as the result of your investigation, has the state of the art advanced to that degree that storage batteries or accumulators may now be safely, practicably and economically installed to meet such cases?

Mr. Hewitt: Yes, sir, I think the batteries can undoubtedly be installed in such cases with economy. It is merely a question of size. If you install a battery powerful enough to do the work, it will do it well and reliably. The trouble in most cases has been an over-rating of the batteries. The batteries are expensive, and in most cases the railroad companies have been afraid to buy a battery large enough to do the work well. If you buy a battery which is too small it will go to pieces. If you pay enough money to get one that will last you for years, it will do the work well, and will be a valuable auxiliary. Whether it will be a saving to any considerable extent in this particular case, I could not say, off-hand. It could be figured out and possibly effect a considerable saving. From what you have said, I can see that if you are paying for a 24-hour day, and you could accumulate a certain amount of power in an accumulator, you might reduce the amount of power which you are paying for; in other words, if you are paying for 1,000 horse-power-hours, you might reduce it at the end of your present contract to a lower amount, and use your power then the whole 24 hours. That is a possibility; whether it would save you money, I would not wish to say. It would have to be considered the expense of the battery, maintenance, and such things would have to be figured out. As far as the physical possibilities go, it is perfectly feasible.

Mr. Dyer, of Augusta: I offer a resolution of thanks to Mr. Hewitt for this very able paper. It is certainly one in which we have all been much interested, and we are under many obligations to Mr. Hewitt. I also move that the paper be received and spread upon the minutes. Carried.

President McCulloch, in putting the motion, said: Mr. Hewitt also deserves great credit for having been present and read his paper, and answered the questions asked of him. One hundred times the force and value is given to the paper, by being present and able to follow it out and answer questions as Mr. Hewitt has done. (Applause.)

The President: The next paper is on "Power, Distribution and Use of Multiphase Current Transmission for Ordinary Street Railways," by Maurice Hoopes, electrical engineer, Lynn & Boston Railway Company, Lynn, Mass. Mr. Sergeant says that Mr. Hoopes intended to be here and read his paper, and answer questions, but has been compelled to abandon his work, and go away for recuperation, and as he is unable to be here the secretary will read the paper.

The secretary read the paper, as follows:

#### POWER DISTRIBUTION AND THE USE OF MULTIPHASE CURRENT TRANSMISSION FOR ORDINARY STREET RAILWAYS.

By Maurice Hoopes, Electrical Engineer, Lynn & Boston Railroad Company, Lynn, Mass.

The subject that has been assigned to me for discussion is one that has received considerable attention of recent years. Aside from the demands of what is usually considered steam railroad service, the business of the ordinary urban and suburban railways has grown lately in a way that requires some means of augmenting the usual method of power distribution. Lines have been extended to greater distances from power stations, and traffic has increased on lines which always have been remote from their points of power supply. These conditions have arisen at places where disadvantages of location or lack of sufficient load would render additional power stations unprofitable. To meet such demands, several methods have been devised. The consideration of the comparative merits of these systems is the principal purpose of this paper. Before undertaking this task, however, the writer desires to discuss some of the conditions met with in the operation of the ordinary 550-volt distribution system, some of the points raised have been frequently made. For these, an apology is offered in advance, the excuse being that they are sufficiently important to bear reiteration.

The usual electric railway distribution system, with its copper network as one, and its iron network as the other half, offers

Maurice Hoopes, electrical engineer of the Lyon & Boston Railroad Company, received his early experience with the Edison Electric Illuminating Company of West Chester, Pa., where he served one year as assistant superintendent and one year as superintendent. He gave up this position to begin the course of electrical engineering at Cornell University. A prolonged illness ended his collegiate training, and upon his recovery he was appointed to the superintendencies of the West Chester Street Railway Company and the Edison Illuminating Company. After two years of service Mr. Hoopes resigned these positions and became the engineer of the Lynn & Boston which was the consolidation of the various railway companies north of Boston. This position which includes both electrical and steam engineering, he has held for the past five years and has been instrumental in solving many important problems which have presented themselves on this system. Some interesting features of his work have been described in these columns and his convention paper is based on the experience with alternating and direct current distribution.

rather more complicated problems than does the ordinary form of all copper circuits. The latter system is symmetrical, whereas the former is likely to have greater resistance in the copper than in the iron portion. A rule that holds good of both systems is that the maximum benefit in reduction of total resistance, due to the addition of a given amount of conductor, results when the addition is made to the parts in which the drop is greatest per unit of length. An observance of this rule is important in adding to distribution systems. This demands a careful analysis of existing conditions. Before adding feed wire to a railway circuit, it is important to know the drops, under usual load, of the parts of the circuit. These may be found by the use of pressure wires, or by short circuiting the trolley wire to the rail, and passing a given current through the circuit, measuring the total drop and deducting the calculated overhead resistance from the total resistance thus found. Private telephone lines serve the purpose of pressure wires to measure track drops, and public lines, connected through the exchange may be used without interference with the service. An exception to the general rule, that the copper should be added to the part of the circuit showing the greatest resistance, is the case of a poorly bonded track that may show less resistance than the overhead. Re-enforcing such track with overhead copper connected to each end of all special work may result in the greater decrease in the total resistance of the circuit. This is really a special application of the general rule, rather than an exception to it, however.

Means for regular and easy measurement of track joint drops should exist. For tracks having frequent high resistance joints, there is no better way than walking over it with a low reading voltmeter connected to prongs on the end of a stick, that it may be bridged across joints. For detecting poor joints in good track, where they are far apart, and for the general inspection of the condition of track wiring, a car is convenient. A box trailer with each wheel insulated from all others, and a voltmeter connected between the two wheels on each side of the car, may be used. A third meter connecting the two opposite wheels will indicate defects in cross bonding. The writer considers that it is unnecessary to complicate the measurements by attempting to measure the resistance of the joint. His experience is that, if a bond is loose enough to have abnormal resistance, it will get worse rapidly and show excessive drop with even small amounts of current. It behaves very much as did Longfellow's little girl, and is either "very, very good," or "horrid."

It is universally recognized that the maximum efficiency is obtained from a distribution system when it is operated as a whole, and not divided into sections. The liability of accident to railway trolley wires makes it necessary to separate them in such a way that trouble at one point will not block the whole road. These sections should be as few as possible, while accomplishing the purpose for which they are designed.

Where one road has two or more power stations, the sections approximately equidistant from each of the two stations should be connected with both. They may then serve to equalize load between stations, the common section being cut loose from the station needing to decrease load. Two feeders to such a section, one from each station, constitute a tie line between stations. If desired, the potential may be raised in one station to a point that will deliver current into the other. Unless the drop in the combined feeders is excessive, it will probably be safe to allow the section attached to take the increased potential. Tie lines between stations which serve none but emergency purposes, are expensive, especially if the stations are distant from each other.

Where the ordinary methods of distribution are not applicable

because of the prohibitive amount of copper necessary, some one of the following systems is commonly used to care for the particular section:

1. A "special generator" run at increased voltage and usually over-compounded as much as possible, handling the section and no other load.

2. A "booster," consisting of a series wound generator, connected in series with the feeder as it leaves the main station bus bar. The field turns of this generator should be such as to make the e. m. f. of the armature as nearly as is possible equal to the drop in the feeder, throughout all ranges of current.

3. The "three wire system." This requires the division of the section into two. One half is then supplied from the regular bus bar, and the other from a special generator, with the polarity reversed, to bring the trolley wire opposite in potential to that of the rest of the system. The trolley wire should be so divided into the two half sections as to leave, as nearly as possible, equal loads on the two at all times. With this arrangement, the current in the track is only that flowing from the cars on one half section to those on the other. If these half sections are located near each other, this path through the track is very short. For this reason, it is usual to make one track of a double track road one half, and the other track the second half section. Unless conditions are such that the cars are likely to be bunched on one track this seems the better way of dividing. In addition to conducting current between cars, the track has to conduct back to the power station the excess in current used on one half section over that used on the other.

4. The "alternating current transmission system." The only form of alternating current system desirable for railroad work consists of high voltage multiphase generators (or low voltage generators with step-up transformers) in the main station, connected with one or more sub-stations containing step-down and rotary transformers. There are some half dozen such systems in use in this country, of which the best known are those from Lowell to Nashua, and from the station of the Niagara Falls Power Company to Buffalo.

With any of the foregoing systems, the storage battery may be applied as an auxiliary. In a railway power station, a battery is useful to the extent that it improves the station capacity and fuel economy by removing the immediate fluctuations. The writer considers that there are few instances where a battery can be installed, with resulting profit, where its function is the storing of power one hour for use the next. Except with very short time peaks, the battery costs as much as the additional generating apparatus. Particularly in small stations, however, there is such a variable load that it is impossible to average the full load from the station for a period of time, because of the inability to handle the very great short time overloads that such an average load demands. In such a station, a battery may result in a considerable increase in station capacity, and, by allowing the engines to operate at practically constant loads reduce the fuel consumption greatly. While a battery may do these things in the station, it may do even more, remote from the station. In the latter location, it will keep the potential near it practically constant, and will also maintain uniform current flow between the station and the particular point, thus adding the advantages of regulation and greatly increased copper efficiency.

One side of the story makes a pretty good case for the storage battery; unfortunately, the other must be told. The first cost of a battery is so very great that reasonable interest and depreciation on the amount invested will more than consume the apparent saving, in many cases. Especially is this so in the case of a battery located on the line, where it has been shown that the gross saving is the greatest. This is true because it requires a very much larger investment in the battery to care for the load variations of a given station if the batteries must be divided up among several sub-stations, the load factor of each of which is necessarily lower than that of the main station. The sum of the maximum variations of the several stations is always greatly in excess of the maximum variations in the main station. If, however, a power station were to be located at a considerable distance from a single center of distribution, through which all feeders from the station passed, it is quite probable that a battery placed at the latter point, would result in a net saving, due to its giving each, the station and copper a uniform load.

When it becomes necessary to select from the foregoing list the most suitable system for a given case, there are many considerations to consider in the decision. Either of the first three, the special generator, the booster, or the three wire system, may be arranged with the apparatus in any railway power station, assuming that it includes a reserve generator of the necessary size. It is better to use standard railway machines for these purposes, and, if possible, to arrange the station so that any one of the regular station machines may be used. It frequently occurs that one or more sections of line fed from a certain station have copper enough leading to them to care for them properly at all times, excepting a few hours on each ordinary day, and for longer periods on heavy days. While the work may be quite variable at times of light load, when the load increases it becomes more nearly uniform. Such sections may be satisfactorily supplied over the copper designed for the lighter load, by raising the voltage on the station end of the feeder during heavy loads. Usually, the margin in the field rheostat will allow the increase of voltage on any one of the generators, to a point considerably above the normal. When this is not so, it is possible that the generator speed may be increased, unless limited by the requirements of safety in the driving engine.

In one or both of these ways, it is often possible to get from 700 to 750 volts from a standard 550-volt machine. This increase enables the heavy load on the section to be handled very satisfactorily. The voltage at the feeder end necessarily varies with the load, and with ordinary fluctuations there may easily be 100 volts difference between the minimum and maximum. A recording voltmeter placed at the feeder end will show a very inky piece of paper, after a run. In practice, on a line which the writer finds it necessary to handle in this way, he gets variations from 450 to 550 volts. The minimum is infrequent, however, and the schedule is made apparently as well as though the potential were absolutely uniform.

Considering the question of abuse of apparatus, the increased voltage is not likely to injure a generator of modern construction. Practically, the only additional care that seems necessary is of the generator fields, noting that the increased current in the shunt windings does not heat them above safe temperature. So long as the potential at the car stays under 600 volts, there is little probability of trouble with equipment. Although the writer has had no such experience, he has known of cases where higher voltages have caused the arcs at the controller contacts, when breaking, to jump to the iron frames. This difficulty has been experienced more particularly on small roads using boosters, where one car might constitute the entire load on the booster. At times of throwing off the power, the booster holds up its potential for a sufficient time to result in a very greatly increased voltage during the time of the controller opening.

The method just described has the advantage of simplicity and economy. Cases arise, however, when the very great fluctuations in load make its use impracticable, with a line which, at certain times, carries very heavy current, as compared with the average, there must be some means of automatically raising and lowering the voltage at the station end of the feeder, to properly compensate for the variable drops. To accomplish this, a booster is used. As has been said, this machine is a series wound generator, connected into the feeder as it leaves the main bus bar, and so proportioned that a given current through it will give sufficient field strength to induce an e. m. f. in the armature equal to the fall of potential which the same current causes in the feeder. In practice, this condition is only approximated. Were the generators to have a perfectly straight characteristic curve, of proper pitch to match that of the feeder drop, the feeder and potential would exactly coincide with that of the power station. The curves of all dynamos drop away towards the horizontal as the magnets approach saturation. This results in the booster failing to compensate wholly for drops of currents above a certain amount. In practice, however, boosters are used which raise a feeder potential to 1,000 volts, and care for variable loads without allowing the light load voltages to rise at the feeder ends, to dangerous amounts. The system has the advantage of caring for extreme overloads on particular feeders, and is useful in cases where, for short periods of time, the feeder load is such as to cause excessive drops, and the time is not great enough to justify increased copper investment. On the other hand it is expensive of operation, due

to the facts that it wastes considerable energy, and that it generates this wasted energy in rather an extravagant way. If the booster is engine driven, the engine has widely fluctuating loads to handle, the load varying as the square of the current in the feeder. These variations necessarily result in a very low economy for the engine. With a motor driven booster, there are the constant losses of the two machines to meet. These are not so great as those of the engine and booster, but the necessity of keeping a particular generator for use as a booster limits the flexibility of the arrangement as compared with one which permits the use of any of the regular station generators, and, moreover, the addition of a motor booster does not increase the capacity of the station, as the power to drive the motor must come from the engines. The compounding of the standard types of railway generators is usually such that, when full load current is passed through them, the series turns alone will raise the fields to a point that will induce nearly normal e. m. f. in the armature. This adapts the machine for use as a booster on almost any line, excepting one requiring more than 100 per cent increase of potential at times of full load. As lines when so overloaded would be much better provided for by the addition of more copper, they need not be considered. In most cases, it is necessary to cut down the e. m. f. of the standard generator in order to secure the proper ratio of e. m. f. to current, for boosting, and this may be done by decreasing either its speed or the number of field turns. The former method has the advantage with an engine driven unit of improving the engine economy by lessening the friction losses and keeping the cut-off at a less wasteful point, when the latter is the simpler way. To accomplish this, the writer uses a long German silver strip of sufficient section to carry the proportion of current that it is desired to shunt out of the fields. This strip is fastened to the generator frame, connected across the terminals of the series field and doubled on itself in such a way that a clamp may be slid back or forth on it, raising or lowering its resistance. Knowing the resistance of the feeder upon which the machine is boosting, the clamp may be shifted to the point where the ratio between the readings of the voltmeter and ammeter is equal to the feeder resistance, and the proper adjustment reached.

For temporary uses, it is possible to make the necessary switch-board connections with flexible cables as the only adjuncts to the apparatus on the regulation board. A cable which may be attached to the positive lead of any of the generators, at the switch-board, and to any feeder, answers the entire purpose. With some boards, it is only necessary to have terminals on the cable that may be inserted into switch jaws. If the generator leads and the feeders happen to terminate in switch blades instead of jaws, the cable must have its ends fitted to clamp quickly to these blades. With this preparation, in order to transfer a particular feeder to a special generator for the purpose of increasing the voltage upon it the cable should be attached to the positive generator terminal, the other end hung (convenient to the feeder switch, the generator built up already for use, the feeder opened and attached to the cable, and finally the circuit breaker and negative generator switch closed.

If it is desired to extend this system to booster working, it is necessary to have a second cable leading from the positive bus bar and capable of connection to the negative terminal of the booster. It is best to include a circuit breaker in this cable to protect the booster, as the regular generator circuit breaker will be cut out.

At best, however, cables are troublesome appliances and allow only comparatively slow transfers. Moreover, it is impracticable to arrange cables so that two generators may be run in parallel on the special high voltage service. Where a new board is being installed, and where the circumstances justify the alterations in an existing board, such a one as is shown in Fig. 1, meets the required conditions. The two equalizing bars make it possible to run two or more machines on each the regular and high voltage at one time. With the arrangement, any two combinations of feeders and generators desired may be had. When running the "special generator," the negative switches are thrown up, and the positive and equalizing switches on the special machines thrown down. The switches on the feeders needing the increased voltage are likewise thrown down. If it is desired to use the auxiliary bus bar for booster purposes, the equalizing switch is left open, and the adjustable field shunt applied, the negative generator

switch is thrown down, after closing the booster circuit breaker, and the feeder is transferred down to the auxiliary bus bar. This puts the booster generator in series with the particular feeder. One very important thing in this connection is to make sure that the shunt field circuit is open on the boosting generator. It might be advisable to interlock the field switch with the negative generator switch in such a way that the latter could not be thrown down except with the former open.

The drawing of the board shows a wattmeter and an ammeter in each bar. By providing a double throw switch connected in such a way as to open the lower wattmeter from the feeder board, and connect it to the upper bus bar on the generator side of the ammeter shunt, the four instruments will be in series between the

FIG. 1.

generators, all running on the lower bus bar, and the feeders all running on the upper bus bar. This offers convenient means for checking meters, care being taken to see that current passing through the diagonal bar, on the back of the instrument panel, does not introduce an error into the wattmeter indications.

In a modern station of few large units, it is improbable, were the necessity for booster service to exist, that one of the large generators could be spared or would be desirable for the purpose.

In such stations, however, it is usual to install a smaller machine to carry the all-night and other light loads. This machine might be relied upon for the booster work. If the engine driving it have its governor arranged to adjust for a large variety of speeds, both above and below normal, and the unit be designed to run safely at the increased speeds, the combination will be found very convenient for meeting all classes of demand. The speed may be dropped for booster working, and raised when the generator is run at high voltage on a particular feeder. With this arrangement of dependence upon an individual unit for the special service, it is of course unnecessary to equip the whole switchboard with the extra negative bus bar. The double positive bus bar will be found convenient in any station, however.

The "three wire system," although very useful in lighting work, has been of little service in railroad distribution. Its value for the latter purpose has been considerably over-estimated, although there are places where its use has resulted in the maintenance of a satisfactory potential on sections of track, using the same copper, when the usual system could not approach doing it.

The advantage of the three wire system is due to the fact that it enables the use of double the usual potential for distribution, thus in the perfect case requiring but one-fourth the copper to transmit a given current at a given loss.

This law, that the amount of copper varies inversely as the square of the potential, is because doubling the voltage halves the current for a given amount of energy. The same percentage of loss allows a loss of twice the number of volts, and this, with but half the current, admits of the use of copper having four

times the resistance, hence one-fourth the weight. The "perfect case" just cited is one in which no third or "neutral" wire is necessary. Such an one does not exist in practice, and this neutral wire has to be supplied to conduct the excess of the current used on one side of the system over that used on the other, between the generators and the motors. In railroad work, the rail is used as the neutral conductor. It is seldom that a whole road is operated on the system, the common practice being to apply it to only those parts on which the ordinary system is insufficient. Where there are but one or two sections to operate with the reversed potential, the switchboard described may care for them satisfactorily. If one generator is made to build up with reversed polarity, and is coupled into the auxiliary bus bar, it will handle such feeders as may be thrown upon it as the negative side of a three wire system. The generator may have its residual charge reversed in a number of ways, one of which is to have the shunt field wired through a double throw switch on the machine, arranged to disconnect the field coils from the armature and connect them in the reverse direction to a pair of charging wires fed from the switchboard. The machine may have its residual charge brought back to the usual direction by the commonly used means of throwing in the positive and equalizing switches, with the negative open, and allowing the current shunted from the series coils of the other machines to energize its series coil. Where three pole switches are used on the generators, the shunt field double throw switches may be omitted, and the field reversed through the series coil by using an X-shaped pair of contact pieces insulated from each other at the point of intersection. These may be pressed against the switch jaws in such a way as to reverse the current shunted from the other series coils through that of the machine to be reversed. Where the three wire system is the regular system of operation, and the sections are divided equally between the two sides of the system, a regular three wire board is preferable. For a less general use of the system, the method described answers as well. The arrangement then becomes the same as that of the "special generator," with the polarity reversed, and the potential on the machine may be raised above normal, and the advantage of greater allowable drop in the copper added to that of the saving in track drop, due to the reversed current flow.

The writer has said that the value of the three wire system in railroad service has been considerably over-estimated. This statement probably needs explanation. In lighting work, the three wire system saves 62½ per cent of the copper. Each wire has to be but one-fourth as large as with the two wire system, but it is usual to make the neutral of the same size as the other wires, thus requiring three wires, each of one-fourth the size of those of a two wire system, hence the use in the three wire system of three-eighths, or 37½ per cent, of the copper necessary in the two wire system. Because this is true of lighting work, it is often assumed to be true of railway work. It is not, however, and in no case, where the track renders any appreciable service as a conductor, can the saving from the adoption of the three wire system approach the above figures. In general, its use will make a gross saving of the loss in track (assuming that there is no copper paralleling the track that may be used as a positive feeder). The net saving will be this gross loss in track less the track losses due to the passage of current from car to car, and of the excess of current due to lack of balance, back to the power station, and the increase overhead loss due to the greater drops in the divided feeders than in them when

FIG. 2.

## LOSSES IN WATTS.

|          | TWO WIRE SYSTEM                 | THREE WIRE SYSTEM               | SAVING |
|----------|---------------------------------|---------------------------------|--------|
| + Feeder | $60^2 \times 1 = 3600$          | $20^2 \times 2 = 800$           | } -400 |
| - " "    |                                 | $40^2 \times 2 = 3200$          |        |
| Track    | $60^2 \times \frac{1}{4} = 900$ | $20^2 \times \frac{1}{4} = 100$ | } 800  |
| Total    | 4500                            | 4100                            | 400    |

combined. The sketch, Fig. 2, may present this more intelligibly. It illustrates the simple case of an unbalanced three wire system, and shows that its losses aggregate 4,100 watts under the particular load. If this system were changed to a two wire one by throwing the two feeders in parallel, it would save 400 watts in the feeders, and lose 800 more in the track, leaving a net loss of 400 watts, or about 10 per cent of the total loss. Such a difference as is shown by this hypothetical case would not justify the complication introduced by the system. The only conditions where the method seems to be applicable, are those of excessive track losses with fair opportunities for balanced load. Such a case existed on the Lowell & Suburban road. They have a heavy business over a double track line to their park, some six miles from the power station. By changing to positive feeders those formerly used as overhead returns, and operating the line as a three wire one, they very greatly improved the efficiency of the distribution system.

In the selection, from the various systems of distribution, of the one best adapted to a particular instance, there is always a large number of variable factors to consider, and usually more or less speculation as to the values of certain ones on which no accurate data are accessible. This makes it impossible to work from fixed laws, and demands individual consideration of each case. For these reasons, there is considerable room for divergence of opinions in the matter. The writer has given his ideas as to the comparative infrequency of cases in which the three wire system is desirable. The booster has a very much more general application, and is suited to a greater number of cases than is any one of the other systems. Nevertheless, wherever work can be satisfactorily handled by a special generator, it should be, unless the change involves abandoning existing apparatus. The last method saves considerable over the booster, and is preferable for its simplicity. The only limiting condition to its use in satisfactory regulation.

The alternating current system, with rotary converter sub-stations, competes with the booster and special generator in cases where the load factor (the ratio of average to maximum load) is high, and where the regular 500-volt transmission will suffice during only a few of the 24 hours. In such a case, the copper losses, because of the length of time during which they are excessive, are so great that they may often exceed the entire expense of an alternating transmission system. The latter system also enters into competition with the independent power station for that class of business that is too remote from an existing station to admit of satisfactory handling by the other transmission methods, and too small to furnish load for such a station as may approach in economy the station from which the alternating transmission would be operated. Cases of each kind arise with city roads, in their needs for transmission to suburban centers of load, and with interurban roads.

The roads which the city station receives from the suburban centers have usually a very low factor. At morning and night, they are excessive, and through the remaining hours comparatively light. Were an alternating transmission system installed for such use it would probably lie idle for a large part of the time, its copper being used to transmit direct current. During the heavy hours, it would be called into service. This same service might be rendered by raising the voltage on the direct current feeders by use of the "special generators," and allowing the loss, which has been from 5 to 10 per cent during the light load, to become 25 or 30 per cent. In this way, the line may

carry three or four times as much current, and maintain the voltage at the distant end.

In comparing the systems, it is necessary to compute the annual cost of each, including the items in the following list:

### Alternating Current.

Fixed charges and repairs on main station; static transformers, if any, and on sub-station, station and rotary transformers, and accessories.

Fixed charges on sub-station land and buildings.

Sub-station labor.

### Direct Current.

Interest, depreciation, and repairs on such increased cost of engines and generators, as is occasioned by their being fitted to furnish increased voltage.

Cost of fuel to produce output representing difference between losses in direct current feeders, and those in alternating current feeders and transformers.

This assumes that the same amount of copper is used in each system, that the alternating system does not remove the need for sufficient copper to handle the load with direct current during a part of the time, and that this amount of copper will suffice for heavy loads by means of the increased direct current potential transmission. Should the load be of such a nature that the alternating transmission would be operated throughout the whole time, there may be a correction made in its favor of the annual cost on the increased amount of copper necessary for the direct current system over that for the alternating system. It is probable that the direct current generator and the engines need not be increased in cost more than 10 per cent by the requirements of the increased voltage. The writer has said that he is operating satisfactorily with machines designed for the standard voltage. Points which should be made against the alternating current system, which cannot be given exact money values, are the danger to life from the increased voltage, lack of uniformity in the equipment, making lack of flexibility in the stations (where, under the other arrangement, any generator may serve any demand), and the danger of delays due to the increased complication of the system, it sometimes requiring 15 or 20 minutes to start the sub-station machinery and get it into service after it has been stopped in the midst of load by accident. These points of disadvantage are very important ones, and operating companies can well afford to expend considerable money to avoid them. Especially is it undesirable to install for railroad work a system which may be disturbed by the extreme overloads such work introduces, and which cannot be restored to an operative condition immediately the load is brought within bounds. With the rotary transformer system, any short circuit or extreme load, which is not relieved by the sub-station direct current circuit breakers, may stop the rotaries and shut the power off the line during the long interval it takes to start them and put them into service.

In the comparative estimate, the results depend more upon the local factor than any other condition. With it sufficiently high, the alternating transmission may show an economy over the direct current for areas within a very few miles of the power station. Unfortunately, however, the yearly load factor is usually very low on railway work. With such a condition, it is cheaper to have excessive losses in copper at times of heavy loads than to carry the necessary equipment of alternating transmission apparatus to keep the losses down at such times. The railway manager naturally insists that the voltage be maintained reasonably near its normal value over the whole road at times of heaviest business. Estimates that show immense costs for copper to accomplish this under the regular distribution system make him turn to the consideration of additional power stations and multiphase transmissions. If he can be shown that he may care for his maximum loads over the existing copper by simply raising the voltage on the station end of the sections of heavy loss, and pay for the loss with coal instead of with interest and depreciation on a great amount of additional machinery, he is likely at least to determine carefully which he can better afford to do.

While, in the writer's opinion, the majority of cases may be best handled by direct current distribution, there are many instances of need for a distribution system where none but the alternating current system is applicable. Where water powers are used, they are almost always so remote from the center of load that very high potentials must be used for economical trans-

mission. Long interurban roads operating so few cars that load can be had for only one power station bring a condition where distribution must be accomplished by sub-stations, on the alternating system. The Lowell transmission presents a case where it was a problem whether to care for the new territory with a separate station, or to transmit from the existing station. So much has been written about the multiphase current system that was decided upon and installed there, that it is unnecessary to attempt a description of it. Mr. Sullivan, the general manager of the company, has kindly furnished the writer with a copy of the estimates from which the choice of systems was made. He states that operation justifies the estimate in its statement of the cost of the multiphase system. It showed the cost of power delivered to the trolley wire to be for the transmission system 70 per cent of that for the separate power station. There were no figures showing for what this work could have been done with a hooster system. Inasmuch as the latter method has been used successfully in place of the other, temporarily, it would be interesting to know its comparative cost. Tests of the Lowell system extending over 18 days show an all-time efficiency of 70 per cent as measured from alternating generator output to rotary converter output, the losses being those of two sets of static transformers, line and rotaries. The maximum efficiency for any one day was 73 per cent. The voltage regulation at the sub-station is about equal to that of a well governed steam driven power station.

The writer has said that the use of alternating currents for ordinary electric railways is limited to the rotary converter system. This is due to the fact that alternating current motors, in their present state of development, are not adapted to the needs of such railways. As yet, their use for traction purposes is limited to a few European roads, of which the best known is in Lugano, Italy. Alternating motors have the disadvantages of limited torque and tendency to synchronism. This makes them poorly adapted for the uses of any line but one having runs at practically uniform speeds, and few stops. These conditions are those of a through express service between cities. Accommodation and ordinary street railway services are such as can only be handled satisfactorily by direct current motors. At first notice, this fact seems rather contradictory to one's ideas of the flexibility of alternating currents. The ideal system has been thought to be one composed of a generating station containing large multiphase generators, with lines distributing current at a potential high enough to require but a comparatively small amount of copper, static stop-down transformers, and motors that may be regulated throughout all desired variations of speed by merely changing the impressed e. m. f. with a controller depending upon the use of various ratios of transformation. This dream included the freedom from the cars of commutators, and pictured a car equipment that would need a minimum of attention. Were it possible to realize all of those advantages, it is probable that the somewhat serious complication introduced by the necessity for two trolley wires might be tolerated. There seems to be little probability, however, of an early solution of the problem of adapting the alternating motor to the intermittent work of the street railway.

In conclusion, the writer desires to say that the title of this paper may have led some to expect rather more particular attention to the multiphase transmission system, and less about direct distribution. He has, however, given the various systems the same relative importance in the paper that he considers them to have in application. Hence, the subordination of the alternating current system in the consideration of the general subject of "Power Distribution."

Mr. Kelly, of Columbus: I move that a vote of thanks be tendered to Mr. Hoopes, for his able paper, and that it be received and placed on file. I also move that a telegram be sent to Mr. Hoopes congratulating him on the paper, and expressing the hope that he may soon be restored to health. Carried.

Mr. Hewitt: I trust the meeting will pardon a few words in reference to this paper. It is a matter which has interested me a great deal. I have done considerable figuring on such transmission, as it is the closest competitor to the storage battery and booster, of the former of which I spoke earlier in the session. As far as the problems have come up in ordinary street railway work, with such distances as ordinary roads handle, I have been unable to figure any economy in the multiphase transmission, as compared with the direct, using the booster. When you get to distances beyond, possibly, 15

miles, the problem then becomes more favorable to the alternating current. There are several things to be considered. In the first place, if you have a long line already running, you have copper which you are already using on the line. The first thing you must consider is whether this copper can be used in alternating transmission, should you use such; and, in the second place, could the cables be used economically in an alternating current transmission. Very frequently they cannot. If you have a cable of 500,000 circular mils in use, and you want to use an alternating transformer of high potential, in which you only require a No. 0 wire, you do not wish to use a wire of 500,000 circular mils, where No. 0 wire would suffice, and you do not want to throw it away.

That becomes a serious question, where the lines are underground, as they are in Philadelphia and other large cities, and the problem is largely magnified, for the reason that the insulation cost of three cables to run the three-phase transmission becomes enormous, as compared with the cost of the copper, the extra copper for the single cable to run the direct current; and in the cases that we have met with in Philadelphia, for our long lines, where we run underground cables for a large part of the area, the difficulty has been that the insulation cost of three cables made them cost more than to use the single cable and use more copper. We figured out very carefully the question of alternating three-phase transmission, in place of our battery, and we found the battery more economical; and I think the results have shown conclusively that such is the case. From what I gather from Mr. Hoopes' paper, I think he confirms the conclusions which we have reached. As I stated before, when you get to long lines, you then get to cases which are more favorable to the three-phase, and it is a question in my mind whether we are not on the eve of a very successful three-phase motor, and instead of using the rotary transformers we will use the static transformers with a three-phase motor on the car. I feel sanguine of the future possibility of this motor. I have seen such motors working experimentally, and they bid fair to give very good results.

The President: The next business is the appointment of the nominating committee to nominate officers and select the place for the next meeting. If there are any gentlemen who desire that the next meeting should be held in their respective cities, we should be glad to hear from them. I will appoint as the nominating committee, H. M. Watson, Buffalo, chairman; George B. Kerper, Dayton; Ernest Woodruff, Atlanta; W. Worth Bean, St. Joseph; Albert T. Potter, Providence; John A. Rigg, Reading; and E. S. Goodrich, Hartford.

N. H. Davis, of Cincinnati, presented an invitation on behalf of the city. Mr. Graham, of Boston, followed with an invitation for Boston, and Mr. Taylor, of Omaha, presented the claim of that city.

The meeting then adjourned until Thursday morning.

#### Thursday's Session.

President McCulloch called the meeting to order at 11 a. m.

The secretary read a letter from H. H. Vreeland, of New York, and a telegram from Thomas H. McLean, of the City of Mexico, regretting their inability to be present at the meeting.

The secretary read a letter from H. H. Littell, vice-president and general manager of the Buffalo Railway Company, inviting the delegates to visit the power houses of that company.

The President: I will say that during the meeting of the Executive Committee here last February, Mr. Littell very kindly showed us through his power house, and it is well worth anybody's time to go over to see it. There may not be anything there newer or better than many of us have, but we will all find lessons in tidiness, neatness, and care that are good things for us to see; and the manner in which they handle their coal is very interesting. I will now call for the report of the committee which was appointed two years ago, at the Montreal meeting, to confer with other societies as to the formation of standard electrical rules for construction and installation of electric wires. Frank R. Ford was appointed chairman of that committee.

Mr. Bacon: I am a member of the firm of Ford, Bacon & Davis. Mr. Ford was appointed by this Association to meet several other electrical bodies, to prepare a set of rules governing electrical installation for light and railway systems, and not being able to be present today, he requested me to make his report.

Mr. Bacon read the following report:

NEW YORK, Oct. 15, 1897.  
Secretary American Street Railway Association, Niagara Falls, N. Y.

DEAR SIR:—

Supplementing the reports of July 21, '96 and October 20, '96, made

by me as delegate of the American Street Railway Association to the National Conference on Standard Electrical Rules, I would state that upon December 11 and 12, the Committee on Code of this conference adopted its final report. The following associations were represented by delegates:

American Street Railway Association.  
 American Institute of Architects.  
 American Institute of Electrical Engineers.  
 American Society of Mechanical Engineers.  
 Factory Mutual Fire Insurance Companies.  
 National Association of Fire Engineers.  
 National Board of Fire Underwriters.  
 National Electric Light Association.  
 Underwriters' National Electrical Association.

As a result of this conference, a revised set of rules has been formulated, to which the name "National Electrical Code" has been given, a copy of which is herewith submitted.

This code has already been adopted or approved by all of the bodies forming the conference as above stated, with the exception of the American Society of Mechanical Engineers and the American Street Railway Association. At the next meeting of the former society, the question of adoption will come up and favorable action will undoubtedly be taken.

As the meeting of the American Street Railway Association is the last of the societies and associations named above, it is consequently the last one to which this code is submitted for approval.

As representative of your Association I was appointed secretary of the Committee on Code which performed the actual work of revising the rules and have kept in close touch with all the details of this work.

The new code contains many desirable amendments as to the technical requirements, having had the advantage of the co-operation of some of the most prominent electrical experts in the country representing the various associations and societies in attendance.

The form of the code has also been entirely revised, so as to obtain a more logical and up-to-date arrangement. This fact is particularly important as previous codes contain many repetitions and interpolations. It is not claimed that the code is perfect, but it can be said that each word in it was carefully considered by a number of men representing the most adverse interests and points of view. Amendments can and will be made from time to time as the progress of the art demands.

The great desideratum of uniformity has, however, been obtained so that now instead of a number of sets of electrical rules governing construction throughout the country, the "National Electrical Code" will be recognized as the one set of rules to which all electrical work must conform. The fact that it has already been adopted by almost all of important bodies represented in the conference insures this result and in order to complete the good work made possible by the co-operation of this Association, I earnestly recommend that the American Street Railway Association give its formal approval to the "National Electrical Code." Respectfully submitted,

FRANK R. FORD, Delegate.

(For an abstract of this code see the REVIEW for August, 1897, page 524.)

Mr. Bean, of St. Joseph: I move that the report of the committee be adopted. Carried.

The President: Last February there was presented to the executive committee a resolution to be acted on at this meeting, which would leave it discretionary with the executive committee to fix the date of the meeting at such time in the months of September and October, as it might think best according to the locality, so that if the convention should be held very far North it could be held a little earlier than this date, and if held in the South it might be held a little later in the season.

The secretary read the proposed amendment, as follows: Mr. Hippee gave notice of the following amendment to Sec. VII of the By-Laws: Insert in place of the words "on the third Tuesday in October, in each year, at such hour and place as shall be designated at the preceding meeting," the following, to-wit: "At such time in the months of September or October in each year as the executive committee may decide to be suited to the locality in which the meeting is to be held; the time to be decided on and each member of the Association notified of the selection by the first day of March in the year in which the meeting is to be held."

Mr. Davis, of Williamsport: I move that the date be fixed not earlier than the 15th day of September.

Mr. Newman, of New Orleans: I come from a city pretty far South, and we would like to have this convention meet in our city one of these days. We do not expect it next year, but we want you to come down there as soon as you can. We want you, when you do come, to come at the most pleasant season of the year with us, and I move as an amendment that the time be extended to include December 15th; say from September 15th to December 15.

Mr. Davis accepted this amendment, and the question being put to the house, the amendment was carried.

The President: Mr. Dimmock, of the Omaha, Council Bluffs Railway & Bridge Company wishes to address the meeting.

Mr. Dimmock: The directors of our interurban line, which I represent, have asked me to endeavor to obtain discussion at this meeting of the Association on the subject of United States mails as to the amounts to be received from the Government for carrying the same, with the object in view of obtaining better rates, and a uniform price for the same, feeling that through the Association channels is about the only way the street railways can obtain fair receipts from this class of service. We do not feel that we can get this subject before you so that you can do much at this meeting but our experience is that the Government is reducing the rates in our vicinity, 50 per cent of what we have received for the past five years; and upon making inquiries of a number of other roads, we find that they have also decreased their receipts from this source. It appears to me that there is no way in which we can do anything with the Government upon this subject except to get it before this Association; and I think, within the next year, if all the members will take this question up, the street railway companies can obtain much larger revenue from this source than they have heretofore.

All I ask is that this subject be taken up and handled between now and the next convention, so that we can find out what rates we can obtain. I do not think that the street railway companies are under any obligation to the Government to carry the mails at a less rate than the steam railroads receive, and in a great many cases they are so doing.

The President: We will discuss this question in a few moments. We have, just coming into our meeting, a body of young men who have been in session, all the time we have been in session, in the room below. It is the Accountants' Association. It is the new branch of this association of which I spoke in my opening address. They are young men; they are hustlers; and they have come here for business, and they have attended to it, and they have set us an example that we will do well to follow in their earnestness and intentness upon their work, and I guarantee that they will carry away from here better and more lasting results than we have carried away from any convention we have ever held. (Applause.) I have the pleasure of introducing Charles N. Duffy, the first vice-president; Mr. Wilson of Boston, the president, having been unavoidably kept at home.

Mr. Duffy, of St. Louis: Gentlemen, we want to thank you for the honor conferred upon us in inviting us to appear before this body, and we assure you of our appreciation of it. We want to thank Mr. McCulloch for his kind mention of our association in his address, and above all, we want to thank the members of this association for the strong resolutions of endorsement and hearty support that you have passed. That means to us a great deal, more than you probably realize; and in that connection we want to thank all the gentlemen who came to our meetings, and those who joined our association, and more especially those who are managers and not strictly accountants. The Street Railway Accountants' Association was organized in Cleveland, March 23-24 of this year. The accounting department of street railways are very diversified. They are largely the result of the ideas of the men in charge or the conditions under which the road is operated; and we feel that it is wise for us to have a convention, and better our work, and learn from one another, just as you operating gentlemen have done in this convention. And that is our purpose—to acquire information from one another and interchange ideas, and to bring out the good points of all systems of accounting for the common good; also to attend these conventions and profit by the exhibits and other advantages which you gentlemen enjoy. We desire, if possible, to promote a simple, wise and elastic system of accounting, which will be economical and uniform, so that as far as possible all street railway accounts shall be on the same basis. That does not mean that I am to know what the other man is doing, or the other man is to know what I am doing; but it does mean that if our general managers want to know how they stand as compared with other companies in the performance of the power plant, or operation of the road, or maintenance of track, or any other department of the work, they can

at least compare things on a uniform basis. (Applause.) That is our idea.

We feel that the accounting department of a street railway company is just as important as any other department, and all we hope to do is to improve our work and improve ourselves in the same way and by the same means that the American Street Railway Association is helping the operating department. Gentlemen, I thank you. (Applause.)

The President: Before discussing the mail question, we have a Committee on Rules for the Government of Motormen and Conductors, appointed at the last meeting, which will now report.

Mr. Kelly, of Columbus, presented the following report:  
To the American Street Railway Association:

Gentlemen:—Your committee appointed at the annual Association meeting in St. Louis in 1896, to consider the advisability of this Association adopting a standard code of rules for the government of street railway employes, begs leave to report, that after careful consideration of the subject, we deem it both necessary and desirable that such a code be adopted by this Association, and, therefore, recommend that a committee be appointed to formulate such a Code of Rules, and report the same in full at the next annual meeting of this Association.

The committee, in thus reporting in favor of the adoption of such a code of rules wishes to disclaim any intention of desiring to make the use of such rules obligatory on any member of the Association but desires that, if such a standard is adopted by this body, that it be left to the discretion of the members to adopt it for their roads in its entirety or select such portions as in their judgment is applicable to their local conditions.

Respectfully submitted,

W. F. Kelly.

Ira A. McCormack.

E. C. Foster.

The President: It looks as if this committee wanted to get somebody else to do the work we detailed it to do.

Mr. Kelly: It was my understanding, Mr. President, that we were to prepare such a code of rules; and so far as I am concerned, personally, I had a number of suggestions that I desired to incorporate in such a code. At a meeting of the committee, some of the members seem to be of the opinion that it was not our business to prepare the code, but simply to report on the advisability of taking action looking to the adoption of such a code. There was a difference of opinion as to what we were to do. I hope the committee will be directed to make such a report.

Mr. Akarman, of Worcester: I move that we accept the report of the committee, and that the same committee be continued for another year, with instructions to report such rules to the convention. Carried.

The President: We will now take up the discussion of the matter brought up by Mr. Dimmock, on the subject of the carrying of mail.

Mr. MacFayden, of Chester: Why would it not be a good idea to appoint a committee to investigate the mail matter, and have it report at the next convention.

The President: That matter will be referred to the incoming executive committee.

Mr. Hield, of Minneapolis: I represent the street railway systems of Minneapolis and St. Paul. In addition to the local service of the two cities we operate a line between Minneapolis and St. Paul, which for the last six years has been the official mail route. We carry box mail only, every car being equipped with a box, and the route is such that we pass the post office in each city. When we started that, there had never been any classification, and we took the lowest classification which was given to railroads, which, I believe is limited to 200 pounds. We carry nothing but letters, so that our weight never came anywhere near that. In addition to the box service we have a regular passage of mail between the post offices every thirty minutes. That is package mail, which goes direct from one post office to another. We continued in that contract, I think, for five years, and have just renewed it. We were never satisfied with the remuneration we were getting and it has been very materially increased. I was surprised at Mr. Dimmock's statement that there had been a general reduction, because that has not been the case with us. We also carry the mail in Minneapolis between one other post office, not a sub-station, but an independent post office in the suburbs. We also carry the mail to four sub-stations, and our remuneration for that service is on a basis of 3 cents a mile. That applies to pouch service; everything except our interurban box service.

Mr. Dimmock: Mr. Hield's remarks go to show that the Government is making contracts in one part of the country that are different from those in other parts; and also shows that the subject is one which can be discussed by the members of this Association to the advantage of each company. I know of a number of roads where the rates have been reduced. I think on account of the shortness of time this morning, it would be well to have this subject up for discussion at the next meeting.

Mr. Hield: I think I am safe in saying that the representatives of the Government drive as good a bargain as they can. They usually get the service at the best rate they can make. There is no legislation covering the subject.

Mr. Jones, of Memphis: Our experience has been a little different from that of Mr. Dimmock. We carry mail to a number of sub-stations, and within the last thirty days the Government notified us of a 50 per cent increase in the amount which it allows us, without any solicitation on our part whatever.

President McCulloch: I will state what occurred on one of the roads in St. Louis, which has for a long time been carrying mail from the city out into the different sections of the county. The contract expired about a year ago. The company was not satisfied with what it had been getting, and the Government declined to increase the rate. They ran the mail car into the car house, and there was such a demand for the mail service, that the Government immediately made satisfactory arrangements.

Mr. Hawken, of Rockland: The representative of the mail department in Washington came to the Rockland, Thomaston & Camden Street Railway Company, to make an arrangement with us to carry the mail, and we fitted up a car and carry open mail. We are allowed 3.5 cents a mile, the same as the steam railroads, and the Government also pays part of the salary of a postal clerk. The postal clerk looks out for passengers, express and baggage business, and handles the car.

The President: We will now listen to the paper on "Discipline of Employes," by George H. Davis, superintendent of the Canal and Claiborne Railroad Company, New Orleans.

Mr. Davis read the following paper:

#### DISCIPLINE OF EMPLOYES.

By George H. Davis, Superintendent, Canal & Claiborne Railroad Company, New Orleans.

##### SYNOPSIS.

1. Introduction and definition of railway discipline.
2. Principles of discipline.
  - (a) Confidence of employes.
  - (b) Fair dealing.
  - (c) Organization and classification.
  - (d) Issuance of orders.
  - (e) Employment to full capacity.
  - (f) Vigilance.
3. Civil service offered as a suggestion and partial solution of questions of discipline in railway operation.
4. Civil service methods as employed by the Government.
5. What features a successful civil service method should include.
6. General questions of employment and promotion, according to civil service methods.
7. Civil service methods employed by the Canal & Claiborne Railroad Company.
  - (a) System of marking.
  - (b) Principles of same.
8. Application of civil service methods to large railway systems.
9. Results of competitive civil service.
10. Conclusion.

Discipline is universally recognized as a necessity in every important industrial undertaking. It is as thoroughly essential to success in the operation of railways, as are the plans and specifications in their construction. In the broad sense it means the government of operatives through whom the equipment is made to do its work, and the efficiency of the equipment varies in direct ratio with the efficiency of its operatives.

A road has good discipline when all employes respect and kindly regard each other; when the officers do their best for the men, and

George H. Davis was born in Oswego, N. Y., in 1865, and is of Scotch and Welsh parentage. Practically all members of the family for four generations were

GEORGE H. DAVIS.

mechanics and millwrights, and were connected with mill and railway construction. The technical experience of Mr. Davis began at the tender age of 10, when he commenced work in the engine room of his father's mill. He was graduated from the Oswego Normal and Training school in the scientific course, and from Cornell University in mechanical engineering. During his college course he was the engineer for the Ithaca Street Railway Company, and upon graduation he entered the employ of J. G. White & Co. in the contract work for the various railway systems in Baltimore. Mr. Davis acted as superintendent of construction in the re-equipping of the Steiway Railroad of Long Island City. For the past three or four years his work has been done jointly with the other members of the engineering firm, Ford, Bacon & Davis, 220 Broadway, New York. Part of this was the complete design and construction of the Orleans Railroad of

New Orleans, the Bergen County Traction Company's lines in New Jersey, and the Canal & Claiborne Railroad of New Orleans. With the latter company he has held the position of general manager since it was equipped for electric traction.

vice versa, and when both officers and men sacrifice everything to the interests of the company.

It is a somewhat difficult task to maintain the conditions as defined, but the nearer this standard is approached the greater the surplus earnings.

Discipline should never be interpreted in the narrow sense that a man is to work as a machine. It is true that "cars should run like clock work" but, to arrive at this result through the constantly changing circumstances that arise, requires the services of men of thorough training, presence of mind and good judgment.

There is no fixed method of maintaining good discipline. It is frequently the result of the natural personal characteristics of the man in charge. There are, however, certain principles which are probably of universal application. First of all, a railway manager must gain the implicit confidence of his officers and men. To do this he must, in general, know the details of the design, construction, operation and maintenance of railways. He must have a universal reputation among his men of being shrewd, vigilant, industrious, honest and perfectly fair in his dealings. He must know them all personally, stand by them, and respect them as gentlemen upon all occasions. He must be thoroughly, popular and able to create among them a spirit of loyalty and enthusiasm in regard to the road and its interests.

A thing of greatest assistance in discipline is complete organization. Every man engaged in railway operation, from president to track-greaser, should have before him in printed form, a full synopsis outlining all the essential features, the exact limit, scope and character of service he is to render.

All officers should have their exact relative rank in the service, which should be thoroughly known among all employees. In this way if conflicting oral orders are given, the order given by the officer of superior rank will be obeyed without question.

Another feature of discipline is the issuance of orders. Many failures to obey orders are due to a misunderstanding or misinterpretation. It is therefore important in railway operation to issue all orders in printed form, clearly and definitely stated. These orders should be sent in explanatory personal letters to all superintendents, foremen, inspectors and starters; and be published on conspicuous bulletin boards at all stations. An order should never be issued except that it meets with the approval of the best officers and men, and, after once issued, it should be an inflexible law, applicable to all employees alike, and if broken, it should in all cases be followed by a prompt severe penalty.

Satisfactory discipline cannot be maintained unless employees in all ranks are worked to their full, natural capacity and physical strength. Idleness and easy positions in railway operation will undermine the best system of government that could be established.

Again, constant watching is a most important factor. The general manager, or whoever is responsible for the receipts, expenses, maintenance and discipline, should spend at least eight hours a day directly on the lines of the company. There should be trusted strat-

egs at both ends of all lines at all times, and at least one inspector for each 30 cars operated.

Written reports for the smallest details of both good and bad features of the services should be insisted upon from all officers of the company, and a false report or statement from any employee should be sufficient cause for his instantaneous discharge. Nothing good or bad in a man's service should be passed with out the manager's recognition. One of the strongest incentives to good work among men who are trying to do their best, is praise. When a motorman saves a pedestrian from mutilation or death from an electric car, his act should be recognized by a complimentary personal letter, thanking him for his skillful work. In general a manager should have only praise for his officers, and among the men 99 per cent of them should be above censure. However, when a man is censured it should be severe and the final preliminary to his discharge. A man should never be discharged except his case is given a thorough investigation, and he is given abundant opportunity for defense. When he is once discharged he should never be reinstated.

Railway employes as a rule, admire a policy which is open, fair and generous. When an unusually large day's work is done in handling a great crowd of passengers, it is no more than fair for the company to share its profits with the men in giving them a few hours extra time, the number of hours being in proportion to the extra receipts. The amount of money thus invested will in the future return to the coffers of the company a hundred fold or more.

Perfect management is something beyond human effort, still, if the problem is earnestly and industriously studied, railways may be operated to the complete satisfaction of the public, the stockholders and the employes.

As a partial solution of the different questions arising in connection with discipline, a competitive civil service system is offered as a suggestion. There are no new principles in this system as commonly understood. It is only a way of carrying out what every successful man has always followed in his business career. He selects the man whom he believes most efficient. He promotes the man who is of the greatest service to him, and discharges the man whose services are of the least value.

All civil service methods employed by the Government, take account only of a man's ability in successfully passing the initial competitive examination. In reality a man's work in the service after employment should have far greater weight in regard to his retention or promotion, than the mere fact that he was able to answer correctly a series of questions, at best having only an auxiliary connection with the work to be performed. Another serious weakness in municipal or Government civil service methods is that often questions are prepared and answers examined by commissioners who know nothing of the business, trade or profession for which they are conducting the examination. In all cases questions should be prepared and examinations conducted by the head of the department under whom the candidate is to work after entering the service. To insure perfect fairness, commissioners may be delegated to criticize the questions, witness the examinations, and judge of the relative merits of all answers. Any successful competitive civil service system for railways, must take into account:

1. The previous history of the applicant, including his railway experience.
2. His knowledge and skill in railway operation, which is covered by competitive examination.
3. His physical condition.
4. The quality of his work after entering the service.

The quality of his work after entering the service is the best criterion by which to judge of his relative value. However, before a man is employed it is impossible to judge of his work, and the only alternative is a broad, practical, competitive examination, which covers samples of his work under the observation of the examiner, together with answers to the most practical questions that may be framed.

In applying these methods to railway operation and maintenance, it is necessary, so far as practicable, to classify the positions of each of the various departments, so that there is a fixed line of promotion from the lowest to the highest rank. This does not mean that a man shall have worked in all ranks of a given branch of the service, or even in all branches of a given department. It does mean, however, that he shall have started at the lowest round of the ladder in some one branch and have learned some one department to perfection, and all departments in general. Railway companies vary widely in reports, insufficient number of names in accident cases, no change,

their classification of positions and the relative importance which they attach to the services of each department. It is not intended at this point to discuss the organization of railway operatives.

A classification so far as civil service methods are concerned may be compared to a river and its tributaries, where the waters of all branches, if they are not evaporated, may reach the desired terminal. In short, it is a question of all being given an opportunity, and the survival of the fittest.

There are, apparently, some difficult features in the general policy of promoting men according to their relative standing, from one department to another, or even from one branch to another of the same department. The skill and experience required in one may be totally different from that required in another, and again a man may show marked ability in one position, while in another he would prove most inefficient. However, if a man is industrious, bright and faithful in one position he will maintain the same characteristics in another, and, as every practical man knows, these qualities of character in an employe are more desirable than all others.

A competitive civil service system if correctly applied, is a most advantageous solution of the question of advancement of employes, and does not interfere with a practical line of promotion. For example, if a vacancy occurs at the head of a given department, all employes ranking highest in the various branches are eligible to compete for the position. In deciding upon the successful candidate, two things should be taken into consideration, the previous standing and record of the competitors with the company, and the result of their competitive examination.

In all departments of the Canal & Claiborne Railroad Company employes are placed upon a basis of competition. Men are employed who have the best standing according to a broad, competitive examination, and are placed in the lowest rank of any given branch of the service.

Promotions in the various branches, so far as practicable, are made consecutively from one rank to another. The company fills every position from among its own employes, provided there is any one in the service competent to take the place. To illustrate, if the position of chief dispatcher were vacant, all starters employed by the company would be eligible to compete for the position. The chief dispatcher prepares all schedules, knows the exact position of every car on the road, and the crew that is operating it. Now, if, upon competitive examination, it was found that no starter employed by the company was able to prepare a thoroughly practical, satisfactory and economical schedule, then no one in the direct line of promotion would be given the position. In this case another examination would be held in which the employes of all departments would be eligible, together with the employes of other companies or outside persons. In this way merit alone is recognized as a basis for advancement, and also the highest standard of efficiency is maintained in the various positions.

So far as practicable the same regulations apply to the transportation department, the maintenance department, and the accounting department.

In the transportation department, in the employment of motormen and conductors, when an applicant presents himself, if he is worthy of consideration after a preliminary conversation and inspection, he is given application and recommendation blanks.

To be eligible for appointment as motorman or conductor, the applicant must be between the ages of 25 and 40, for the position of motorman he must weigh at least 160 pounds and not exceed 210, and must be at least 5 ft. 8 in. in height, he must have had at least one year's experience in the position he seeks, and should be recommended to the service by at least three officers of the company, including foremen, inspectors and starters, and also by at least seven motormen and conductors, who are already in the service. He then obtains the company's physician's certificate with regard to his physical condition. If his certificate, application and recommendations fill the requirements and are apparently satisfactory, they are then given to an inspector who personally investigates his previous record among the employes with whom the applicant has worked, and also among outside persons who know the applicant. If the inspector's report of investigation is satisfactory, the applicant is placed on the lines of the company with motormen and conductors who have the best standing in the service. He rides with these men until he is familiar with the special features of the lines of the company. He is then given the competitive examination. This is intended to be extremely practical and consists of two parts:

1. The applicant takes charge of a car with an inspector who estimates the quality of his work for one trip over each line of the road.
2. He answers a list of questions covering the various things connected with this department of railway service.

Finally, the applicant presents himself at the office of the general manager, where he is questioned in regard to all orders and instructions previously issued by the company, and his understanding of the conditions under which he will be expected to work.

Based upon the above, applicants having the highest standing are given the positions as extra motormen and conductors as fast as vacancies occur.

If inexperienced men are employed at all in the service, they are taken on as conductors and kept in this position for at least six months, and for three months they work without pay. After this work as conductors they break in as motormen, with motormen already in the service who have the highest standing. After six months service of this kind, they are given their examination and are placed on the lines of the company as extra motormen.

To determine the relative standing of employes a system of marking has been adopted, which takes into account.

1. The general quality of a man's work, according to the judgment of the foreman in charge.
2. The value of the special acts in his service as reported by the foreman, and marked in the record of the employe according to a fixed scale kept in the main office.

To illustrate, in the department of transportation, for motormen and conductors, blanks are prepared which contain the names and numbers of every motorman and conductor in the service. At the head of these blanks there is a personal letter addressed to the general manager which reads as follows:

"Dear Sir:—According to my best judgment the quality of service rendered by each employe coming under my observation in my department of the service, being fairly and honestly estimated for today is as follows:"

Opposite the name of the motorman or conductor there is a blank space left for the mark of the foreman. Each foreman, inspector and starter has one of these blanks, and marks after the conductor's or motorman's name the quality of his work for the day, and sends the blank to the main office the next morning. He marks "v. e." for very excellent; "e" for excellent; "g" for good; "f" for fair; "p" for poor, and "v. p." for very poor.

In the main office these marks are reduced to an arithmetical basis and placed in the record of the employes. In determining the marks to be placed in the record, the marks of all foremen, inspectors and starters for a given man are added and the mean taken, which is considered the final mark. In this way the average judgment of perhaps 10 different foremen in regard to an employe's work is obtained.

The marking of the special acts of an employe is on a more definite basis, and has no connection with the judgment of the foremen, inspectors and starters. They simply report the acts. Based upon bulletins, instructions or orders issued, and also upon experience in good railway practice, two lists of acts of employes are made, one delineating all the desirable or commendable features of the service of an employe; the other all the undesirable or intolerable features. For each of the acts in the commendable list, a certain number of points of merit is always given. Similarly for each of the acts in the uncommendable or intolerable list, a certain number of points of demerit is given. To illustrate more thoroughly, a few of the acts mentioned in the merit and demerit list may be given. In the merit list for motormen we have, skillfully avoiding accidents, assistance on minor road repairs, suggestions as to best speed of cars, helping to clear blockades, assistance rendered on special occasions, obtaining names in accident cases, etc.

In the demerit list for motormen we have, running with hands off of brake and controller, looking around while car is in motion, not running on schedule time, feeding car too fast, untidy condition of dress, accidents to persons (serious, medium, slight injury), accidents to cars (serious, medium, slight injury), accidents to vehicles (serious, medium, slight injury), etc.

In the merit list for conductors we have, complete and perfect accident reports, reports as to where the company is gaining or losing traffic, reports as to what passengers say, kindness to aged or infirm persons, assistance rendered on special occasions, obtaining names of witnesses in accident cases, etc.

In the demerit list for conductors we have: Incomplete accident reports, insufficient number of names in accident cases, no change,

not announcing route, streets and transfer points, leaning against door, conversing with passengers inside, short register, bunching fares, ringing up fares when officer boards car, register not turned, shorts and overs, untidy condition of dress, etc.

The marking for general daily reports, together with reports of special acts, is kept in a record book, which allows four pages to each employe, each of the pages being numbered to correspond with the employe's badge number. The first two pages of each employe's record are made up in blank form, allowing space for each day of the month, together with each month of the year. The next two pages are plain ruled, and are used for explanations of each mark given.

The margin of the first page is divided into blank form giving the information regarding an employe which is usually covered by headings placed in application blanks. Each month the points of merit and demerit are balanced. If an employe's record falls below zero he is discharged.

The estimation of the value of a man's services according to the above method, is based upon two foundation principles, one being a check upon the other. Every officer of the company has his own ideal, and, due to the fact that every human being sees the world from a different standpoint from every other human being, the chances are that an employe's work is estimated upon by too thoroughly experienced railway operatives, the average judgment of these men should be correct. Acting upon this principle, favoritism among officers is almost completely eliminated. Some men might be favorites with two or three officers, due to outside circumstances, but this would never extend to the whole to, or even five. A car operative's life is not filled with opportunities to render brilliant services in behalf of the company, and, for this reason some method of estimating his work must be adopted which will give credit for every day's efficient, satisfactory conduct. The method employed has proved by experience to be simple, just and effective.

The second principle used in the estimation of the quality of the service is embodied in the fact that a more just and unbiased decision can be reached in regard to the merit or demerit of an act, if judgment has already been passed on an exactly similar case. Now, by the system of marking mentioned, a list of all possible cases is prepared, and judgment passed upon them, by the general officers of the company, the relative number of points of merit and demerit being fixed. Now, when an act occurs, it only remains to locate it in the list to pass judgment. Hasty or snap judgment passed in a fit of anger on an employe's offense usually results in the greatest injustice to the employe. The reaction among employes is such as to practically destroy their confidence in the company, and always proves detrimental to the best interests of the road.

Promotions among motormen and conductors are always made according to their standing as determined by their records without examination. The "extra" motorman or conductor having the best record is promoted to a "swing" run. Similarly, the "swing" men to "half-and-half" and the "half-and-half" men to "straight day" runs. "Straight-day" motormen and conductors are promoted to the positions of inspectors, starters and transfer agents on their records alone. No account whatever is taken of the relative date at which the employe entered the service.

As mentioned before the same general methods are employed in all departments, but, owing to the fact that the transportation department is the most important of all, the details of the civil service system are carried out most thoroughly in this connection.

To insure perfect accuracy and fairness each employe is invited to examine his own record or that of any other employe at any time. He is also at liberty to inspect the scale of marking by which the records are adjusted.

It is evident that a system of bookkeeping resulting from the methods as described would be more expensive to maintain than other forms of discipline which have been generally employed. It has been found, however, that the extra expense attached to this system is trifling in comparison with the results obtained.

The larger a street railway the more thoroughly applicable are civil service methods. This comes from the fact that, on small roads the general officers of the company come more in contact with the employes, thus being able to judge personally of the quality of their services, regardless of records kept, and too, on small roads the same employe fills several positions in comparison with a thoroughly classified organization which must be maintained in large street railway systems.

Regarding the general results of a thoroughly enforced competitive system, it may be stated that there is as much difference in the quality of work rendered by men engaged by a road operated on a competitive basis of promotion, and a road on which promotion is made according to the position of a man's name in the list, as there is between two railway companies, one having a monopoly of the traffic and the other having a direct paralleling competitor. It has been found by experience in the operations of roads where employes work on a competitive basis, that they invariably do their best. They are gentlemanly in their treatment of passengers, neat and tidy in their dress, and skillful and prompt in the discharge of their duties. They take great pride in the company's fine equipment, its large business, its management and principles of fair dealing. They never fail to praise the company and its service to patrons, and are only too glad to answer in behalf of the company, any adverse criticisms offered by the patrons or the public. They feel from the start that their present and future position in the railway business depends upon the quality of their work, and nothing else.

Legitimate competition is one of the most powerful incentives that can be employed. Men under these conditions are forced to make their best efforts. This is illustrated constantly in all professional, mercantile and manufacturing industries. The piece work system in vogue in New England factories is only one method of competition by which a man is paid according to the quality and quantity of his work.

On a competitive basis the standard of excellence is constantly being raised. When a large number of men are engaged in the same kind of work, there are always a few who will accomplish most extraordinary results, and their work stands as a most effective object lesson to the others. If a man has anything in him, competition will bring it out; if he has no redeeming features, then his services are not required.

Another advantage of the civil service system is that it effectually debars all outside influence and eliminates the "bug bear" commonly designated among the men as a "pull." It also completely obliterates political interference, which is the greatest bane to the efficient services of American street railways.

In conclusion, it may be stated that this system is not urged as a panacea for the ills of railway management, but is merely offered as a suggestion, with the hope that it may be of some slight assistance in improving the successful methods which have always been employed.

Mr. Rigg, of Reading: I move that the paper be received and filed, and a vote of thanks be extended to Mr. Davis. Carried.

The President: We would like to have discussion upon this paper. If there is none, we will proceed to the next paper on "Application of Electricity to Railroads now Operated by Steam Power," by N. H. Heft, of the Meriden Street Railway Co., Meriden, Conn.

Mr. Heft read the following paper:

#### APPLICATION OF ELECTRICITY TO RAILROADS NOW OPERATED BY STEAM POWER.

By N. H. Heft, President Meriden Electric Railroad Company, Meriden, Conn.

The New York, New Haven & Hartford Railroad Company owns and controls about 2,800 miles of main line railroad track in New York, Massachusetts, Rhode Island and Connecticut, of which about 16 miles are operated by electricity on the third rail system and 14 miles on the overhead trolley system. The company also owns the entire capital stock of the Stamford Street Railroad Company and the Meriden Electric Railroad Company, the former operating about 10½ miles of track and the latter about 17½ miles on the overhead electric system. It is through my official connection with the Meriden Company that I am permitted to be present at the meetings of the American Street Railway Association, a privilege which I thoroughly appreciate.

Electric railroading on a large scale is but the development of street railway experience, and, if the future brings success in the efforts now being made to use electricity for heavy work, it will be due, largely, to the courage and enterprise of those who have "blazed the path of progress" and forced the fighting by entering

Colonel N. H. Heft was born on a farm near Carverton, Luzerne County, Pennsylvania, about 50 years ago, and his early education was secured while attending

N. H. HEFT.

the district school during a portion of the winter months. He worked on the farm, in mines, in machine shops and for various railroad companies until he became financially interested in mining and the manufacture of oils. For the past 20 years he has been engaged in railroad construction and in street railway projects. He organized and secured franchises for the Bridgeport Traction Company, and negotiated the transfer of all the horse railway securities in that city to the Traction Company. While president of the Bridgeport Traction Company he was successful in the suits against the Consolidated Railroad Company, and the later franchises were granted to the company over the mayor's veto. About three years ago, when the Consolidated Railroad Company decided to conduct some experiments with electric traction, President Clark placed Colonel Heft in charge of the construction and equipment. The results of this work have been closely

watched by electrical and railroad men and fully described in these columns. Colonel Heft is a great lover of art and in the art gallery of his beautiful home at Bridgeport is one of the finest personal collections of paintings in New England.

into competition with an industry which believed itself, 10 years ago, absolutely secure in its position.

There is little for me to tell you of novelty in the work done by the New Haven Company in Meriden and Stamford. These are ordinary street railway systems, fairly well equipped, and we try to operate them to serve the public properly. Believing, as we do, that a good track is the foundation of a good system, we have thoroughly reconstructed the track in both cities with heavy rails. In doing so we have paid the most careful attention to the matter of the return circuit, bonding the rails so thoroughly as to make them the path of smallest resistance back to the station. We have thus avoided, to a very large extent, trouble with electrolysis. Nothing is more certain to my mind than that carelessness about making a track return circuit is a most serious mistake, and that carelessness about testing and maintaining joint connections is another. I would rather spend a thousand dollars or more in providing ample carrying capacity of rail bonds than to put the same amount of money into the overhead circuit, if, by doing the latter, I should neglect the former.

About three years ago, the New Haven Company found that various electric railways in its territory were gradually extending their operations into the field of interurban work, and that the company's passenger earnings were suffering accordingly. It was at once seen that, by no ordinary methods of changing schedules or increasing speeds could this lost traffic be won back again, and, with characteristic knowledge and courage, President Clark and the New Haven directors determined to "steal the thunder" of its new competitors, and commenced a series of elaborate experiments in heavy electric railroading. It must be confessed that this decision was reached only after some misgivings. To the average railroad man, street railways have, until recently, seemed a pretty sort of toy, fit for apprentices in the art of transportation. Lately, however, he has waked up to the fact that "the tail will wag the dog" unless some radical action is taken, particularly in suburban and short distance work, and, in the eastern sections of the country anyway, railroad men have become modest enough to be willing to look with respect upon the great work which has been accomplished in street railroading.

The first line to be equipped by the New Haven Company was a purely summer road, operated for about four months in the year on the Massachusetts coast from Nantasket Junction to Pemberton, a distance of about seven miles of double track. This line was chosen partly because the main line operation would not be interfered with in case of trouble with the electric trains and partly because of the existing heavy summer traffic which would put the new apparatus and the feasibility of the entire system to a severe test. An overhead trolley line was built, with center pole construction, and everything made very strong and more substantial than was at that time found in any street railway work to our knowledge. At the time of construction of this overhead line, there were no suitable movable switches in the market,

and we had to remodel and have built especially for our purpose those which we finally adopted. One feature perhaps worthy of note is the connection of the overhead switch with the track switch in such a way that both are controlled by a single lever at the switch stand.

The line was operated for the first summer with excellent success and, all fear of trouble having disappeared, an extension of 3.6 miles was made on the main line of the company's Plymouth division, from Nantasket Junction to East Weymouth, this section being operated by the third rail system.

In December, 1896, we commenced work on a new line running from Berlin, Conn., through New Britain to Hartford, a distance of 12.3 miles, 3 miles of which, from Berlin to New Britain is a double track, and the remainder, from New Britain to Hartford, a single track. A power station was built at Berlin, one end of this line, partly because of a desire to test transmission of power to a considerable distance, and partly because Berlin is the center of several radiating lines which may eventually be put into operation by electricity.

The physical characteristics of both these lines have been so carefully and accurately described in technical papers that I shall only refer to them more or less incidentally in the following, confining my remarks chiefly to the results which we have found, and the conclusions which we have reached in our own minds as to the best methods of applying electricity in heavy railroad work.

#### TRAIN SERVICE AND TRAFFIC.

We have learned very thoroughly, in our street railway experience, the lesson of the importance to any transportation agency, working in a thickly populated territory, of uniform fares and a frequent and regular train service—a train service which requires no printed schedule to enable people to know when cars may be found in waiting. The time has come when every progressive railroad manager must recognize that new conditions, and the new character of competition require a complete change of operating methods.

On its Nantasket Beach line, the New Haven Company gave, during the last summer, a regular half-hour service from 6:30 in the morning until 11:30 at night. When unusually heavy boat loads arrived at Pemberton from Boston, trains were run in as many sections as were found necessary to take care of the people, but still the half-hour schedule was not departed from on ordinary days. On Sundays and holidays, when boats arrived at Pemberton every 15 minutes during the greater part of the day, express trains between Pemberton and Nantasket were sandwiched in between accommodation trains in such a way as to give a 15 minute schedule of alternate express and accommodation trains. The time-table this summer required 23 regular trains daily, each way, between East Weymouth and Pemberton. During July and August, the traffic increased to such an extent as to require six motor cars in constant week day service, and on Sundays and holidays 11 motor cars have frequently been called for.

The fares charged on the Nantasket Beach line before the advent of electricity were 10 cents from Pemberton to Nantasket and 18 cents from Nantasket to East Weymouth, a total of 28 cents from Pemberton to East Weymouth. With electric traction they have been placed at a uniform rate of 5 cents from Pemberton to Nantasket and 5 cents from Nantasket to East Weymouth, a total of 10 cents from Pemberton to East Weymouth. Under these new conditions, the traffic has increased enormously on this line; the summer of 1895, the first of electrical operation, showing an increase of 92.6 per cent over the previous summer in the number of passengers carried; the summer of 1896 showing 45.1 per cent increase over 1895, while, in the summer just passed, we have carried nearly three times as many passengers as in the last year of steam operation.

The operation of the line from New Britain to Hartford was commenced in May last, with a regular half-hour train schedule from 6 in the morning to 11:30 at night, and with a uniform fare of 10 cents each way, instead of 23 cents, the former charge. The electric line carries through passengers only between Hartford and New Britain, the passengers for the five way stations being carried by the regular steam trains running on a parallel track. For ordinary every day service, a single open motor car was used during the past summer, while for extra loads, light double truck

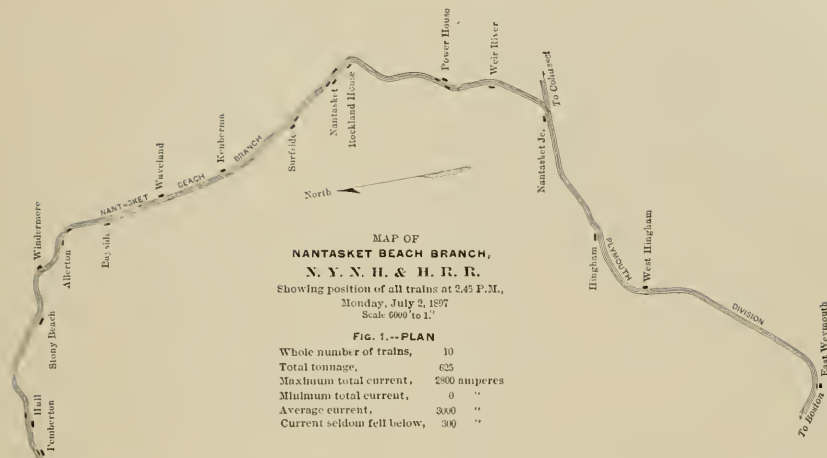

FIG. 2.

trail cars, seating 70 people, were attached. On rainy days a standard closed passenger coach was hauled by the open motor car. On holidays and Sundays, the cars pulled two trailers, the entire train seating nearly 250 passengers. About the middle of August, steam service on the Berlin-New Britain branch was discontinued, and traffic has since been handled entirely by electricity. Sixteen trains each way per day are run, connecting with steam trains.

Under the conditions named on the Hartford-New Britain line we have carried, during the three summer months, 400 per cent more passengers than we carried through the corresponding months of last year.

**SPEED, ACCELERATION AND SCHEDULES.**

I do not suppose that any but a trained railroad man can understand the impossibility of operating trains and maintaining

schedules by steam locomotives in the way that has been done by electricity at Nantasket Beach this summer. There are a great many curves on the line as will be seen by the accompanying plan, Fig. 1; and in addition several grades. There are no excessively sharp curvatures or steep grades, and it is not here that the trouble has come. The difficulty is found in the fact that there are no less than 17 stations on a line only 10.6 miles in length, or an average distance between stations of but about .6 of a mile. To make a run of 10 miles with 16 stops in 26 minutes; to be obliged to do this in order to connect with boats arriving at regular half-hour intervals and to keep out of the way of frequent regular steam trains on the main line of the Plymouth division; to allow but four minutes at each end for unloading, switching (including running around trail car), and loading; and to do this day in and day out, in regular service, through an entire summer; these are things which cannot possibly be accomplished by steam locomotives.

Now the reason why electricity can do this and steam cannot, is found in the tremendous accelerating power of properly designed electric motors, with rotary motion, as compared with reciprocal motion of steam locomotives. By examination of the curve of acceleration plotted from actual tests of a 60-ton train, (see Fig. 2), and of the practical results shown in the curve of speed between stations in a service run on the Nantasket Beach line, (see Fig. 3), as well as the accompanying time chart made up from the company's printed time cards, it will be seen how enormous is this accelerative power.

It will be seen, for example, that a 60-ton train, in running from Windermere to Allerton, a distance of only 1,800 ft., reaches a maximum speed of 31 miles per hour, while in the longer run from Power Station to Nantasket Junction, a distance still of but 5,598 ft., a maximum speed of 39 miles is reached. The entire distance is covered, in regular service, at an average speed of 24.6 miles per hour, including stops.

Between Hartford and New Britain, the 9.3 miles distance is covered regularly by motor cars with two trailers in from 18 to 20 minutes, an average speed of from 28 to 30 miles per hour, while, with a special high-g geared motor, a maximum speed of over 60 miles has been made; the entire distance of 9.3 miles being covered in 10 minutes. On this line a 52-ton train often reaches a maximum speed of 50 miles per hour. The current is cut off at 29 grade crossings when single car trains are run.

It is worthy of note, in this connection, that the line between New Britain and Hartford is in direct competition with a trolley line between the same points but following a more circuitous route. The schedule time of trolley cars is 55 minutes, as against our time of less than 20 minutes, and the rate of fare is 15 cents (including a transfer given for use on the street railways of either city), as against ours of 10 cents for the straight run between the two cities only. The ownership of right of way has a very important influence upon speed and competitive conditions under circumstances like these.

#### CARS AND EQUIPMENT.

The type of car selected for any good transportation service has a direct bearing upon the development of traffic and maximum gross receipts. It has been difficult for steam railroads to depart far from the long established custom of closed passenger coaches of the present standard type, and to adopt open cars, on account of the disagreeable effect on passengers of the smoke and gases from engines. This has naturally thrown a great deal of traffic to competing street railway lines running open cars in summer, on account of the much greater pleasure in riding.

With electric operation, open cars in heavy railroad practice are possible, even at considerable speed, particularly if the front of the car is closed in with glass, and both at Nantasket Beach and on the Hartford-Berlin line, we have used heavy open cars with great success.

The motor car which we have so far used we do not consider by any means the final type, and even now, we have in mind plans of combination cars which we believe will be, on the whole, well adapted for railroad work. The present motor car is very heavily built, with floors of a height equal to that of our standard passenger coaches. It contains 16 cross seats, capable of seating

56 passengers, and the entrance is from either side with three steps. Each car has two heavy railroad trucks, one of which is equipped with two 125-h. p. motors. The total weight of the motor car is 32 tons, and the trailer car of the same type weighs 25 tons. The motors which we have used up to date have been of a type common in heavy elevated railway work. These motors have often been in service for several consecutive days, making 321 miles each day, without apparent injury. We found the motors we are using already in the market when we commenced our experiments, and until recently no attempt has been made by us to specify changes. Under these circumstances, great credit is due the manufacturers for their efforts to meet the difficulties encountered. The experience gained with these motors has served as a basis for building larger and heavier types, better adapted for the severe work which they will be called upon to fulfill to meet our requirements. An important point which we shall specify in new motors is that they shall have the most perfect ventilation possible. The efforts of manufacturers have been hitherto directed towards completely encasing the motors, so as to make them waterproof, but in doing this ventilation has been sacrificed.

We have found it beneficial to blow out our motors several times during the day by means of a blast of air from a hose pipe connected to our air brake reservoir, but this is, at best, but a makeshift.

It is very difficult to dispose of all the necessary cables, wires, brake rods and chains, air brake cylinders and apparatus, switches and other controlling mechanism in the limited space beneath the car floor, as may be readily imagined by those familiar with street railway work. As a consequence, there has always been more or less controversy between those responsible for the placing of the different portions of the equipment, as to who shall have the first right to a given space, perhaps hardly a half a dozen square inches in section. There is also more or less trouble with abraded wires, short circuited shoe hangers, etc., and for our future work we are making an effort to simplify this mass of equipment mechanism by putting some of it, particularly the wires and cables, in a space between the true floor of the car and a false floor several inches below, specially provided for the purpose.

For operating heavy trains of this character, where currents of from 500 to 1,000 amperes are sometimes used, the controlling apparatus must be massive and strong in every part, and the greatest care must be taken to prevent arcing. We have had no trouble with controlling apparatus on our regular equipments, and we consider this branch of the apparatus well perfected.

The danger to station and car apparatus from lightning discharges, which is so important a factor in street railroading where the overhead system is employed, is avoided in third rail work, since the third rail is so close to the ground that it is practically a lightning arrester itself throughout its whole length.

The problem of braking, which is so important a one in street railroading, is found more so with us, since the train weights and speed are enormously greater. The regular Westinghouse air-brake system, with engineer's valve, is used on our electric trains, but instead of steam air compressors, we have an electric motor compressor, controlled by an automatic regulator which has given excellent satisfaction.

Our experience with trolleys on the overhead line at Nantasket Beach, originally put in two years ago, has not been satisfactory. We find it quite impossible to prevent the destruction of trolley wheels by almost continual arcing when attempting to take from the wire the heavy current required in starting and during acceleration, as well as the smaller currents taken at the maximum speed. There has been a good deal of trouble, moreover, in keeping the trolley on the wire in making speed and taking curves, and many trolley poles have been broken. The trolley difficulties have not interfered with the continuous operation of our line, but the cost of replacing wheels and poles has been rather large.

These difficulties have had an important influence in causing us to reach a decision in favor of the third rail. The contact shoes which take the current from the rail to the motor circuit have given, on the whole, good satisfaction, although they are occasionally carried away by the approach blocks at grade crossing when these blocks happen to be slightly misplaced so that the shoes strike them at the wrong angle. The contact shoes are suspended

FIG. 3.

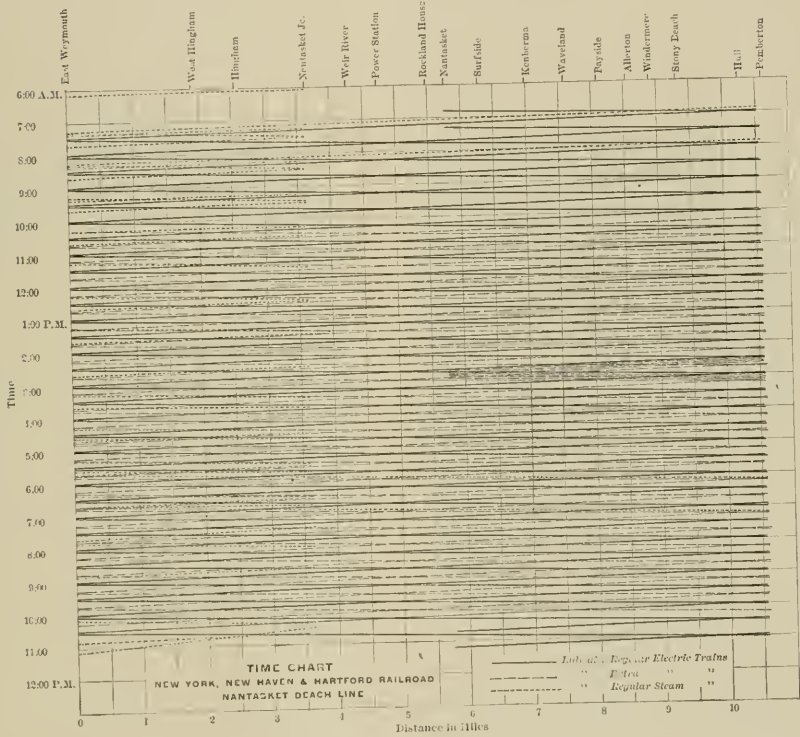

FIG. 4.

by cast iron links, which are intended to be weak enough to allow the shoe to break away easily without doing damage to the frame work of the car. The trail cars are also equipped with shoes and connected with the circuits on the motor car by means of flexible couplings, and it is possible therefore, when the cars are run in train, to bridge the longest gaps found at grade crossings and switches, so that it is not necessary to turn the current off on approaching these. This arrangement makes our trail cars independent of the motor car for heating and lighting.

It will be noted perhaps that the Nantasket motor cars have two trolley poles, as well as contact shoes, and the changing from trolley to third rail simply means the pulling down of the pole and the closing of the third rail switch.

### THIRD RAIL AND RETURN CIRCUIT.

Our third rail and return circuit experience will perhaps be of value to both street railway and railroad managers, as we have undoubtedly made a wide departure from established methods. We have solved a number of interesting problems.

First is the question of insulation. The third rail has a potential of 600 volts above the ground and rests upon creosoted wooden blocks dowelled into the ties, its edges being only 1/8 in. above the tie. Now it frequently happens that water accumulates 2 in. or more in depth over the ties, and, if it were not for our experience to the contrary, we would naturally suppose that, under these circumstances, the line would be directly short circuited between

FIG. 5.

the third and service rails through the water, the distance being but about 2 ft. each way. Nevertheless, we have been able to operate our road without the slightest difficulty when this has happened, and nothing unusual has been noticed at the station, nor has the electrical output, as registered by the recording wattmeter been abnormal. At Berlin we have watched the ammeter closely when we knew the tracks to be submerged in two places 10 miles apart, during a heavy rain storm, and have found that the leakage was almost imperceptible when both cars on the line were at rest and their air pumps out of circuit. At the same time, the wattmeter was standing still. Of course, if a long length of track were submerged, the leakage might become serious, but we have yet to learn how much is necessary to accomplish this result.

We aim to so connect our third rail lines and the service rail return as to have a practically complete metallic circuit of extremely low resistance; as far as possible, disconnected with the ground. We do not believe in grounding our track, and, though ground plates are placed at the station, connected to our generator, by far the largest proportion of the return current comes through the cables connected directly with the track, the percentage coming from the ground plates being extremely small.

The joints of the third rail are bonded by long copper plates, firmly bolted to both sides of the joint, 16 bolts being used in all. These copper plates are tinned before being put into position. Owing to the large area of contact surface, the presence of rust on this surface, does not materially interfere with the conductivity of the joint, as shown by accurate tests.

The service rails are bonded with the greatest care, four copper leaf bonds, having a cross section of copper equal in conductivity to that of the rail, being used. These bonds are inserted in the base of the rail instead of the web, so as to prevent breakage through play at the joints. The copper leaves are cast into end piece blocks in such a way as to weld them thoroughly together in the blocks. The latter are formed into a hollow cylinder, 1 in. in diameter, which passes through a hole in the flange, and by which a large area of contact is secured. Tapered pins are driven into the inside of this cylinder from the top of the flange, and the connection made is very perfect. The form of this service rail bond is shown in Fig. 5. Careful tests have shown that the joints of both third and service rails have now a slightly greater conductivity than an equal length of the rails themselves. Figs. 6 and 7 show our third and service rail joints.

A few words about the danger of the third rail system would be, perhaps, in order. There have been many cases of people who have stepped from the ground to the third rail without feeling the current, and anyone can step upon it from a dry tie without the slightest effect. On all except wet days, our employes work

FIG. 7.

FIG. 6.

about it without trouble, avoiding, of course, putting themselves in direct contact with both service and third rails, but not infrequently "monkeying" with the current in such a way as to get shocks of more or less severity in a sort of horse play. On wet days, they refer to the third rail as being "lively," and are inclined to let it alone. Many of our employes have, however, received the heaviest shock possible to obtain, time after time, and care little about it, though those who are more influenced by electric shocks than others are sometimes thrown off the feet, but recover fully in a few minutes. We do not say that the third rail has no dangers, but we do not consider the danger as being at all serious or one which should interfere with the extension of the system.

As a result of exceptional care which we have taken in bonding our third and service rails, we have found it unnecessary, in any third rail work so far done, to use copper feeders, in spite of the fact that we are obliged to transmit current from Berlin to Hartford, a distance, as before stated, of 12.3 miles, straight away from the power station. This work is made up as follows: From Berlin to New Britain, a distance of 3 miles, there is a complete double track electric road with two 100-lb. third rails and four 74-lb. service rails, all most carefully bonded as described above. From New Britain to Hartford, a distance of 9.3 miles, there is one complete electric track, with 100-lb. third rail and 70-lb. service rails, all carefully bonded, in addition to which we have connected to the service rails of the electric track the rails of the second track, paralleling this the entire distance, at various places, in order to get the benefit of whatever conducting power there might be in this track connected only by its fish plates at the joints. As a result of this work, we are able to run two trains of 52 tons each on the New Britain and Hartford line with an average loss of but 26.5 per cent. The current output of the station at such a time averages about 300 amperes, with a maximum flow of about 700 amperes at a pressure of 600 volts. Of course, if the service were heavier, so that more cars would be required, it would undoubtedly be necessary to reinforce the third rail with feeders.

## COST OF POWER.

In our Nantasket Beach station we have installed two engine-generator units of 800 h. p. and 550 k. w. capacity each. The steam is supplied by eight boilers of 200 h. p. rated capacity each. On heavy days, both these engines are required, but on ordinary days but one only, and this is not fully loaded; the average loads being perhaps one-half the maximum.

In the Berlin station we have installed two engine-generators of 1,200 h. p. and 850 k. w. each. The steam is supplied by 10 horizontal tubular boilers, of 200 h. p. each. One unit only is required in the practical operation of all the cars on the Berlin and Hartford lines, and the average power output is hardly one-fourth of the maximum capacity.

In both stations, our aim has been not to follow out any engineering fads, but to provide apparatus proved by long experience to be of the most simple and durable character. The details of piping and arrangement of steam apparatus have been so thoroughly described in the technical papers that it is unnecessary to refer to them here. We are now running our Nantasket plant condensing and our Berlin plant noncondensing, the loads in the latter being too light to make condensing profitable.

In spite of the fact that these general conditions of operation do not point to a low cost of power, because of the fact that we are working neither station at anywhere near its full capacity, I suppose we are, as a matter of fact, producing power more cheaply than can be done in any power station in the country using coal as a fuel, the reason being that we are burning sparks. "Sparks," as we are accustomed to call them, are the half consumed coals dumped from the extension front of locomotives at the company's various round houses. Nevertheless, there is a great deal of steam generating value in these sparks, as we have found by experience, and they are being carried on the company's cars to our stations at Berlin, Nantasket and Stamford, and charged to the electrical operation at the cost of freighting (including the usual profit to the company for transportation), plus the cost of loading and unloading, a total charge of 70 cents per ton delivered.

In order to burn these sparks, we are obliged, of course, to make some changes in the furnace arrangements, chief among which is provision for the introduction of live steam under the grates, forming a blower or forced draft as well as providing the water which, in decomposition, furnishes the oxygen and hydrogen gases which greatly increase and facilitate the combustion of half-burned coal and add enormously to the furnace heat. We originally supposed that some form of shaking or self-cleaning grate would be necessary in burning sparks, but have found in practice that, with ordinary grates, together with the steam blower, there is no difficulty. In our experimental days, it was thought that it might be necessary to use a proportion of ordinary soft coal with the sparks, and we did so for a while, but it was not long before our firemen were educated to burn sparks only with entire ease, and no other kind of fuel is now used by us. Of course, we have to use a greater weight of this half consumed coal than would be the case with new coal, but still the economy is great, as a good quality of run-of-mine coal costs us, in Connecticut, about \$3.00 per ton delivered at power station.

A few figures as to the cost of power at Stamford may be of interest. This station furnishes current for our street railway system at Stamford and for lighting our railroad stations with 350 incandescent lamps. We are operating one engine only, of 500 h. p. total capacity, direct connected to one 300-k. w. generator. In the boiler room are six 200-h. p. boilers. For the first six months of full operation with sparks only, the total cost of fuel for this station amounted to 3 mills per h. p.-hour or 4 mills per k. w.-hour. For so small a station and one where the average amount of power developed is hardly more than one third the rated capacity of the engine, I believe this to be a low figure. We have recently made, for our own information, for use in larger plants, special tests of the cost of power developed in this way, using for this purpose a water rheostat, in order to load the engine up to more nearly its full capacity. As a result of these tests, we find the cost of fuel for power, with the use of coal, to be 3.2 mills per h. p.-hour or 4.2 mills per k. w.-hour. With the use of sparks, the cost is reduced to 1.9 mills per h. p.-hour or 2.5 mills per k. w.-hour.

At our Nantasket power station this season, the cost of fuel, with the use of coal, has averaged 4.2 mills per h. p.-hour or 5.6 mills per k. w.-hour, while, with the use of sparks, the cost has been 2.1 mills per h. p.-hour or 2.8 per k. w.-hour.

As before stated, our Berlin plant has not been run as economically thus far as it will be when a greater load is put on the engines and it will seem to be in the interest of economy to run compound condensing. At this station, the cost of fuel, with the use of coal, has been 9 mills per h. p.-hour or 12 mills per k. w.-hour. Using sparks as fuel has reduced this cost to 3 mills per h. p.-hour or 4 mills per k. w.-hour.

It is very difficult, of course, if not impossible, to make any direct comparisons between the cost of motive power for electric railroading and that for steam railroading, on account of the different way in which the trains are made up. The best criterion would be the cost of motive power per ton-mile hauled, but even here the results would be of little value on account of the wide difference in conditions, and, as a matter of fact, we have never attempted to make such comparisons.

I have tried to give you, as briefly as possible, some of the results of the pioneer work which the New Haven Company has been doing in heavy electric railroading. They are roughly stated and we cannot pretend that they are in any way conclusive as affecting general railroad practice. For ourselves, however, we have formed some definite ideas as to what is possible for us to accomplish, and our plans for the future are being made with great care by President Clark and the board of directors, with the intention of dealing with the new transportation conditions which confront us in a broad minded and progressive way. It is felt that a great transportation agency of this character owes it to the public from which it has obtained its franchises, to furnish the best possible service and to make the most of the natural advantages which it possesses.

There will always be room, doubtless, for railroads of two characters, the one operating on a purchased right of way, where trespassers can be kept away and high speed obtained, and the other operating on streets and highways, where passengers can be taken up and let off at their own doors. It is possible that, in some thickly settled districts, such as are found in New England and the Middle States, where population groups almost touch each other, these two classes of service may occasionally be performed by the same agency, but there is no reason, ordinarily, why there should not be the most amicable and friendly relations, and not infrequently of a business character, existing between steam railroad and street railway companies.

The reading of Mr. Heft's paper was followed by loud applause.

Mr. Bean, of St. Joseph: I move that the paper just read be received and placed on the record; and that a vote of thanks be extended to Mr. Heft for his able paper. Carried.

Mr. Palmer, of Fall River: I ask Mr. Heft what the costs he has given us represent—the total cost of power, or cost of fuel only?

Mr. Heft: I stated plainly it was the cost of fuel only.

Mr. Palmer: Can you give us any figures which will show us the total cost of power per k. w.-hour or per car-mile?

Mr. Heft: That would depend entirely on the conditions at your station. No two stations would have the same conditions. At Stamford you can notice that our power costs us a great deal less, because we are running nearer to the normal capacity of our engines. At Nantasket the economy is not so great, and at Berlin, where we are only running the high pressure side of the engine, it costs a great deal more. This is true also of the labor. The labor where the large engines are costs more than it does with the small engines, where you are running away below your normal load. If we were running our Berlin station up to its normal capacity, we would show a greater economy in fuel and labor than in the other power stations, because there is a certain fixed charge which we are subjected to at all stations, and the amount of that depends on the size of the station and the number of units.

Mr. Palmer: I appreciate that what you say must necessarily obtain, but what I wanted to find out was whether you had at hand or could give the cost for any one particular station?

Mr. Heft: We have that information in our office. I did not put it in this paper.

Mr. Palmer: It seems to me that it would be very interesting for

some of us who are operating street railway power stations to be able to compare our cost of production of power with the cost of production of power in these plants which have so recently been fitted up with everything of the latest type, and I should like to be able to compare some of the figures which we have made with some of those which the New York, New Haven & Hartford has been making in its stations. For instance, the total cost per k. w.-hour delivered at the switchboard, including all expenses which should properly come in—taxes, insurance, interest, labor, supplies, and everything so chargeable to it.

Mr. Heft: I will say through you, Mr. President, to the members of the Association, that we will very gladly furnish any of these data that you ask for, upon application at our office. We will supply any of our plans, maps or data sheets. We have nothing that there is any mystery or secrecy about, and we will be glad to place it at the disposal of any member of the Association. (Applause.)

Mr. Newman, of New Orleans: What is the cost of the sparks?

Mr. Heft: I stated that to be 70 cents for a ton of 2,000 pounds. These figures are based against coal costing \$3 a ton. While the sparks do not cost our company anything (it is really an expense to get rid of them, as every steam railroad man knows), we pay our motive power department of the road the cost of handling and loading, and the freight department the freight between the points where it is loaded and our power station.

Mr. Durbin, of Denver: Can you give me some idea of the relative cost of construction—of the third rail system, as compared with the overhead and feeder system, in this case?

Mr. Heft: I think, if I recollect the figures aright, that the third rail construction costs us, for the third rail, bonding of the rail, and cables at the grade crossings, and bonding of the surface rails, about \$3,000 per mile. Figured against our cost at Nantasket, it is about one-half; but I will also furnish those figures to any one. We have them made up in our office. I did not think of bringing these items with me.

The President: We will proceed to the next order of business, which is the paper on "Best Methods of Settling Damage Cases and Prevention of Accidents by Use of Fenders or Otherwise," by W. J. Hield, of Minneapolis.

The following subject was assigned to C. G. Goodrich, vice-president of the Twin City Rapid Transit Company, but owing to press of other work he was unable to devote to it the necessary time, and it was referred to Mr. Hield, general manager of the same company.

Mr. Hield read the following paper:

#### THE BEST METHOD OF SETTLING DAMAGE CASES AND THE PREVENTION OF ACCIDENTS BY THE USE OF FENDERS OR OTHERWISE.

By Willard J. Hield, General Manager, Twin City Rapid Transit Company, Minneapolis-St. Paul.

It is hard to handle, in a short paper, this most difficult subject which is today perplexing the officials of all large street railway systems. However, as the study of these questions is made imperative by reason of their serious importance, I venture to offer a few ideas which I trust may prove of some interest, if not of value.

Like all other professions, the law has in late years given rise to many specialists, among whom the personal injury lawyer is most prominent to the street railway manager. His untiring efforts have wrought such a change that the question of settling damage cases today is vastly different from what it was a few years ago. The general manager or superintendent can no longer personally adjust the claims against his road, but must employ men for that particular purpose. It is now necessary for him to have a claim department, the system of which should be perfect in detail and work in true harmony with his operating department, both for the prevention of accidents and the settling or fighting of damage cases. The secret of success in handling damage cases, lies, no doubt, in their being properly looked after from the start; i. e., from the time they are first reported. How to do this varies as to the different cases, but no case should ever be handled by any one but an honest, careful and experienced claim agent. For such work men must be naturally qualified; they should ever have the interests of their road at heart and yet not

be blinded by too great a prejudice in its favor; they should have sound, shrewd judgment and be pains-taking and careful of detail to the highest degree. Like the true physician, they should be of a happy, calm temperament, and also like him, should ever be ready to answer a call. The successful claim agent should have the faculty of handling all sorts of people without friction. His keen perception should reveal to him the nature of each case, but he should never betray anxiety for settlement.

Every claim department should have a good system for securing reports of accidents, for obtaining evidence, and for keeping such files and records as may be necessary for its work.

The only accidents which demand serious consideration are those in which personal injury is involved. These may be divided into the three following classes:

1. Those in which there is an undisputed liability and which, as a rule, should be settled as soon after their occurrence as possible.
2. Those in which there is a doubtful liability and which, generally, should be settled after careful investigation.
3. Those in which there is clearly no liability and which should therefore never be settled.

Frequently cases may prove exceptions to these rules, but in handling them under such a classification or any other, the following suggestions would seem to be of importance:

1. It is of great value in every case to acquire a knowledge of it as early in its history as possible. Procrastination is ever dangerous and the claim agent should have for his motto—"Time is the essence of success."
2. Evidence should be carefully secured in every case soon after the accident. Too much can never be reported to the department and what may seem of little importance at the time of the accident, may prove most valuable in preparing the case for trial.
3. In nearly all unsettled cases (particularly in serious ones), an examination by one or more surgeons in behalf of the company is desirable.
4. Assistance and kindly tender of services, immediately after a serious accident, are more in place than advances for settlement.
5. Admission of the company's negligence is seldom necessary, but the true rights of the claimant should not be denied; as by antagonizing him all chances of settlement may be lost.

6. Whenever possible a sworn statement should be secured from the claimant, giving his history of the accident and stating as nearly as possible the damage done. Such an affidavit, carefully and truthfully drawn and signed before witnesses—who should also attest it—may often prove most valuable either in settling or fighting a case. By it the claims of the interested party are clearly defined and limited, so that any subsequent intention to change them may be checked.

7. In every case the claim agent should be fair but firm. Too cheap a settlement is not the best settlement, but one too expensive is quite as bad and perhaps worse. However, the claim agent can generally keep the claimant good-natured and insist upon his acknowledging that the settlement is a fair one at the time it is made, and thus prevent his feeling or talking ugly about it later.

8. A full release of all claims should be taken from the claimant, and its contents explained to him fully. This is of great importance, as the validity of releases is often disputed, and it is then quite necessary to show that they were properly taken. On this account it is best to explain the release to the claimant before witnesses (who should also attest it), or to make him acknowledge later before them that he executed it of his own free will understanding its nature.

From these suggestions one may deduce that the method best adapted for the handling and settling of damage cases is to be prompt, thorough and careful, with a liberal use of sound, common sense. Whether a case should be speedily settled, or not settled at all, is a matter which must be decided from the peculiar circumstances which it presents and not by any fixed rule. As a general thing, however, it is well to settle all cases where the injured parties are inclined to be fair, according to the merit each case contains, and fight all cases in which the claimants are very unreasonable or where fraud is apparent. This rule carried out with the right spirit will prove a valuable policy for any road. If a case is settled, let it be done with due consideration of

WILLARD J. HIELD.

Willard J. Hield was born in Janesville, Wis., May 10, 1863, and is of English extraction. His early training was received in the schools of Janesville, in Beloit College and Madison University. Mr. Hield went to Minneapolis in the summer of 1887 and at once entered the employ of the Minneapolis Street Railway Company. He successively filled the positions of office man, book-keeper, purchasing agent, store-keeper and cashier until the strike of 1889, when there were some thrilling experiences in the various capacities in which he acted. During the time Mr. Hield was in charge of the steam line to Minnehaha Falls and Lake Harriet, he was severely injured. In 1891 he was appointed superintendent, and later general manager of the Minneapolis system, and when this was consolidated with the St. Paul Street Railway Company he became general manager of both systems.

justice, and if it be fought, let every effort be made to fight it in the fairest and most efficient way possible.

It is not usually desirable that the claim agent should make offers of settlement, but rather it is advisable for him to draw his man out and get him to state definitely, if possible, what sum he really thinks he should be paid. Generally, such a sum can be considerably cut down, no matter what the case, but if it is not an unfair amount, in consideration of the injury, it should be paid. Seldom pay more to a lawyer than to the injured party himself and do not settle a case simply because suit is threatened or commenced. Never settle out from under an attorney who has been professional and courteous in his relations to the road, yet when an unprincipled damage lawyer is interested in a case, do not hesitate to disregard him in settling it. When a good one to fight, the case should not be settled simply because it will cost less. It is ever well to remember, both, that victories in court are a great benefit and that defeats are a great loss.

While as a strict matter of law it may not be correct, yet it is always well to give some consideration, when settling a case, to the circumstances of the injured party and allowing such personal interest to enter into the transaction as will not be inconsistent with good business. As a general thing the claim agent should listen with apparent indifference to the claims of such persons as Jewish peddlers, loud-talking, and bull-doing men, sharp tongued women and all others whose claims have either the appearance of fraud or unreasonableness; with apparent interest and sympathy to those other few cases which seem to merit it.

The gist of the foregoing may be expressed in these few words: Have good claim agents of sound judgment, who will not settle cases by arbitrary rules, but who will rather consider them each in its peculiar details, weighing well the seriousness of the injury, the manner of the accident and hence the liability involved, as well as the circumstances of the claimant.

The old saying that "An ounce of prevention is worth a pound of cure" was never better applied than to the accident features of a modern street railway system. The rapid transit now in

vogue upon the busy thoroughfares of our cities, whether by means of the trolley or the cable, has greatly increased the number of street railway accidents and hence has caused the question "How to avoid them?" to be of very serious interest.

For this purpose the following points seem to be of particular interest:

1. It is very important for the prevention of accidents, as before stated, that the operating and claim department work in perfect harmony and unison with each other to this end.

2. The employing of none but good men is most essential and having employed good men, it is quite important to keep them good in the fullest sense of the term.

3. Carefully drawn, explicit rules for operating cars made with due regard to the various local conditions should be rigidly enforced and intelligently observed.

4. Speed on various lines should be regulated according to the chances of accident presented.

5. Every car should be equipped with the best controlling apparatus, gong and headlight, and also be provided with such devices for the prevention of accidents as may seem practical.

By this last statement several good devices for the prevention of accidents are rather indefinitely referred to, among which the fender and the safety gate should be placed at the head. Experience has shown that the fender is seldom a nuisance and is frequently of great value. A simple type will be found to be very practical which, while it does not insure against injury, yet very often prevents serious results. The dropping or lowering of the fender is seldom of any benefit, as motormen are generally too much occupied in stopping their cars when a collision is imminent to pay attention to the fender. In many cases where the speed of cars has been reduced from a fast to a slow rate the fender will pick up persons with no harm resulting, who, without it would surely go under the car. Where the collision occurs while the car is under great speed, serious injury is not unlikely, but even in these cases loss of life and limb may frequently be prevented and money saved in the long run.

The safety gate, with which all motor cars in Minneapolis and St. Paul are equipped, and which was not generally approved upon its introduction but a few seasons ago, has demonstrated its great value and practicability by almost annihilating those accidents which occur through boarding or alighting from cars. The danger of these accidents increases with the number of passengers carried and with nearly every road, they cause a large part of the injury and damage expense. They present to the fakir the best opportunity for making a case, and always give the jury a good chance to give the plaintiff the benefit of a doubt. The safety gate is practical for any city. In fact, we have seen its best use when our road was earning over three times its ordinary receipts. With it the conductor has but one part of his car to watch while giving the starting bell, and in case there is reason for passing persons at crossings, there is no danger from their trying to board the moving car. It also affords protection to people standing on the rear platform in case of a car rounding a curve at high speed, or on other occasions, when a passenger, through his own condition or carelessness, or the operation of the car, is liable to fall off.

The gate, being operated by the motorman, should never be opened until the car is at a stand-still, and should always be closed just before the power is applied for starting. After the public becomes accustomed to the safety-gate, its operation demands no change of running time from that used before its introduction. The most timid, whether old or young, will walk without fear to the gate while the car is stopping and thus take but little time to alight. The gate is also of great service in handling large crowds at the parks where people seem to lose their common sense, as well as all ideas of propriety, and try to board and hang on to cars regardless of the danger involved. In such instances the value of but one entrance to the car is quite obvious, as at any moment the crowd may be checked by the closing of the gate and the car started.

The value of both the fender and safety-gate can best be understood by closely watching their use. Both are eminently useful and practical. They each have also a good moral and instructive influence; they caution both the public and the trainmen against accident, and also cause the community to realize that a soulless corporation has some regard for life and property and sincerely

desires to avert accident to them. They also give to the trainmen an assurance in operating the cars which is of itself of considerable benefit.

Screens for the sides of cars (when the trolley posts are between the tracks), sand-boxes always filled with sand, and many other devices, are also of considerable importance and tend each in their way, to reduce the number of accidents to the minimum.

It is not possible, however, to operate cars entirely without accidents and in studying the problem we should not look for perfect results.

The above presents roughly a few ideas suggested by long experience after trying nearly all the remedies known, and gives one the firm opinion that it is essential, so far as possible, to have the best equipment, including practical safety devices, and the best men obtainable for operating the cars and for the claim and other departments, governed and aided by the best rules and supported by the best policy.

Mr. Rigg moved that the paper be received, and a vote of thanks returned to Mr. Hield. Carried.

Mr. Davis, of Williamsport: I move that the papers to be read at the meeting be printed 15 days in advance of the meeting, and distributed among the members. Not agreed to.

The President: The report of the nominating committee is now in order.

Mr. Watson: The Committee on Nomination of Officers for the ensuing year reports in favor of the following persons:

President, Albion E. Lang, of Toledo, O.

First vice-president, W. Caryl Ely, of Niagara Falls, N. Y.

Second vice-president, John A. Rigg, of Reading, Pa.

Third vice-president, Edwin C. Connette, of Nashville, Tenn.

Secretary and treasurer, T. C. Penington, of Chicago, Ill.

Executive committee, Robert McCulloch, of St. Louis, Mo.; C.

Densmore Wyman, of New Orleans, La.; Henry C. Moore, of Trenton, N. J.; John M. Roach, of Chicago, Ill., and Robert S. Goff, of Fall River, Mass.

For place of meeting the committee recommends Boston, Mass.

Respectfully submitted,

|                                 |   |                               |
|---------------------------------|---|-------------------------------|
| Committee<br>on<br>Nominations. | { | H. M. Watson,                 |
|                                 |   | A. T. Potter,                 |
|                                 |   | John A. Rigg,                 |
|                                 |   | E. S. Goodrich,               |
|                                 |   | W. Worth Bean,                |
|                                 |   | E. Woodruff,<br>G. B. Kerper. |

Mr. Shaw, of Boston: I move that the report be accepted. Carried.

Mr. Bean, of St. Joseph: I move that the secretary be authorized to cast the ballot of the Association for the gentlemen nominated.

The secretary duly cast the ballot.

The President: I declare the gentlemen duly elected.

The meeting then adjourned.

#### Friday's Session.

President McCulloch called the meeting to order at 10:15 a. m.

Mr. Kerper, of Dayton: I move that a vote of thanks be tendered to the president, the vice-presidents and the executive committee for the able manner in which they have conducted the affairs of the Association during the past year. Carried.

Mr. Rigg, of Reading: Mr. President, I desire to offer the following resolution:

Resolved, That the members of the American Street Railway Association in annual meeting assembled express their thanks to the several Passenger Associations of the United States for their courtesy in granting reduced rates to the members of this Association and their friends who are in attendance upon our annual meeting. Carried.

The President: These Passenger Associations are very courteous but they give us no more than any other Association with one hundred delegates can receive. I believe we should have a single fare for the round trip. I have therefore considered it wise to appoint a Committee on Transportation. I will name on that committee, the

secretary, T. C. Penington, James H. McGraw, of the Street Railway Journal, and H. H. Windsor, of the STREET RAILWAY REVIEW.

Mr. Bean: Mr. President, I move that a sincere and hearty vote of thanks be extended to his honor, Mayor Hastings, who so warmly welcomed the Association to this city; to the general committee, the committee on banquet, the committee on exhibits and the committee on entertainment, for the complete arrangements which they made for our entertainment and the thorough manner in which they were carried out; to the Niagara Falls Hydraulic Power & Manufacturing Company, the Niagara Falls Power Company, the Niagara Falls Paper Company and the Carborundum Company, for the opportunity of inspecting their interesting plants; the International Hotel Company, for unceasing attention; to the Buffalo Railway Company, the Niagara Falls & Suspension Bridge Railway Company, the Niagara Falls & Lewiston Frontier Railroad Company, the Great Gorge Route, the Buffalo & Niagara Falls Railway Company, the Niagara Falls Park & River Railway Company, and the Niagara Falls Navigation Company, for transportation facilities furnished to the delegates and visitors, and for which we desire to express our deep appreciation. Carried.

Mr. Rigg: I desire to move a vote of thanks to the ladies of the reception committee for their kindness in entertaining the ladies of the convention. Carried.

The installation of officers then followed.

President McCulloch said: Mr. Lang, I am glad to turn over to you, sir, the gavel of the Association. I hope that you will hold the office of president of the American Street Railway Association with as much pleasure and satisfaction and as much pride as I have, and I wish you the same courteous treatment and the same support in your administration that I have received. (Applause.)

President Lang: Gentlemen, I dislike very much to open my administration with an apology for my late arrival at the ball; but you all know what a pleasant evening we spent last night, and it did not end with the ending of the day, but only with the beginning of the next day. I wish to assure you of my profound pleasure in being called to this office. I deem it a great honor, from the fact that I was in no sense a candidate for the office. My place in the Association has simply been that of a quiet and earnest listener, endeavoring to learn all I can for the property I represent. We have had opened up to us in the papers presented at this meeting a number of interesting questions that will command our earnest attention, and some of the improvements suggested we will want to introduce in our systems in the course of the coming year. Other questions will arise which will require our attention at our next meeting. I do not think it is proper at this time to enter upon the discussion of any questions of a practical nature. If I am as successful as my predecessor, and as successful as his predecessors have been in keeping up the interest in this organization, I shall be very thankful. It does not lie entirely with the officers of the of the Association to make a success of the Association; it depends upon its members, and as we send out communications during the year asking for suggestions for topics to be considered at the next meeting and the assignment of persons to prepare the papers, I hope you will give the matter your prompt attention. (Applause.)

The meeting then adjourned to convene in Boston in 1898, on such dates as may hereafter be designated by the executive committee.

#### SECRETARY PENINGTON'S GOOD WORK.

The re-election of Secretary Penington was a foregone conclusion, and was at once a compliment to the excellent work of that official, and a wise selection on the part of the Association. Mr. Penington has from the first day of office conducted the business with promptness and impartiality. Last year he had the official proceedings, a work of considerable magnitude, edited, printed and delivered within 30 days. He has followed up the program with a result that the business of the Association was this year conducted with less loss of time than at any previous meeting. He conducts the business of his office with the greatest possible economy consistent with the dignity of the Association, and fully deserved the vote of thanks which was given him at the recent meeting.

At the banquet Mr. Penington surprised the toastmaster and everybody else by promptly responding with a speech when called upon, and although the hour was late his friends would gladly have listened longer.

## THE ACCOUNTANTS' CONVENTION.

**Street Railway Accountants Hold Their First Annual Meeting—Large Attendance—Good Papers—Exhaustive and Valuable Discussions—Recognition by the American Association—The Great Work of Standardization of Accounts at Last Actually Begun.**

The first regular meeting of the Accountants' Association was a most gratifying success, and promises a long and useful organization. The meeting room was convenient, being on the first floor of the convention building, and the entire proceedings from beginning to end were conducted with expedition and thoroughness. The sessions were well attended, and many managers found time to drop in and by their presence and kindly words of encouragement endorsed the enterprise. The results were highly satisfactory, and while much remains to be done, in fact the Association is now really for the first time fully equipped for work—the outlook is all that could be wished.

The American Association extended the strongest kind of encouragement and endorsement and a large number of new members were added.

The papers were good, and it was a matter of general regret that the volume of preceding work prevented the presentation of the last two papers, on the program, which were prepared by Mr. Hibbs, of Jersey City, and Mr. Davies of Cleveland. These papers will be taken up next year.

It was a matter of general regret that President Wilson, of Boston, was at the last minute prevented from coming on account of work in connection with the State Railroad Commissioners, which could not be deferred; but Mr. Duffy, first vice-president, of St. Louis, made a fine presiding officer, and wielded the gavel with great tact and impartiality.

The Accountants kept long hours, but left enough unfinished business to occupy profitably the time of another meeting. The great work, was however, the report of the Committee on a Standard System of Accounts. What this means is realized by all accountants; or they think they realize it. As a matter of fact the enormity of the work can only be appreciated by those who carried the load. The committee on this work consisted of C. N. Duffy, St. Louis, chairman; W. F. Ham, Brooklyn, and J. F. Calderwood, Minneapolis. This committee did a vast amount of work in correspondence and individual classification during the interim between the Cleveland meeting and its meeting at the Falls, where it worked for four days and nights previous to the convention. The several plans were merged into one, and the result was the most excellent report of this committee. In its deliberations, the committee had the presence and advice of Secretary DeFreest, of the State Board of Railroad Commissioners of New York. The arduous work of these gentlemen entitles them to the thanks of every street railway in the land. That a better committee could have been chosen is hard to believe.

Secretary Brockway proved a most efficient officer, and upon him naturally fell an unusually large amount of work in arranging for the meeting. He conducted his office with promptness and great efficiency, and while not seeking re-election was unanimously chosen for another year.

It was a graceful compliment also which re-elected President Wilson, who will now have an opportunity to preside in his own city.

The stenographic proceedings of the meeting fill 271 pages of type written copy and constitute a valuable fund of information. It is with regret we are unable to publish these discussions in full, but very much of it is of a more or less confidential character. The actual members will be furnished with a copy for their exclusive use by the secretary.

### Tuesday Morning.

It was 11 o'clock Tuesday morning that Vice-President Duffy of St. Louis sounded the gavel and the first annual convention of the Street Railway Accountants' Association of America was begun.

After roll call the vice-president announced the absence of President Wilson of Boston, and read a telegram from that gentleman explaining why he could not attend and wishing the meeting great success.

The reading and approval of the minutes of the Cleveland meeting followed, after which the chair announced the president's annual address, which was read by the secretary as follows:

### PRESIDENT'S ADDRESS.

Gentlemen of the Association:—

I have steadily looked forward to this occasion from the day our Association was formed and it is with the deepest regret that I am forced to delegate the reading of my address to another.

With the rapid development of electricity as applied to the street railway business has come a very decided improvement in many ways. There has been a marvelous appreciation of real estate in the outlying districts and a great improvement in the streets of both the cities and towns. The small wage earner can now afford both the time and money required to travel back and forth from a pleasant home in the suburbs to his work in the city. The rolling stock has greatly improved and the comfort of this mode of traveling has greatly increased. Everything connected with the business has received careful attention, even to the accounting and it is a matter for congratulation that although this is the first regular convention of this Association, not a little has already been accomplished toward improving this department, by the comparatively few members who attended the meeting when this Association was formed in the city Cleveland last March.

Those of you who were present at that time will remember the enthusiasm that was shown by all present, not only to learn something for their own use, but to do what they could in the way of imparting information to others, and the papers that were presented on that occasion showed that much thought and time had been expended in their preparation, and the general discussions which followed the reading of each, clearly indicated the deep interest all present took in every department of street railway accounting. Some people claim that it is hardly fair to ask them to give to others, the value of what has cost them much time and thought in perfecting, but it is a pleasure to know that this feeling does not exist to any great extent among the members of our profession, and that most of them consider that it is no more than courtesy to impart to others what their experience has taught them. It is very unusual if one does not obtain some useful information by a comparison of methods. Every one is very apt to be prejudiced in favor of the way he has been keeping his accounts, but the chances are that there may be some points which he has overlooked, that some other person has observed, and if he does not find some improvement worth adopting, may find some mistakes that he will be able to avoid.

As our constitution states one of our chief aims is "to promote the adoption of a uniform system of accounts" and the most important subject that will come before this meeting is the report of the committee who was appointed to investigate (as far as the limited time would permit) the different methods now in use and give at this meeting the conclusions at which they have been able to arrive. The three gentlemen who so kindly consented to assume this very arduous task undertook what it is sincerely hoped will be the beginning of the end of this question, and in the limited time which they have had to prepare their report have accomplished much more than could possibly have been expected when the matter was first suggested.

This question has been brought up several times by the American Street Railway Association, but they have so many important subjects to consider that they have been unable to do much more than suggest that certain methods be approved. It is a great pleasure for me to state that they thoroughly approve of this Association and most heartily endorse our aims and objects and their executive committee has assured your officers that any encouragement that they can offer will be most heartily given. They have already tendered us the use of their meeting place as well as the great privilege of attending any of their meetings, their banquet, and in fact all of the privileges to which their members are entitled and we shall always feel deeply grateful for their hearty support and endorsement.

What we greatly desire now is to increase our membership and while we are particularly strong in certain localities, we wish to represent all sections of America. Among the applications which have been favorably acted upon by the executive committee was one from the Republic of Mexico, and as the two principal street railways of the Dominion of Canada were already enrolled upon our membership, it was particularly gratifying to obtain a representative from the neighboring country at the South. Before this convention adjourns it is sincerely hoped that our membership will have increased to a very large number, and if every member will earnestly try to induce some of the many street railway men whom they will meet during the next few days to join our Association, this can easily be accomplished.

Before closing I wish to say a word or two about our very good friend H. H. Windsor, of Chicago. To his energy and ability we owe nearly all of our present success, the idea of such an Association was only suggested to him when he immediately took hold of the project and devoted much valuable time and no little money toward bringing us together, and when this was accomplished he continued in many ways to direct and encourage us, and ever since has evinced a deep interest in everything pertaining to our welfare.

We also owe our gratitude to the members of our fraternity in the city of Cleveland who so kindly entertained us when we met in their beautiful city last spring, and we shall always remember the generous hospitality which they extended to us on that occasion.

The annual report of the Executive Committee was then called for, and read by C. B. Reavis, of Augusta, Ga.

Gentlemen: The objects of our Association, the business transacted by us at Cleveland at our organization meeting, are too well known by all to need any remarks from us regarding them, but from the adjournment at that meeting to our convening here there is due from us an account of our stewardship.

At the Cleveland meeting there were represented 25 roads, since then we have received applications from and elected to membership 12 others, a list of which is given in the secretary's report, making 37 in all. We have lost one, the Cincinnati Street Railway Company, leaving us at the present time 36 companies in good standing from 19 different states and 3 countries.

The books of the secretary and treasurer have been examined and found correct, and show a balance of \$222.08. In this connection it is proper for us to say that the great burden of getting our affairs in shape, of arranging program and keeping in touch with the members has fallen upon our secretary and it gives us pleasure to state his work has been done thoroughly and well. His management has been a most economical one as his detailed report will show.

Our meeting at Cleveland has borne fruit in the way of increased membership, so let us keep up the pace set at that meeting for

hard and faithful work until we have upon our rolls every road possible.

Respectfully,

The Executive Committee  
(Niagara Falls, N. Y., October 19th, 1897.)

Secretary-Treasurer Brockway, Toledo, made his annual report as follows:

To the Executive Committee:—

In presenting this first annual report of the secretary and treasurer I wish to attract your attention to a fact which has its bearings upon the past, the present and the future of the Association, viz.: that the Association has been in existence but seven months and during that time the organization has had to be planned throughout, almost entirely by mail, and those plans placed in operation. But the matter of the most importance, that which has caused the secretary the most concern, is that every act, every letter written, every idea placed in practice has had to be in the nature of the case a precedent, many of which will still be in effect many years, perhaps as long as the Association shall live. Thus the importance of not only making progress as quickly as possible, but in the right direction and manner has always had its place in whatever has been done.

In obtaining the books of record, the stationery and circulars required, a due economy has been observed which has given you respectable stationery, but at moderate cost.

We came away from the organization meeting at Cleveland with 25 actual membership companies. Since then there have been added the following:

The People's Railway, St. Louis, Mo.  
The St. Louis & Suburban Ry., St. Louis, Mo.  
The New Orleans Traction Co., New Orleans, La.  
The Lowell, Lawrence & Haverhill Ry., Lawrence, Mass.  
The Richmond Traction Co., Richmond, Va.  
The Compania de Tranvias de Mérida, Mérida, Mexico.  
The Lindell Ry., St. Louis, Mo.  
The Missouri Railroad, St. Louis, Mo.  
The Elmira & Horseheads Ry., Elmira, N. Y.  
The Worcester Consolidated Ry., Worcester, Mass.  
The Birmingham Railway & Electric Co., Birmingham, Ala.  
The Kokomo City Street Ry., Kokomo, Ind.

Twelve in all, making 37 companies from 19 states and in 3 countries. One company, the Cincinnati Street Railway Company, Cincinnati, has withdrawn from membership, leaving a net membership on this date of 36 companies.

Receipts and Expenditures:

|                                                                                                            |          |
|------------------------------------------------------------------------------------------------------------|----------|
| There have been received from dues 37 companies, at \$10 .....                                             | \$370.00 |
| And expenditures made for stationery and printing .....                                                    | \$46.53  |
| Postage .....                                                                                              | 31.00    |
| Expenses of the committee for a standard system of accounts for stationery and postage for circulars ..... | 24.23    |
| Secretary's office expenses .....                                                                          | 18.95    |
| Secretary's traveling expenses, exclusive of railroad fare .....                                           | 8.61     |
| Expenses of Cleveland meeting .....                                                                        | 18.50    |
| Total expenditures .....                                                                                   | 147.92   |

Leaving a balance in the Home Savings Bank, Toledo, O. .... \$222.08

Arrangements have been made whereby the Association will receive interest at 3 per cent upon the monthly balances in the bank.

The secretary is under obligations and wishes to announce in this public manner his thanks to Capt. Robert McCulloch, president, and T. C. Penington, secretary of the American Street Railway Association, and to H. H. Windsor, of the Street Railway Review, and E. E. Higgins, of the Street Railway Journal, for the invaluable assistance rendered and the cordial manner in which they have responded to our needs.

Respectfully submitted,

W. R. Brockway,

Secretary and Treasurer.

(Toledo, Ohio, October 16th, 1897.)

Mr. Reavis, chairman of the auditing committee, reported on the examination of the treasurer's accounts, which were found correct, and complimented that officer for the excellent manner in which the accounts and records had been kept and the economical management of the office.

On motion of Mr. Ham, the chair appointed as a committee on Blanks and Forms for this convention, Messrs. King, of Washington; Durbin, of Denver, and Burlington, of Columbus, O.

A nominating committee was then appointed, consisting of: Mr. Durbin, of Denver; Mr. Hibbs, of Jersey City; Mr. Stratton, of Birmingham; Mr. Wallis, of Fitchburg, and Mr. McDole, of Cleveland.

The chair then called for the paper "The Care and Handling of Fares from Passenger to Bank," by C. L. Wight, auditor of the Toledo Traction Company.

Secretary Brockway: I wish to say, gentlemen, that Mr. Wight was unable to attend at the last minute, although fully counting on doing so. Reports were called for which made it impossible for him to get away in time. He has, therefore, sent his paper by me. In explanation let me say he has sent here a set of blanks which entirely cover the subject of the paper. I believe he intentionally shortened his paper, under the expectation of using these blanks in the further explanation of it, and I think you will find the blanks will explain whatever of detail has been omitted from the paper.

C. L. WIGHT.

Charles L. Wight, secretary and auditor of the Toledo Traction Company, is a native of Massachusetts. In 1870 he went to Chicago and was engaged with the American Bridge Company for a year at the end of which, without solicitation on his part, he received a government appointment at the headquarters of the railway mail service. In August, 1889, Mr. Wight accepted the office he now holds with the railway company, and later became auditor and treasurer of the lighting companies in Toledo.

## THE CARE AND HANDLING OF FARES FROM RECEIPT TO BANK.

By Charles L. Wight, Auditor, Toledo Traction Company,  
Toledo, O.

Under this title I will endeavor to explain the method at present used by the Toledo Traction Company. Please bear in mind that this company issues several different kinds of tickets, and that companies receiving all fares in cash have much advantage in economy of time, blanks and accounting.

One of the objects of our association is to enable members to compare methods of accomplishing a certain result, and in so doing, detail of method together with an exhibit of forms used should be given to be of practical value.

Following is a list of blanks, with a brief description of their uses:

1. "Conductors' Report," in which is noted the number of cash fares and of each issue of tickets received as fares; the statement of the register, the number of transfers, etc.; accompanying this report is a punch slip used to verify the 3-cent and 1-cent fares received. This report with the
- 2-3. "Conductors' Cash Envelope," containing all cash, tickets and transfers received, is deposited with the station clerk, who gives his receipt therefor. Deposits are made at the station, at the end of the run for the day.
4. "Division Superintendent's Report" of returns from the station of all money packages, which is checked up at the main office on its delivery at 8 a. m. each day. (These packages, together with the conductor's report, are kept in the safe at the station during the day and delivered to the auditor as above stated.) This method gives the conductor, and also the division superintendent, a receipt for all returns.
5. "Division Superintendents' Register Report," giving statement of register of each car at time of leaving on first trip and when arriving from last trip at night. The reports from conductors must agree with this statement, thus making a perfect check on rings as shown on conductors' reports.
6. "Division Superintendent's Punch Slips and Transfers" issued by them to conductors giving the number of the conductor, the serial number of transfer and the number of the punch slip.

The foregoing is an outline of our methods in the care of receipts from the collection of the fares to their delivery at the main office; observe that we do away with the counting of money, etc., at the station and the employment of receivers. The entire work is done in the auditor's office and under his personal supervision, at much less cost of labor and with less liability of loss.

7. "Counter's Cash Statement" used by counters to verify the total returns of the routes for the day. Each envelope received from the conductor is first examined and if in any way mutilated or unsealed, notation is made of such fact. We count the tickets and transfers first to be sure that no money is mixed with them, then the cash. No two opened reports are allowed on the table at the same time.

If the returns enclosed do not correspond with the conductor's report, an actual inventory of contents is made on the back of the envelope and certified by at least two clerks. If more money is enclosed than called for by rings as shown on report, it is returned to the conductor. The cash is thrown into a pan provided with compartments for the several denominations, and on the completion of the counting of routes, the money is placed in coin wrappers and the counter's cash statement made out and given to clerk in charge; all shortage and over-payments are also noted on this slip.

8. "Shortage Notices." The clerk in charge of the counters sends daily, all notices of shortages or over-payments to the station clerks, whose duty it is to make the collection from the conductors and forward returns to the main office.

"Bank." All metal money is placed in coin envelopes stamped with our company name and the number of the clerk enclosing it, as well as the date. In preparing the money for deposit the amount is checked in detail by two clerks. A deposit slip is made in carbon duplicate, and the signatures on all checks (giving amount) is placed thereon.—We have special strong boxes for bank use, one key of which is kept by the bank teller. We make the deposit at 10:30 daily.

9. "Record of Earnings by Route." This statement is made by the clerk in charge of the counters and is designed to be a check on the counters and the record of the earnings of each line. It gives the number of runs, conductor's and motorman's name, number of badge, car number, etc., as well as the number of cash fares and tickets received in detail. The total amount due from all conductors on the line must correspond with the counter's cash slip. (See No. 7.)

10. "Record of Earnings of all Routes." On this statement, we consolidate the footings of the route statements, thus giving the total receipts for the day.

General.

I have taken from my "General Earnings Record" a copy of the headings which are herewith exhibited. This book is divided by extra heavy leaves into five sections. In the first division the record of earnings, together with the record of the receipt of tickets in detail is kept by routes daily for each month.

The second division is for totals of all routes daily for each month.

The third is for the summary of each route each month for one year.

OFFICE OF THE TOLEDO TRACTION COMPANY, Toledo, O., 1897

Your Report calls for, Amount Received, Date, Conductor

You will please enclose in accompanying envelope the balance due as above stated, and hand same on RETURN TRIP to Station Clerk or Collector. If you have reason to believe this above charge is not correct, come to the office and explain your report.

THE TOLEDO TRACTION COMPANY.

REMARKS.

suspense account and only credit the earnings when the ticket is returned.

Mr. Brockway: I should fancy that Mr. Wight's deposit at 10:30 is for the second day previous instead of the day previous, because the report says they do not go to the office until half past eight, and I do not think they could count the earnings of the day in an hour or two.

Mr. Green, of Chicago: We deposit today what we earned yesterday. The earnings of yesterday would be in the bank at 10 o'clock this morning.

Mr. Ham, of Brooklyn: I do not believe it is possible for them to do it with their system.

Mr. Brockway: I know I can't.

Mr. Green: The money is all turned in after 6 o'clock at night. It is not in until 1 o'clock.

Mr. Hibbs: We have ours deposited every trip.

The Chair: When do you deposit your earnings in the bank?

Mr. Hibbs: Ten o'clock in the morning; just as soon as the bank opens.

The Chair: Are you one day behind on earnings in your deposits?

Mr. Hibbs: No, sir; we deposit for the previous day. The tickets and transfers are examined, the day card is totaled up from the trip envelopes and the cash counted.

Mr. Wallis, of Fitchburg: You have receiver's safes?

Mr. Hibbs: We have abolished them all.

The Chair: I think it would be well to understand that there are a great many roads which do not use the receiver's system at all. There are a great many other roads which deposit their money every trip; there are still other roads which deposit their tickets every trip, and their money once a day. Now, in St. Louis, we have seven companies, and the receiver system is not in use on any one of them. That is pretty generally the custom so far as we know it, except with Mr. Green, in Chicago, and Mr. Calderwood, in Minneapolis.

Mr. Calderwood: We have tried all systems, I think; the receiver system, the system of depositing in envelopes each trip, depositing it two or three times a day, but the most satisfactory system in our experience is the receiver system. In fact all our stations are now so consolidated that they are large stations, and in all of them we have a receiver. He receives the money. The conductors turn in their transfers and tickets each trip, in an envelope; or in some cases each half trip as they pass the starter's stand which is located on the loop around which all the cars pass, with the exception of one line where provision is made at a drug store to receive the tickets and transfers from that line. The cash is turned in at the end of each run by the conductor, who goes in with his trip sheet and turns in the entire amount of cash on that run to the receiver. Everything is done in the presence of the conductor, and the amount received and by whom is written in ink across the trip sheet. The receivers at the stations assist in keeping the pay rolls and do other work, so their time is fully employed. The actual amount of time which they use in receiving of the cash is comparatively small. The cash is gathered up twice a day from the receivers at the stations by a man who brings it to the office. He receipts for it. The cash is counted up and deposited the next day. We deposit each day the exact amount of the receipts to a cent.

Mr. Ham: My experience has been so nearly like Mr. Calderwood's there is almost no occasion for me to say anything; but I am satisfied that if the stations are reduced in number, that is if you do not have a great many stations separated by long distances, etc., that there is no question but that the receiver system is absolutely the most economical and the most satisfactory. There is then no question between the conductor and the company as to the amount of money turned in. Before that we had shortages that sometimes ran into considerable amounts, complaints from counterfeit money being turned in, plugged money and Canadian money, and the turning in of short accounts purposely. Now we have nothing of the kind. The receiver makes no endeavor to verify the day card or the trip sheet at all; he simply takes what is given him and asks no questions. The receiver also counts the tickets, which with us is no serious problem. Our receivers go on duty in the afternoon when the morning runs pull in, and they work about 10 hours a day, or into the night. When I go into the office in the morning, at half past

eight, I have a slip on my desk which shows the total receipts for the preceding day; and half an hour, or an hour later, I know what the receipts were by each of our individual lines, of which there are 20; and a very short time after that I know what were the average car earnings for each line for the previous day.

As to the sale of tickets I should condemn very strongly the crediting up on day of sale; I think as Mr. Hibbs states it should be carried in some sort of suspense account. Unless you do this I do not see how you are going to correctly show the earnings of each line. Tickets may be sold in large quantities, but you do not know what line is going to be benefited by them, or what day they are going to come in; but when you treat each ticket as so much cash, it becomes no problem at all.

Mr. Ross, of Montreal: Before my connection with the company they used the register system and also the fare box; and concluded that the fare box was the better of the two. In this way no money is handled except at the accountant's office. We issue the portable fare box to the conductor and he collects the fares from the passengers in those boxes; the passengers have to put their fares in the box; that box comes into the accountant's office and is counted every trip by a girl. Six to eight girls are required to do this work. We have four different kinds of tickets: the cash fare is five cents; there are laborers' tickets, school tickets, 6 for a quarter and 25 for a dollar; and we carry those tickets in the ticket sales account. We only credit the earnings of the tickets as the tickets come in. The fare box makes it very easy; and we know by nine o'clock the next morning exactly what our earnings were for the previous day.

Mr. Hibbs: When you have varying rates of fare on the same line, how do you carry that; say, 5, 10, 15?

Mr. Ross: We have columns for that on the earnings sheet. We supply the conductors with a certain amount of tickets which they pay for when they start out in the morning, and they sell them to the passengers. Transfers are not deposited in the box, but are turned in by the conductor separately.

Mr. King, of Washington: We use a deposit safe of our own design, which we had made to order. In this safe is a cylinder with segmental boxes. There is a crank which these boxes fit on, which is turned. The top of the safe is numbered; conductor No. 1 has his box, and so on. In order to get his deposit into his proper box all he has to do is to turn a pointer on the top of the safe opposite his own number, and this connects the slot in the top with his individual compartment. By this means we can have our men turn in as often as desired, either once a trip, several times a day, or once a day. We have had very little trouble with fares getting mixed; and very little trouble with shortages. In the morning the contents of the safe are taken to the counting room. We handle 12 kinds of tickets. Every company in Washington is entitled to issue tickets, all of which are exchangeable and taken on any car. The night man copies the total of each conductor's book on one large sheet, which is placed out for the counters in the morning. From that total sheet is made up the receipts of the day. This is then compared with the registers to see that it corresponds with the sum total registered by the various men. We furnish each conductor with \$15 in change in the morning when he goes out, and require him to keep it and his receipts separate from any money of his own; at night the change money is turned in.

M. G. McDole, of Cleveland: Our conductors turn in their reports once each day. It is turned into the receiving safe at the station. In the morning it is taken from the safe, placed in strong boxes and sent down to the main office, to the counting room. There is a cashier in that counting room who takes charge of those boxes. We have a regular force of clerks who do the counting. Some count the cash, verify the conductors' slips, and pass the slips on to others who do the ticket counting. Our deposit is then turned over to the cashier who gives the cashier of the counting room a receipt for the whole deposit. He verifies all the tickets, they are all put up in packages of 100 each, and a label put on the package showing by whom the package was counted. These tickets are verified afterward by the assistant cashier. The deposit goes to the bank about 11 o'clock, and the ones who do the counting make out shortage slips and over slips, and the receiver at the station collects all shortages and pays the overages. Up to this summer we have always had the counting force work Sundays, thinking we could not do without it. We finally decided

that by getting down earlier Monday morning they could get out their two days' work on Monday, thereby having a day off Sunday. Saturday's run is all taken care of by itself first; then they start on the Sunday's run, and get that into the bank before it closes. This makes two bank deposits on Monday.

(In reply to a question Mr. McDole stated they used a receiving safe and not receivers, at the stations, the safes being strong boxes).

In discussing the question of shorts and overs, the Chair said: "The way we do it is this: a man is short or over either because he has taken the register wrong, because he has made a mistake in his addition or subtraction on the trip card, or because he has failed to put in the requisite amount of cash, or he may have put in mutilated money. On the sheet that we put out on the bulletin that is all posted, how the mistake occurred; and he is at liberty to get all the explanation or information he wants when he comes to the office. During the past five years we have introduced a record showing exactly how many men are in any line of work, and whether or not they were on the error list, and it so for what reason. We have a sheet with 31 spaces. For instance, we have John Jones on the short list, on the second or third as the case may be; and at the end of the month a tabulation is made of that and the list is put out. When I left home there were 40 per cent of the conductors of the Citizens line that were not on the error list at all for the month of September. We have one man that never was on the error list for all of 1895 and only once in 1896. I mention this to show that these men can be encouraged to do their work accurately."

Mr. King: We have practically the same system in force and find it very successful. We have conductors that did not make an error once last year.

Mr. Wallis: Our money, as I said before, is received in safes, and counted by a clerk who puts on the outside of the envelope the amount in silver dollars, halves, etc., and foots it up at the bottom. We require the conductors to keep their account in the same way. So far I have found the receiver's safes to be very satisfactory although we have had them in use only a short time. We have had much less trouble with shortages and overages since that time. Whether it is due to greater care on the part of conductors because they know they are responsible and cannot blame the night foreman or the receiving clerk, or what, we do not know. It makes the conductors feel secure and leaves them with a certain amount of responsibility which they did not feel before.

Secretary Brockway: I require all conductors to report on each round trip. I do not use the day card as I explained in my paper of last year. Each trip is reported separately by itself.

On motion of Mr. Burlington adjournment was taken to 9 a. m. Wednesday morning.

#### Wednesday Morning.

The chair called the meeting to order at 9:45 Wednesday morning and after the roll call, the secretary announced the addition of seven new members since the previous day.

The next order was the reading of Mr. Calderwood's paper on transfers.

#### THE HANDLING OF TRANSFERS; FROM THE PRINTER TO THE FURNACE.

By John F. Calderwood, Auditor Twin City Rapid Transit Company, Minneapolis-St. Paul.

In the management of street car transfers, as in the many other affairs of practical life, the proof of the pudding is in the eating, so I shall confine myself to a plain statement of facts—in other words to tell you, as succinctly and clearly as possible, how the Twin City Rapid Transit Company conducts its transfer business, or as the program has it: "The Handling of Transfers; from the Printer to the Furnace."

In order that the transfer system which we have evolved—for, by the very nature of the business, it must be a growth governed by local conditions, not a creation springing full-fledged from the brain of any mortal Jove—I shall dress just enough to indicate the policy of our company toward its patrons. It is to avoid all semblance of arbitrary rules wherever possible, when coming in

contact with the public, and particularly in giving transfers. We believe the street car business should be run as nearly like any other business as possible; we have transportation to sell and the better the service we can give, the more politely or considerately we can treat our customers, the more patronage we will have. We believe the public have rights which, upon a purely business basis, it pays us to respect, and in the matter of transfers we believe we more than fulfill every requirement of what was regarded, at the time of its adoption by our city council, as an exacting and sweeping transfer ordinance.

A theoretically perfect transfer system, so far as the service of the public is concerned, is one by which it is made possible for a person to start from any given point and reach his objective point by the shortest route and the quickest time.

A sincere effort is made in our system to reach this ideal. Not only do we try to give the quickest and best service for the passenger, but the conductors are expected to use judgment in carrying it out. In short, we do everything we can for the public—grant every reasonable request or concession—and do it cheerfully. And when we are compelled to refuse, we make it a point to show why the request is not reasonable. And I want to say right here that this policy pays. It pays in the harvest of nickels, for I believe that people will frequently walk or provide other means of transportation, when they would otherwise ride on our cars, because they have a real or fancied grievance against the company. But this is only a small part of the advantage of a liberal policy. I have noticed that in those cities where the first consideration—and the only one, apparently—is to snatch every nickel in sight, where arbitrary rules are imposed and the employes reflect the austere character of the management, the 3-cent fare epidemic has raged.

I think I can truly say that the people of Minneapolis and St. Paul, as a whole, are friendly to the Twin City Rapid Transit Company. We have repeated evidences of good will from the patrons of our lines, the press, the officials of our cities and public sentiment generally. We do not live over a volcano which has to be smothered with a blanket of subsidies, and I believe that one of the strongest of the bonds which bind the average citizen to us is a belief that Minneapolis and St. Paul have one of the best and most liberally managed street car systems in the country.

In the first place we have two cities, Minneapolis, with a population of over 200,000, and St. Paul only a few thousand less, lying side by side—a rectangular, or, perhaps, more accurately described as an elliptical city, with two foci the circumference of which embraces 150 square miles. The two foci—the business centers—are about nine miles apart, and are connected by a great Stamesa artery, the Interurban line running principally on University avenue, as the street is called in both cities. About each of these foci we have a loop and around the two loops, as the several car lines join the main stem, are the transfer points. Here nearly all the transferring is done, although this is slightly more general in Minneapolis than in St. Paul. The city of Minneapolis is grid-ironed by our tracks running almost parallel and brought together about the Minneapolis loop. In carrying the lines to one focal point it has been found necessary to cross them occasionally before reaching the center, and at each of these crossings transfers are effected. What I have said about Minneapolis applies, in a general way, to St. Paul, so I will not particularize further.

As stated, our policy is to give the best and most satisfactory service possible. We have a uniform 5-cent fare in both cities and a man can ride from the Falls of Minnehaha, in the southeastern corner of Minneapolis, to Shingle Creek, 12 miles; to Lake Harriet, our local Coney Island, 10 miles; or to Columbia Heights, 14 miles, for one fare. Or he can transfer to the Interurban, the greatest and most popular of our lines, and ride half way to St. Paul, where, without change of cars, he pays another fare and can reach any point in St. Paul. By transferring to the West 7th street line he can go back to the Fort Snelling bridge, but a little more than a mile from where he started, having traveled a distance of about 20 miles from the starting point.

I fancy I hear some gentleman remark, "What do they expect? No wonder your patrons are satisfied and friendly." I acknowledge his point; we give long rides, because Minneapolis and St. Paul are preëminently cities of homes and a large proportion of

our people live under their own vines and crabapple trees. But notwithstanding the length of the average ride, we believe it pays to treat the public with liberality. If any man among you doubts the wisdom of a liberal policy, let him come to the Twin Cities of Minnesota for an object lesson.

I have already said so much by way of introduction that I shall be forced to plunge right into the technique of the transfer business. I want to preface my remarks, first of all, by saying that I bring you no fine-spun theory of toy working model. I have with me the entire paraphernalia of a system of transfers, including the reports upon which they are checked up and the records of the conductors verified, so that any average business man—he need not be an expert accountant—can readily understand the plan. I need only add that it has worked well under all circumstances and is more satisfactory than we had hoped at the time it was instituted.

As most of you know, the Twin City Rapid Transit Company operates all the street car service of Minneapolis and St. Paul, all electric, except one line, the 4th street cable, running up St. Anthony Hill in St. Paul.

The ordinances of both cities require that transfers from one line to another be given "at the first intersection." No extra charge is made for the transfer ticket. A passenger, having paid his fare, is entitled to a transfer. But no second transfer is issued to the passenger who has presented a transfer, except on three or four extensions to the main lines. Transfers are registered the same as cash fares and are cancelled by the conductor receiving them by punching the head of the transfer, thus indicating who received it.

Transfers are issued by conductors at all points of intersection, entitling the passenger to a continuous ride in either direction upon the first car leaving the point of transfer, the hour and minute when the transfer becomes void being punched on the margin (a maximum limit of 10 minutes being allowed after the time of issue).

Conductors are required to issue transfers to the several lines as they are reached. After passing the first intersection, or transfer point, transfers are issued to passengers desiring them immediately as the fares are collected, thus avoiding the issuance of a transfer upon a transfer, the conductor punching the transfer (upon a 10-minute or less limit) for the time the car is due at the point of transfer.

I realize that I am not regalling you with a chapter of light literature; I incline to the prosy and the subject is necessarily technical, but I prefer to follow it out upon this line, because I believe if there is anyone here really interested in how we manage the transfer problem, with the aid of the blank forms which I have brought with me, he can find it out after he has heard me through.

One essential about any transfer system is simplicity—it must be such that the men who put it into execution can fully and clearly understand and that the public will readily comprehend. Another important feature is that it should involve as little work as possible on the part of the conductor to issue them. He is frequently crowded and it will not do to have some elaborate or time-consuming method of issuance.

Now having reviewed the conditions in a general way, my purpose is to give you next a complete story of the transfer—"from the printer to the furnace"—and then to take up, as briefly as I may, some of the principal reasons why we have adopted each feature.

The transfers which we use are our own design and are printed for us by the Globe Ticket Company, of Philadelphia. At present we are using 11 different colors of paper and ink, the idea being to have a different color for each line of tickets. The several colors of tickets enable the conductors and also the transfer clerks in the office, to tell at a glance from which line they were issued.

The transfers have the conductor's transfer number printed in a conspicuous place. They are also consecutively numbered (in red), as you will notice upon examination. The conductor's number on the transfer indicates which conductor issues the transfer, but it has no reference to the number on his badge, as will be observed by an examination of Form 379, where both are given. Samples of the transfers of the several lines are here among the other forms. They are practically self-explanatory.

The transfers are put up in tabs of 100, and when received from the printing office they are done up in bundles of 500, and enclosed in a paper wrapper for convenient handling. We carry a 60-days supply of tickets for each line, a record of the amount of stock on hand being kept in a stock record book, (of which I have several sample pages here), to show the exact number on hand for each conductor. The transfer stock is kept in a large case arranged for the purpose, at the principal office.

Transfers are sent out in quantity to the stations once a week. Each station keeps a daily transfer report book for each line of tickets. When a conductor reports for duty, before taking his car, he calls for his transfers (enough for the day) and his punch; one conductor's transfer number being used for each run. When the conductor is relieved, he turns in the punch and the unused transfers. A record is kept in the report book at the station of the first consecutive number (the red figures) of the ticket of each conductor's transfer number. This is put down when he begins and is called the "beginning number" or "commencing number," and a corresponding "ending number" is entered in the report book to show the first number on the pad of current transfers when it is turned in, whether all or only part of the time card run has been made. And the difference between the beginning and ending numbers gives exactly the number of transfers issued by the conductor. These report books are made out in duplicate, the original sheet being torn out and sent to the principal office daily and the carbon copy kept in the book for reference. The same report also shows the fact if an "extra" or "relief" conductor use the same transfer number.

For each car line there are special orders directing the issuance of transfers by conductors. As a general rule the conductor, after having collected the fares on a car going toward the loop, passes up the aisle and announces, "Transfers" which are issued just before the first intersection, or transfer point, is reached. After passing the first transfer point, transfers, if desired, are issued to passengers as they pay their fares, the conductor punching the transfer so as to allow 10 minutes after the car is due at the point of transfer, the transfer ticket being good on the first car leaving the point indicated by the punch mark.

Conductors are required to keep a record on a trip envelope, Form 150, of the number of transfers for each half-trip. This is done by the conductor putting down the first consecutive number (in red) which appears upon his pad when he starts away from the loop; also, when he reaches the other end, and again, when he has completed the first trip. The differences between these three "consecutive" numbers shows how many transfers were issued on each of the two half-trips. The trip envelope also has a report of the leaving time at each end, or half-trip, the number of fares registered and how many of these fares were transfers from other lines. Within this trip envelope the conductor puts all the transfers he has received and accepted for fare, but no money. The difference between the fares registered and the transfers turned in shows how much cash is required to be paid in by him at the end of his day's work. It also shows the maximum number of transfers which a conductor may issue during the day—that is, if he should issue one transfer for every cash fare received.

If the conductor mis-punches any transfers, or, if he takes up those already issued and issues new ones instead (as in case of a blockade, or when the passenger changes his mind and wants to take a different line than at first intended), these transfers are turned in in the current trip envelope, with Form 414 attached, giving a full explanation. If the conductor has any transfers punched and not used when he is relieved, he turns them in in the last or relief trip envelope, attached to Form 414. Transfers that are past due when presented by the passenger, or which for any other reason, are not good when presented for fare, and for which the passenger refuses to substitute cash fare, are also registered and turned in in the current trip envelope attached to Form 414 with full explanation.

The trip envelopes are dropped in a box each trip as the car passes the starter's stand on the loop. This is one of the distinctive features of our system and I want to call it to your special attention. The reason is that we want to remove all temptation to manipulate the transfers, which might be possible if the conductor retained them to the end of the day; we do the book-keeping for the conductor, and by doing it in detail—trip by trip—

we not only make it practically impossible for him to commit a great fraud, but we render it unsafe for him to attempt to do any crooked work at all. By our system of cross-checks we know more about a transfer than the conductor himself.

As every street car man knows, the hane of the business is that too many people handle the receipts, and the gentlemen here know what the public does not know, perhaps, that the great objection to a liberal transfer system is that it opens the way for fraud and dishonesty, unless properly guarded.

While I am among those who believe that there is no effectual substitution for honesty, I think we can do much toward making men reliable and trustworthy by showing them that dishonesty is sure to be found out, and that it doesn't pay. Our company has comparatively little trouble from this source; and, while our conductors and motormen are, as a class, above the average working man in executive ability and attention to their work, we regard it as the duty of the auditing department to see to it that nothing fraudulent is permitted. I think we have a system which effectually accomplishes this purpose.

I have covered half the journey of the transfer, from the printing office to where it has done its mission, been placed in the trip envelope by the conductor who took it up, and by him put in the box at the starter's stand. From there it is taken, with thousands of its kind, to the principal office to be checked up. The first verification is as to the number of transfers turned in. They must correspond with the number indicated on the trip envelope in which they were enclosed. If the number is not correct, note is made of it and the balance in cash is required. If the report is found correct, the transfers are turned over to the transfer clerks to be checked up for errors in transferring. First, we examine all the envelopes of each conductor to see if the transfers reported issued, as shown by the commencing and ending numbers, were in consecutive order; and next to see whether the conductor issued more transfers than he had cash fares on that particular trip. After this the transfers are again examined as to date, point of transfer and time, the checkers knowing the exact running time between transfer points. In case transfers are found punched ahead, they are looked up and compared with the report for that particular time upon the envelope of the conductor who issued them. These errors and any others are reported to the instructor who takes them up personally with the conductors at the stations.

The principal abuse of any transfer system is in the speculation by conductors who try to cover up their theft by trading transfers. In fact, there are those who claim that it is impossible to stop stealing so long as transfers can be turned in for cash. Perhaps absolute prevention of theft is impossible; I will go farther and say that, even where no transfers are given, men have been able to steal for a time.

One of the checkings is to test the probable trading of transfers. If one conductor is receiving four, five or more transfers at any one time, at any one point, from any other conductor, with anything approximating regularity, it may be regarded as a symptom to be inquired into. In a case of this kind an inspector is detailed to watch this transfer point and to ascertain whether the matter is as it should be. When any crookedness is in progress a checking system like this is certain to supply the clue, and it is seldom difficult to ferret it out with the pointer thus furnished.

Still another check is furnished when the transfer reports from the stations, Form 379, are compared with the consecutive transfer numbers on the trip envelopes, to see if the conductor's report agrees with the beginning and ending numbers on the relief's or station reports. Each conductor has a regular punch. It is used by no one else and when he is off duty it is kept at the station. A transfer number may be used by more than one conductor, as in case of extras or when the full time card is not run by the same conductor, but the punch is never used by more than one man. A cut of the die of each punch, with the name of the conductor to whom it is charged, is kept at the office, and regular examinations of the punch marks are also made. I believe that, with this system of checking, it is practically impossible for conductors to trade transfers without our being aware of the manipulation.

When all the examinations have been completed, the transfers are carefully gathered and thrown under the boilers of our engine house and burned.

In conclusion, I will briefly take up the advantages and disadvantages of a transfer system such as we have put into force. A

liberal construction of our ordinance, giving transfers at the first intersection, results in a considerable percentage of passengers changing cars at outlying points, which enables them to get to their destination with the least loss of time. This avoids congestion and overcrowding at the down-town transfer points, which might result if we had only a few central transfer points. On the other hand, it makes it possible for passengers to double back with a single fare. For instance, a man can come down town on the 4th avenue line, in Minneapolis, taking a transfer and getting off at the post office, which is at the transfer point. He can get his mail from his box and go back on the 1st avenue line, these two lines being only from three to five blocks apart. To what extent this is done I cannot say, but it cannot be enough to make it worth while to consider it against the moral advantage of a satisfactory transfer system.

It is true that a transfer system like ours entails considerable expense which might otherwise be avoided. I have made no close figures upon this item, but you can get some idea when I tell you that we use from 12 to 13 millions of transfers a year, which is over 20,000 every day and a corresponding increase when travel is heavy.

Owing to the transformation from horse cars to the electric system, and the fact that several extensions have been built, it is impossible to estimate to what extent our earnings have been affected as a result of our present transfer system.

Mr. Durbin: I would like to ask whether the passenger is required to take the car at the intersection or whether he is permitted to walk along in the direction that the car is going.

Mr. Calderwood: He is required to take the car at the point of intersection. If the passenger happens to make a mistake and does not understand it, we do not put him off or require him to pay his fare; simply explain to him that he should not do that. Those are the instructions which the conductors have.

Mr. Ross: Do you not think it better in case a conductor puts a wrong date on a transfer to charge him with it? We take 5 cents from them for putting in a wrong date. There is very little excuse for that.

Mr. Calderwood: We have never made it a point to collect from conductors on that. We take the matter up with them, and if they repeat it, then it counts against their record.

In response to the question by Mr. Hibbs, several members replied that transfers were not registered on their roads.

C. D. Meneely, of Brooklyn: Last spring we put on a few transfer agents to see what the result would be. On a majority of the lines on which the experiment was made the percentage of transfers issued was considerably decreased. The number of transfer agents has been increased until now we have 40 or 50 agents. The result has been in the main excellent on most of the lines. The decrease in transfers issued has been from 3 to 5 per cent, and at the same time the cash fares have kept up. At one transfer point the decrease in transfers issued has been 25 per cent. We check all transfers.

Mr. King: The transfer system has been in use in Washington a great many years. Long before transfers were reached in other cities it was a general thing in Washington, and the various companies there have been all over this ground in all its phases. The Capital Traction Company originally issued transfers; had the conductor issue and register them with the same register he used for other fares. The system was unsatisfactory and they adopted the system of transfer agents. This was before the time limit came into use and the transfer was good for all day. By the agent system a large saving was effected. Later, since the time limit transfer has come into use, they have abandoned the agents, do not now register transfers, and have the conductors issue them. The Metropolitan Company of our city did the same thing. They had transfer agents and found that hundreds of people would walk in on the transfer agents in busy hours and they found they were making serious losses. So they abandoned that plan and allowed the conductor to issue them; nor are they registered. There was a saving of 20 per cent in the number of transfer passengers carried under the new plan.

Mr. Ham: I think that everything, I do not care what it is, whether it is a pass, or a transfer, or cash, should be rung up. Now, it is impossible for anyone to ride on our road, with the exception of the man who wears a uniform with his authority right on the face of it, like a policeman, or an employe with a

very prominent badge on his cap, firemen in uniform, etc., to ride free. That means that everyone outside of these uniformed people must be rung up. We have two registers, one for cash fares and one for transfers. As the transfers are all registered immediately after passing the transfer point, and nowhere else, it makes the plan a simple and very effective one.

Mr. King: We formerly registered all our transfers, and found after we quit registering that there was no increase in the number issued.

The Chair: We will now pass to the next paper, "Pay Rolls," by Mr. Henry, of St. Louis.

## TIME-KEEPING, PAY ROLL AND METHOD OF PAYING.

By Frank R. Henry, Secretary Missouri Railroad Company,  
St. I. Louis.

### TIME-KEEPING.

The system herewith presented is one which the Missouri Railroad Company of St. Louis, has followed for some time. Our manner of keeping time is by the hour for conductors, motormen and track laborers. Other employes by the day. The time is kept by the foreman or superintendent of each department in the following manner: The foreman of the car sheds is the timekeeper of conductors and motormen and all men that are strictly under his charge. The time table indicates the number of hours and fractions thereof in tenths for each run made, and at the end of each day's run, the foreman records opposite their names in his time book the number of hours made, as indicated by the run upon which they were assigned. The total of time for the day must agree with the total hours of the time table.

The foreman is required to group the time of the day men under the classification furnished by the office, i. e., the time of car cleaners, switchmen, watchmen, stable men, shed men, etc., must be recorded under their respective headings and should an employe be taken from one class of work to another, the time must be charged upon each class separately.

The master mechanic of the repair shop keeps the time of the men under his charge. Keeping the time of labor on car bodies, trucks, car painting and motor repairs separately.

In the machine and blacksmith shops the time is kept by the head mechanic, which with an itemized statement of time and amount of work turned out is given to the master mechanic for his approval and returned to the office by him with his time book.

The time of track laborers making the ordinary track repairs is kept by the track foreman, keeping the time of all new construction separate from regular work. We find it necessary to have a timekeeper whenever a large force of men are employed on construction or reconstruction work. Each timekeeper is furnished with two time books, one printed for the first 15 days of the month, the other for the last 16 days. The necessity for this is that we pay twice a month. The time is totaled and the calculations extended in the time book by the timekeeper and it is then returned to the office, from which we proceed to check off the time and make up the pay roll. The time book is then returned to the timekeeper to be used for the same period of the next month.

### PAY ROLL.

The pay roll is ruled as follows: First column for number, second for name, the five succeeding columns in which to enumerate the class of work or classifications under which work has been rendered. The remaining columns are such as are usual to pay rolls for total time, rate, amount paid, amount due and total amount. After all the names and amounts have been copied from the time books and properly classified, the names are numbered and the pay roll totaled, each classification being footed separately so as to show the amount of each and for convenience in comparison.

### METHOD OF PAYING.

An envelope is prepared for each employe, placing thereon the pay roll number, name and amount of pay due, deducting any amount that may have been advanced thereon or other charges such as accident insurance, uniform account, etc. Having prepared an envelope for each person on the roll in this manner, they are then checked back to catch errors, and to be assorted alphabetically. The money is placed on the envelope face up,

FRANK R. HENRY.

Frank R. Henry first saw the light of day in St. Louis, July 3, 1867. His father, Wm. D. Henry, was one of the oldest railroad veterans in St. Louis. After a preliminary education in the public schools and a course in Jones' Commercial College, he became assistant to his father who was secretary and treasurer of the Missouri Railroad Company. In 1891 Mr. Henry was elected secretary and treasurer of that company, which position he now holds.

change being put inside to facilitate handling, the money recounted by another person, and put inside the envelope and the latter sealed.

The pay is delivered to each employe in person on pay day, upon calling at the office, except the construction gang; they are paid at the place of work. Each employe receipts on his envelope and drops it into a box provided for that purpose; this is done for future reference. They are then taken out of the box and assorted numerically. Should a number be missing we turn to the pay roll and see to whom such number envelope was given; the timekeeper is then requested to have him call at the office with his envelope. In case he has lost or misplaced it another envelope is prepared for him to receipt.

Mr. Wallis: I would like to ask whether the conductor receipts the envelope immediately on the receipt of the money, or at any subsequent time?

Mr. Henry: He receipts it at any subsequent time. We simply do that for future reference. We found that frequently a man would claim that he had paid the amount at some previous time, but when we show him the envelope and the amounts deducted on such and such dates, that convinces him. We sort the envelopes immediately after pay day, and see what are missing, and then get them in.

Mr. Wallis: Do you ever have any dispute as to amount in the envelope?

Mr. Henry: In 14 years' experience I have had four men claim their envelopes were short. In those cases I simply made it good; out of the four two came back to the office and returned the money, having found it in their clothes. At that time we were paying in gold, and I suppose the coin slipped out; it was a \$5 gold piece, and easily overlooked.

Mr. Babcock, Elmira & Horseheads Railway: We have recently adopted a scheme in paying off which we find works very nicely, and it furnishes a receipt for the money. We have a form reading, "Received from the E. & H. Railway Co. \$...." with a blank for the nature of the service rendered and for the date, and at the bottom, "My number is so and so on pay roll of such a date." We issue that to each man who comes to the office, he presents it to the cashier, who compares it with the envelope which has the pay roll number on it, and also the man's name. It is necessary for him to sign that ticket before he can get his money; and he can assist it and give it to any one he chooses, who can come and get the copy for him. We find that this lessens the work at the office considerably and has been an accommodation to the men. Sometimes they get their money on pay day, sometimes they wait two or three days. It works very smoothly and is a simple arrangement.

Mr. Williams: I would like to inquire if anybody here uses the bank check system of paying?

Secretary Brockway: I can explain that system on some of the

steam roads, but I have never seen it in operation on a street railway. The railroad with which I was formerly connected had something like 2,500 men. Of that number 1,500 were paid by check, covering about three divisions. The other division were paid by the pay car system on account of the line running through a mining district with no banks. The checks were simply sent out to the station agents and the section men. The station agents were supposed to cash those checks. Some trouble was experienced by the station agents shaving the checks 2 or 3 per cent, although detection resulted in dismissal. Otherwise the system worked acceptably, but it made more work in the office.

Mr. Williams: I would like to ask Mr. Brockway a question? When he gives those checks he must make them to a certain account in his bank—how does he make his division as between, say, construction and operating expenses; does he do it through the check to the bank or the check to the employe?

Mr. Brockway: The system which that company followed was that of having three bank accounts, two for operation and one for construction. But the construction men were nearly always paid in cash.

Mr. Hibbs: I was connected for three years with the Pennsylvania Railroad and their entire system is paid by check. Division superintendents and people in charge of departments make what is known as a check roll. This is forwarded to the auditor's department, where is made up the pay roll check roll and the checks are all drawn on one bank. The checks are cashed anywhere without discount. The checks are forwarded to the party making the check roll, who has a car going over the division, and they are surrendered to the men to whom they are drawn, who sign a receipt for them on the pay roll.

W. M. Barnaby, Brooklyn Heights Railroad: I was connected with the Erie for several years when they paid their entire force, some 15,000 men, by check. They had a printed form of endorsement on the back of the check which was virtually a certificate that they had been paid in full. These checks were drawn payable at the various banks along the line.

W. S. Dimmock, Omaha & Council Bluffs Railway & Bridge Company: We pay entirely by check. A man can get his money any time during the month before pay day and we have him sign what we call a due bill. We pay him by check every time. At the end of the month we surrender the due bill to him and have him sign a voucher. We have never had a dispute since we adopted this system.

Mr. Reavis, Augusta, Ga.: Our system of paying is almost identical with that of Mr. Henry. We pay by the envelope system as he does, but we have the men sign the pay roll direct. The deductions that Mr. Henry speaks of, if any, are entered in a column provided on the pay roll, for that purpose, stating for what they are made. Mr. McCarthy, formerly of the Metropolitan of Kansas City, told me their system was to make one check for the total amount. The pay rolls are distributed and charged up at that time. The check is simply for a gross amount, say \$3,000. They then have a check of a different color, that is given to the men individually for the amount due them. These checks, when they come in, are attached to the pay roll and filed away with it.

Homer Loring, Union Street Railway, Saginaw: We have recently adopted a check system similar to that just described. We make up our pay roll and then have a special account at the bank of an equal amount. We deposit a check for the amount, say two days in advance, and then give out the checks. It gives us no trouble and has worked very satisfactorily. We used the envelope system before that, but consider the checks less work. We pay twice a month. At first we took a receipt from the men, but lately have not done so and do not consider it necessary. We have about 150 employes.

Mr. Durbin, Denver Tramways: We pay all our shop men, track men and power house men by checks. We have a distinctive feature in paying our train men, allowing them to pay themselves each day. The conductor pays himself and his motorman at the end of each day's work. This has been in operation on our road for about eight years and we like it as well as anything we have. It is a very simple system and we keep a check on it in exactly the same way that you do with a register. The car is signed out in the morning and signed in again at night by the man in charge of the car house, and the conductors agree between themselves as to the time they are relieved. At the bottom of the trip sheet the conductor and motorman each sign

a receipt stating at what rate they pay themselves. We have several rates; 17½ cents per hour the first year, and 20 cents an hour after that time. They state the rate and the amount they have deducted, and sign their names. We check them up in the office the next morning, and if a man takes out too much we send him a notice, or, if he does not take out enough we send him a notice. We formerly had a great deal of trouble with garnishments, when we paid twice a month. We have not had a single garnishment since we adopted this system. Further, there is no complaint on the part of the men, if there is any it is on our side, owing to their taking out too much, for which we call them in. I know at first blush this will not strike some of you favorably, but I am satisfied that after investigation you would find it a great saving of labor in your auditor's office. No timekeeper is required; the conductors do your bookkeeping, and we have only one clerk to check 150 men. It works beautifully, and there is no trouble whatever about it.

John I. Beggs, Milwaukee Electric Light & Power Company: It would not seem to me that you had obviated a great deal of bookkeeping by that method—my company, Mr. President, is not a member of this Association, although I propose to make it one. I feel, gentlemen, that this matter of accounting is one of most vital importance in the operation and management of every street railway in the United States. I possibly pay more attention to this for the reason that a good many years ago I spent a good many years at a desk in charge of a very large corporation's books, and prior to that spent some few years in teaching in Bryant & Stratton's Commercial College. My own impression is that the system of paying with checks appeals most strongly to a manager—and I claim to be manager of the accounting department as well as of the road—for the reason that I believe you have more accurate records in your office; I believe the work is reduced; and that you have some evidence of payment. I was for many years in Harrisburg, and familiar with the check system of the Pennsylvania Railroad, and it was as a result of that knowledge of its operation that I was led in these latter days in connection with a street railway to try to convert my auditing department—I always try to "convert" my accounting department—to the advisability of getting our entire force on a basis of payment by checks, as I believe it will reduce labor in the office, and at the same time be more in accord with good commercial practice. I am likewise in charge of another corporation in the city of Cincinnati—not a street railway—and they pay by this same method of having the conductors serve as their accounting department and cashier. I must say it does not appeal strongly to me. I do not believe in having 600 or 700 men, or, as in the case of some gentlemen here, probably as many as 2,000 men, acting as cashier and first saying what portion of our receipts is theirs. I want that money first to go into the bank. It is ours first and it is for us to determine how we shall pay the men. I am one of those who believe in trying as far as possible to be fair, and to lean over backward even, in fairness toward your men; but the point I want to make is, I do not see how book-keeping is avoided. It seems to me you must go over every one of these time sheets every day with just as much care as though you were compiling them to be kept until the middle of the month, or the end of the month, which ever you make your pay day. You have every one of these men, who may possibly make a mistake, to deal with. Instead of dealing with your man who may claim you have made a mistake once or twice a month, you have the possibility of dealing with men, who do not claim to be "figure wrestlers" 30 times a month. In the matter of garnishment I do not see how you avoid it, because they can require you to hold all that is to become due to a man, as well as what is already due him, until the garnishee is released. We can much more readily pay by check than the steam roads which have been mentioned, for the reason that all of our men are in the city. Your checks are as good as cash. Many people, in fact, prefer the check; every merchant with whom they deal will gladly cash the check.

Mr. Durbin: I will try to answer the gentleman's question as to the saving. I was the auditor of our company before becoming superintendent, and originated this plan. We used to pay our men twice a month by check. We took the time that the car went out in the morning and the relief time and kept a regular pay roll. Twice a month the men would come in and get their pay. One man would say, "I am short." Now, he may not have been short, but thought he was; and immediately another man would

say, "I am short, too." Then you had to take the time and go to work to show the man that he was mistaken, and that takes considerable time. Our work of checking up the time is done by the same man who checks the registers, and in exactly the same way. The time of the car going out is put down by the starter; the time in is put down by the car house foreman; and the time that the man is relieved is agreed upon between him and the man who takes the car. It takes but a moment for the man who checks the registers to look at that and see that it is all right. There is absolutely no complaint from the men as to their time—there cannot be—because the man has it in his own power to take the money out. It is perfectly safe; just as safe in one case as in the other. We figure in the wages as so much receipts and keep an account of it on our cash book in that way. Now, as to garnishments, our courts have held that you cannot garnish a man for money that is not yet due him; you cannot garnish a day's wages. I also claim that the cash system is better for the men themselves, because it enables them to buy for cash, and they have their money in their pockets, thus having a tendency to prevent temptation.

Mr. Barnaby: I cannot see for my part how the check system is a good system, especially on a road which pays off 4,000 men every week, as we do.

The Chair: Won't you state your system?

Mr. Barnaby: I think our system is a very compact and a very easy one. Of course, I suppose local conditions affect this matter also. The pay rolls are under the supervision of the heads of the departments in which the work is done. That is, the foreman of the depot has entire charge of the line roll, of the operating department, including the starters, foremen, register takers and one or two men in the depot, conductors and motormen, and watchmen if there are any. He certifies every week when he makes up his pay roll that the time is right. He has a time book and makes his pay roll from that. This pay roll is certified again by the division superintendent, who has three or four lines, comprising a division, and then in turn that is again vided by the general superintendent. Then that goes to our pay roll department and all the calculations are gone over. Our week ends on Friday. It is then turned over to the paymaster, who takes it to the power station. The same method is pursued in making that up. That is, the man in charge of the work certifies that there are so many dynamo men so many hours; so many engineers; so many boilermen. The accounting department distributes it, showing so much for maintenance of boilers, so much for maintenance of engines, so much for the different ramifications of the accounts. The men at the power stations are paid on Saturday by just paying those men in person, the foreman of each class of men certifying to their identity.

The Chair: Is the money paid in envelopes?

Mr. Barnaby: The money is paid right out of a box. He goes to the bank and gets the amount in convenient money; looks over his roll and sees what shape he wants it in. That is the process Monday, Tuesday, Wednesday and Thursday, and the roll is completed. The roll is turned back in. Periodically he turns in unclaimed wages, which is kept until such time as it is called for. No receipts are taken; and as far as my experience goes, or my recollection, I have never heard of any trouble between the men and the paymaster. If there is any dispute as to the time, it is referred back to the head of the department. If it is a conductor or motorman, he goes to the foreman of his depot. We do not pay our men by hours, as most of you do. The men are paid \$2 a day for 10 hours on the rail in 12. The tables are made up on the basis of trips. Six trips constitute a day's work on one line; five on another; four on another, and as we know that the time tables call for so many trips, and there is a record of the trips run, it is very easy to check off. So many trips made at a certain rate is bound to make a certain sum of money, varying with the fractions where the rates are 33 1/3 cents for trips.

The Chair: I will say that I personally pay our men, about 600 of them, just exactly as your paymaster does. The money is distributed directly to the men by myself. There is no receipt taken; and I want to get away from the labor of writing envelopes, putting the money in them and then handling them afterwards.

Mr. Barnaby: It seems to me that it is just as easy to pay a man \$15 or \$12.50 by taking it out of a box and counting it right in front of him.

The Chair: That is my idea exactly. You both see the transaction.

Mr. Barnaby: Of course, you can balance in one instance, after you have made up your envelopes and find an error. If you pay a man 50 cents too much you are out. But that is a mere matter of being careful; that is all.

Mr. Dimmock: You pay four times a month because the law compels you to do so?

Mr. Barnaby: Yes; we pay practically every week. We split the week according to the end of the month.

Mr. Dimmock: Does the law of the state of New York compel you to pay four times a month?

Mr. Barnaby: Yes, it does.

Mr. Hibbs: May I ask you, Mr. President, if you do not take a receipt for the money that is paid out by the paymaster?

The Chair: No, sir; I am the paymaster.

Mr. Hibbs: I was not questioning your integrity at all—(laughter)—I want to know what protection the company has. (Renewed laughter.)

The Chair: It has none, sir.

Mr. Barnaby: In Brooklyn we have not reached the point where we believe in the total depravity of men. We have one or two men that we trust to be honest, and of course we look to them to deal honestly by us. You are bound to trust somebody. You have to trust the timekeeper, you have to trust the foremen, you have to trust the paymaster. You can't always be putting a surety company back of every man.

Mr. Hibbs: Suppose there is a question between the paymaster and the man as to whether he has received his money or not?

Mr. Barnaby: The man is paid right in the presence of his chief, you might say. That is, the foreman is right there and checks the book while the paymaster checks the pay roll. When the man comes up, he says, "Brown, what are you, a conductor or motorman,"—"How much is coming to you?" Brown answers, \$12.50." The paymaster looks at the roll, finds the amount, checks it off and passes the \$12.50 over to the man. The names are put in an alphabetical list, the conductors being on one sheet and the motormen on another.

Mr. Hibbs: In paying unclaimed wages, you merely take the check for it?

Mr. Barnaby: He gives the line on which the man works and the amount of money that has not been called for in a week, and that is turned over to the cashier. Then if the man wants his money he goes to the foreman; the foreman keeping the check on his books knows that that man has not been paid; probably designates it with an "X" as uncalled for money. He issues an order on the cashier for those unpaid wages. That is sent to the office. Either the man can call at the depot when the paymaster is there, which I think they do very often, as our office is down in the heart of the city, and the car barns are some distance away, or come to the office.

Mr. Hibbs: Our system is very similar to Mr. Barnaby's, but we require a receipt for every dollar paid out.

Mr. Beggs: I am very glad, indeed, and feel under obligations, for this discussion. I am very thoroughly confirmed in my own mind, too, after hearing it that I shall put the check system into effect with the least possible delay, both as a means of economy in the accounting department and for greater convenience to the men who are receiving this money. I think it will require very much less labor in the accounting department. A man will make out a check in almost the same time that he would make out an envelope, if you are going to adopt that system; he would make out the check with the same amount of labor, the same number of strokes of the pen and the same waste of ink. By the methods just described here these men must come at a specified time to meet the paymaster or else he must devote a whole day or parts of several days to it; he must spend three or four days a week meeting the men.

Mr. —: We have a paymaster and an assistant whose whole time is devoted to paying the men. My idea would be to have a pay roll made out in your accounting department, and sent to the different car stations, and as the motormen and conductors come in, whatever time it may be—if, for instance, you pay as we do, on the 5th and 20th of every month—as these various crews come in the check is there at any time and they have not to wait; if it is in the power house the same thing is true; at any time when they come on or go off they get their checks; they sign the pay roll and that pay roll goes back to the accounting department. If any man has not turned up for his check, that check

goes back to the auditing department; and if he has not his pay within a reasonable time, say, within 48 hours, by the time your pay roll goes back, he then puts in his appearance at the principal office of the company and gets his check there. It seems to me the amount of accounting is greatly reduced. That has been the great difficulty and the reason why I have been seeking some other means of making payment to our men; because to a certain extent our accounting department is paralyzed for two or three days on account of making up the pay roll, getting the money out of the bank, counting it out for each particular man. If you want anything from the accounting department just at that particular time you cannot get it because they are in the throes of making up the pay roll and getting the money ready to distribute to the men; whereas you can take a couple of clerks, young men who are good penmen, and make out your checks; and you have virtually a receipt from your men, and the best receipt you can possibly have, as an evidence of payment to them.

Mr. Barnaby: There is a distinction to be drawn here. The last speaker seems to have confused the work of paying with the accounting. The paymaster's department on our road has nothing whatever to do with the accounting of the pay rolls. That is done by the auditor's department. That is all checked up, the calculations and the proper headings, to see that maintenance of way is not charged against construction of buildings and so on. That accounting department is an entirely separate and distinct thing from the mere labor of paying the men. All the paymaster does is to pay the men. That is all he has to do. As far as the delay in receiving the money is concerned, the same process is pursued by us, practically, as the gentleman speaks of; that is, the first car out is paid first and just as soon as that car has made a round trip the paymaster knows he has covered the road; and he pays the people employed about the depot during the intervals between the cars.

Mr. Begg: It would seem to me then that the whole paymaster's department of your road is an unnecessary expense. You say, and I agree with you, that the matter of accounting is done in the accounting department; and if a check were drawn at the same time it would virtually increase the labor but very slightly, and you would have reduced your expenses by the whole cost of your paymaster's department, besides giving the men their money much more promptly and satisfactorily.

Mr. Barnaby: While you say it is just as convenient to pay a line having 4,000 or 5,000 men with checks as to give them the actual money, I disagree from you there. I do not know what the conditions are in other cities, but I have no doubt that in Brooklyn nine-tenths of them would find their way to a liquor saloon to get their checks cashed, for about our car houses there is always a number of saloons. That seems to be a necessary concomitant that goes with a car barn. I do not know why it is, but it is so. There is no local bank there, and in any case a bank does not do that work for nothing. You must give them some consideration for cashing the checks, or else the saloon keeper is going to cash them for a consideration. I think that would be a very disagreeable feature of that system at the outset.

Mr. Hibbs: Is it Mr. Begg's idea to have those checks drawn to bearer or to order and have them endorsed?

Mr. Begg: I should have them drawn to order with what would virtually be a receipt on the back of the check.

Mr. Williams: Although a small road, we think we have a good system with reference to paying. We pay by check to order. Previous to that we paid the cash in an envelope. We pay every week, by the way. We found it took quite a little time for the men to come in off their work if they were out a little bit; and also if there was any dispute they had to go to the foreman and the foreman would have to be brought in before the paying clerk. We consider the check system the better. With regard to the liquor question, we find, though, as I have said, a small road, that the check system has been quite a check on the liquor traffic in the vicinity of our pay station. (Laughter). The men do not feel like going into a liquor store to have their checks cashed. They take the checks, put them in their pockets, go home to their families, clean up, go down town and go to their grocers and say, "Here, will you cash this check, please?" The grocer takes out the \$6 or \$7 that the man has got tick for that week and the rest goes to the man's family. The man isn't in the habit of going to a liquor store and spending 15 or 25 cents on the cashing of his

check. He pays his honest bills, and the storekeepers in the small town we have appreciate it very much.

Mr. Babcock: I have listened to the discussion with considerable interest, and although ours is a small road also, paying about 150 men a week, we have followed the system that some of your larger roads have, but with this slight difference—and it seems to me that our system covers some of the advantages of the check system and at the same time does away with some of the objections. Our pay rolls are made up by the superintendents of the different departments, and the superintendent of the department who makes out the pay roll also makes out his little blank form that I spoke of, which is of such a character that if lost anywhere the person finding it would never dream what it was good for. It is good for nothing until it has the man's name to it, until he signs his name, and there is a place also for those who cannot sign their names to make their marks and have it witnessed by the superintendent. Our little blank form, as I said before, reads: "Received from the Elmira & Horseheads Railroad Company, \$—, in full for services rendered," with a place for the date. So you see it is a receipt in full. There is also the place for the signature, and at the bottom it gives the number on the pay roll and the date of the pay roll. Now, that is all made out by our superintendent or foreman of the shop, which ever the case may be. The man then brings that ticket to the office after 4 o'clock on Monday—Monday is our pay day. The money is then ready for him. If he cannot come conveniently at that time he can give it to his wife, or to his boy, and he signs his name to the ticket. The name and the number on that particular pay roll must agree with the amount or else the cashier does not honor it. But once he gets his money we have a receipt. That we file away among our pay rolls. That does away with all the confusion of getting a signature when you have a crowd of men all signing the pay roll at one time.

Mr. Read: We are a small road, but I would like to state how we obviate disputes with regard to payment of the men. We furnish each man with a time book, quite a small thing, with a place for the date, the number of the car, and whether motorman or conductor, the number of hours he has put in and a place for him to sign. When they put their reports in they enclose this slip daily. The relief man does the same thing. The car runs so many hours a day. When the report comes in the time ticket is checked up, and the time of the relief man, the motorman and the conductor amount to just the time that the car has run. That is done every day, checked every day, and it settles the man's time. When pay day comes around, should there be any dispute we are not obliged to run after any one to find whether the man has made that time or not. We simply take the time slips and produce them. I might say, too, there is a stub in his time book where he is supposed to keep a record of what he puts in at the office. With regard to the barn men, they hand their slips to the foreman. He O.K.'s these slips and puts them in to the office. We have no trouble at all with disputes as to paying the men.

Geo. D. Fearman, Hamilton Street Railway Company: We take the total hours that the car has run each day, and then for any extra cars the foreman hands in a slip, and we keep the record of that in a book. We pay twice a month, and at the time of each pay we take, like 13 days, the regular hours, and then add the extra hours to that; and that has to agree with the total hours. If there is any mistake we look over each day's work and get the mistake down to a particular date.

Mr. Dimmock: Those gentlemen here that are or have been connected with steam roads well know that all over the country they have a register where their conductors register in and out. Our system is the same as that of the steam roads. We simply have a register. They place their names on it when they go out, and the same thing when they come in, with the time, and that is turned over to the auditing department. The men know nothing further about the accounting until they are paid off. If there is any dispute about it it is simply referred to the register, which is in their own handwriting; and in that way we have very little dispute.

Mr. Hibbs: Ours is made up from time slips, as Mr. Dimmock states, or the register; but they are examined in the auditor's office from the day card; that is, conductors and motormen.

The Chair: This question seems, like a great many others in connection with accounting, to be one of local conditions and

individual ideas. I think we have all learned a great deal. I am very sure I have, right here, on this question. It strikes me that the three important questions are as to whether you should use checks or not, whether you should use envelopes or not and whether you should get a receipt or not. If there is no further discussion on this subject we will proceed to the next order of business, "Materials and Supplies Accounts from Purchase to Use," by W. G. Ross, comptroller, Montreal Street Railway Company, Montreal.

#### MATERIALS AND SUPPLIES ACCOUNTS FROM PURCHASE TO USE.

By W. G. Ross, Comptroller Montreal Street Railway Company, Montreal.

The purchasing and storekeeping of materials and supplies are of great importance to street railway companies, requiring careful and constant watchfulness both on the part of the purchasing agent to secure the best materials at the lowest price, and of the storekeeper to see that they are properly handled and distributed. In the purchasing of materials and supplies the company cannot be too careful in the selection of the man appointed as purchasing agent—his honesty must be beyond all question, and his capabilities and experience such as to warrant his appointment to this most important position.

In purchasing it is advisable, wherever possible, to call for tenders or quotations, and the lowest should invariably be accepted, and no favoritism shown. Price lists of standard goods should be kept carefully at hand, and catalogues systematically filed. Materials purchased should be the best obtainable, and careful watching required to purchase the most modern and best goods, it being false economy to purchase anything but the best. Especially is this the case in the electrical equipment of the cars—it is here that the great expense of maintenance come in, probably more than one-half of the supplies purchased for repairs are on this account, and experience has shown that it is only the best material that will stand the great strain that the electrical equipment is called upon to bear.

Great care should also be exercised in the purchasing of new electrical equipments, as changes, improvements and economies are rapidly taking place as the defects and weaknesses of the apparatus become apparent. By reason of these continual changes and improvements the purchasing agent should be in close touch with the manager and the heads of the shop departments, and consult with them, as also with the storekeeper, to see that the smallest possible stock of materials is kept on hand, and that no accumulation of out-of-date articles takes place. All purchases made should be ordered on an official manifold form, plainly numbered and having stated thereon the places goods should be delivered (no allowance for packing) and that all invoices must state Order No. and accompany goods.

The storeroom should be conveniently situated near the principal shops of the company, and should be so arranged that supplies can be easily handled. All material and supplies, whether for construction or operation, should be in charge of a storekeeper. When material is required a requisition on the storekeeper should be made out on a regular printed form, signed by the foreman in charge and countersigned by the superintendent of the department. The requisition should state the article, quantity, and what required for, opposite which the storekeeper fills in the value, as it is from these requisitions that he classifies the actual material used during the month under the different headings for his monthly statement furnished the office.

The storekeeper should keep careful watch on his stock, keep it as low as possible, and see that there is no accumulation of out-of-date articles. When any supplies are required by him he should make out a requisition on the purchasing agent, giving the date for which it is required.

The storekeeper should keep a stores ledger, with accounts for the principal articles, in which ledger should be entered in the debit the invoices of goods as received, and the credit material used—the balance should agree with his stock in hand.

All manufacturing or construction work should be done on a numbered shop order, appropriation for such work having first been duly made by the directors of the company.

The storekeeper should have charge of all scrap material; he

W. G. ROSS.

W. G. Ross was born in Montreal, August 6, 1867. As early as 1886 he was associated with his father as an accountant and auditor. He became successively secretary, treasurer and assistant manager of the Windsor Hotel Company. From 1892 he has been with James Ross who controls many of the large street railway interests in Canada. Mr. Ross has acted as private accountant and has reorganized the accountability of the various companies. At present he is auditor of the St. John Railway Company and comptroller of the Montreal Street Railway Company. Mr. Ross is a member of the Chartered Accountants of Montreal.

should have convenient places for safe storing, and the purchasing agent should dispose of same as frequently as possible, so as to prevent any accumulation.

All payments for materials and supplies should be made only on the company's own weights.

Returns of scrap material turned in to the storekeeper should be made direct to the office from the foreman of the shops, and no delivery of scrap material sold by the storekeeper should be made without an order from the office stating that payment has been received.

In the smaller companies it is desirable for the sake of economy to combine the position of purchasing agent and storekeeper; where this is done it is important that the purchasing should be done under the direct supervision of the manager.

In conclusion, the official in charge of the office should keep careful oversight of material and supplies from their purchase till consumption, watching the prices paid as also the returns of the storekeeper of the material used, as on him the management must depend to a great extent to see that the company receives full benefit from these important departments.

On motion of Mr. Beggs, it was voted to make the annual dues cover the calendar year, from January to January.

Adjournment was then taken until Thursday morning.

#### Thursday Morning.

Vice-President Duffy called the meeting to order promptly at 10 o'clock, and announced a discussion of Mr. Ross' paper read the previous day as the first order of business.

Mr. Brockway: May I ask Mr. Ross how he keeps track of material which is charged to the account immediately on purchase—if it is not all used this month. Say, for instance, you should buy a small quantity of anything and charge it out immediately to the account to which it referred.

Mr. Ross: I do not charge anything out immediately.

Mr. Brockway: It all goes to the storehouse?

Mr. Ross: It all goes to storage.

Mr. Hibbs: Do you carry your coal in the general store account, coal used at the power house and so on?

Mr. Ross: Yes.

Mr. Hibbs: You don't have a separate material account for power house?

Mr. Ross: No. We get a return from the power house on the coal used during the month.

Mr. Hibbs: Instead of carrying it in a separate account you carry it in the general store account?

Mr. Ross: Yes.

The Chair: Do you throw everything into your stores account, sand and salt and coal and everything?

Mr. Ross: Everything goes into stores.

Mr. Brockway: Do you find you keep such close track on it when you take your inventory that you hit it pretty closely?

Mr. Ross: Yes.

Mr. —: We buy a great deal of stuff that is not worked up, and there is quite a little labor to be put on it before the article will be charged out of the stock. What method do you have of adding the labor to this raw material? The labor, of course, would go into pay roll and would not appear in the supply account.

Mr. Ross: Mention an item?

Mr. —: Well, we buy brass and it is worked up into little castings that are used on the armatures or some electrical part. Now, the regular charge is to stock and then they merely arbitrarily charge a percentage, what they think would be the labor. Of course it is hard to compute what the labor is on any one thing, where a great many are made and the pieces are small and large together, one being probably ten times as much as the other, the labor being charge to stock and the goods being charged out at the increased cost which is supposed to take up the accumulated labor charge that has been thrown into the stock, and would ordinarily wipe it out. You didn't speak of that.

Mr. Ross: We don't have any manufacturing of that sort at all. We buy all of our brass castings complete. I should not see any difficulty in that; it is simply charged to stores.

Mr. Hibbs: We render regular invoices from the repair shops the same as any outside party.

Mr. Davies: How often do you check off your store stock account by taking an inventory?

Mr. Ross: Once a year. We just completed our inventory before I left. Our year commences the 30th of September, and we were only out about \$200 in the year on materials. It is our custom to make out requisitions, and when the requisitions come in from the shops for materials they specify for what the material is to be used, and the storekeeper keeps a blotter from which he gives a return at the end of the month showing where the different material has been used, and we give him credit for that.

Mr. Brockway: I noticed that Mr. Calderwood in his paper in the "Street Railway Review" a short time ago had an excellent article on materials and supplies. Do you have that method which I have referred to, Mr. Calderwood, of buying small quantities of material and charging it directly to the account interested instead of throwing it into materials or supplies account?

Mr. Calderwood: No; everything goes into store house, every article of supplies.

Mr. Brockway: Is that true of transfers?

Mr. Calderwood: No; the transfers go right into the operating department.

Mr. Brockway: You charge the bill for those transfers out directly?

Mr. Calderwood: Yes. We handle our transfers a little differently.

The chair then called for the report of the committee appointed at Cleveland, on a Standard System of Accounting. This committee consisted of C. N. Duffy, chairman, St. Louis; W. F. Ham, Brooklyn, and J. F. Calderwood, Minneapolis. The task was much greater than any ever assigned to any committee in either Association, and involved an enormous amount of work. Upon its appointment the committee went immediately at work to secure the necessary data, and while somewhat handicapped in its work by reason of being obliged to confer by correspondence, the work was systematically laid out, and each member devoted a large amount of his personal time. The result was that each member brought to Niagara a carefully worked out plan, and out of these three plans, the report was evolved. The committee was in session all of the four days preceding the convention, its labors lasting until after midnight each day. While each member is extremely modest in speaking of the work performed, it is due them that the fraternity know and appreciate the volume of the undertaking. The result has been most highly gratifying to all concerned. The work of the committee places the entire street railway fraternity under lasting obligations, first to the Accountants' Association which created and furnished the committee, and second to the gentlemen who actually did the work. It could not be expected that an undertaking of so much moment should be perfected in six months, and the committee intended its report should be still further studied and improved; and the Association acted wisely, although it is asking a good deal of the three gentlemen, when it continued the same committee as the permanent committee on this report.

The report was presented by Mr. Ham, who prefaced it with the following remarks:

We communicated with the state boards of railroad commissioners of Massachusetts and New York, asking them to be represented at this meeting. The Massachusetts board was unable to be represented on account of the fiscal year of the railroads of that state closing on September 30. The secretary of the State Board

of Commissioners of this state, Mr. DeFreest, has been here and we have profited very largely from what he has said to us. He has shown an interest in this work which is very encouraging; and, speaking for myself, as a New York member, and for other New York members, I believe we shall have no difficulty in getting Mr. DeFreest to work heart and soul with us in this movement. Now, that means a great deal to New York roads, because they are compelled to keep their books as the state requires, and if we can bring them to meet our views in the matter, the situation is simplified to a very large extent. Now, we differed from Mr. DeFreest in many particulars, but he says that on small things he is not inclined to quibble. He sees the advantage of this thing as a national movement and is very much interested in it. He thinks, and we are convinced by him, that we are wrong in one matter, inasmuch as we do not carry it quite far enough. What we have said is all right, except that we should have it read "Income from Sale of Power"—"Cost of producing power sold is to be deducted from cost of operating power plant," and that "profit or loss, if any, resulting from the sale of that power is to be carried directly to income account, either as income from other sources or as a deduction from income," because the point was brought up in this light, that it might be possible for a company to operate its power plant for \$500,000 a year, but it sells \$600,000 worth of power, making a very large profit on it. You cannot very well deduct \$600,000 from \$500,000 without getting into difficulty; and that seems perfectly right and logical. The only point that we then wanted to ask him, was, "How are you going to arrive at the cost of that power, that is, the true cost?" and it seemed not to be a difficult matter to take the actual cost of operating a power plant, just as we have it here; add to that the expense of maintenance of the power plant, approximation of the interest on the amount invested, depreciation and such things as that.

#### REPORT OF THE COMMITTEE ON A STANDARD SYSTEM OF ACCOUNTS.

Niagara Falls, N. Y., Oct. 21, 1897.

*To the President and Members of the Street Railway Accountants' Association of America:—*

Gentlemen:—At the organization meeting of your association held in Cleveland, March 23 and 24, 1897, a resolution was adopted appointing a committee to consider the question of a "Standard System of Street Railway Accounting," covering the classification of operating expense accounts, classification of construction and equipment accounts, and form of annual report. The character and scope of the work assigned to this committee, as understood by it, is expressed in a circular letter mailed on June 15, 1897, to 717 street railway companies of the United States, Canada and Mexico, asking for copies of their blanks and forms and for suggestions as to classification.

The following gentlemen responded to the circular letter, forwarding blanks, forms, etc., which were of valued assistance, and materially aided the committee in the work of preparing its report:

H. C. McJilton, auditor Baltimore Traction Company, Baltimore, Md.

Dana Stevens, auditor The Belt Railway Company, Washington, D. C.

S. A. Frazier, secretary and treasurer Centralia & Central City Street Railway Company, Centralia, Ill.

Frank R. Greene, secretary Chicago City Railway Company, 2020 State Street, Chicago, Ill.

H. P. Bradford, general manager The Cincinnati Inclined Plane Railway Company, Cincinnati, O.

P. V. Burlington, secretary and auditor The Columbus Street Railway Company, Columbus, O.

E. D. Hibbs, auditor Consolidated Traction Company, Jersey City, N. J.

C. Wuestefeld, manager Elgin City Railway Company, Elgin, Ill.

E. S. Doud, secretary Lehigh Traction Company, Hazelton, Pa.

F. E. Smith, auditor Lynn & Boston Railroad Company, Lynn, Mass.

Edward Daniell, secretary, treasurer and superintendent Menominee Electric Light, Railway & Power Company, Menominee, Mich.

W. F. HAM.

C. N. DUFFY.

J. F. CALDERWOOD.

C. N. Duffy was born in St. Louis, August, 14, 1859 and received his education in that city, first at a private school and later in St. Louis University. At the age of 14 he became a shipping clerk in a grain house and continued in the mercantile business for 12 years, holding various positions. In May, 1886, he was chosen secretary and treasurer of the Union Railroad Company and in 1888 he was also elected to fill the same positions with the Citizens' Railway Company. The National Railway Company of Chicago absorbed the Citizens', Cass Avenue, Northern Central and Union lines in 1889 and Mr. Duffy was chosen secretary and treasurer of these four companies.

William F. Ham, secretary of the Nassau Electric Railroad Company of Brooklyn, was born in Lewiston, Me., March 15, 1870. After fitting for college he entered

Bates' College in 1887 but was obliged to withdraw at the end of a year because of serious illness. In 1889 Mr. Ham went to New York and engaged with the Equitable Life Assurance Society, being with that company for four years in various capacities among them chief book keeper for one of the large subordinate corporations and later as private secretary to the second vice-president. He left the Equitable to go with the Johnson Company as assistant in the New York office where his acquaintance with railway men commenced. The Nassau Company having in view the lease of the Atlantic Avenue Lines, Mr. Ham was offered the position of cashier and accountant which he accepted. In April of the present year he was elected to his present position. Since his connection with this company he has had entire charge of the accounts and brought the system up to a point of high efficiency.

W. G. Ross, comptroller Montreal Street Railway Company, Montreal, Can.

John Mahoney, vice-president and general manager People's Railway Company, St. Louis, Mo.

Robert Lehman, secretary and treasurer St. Louis & Suburban Railway Company, St. Louis, Mo.

W. B. Brockway, auditor Toledo, Bowling Green & Fremont Railway Company, Toledo, O.

H. L. Wilson, auditor West End Street Railway Company, Boston, Mass.

Geo. S. Rolins, auditor St. Joseph Railway, Light, Heat & Power Company, St. Joseph, Mo.

Proper acknowledgment was made to each gentleman who responded, but we desire to take advantage of this opportunity to again thank those gentlemen for the interest manifested and the cooperation extended.

In this connection, we desire to express our thanks to the Street Railway Review and the Street Railway Journal for their kind offers to do everything in their power to help the committee in its work and promote the success of the Accountants' Association. Both papers rendered the committee and the association valuable assistance in publishing the circular letter and commenting on same in their editorial columns. We are also indebted to Edward E. Higgins, editor of the Street Railway Journal, for the valuable suggestions contained in his editorial, which appeared in the August number of the Street Railway Journal, on "A Standard Distribution of Street Railway Receipts and Expenses."

The committee also desires to thank the representatives of the State Boards of Railroad Commissioners of New York and Massachusetts, for their courtesy in responding to requests for the classification of operating expenses and form of annual report, as prescribed by each state board respectively.

In taking up the subject of a "Standard System of Street Railway Accounting," there are many points that present themselves for consideration. Without intending to go into an exhaustive discussion of them, your committee deems it wise to bring to your attention some of these points, as they have an important bearing on the subject.

The adoption and use of a standard system of accounts for street railways is entirely practical, notwithstanding the objections that may be urged to the contrary. The argument may be advanced that there would be serious objections to changing present methods and systems on the part of the accounting officer, manager, officers, directors, or stockholders of some roads, for various reasons; objections may be raised on the ground that

special ruled account books, form of reports, etc., would have to be discarded, because they would be useless with a change of system; it may be urged by the street railways of Massachusetts and New York, that they are obliged to keep their books and accounts as prescribed by their respective State Boards of Railroad Commissioners, and for that reason they would object to using any other system. In answer to these or any other objections that may be raised, your committee submits that they should not be allowed to stand in the way of adopting a standard system. If the difficulties referred to above prove to be insurmountable, it should be remembered that a standard system could be conformed to, without changing the methods and system now in use on any one road. Unquestionably it would be far better for all to follow, from beginning to end, any standard system that would be adopted. As far as our Massachusetts and New York friends are concerned, your committee suggests that this association should confer with the State Boards of Railroad Commissioners of Massachusetts and New York and secure their cooperation in the framing, adoption and use of a standard system. We firmly believe that this can be done. What has been accomplished in the steam railroad field, can be accomplished in the street railway field. We appeal to you to see that it is accomplished. Your committee desires to impress upon the members of this association the value and importance of the adoption and use of a standard system. We do not consider it necessary to advance any arguments in support of this proposition, as it is assumed that this association is unanimously in favor of it. We most respectfully urge that the proper action be taken by this association, now in convention assembled, to successfully overcome all difficulties, so that the desired results may be accomplished now.

With that end in view we would recommend that a permanent committee be appointed for the promotion of the adoption and use of a standard system. In order to bring this about we would suggest that the report of this committee be placed in the hands of the permanent committee with full power to make such additions or alterations as it may deem proper; with authority to confer with the proper officials of any state prescribing a standard system of keeping street railway accounts, and with street railway companies, whether members of this association or not; and to submit a printed report at the next annual meeting of this association, with instructions to have a printed copy sent to each member of this association at least sixty days before the annual meeting takes place.

There are many other questions concerning the adoption and use of a standard system that could be discussed at length; for

example, the method of making charges in operating expenses; the pro-rating monthly of the yearly expense of water, taxes, insurance, interest, or any other charge that it would be desirable to pro-rate; the extent that detailed and statistical information should be furnished, so that the management of the road will profit by such information; the difficulty of putting into practical operation, any standard system that may be adopted, because of the dependent position occupied by the accountant, with reference to relying upon subordinates and heads of departments for information as to the basis of charges; the extent to which conditions of operation affect results and comparisons, and the necessity of taking them into consideration; the proper unit as a basis to figure from, whether per car, per car-mile, per passenger, or per mile of single track operated; the care that should be exercised in making charges to construction and equipment accounts; the necessity of charging off annually a certain amount for depreciation; and the creation of a sinking fund or surplus account, that will really be what it means, with the amounts credited invested in a safe, interest earning investment. These, and many other questions could be gone into here, but your committee has thought it best not to do so, further than presenting them to your notice. It was supposed that the exhibits accompanying this report would furnish ample matter for discussion, and that all such questions would be taken care of, in discussing the exhibits.

Appreciating the magnitude and importance, as well as the delicacy of the work undertaken by your committee, as outlined in its circular letter, realizing the difference of opinion and practice that prevails among street railway accountants, as to the methods and systems used, as evidenced by the blanks and forms sent to your committee, we invite careful consideration, full discussion and the most severe criticism of the following report.

Very respectfully,

C. N. Duffy,  
W. F. Ham,  
J. F. Calderwood,  
Committee.

The following classifications are prepared to meet the requirements of a street railway constructed and operated as an overhead electric road. They could be easily arranged and adapted for use on an electric railway using an underground or third rail system, and could also be easily changed to meet the requirements of a cable railway or one operated by any other power. All that would be necessary to make the classifications practical for use on any other than a street railway constructed as an overhead electric road would be to change the technical names of the appliances used on any one of the other systems mentioned.

#### CLASSIFICATION OF OPERATING EXPENSE ACCOUNT.

*"A" Maintenance of way and structures :*

1. Repairs and renewals of track and roadway construction.
2. " " " " electrical track construction.
3. " " " " buildings and improvements.

*"B" Maintenance of equipment :*

4. Repairs and renewals of steam plant.
5. " " " " electrical plant.
6. " " " " cars.
7. " " " " electrical car equipment.
8. Renewals of horse and vehicle equipment.
9. Repairs and renewals of miscellaneous equipment.
10. " " " " shop tools and machinery.

*"C" Conducting transportation :*

#### OPERATION OF POWER PLANT.

11. Power plant wages and superintendence.
12. Fuel for power.
13. Water for power.
14. Lubricants and waste for power plant.
15. Miscellaneous supplies and expenses of power plant.
16. Hired power.

(Note.—Income from sale of power is to be deducted from cost of operating power plant.)

#### CAR SERVICE.

17. Superintendence of transportation.

18. Wages of conductors.
19. " " motormen.
20. " " other car service employes.
21. " " car house employes.
22. Car and motor supplies.
23. Miscellaneous transportation expenses.
24. Cleaning, watering and sanding track.
25. Removing of snow and ice.

*"D" General Expenses :*

26. Salaries of general officers.
27. Salaries of clerks.
28. Printing and stationery.
29. Miscellaneous office expenses.
30. General stores expenses.
31. General stable expenses.
32. Advertising and expense of park properties.
33. Miscellaneous general expenses.
34. Legal expenses.
35. Injuries and damages.
36. Track rentals.
37. Rental of land and buildings.
38. Insurance.

#### CLASSIFICATION OF CONSTRUCTION AND EQUIPMENT ACCOUNT.

1. Organization.
2. Engineering and superintendence.
3. Right of way.
4. Track and roadway construction.
5. Electrical track construction.
6. Real estate used in operation of road.
7. Investment real estate and improvements.
8. Buildings and improvements used in operation of road.
9. Power plant equipment.
10. Shop tools and machinery.
11. Cars.
12. Electrical car equipment.
13. Miscellaneous equipment.
14. Interest and discount.
15. Miscellaneous.

#### FORM OF ANNUAL REPORT SHOWING INCOME ACCOUNT.

| Surplus December 31, as per general  |       |
| balance sheet .....                  | ..... |

In attempting to establish a uniform and standard system of street railway accounting your committee has constantly kept in mind that it was trying to establish a system which would be applicable not only to the large roads, but to the small ones as well; to the road that runs a thousand cars as well as to the road that runs a half dozen.

This requires an elastic system of accounting, a system which rests on a common foundation, with details so arranged that they can be made to meet the varying requirements of any and all roads. Most important of all, we must have a foundation upon which all can work to advantage, which will not require more than the customary amount of bookkeeping and accounting and which will contain the general features which the street railway manager has been accustomed to look for.

It has been our aim to make the classifications so distinct and so clearly defined that there can be no mistake and that the same constituent elements will at all times be embraced in these different classifications.

The fundamental principle underlying the efforts of your committee was found in the determination to agree upon a minimum number of accounts consistent with furnishing the necessary information to place the management at all times in touch with not only the operation of their particular system, but with that of any other system.

Classification of Operating Expense Accounts.—We have divided the operating expenses into four general divisions: A. Maintenance of Way and Structures. B. Maintenance of Equipment. C. Conducting Transportation. D. General Expenses. The first two divisions have a direct effect on the physical condition of the property; the last two include only such items as are strictly operating expenses, and have no direct effect upon the physical condition of the property.

With reference to the first two divisions covering maintenance accounts, the important consideration seemed to be whether or not it was desirable and practicable to make a separation between repairs and renewals. In the operation of electric street railways, offering as they do many opportunities for adopting a variety of electrical and mechanical devices with variance in the economy of maintenance, this separation would seem of value and importance, especially so when we consider the repairs and renewals of the larger and more expensive units of our large apparatus, such as generators, etc. As an abstract proposition this looked very feasible, and recognizing the many advantages of such a separation, the committee attempted to work out a plan which would embody this separation. A closer and more careful analysis of the component parts of each of these two divisions led the committee to believe that in very many cases such a separation would be nothing more than a distinction without a difference. While it might be possible to make such a separation in the larger units, it did not seem to be practicable to make this separation throughout without causing a great deal of confusion and an endless amount of work in arriving at results which in the end would be both unsatisfactory and incorrect.

As it is essential to have information as to the amounts expended in renewals, the committee suggests and recommends that the most feasible way to present this information would be in the form of an analysis of the maintenance accounts showing the items properly chargeable to renewals, distinct from repairs.

As an illustration of the point: assume that the account of repairs and renewals of track and roadway construction amounts to \$10,000 for a given period, an explanation would be made showing that of this amount \$5,000 was expended in constructing a certain length of track and the balance consists of ordinary repairs. While the separation shown in this case is comparatively easy, the task becomes more difficult and results more unsatisfactory in attempting to make such a separation with reference to electrical car equipment.

Coming to a consideration of the accounts under the general heading of Conducting Transportation, we have grouped these into, first, Operation of Power Plant, and second, Car Service. In the former the only feature which requires special mention is the deduction of income from sale of power from the cost of operation of power plant. This is probably a radical change from the present method, as this item is usually shown under miscellaneous income.

As the cost of producing any power that may be sold has been included in operating expenses, and as all amounts received from sale of power may be assumed to represent approximately the actual cost of the production of that power, it seems proper that it should be shown as a deduction from the cost of operating the power plant. To show the logic of this proposition an illustration may be made of two electric roads, one of which has no power plant and buys its power outright from another company. In this case the first company would have no expense of operation of power plant other than hired power; and cost of operation of the power plant of the second company would be increased by the amount of power which it had furnished to the first company, throwing it out of all proportion of what would be produced for the operation of its own cars; and the actual cost of producing power for the second company can only be shown by deducting from the cost of operating the power plant of the second company the amount received from power furnished the first company. To make this even more clear, suppose in the above instance that each company operates 100 cars, making a total of 200 cars; the cost of power for operating these 200 cars is, say, \$100,000, of which \$50,000 is shown as hired power on the books of the first company and \$100,000 less the deduction of \$50,000 for sale of power, leaving \$50,000, on the books of the second company.

With regard to the accounts Cleaning, Watering and Sanding Track and Removal of Snow and Ice, the committee has recognized the wide diversity of opinion and practice in classifying these accounts. The point at issue is whether they should be treated as maintenance charges or as transportation charges. In deciding this question the committee has followed the general principles that all maintenance charges have a direct bearing upon the physical condition of the property, while transportation charges do not. The physical condition of the property is not in any way benefited by either of these accounts, and therefore they properly belong to transportation.

Coming now to a consideration of the accounts under General Expenses, the committee has thought it best to provide the account Printing and Stationery, and to include in that one account the cost of all printing and stationery of every description, except the cost of printing transfers and tickets charged in Transportation; printing of law briefs, etc., charged in Legal Expenses; and the cost of printing posters, dodgers, handbills, etc., for advertising purposes charged in Advertising and Expense of Park Properties. With this arrangement all printing and stationery except the above items, would be charged in a general printing and stationery account. Your committee deemed it preferable to do this rather than distribute the cost of printing and stationery over a number of other accounts, the result of which would be that the total cost of stationery and printing would be lost sight of. Furthermore, the amount expended in printing and stationery would not justify the expense of accounting in order to distribute it among the various accounts, although the amount in the aggregate is an important item. Should the question be asked why the cost of printing transfers and tickets has been charged to Conducting Transportation and the cost of conductors' trip sheets, envelopes, etc., left in General Expenses, the reply is that the former have no connection with accounting, and the latter have.

The committee has thought it best to have the account General Stores Expenses to provide for such expenses in the case of roads that operate a general stores department. If such an account were not provided it would be difficult to charge such expenses to any other account.

The committee has also provided the account General Stable Expenses, for the reason that it was deemed advisable to have all general stable expenses in one account rather than to attempt to distribute such expenses among the various accounts benefited thereby. Such a distribution would be difficult and unsatisfactory,

and besides, the total cost of general stable expense would be lost sight of. In the case of construction work causing an abnormal increase in this account, such charges as are proper should be taken out of this account and charged in construction accounts.

The committee has recognized the wide difference of opinion and practice in the matter of Injuries and Damages, with reference to placing it in Conducting Transportation, or in General Expenses. Many arguments can be advanced in support of the disposition of Injuries and Damages to either, and the committee has fully and carefully considered the question from all points of view. It has finally decided to place it in General Expenses for the reason that a large portion of the account is not properly chargeable to transportation. In the first place, the measure of damages assessed in many cases rests upon the prejudices and whims of juries, and their findings are beyond the control of the manager of the road and therefore should not be charged in transportation. Again, damage claims may be settled or judgments paid as the result of accidents occurring in which there is no connection with transportation. Again, it appears to be both reasonable and consistent to put damages under the same general heading as Legal Expenses, where the latter unquestionably belongs, on account of the close relationship of one to the other.

With regard to Track Rentals, the committee has recognized that this is another account concerning which there is an equal difference of opinion and practice as to where it properly belongs. Some hold that it properly belongs to Conducting Transportation, other to Maintenance of Way, on the ground that Track Rentals are really an avoidance of maintenance charges, and others still to General Expenses. As a matter of fact the occupation and use of the tracks of one street railway company by another in cities is attended by varied conditions, and in arriving at the compensation to be paid, there are many questions that have to be taken into consideration. For example, the amount of revenue that the lessee will take away from the lessor by reason of operating its cars over the tracks of the lessor; the portion of the franchise taxes on a mileage basis that the lessee should bear; the interest on cost of construction and the cost of maintenance and renewals of not only the track and roadway construction, but the electrical track construction as well; the expense of cleaning, watering and sanding track and removing of snow and ice, which should be borne proportionately by the lessee; and the hindrance to the lessor in the operation of its cars that may result by reason of conditions under which the cars of the lessee are operated. For these reasons as well as for others that might be advanced, your committee has determined to place the account in General Expenses.

In the above discussion, the committee has dwelt only upon such features as seem to require special mention. Appended to these remarks is a detailed classification of operating expense accounts intended to show clearly and beyond question the items to be charged to each account. Incidentally the committee calls attention to the fact that any money received from the sale of old material or scrap should be credited to the account to which the material was originally charged. The committee has worked under the disadvantage of prosecuting its work by correspondence and has been limited in time. For this reason it may be that improvements in phraseology and in expression will suggest themselves. We believe, however, that the classification of operating expenses as submitted contains the essential features required in a simple, concise and elastic system of street railway accounting, and that it can be adopted and used by all railroads, large or small, under all varying local conditions. If further separation and classification is desired by any or all companies to meet varying local conditions, it can be done without disturbing in the least the present classification, by the use of other accounts carried as sub-divisions of the prescribed accounts, or if still further itemization is desired each account may be carried in detail on separate distribution of expense books.

The committee feels that, under the circumstances, it has done satisfactory work, and earnestly hopes that the classification suggested may be adopted as a standard with such modifications as may be deemed desirable.

#### CLASSIFICATION OF OPERATING EXPENSE ACCOUNTS.

##### "A" Maintenance of Way and Structures.

1. Repairs and Renewals of Track and Roadway Construction. This account embraces the cost of labor, materials, supplies, tools and expenses of repairs and renewals of track and roadway construction, including renewals of ties, renewals of rails, repairs and renewals of joints, repairs and renewals of special work, such as crossings, crossovers, curves, guard rails, frogs, switches, etc.; ballasting, repairs and renewals of paving, repairs and renewals of bridges, culverts and subways; repairs and renewals of crosswalks; wages of roadmasters, track foremen, laborers, watchmen and others employed in above work; cost of punching, drilling and cutting rails, except for track wiring. When track is taken up, the labor expended therefor should be charged to this account whether another track is laid to replace it or not. The cost of tracks in car houses is included in this account.

2. Repairs and Renewals of Electrical Track Construction. This account embraces the cost of labor, materials, supplies, tools and expenses of repairs and renewals of electrical track construction, including cost of taking up, resetting and painting poles; repairs and renewals of trolley, feed, guard and supplementary wires and track bonding, underground feeders and conduits.

The expense of taking up and relaying paving when necessitated by repairs and renewals to electrical track construction is chargeable to this account and not to account No. 1.

3. Repairs and Renewals of Buildings and Improvements. This account embraces the cost of labor, materials, supplies, tools, and expenses of repairs and renewals of buildings and improvements, including power houses, repair shops, blacksmith shops, machine shops, paint shops, carpenter shops, car houses, stables, office buildings, depots, stations, switch tenders' houses, store houses, sheds, coal bins; and improvements in connection with same, including drainage, water, gas and sewer pipes and stationary fixtures belonging thereto, heating and lighting apparatus and fixtures, other stationary fixtures, sidewalks, street paving on streets in front of and adjacent to buildings, fences, sheds, out-houses, etc. Repairs of pits in car houses and shops, and repairs and renewals to docks and wharves are to be charged to this account. Repairs to track in car houses and yards must be charged to account No. 1, and repairs to electrical track construction in car houses and yards must be charged to account No. 2.

This account includes the cost of labor and material used in replacing buildings, sheds, etc., that have been destroyed or injured by fire or otherwise become unfit for use. The replacing of a better or more expensive building or parts thereof should be charged to this account to the extent of the ledger value of the buildings or parts thereof rendered unfit for use, and the balance should be charged to construction account.

This account should not include repairs and renewals of buildings and improvements not used in connection with the operation of the road.

##### "B" Maintenance of Equipment.

4. Repairs and Renewals of Steam Plant. This account embraces the cost of labor, materials, supplies, tools and expenses of repairs and renewals of steam plant, including engines and engine parts, appliances and fixtures, belts, belt tighteners and fixtures, receivers, lubricators and oiling devices, shafting, clutches, cranes, hoists and other engine room appliances; boilers, boiler fittings and appliances; furnaces, economizers, stacks, mechanical draft machinery, pumps, feedwater heaters, purifiers, tanks, condensers, coal and ash conveying machinery and other boiler room appliances; piping and steam fitting, including valves, separators, water and sewer connections and water meters.

5. Repairs and Renewals of Electrical Plant. This account embraces the cost of labor, materials, tools, supplies and expenses of repairs and renewals of electrical plant, including generators and generator parts, switchboards, cables and feeder terminals and wiring in connection with same, storage batteries, transformers,

boosters, rheostats, circuit breakers, ammeters and other electrical equipment.

6. Repairs and Renewals of Cars. This account embraces the cost of labor, materials, supplies, tools and expenses of repairs and renewals of car bodies, including roofs and bonnets, window and deck lights, platforms, sashes, bumpers, draw bars, gates, steps and grab handles, painting, varnishing and lettering, curtains and curtain fixtures, car seats and covering for seats, stoves and stove fixtures, electric heaters, electroliers, headlights, stationary fare registers, gongs, bells, bell cord fixtures, brass fixtures and trimmings, signs and sign fixtures, sand boxes, track brushes and snow scrapers; trucks, including wheels, bases and oil boxes, truck frames and parts, including pedestals, springs, etc., brake shoes, brakes and brake appliances, fenders, pilots and life guards. This account includes the cost of new cars and trucks purchased to keep good the original number, less the value of old material or insurance received.

7. Repairs and Renewals of Electrical Car Equipment. This account embraces the cost of labor, material, supplies, tools and expenses of repairs and renewals of motors, including armatures and parts, fields and parts, commutators and parts, gears, gear cases, gear case brasses and supports, pinions, brasses, bearings and brush holders, controllers, controller resistances and parts, rheostats, lightning arresters, cut out boxes, wiring and connections for power, light and heat circuits, trolley wheels, forks, poles, bases and bushings.

This account should include the cost of shifting summer and winter equipment. Electrical car equipments purchased to make good the original number are to be charged to this account less the value of old material or insurance received.

8. Renewals of Horse and Vehicle Equipment. This account embraces the cost of renewals of horses, depreciation of horses, renewal of harness equipment, renewal of vehicle equipment of every description not operated by mechanical power. The feed, stable expense and shoeing of horses and repairs of harness and vehicle equipment is charged to General Stable Expenses.

9. Repairs and Renewals of Miscellaneous Equipment. This account embraces the cost of repairs and renewals of freight, mail, express and supply cars, water and sprinkling cars, sand cars, salt cars, snow plows, sweepers, scrapers and miscellaneous snow equipment.

10. Repairs and Renewals of Shop Tools and Machinery. This account embraces the cost of repairs and renewals of shop tools machinery, and appliances, including engines, boilers, shafting, motors, etc., coal, coke, lubricants and waste, and miscellaneous supplies and expenses of general repair shops, including superintendence.

#### *"C" Conducting Transportation.*

11. Power Plant Wages and Superintendence. This account includes the wages of all employes of power plant, except when employed on repairs or renewals.

12. Fuel for Power. This account includes cost of coal or oil used as fuel or other fuel delivered at power plant.

13. Water for power. This account includes cost of water used for lubricant purposes only.

14. Lubricants and Waste for Power Plant. This account embraces the cost of lubrication of power plant.

15. Miscellaneous Supplies and Expenses of Power Plant. This account embraces the cost of carbon brushes, tools and other supplies and expenses of the power plant not otherwise provided for.

16. Hired power. This account embraces cost of power furnished by other companies. Income from sale of power is to be deducted from the expense of operation of power plant.

17. Superintendence of Transportation. This account includes the wages of division superintendents and their assistants, aids, inspectors, road officers and others employed in superintending transportation.

18. Wages of Conductors.

19. Wages of Motormen.

20. Wages of other Car Service Employes. This account includes wages of starters, transfer agents, switch tenders, trail car couplers and other car service labor.

21. Wages of Car House Employes. This account includes

wages of foremen, watchmen, car placers, shifters, etc., motor inspectors and cleaners, lamp and headlight tenders, car oilers, wipers, car cleaners, car stove firemen and other car house employes not employed on repairs. This account should include the cost of shifting cars from one point to another for the purpose of transportation. If, however, the cars are shifted for purposes of repair the cost of so doing should be charged to account No. 6 and No. 7.

22. Car and Motor Supplies. This account includes cost of supplies for car oiling, incandescence lamps, illuminating oil and supplies, supplies for car cleaning, water for car cleaning, fuel and supplies for car heating, bell and register cord, trolley rope, carbon brushes for motors, lubricants and waste for motors, tools and other supplies except for "Repairs."

23. Miscellaneous Transportation Expenses. This account includes services and expenses of special inspectors, printing transfers and tickets, cost of conductors' books, spears, punches, portable registers, tools for motormen, employes' badges and uniforms when paid for by the company; cost of getting derailed cars on track and removing obstructions and wreckage, and miscellaneous car house expenses not otherwise provided for.

24. Cleaning, Watering and Sanding Track. This account embraces labor, materials, supplies, tools and expenses of cleaning, watering, sprinkling and sanding track, including wages of curve cleaners and greasers, track brooms, curve grease, etc., expense of removing dirt from track, wages of men employed in operating water and sprinkling cars, and cost of water for same; cost of sand, including wages and expenses of hauling, drying and distributing same and of sanding track. This account does not include cost of sprinkling rendered necessary by repairs or construction of track or paving.

25. Removal of Snow and Ice. This account embraces labor, material, supplies, tools and expenses of removing snow and ice, including cost of salt delivered in car house or bins and wages of men engaged in salting track and in operating snow plows, sweepers, scrapers, etc.; cost of shoveling and removing snow and ice whether done by the company or otherwise. This account does not include rattran for sweepers or other repairs of snow plows, sweepers, scrapers, etc., included in account No. 9.

#### *General Expenses.*

26. Salaries of General Officers. This account includes salaries of president, vice-president, general counsellor or solicitor, secretary, treasurer, auditor, general manager, assistant general manager, chief engineer, general superintendent, purchasing agent, together with all officers whose jurisdiction extends over the entire system.

27. Salaries of Clerks. This account includes salaries of paymasters, cashiers, receivers and all clerks in general office and clerks for heads of departments. It should include the salaries of clerks employed in handling and counting receipts, transfers and tickets whether employed in the general office or in other places.

28. Printing and Stationery. This account includes all printing, stationery and stationery supplies, except printing of transfers and tickets, chargeable to account No. 23; printing of briefs, etc., charged to account No. 34; and signs, posters and other advertising matter charged to account No. 32.

29. Miscellaneous Office Expenses. This account includes cost of repairs and renewals of office furniture and fixtures, office supplies and expenses, including coin bags, money wrappers, money tags, postage, cost of telegrams, newspapers, periodicals, towel service, wages of janitors, porters and messengers, and all other miscellaneous expenses of general office.

30. General Stores Expenses. This account embraces all salaries and expenses in connection with maintaining stores departments, including cost of the distribution of all material and supplies and collection of scrap material.

31. General Stable Expenses. This account includes food, horse-shoeing, labor and miscellaneous stable expenses, ordinary repairs of harness and vehicle equipment. Renewals and depreciation of horses and renewals of harness and vehicle equipment are charged to account No. 8.

32. Advertising and Expense of Park Properties. This account includes the cost of advertising, together with all expenses incurred in maintenance of parks, park properties, resorts, etc., expense of all music and cost of entertainment provided by the company.

33. Miscellaneous General Expenses. This account includes cost of public telephone service, cost of operating private telephone system, subscriptions and donations, traveling expenses of gene al officers and others connected with general office; contingent expenses connected with general management, not otherwise provided for.

34. Legal Expenses. This account includes the salaries and expenses of solicitors, attorneys, their clerks and attendants and all expenses of their offices (when in the full employ of the company), such as law books, printing briefs, legal forms, testimony, etc., also fees and retainers paid, services of attorneys who are not regularly employed by the company, also fees and other expenses of arbitrators for settlements of disputed questions, cost of suits, special fees, notarial fees, expenses connected with taking depositions, and all legal and court expenses of every kind not otherwise provided for under the head of "Injuries and Damages."

35. Injuries and Damages. This account includes all charges on account of persons killed or injured, such as gratuities and compensation paid injured or disabled persons, their creditors, heirs, relatives and attorneys, salaries and expenses of surgeons, fees and expenses of doctors, coroners, undertakers, witnesses and others (except lawyers' fees and court expenses), nursing, hospital attendance, medical and surgical supplies, also wages and expenses of others occupied in connection with the adjustment of claims. It also includes injury to property damaged and all charges in connection with the adjustment of such claims.

36. Track Rentals. This account includes rents paid, for lease of track and terminals.

37. Rent of Land and Buildings. This account includes rents paid for land and buildings used in the operation of the road.

38. Insurance. This account includes cost of insurance, including Fire, Casualty, Employer's Liability, Fidelity, Profits and other insurance.

#### *Deductions from Income.*

Taxes. This account includes all taxes on real and personal property used in the operation of road, franchise taxes, taxes upon gross earnings and capital stock, car licenses, wagon and vehicle licenses. Taxes upon property not used in the operation of road should not be included in this item, but should be deducted from income from other sources, or charged direct to profit and loss.

Interest. This includes interest on funded debt and interest on floating debt.

#### **Rentals of Leased Lines.**

##### **CLASSIFICATION OF CONSTRUCTION AND EQUIPMENT ACCOUNT.**

1. Organization. This includes all expenses incurred in effecting organization, including legal expenses.

2. Engineering and Superintendence. This includes wages and expenses of engineers and draughtsmen, superintendents, etc., on preliminary and construction work.

3. Right of Way. This includes all expenses incurred in connection with the securing of or paying for right of way.

4. Track and Roadway Construction. This includes cost of track and roadway construction, including material, supplies, tools, expenses and labor, excavating, grading, ballasting, bridges and culverts, paving, ties, rails, fastenings, complete, welded joints, special work, tools and appliances miscellaneous track material, supplies and expenses; labor laying track, hauling and distributing material. The cost of tracks in car houses to be included in this account.

5. Electrical Track Construction. This includes cost of electrical track construction, including material, supplies, tools, expenses and labor; poles and pole fixtures, material for setting poles, paint for poles, wire, overhead and underground devices, tools and appliances; miscellaneous material, supplies and expenses, labor setting poles, painting poles, wiring track, put'n'g up overhead line construction, hauling and distributing material.

The cost of electrical track construction in car houses to be included in this account. The cost of underground conduits and feeders where underground wire construction is used is also to be included in this account.

6. Real estate Used in Operation of Road.

7. Investment Real Estate and Improvements. This includes cost of land and buildings not used in operation of road.

8. Buildings and Improvements Used in Operation of Road. This includes cost of all buildings and improvements in connection with same, including excavations, foundations, drainage, water, gas and sewer pipes, and stationary fixtures belonging thereto, heating and lighting apparatus and fixtures; other stationary fixtures, side walks, street paving on streets in front of or adjacent to buildings, fences, sheds, outhouses, etc. The cost of tracks and electrical track construction in car houses is not chargeable in this account.

9. Power Plant Equipment. This includes cost of steam and electrical plant complete, exclusive of buildings, including machinery, foundations and installation.

10. Shop Tools and Machinery. This includes cost of shop tools and machinery for general repair shops, car houses, etc., including foundations and installation.

11. Cars. This includes cost of car bodies, trucks and car fixtures.

12. Electrical Car Equipment. This includes cost of motors and electrical car equipment complete.

13. Miscellaneous Equipment. This includes cost of water, sprinkling, sand, salt and supply cars, freight, mail and express cars, all other cars exclusive of those charged in account 11; cost of snow plows, sweepers and scrapers; cost of horse and vehicle equipment, including tools necessary in the use of miscellaneous equipment.

14. Interest and Discount. All interest and discount paid and received in connection with funds for construction should be charged or credited under this heading.

15. Miscellaneous. This includes miscellaneous expenses, office expenses, wages of clerks and all other expenses that would not be included in any of the other accounts enumerated above.

The Chair: We have Mr. Sergeant with us, first vice-president of the American Street Railway Association, and general manager of the West End Street Railway of Boston. Mr. Sergeant, we would be glad if you would make a few remarks to the Association.

Mr. Sergeant: I thank you very much, Mr. President, for the opportunity afforded me to say a word, because, for one thing, I have always been very much interested in accounts. I feel, and always have felt, that the real foundation of the business of street railroads was correct accounts. I have seen concerns go to wreck and ruin for the lack of that very thing and an inability to get out of the slough of despond, because they did not know what they were doing. I have been very much interested in the report of your committee, that portion of it which I have heard, and the arguments advanced seem to me to be very sound; and the general position which you have taken in regard to classification, leaving it to the individual company to elaborate any detail, all within the elastic limits of the system you have provided, seems to me to be fundamentally right. It would be impossible to meet the differing conditions of all the different companies by any one complete, detailed schedule; but by a schedule such as you have suggested you are going not only to afford the most valuable information to many new corporations, small companies, people without railroad experience, who need just such a chart to keep them right; but you are going to get reports into a uniform shape so that comparisons can be made, and that, if the accounts are kept properly, under the headings that you have prescribed, will, it seems to me, be invaluable. There is one word that I would like to say here in regard to accounts in general, and one point that I think ought not to be lost sight of—that sometimes we are given, in studying the details of accounts and the question of classification for this or that item, to make that the main thing and to lose sight of the real principle underlying all accounts, namely, that the whole accounting system should be such that the results will be sound. I suppose you have all studied more or less the reports of European railroads and street railways. There is

one account in the report of every European street railway that I have ever seen that is too often missing in the accounts of our own railways. I refer to the depreciation account. I have never seen a European report without it. I have seen a great many American reports without it, or possibly having it pretty well buried. Now, there may be reasons for burying it up, but there certainly are reasons why the matter of depreciation should be fully recognized and cared for year after year, so that in the end, when our franchises expire we may have something left. I thank you very much, gentlemen, for this opportunity of addressing you.

The Chair: Now, gentlemen, I think it would be well to proceed with the consideration of the report just presented by Mr. Ham.

Mr. Hibbs: I would like to ask what the intention of the committee was as to the appointment of another committee. Is that to refer the adoption of this classification to some other committee?

Mr. Ham: The object of that is more particularly to promote the adoption of this thing. We must remember that simply to say that we approve of the report of this committee and adopt it, means nothing. That may mean that we have given the Association a satisfactory report, but I do not think that that means that any one of us would go away from here with the intention of adopting this system. Now, what we want, if we have gained anything, is to have the system adopted; and I believe that to adopt anything you have to push it. While, as railroad men, we do not believe in promoters, yet this is what we want now; we want some promoters.

The Association then took up the consideration of the report, item by item, discussing every point fully, and adopted the report as printed above. This discussion lasted all of Thursday morning, Thursday afternoon and until noon of Friday, and would fill 30 pages of the "Review." It is extremely interesting to accountants, and contains a fund of information as to the distribution of accounts. This complete report will be published by the Accountants' Association and furnished to members only. This discussion alone is worth many times the price of the yearly dues, which are nominal, and managers and accountants desiring a copy can arrange for same by addressing W. B. Brockway, Secretary Street Railways Accountants' Association, Toledo, O.

This discussion gives the reasons why the various members are in favor of certain items being charged under given heads, and goes into the minute details which are apt to puzzle the accountant with whom the item appears only at rare intervals. It really is a post graduate course in street railway accounting.

The committee on standardization was made a permanent committee for the coming year.

After discussion as to date of next year's meeting the matter was left to the Executive Committee with power to act, as to what days in the week the meeting should be; it being understood that the meeting should be in the same place and week, as that of the American Association.

The Committee on Resolutions presented the following which was unanimously adopted:

Whereas, The Street Railway Accountants' Association of America, assembled in its first annual convention feels greatly indebted to the citizens of Niagara Falls for the warm welcome and generous hospitality extended to the delegates; to the officials of the street railways who have accorded the delegates free transportation in the use of their handsome equipment; to the American Street Railway Association for its cordial sympathy and substantial endorsement in the work of the new association, and for the invitation extended by its president in behalf of the American Street Railway Association to visit its convention, and for the enthusiastic welcome there given; to Secretary Charles De Freest, of the New York State Board of Railroad Commissioners, for his frank and hearty interest and valuable suggestions which materially aided the Association in its deliberations; to H. H. Windsor, of the Street Railway Review, and E. E. Higgins of the Street Railway Journal, for their unremitting efforts to promote the success of this body. Now, therefore, be it

Resolved, That the Street Railway Accountants' Association of America, desires to express in this resolution its unforgotten thanks and appreciation for all the hospitality, courtesy and assistance thus rendered it as a body; and, further, be it

Resolved, That these resolutions be spread upon the minutes of the Association and copies of the same given to the press.

Chas. D. Meneely,  
P. V. Burlington,  
Theodore J. King,  
Committee.

Two other papers had been prepared and announced on the program, "Statistics, Their Use and Abuse," by E. D. Hibbs, auditor of the Consolidated Traction Company, Jersey City, and "Car Mileage—How Arrived at and Its Use," by H. J. Davies, assistant secretary of the Cleveland Electric Railway. The extreme lateness of the hour, however, did not admit of suitable time being given to the reading and discussion, and by motion, and with the consent of the authors, these two papers were deferred until next year.

A vote of thanks was given Vice-President Duffy and Secretary Brockway for their excellent work.

The nominating committee then reported, and on motion the secretary cast one ballot for the ticket, as read. The officers for 1898 are as follows:

President: H. L. Wilson, Auditor West End Street Railway Company, Boston.

First Vice-President: E. D. Hibbs, Auditor Consolidated Traction Company, Jersey City.

Second Vice-President: P. V. Burlington, Secretary and Auditor The Columbus Street Railway Co., Columbus, Ohio.

Third Vice-President: A. H. Ford, Secretary New Orleans Traction Company, New Orleans.

Secretary and Treasurer: W. B. Brockway, Auditor Toledo, Bowling Green & Fremont Ry. Co., Toledo.

Executive Committee: The Officers and

Wm. F. Ham, Secretary Nassau Electric R. R. Co., Brooklyn.  
H. J. Davies, Assistant Secretary The Cleveland Electric Ry. Co., Cleveland.

F. R. Greene, Secretary Chicago City Railway Co., Chicago.  
J. M. Smith, Comptroller Toronto Railway Co., Toronto.

A telegram of congratulation was sent to President-Elect Wilson, and after the installation of officers, the meeting adjourned.

The following new members were admitted to the association at the Niagara Falls meeting in addition to the companies named in the report of the secretary and treasurer that acquired membership between the Cleveland and Niagara Falls meetings:

Columbia Railway Co., Washington, D. C.  
Brooklyn City & Newton Railroad Co., Brooklyn, N. Y.  
Memphis Street Railroad Co., Memphis, Tenn.  
Metropolitan Railroad Co., Washington, D. C.  
West Chicago Street Railroad Co., Chicago, Ill.  
Union Depot Railroad Co., St. Louis, Mo.  
Milwaukee Electric Railway & Lighting Co., Milwaukee, Wis.  
Tonawanda Electric Railroad Co., North Tonawanda, N. Y.  
Denver Consolidated Traction Co., Denver, Col.  
Colorado Springs Rapid Transit Railway Co., Colorado Springs.  
Wilmington City Railway, Wilmington, Del.  
Hamilton Street Railway Co., Hamilton, Ontario.  
Fitchburg & Leominster Street Railway Co., Fitchburg, Mass.  
Manchester Street Railway Co., Manchester, N. H.  
Columbus Central Railway Co., Columbus, O.

#### SOCIAL FEATURES AND EXCURSIONS.

The many celebrated points of natural interest at the Falls, resulted in calling out a large attendance on the part of the ladies, and these were very nicely cared for by the committee of 25 local ladies who were constantly in attendance. The hall was set in motion early on the first day by the General Electric Company, which chartered all the trolley-cars and other vehicles in the city and tendered a ride to the ladies. The party of about 150 set out from the hotel at 9:00 a. m. and after crossing to the Canadian side drove up and down the river viewing the Falls. In the afternoon everybody took the cars and visited the two power plants and many of the industries which are electrically operated. In the evening there was music and a dance at the hotel, for those who desired, while others sauntered through the corridors visiting with friends, or went to the convention hall to see the exhibits.

Wednesday morning the ladies were taken down the Gorge road, and in the afternoon accompanied the gentlemen who went on the excursion over the "Canadian Route." On this trip the party walked across the suspension bridge and took special cars going up the river to Chippawa Falls, thence back through Niagara and down the river to Queenston, where a steamer brought the party to Lewiston and the return was made on the American side over the Great Gorge road. It was dark and rain was gently falling when the hotel was reached. That evening there was music and dancing at the hotel.

Thursday morning the ladies made a trip in carriages provided by the ladies of the city, and made the tour of the Islands on the American side, and in the afternoon some went to visit Ft. Niagara and others made short trips in parties of twos and threes. In the evening the exhibit hall was open to the citizens, and the annual banquet was given at the International. Four hundred guests were present, and the dinner and speaking lasted until past midnight. The toasts and speaking were as follows:

"The City of Niagara Falls," the Hon. Arthur C. Hastings; "The Association," Smith P. Galt; "Wit and Humor of the Bar," Henry W. Box; "The Evolution of Niagara," the Hon. Thomas V. Welch; "The Technical Press," Henry H. Windsor. W. Caryl Ely was toastmaster.

One of the most enjoyable incidents of the convention week was the dinner given on Tuesday evening by J. G. White, of J. G. White & Co., contractors, 29 Broadway, New York, at the Buffalo Club: The party was taken from the Falls on a special car of the Buffalo & Niagara Falls road, which is one of the many lines built by Mr. White's company; the return trip was made in the small hours, and the road showed what it could do in the way of speed. Among those present were: President McCulloch, of the association; State Railway Commissioner Ashley Cole and C. R. DeFreest, the secretary of the commission; J. G. White, C. R. Huntley, George Urban, Jr., J. B. Marston, L. B. Stillwell, H. M. Watson, W. M. Habirshaw, T. C. Martin, W. J. Clark, W. F. Zimmermann, J. H. McGraw, E. E. Higgins, G. Tracy Rogers, N. H. Parker, C. W. Price, F. S. Kenfield, C. S. Sergeant, Charles T. Ballard, W. Caryl Ely, F. W. Brooks, W. A. Brackenridge, T. C. Pennington, Captain J. Brinker, G. H. Dunbar, H. H. Harrison, D. B. Dyer, E. F. Thurston, H. J. Pierce, H. St. C. Denny and H. H. Littell.

#### LETTER FROM C. D. WYMAN.

New Orleans, La., October 12, 1897.

Robert McCulloch, Esq., President, American Street Railway Association, St. Louis, Mo.:

Dear Sir:—I have been anticipating with a great deal of pleasure the privilege of answering "Here," when the Secretary should call the name of the New Orleans Traction Company on the occasion of the assembling of the members of the Association in the Convention at Niagara Falls on the 19th. I have during the year, from time to time, jotted down a statement of problems which have arisen in my practice of the science of electric railroading, and which had caused me to stumble, to present them for solution to the many gentlemen so much more expert than myself in these matters, who would be present at the convocation. From the papers to be read, I looked for great gain and help, and from the discussions likely to arise, I expected to get at facts and figures which would be of great use to me; while on the social side, I have been longing for a glimpse of the natural beauties which surround the convention location, and for the chance of exchanging greetings with the many friends whom I have loved and respected for so many years, and to whose intimacy I have been so kindly admitted during our acquaintance. You can then readily judge of how great my disappointment is in not being able to compass any of the above list this year. To be obliged to be absent from my place in the convention hall this year causes more regret than I can express in words.

The hospitality of the city over whose principal railway system I have the honor to preside, is proverbial. When a stranger arrives in our midst, especially if he be a celebrated personage, without reference to whether that celebrity arises from good or ill characteristics, or whether his stay may prove disagreeable, subsequent to his advent, the good citizens of this Crescent City, turn out en masse to greet him, and spare no pains to make him welcome, and least he should find anything wanting in his re-

ception, and hasten his departure to bestow his attention upon other places, they do their utmost to keep him to themselves. The only instance on record where such hospitality was not in evidence, occurred, as I understand it, when General Benjamin F. Butler paid New Orleans a visit a few years ago, but even on that occasion, whatever the citizens lacked in cordiality toward the old general, it is reported, they made up to him in the liberal bestowment upon him of their spoons. Even after he had left New Orleans (the only thing I believe he did not take with him) he was invited to return, but the invitation was couched in such terms of earnestness, it is possible the general feared the citizens might overdo it, and he declined.

We have in our midst today, a guest who came to us about two months ago? He did not announce his arrival, but with the alertness peculiar to our people, some one (name unknown) found him out, and ever since he has been with us, and the recipient of most careful and constant attention. We promptly notified the world at large of his advent, and the residents of towns and villages outside of our precincts have ably assisted us in preserving from ruin our reputation for hospitality by permitting our guest to leave, and have come to our assistance by instructing the railroads in rules of etiquette through the reading to them of excerpts from "Winchester's Metallic Edition of How to Perforate the Human Body," to which lectures, the common carriers have listened with great interest, showing their appreciation of the subject-matter "in hand," by reversing levers. Thus have we been assisted by the country round about us, and in the city, old and young, rich and poor, educated and illiterate, have not failed to do our distinguished guest reverence. Wherever he has taken up his domicile, and he has been gracious enough to go about to a good many places, the premises have been elaborately decorated with his colors. Over the portal of each residence that he has visited, has been hung his flag. This is two hued; one half recalls an orange, and the other, a strawberry, the tout ensemble of the whole being not unlike a Martini cocktail with a cherry in it. In front of his abode, night and day, a committee on reception, to the number of two, are always at hand to see that the guest is not unnecessarily disturbed, and that none of the inmates of the residence wherein he is ensconced, so far forget their duties as hosts, as to leave the premises. When his lordship finally concludes to depart from any particular residence or hotel, there is such sorrow, that those he has left behind, purify their minds and bodies the better to bear up under the heart-rendering leave-taking, and so sacred are the articles that have been worn by the departed guest, that everything he has touched, even including the bed on which he has rested, is incinerated, so that mortal hands of common clay may never profane these sacred sundries. For fear that this guest when he walks the streets, should accidentally find dirt or the slightest bit of filth thereon, a coating of lime has been made to adorn the edge of nearly all sidewalks. On a bright moonlight night, when the thermometer registers 85 degrees Fahrenheit, the eye is deceived into thinking it has been snowing, but the other senses are not. Every car within my jurisdiction, which is in actual service, is daily treated to a bath consisting of a solution of bi-chloride of mercury, so that should our guest ever enter one, he will not be liable to contamination through contact with other passengers. So great is the awe and reverence in which we hold him, that his name is mentioned with bated breath, and therefore, I forbear here to pronounce his august appellation. It is possible that you and the gentlemen of the convention will, without further description, be able to recognize the one of whom I have been speaking. You will therefore see that my duties as a citizen, as a hospitable inhabitant of this southern land, cannot be easily set aside for the purposes of my own pleasure, and I am therefore denied being with you at the convention.

I trust all your deliberations may be thoroughly harmonious, engaging in interest, full of suggestion and assistance to all who shall participate therein, and that you may all have the best and jolliest time ever granted the American Street Railway Association's delegates and friends. Bear in mind please, that I am with you in spirit, and accept my most cordial greetings for yourself and all my street railroad associates.

Most sincerely yours,

C. D. Wyman.

## THE EXHIBITS.

And now for the exhibits; for what would a convention be without the display, the seductive souvenir and the genial supply man. All these have grown to large proportions, and certainly constitute a most important part of the convention.

This year we had the advantage of practically everything under one roof, and building comfortably warm,—though it was a kind providence which was chiefly responsible for the latter fact. The classification was the best yet attained, but this can be still further improved by insisting that all operating exhibits which produce much noise be relegated to a distant portion of the building, as far removed from the session rooms, and everybody else, as possible. During a good part of the time one single operating exhibit made sufficient noise to make it almost impossible to converse in the main hall, and those in the back part of the two session rooms might as well have been in the Cave of the Winds for all they could hear. We recognize the right and necessity of making a noise, (though a manager would never dare to make such a noise on the street) but the rights of others should also be recognized, and many an exhibitor lost valuable opportunities of explanation, simply because a manager had reached a point where he could longer endure having his ear shouted into.

The placing of exhibits this year was gratifying. Never before had so many been in place on the opening morning as this year. The decorations were pleasing and as a rule not overdone, and while there was a sad lack of room in which to spread out, still in the aggregate a vast amount of apparatus and goods were shown, and the exhibit as a whole was very satisfactory, and certainly was creditable to the supply men. A gentleman whose business required his presence with the display at several other conventions during the year, and who attended the street railway convention for the first time, expressed his amazement at the magnitude of the exposition, and stated that without question it comprised the largest and best display made by any association during the whole year.

The lighting arrangements were excellent, as were also the facilities for power to operate the various apparatus which it was desired to show in motion. The railroad switch to the main entrance was a greatly appreciated feature of unloading, nor were any complaints made as to excessive charges for teaming, carpenter work, etc.

The general expression among supply men was that managers devoted more time than usual this year to a careful study and inspection of the displays. Also a larger number of orders were booked this convention than in several years. In fact, we know of several managers who purposely deferred placing orders several months in order to do so at the convention after a comparative examination. There were a smaller number of fake devices this time, and it is a matter of congratulation that these exhibits are decreasing each year.

Altogether the exhibit hall was something to be proud of, and illustrated as is done in no other manner, the magnitude and importance of the industry which calls it into existence. The arrangement for barring out the general public during those hours in which the railway men desired to make inspection, was highly satisfactory; and the setting aside of Wednesday evening for the citizens was gladly availed of, and a large number turned out then.

The telegraph and telephone facilities in the building were appreciated, and the city cars were run with sufficient frequency between the hall and hotels, to accommodate everybody nicely.

The exposition of street railway appliances, of 1897, will go on record as a grand success in all respects.

The Pettingell-Andrews Company, of Boston, exhibited the Trojan jack.

Obe. Cullison, of York, Pa., exhibited the Cullison automatic car fender.

INTERIOR EXHIBIT, J. G. BRILL COMPANY.

INTERIOR EXHIBIT, PECKHAM TRUCK COMPANY.

Julian L. Yale & Co. of Chicago were represented by Townsend V. Church.

The Akron Kleant Company had an exhibit in charge of W. F. Dresler.

J. Paul Baker attended in the interest of the Baltimore Car Wheel Company.

George F. Brandon of Utica, N. Y., exhibited a new life guard of his invention.

Franklin Rice represented the Dayton Automatic Car Switch Co., of Dayton, Ohio.

Herman Falk and C. S. Jones represented the Western Gear Company, Milwaukee.

A. H. Sisson of the Jewett Car & Planing Mill Company, Jewett, Ohio, was present.

W. E. Dutton was present in the interests of the VanDorn Iron Works, of Cleveland.

E. F. DeWitt, the well known sand box man, had a nice space and an interesting exhibit.

W. E. Tench represented Craze & Tench of Buffalo, general contractors for public works.

The Watson-Stillman Company, New York, was represented by Henry A. Boyd of Buffalo.

A. G. Hathaway of Cleveland was present greeting his friends and laying pipe for new business.

F. G. Fuller represented W. R. Brixey of Day's Kerite. Mr. Fuller was warmly welcomed.

C. E. Greene, of Niagara Falls, exhibited a line of high voltage glass and porcelain insulators.

Frank McGovern, of the firm of Rossiter, McGovern & Company, did the honors for his concern.

The Seamless Structural Company, Milwaukee was represented by Garson Myers and Frank Randall.

The Paige Iron Works of Chicago were very ably represented by their engineer, E. S. Nethercut.

The John Stephenson Company, distributed a valuable little book of tables of cost of construction, etc.

John A. Stewart, president of the Stewart Electric Company, Cincinnati, represented his company.

Robert Skeen of the Skeen Electric Switch & Signal Company showed its appliances in operation.

Bailey Whipple, general sales agent of the Jandus Electric Company, was in charge of its exhibit.

H. M. Daggett, Jr., represented the Lombard Hydraulic Brake Company of 61 Hampshire street, Boston.

The Bibber-White Company, 49 Federal street, Boston, was represented by Charles E. Bibber, treasurer.

F. D. Russell, manager of the Rochester Car Wheel Company, Rochester, N. Y., represented his company.

The Chicago Insulated Wire Company was represented by its secretary and treasurer, William M. Smith.

The Heine Boiler Company, St. Louis, made no exhibit, but was represented by H. B. Ham, its Boston agent.

Frederick R. Chase was in attendance in the interest of Hoopes & Townsend, bolt, nut and rivet works, Philadelphia.

THE WESTINGHOUSE EXHIBIT.

L. A. Sayre displayed a full line of the conductor's and office cancelling punches manufactured by L. A. Sayre & Co.

M. B. Austin of Chicago and E. T. Spencer of St. Louis represented the Safety Insulated Wire & Cable Company.

B. F. Swartz was present in the interest of the Lehigh Car, Wheel & Axle Works, McKee, Fuller & Co., Catasauqua, Pa.

The St. Louis Register Company and the Hildreth Varnish Company were represented by Giles S. Allison of New York.

John T. McRoy of Chicago exhibited samples of his four and six-tube vitrified clay ducts for underground conduit work.

J. M. Jones, Jr., of J. M. Jones' Sons, West Troy, N. Y., street railway car builders, was present throughout the convention.

E. T. Warner, treasurer, represented the Parrish Signal Company of Jackson, Mich., manufacturer of automatic electric signals.

The Solar Carbon & Manufacturing Company of Pittsburg did not exhibit but was represented by F. M. Laughlin and H. E. Webb.

Joseph Pomeroy of Pomeroy & Fischer, 28 and 30 Frankfort street New York, showed with a line of paints, colors, varnishes, etc.

The Webber Rail Joint Company, of New York, exhibited samples of the Webber rail joint, being represented by Richard Devens.

Scott H. Blewett, second vice-president of the Missouri Car & Foundry Company, was another of the large delegation from his city.

Samuel W. Glover of the Post-Glover Electric Company, Cincinnati, was present and worked hard for that city for the next convention.

J. M. Atkinson began representing his firm on Monday afternoon and continued to do so with a great deal of vigor until it was all over.

Albert B. Herrick, of Herrick & Burke, of 150 Nassau street, New York, displayed that firm's portable and adjustable testing switch-board.

McCardell, West & Co. of Trenton, N. J., exhibited the "Trenton" emergency wagon on the track space. Represented by J. R. McCardell.

The Springfield Manufacturing Company, of Bridgeport, Conn., was represented at the convention by J. T. Griffin and G. W. Jackman.

O. R. Sackett & Co. of Niagara Falls exhibited their automatic trolley catcher, which attracted considerable attention and favorable comment.

The Detroit Stove Works had a line of seat and floor car heaters, all cast iron with parts interchangeable, which was in charge of H. L. Schutt.

The track exhibit of the McGuire Company of Chicago, was a large double sweeper built for the North Hudson County Railway Company.

The A. Mertes Manufacturing Company, Allegheny, Pa., was represented by J. M. Parsons, superintendent, J. A. Donaldson and Charles Surrit.

B. D. Tillinghast represented the Duff Manufacturing Company of Allegheny, Pa., which exhibited a complete line of track and other railway jacks.

The Leonhardt Wagon Manufacturing Company of Baltimore exhibited on the track two types of emergency wagon. Represented by William M. Ives.

E. J. Robinson, general manager of the Laclede Car Company, St. Louis, looked after the interests of his concern and was welcomed by many friends.

The New York Car Wheel Company was represented by John A. Gardner, of New York, J. H. Yardley, of Philadelphia, and J. D. Rhodes, of Pittsburgh.

Baker & Co., manufacturers of platinum, Newark, distributed a tasty booklet describing the source of supply and giving other interesting information.

THE STERLING SOUVENIR.

The Hunter Illuminated Sign Company and the Hunter Automatic Fender Company of Cincinnati were represented at the convention hall by Lytle J. Hunter.

The Trojan Button Fastener Company, Troy, N. Y., showed the Ham bronze sand box which is manufactured by it. The exhibit was in charge of R. H. Ham.

D. C. Sweet of Springfield, Mass., exhibited one of his car wheel grinding machines which was displayed in a conspicuous place and attracted much attention.

J. G. White & Co., engineers and contractors, 29 Broadway, New York, were represented at the convention by J. G. White, H. H. Harrison and G. H. Walbridge.

The Okonite Company had an exhibit of feeders that called for many compliments. The company was represented by Capt. Willard Candee and J. N. Partridge.

The J. G. Brill Company displayed on the track space one of its standard vestibuled snow sweepers and a standard 10-bench open car mounted on a 21-E truck.

Gustave Fischer, chief assistant engineer for the tramways at Sidney, Australia, took advantage of the convention to become acquainted with the way "we do things."

Herman Hirsch of New York, representing C. Buschner, displayed a truck model equipped with roller bearings which it is claimed save 33½ per cent in motive power.

The Columbia Incandescent Lamp Company of St. Louis was represented by its secretary and treasurer, A. C. Garrison, who was present throughout the convention.

A. W. Morrell of the electrical department of the Miller-Knoblock Company, South Bend, Ind., called particular attention to his method of refilling commutators.

The American Mutual Indemnity Company of Scranton, Pa., was represented by the genial Newton Jackson, the general superintendent, who made himself ubiquitous.

Joseph E. Lockwood, president of the Michigan Electric Company of Detroit dealer in electrical machinery and supplies and agent of the General Electric was in attendance.

J. R. Cravath of the Cravath Manufacturing Company, Chicago, exhibited his excessive current recorder and attracted more attention than any of the small exhibitors present.

John A. Roebling's Sons Company, was represented by General Manager Shippey, Messrs. Cockey, Walsh, William Doyle and Western manager George C. Bailey of Chicago.

The Partridge Carbon Company was represented by the president, E. F. McIntosh, and the general manager, James Partridge. Everybody got a "Scratch him on the back" card.

The Milwaukee Rail Joint & Bonding Company exhibited the Austin patented rail joint which is meeting with so much favor. Its representative was E. E. Warner of Milwaukee.

The exhibit of the Billings & Spencer Company was made in connection with that of the Central Electric, of Chicago, which had a full line of the B. & S. supplies nicely displayed.

Roland Gerry was at the convention representing Jones & Laughlin, Limited, of Pittsburgh and distributing the well known little books of "Useful Information for Business Men."

The business of the Keystone Electrical Instrument Company was cared for by J. F. Stevens of Philadelphia, who exhibited some new switchboards, meters and special apparatus.

The Clark Street Car Brake Company had brakes applied to trucks in the exhibit of the Steel Motor Company and the Murphy wheel grinder. Represented by Horace F. Clark.

Robert H. Derrah, clerk to the president of the West End Boston was present at the convention and distributed copies of his "Street Railway Guide for Eastern Massachusetts."

CHRISTENSEN AIR BRAKE EXHIBIT.

A curve-taking trolley harp and a crossing-taker patented by W. H. Russel are described in the prospectus of the Russel Manufacturing Company, represented at the convention by Mr. Russel.

The Dorner & Dutton Company of Cleveland, exhibited two of its trucks; the single truck was under the car of the G. C. Kuhlman Company and the double truck in the hall. Represented by W. A. Dutton.

The Railway Register Company, New York, was represented by its general manager, Edward Beadle, who has attended nearly every convention since the organization, and President H. W. Watson, of Buffalo.

EXHIBIT OF THE GENERAL ELECTRIC COMPANY.

The Electric Mutual Casualty Association, of Philadelphia, was well represented at the convention by the secretary, W. W. Wharton, and a large number of its members. Headquarters in the hall were at Space 40.

President Meachem and Secretary Vosburgh, of the New Process Rawhide Company, Syracuse, were both present renewing acquaintances with a large number of customers, and adding some new ones to the already long list.

The Standard Paint Company was represented by the western manager, J. G. Shainwald, who accompanied the Chicago delegation. The "P. & B." souvenirs were handsome leather books, white for ladies and black for gentlemen.

The Taunton Locomotive Manufacturing Company of Taunton, Mass., displayed two of the well-known snow plows, one of which was sold to the Buffalo railway. This company was represented by Wendell & MacDuffie of New York.

George S. Whyte of the Leschen-Macomber-Whyte Company of Chicago, western agent for the Crefeld Electric Works, represented his company and distributed leather match safes as souvenirs; also "The Clank of the Ice," by Eugene Field.

The Duquesne Forge Company, Pittsburg, was represented by David S. Bissel and exhibited forged steel gears for motors, the first to be placed on the market. This company has been engaged in making heavy forgings for the last 40 years.

George M. Brown, manager of the Pearson Jack Company, 156 Fifth Avenue, New York, was present to exchange greetings with his old friends and advise strangers as to the 15 street railway companies which use the Pearson replacing jack.

The G. C. Kuhlman Company of Cleveland exhibited a closed vestibuled car, 42 ft. 6 in. over all, provided with longitudinal seats, which was very handsome in appearance and caused much favorable comment. Mr. Kuhlman represented his company.

One of the most novel exhibits was that of the Paper Vending Machine Company, of St. Louis. It was a mechanical and noiseless newsboy for street cars—a cent in the slot machine. Robert A. Schlegel, president of the company was in charge.

Charles R. Brown represented the Pratt & Letchworth Company, of Buffalo, which exhibited a line of car castings, both malleable iron and steel, being the only company showing steel castings. H. C. Edson and President Letchworth were also present.

The Bowen face protector for motormen, the simple, cheap and safe substitute for vestibules on street cars was shown by the inventor, John Bowen. Mr. Wendell, of Wendell & McDuffie, New York, who will handle this device, was also in attendance.

Edmund G. Fischer, manager of the railway department, represented the McMullan Woven Wire Fence Company, of Chicago, which showed samples of its fencing so much used on steam roads. Green seal card cases were tendered as souvenirs.

The Mitchell Tempered Copper Company, which makes a specialty of pure tempered copper castings, commutator bars and segments was represented by J. G. Ruhl, who put in his appearance on Wednesday and remained throughout the convention.

The American Rail Joint & Manufacturing Company of Cleveland was represented by W. E. Ludlow and showed samples of its joints, the American "standard," which were displayed in the convention hall. The company also had an exhibit at the International.

D. N. Long of LaSalle, N. Y., exhibited an acetylene headlight for street cars which has been in service on the Buffalo & Niagara Falls road and proved eminently satisfactory; a recent order was taken for Kansas City. The exhibit was in charge of L. A. Dietrick.

W. J. Kauffman and L. A. Loichat represented the Kauffman-Conkell Company, of Canton, O., and displayed working models of an improved section insulator, and the K-C emergency trolley system. Both of these devices were examined with much interest.

T. C. White, manager of the electrical department of the Central Union Brass Company of St. Louis, represented his company and displayed a line of electrical and railway supplies. The souvenirs of this company were miniature commutators and were much in demand.

The Garl Electric Company of Akron, Ohio, had a handsome exhibit of portable telephones for street railways, hotels and factories, which was in charge of M. Garl. Connection was established between the Kuhlman car on the track and the space in the convention hall.

A. O. Morton of Boston showed a full line of street car jacks from 8 tons to 70 tons in capacity; also the sure drop track jack, which is claimed to be the only one with a positive trip, and the ball-bearing jack for heavy bridge work. H. A. Norton and E. T. Trefether were in charge.

THE STANDARD AIR-BRAKE EXHIBIT.

The Brandt automatic car sliding door which is impossible to jar open was the subject of much favorable comment by reason of its simplicity and effectiveness. This door and the Zimmerman eccentric brake were exhibited by S. W. Brandt of Brandt & Zimmerman, Troy, N. Y.

The Buda Foundry & Machine Company, of Chicago, exhibited the Paulus track drills, showing drills for T-rails and 11-in. girders. With this drill driven by hand a  $\frac{3}{8}$ -in. hole was put through a  $\frac{3}{4}$ -rail web in 1 minute and 28 seconds. The company was represented by Charles Parsons.

The Cambria Iron Company of Johnstown and Philadelphia exhibited sections of rails of different types, girders, guards, T's, etc., and specimens of its rail joints. Also an extensive series of drawings. W. A. Washburn of 33 Wall street, New York, represented the company.

P. C. Ackerman of New York, F. A. Donohoe of Chicago and Frank B. Porter of New York, attended the convention to represent the American Electrical Works of Providence, R. I. The souvenirs of this company were most useful for an occasion of this kind, being decks of playing cards.

Allen V. Garratt, chief engineer, represented the Lombard Water Wheel Governor Company, of Boston, and exhibited photographs of recent designs for governors for steam and water power plants. Many requests were received for the literature of this company on the subject of governors.

The Pennsylvania Steel Company, of Steelton had secured space inside the hall but preferred to exhibit outside and was located just outside the main entrance where a few of its frogs, switches and a sample of its steel tie work were displayed. The company was represented by C. W. Reinhoel.

The Cleveland Frog & Crossing Company of Cleveland, O., made a display of special work comprising one steel center frog, one cast steel center frog, one spring rail frog, one split swing switch and one derailing switch. The company was represented by G. C. Lucas, Frank A. Lapham and A. Powell.

The exhibit of the portable car safes and registers made by the Mehling Manufacturing Company of Cleveland was located at the International. The company was represented by F. B. Many, manager, and F. R. Briggs, general agent. We are advised that this safe has been adopted on seven roads since April.

John Murphy, general superintendent of the United Traction Company, of Pittsburgh, and president of the Murphy Manufacturing Company, exhibited the car wheel grinder of his name. The grinder was shown in operation dressing the wheels of a Baltimore truck. Mr. Murphy was assisted by John Daly.

The Electric Storage Battery Company, of Philadelphia, had in its exhibit 55 "chloride" accumulator cells, giving a 110-volt current; these were connected to a switchboard arranged to demonstrate the value of the storage battery as a regulator for power stations. The display was in charge of J. Y. Bradbury, of Philadelphia.

A practical test of the Rochester hose bridge was made by every car running to the convention hall and there were few exhibits that were examined with any greater interest or by so large a number of railway men. R. P. Barbour was in attendance. The bridge weighs 180 lbs. and will carry 30 tons; it collapses to 6 in. in width.

The Barney & Smith Car Company of Dayton, Ohio, occupied space near the entrance of the assembly room and exhibited its new class G single truck and its class H double truck, which is also new; both of these were equipped with General Electric motors. H. E. Esterbrook, H. Tessyman and F. E. Huntress represented the company.

The VanWagoner & Williams Hardware Company was represented by the president, C. S. VanWagoner, and by its agents, C. N. Wood, of Boston, Mayer & Englund, of Philadelphia, Hayes & Arthur, of Cleveland, Eugene Munsell & Company, of Chicago, James Clark, Jr. & Co., of Cincinnati, and Arthur H. Partridge of St. Louis.

The E. T. Burrows Company of Portland, Me., was prominently located on the aisle in the main hall. On either side were models showing open and closed car curtains in eight different styles. Within 60 days its No. 83 has been specified on over 400 new cars. The new open car fixture was highly commended by all who examined it. The exhibit was in charge of H. H. Russell and W. S. Calhoun.

D. J. Sinclair, of Caledonia, Livingston county, N. Y., displayed the automatic coupling patented by him. This coupling is simple to operate, sure in action, and while especially adapted to trolley cars or traction engines, can be used for all kinds of lifting, holding and drawing. Mr. Sinclair was kept busily engaged in explaining its operation, and it received many commendations for its good points.

The Corning Brake Shoe Company of Corning, N. Y., was represented by Francis Granger and H. T. Mercur, and had a very handsome exhibit on the main aisle. The Corning shoe has a chilled body with soft cast iron insets. Shoes were shown which had run 55,000 miles on the Buffalo & Niagara Falls line and some on the Fall Brook Railroad with records of over 25,000 miles and 11,000 stops.

R. G. Woodward of the R. Graham-Woodward Equipment Company, 26 Cortlandt street, New York, was present showing the "Standard" bicycle holders and the automatic track brake manufactured by this concern. The working model of the brake was exhibited at the Cataract House and was commended by all who saw it.

Will Christy of the Akron, Bedford & Cleveland was prominent at the convention. With him came the W. & W. oil journal box. This

corner of Walnut and 6th streets, a block above the convention hall, and nearly all the delegates took the opportunity thus afforded for seeing this switch in operation. The company was represented at the convention by its president, W. C. Wood, R. A. Baldwin and M. W. Conway.

The Clonbrock Steam Boiler Company of Brooklyn was represented by its president, Thomas F. Morrin, and showed models of

box is but a trifle longer than the ordinary box and requires that the axles be extended 2 or 3 in. In this extension is a simple form of centrifugal pump which throws the oil up into channels which conduct it directly to the bearing, keeping the latter bathed in oil.

One of the automatic electric switches of the New York Switch & Crossing Company, Hoboken, was installed on the Gorge road at the

Morrin "climax" boilers and photographs of a number of the plants which have been recently installed; among these was that at the Nashville Centennial, which aggregated 2,500 h. p. The souvenirs were sets of photographs, mounted on heavy cards and tied together by a silk cord.

The Columbia Machine Works, Buehler & Platt of Brooklyn, were

represented by George Buehler and W. R. Kerschner, who seemingly had things their own way and took 25 trial orders the first day of the convention. The exhibit comprised car trimmings, commutators, bearings, trolley wheels, bearing metals, forged commutator bars and controller parts, and was quite an attractive one.

The American Car Company of St. Louis, exhibited one of its cars on the track space in front of the convention building. It was mounted on maximum traction trucks and seated 36 persons, the seats being of the reversible cross-bench type, built by the Scarritt Furniture Company of St. Louis. President Sutton and E. J. Lawless of New York, eastern agent of the American Car Company, attended the convention.

W. T. Van Dorn of Chicago represented his company and exhibited his automatic couplers for street cars and the ball and socket joints. On the wall was a handsome collection of framed photographs and blue prints showing the couplers as adopted by various companies. Mr. Van Dorn said that he had no kick coming, having sold 140 couplers and 140 ball joints within 20 minutes after the convention assembled.

The Taylor Electric Truck Company, of Troy, N. Y., exhibited two of the Taylor double trucks, one equipped with two motors (four to the car) and the other with one motor (two to the car) and its latest design of single truck, which were displayed inside the hall. On the track outside was an improved heavy single truck with extension trucks for long open cars. John Taylor, A. T. Reynolds and G. A. Tupper were in attendance.

F. W. Sargent represented the Sargent Company, of Chicago. In addition to the "diamond S" brake shoe, composed of expanded steel and soft cast iron, the company exhibited models showing the use of expanded metal with soft composition filling. Among those displayed were shoes which had been subjected to service tests on both steam and street roads. Mr. Sargent was assisted by A. T. Herr and G. H. Sargent.

As for many years past the John Stephenson Company of New York made no exhibit at the convention. But D. W. Pugh represented the company and spent the four days in visiting with his old friends and making new ones. The Stephenson souvenir this year was the one adopted as "standard" by the company, a leather memorandum book; on the inside covers are the original tramcar built by John Stephenson in 1831 and the 1867 model.

The Monarch Stove & Manufacturing Company, of Mansfield, O., exhibited the "monarch" track cleaner. In the convention hall were a sample cleaner and a handsome full-size nickel-plated model made for exhibition purposes solely; outside, two other "monarchs" were attached to cars exhibited on the track space. All attracted a great deal of attention. The company was represented by E. C. Baxter, general manager, Fred Dew and W. T. Hurst.

The exhibit of the Steel Motor Company, of Johnstown, Pa., was in connection with that of the Johnson Company, that company's trucks being equipped with the steel motors. The single truck had the steel motor and the Clark hydraulic brake (made by the Steel Company). In all, three motors were shown, being of 25, 30 and 50 h. p. respectively. The company was represented by J. A. Rutherford, O. D. Henry, R. T. Lane, secretary, and J. A. Thomas.

The Gold Street Car Heating Company, of New York and Chicago, had a very handsome booth and displayed a full line of its heaters. Great interest was displayed in its new spiral, wrought iron enameled, on which the German silver wire is wound. The souvenirs of this company were canes, which were much sought after. The company was represented by E. E. Gold, president; W. E. Banks, treasurer; John E. Ward, manager; E. H. Gold, H. E. Beach and F. Weston.

The H. W. Johns Manufacturing Company exhibited a full line of overhead insulating material, including its latest design of toggle clamp pole insulators. These are now made and shown for clamping feeder cables from No. 0000 up to 1,000,000 c. m. in area. There was

also a full line of the H. W. J. electric heaters for both cross-seat and panel cars; these were shown in operation. The exhibits were in charge of J. Emery Meek, of New York, and H. H. Luscomb, of Boston.

The McGuire Manufacturing Company of Chicago was represented by W. A. McGuire, W. J. Cooke, George Collins and George Hubbard. There was an extensive exhibit comprising the McGuire standard suspension motor truck, the Columbia heater, the "new Columbia," ratchet brake handles, etc. Two of the McGuire double trucks were displayed in the General Electric space also. The souvenirs were aluminum-mounted magnifying glasses and were very much sought after.

Dillworth, Porter & Co., were represented by their New England agent, William F. Ellis, of Boston, and exhibited the Goldie spike and the Goldie claw safety tie plate. The Continuous Rail Company's joint with the base support rolled with the rest of the bar, and J. H. Sternbergh & Sons' "Harvey" grip, rolled thread, steel bolts were also displayed. The handsome photographs of the interior of the Boston Subway shown by Mr. Ellis were the best that we have seen of that work.

The Charles Scott Spring Company was represented by H. C. Johnson of the railroad and D. S. Roche of the street railway department. The exhibit was most tastefully arranged and included specimens of all the different types of springs manufactured for the use of street railways, from sash springs down to truck springs; among them was the three-quarter elliptic now so common on the latest types of trucks. This year the company had its usual souvenir—a leather covered memorandum book and pencil.

At the sign of "We design; others copy," was to be found F. A. Estep, president of the R. G. Nuttall Company of Allegheny, Pa. There were displayed specimens of the gears and pinions, bearings, trolleys and other lines of street railway supplies, making a very attractive exhibit. The company was further represented by its agents, C. N. Wood of Boston, George Povost of Pittsburg, Charles Mayer, of Mayer & Englund, and Hayes & Arthur, of Cleveland. A new catalog made a souvenir that was appreciated.

Wm. Wharton, Jr. & Co., of Philadelphia, were represented by R. K. Polk, manager of the rolling mill, J. C. Robinson of Harrington, Robinson & Co., New England agents, and Victor Angerer. They displayed a 9-in. girder crossing and several styles of switches; the Wharton standard; the West End of Boston standard and the Union Traction of Philadelphia standard both of which embody features of the Wharton; the Carver switch. Also the well known unbroken rail special work was shown as adapted for the use of half-groove rails.

The exhibit of the International Register Company of Chicago was an extremely interesting one. In addition to the different registers mounted as for use there were displayed working models showing the operation of the interlocking device, which is a feature of this company's double registers, having two totalizers. These models had the ordinary faces removed and plain glass substituted, and the mechanism being nickel-plated they presented a handsome appearance. A. H. Woodward, the manager of the company, W. H. Brown and C. N. Wood were in attendance.

The Duplex Car Company's car made by the Jackson & Sharp Company which was illustrated in the October REVIEW, page 701, was mounted on a Peckham extra long truck equipped with General Electric motors and electric brakes and was running on the Gorge road during the entire week. J. A. Lowell, president of the company, and George Moore, the inventor, were in attendance and were much gratified at the interest taken in the car. It is an ideal car for observation purposes. A New Haven double fare register kept tab on the number of passengers.

The Creaghead Engineering Company had a very complete exhibit of its well-known flexible brackets, both plain and ornamental, which have become standard for high speed roads. The arms are of steel and the fittings of malleable iron. It also exhibited a full line of overhead material, malleable iron pole fittings, cross arms, section

insulators, crossings and Bourbon strain insulators. The display was nicely arranged and was in charge of G. R. Scrugham. J. A. Cabot was also there. The souvenir of the company was a neat steel pocket rule in a leather case.

Pullen's rail joint box is a device which allows track repairers to tighten up loose bolts without the tearing up of the pavement. The

box lies along the outside of the rail and is just wide enough to allow the insertion of a bar where the cover is removed. It has been in service on the tramways in Sydney, Australia, the past three years and has given excellent satisfaction. Orders have recently been placed for boxes for 26 miles of track. Henry W. Peabody & Company, 58 New street, New York, represent the patentee in this country and exhibited at the convention.

The New Haven Register Company displayed the latest types of its registers, including the double type as used on the Akron, Bedford & Cleveland, the Calumet of Chicago, the Market Street of San Francisco, the New York, New Haven & Hartford, and in Louisville, and the triple type. The company was represented by Willis M. Anthony, president; F. Coleman Boyd, vice-president and general manager; John S. Bradley, secretary and treasurer; A. W. Chappell and A. N. Loper. Visitors to the exhibit received a very handsome bronze paper knife as a souvenir.

E. P. Sharp of Buffalo had "Any old thing" and was proud of it. His object in exhibiting was to call attention to the fact that he has repair parts for a large number of types of apparatus still used by street railways, but so far obsolete that the manufacturers can not be relied upon to furnish them. These parts Mr. Sharp bought when the manufacturers wished to reduce stock and can supply about anything desired. Two motors were displayed, a Sprague and an S. R. G. Sharp's combined price list and convention program was in the hands of all. E. C. Fletcher assisted Mr. Sharp.

The D. & W. Fuse Company furnished an object lesson to all who were interested in fuses. This fuse is positively non-arcing and even those in the closest proximity to it did not know that one had been burned out until told of it. They are made for currents of from 1½ to 200 amperes and from 500 to 2,500 volts, for railway, alternating, power, feeder and subway circuits. L. W. Downes and A. W. Hutchins presided at the experiments. The souvenirs distributed by this company were alleged to be working models; but on opening them, the fuse proved to be a cigar of excellent quality.

The representative of the Meaker Manufacturing Company, of Chicago, could not have been an Irishman or he never would have festooned his booth in green and orange. The exhibit included the well known Meaker registers as used on the North Chicago Railroad, the Union Traction Company's lines in Philadelphia (this company has over 2,800 Meaker equipments), nearly all the St. Louis Railroads and the Union Railway of New York. There was also a model showing the method of mounting. President J. W. Meaker presided over the exhibit in person, and ably represented his company.

The Fuel Economizer Company, of Matteawan, N. Y. was represented by P. J. Challen, and exhibited models, among them the \$1,200 one exhibited at the World's Fair, which was lost and but recently recovered, showing the construction and method of application of the Green economizer, and a number of sample castings. Leather card cases and memorandum books were distributed for souvenirs. This company has recently closed an order for economizers for the "Alley L," of Chicago, and just completed an installation in the new Harvard power house of the West End road of Boston.

Forsyth Brothers & Co., of Chicago had one of the most prominent exhibits at the convention, and were kept busy showing their curtains and fixtures to the visiting delegates. A full-size cross-section of one of the cars now building for the North Chicago Street Railroad, showed their curtains and anti-friction roller tip fixtures to good advantage. In addition to this they had a fine mahogany frame holding six curtains and fixtures; these also were of full size. George H. and W. H. Forsyth were at the convention. Elmer P. Morris also represented them and their goods were shown by the American Car Company.

The Joseph Dixon Crucible Company was represented by A. L. Haasis and John H. Baird, and exhibited its graphite paint for trucks which will stand sand abrasion and will last for four seasons, its paint for roofs and stacks which is unaffected by sudden changes of temperature, and its new compound known as graphited wood grease. This last is made up of cedar pulp, flake graphite and fats and oils; it will cause the worst gears to run without noise, and it does not ooze out between the laps and the cases. Another new compound was the graphite dynamo commutator lubricant for arresting sparking on the commutators.

The handsome and artistically arranged exhibit of the Ohio Brass Company was the first thing to catch the eye upon entering the convention hall. A full line of track-bonding and overhead construction

materials was displayed; also supplies for cars, commutators, headlights, steel gongs, bearings, bearing metals, adjustable track-brush holders, wire track brooms, type D hangers, figure 8 devices, "dirigo" insulation in its various forms, pole brackets, etc. Thermometer buttons were given for souvenirs. The exhibit was in charge of C. K. King, secretary, and A. L. Wilkinson, special representative of the company.

The Consolidated Car-Heating Company of Albany, N. Y., showed a full line of car heaters and regulating switches. The method of operating the switch was illustrated by connecting in banks of lamps to represent the heaters. This switch gives five different intensities with a six-heater equipment, the several positions giving six in series; four in series; six in multiple-series, three series; four in multiple-series; six in multiple-series; two series. The exhibit was in charge of James F. McElroy, consulting engineer of the company and he was assisted by H. N. Ransom, eastern representative, and W. P. Cosper, western representative.

J. J. Kennelly of 446 West 47th street, New York was at the Imperial and exhibited a new fare register. The model shown was for exhibition purposes and shaped like the cross section of a car body; "up" or "down" was indicated on the transom, the trip fares in the center, and the total fares in the bottom of the face. A feature of the register is the manner in which the conductor takes the reading; he carries small cards, one of which he places in the register at the end of each trip before setting it back to zero; the operation of setting the register embosses the reading of the totalizer on the card, making a record that cannot be inaccurate.

At the exhibit of the Crane Company of Chicago, the first thing that we saw was G. A. Hurd's aluminum valve; Mr. Hurd was also there. The 24-in. extra heavy steam gate valve was recognized by every street railway man because all of them have pictures of it. The fittings for the most part were extra heavy valves for street railway power houses and specimens showing the different ways of attaching the flanges to pipes; there were also back pressure valves and steam traps. A special feature was the line of brass globe and check valves in the smaller sizes which were designed for pressures of 2,000 lbs. and 5,000 lbs. R. T. Crane, Jr., was also present.

The watch-word at Space 33 was, "This is the Falk joint; make a joint affair of it." The exhibit comprised many samples of the cast-welded joint, but the thing that proved most attractive and interesting to visitors was the new process recently perfected by the company, by means of which rails may be readily and completely cleaned of scale and rust, so that a perfect weld of the best conductivity is insured. As a side issue the arithmetical paradox,  $2 + 1 = 1$ , that is 2 rails + 1 Falk joint = 1 rail, was propounded, and it remained unchallenged. H. W. Falk, president of the company, E. A. Wurster, secretary and treasurer, and H. L. Prather, general superintendent, took turns at presiding over the exhibit.

The Consolidated Car Fender Company of Providence displayed two of its fenders attached to a dummy car so that the method of operation might be easily and clearly shown. It proved of great interest to managers and was closely examined by the delegates from cities where the fender ordinance is a new thing. The fender is now in use on over 4,000 cars in 53 cities and towns. In addition there were shown the special fittings for attaching the fenders to different types of cars. The company was represented by A. C. Woodworth, general manager; A. C. Woodworth, Jr., superintendent, and George H. Hale, general agent. For souvenirs there were old-fashioned pocket books with fender data on the inside.

The exhibit of the Diamond Truck & Car Gear Company of Kingston, N. Y., was arranged along the west wall of the hall; the background was tastefully draped and ornamented with groups of photographs and blue prints showing the cars on the different roads where the "diamond" truck is in use. There were four trucks, the No. 3 and the No. 5 singles and a pair of double trucks; one of these latter was displayed on the General Electric floor fitted with motors; all were sold and immediately after the convention delivered one to Hamilton, one to Jamestown, and two to Buffalo. The company was represented by W. H. Wilkinson, general manager, W. H. Ten

Broek and E. F. Hutton. Memorandum books were distributed as souvenirs.

The "brightest spot in the hall" was the title given the space of the Central Electric Company. The "Helios" enclosed arc lamps which burn 150 hours on a 500-volt circuit without trimming, and 150 incandescents, furnished the light. The exhibit included the largest commu-

tator bar (20 lbs.) ever drop-forged, the largest piece of mica west of New York city, Billings & Spencer overhead materials, Bound Brook graphite bushings and bearings, Partridge brushes, trolley poles, gongs, harps and wheels; also the Central Electric crossover and figure 8 clip. Garton lightning arresters were shown in operation. The exhibit was in charge of W. R. Garton, manager of the railway department, who was assisted by H. E. Adams, the New York representative.

The Sterling Supply & Manufacturing Company of 141-155 East 25th street, New York, displayed its exhibit in parlor 234 at the International, being represented by William Tiffany, secretary, Louis E. Robert and Frank A. Morrell, who entertained visitors in a most hospitable manner. The register exhibit comprised the standard No. 1, of which there are 2,500 in use on the Metropolitan of New York, the No. 3 clock dial and the No. 7 square dial numeral register which were exhibited for the first time. In addition there were shown the cable and electric brake which has been in use on the Metropolitan for the past three years and the Sterling sand box. Almost all the railroad men were sufficiently interested in the Sterling exhibit to make a visit, which fact was very gratifying to the company. Miniature clocks gold mounted for desk use were distributed for souvenirs.

The attractive and interesting exhibit of the Mica Insulator Company, of New York, Chicago, London, was prominently located at the left of the main entrance. Commutator rings, segments, troughs, tubes, discs, plates and various forms of insulation were largely displayed, and were of special interest to all electric railway men. The company's new product known as M. I. C. compound was for the first time exhibited. Some to different grades and styles of mica-ite and empire cloths and papers were shown. This is probably one of the largest exhibitions of insulating material exclusively ever made and goes to show the progress which the company have made during the past four years. Charles E. Coleman, of the Chicago house was in attendance and had charge of the exhibit. Franklin Brooks, vice-president of the company, was also in attendance one or two days.

The exhibit of the Wells & French Company, of Chicago, was in charge of its eastern representative, Frederick Saxelby, of 100 Broadway, New York, and consisted of a Curtis non-oscillating truck, equipped with two Westinghouse 12-A motors and the Price momentum friction brake. In order to show the brake in operation the truck was blocked up to permit the wheels to clear the track. By this arrangement there was only the momentum of the wheels, axles and motors to overcome, and as the brake levers were designed for use with a heavy car and trailer, it was well calculated to test the adaptability of the brake for light pressures. The tests showed that the brake worked with certainty and without shock under all conditions. This particular truck was equipped for the use of either the momentum or hand brakes; when desired the hand brake is made to act on a separate set of shoes.

The exhibit of the Pantasote Leather Company was made extremely attractive by the liberal use of handsome specimens of pantasote in decorating the walls. At either side of the entrance were models, one showing the curtains as applied to closed and the other to open cars. Pantasote, as is well known, is made up in any pattern desired, and some beautiful ones in gold were exhibited. The material is waterproof, odorless and durable. The most delicate and expensive silk fabrics may be used in connection with it, so that curtains may be made which present an exterior surface that is dirt, water, and sun-proof and yet have tapestry for the inside of the car. Ten thousand of these curtains have been sold for the Wagner palace cars. The company has severed the connection that has existed for six years with Clarence Whitman & Co. as sales agents and will henceforth dispose of its own goods. John M. High of New York and H. M. Grier of Chicago were in charge.

The Christensen Engineering Company of Milwaukee had probably the most conspicuous space in the hall, as its exhibit was displayed on the raised platform at the end of the main building. There were three automatic motor compressors and one axle driven compressor shown in operation. The largest had a capacity of 48 cu. ft. of free air per minute and was connected to a rack of 12 cylinders for automatic air braking. The second was of 14 cu. ft. capacity and connected to the cylinders for a motor car and two trailers—a 60-ton train. The third was of a smaller size, 9 cu. ft. All were equipped with automatic current controllers. The axle compressor was mounted on a Dupont truck, equipped with Steel motors. This type occupies but 7½ in. of the length of the axle. There were also shown miscellaneous parts of the motors, compressors and braking apparatus. The company was represented by N. A. Christensen, of the home office, Garson Myers, of Chicago, and Frank Randall, of the eastern office.

The Johnson Company exhibit comprised crossings special work and trucks. The P. R. R. standard steam crossing shown is so called because it must be laid down by all trolley roads crossing the Pennsylvania; it was of 80-lb. T-rails with unbroken main rails, lift rails to carry bad wheels, and guard rails; the total weight was 4,072 lbs. The special feature of the Johnson standard 9-in. girder crossings is the "guarantee," a Harveyized octagonal plate placed at the rail intersections; this piece may be renewed and guarantees a long life for the work; the "guarantee" is also used on switches and on steam crossings. There were three Dupont trucks also, one single and two double trucks; one of the latter equipped with Steel Motor Company's motors was in the Christensen Air-Brake exhibit. The Johnson Company was represented by Daniel Coolidge, vice-president; A. S. Littlefield of Chicago, W. E. Boughton of Philadelphia, O. C. Evans of Cincinnati, H. C. Evans of New York, R. Clitz of Boston, W. W. Kingston of Atlanta, and E. B. Entwisle, chief engineer.

Eugene Munsell & Co., of New York and Chicago, made a very fine display of their India and "amber" mica, both in the sheet as it comes from the mines, and segments for railway motors. The exhibit was made in connection with that of the Mica Insulator Company. Several sets of a variety of sized segments were attractively displayed beneath a large signboard on which was shown a full line of Van Wagoner & Williams Hardware Company's drop forged copper segments, for whom the company is general western selling agent. At the entrance to the booth was shown India mica cut in sizes from 9 16 x 4¼ to 8 x 10 in. This large range of sizes show that the firm is prepared to furnish "mica" in almost any size, shape or pattern. A souvenir in the form of a "mica mine" puzzle was given and probably sought for as much as any one souvenir at the convention. Parties not in attendance can secure these souvenirs by writing the company at either New York or Chicago. The exhibit was in charge of Charles E. Coleman, of the Chicago house.

The Edison-Brown Plastic Rail Bond Company of 120 Liberty street, N. Y., had an attractive and interesting exhibit and was represented at the convention by Harold P. Brown, Franklin Sheble and Frederick Reeve. In the exhibit was an angle plate removed from the track of the Camden (N. J.) & Suburban after two years service; though the plate had evidently been under water and was badly rusted, the plastic was in perfect condition. The methods of applying the different bonds were all shown; in this connection it may be mentioned that the road at Hamilton, Ont., is to be rebonded, using the E. C. A. bonds. Blue prints were displayed showing the bonding for the tramways of Dublin and Blackpool, the Central Underground of London and the government tramways of New South Wales, contracts for which have been taken by this company. There was also a 2-h. p. gasoline engine with flexible shaft used for cleaning rails previous to bonding which was built after the design of Gustave Fischer, general manager of the N. S. W. Government tramways.

The display of the Westinghouse Electric & Manufacturing Company in its exhibit attracted a great deal of attention owing to the fine and large "booster outfit" which the company had on exhibition. This "booster" consisted of a compound wound motor driving a 460-h. p. series wound generator, and a marble switchboard with the necessary appliances for operating the machines. Besides this the company showed a complete line of switchboard appliances, such as lightning arresters, circuit breakers, switches, ammeters and voltmeters. On pedestals fronting the exhibit were shown the well-known types of Westinghouse motors from the ordinary standard street car motor to the locomotive size. Some other motors were placed on trucks of various make throughout the exhibition hall. The following were in attendance at the convention from the Westinghouse Company: E. W. T. Gray, E. H. Heinrichs, J. B. Lyford, Jr., R. F. Storer, B. T. Mallett, Robert Siegfried and Arthur Hartwell, of Pittsburg; W. F. Zimmerman, New York; R. S. Brown, Boston; C. A. Bragg, Philadelphia; J. R. Gordon, Atlanta, Ga.; Maurice Coster, Chicago; Paul T. Braz, Syracuse; F. T. Freneyar, Buffalo; W. K. Dunlap, Niagara Falls, and M. McLaren, Pittsburg, who was in charge of the exhibit.

Elmer P. Morris and J. C. Dolph had an exhibit of their own located in two rooms on the ground floor of the Cataract, just across the street from the International. The favorable location and the

many attractions provided made this exhibit a popular resort for the delegates in the evenings; there was a "hot time" there on the 13th. Mr. Morris represented the following manufacturers: Wheeler Reflector Company, oil and electric head lights; Hemingray Glass Company, insulators; Hope Electric Appliance Company, switches,

cut-outs and specialties; Forsyth Brothers Company, car curtains and fixtures; Harrington Illuminated Sign Company; Electrical Equipment Company, overhead line material; Simonds Manufacturing Company, gears and pinions; Keystone Electrical Instrument Company; Point Marion Manufacturing Company; McGuire Manu-

facturing Company. Mr. Dolph was present in the interests of these companies: Forest City Electric Company, roll drop and drop forged commutator bars, protected rail bonds; Sterling Varnish Company, extra insulating varnish; Catskill Foundry & Machine Works, iron and steel gears and pinions; American Mica Company, India and amber mica; D. & W. Fuse Company, railway cut-outs, enclosed fuses, etc., and J. C. Dolph & Co. dealers in carbon brushes, head-lights, trolley fittings, ratchet brake handles, incandescent lamps and sand boxes. All the goods exhibited were artistically arranged and made a very handsome display.

The Peckham Company had the most extensive truck exhibit at the convention; it comprised six double trucks, one single truck (one of 100 now building for the Cincinnati Street Railway), two side frames, a locomotive truck and one of its rotary snow plows that had been in use for two years on the Buffalo Railway. Nearly all the apparatus was of new design and exhibited for the first time. Type No. 15 is an extra heavy, swing bolster truck for interurban lines; like all the Peckham trucks it is triple cushioned. Type No. 14 is for city service. The 14-A is a swing bolster truck for heavy service; in the 14-B the motors are suspended outside of the axles enabling the wheel base to be reduced to the very short distance of 4 ft.; the 14 C is a double truck with four wheels of the same size but provided with a maximum traction device by which the proportion of the weight carried by the driving wheels may be varied within wide limits; the 14-D is a swing bolster maximum traction truck with graduated braking gear. There were also Peckham trucks in the exhibits of the electric companies. The representatives of the company present were President Peckham, E. G. Long of New York, C. S. Ackley of Kingston, Arthur Field of Boston, and J. A. Hanna and W. H. Gray of Chicago. The Peckham souvenirs were the handsome leather memorandum books and pocket books that have proved so popular at former conventions. The handsome celluloid cards displayed on the trucks attracted much notice. Headquarters were also maintained at the International, where models of the trucks were displayed. Lady visitors were presented with what was perhaps the handsomest souvenir of the convention, a transparency of the Falls.

The J. G. Brill Company had a very extensive exhibit. In the Brill space were shown four trucks of the well-known types; the 21-E single truck with solid forged side frames, of which type the West End of Boston has ordered 300 since March; the No. 27, the "perfect" truck; the No. 27-D, the "universal" truck, and the "eureka" maximum traction truck. Also, there were two No. 27 trucks in the exhibit of the Standard Air-Brake Company used to display the compressors of that company. Outside were a standard vestibuled snow sweeper equipped with three motors, and one of the standard 10-bench open cars, mounted on a 21-E truck. In addition to these which were at the convention hall, mention should be made of that other exhibit to which attention was called in a pamphlet entitled, "Brill Cars and Trucks at Niagara Falls and Vicinity;" the entire equipment of the Gorge road was by this company, consisting of 12-seat open cars mounted on "eureka" maximum traction trucks; all the rolling stock of the Buffalo & Niagara Falls line is mounted on Brill No. 27 trucks, of which the general manager, Mr. VanHorn, says: "During the two years that they have been in service here, none have ever left the rail;" the other roads in the city and vicinity using Brill trucks are the Niagara Falls & Suspension Bridge, the Niagara, Whirlpool & Northern, the Lewiston & Youngstown, the Buffalo Railway, and several of the suburban lines out of Buffalo. There were present from the company, John A. Brill, S. M. Curwen, W. H. Heulings, G. M. Haskill, Edward Brill and H. H. Archer. The souvenir presented to visitors was a graphical electric traction computer, handsomely bound in leather, designed by William Cox, of New York, and copyrighted by the Brill Company; it will prove useful in any technical man's office.

The Standard Air-Brake Company had a striking exhibit which greatly eclipsed those of former years. Not only was it an object lesson, but it showed the great progress made by that energetic company, which was the first concern to build street railway air-brakes, and the exhibit practically illustrated the different types of apparatus manufactured, from the beginning of its business to date. The apparatus was in charge of the company's managing director, E. J.

Wessels, and was assisted by the chief engineer, E. H. Dewson, Jr., George E. Pratt and C. B. Fairchild, special agents, H. B. Taylor, assistant engineer, and E. E. Robinson, foreman. On entering the exhibit on either side was to be found a Brill No. 27 truck, the one on the left equipped with the well-known duplex compressor, direct axle-driven. There are many of this type in service here and abroad; thirty are completing their third year of active service on the Buffalo Railway. On the right was shown the well-known geared compressor, which is the standard on several roads in the United States and Canada. This type has proved admirably suited for heavy traction and high speeds. Back of the duplex was shown the hollow spindle brake-cylinder with fulcrum on back head for equalizing double truck brake rigging. A handy attachment enabled delegates to see how quickly and easily pressure can be applied. The attachment embraced a graduated spring, with a pressure indicator which showed the range from minimum to maximum, the latter being equal to an emergency stop. There was also shown the well-known Standard interlocking handle for working the controlling valve and the chime whistle. Adjoining this stood the automatic current controller, which excited favorable comment from the many delegates who watched the precision and accuracy of its movements, and were surprised at the narrow limits within which it operated. Next to this was the water and dust proof electric compressor in which freedom from vibration and noise was very remarkable. The ease with which it compressed air quickly, and the remarkable small space it occupied excited much interest. The motor compressor was piped to a 14 x 48-in. special reservoir. Next was shown a No. 1 brake cylinder with attachments, showing the manner in which trail cars are braked. In addition there was a profusion of special hose, couplers, gages, regulators, and mufflers, the whole giving a comprehensive idea of the entire system, and showing its simplicity as well as the substantial character of the apparatus. The display was augmented by views of cars and trains in different parts of the globe on which Standard air-brakes are used. The World's Columbian Exposition diploma and medal were also displayed, and a striking sign proclaimed that the Standard was first in the field and the only concern which had received a diploma and medal. The company's Australian agents, Noyes Brothers, were represented by Edward Noyes, the senior partner, of Sydney, New South Wales, who was an interested spectator and gave those who inquired a graphic report of the satisfaction which Standard air-brakes had given in the distant colony in which he resides. Great credit is due Mr. Wessels for his untiring energy, which has not only kept his company at the head of the street railway air-brake industry, but has led to the building of a large and constantly increasing business.

The General Electric Company made the most extensive exhibit at the convention hall, confining it however to motors, controllers, meters and subsidiary apparatus. It occupied the southwest corner of the main hall, and, brilliantly illuminated, formed a centre of attraction for the entire fraternity. The motor exhibit comprised examples of the latest types G. E. 51, 52, 53, 55 and 57 motors. The G. E. 55 of 175 h. p. capacity attracted much attention. This was not mounted; the others were all shown in motion mounted upon trucks. One McGuire pivotal truck was equipped with a G. E. 51 80-h. p. motor on one axle, and an electric brake on the other, both controlled by a B-7 controller. Another truck of similar make and type carried on one axle a G. E. 53 50-h. p. motor of special build for narrow gage work, and an electric brake. A Brill No. 27 truck was equipped with two G. E. 57 50-h. p. motors, with an electric brake on each axle. This is the equipment used in the high speed work in the Cleveland & Lorain road. To accommodate both motor and brake on the same axle the wheels are dished. The equipment was controlled by a B-8 controller. A "diamond" truck also carried two G. E. 57 motors, without brake equipment. On a Peckham flexible cantilever truck were mounted two G. E. 52 57-h. p. motors with K-10 controller. All these equipments were arranged to show the operation of both motor and brakes. The equipments of the two McGuire trucks were controlled by one controller, and were run either singly or both together. On each of the above equipments was set a Thomson recording car meter for use on the car itself, serving to show how a check may be placed on the performances of the motorman with the controller. In the exhibit of the Barney & Smith Car Company, two G. E. 1,000 motors were mounted upon a pair of class H trucks. In the Peckham Truck & Wheel Company's exhibit two G. E. 52

motors were mounted on a cantilever truck. The Duplex Company's car running on the city tracks was also equipped with G. E. apparatus. Armature construction was exemplified by two completed G. E. 52 armatures, a full set of motor mica insulations, a series of armature coils ready for application to the core, and a number of field coils; also several complete sets of motor commutators bound and headed for shipment. The gear work was well represented, all gears and pinions shown coming from the gear plant of the General Electric Company. Three boards were erected in the exhibit space on which were mounted circuit breakers, switches, lighting arresters, meters, etc. The illumination was very elaborate; among the signs was one giving the railway record of the company: 2,137 generators, aggregating 512,213 h. p., 36,101 motors, aggregating 1,059,060 h. p. and 40,000 series-parallel controllers. The writing room of the International was handsomely decorated and served as headquarters; in a small booth here a continuous X-ray exhibition was given; parlor D was the social annex. Among the many courtesies extended was a tally-ho party to Canada on Tuesday. The interests of the company were cared for by W. J. Clark, general manager, W. B. Potter, chief engineer, Ralph H. Beach, L. D. Tandy, J. G. Barry, Lee H. Parker, F. E. Case, W. G. Carey, E. D. Priest, F. M. Boyles and H. Kernochan, of the railway department; Edgar Carolan, of the foreign department; J. R. Lovejoy, general manager, H. C. Wirt, chief engineer, and J. H. Aitken, of the supply department; C. D. Haskios, of the meter department; F. M. Kimball of Boston, T. Beran of New York, and A. D. Page, manager of the incandescent light department, Harrison, N. J., who were the convention committee; the sales offices were represented by W. G. Bushnell and A. B. Shepard, New York; T. P. Bailey, Chicago; E. D. Mullen and W. J. Crowley, Philadelphia; C. C. Pierce, of Boston; W. F. Hays and F. B. Striesby, Cincinnati; S. W. Trawick and A. C. Tenney, Atlanta; F. F. Barbour, San

Francisco; George D. Rosenthal, St. Louis; T. H. Fearey and D. F. Potter, Buffalo; Irving Hale, Denver.

- Among others who were represented at the convention were:
- The F. P. Allis Company, J. B. Allan.
  - The Washburn & Moen Manufacturing Company, H. T. Pratt and N. R. McLeod.
  - Siemens & Halske Electric Company, H. C. Spaulding.
  - C. B. Arthur, street railway supplies.
  - Missouri Car & Foundry Company, Scott H. Blewett.
  - Brownell Car Company, F. B. Brownell.
  - F. C. Boyd.
  - Railway Register & Manufacturing Company, Edward Beadle.
  - St. Louis Car Company, Jilson J. Coleman.
  - Western Electric Company, Samuel A. Chase.
  - Elliott Frog & Crossing Company, W. H. Elliot.
  - E. C. Fletcher.
  - Heine Safety Boiler Company, H. B. Ham.
  - Q. & C. Company, Edward W. Hodgkins.
  - Hayes and Arthur, Scott R. Hayes.
  - Jackson & Sharp Company, J. Montieth Jackson.
  - Simmons Manufacturing Company, John Jackson.
  - Rossiter, MacGovern & Co., Frank MacGovern.
  - Bethlehem Iron Company, E. M. McIlwain.
  - Naugle, Holcomb & Co., E. E. Naugle and George Weston.
  - Billings & Spencer Company, W. B. Post.
  - Laclede Car Company, E. J. Robinson.
  - Dick Kerr & Co., London, Charles S. Schultz.
  - Forest City Electric Company, G. A. Thomson.
  - John Stephenson Company, J. A. Tackaberry.
  - New Process Raw Hide Company, A. C. Vosburgh.

The technical press was represented at the convention as follows:  
**STREET RAILWAY REVIEW:** H. H. Windsor, F. S. Kenfield, H. J. Kenfield, Daniel Roysse, George A. Barnes, G. J. M. Ashby.  
**Street Railway Journal:** James H. McGraw, E. E. Higgins, John B. Bennett, W. A. Taylor, H. W. Blake, Charles B. Fairchild, Jr., C. S. McMahan.  
**Electrical World:** W. J. Johnson, J. V. S. Church, Charles A. Child, Clarence E. Stump.  
**Railroad Gazette:** John N. Reynolds, E. A. Simmons, Arthur J. Wood.  
**Electrical Engineer:** W. F. Hanks, J. R. MacConnell, T. C. Martin, John Balch.  
**American Electrician:** W. D. Weaver, E. E. Wood.  
**Western Electrician:** J. B. O'Hara, Frank L. Perry.

**Power:** H. M. Sweetland.  
**Canadian Engineer:** E. B. Biggar.  
**Engineering News:** John J. Swann.

### PARLOR EXHIBITS.

Each year seems to show a decreasing tendency to exhibit in the parlors, and those who use them to do so chiefly for the convenience of having a quiet place for their friends to drop in and rest, and where a little business can be discussed undisturbed by the crowd.

At the International the General Electric had ground floor parlors, and provided various little entertainments. The rooms were hung with fine photographs of electric work.

The J. G. Brill Company, the Christensen Engineering Company, the Peckham Company and the Sterling people each occupied pleasant parlors, which were made attractive with pictures, flowers and decorations, and proved very pleasing.

At the Cataract the Garton-Daniels, Forsythe Bros., Elmer P. Morris and the Forrest City Electric, used parlors on the ground floor.

### CONVENTION NOTES.

The local roads on both sides of the river were very generous in providing free transportation. Heretofore the value of a free ride has not been to exceed 5 cents, while many of the Niagara trips which were so freely furnished represented a 50-cent ride. And scarcely a delegate but went over the best rides at least twice. Then, too, the Suspension Bridge was free to the delegates either on foot or in carriages, and the ferry at Lewiston, and the owners of the Maid of the Mist, which had gone into winter quarters, brought out the brave little craft, and she was kept busy during the entire four days. Altogether the transportation companies at the Falls did themselves proud in their treatment of the delegates, and will be long remembered for the unsurpassed trolley rides with which the Niagaras abound.

It was a graceful act of the executive committee to order the making of a steel engraving of William J. Richardson, who was for so many years, as he was the first, secretary of the Association. The portrait will appear in the official proceedings of this year, and as the Association has had but two secretaries in all these years, it was ordered to include the portrait of Mr. Penington also.

The Christensen Engineering Company, Milwaukee, was the author of a happy and much appreciated courtesy which made glad the hearts of the ladies. The supply of cut flowers in Niagara was very limited, as many discovered too late to send elsewhere. Garson Myers had ordered a large quantity of American beauty and other roses from Buffalo which he distributed among the ladies, so far as he could obtain addresses, on the evening of the banquet.

A luncheon was given in honor of President-elect A. E. Lang October 22 at the Buffalo Club by H. M. Watson. The guests were returning home from the convention and this continuation of the festivities was greatly enjoyed by all present. G. P. Kerper, of Dayton; Secretary T. C. Pennington, of Chicago; H. M. Littell, Brooklyn; C. S. Sergeant, of Boston; E. C. Foster, Lynn; H. W. Box, H. H. Littell and C. M. Bushnell, Buffalo, and others were guests with the president.

Nearly all who crossed the Suspension bridge had their attention attracted to the four barrels which hung over the side of the railing midway in the stream. Each was painted a different color and hung by a small rope. The explanation lies in the fact that these were the

barrels for the daily race, which is one of the amusements of the Falls. At a certain time every day they are cut loose simultaneously, and the contest is to see which barrel travels a given distance down the rapids and passes the goal first. Pools are sold on the race, which it must be admitted is about the fairest conducted of any race possible.

When the accident on the New York Central was known it was feared some of the convention people were in the wreck. Although two or three were on the train, none were among the injured. Mr. Peckham and J. H. McGraw had both intended taking this train, as had a number of others, but fortunately remained in Buffalo until the next train. Mr. Crossman, the official stenographer, and his wife had berths engaged, but at the last minute decided to remain a few hours longer. Their baggage, containing the stenographic notes, were in the wrecked baggage car that was under water several hours, and while the shorthand notes were somewhat blurred, are for the most part still decipherable.

### THE HEADQUARTERS' LANDLORD.

One of the most important persons in the whole Niagara town, during the convention, from the standpoint of some 600 delegates who put up at the International, was the landlord, S. A. Greenwood. He has been constantly in the hotel business for 15 years and has worked his way up from night clerk to manager of the house. In the meantime he has been connected with the Spencer House, Niagara; the St. Louis Hotel, Quebec; a World's Fair hotel in Chicago; finally bringing up as manager of the house with which he started. He has had a large number of big gatherings during the past season. Mr. Greenwood is married and has two interesting little sons.

S. A. GREENWOOD.

### PERSONAL.

S. S. Neff has been appointed superintendent of the Chicago Union Loop.

B. W. Peterson has been elected director in the Wheeling Railway Company to succeed P. B. Dobbins who died recently.

H. M. Littell visited Chicago after convention, spending two days visiting the street railways here, and calling on the REVIEW.

H. R. Conklin, who has been manager of the Citizens' Traction Company of Oshkosh, Wis., since its construction, has resigned.

Wm. H. Harrington, has resigned the superintendency of the Southbridge (Mass.) & Sturbridge Street Railway Company on account of poor health.

E. M. Green has accepted the superintendency of the Signal Mountain Railway Company of Chattanooga, Tenn., succeeding H. A. Nicholl who recently resigned.

Frank De Ronde, the genial general sales agent of the Standard Paint Company made the REVIEW office a call when on his way to Denver, Col., to attend the Bridge Superintendents' Convention.

J. L. McCreary, electrical engineer of the Citizens' Street Railroad Company, was married to Miss Blanche Moore at the home of her parents in Indianapolis, November 3. We wish for Mr. and Mrs. McCleary a long and happy married life.

Lemuel Ammerman, president of the Lackawanna Valley Traction Company, and the vice-president of the Scranton & Pittston Traction Company, died at Blossburg, Pa., October 8, at the age of 51. He was also vice-president of the Brookside Coal Company, the Spring

Brook Water Supply Company, Wilkes Barre, Pa., and the Mansfield Water Company. Mr. Ammerman was comptroller of Scranton in 1887 and was a member of the 52nd Congress.

George E. Pratt, the late secretary and general manager of the Hunt Air-Brake Company, of Pittsburg, has severed his connection with that concern and entered the service of the Standard Air-Brake Company as special agent. Mr. Pratt was an earnest worker in the air-brake field, and as he thoroughly believes in air-brakes, decided to continue in the business. We predict for him a long and successful career in this field. His hosts of friends will doubtless be interested on learning of this new connection. It is certain that Mr. Wessels is surrounding himself with the best representative men in the various branches of the company's business.

## NEW PUBLICATION.

The Colliery Engineer and Metal Miner announces that with the November and all subsequent issues the title of the paper will be Mines and Minerals. This alteration is not indicative of any change in ownership, editorial management or scope of work. Originally the paper was devoted only to coal mining but its field gradually broadened until it embraces the prospecting for, development and mining of all minerals. It is a leader in its field, and a credit to technical journalism.

## THE TERRE HAUTE TROUBLE.

To all appearances the mayor of Terre Haute has taken a most unprecedented and unfair advantage of his official position to carry out a personal spite. The Terre Haute Electric Railway was assessed for a very large sum as its share of some extensive street paving improvements; which amount, owing to the reduced earnings common to all lines during the past two years, it was unable to pay in a lump sum. The last legislature authorized the city to extend the time of payment by a lower rate interest bond than the one first made. The city council recognized the justice of the case and adopted an ordinance to carry out the plan. This the mayor refused to sign, claiming it was unconstitutional, and since its passage in June the ordinance has been reviewed by some of the best lawyers in the country who declared it sound. The mayor, however, refused to be convinced, and on October 17, before daylight, when it was impossible for the road to get funds in bank in time, made a levy on the road and placed it in a receiver's hands. Part of the indebtedness for which the road is sued is not yet due, and had the mayor signed the bonds as authorized by his city council, no part of it would have been due. The citizens declare the action of the mayor an outrage, the daily press of the city repudiates it, and at its first succeeding meeting the city council passed a unanimous and highly complimentary resolution expressing its confidence in President Harrison, and urging the receiver not to disturb the old management.

We are informed on good authority that this same officious mayor is 17 years in arrears for county taxes, and that the county is unable to collect from him. He is also in arrears for city taxes. That a man of his type should ever be entrusted with authority which makes possible so high handed and outrageous a proceeding as this seizure of the Terre Haute road, is at once a matter of regret and disgust. Mr. Harrison has given his city a road and a service equalled by few cities of its size, and is deserving of better treatment in return for what he has done. It will be a hard task to extricate the company from its dilemma, but we believe Mr. Harrison is equal to the task and will eventually come out with flying colors.

## THE REVIEW WINS A SILVER MEDAL.

We have just received advices from the Brussels Exposition that the STREET RAILWAY REVIEW has been awarded a Silver Medal and a Diploma of Honor, on its exhibit of current and bound volumes of this magazine. The award is made for the best technical publication of its class, and includes excellence in printed matter as well as typographical arrangement and illustrations.

This makes the second medal we have won, the first having been awarded at the World's Columbia Exposition.

The exhibit of the Chicago Trade Press Association, of which this publication is a member, also won a medal at the Brussels Exposition for the best exhibit of technical and trade journals.

## SHORT HEADWAY IN CINCINNATI.

Ordinarily we measure the headway on street railways in minutes and we believe that there are roads where hours are the units, but there is one particularly busy street crossing in Cincinnati where a count showed 48 cars between 5 and 6 p. m., October 16, an average of one every 8.4 seconds. It should be stated that there was nothing extraordinary about this days traffic.

The diagram roughly illustrates the layout of the tracks at this corner; those marked "C" are cable lines; the others are electric lines. The traffic was as follows:

|                                     |     |
|-------------------------------------|-----|
| South on Walnut street.....         | 23  |
| East on 5th street, south side..... | 142 |
| East on 5th street, north side..... | 112 |
| West on 5th street.....             | 151 |

Sylvester T. Everett has been given judgment against the East Cleveland Railway Company for \$10,750 as commission on loans which he negotiated.

The Louisville City Railway Company on October 7 paid the judgment for \$25,117 franchise tax. The contemplated appeal to a higher court has been abandoned.

A new motor car has been received by the Cincinnati, Hamilton & Dayton Railroad from the Baldwin Locomotive Works, to be operated over its lines in competition with the Cincinnati & Miami Valley Traction Company.

A hot fight at the annual election of the Southwest Missouri Electric Railway resulted in a change in the board of directors. General Manager A. H. Rogers and Vice-President E. Z. Wallower were defeated for re-election. The new officers are W. W. Cahoon, president; J. F. Harrison, vice-president; C. F. McElroy, secretary; D. R. Goucher, treasurer, and F. H. Fitch, superintendent, all of Carthage. The Southwest Missouri Electric Railway is the longest interurban in the west. It is in good physical and flourishing financial condition, its receipts for the fiscal year having reached \$115,000, with fixed charges of but \$30,000. This favorable showing will probably inaugurate a policy for the retirement of outstanding bonds.

## TRIAL TRIP OF THE PATTON MOTOR.

Invitations were extended to the street railway, the railroad and consulting engineers of Chicago to be present November 2 at the inaugural trip of the improved Patton motor car. About 75 guests, including G. W. Knox, Electrician of the Chicago City Railway, John Lundie, consulting engineer of the Illinois Central, F. K. Dorrance of the Houston & Texas Central Railroad, A. M. Kinsman, chief engineer of the Lake Michigan Car Ferry Company, a representative of the STREET RAILWAY REVIEW and others, inspected the motor and occupied a passenger coach which was drawn over the tracks of the Chicago stockyards by the motor car. The coach was very heavy, weighing 60,000 lbs. exclusive of the passengers, which was a severe test for a motor car equipped with a 25-h. p. engine. With a lighter coach a speed of 15 miles an hour was attained.

This car was equipped with a 25-h. p. gasoline engine direct coupled to an 8-pole, shunt-wound generator, with a capacity of 60 amperes at 250 volts. The engine is fed from a 25-gal. tank of gasoline and the water jacket from a 75-gal. tank, both placed on top of the car. The steam which comes from this tank will be used in heating the trail cars. In compartments in front and back of the engine are 100 storage battery cells and these are connected in multiple with the motors. A 35-h. p. motor is geared to each of the two axles of the truck, and they are operated from a series-parallel controller of standard make. While in service the engine is run at normal speed with full load, charging the storage batteries when the motors do not take all the current. The battery takes the fluctuations of the load and at no time does it remain discharged. In this service it is stated that the batteries deteriorate very slowly. The consumption of the engine is 2½ gals. of gasoline per hour. Baffle plates muffle the exhaust so that there is little noise in its operation. The motor car has been perfected and the recent test demonstrated that it is capable of arduous service.

During a recent entertainment at Harrison Park Casino, Terre Haute, Ind., an audience of 4,000 gathered. The facility with which the street railway company handled this large crowd called forth the following comment from the Terre Haute Gazette: "The street car company cleaned up that great crowd as if it was a few paltry hundreds in number. When the last car took on its load the crowd had disappeared. All had been cared for and were carried to their homes swiftly and easily."

## MASON CITY &amp; CLEAR LAKE INTER-URBAN.

An interesting interurban line which seems to have stepped into a good paying business from the very start is the Mason City & Clear Lake (Iowa) Railway. The road was opened on July 3rd of this year, and forms the connecting link between Mason City, a place of 15,000, and the lake which is the only resort of the kind for many miles around. The resident population at the lake is only about 1,500, increased during the summer by 2,000 cottagers upon the shores. The chief revenue is in the freight business, which is good throughout the year, as the road connects with the Iowa Central and handles all its passenger and freight between Mason City and the lake. Tickets are sold through by the Central from all points on its line and pas-

ELECTRIC LOCOMOTIVE.

sengers change cars. The freight in car loads is transferred in the original car both ways. In addition the electric line does all the switching for the Central to the stock yards, and this forms a good business in itself. Switch tracks are also laid to all the manufacturing establishments in Mason City.

There are 17 miles of track, the distance to the lake being 11 miles. The heaviest grade is only 3 per cent, and short; 65-lb. T rails are laid. The rolling stock includes one 45-ft.

A LONG TRAIN—CLEAR LAKE &amp; MASON CITY LINE.

BAGGAGE AND EXPRESS CAR.

car with four 50-h. p. motors; five 40-ft. open trailers; one closed trailer 45 ft. over all; one baggage and express 35-ft. car; two combination passenger and baggage cars with 22-ft. body and 32 ft. over all on Peckham extra long trucks; two 16-ft. body city cars on Peckham 7-B excelsior trucks; two flat cars one of which is rigged as a tower car, and one dinky locomotive 16-ft. over all with two 75-h. p. motors, weighing nearly 10 tons. This has hauled eight loaded stock cars in one train and as high as 25 empty box cars.

The rolling stock is equipped with Standard air-brakes; on the electric locomotive is a 1½-h. p. electric compressor governed by the Standard automatic controller. This locomotive frequently draws trains of seven or eight trailers all braked by air. The trailers require only one pound of air and the locomotive two pounds for effective braking per stop. One of our illustrations shows the train, in the vestibule of which the Standard motor-compressor is located. An excellent opportunity for demonstrating the value of these air-brakes recently arose. The superintendent was running a train consisting of the locomotive and one trailer, and while approaching the city with speed reduced to 15 miles per hour, a runaway horse with buggy attempted to cross the track. This buggy contained a woman and three children. The superintendent made an emergency stop which brought the train to a standstill ¼ ft. away from the buggy, which had been overturned on the track by the frightened horse. The officials have been so pleased with the installation that they gave to the Standard Company a testimonial from which the following is quoted: "Our air brakes have been put on by your Mr. Taylor and are working with entire satisfaction. This work was done in a workmanlike manner and according to contract, and we are well pleased with everything." It is a significant fact that the Standard system has been so well designed that it is only

necessary to apply the air-brakes on the locomotive and three trailers in order to promptly bring the whole train of eight cars to a standstill.

The schedule time on the main line is 38 miles per hour and on a portion of the road a speed of 48 miles is reported. The wheels are 4-in. tread and 1-in. flange, and weigh 500 lbs. All the trucks are Peckham, and W. H. Gray of the Chicago office taught the motormen and opened up the road.

A fine power station was erected by the company, and two Allis engines installed, one of 150 h. p., and one of 250 h. p. The officers are: W. E. Brice, president and manager; L. Ong, treasurer and superintendent, and S. Emery, general passenger and freight agent.

### M. I. C. COMPOUND.

The M. I. C. compound is an enamel for the insulations and coatings of motors, armatures, fields, wires, cables, transformers, overhead line construction and all bare metal surfaces. This product is made chiefly of refined linseed oil, asphalt and rubber; it is black in color, and is manufactured in four grades. It does not contain carbon-disulphide or other objectionable materials; is non-corrosive, impervious to moisture, has no offensive odor, stands high temperature and can be reduced to any desired density of solution with turpentine or benzine. The Mica Insulator Company is sending out circulars to which are attached pieces of sheet copper coated with the M. I. C. compound and baked for three hours at 300°F. There is no indication of the compound cracking until the copper is ruptured.

### A NEW INTERURBAN FOR CLEVELAND.

The Cleveland, Medina & Southern Railway Company has been incorporated, and Secretary Gibson states that negotiations are now in progress for the construction of the first section, which is to be 55 miles in length. The construction will be substantial, but not excessively expensive. Steel rails, 65 lbs. to the yard, will be laid on oak ties. Side pole suspension will be used through cities and villages. The motor cars will be built for heavy service and equipped with four 50-h. p. motors. The officers of the company are F. C. Goodman, president; F. C. McMillan, vice-president; A. R. Gibson, secretary, and J. W. Roof, treasurer; with offices at Cleveland.

MASON CITY &amp; CLEAR LAKE CARS.

## A NEW SYSTEM OF DOUBLE TRUCKS FOR ELECTRIC RAILWAYS.

The question whether single or double trucks should be employed under the heavy electric cars that have become common within the last few years is no longer open to argument, as is shown by the universal adoption of double trucks on interurban and long suburban lines; while for lighter cars and lower speeds there is a tendency also in the direction of their adoption in many places. This tendency to mount even light cars for city service on double trucks is more marked in the east than in the west.

It requires but little consideration to convince one that the truck as evolved in steam road practice will not suffice for electric service, because in the latter the truck is the locomotive as well as the carrier of the car, and the demands on the electric truck are much greater than on those under non-motor cars having the same weight on the rails. Appreciating these facts E. Peckham, president of the Peckham Motor Truck & Wheel Company, has a full line of double trucks adapted to any and all conditions of service, from light suburban to the heaviest trunk line service. Last year he designed and placed upon the market his double cushioned swivel truck known as

of the No. 14 type as well as the No. 15 and No. 17 have the swing bolster, which has been adopted on steam roads. The bolster is a truss formed by the combination of a channel bar and a truss bar supported by adjustable supports which are hollow and receive the bolts holding the lower half of the swivel plate in position. The principle in view in the design of this truck was to keep the bolster as narrow and as low down as possible and the wheel base short, so that the wheels might swing between the sills of the car on curves. The No. 14 truck is double cushioned, the bolster being carried on two half elliptic springs in pockets on the upper part of side frames, which are supported and cushioned upon the journal boxes. Being flexibly supported centrally over the journal boxes, they act as equalizers and permit any one wheel to lift without communicating motion to the car. The second cushion given by the helical yoke springs supporting the side frames on the journal boxes, relieves the side frames and half elliptic side springs, relieves the bolsters from shocks and gives an easy riding car under all conditions. The brake rigging is of the standard double upright lever type; the floater is

FIG. 1—STANDARD NO. 14.

No. 14, and has recently added seven other double trucks, each adapted to some particular conditions, so that the entire field of electric traction is covered. Of these, five are modifications and improvements of the No. 14, but of a heavier construction, and are as follows: No. 14-A for high speed service, suburban and elevated; No. 14-B for use where there are many curves of short radius; No. 14-C and 14-D for maximum traction service; No. 14-A C a modification of No. 14-A with the special features of the No. 14-C added; No. 15, somewhat similar in design to 14-A, but much heavier, and No. 17, a locomotive truck designed for the heaviest service.

The No. 14 truck is built in two weights; light weight, which is shown in Fig. 1, for service under light interurban cars, and extra heavy for heavy interurban service, which latter differs from the one illustrated in that heavier side bars and pedestals are used and the addition of a "bridge truss" between the top and bottom members of the side frames in order to provide increased support for the bolster. In the No. 14 truck the bolster is fixed, but flexible; the others

equipped with a curved bar upon which the connection to the sway bar moves by means of a roller, and thus permits the truck to turn under the car without altering the position of the brake shoes, making a close adjustment of the brakes possible. The brake beams are flat with M. C. B. heads, and they are provided with adjustable release springs.

The No. 14-A truck shown in Fig. 2, is more heavily constructed in all its parts than the No. 14. Instead of a stationary bolster working on guide pins provided in the latter, this truck has a swing bolster made up of two channels, set on edge and held together by cover plates and the female swivel plate. This bolster is carried on the spring plank by means of one half elliptic spring and two helical nest springs. The side bearing plates attached to the car bolster and bearing upon the cover plates, admit of a limited rocking motion of the car governed by the stiffness of the nests. This motion adds greatly to the ease of riding, as it permits the wheels on one side of the truck to rise independently of the car body.

FIG. 2—TRIPLE CUSHIONED NO. 14 A.

The spring plank is supported by four links of M. C. B. standard length, which in turn are carried on two transverse bars, which rest in pockets on the side frame of the truck. At each end of these transom bars are located spring pockets with rubber cushions, one at each end, which support the male bearings, to which the links are secured. The rubber cushions, in addition to acting as springs, break the force of the blow between the rail and the car. The transom bars previously referred to are secured to both side frames, together with the end cross member, bolting them in rigid alignment. The transoms likewise act as a guide for the bolster, preventing it from moving in a direction longitudinal with the car and also carry the nose bars which support the motor through riveted pockets.

the bolster and the elliptic springs; but a portion of this weight is carried on a roller which works on a plate on the underside of the car body framing throwing 70 to 80 per cent of the weight on the two driving wheels. The casting carrying the roller is supplied with a guide which prevents the side movement of the roller and casting with relation to the truck frame, the roller permitting the truck to swivel under the car. By this method the advantages of a maximum traction truck are gained without making the bearing plates at the end of the bolster carry the car body, giving much less friction on curves. The location and relative stiffness of the springs can be so varied as to alter the percentage of weight on the driving wheels from 50 to 80 per cent of the total weight.

FIG. 3.—SHORT WHEEL BASE NO. 14 B.

The No. 14-B truck Fig. 3, is designed for use with two motors where a short wheel base is essential to swing between narrow car sills or around sharp curves. In order to accomplish this the motors have been swung outside the wheels instead of inside, and the motor support bars have been hung, through springs, to the outside transverse member of the truck. The cantilever construction of side frames similar to that used on the single trucks of this company renders this arrangement perfectly safe and permissible. One motor may of course be used instead of two on this truck, in which case the weight on the driving wheels will be about 60 per cent of the total weight carried. The wheel base in this truck can be reduced with 33-in. wheels, to 45 in. should it be desired but it is not recommended that the wheel base be less than the gage of the track upon which the truck is to run. The difference between the 14-A and the 14-B is that the motors are outside the wheel base in the latter; otherwise the side frame and the swinging bolster are in every way the same and the parts of the two are interchangeable.

No. 14-C, Fig. 4, is a maximum traction truck in which the wheels are all the same size and is built on the same general lines as the No. 14. The greater portion of the weight of the car body is carried on

The No. 14-D maximum traction truck, Fig. 5, is designed on the same general lines as the No. 14-C, but works on an entirely different principle. The bolster is of the swinging type used in the No. 14-A truck and is located as near as possible to the large or driving wheels, while the motor is supported on the cantilever extension projecting outside of the driving wheels, the same as in the 14-B with the double object of leaving room between the driving and pilot wheels for the bolster and increasing the weight on the driving wheels. The principle upon which the truck operates is that of increasing the weight on the leading outside pilot wheel. It has been thoroughly proved both in theory and practice that when a four wheel truck is rounding a curve the leading outside wheel is the only one which has any tendency to ride the rail; in fact, the tendency is for the rear axle to assume a position radial to the curve on which the truck is running. The truck as shown is intended to be placed under the car body so that the pilot wheels shall be turned toward the end of the car in each truck, but its construction is such that the large driving wheels may be used as the end wheels if desired. The location of the motor and bolster is such that about 85 per cent of the total weight carried on the four wheels is carried on the two driving wheels.

FIG. 4 DOUBLE CUSHIONED CENTER BEARING NO. 14 C.

FIG. 5—TRIPLE CUSHIONED SWING BOLSTER CENTER BEARING NO. 14 D.

On the end of the truck frame beyond the pilot wheels is located a segmental track upon which works a roller to which pressure is transmitted from the car body through a spring. This pressure is capable of adjustment. The roller with its supports being secured under the car body, when the truck runs into a curve the pilot wheels swing beneath this roller in such a manner as to transfer its position on the slide toward the outside pilot wheel on the curve. In other

permit of the swinging of a half elliptic spring between them. This bolster is built up in truss form of two flat bars of a thickness and width suitable for the car bodies to be carried. These bars are trussed by the adjustable posts. Secured to the top bar of the bolster are the regular King side bearing springs to provide for a slight rocking motion of the car body. The bolster is supported at each end by one or more half elliptic springs. The number depending on

FIG. 6—NO. 15, EXTRA STRONG TRIPLE CUSHIONED SWING BOLSTER TRUCK.

words, the pressure transmitted to the pilot wheels through the roller is the same whether the truck is on a curve or on a tangent, but on a curve is so distributed that a greater portion is thrown on the outside pilot wheel than on the inside, consequently preventing the flange of the outside pilot wheel from riding the rail. The side frame of the truck is built on the cantilever principle common to all Peckham trucks, and is provided with a yoke for the pilot wheels sufficiently low to swing under the steps of an open car.

The weight of the car body to be carried. The ends of these springs are carried in the universal links, which permit of a motion both longitudinal and transverse with the axis of the truck, thus permitting the span of the springs to increase as the load comes on them and at the same time acting as links providing for the transverse swinging of the truck bolster. These links are supported upon four helical springs, making three sets of spring cushions on the truck, insuring a very easy riding truck. The bolster is guided between the transoms to prevent motion in a direction longitudinal with the car body. These guides serve to transfer the draft of the motors from the truck to the car body. The location of the half elliptic springs between the bars of the side frame permits the drawing down of the bolster to the narrowest permissible width, thus shortening the wheel base of the truck. This location of the elliptic springs also imparts to them the properties of an equalizer, permitting any of the wheels to rise independently of the car body and supplementing in this direction the action of the yoke springs located directly over the journal boxes. The motors are supported on the transoms. These transoms are rigidly secured to the side frames of the truck and together with tie rods through the lower bars, keep them rigidly in line.

FIG. 7—NO. 17 LOCOMOTIVE TRUCK.

The No. 14-AC truck is built on the same lines as the 14-A. In addition it has the special features of the 14-C, namely, the half elliptic spring located outside of the wheels on one end and the bearing on a rubbing plate under the car body to the roller, thus throwing more weight on the pair of wheels driven than on the other pair. This truck, of course, is intended for use with one motor only. It can, however, be made interchangeable with the 14-A and either two motors may be used as in the plain 14-A truck, or the additional half elliptic spring may be placed on the end and one motor used as on the maximum traction truck.

The No. 15 swivel truck, Fig. 6, is designed for interurban and elevated road service and can be used as an electric locomotive. It is built heavier throughout than the No. 14 and the two sets of bars composing the middle of the side frame are placed farther apart to

The No. 17 truck, Fig. 7, is designed for trunk line work under heavy cars with extra heavy motors as an electric locomotive. The side frames are constructed in one piece of the best cast steel, and the weight of the car is resting upon the frames, which are supported upon double coil springs carried on the journal boxes, the same as in all Peckham trucks, while the weight of the motors is carried upon springs secured to motor suspension bars, secured at each side to independent equalizing bars resting directly upon the boxes. Swung by four links from the side frames are cross bars supporting the bolster plank. It will be noted that the construction of this truck permits the side frames and bolster to be raised off the wheels without disturbing the motor, so as to permit of easy access to the motors for repairs.

A CHARITY FAIR IN YUCATAN.

The manager of the Campaña de Tranvías de Mérida, Yucatan, Mr. Escalante y Peon, recently organized a kirmess or charity fair which was held at the pleasure resort of the tramway company, and proved to be a great success. A junta of 12 prominent citizens lent their aid, and after a few weeks of preparation the fair was opened on September 18. There were eight stands or booths provided for the sale of flowers, ice cream, cigars, beer, toys, etc., and at each booth four young ladies of the best families acted as saleswomen. Almost everything for sale was presented by the merchants and families in Mérida, and while 15 cents was the selling price fixed, that paid ranged from 25 cents to \$1. It is related that these high prices were paid by the young men who were deeply interested in the ladies presiding at the booths.

Flowers in particular brought high prices; the roses which each of the four ladies at the flower booth wore, were auctioned off, the minimum price realized being \$38. The most costly dish of ice cream was purchased by a young man who was inveigled into agreeing to pay 25 cents per spoonful for the glass eaten by his fiancée, and she ate it with a salt spoon, 120 spoonfulls.

The fair continued for three evenings and the resources of the tramway were taxed to carry the people desirous of attending. The receipts, including the earnings of all the pleasure apparatus at the park which were donated by the company, netted \$4,500, which amount was turned over to the trustees of the city hospital.

BRILL'S ELECTRIC TRACTION COMPUTER

The souvenir of the Brill Company at the convention was one of Cox's computers designed to immediately, and without any calculation whatever, give the effective horsepower necessary to propel any load at various speeds and also upon various grades, thus solving by the simplest mechanical means an often perplexing problem. It is based

$$2,000 G + T$$

on the formula  $h. p. = L \times S \frac{2,000 G + T}{33,000 \times 100}$ , where L is the

load in tons of 2,000 lbs.; S, the speed in feet per minute; G, the grade in per cent; T, the tractive force per ton in lbs. It is also specially designed to give the h. p. required for the different styles of Brill trucks. Those who did not secure one of these computers at the convention may do so by writing to the company.

SCENES AT A CHARITY FAIR IN YUCATAN.

## THE CAPITAL TRACTION OF WASHINGTON.

As noted in our last issue the Capital Traction of Washington, D. C., has decided to adopt the underground electric conduit system instead of rebuilding the cable plant which was destroyed by fire, and the contracts have been let. Pending the completion of the installation horses will be used for the motive power.

David S. Carll is the chief engineer and associated with him as principal assistant engineer is William B. Upton. Dr. Louis Duncan has been appointed consulting engineer. The directors have appointed George T. Dunlop, Henry Hurt and Samuel L. Phillips as a building committee.

The system adopted is the underground conduit controlled by the General Electric Company, and that company has the contracts for generators, motors and accessory electrical apparatus. A large portion of the cable conduit work has been let to the National Cable & Conduit Company of

On February 18, 1894, the business was incorporated under the title of the Sterling Supply & Manufacturing Company with a capital stock of only \$15,000, and located at 97 Bank street. Mr. Carson occupied the double office of president and general manager. At this time he was making Sterling registers and Sterling sand boxes, having acquired the patents and business of Benton & Keyes then manufacturing the Benton register. The business was energetically pushed and in March, 1896, it was found necessary to increase the capital stock to \$100,000, the money going into new machinery and tools. Again in June of the same year the capital was enlarged to \$200,000, and in April, 1897, greatly enlarged quarters were secured in the new Lexington Avenue Cable Building, 141-155 East 25th street where the Sterling Works occupy three-fourths of an entire floor, comprising over 25,000 sq. ft. This building is undoubtedly one of the most complete manufacturing buildings in the country, and with finest machinery and conven-

VIEWS IN THE WORKS OF THE STERLING COMPANY.

New York. John A. Roebling's Sons Company will furnish and install the lead-covered paper-insulated cable. Some 214,000 ft. of 1,000,000-c. m. cable will be used. The Baltimore Car Wheel Company has the contract for 70 "Lord Baltimore" trucks, and the American Car Company of St. Louis will furnish the bodies. The street work has been let to E. Saxton and was begun the early part of this month.

## STERLING SUPPLIES BY A STERLING COMPANY.

When J. H. Carson organized and became the head of the Sterling Company, in New York, in 1892, he determined that the company and all its products should be worthy of the name he gave them; and how fully that determination has been carried out is evidenced in the magnitude to which the business has grown, and upon hundreds of street railways where one or more of the several products of the company have been adopted as standard. Like many another concern of modest beginning this company has grown to large proportions, in fact its history is one of remarkable expansion and development, made all the more creditable by reason of the depressed times with which it had to contend.

iently arranged plant, nothing is wanting to furnish ideal conditions for turning out the work.

The present officers of the company are J. H. Carson, president and general manager; Perry Tiffany, vice-president; and William Tiffany, treasurer. It is making Sterling registers, Sterling sand boxes, Sterling safety brakes, Sterling fenders, car trimmings and general street railway supplies. Within the last year it has added a department for the manufacture of overhead material of all kinds, and is not only selling to consumers, but is furnishing some of the largest supply houses in the country with their entire stock in this line. Since this company started it has been a constantly increasing success, and its registers, brakes, sand boxes and fenders have entirely equipped some of the largest roads in the country, including the great Metropolitan system of New York.

The Sterling register is too well known for its excellent work to need extended mention here, over 12,000 of these machines being in use, and are standard on some of the largest roads in the country. Notable among these is the Metropolitan Traction Company of New York. Some 2,500 Sterling machines are in daily use in that city. A new type of Sterling register has just been put on the market, which we illustrate herewith. As shown, it

# MAYER & ENGLUND,

10 SOUTH TENTH ST. PHILADELPHIA, PA.

## Electric Railway Material and Supplies

OF EVERY DESCRIPTION.

*We carry a Large and Complete Stock of Everything needed for the Construction, Equipment and Maintenance of Electric Railroads.*

HIGHEST CLASS MATERIAL AT LOWEST PRICES.

NUTTALL GEARS, PINIONS AND BEARINGS.  
 UNION STANDARD TROLLEYS AND PARTS.  
 PARTRIDGE SELF-LUBRICATING CARBONS.  
 INTERNATIONAL REGISTERS AND REGISTER FITTINGS.  
 VAN WAGONER & WILLIAMS CO. COMMUTATOR SEGMENTS.  
 COMMUTATORS REFILLED. ASSEMBLED BARS AND MICA.  
 ELECTRIC HEADLIGHTS. ELECTRIC CAR HEATERS.  
 MOTOR AND CONTROLLER REPAIRS, ALL KINDS.

**STANDARD OVERHEAD MATERIAL.**

Prompt Shipments from Stock. Send for Catalogues.

indicates the direction of the car, the trip fares, and the total. All figures are plainly indicated and can be seen readily from any part of the car. The new numeral register is a very handsome machine, compactly built, and being

simple in construction will not readily get out of order. These registers are made in both single and double, as desired.

The mainspring of the whole enterprise has been and is J. Henry Carson, who has just reason to look back with pride on what had been accomplished in the past few years. He was born in Baltimore in 1861 and his education, begun at St. Paul's school, Concord, N. H., was rounded out at Yale and Columbia. He then spent five years in a Wall street banking house, after which he was for two years assistant manager of the factory of the Otis Elevator Company. These two positions gave him an unusually fine experience in both business and mechanical lines. Mr. Carson is happily married, a royal entertainer, and a member of several New York clubs.

William Tiffany, treasurer, was born in Newport, Rhode Island, in 1868. After finishing school in this country he went abroad, where he attended a German university, after which he spent a year in a banking house in Stuttgart, Germany. Upon returning to this country he decided to make his fortune in the far west, and spent several years in running a ranch in Washington territory, after which he returned to New York and became actively interested in the Sterling Supply & Manufacturing Company.

The traveling representatives are widely and favorably known to the street railway fraternity through their long connection with the Lewis & Fowler Company. They are Frank A. Morrell and Lewis E. Robert. The general steam and railway supply department is represented by J. A. MacDonald.

The Western Electric Company has secured the services of A. McNab Little as traveling salesman.

J. G. White & Co. have received the contract for extensions of the City Passenger Railway in northeast Baltimore.

The Detroit Construction Company has obtained the contract for the overhead work and the Carnegie Company for the rails for the Dayton & Eaton Electric Railway, Dayton, O.

The John A. Roebling's Sons Company of Trenton, N. J., has been awarded the contract to supply the Capital Traction Company of Washington with 1,000,000 ft. of cable wire valued at \$214,000.

The Western Electric Company of Chicago has adapted its long burning arc lamp for a 550-volt circuit, five being used in series. This lamp is well suited for illuminating car barns, power stations and shops.

The Railway Street Car Indicator Company has been incorporated at Edenton, N. C., to manufacture station indicators. Capital stock, \$100,000; incorporators, H. Q. Donnan, W. G. Summerell and B. E. Byrd.

The New York office of the Pearson Jack Company is now located at 245 Broadway, and is in charge of G. M. Brown, who will be glad to see his friends there. The head office will hereafter be at 64 Federal street, Boston, Mass.

G. W. Chance, railway engineer, has opened a new office in Philadelphia at 915 Rothschild building, 14 South Broad street. Mr. Chance has sent out a pamphlet giving a discussion on "Electric Railways" and some interesting estimates on cost of construction and equipments.

The Third Rail Electric Railway Appliance Company has been incorporated at Jersey City, N. J., to operate extensively in the vicinity of that city. The capital stock is \$1,000,000, and the incorporators are Postmaster Robert S. Jordan, Charles N. King and Nelson R. Vanderhoof.

Field & Co., of New York, have received the contract to build the new electric road at Port Jervis, N. Y. The officers of the Port Jervis Electric Railroad Company are Martin B. Waller, president, George N. McKibbin, vice-president, C. J. Field, treasurer, and H. J. Cox, secretary.

Forsyth Brothers & Co., who were the originators of the anti-friction roller tip curtain fixture and hold the foundation patent of a rocking or tilting head having friction surfaces of diverse holding power, have recently established agencies in Montreal and New York, and are also represented in London.

The Westinghouse Electric & Manufacturing is circulating a pamphlet on "Automatic Circuit Breakers." These are for voltages not exceeding 750 and range in capacity

from 15 to 2,000 amperes. There is a good description of the apparatus with illustrations and tables giving dimensions and connections.

The Citizens' road of Indianapolis, on October 30, closed contracts with the Consolidated Car-Heating Company of Albany, N. Y., for electrical heating equipments for 100 cars. W. P. Cosper of Chicago, made the sale. We are advised that this makes a total of 300 equipments placed by Mr. Cosper within the last 60 days.

The Sprague Electric Company has been incorporated at Watessing, N. J., to install the system of Frank J. Sprague for using electricity on elevated, suburban and branch steam roads. The company will also take over the property of the Sprague Electric Elevator Company at Watessing. The capital stock is \$5,000,000 and the largest stockholders are J. Pierpont Morgan and John W. Mackay. Albert B. Chandler will be president and managing director.

The two Siemens & Halske generators installed in the power plant of the new Lorain & Cleveland road are doing excellent work. These machines are their 400-k. w. type and run at 80 r. p. m. At no load the voltage is 630 and at full load 700 volts. They are direct connected to C. & G. Cooper compound condensing Corliss engines. Stirling boilers are used. The entire equipment of the station is high grade, the aim of the builders being to make it a strictly model plant.

In order to insure prompt delivery which is an important item to the electric trade, A. O. Schoonmaker, mica dealer and importer of New York, has placed a stock of his well known India and "amber" mica with his agents: John Child, Monadnock building, Chicago; Hayes & Arthur, Cuyahoga building, Cleveland; Central Union Brass Company, St. Louis, and Reger & Atwater, San Francisco. Orders sent to these parties will receive prompt attention and be filled at the best prices.

The Westinghouse Electric & Manufacturing Company has lately distributed catalogs, describing new alternating current apparatus, especially that used for high voltages. Railway motors No. 49 and No. 38 B, designed for interurban or heavy electric traction, are described and the principal dimensions given. All these circulars are handsomely illustrated and are of uniform size, so that they may be bound and preserved as they are issued from time to time.

The Q. & C. Company of Chicago, has issued a catalog describing and illustrating the Bryant cold metal sawing machines. These saws have met with great favor and are in use in many of the shops of the principal street railway companies, among them being the Chicago City Railway, the Brooklyn Heights Railway, the Manhattan Elevated, the Toronto Street Railway and the West End of Boston. The saws are made in many forms, namely, the portable rail saw, shop saws, circular saws mounted for different purposes, either belt or motor driven; views are also shown of machine grinders for these saws.

The Buckeye Engine Company of Salem, O., reports that the orders which it has booked will necessitate working overtime, the capacity of the works being crowded. Among

recent sales we note the following: Union Iron & Steel Company, Youngstown, one 17½ and 35 x 36-in. and two 15½ and 30½ x 33-in. tandem compounds; Sumter (S. C.) Electric Lighting Company, one 16 x 32-in.; New York Floating Elevator Company, two 20 x 18-in.; Goodnow Building, Detroit, one 13 x 24-in.; Diamond Rubber Company, Akron, O., one 8½ x 12-in. vertical and one 14½ and 26½ x 33-in. tandem compound; Diamond Match Company, Barberton, O., one 6½ x 12-in. and one 14½ x 24-in. for the factory at Rio Janeiro, Brazil; Thomas Potter Sons & Co., Philadelphia, one 13 x 21-in.; Chesapeake & Ohio Elevator Company, Newport News, Va., one 18¾ x 30-in.; Concord (N. H.) Land and Water Power Company, one 17½ and 30½ x 18-in. cross compound; United Brethren Publishing House, Dayton, O., one 16½ x 18-in.; Gibson House, Cincinnati, one 10 x 14-in. and two 13 x 16-in. direct connected engines; Greenfield (Mass.) Electric Light & Power Company, one 14½ and 25 x 24-in. cross-compound; Hamilton & Co., West Newton, Pa., one 11 x 18-in.; Ohio Valley Electric Company, Bellevue, Pa., two 14½ and 25 x 18-in. direct connected tandem compounds.

During the last month business has been brisk with the McGuire Manufacturing Company. It has delivered a part of the order for trucks recently received from the Consolidated Traction Company of Pittsburgh, and has also secured an additional order for 52 more trucks for this same road. It has delivered about one-third of the equipment for the "Alley L" road, which is now being equipped with electricity. Six cars, which have already been fitted with these trucks, have been run experimentally on the "Alley L" and on the Metropolitan, and have been found to meet the requirements for elevated service in a most satisfactory way. In addition to this the company has built a large number of combined snow plows and sweepers, among them sweepers for the Chicago City Railway, North Hudson County Electric Railway, New York & Queen's County Railway, Camden & Suburban Railway, Suburban Railroad, Chicago & Englewood Railway, and others; and the sweeper trade promises to surpass that of any previous year. The "New Columbia" stove has also proved to be a wonderful seller. In nearly every case where samples have been sent out or shown orders have been received. The magazine and other features of convenience of this stove, together with its great capacity and high ornamentation, render it very popular. Large numbers of the popular "Columbia" heater, which has been so extensively used, are also being shipped this year. A new feature is the manufacture of double key-seating machines for cutting key-ways on two axles at the same time. These are used in the factory and have been supplied to many of the car manufacturing companies, among them the Terre Haute Car Company and Jones & Laughlin. The company is also overhauling a large number of the very early types of street railway trucks of 1890, making them into the latest and most improved types, embodying the three-quarter elliptic spring and suspension features of the improved "A1" truck.

County ownership of a proposed trolley line between Elizabeth and Plainfield, N. J., is advocated by citizens of Union county, who met recently at Elizabeth and perfected an organization to effect their object. Senator Vail of Rahway is president and Lewis Quinn of Elizabeth secretary.

## VAN DORN'S LATEST.

The accompanying cut represents Van Dorn's latest improved automatic coupling No. 8 for heavy traffic. This coupling and attachment was applied to the electric motor cars of the Waterloo Underground Railroad of London, England.

Mr. Van Dorn claims that this is the most simple and com-

compact coupling that has ever been placed on the market, and is superior to anything else ever constructed, for any class of service where they want a solid train. A slight modification can readily be applied to any class of cars and will be the leading coupling on all roads where they intend making great speed.

## STAR SOLDERING STICK.

The Western Electric Company of Chicago, has just introduced a soldering stick which is intended to obviate the dangers of poorly soldered joints. It is composed of carefully prepared and pure chemicals which are non-corrosive and at

the same time make a very superior flux for soldering. The wire is well cleansed and the flux enables the solder to unite firmly with the wire. The stick comes in convenient size,  $\frac{7}{8}$  in. diameter and 6 in. long.

## WABASH CHAIR CARS TO STAY.

When the Wabash Company opened its new Chicago-Buffalo line, it took the position that it could not afford to discriminate between the eastern and western lines in the matter of free reclining chair cars, and at once began running these cars on the new line between Chicago and Buffalo and New York. There was a vigorous protest from the eastern competitors of the Wabash against this innovation, but the Wabash officials continued running the cars. Then certain of the eastern lines took the matter up with the Joint Traffic Association with the view of compelling the Wabash to withdraw the through chair car service.

The board of managers has just announced that it has stricken the subject from the docket, thus practically deciding that the Wabash has the right to operate these cars on all portions of its lines.

Herbert W. Smith has accepted the position of manager of the railway department with the Bibber-White Company, and his headquarters will be at 49 Federal street, Boston.

The Creaghead Engineering Company, Cincinnati, has received the contract to supply overhead material for 22 miles of the Springfield & Southwestern Railway, Springfield, Mass.

The Groat Car Fender Company has been incorporated at San Francisco, Cal., with \$500,000 capital stock by Silas Groat of San Luis Obispo, Charles W. Fay, Philip S. Fay, Thomas Mahoney of San Francisco and N. W. Spalding of Oakland.

The Eastern Machinery Company of New Haven, Conn., has published a catalog describing and illustrating its improved friction clutches, clutch pulleys and friction cut-off couplings. This apparatus is built in all sizes, suitable for light and heavy work, and is guaranteed to be made of good material and free from defects in workmanship.

The Richmond Railway & Electric Company has been selling six tickets for 25 cents, the conductors having them for sale. They took this opportunity to do some speculating, turning in tickets instead of cash fares and pocketing the profit. This was not noticed until the conductors became so careless as not to punch the tickets when investigation soon revealed the state of affairs.

The Electrical Exhibition Company has closed a lease for the Madison Square Garden building for the electrical and kindred industries exhibit to be held in May, 1898. The amphitheatre, with arena circles, concert hall, assembly hall and machinery hall in the basement afford a total of over 100,000 sq. ft. of floor space, much more and much better arranged than at the former exhibition.

General Manager Wessels, of the Standard Air-Brake, is a firm believer in doing things promptly. He is always among the very first to secure accommodations at the next convention place. The following letter from Secretary Penington to Mr. Wessels explains itself: "In compliance with your request of the 9th inst. I enclose you herewith bill for twenty-five dollars (\$25) covering two hundred and fifty feet of space at Niagara Falls convention. You have established a record with the Association, as you are the first one to ask for a bill for space. You will get every inch of space allotted to you."

## CALIFORNIA.

Of course you expect to go there this winter. Let me whisper something in your ear. Be sure that the return portion of your ticket reads via the Northern Pacific-Shasta Route.

Then you will see the grandest mountain scenery in the United States, including Mt. Hood and Mt. Rainer, each more than 14,000 feet high, Mt. St. Helens, Mt. Adams and others. You will also be privileged to make side trips into the Kootenai Country, where such wonderful new gold discoveries have been made, and to Yellowstone Park, the Wonderland not only of the United States, but of the World. Park season begins June 1st each year. Close railroad connections made in Union Station, Portland, for Puget Sound cities and the east, via Northern Pacific.

#### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

#### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. DECEMBER 15, 1897. NO. 12

IT is difficult to understand, what, except the very prevalent belief that any corporation is fair game, could lead a farmer to allege that he had suffered actual damage by reason of the building of an electric railway in front of his farm. The advantages are so apparent that the award of 6 cents damages where \$5,000 was claimed in the Wisconsin case, the facts in which are given on another page, will probably excite little surprise. This case is, however, important as a precedent.

WHAT to do with the pleasure resorts in the winter? is a question which a good many managers are asking themselves just now. While the merry-go-rounds and the roller coasters are out of season, and the soda fountains are dry, there are other ways in which, with suitable weather, these parks may be made good revenue earners. The experience of such roads as have taken pains to properly care for the riding which can be worked up by providing good skating, has been that this business can be expanded into large proportions. Smooth ice kept clean, plenty of light, a shelter in which to warm, and where the volume of business warrants, a brass band, all unite to draw large crowds. Young America, and a good many who are not so young, take an interest these days in out of door sports; it is a most encouraging outlook from a physical point of view, and should be encouraged liberally. The manager who has a suitable pond or lake, and will take the trouble to provide a

program of winter sports such as prevailed 25 years ago will find his reward in loaded cars at an hour of the day when otherwise travel would be light, and besides will make himself and his road popular with thousands.

DURING the last political campaign when so much was being said about the scarcity of gold, we referred to the fact that one of the roads in St. Louis, had for years made it a practice to pay its employes in gold. The suggestion is now offered, that those companies which desire to give an object lesson, can do so in no better way than by using gold in filling the pay envelopes each month, where the check system is not employed. At first thought it would seem to involve increased work in the paymaster's office, and probably would for a few weeks until the clerks had become accustomed to its use, but those who have had occasion to handle gold report it is quite as convenient as currency. One thing is certain, if the men were paid in gold month after month they would be convinced that the yellow metal was actual money and not, as most of them now look upon it, a curiosity.

ATTENTION is being drawn to the desirability of operating funeral cars in such cities as the location of cemeteries and electric lines renders such a service practicable. The REVIEW, ever since its start has steadily advocated such a service as highly desirable and appropriate. It furnishes transportation with which carriage service is not to be compared, from point of economy either of money or of time. The drawn curtains of the funeral car enable the occupants to shut out the gaze of a curious public, and in stormy weather the car provides transportation in comfort and without the dangers incident to a long, slow ride in carriages. In all respects it is an advance and improvement on the carriage service and where a special car is reserved for this purpose there can be no objection from a sanitary or sentimental view. The cost for this service as compared with carriages is so very considerably in favor of the car, as to constitute a feature where alone merits endorsement of the funeral car. Of course there are cities where the local conditions are not so favorable, but these are growing less each year as the network of electric lines in each grows to include all parts of the town.

LITTLE is heard in these days of that once great cause for apprehension, electrolysis. Like other things it has had its day and the daily press which formerly devoted columns under the most startling scare heads, to the doom which was about to come upon the world from this new danger, with characteristic consistency never thinks to give a line to setting the public mind right in a matter which has been fully solved; and where it did exist in a few isolated cases, has been corrected. Nevertheless the old scare is raised occasionally, and if there proves to be any foundation for the fear, it need cause no anxiety for it is not only evidence of faulty construction, but involves a waste which no company can afford to continue even if it were not otherwise disposed to remedy it.

In this connection a very interesting fact is developed. One of the best railway electricians in the country discovered what to all appearances is a most pronounced case of electrolysis in a gas pipe in this city, but which at the time he made the excavation was many miles removed from any electric line, and indeed was separated from the nearest line

by a river. It is valuable evidence and convincing, that destruction of water pipes can and does occur without the presence of trolley lines, and the question naturally arises whether the electrolysis in the past which has been discovered since the advent of electric lines was due to them to any such extent as has been supposed. While there were in the early days unmistakable cases traced to these lines, it is not unlikely that natural earth currents and acids in the soil largely contributed to the results in many cases, which were discovered by reason of the construction of electric railway lines.

A NOVEL arrangement has been in operation in Denver during the past three months, which has proved very popular and successful, and is a scheme which might be copied with advantage in many other cities. One of the roads leased a large observation car to local parties, who obtained the privilege of using the tracks of the several companies. This car makes one trip in the morning and another in the afternoon, picking up its load at the leading hotels, and a complete detour of the city is made. In this way for a nominal sum the thousands of tourists who visit Denver are taken to all the points of interest, and the guide in charge explains everything as the trip is made. The company is sure of a stated revenue in rental, the city profits by being seen, and strangers do not miss some of the best sights as is likely when they try to pilot themselves about.

CLEVELAND has become one of the principal centers for electric interurbans in the country, and the advantages both to country residents for 30 miles in all directions, and the business interests of the city, are already well established. There has been a growing demand for the transportation of freight in addition to the excellent passenger and mail service rendered, and the several lines are making preparations to take care of this new department. The steam roads running into Cleveland threaten to take steps with a view to blocking this additional drain on their revenues, and announce proceedings will be taken to have the transportation of freight within the city limits declared a violation of franchises. It is doubtful if they can succeed in this movement, and even if they do, the public demand for the service will surely compel the city council to adopt such a general ordinance as will specifically provide for freight transportation. There can be no more objection to freight being drawn through the streets, enclosed in neat cars, than to the teaming of the same merchandise in wagons; and the wear upon the streets is saved by the rail transportation.

WE chronicle this month two bad accidents; both head-on collisions, and both alike due to heavy fog. The accidents were on suburban lines, where high speeds are in vogue. In each case both motormen were killed. In one a passenger was killed, and on both occasions the passengers were more or less injured. As will be presumed, each line was a single track road. Blame cannot be attached wholly to the car crews; in fact one of the cars was being operated by the superintendent, who was one of the killed. It was an accident that the accident occurred.

That there is a lesson in these disasters no one will try to deny. It does not appear that there was any intentional disregard of orders—only a misunderstanding; and one car one minute ahead of time in passing the turnout. Those to

whom any censure might be due, are beyond the reach of mortal tongue; but even were they here, it could not bring the other dead to life, comfort the fatherless or mend the broken bones.

This is one of the problems which suburban and inter-urban roads must take up and solve at once if they have not already done so in a satisfactory manner. Only a few weeks ago a similar accident occurred just outside this city, and it was only through rare good fortune that none of the injuries were fatal. A system must be provided at once which is absolute. We cannot afford to leave undone anything reasonable which will make a repetition unlikely. Not a moment should be lost; in the meantime let the greatest possible care be used.

THE year closes with greatly improved conditions over twelve months ago, while the outlook is decidedly better. In our pages devoted to trade news will be found the reports of a large number of important concerns, many of which are running full time with a strong list of orders ahead; while others are running night and day and are already behind. Engine builders are particularly busy, and while not all their output is destined for railway power plants, every machine is being bought to put in motion additional wheels of industry, which necessarily means the employment of more men who will once more need the street car in getting to and from their daily work.

\* \* \*

Capital for legitimate railway extensions, and new lines, is becoming more easy to secure, and the indications are for a fine year's business in all departments of railway supplies. A very considerable amount of reconstruction is already determined on for next spring, and this will increase in volume after the annual meetings in January. As an evidence of better earnings we note that many roads are reporting larger earnings for the fall months than for the summer months preceding. As the summer earnings have always been counted on to average up the winter season, the lesson of increased revenues is especially encouraging.

\* \* \*

As a rule we find the manufacturing industries of the west more active than those of the Atlantic states, but this is easily accounted for in the fact that the farmers west of the Mississippi have had a very prosperous season and have been paying off millions of mortgages long past due, and this money is now again seeking investment. That portion of it which cannot be put back on farm mortgages is now turning its attention to other investments, and is being put into new enterprises and operations which have been trying to struggle into existence for several years past.

\* \* \*

The improved condition of the great army of western buyers will soon make itself felt in the demand for eastern manufactured products and in the course of the next few months we should see a general resumption of work in hundreds of eastern factories not yet in operation.

All these various conditions take time to work themselves out, but are sure to come with time; and then the street railway interests of the whole country will feel the benefit in the increased volume of that regular every day traffic which constitutes the bone and sinew of their earnings.

The car builders have not yet regained the activity they formerly enjoyed, but after the first of the year the orders for summer cars for early spring delivery may be counted on, and the probability is that these orders will come in such a rush that resumption in this department will be very rapid. This will naturally lead to better prices for the builders, and companies which know they must enlarge their equipment next year, and can see their way clear to place orders now, will undoubtedly save money by taking advantage of the present prevailing low prices.

\* \* \*

Interurbans will command more attention this year than ever before. The success which has attended the operation of these lines, and their varied possibilities, has been a surprise to the public, and we anticipate the large proportion of new tracks laid in '98 will be for this service. Where the interurbans have come into competition with established steam roads they have been able to divert almost the entire passenger business, and are already cutting into the freight revenues. The frequent service and lower fares possible with electric operation, make competition by steam lines both difficult and expensive. Investors are waking up to a realization that when the difference in cost of construction and freedom from the burdens imposed in cities is considered, the interurbans are by no means less attractive than city lines. Hence the development of these country lines is surely destined to grow into large proportions during the next few years.

#### AMERICAN ASSOCIATION REPORT FOR 1897.

Secretary Penington has mailed his official report of the Niagara Falls convention, an interesting document of 266 pages—the largest ever issued by the American Street Railway Association. It has been brought out with promptness, particularly in view of the difficulties which attended the work this year. The stenographic and other records were for some hours in the Hudson River, having been submerged by the wreck, and it was a matter of no small moment to decipher and study out the blurred and water soaked notes. However they were not sufficiently damaged to make them illegible and the report covers all the doings and discussions of the Association and the people who participated in it.

As usual a steel engraving of the president appears; and this year, by instructions of the executive committee, the portraits of the only secretaries the Association has had in all the 16 years of its existence:—Wm. J. Richardson and T. C. Penington. In addition to the list of delegates and their ladies, the names of exhibitors, and all attending supply men are given, a desirable feature for reference.

#### OFFICIAL REPORT OF ACCOUNTANTS' ASSOCIATION.

The official report of the first annual meeting of the Street Railway Accountants' Association of America, is out and is being mailed to members of that association by Secretary W. B. Brockway, the compiler. The report covers 216 pages of fine type, and contains not only all the papers read before that body at the recent Niagara Falls convention, but a verbatim report of the entire discussion which ensued, and which was not published elsewhere and can

only be obtained in this way. Each copy is numbered and registered and obtainable only by members of the Association. The amount of information of the highest possible value to every company is worth many times the cost of the annual dues which are nominal. Many companies are unable for various reasons to send a representative from the accounting department to the meeting, but no roads in good standing are debarred from becoming members and securing the report for their own use.

The report is highly creditable to both the Association and Secretary Brockway, and has been issued with great promptness, especially in view of the fact that this is the first volume and there was no precedent to guide. Every street railroad in the country ought to be in possession of a copy, and information as to how this can be secured may be had by addressing W. B. Brockway, Secretary Street Railway Accountants' Association of America, Toledo, Ohio.

#### STORE ENTRANCES TO ELEVATED STATIONS.

The Union Loop passes most of the large department stores in Chicago, and it was suggested at an early date to build passageways from the elevated stations to the second floors of the stores. This met with opposition, as the small dealers thought such an arrangement would give the larger stores undue advantage and one suit it now pending on this question. This did not deter one large mercantile firm from connecting its sales rooms with an elevated station on

BRIDGE TO UNION LOOP, CHICAGO.

Wabash avenue. The bridge is 33 ft. long and 6 ft. wide, and made of steel and glass. The two steel girders supporting the structure are securely attached to the building, but the opposite ends rest on rollers to provide for the vibrations of the elevated tracks. As seen in the illustration there are eight large plate glass windows on each side and the roof is of glass. The wainscoting and doors are of mahogany. Above the the windows inside and out are rows of incandescent lamps. The steel work is all decorative and painted white, giving the bridge a handsome appearance.

## THE DETROIT COLLISION.

On December 4, about 1 o'clock in the afternoon, two cars on the Detroit & Oakland Electric collided, head on, near Pontiac. The accident occurred at the bottom of two hills, down which the cars were moving at high speed, in the attempt to recover lost time; the situation was rendered worse by icy rails. A heavy fog prevented the motormen from seeing more than a few rods. The superintendent, John Savage, who was operating one car, the motorman of the other car, and one passenger who saw the danger and stepped into the vestibule to warn the two men were killed. Of 42 passengers, 22 were more or less injured, and the cars which were new 40-ft. double truck, were reduced to

JOHN SAVAGE.

fragments—a total wreck. The dead were frightfully mutilated, Superintendent Savage having both legs completely severed from his body.

The sleet which had been falling all day, had thrown the system out of schedule, on account of the extra time consumed in making stops and starts, and it was in the effort to restore regular running time that the superintendent boarded the wrecked car. As he often did when on a car, he relieved the motorman, who stood beside him, and was nearly killed. The company did everything in its power in caring for the dead and injured, which it did promptly and regardless of expense.

In this connection it is proper to call attention to the fact that the presence of the vestibules made it impossible for men inclosed therein, to escape, although it was evident that two of them made a desperate effort to do so, after current was cut off, and succeeded in getting part way through the window.

John Savage, the dead superintendent, had been engaged in railway work in Detroit for the past 16 years, and was very highly thought of by both officials and the men. He had held his present position one year. He was 38 years of age, and leaves a wife and five children.

## STREET RAILWAY MAIL SERVICE.

The report of the general superintendent of the railway mail service just issued for the fiscal year ending June 30, 1897, shows a gratifying increase in the use of street railways, though the superintendent expresses himself as doubtful whether this class of service can be made to accomplish what was hoped of it when the system was inaugurated and says:

"The runs are as a rule too short to admit of the distribution of any great quantity of mail either way. It was hoped that on outward trips from the main office or depots we would be able to distribute the mail for carriers, so that upon arrival at the several branch offices the mail would be arranged in such shape that the carriers might start immediately upon their runs, and that on inward trips the mail taken from the branches or collectors might be distributed and pouched to outgoing trains, and thus avoid delay in the main office. We do indeed accomplish a great deal in that direction, but lack of time, as already referred to, and lack of facilities on account of the

limited space obtainable, has prevented us from accomplishing all we wished to do. I am still of the opinion, however, that the service is worth all it costs, and that it would be a step backward to abandon it. By arranging matters so that collectors can connect with the postal cars on street-car lines, considerable time can be saved by having the mail properly sorted up, canceled, and distributed in part before arrival at the main office or railroad station. More to this end could be accomplished, probably, if what might be strictly called the city service were placed in charge of the postmaster or superintendent of mails in the postoffice than if retained, as at present, under the jurisdiction of the railway mail service. It is all performed within the territory covered by the delivery of the postoffice, and does a class of work for the proper performance of which the people have always been accustomed to look to the postmaster. It is so closely in touch with the collection and carrier service, and its successful operation depends so much upon its relations with these branches, that in my judgment it could accomplish the greatest good if placed under the same control.

"There are, of course, a number of electric lines throughout the country which perform the same service practically as a regular railroad line, running, as they do, beyond the limits of any one city, and supplying a number of independent offices. Such service should, of course, be controlled by the railway mail service, but the lines running entirely within the limits of a city can be handled more harmoniously and satisfactorily, I think, through the local office.

"If this change is made, these cars should, of course, be manned by clerks from the postoffices and not by railway postal clerks, as is the case to a great extent at present; and such clerks should be taken up on the postoffice rolls, as an offset for the postoffice clerks on railroad lines working city mails, who can be taken up on the railway mail service rolls, as suggested in a preceding section of this report.

"I merely suggest these changes for your consideration. If, in your judgment, this service should still be controlled from this office, I assure you it will be my constant effort to promote its efficiency and extend its usefulness."

The statistics for the year ending June 30, and those for the previous year, are given below:

### STREET RAILWAY POSTAL CAR SERVICE.

|                                                     |         |           |
|-----------------------------------------------------|---------|-----------|
|                                                     | 1896.   | 1897.     |
| Number of routes.....                               | 21      | 33        |
| Miles of routes.....                                | 198.58  | 303.68    |
| Number of cars.....                                 | 45      | 65        |
| Number of round trips with clerks per day.....      | 195½    | 343       |
| Annual miles of service with clerks.....            | 907,863 | 1,619,820 |
| Estimated pieces of mail handled daily.....         | 505,481 | 593,860   |
| Average number of closed pouches handled daily..... | 398     | 568       |
| Number of crews.....                                | 60      | 87        |
| Number of clerks appointed to lines.....            | 75      | 102       |

### CLOSED POUCH SERVICE ON STREET RAILWAYS HAVING NO POSTAL CARS.

|                              |           |           |
|------------------------------|-----------|-----------|
|                              | 1896.     | 1897.     |
| Number of routes.....        | 126       | 146       |
| Miles of routes.....         | 726.84    | 798.24    |
| Annual mileage.....          | 1,986,838 | 2,368,786 |
| Pouches handled per day..... | 1,924     | 2,485     |

On December 1 the street car postal business in that division comprising the North Atlantic states and the peninsula of Maryland and Virginia was placed under the charge of postmasters in the several cities where such service exists. Four large cities are included in the division, New York, Philadelphia, Brooklyn and Rochester.

## CONNECTICUT STATE ASSOCIATION.

The Connecticut Street Railway Association meets January 12, at the office of the Fair Haven & Westville Street Railway in New Haven.

An interurban to connect Morris, Ill., with Lake Geneva, Wis., has been incorporated.

As the year draws to a close we pause for a look backwards to observe the progress made and to compare our present condition and future prospect with those obtaining a year ago. At that time the country had just emerged from one of the most bitter and hardly fought political contests in its history, and business was completely prostrated. The situation during the latter part of 1896 was the worst ever known and yet we were all thankful at the end of the year that we had escaped a great calamity. The business done this year was on the whole satisfactory though it was disappointing to many, but because of low prices and small profits, for the volume was fairly good. The immediate future apparently holds no such frightful nightmare as we experienced in 1896 and the prospects are bright.

In reviewing the year in the field of street railroading we first turn to the

## ELECTRICAL PROGRESS

The past year has witnessed advancement in every branch of electrical industry, although no remarkable discoveries or developments have been made. The latest and perhaps the most far-reaching electrical innovation is Edison's method of electro-magnetic separation of iron from low grade ores. Great advancement has been made in the utilization of water powers, and once more the water fall seems destined to regain its lost prestige as a source of power. The adaptation of the dynamo and the motor for such service has made this possible, and what is of equal importance—improvements in the transformers and line materials have permitted very high voltages and the transmission of current for long distances. America is in the lead in this work, for already 70,000 h. p. is available for manufacturing, light and the operation of street cars, and plans are complete for developing several times as much more. Niagara has attracted the attention of the whole world this year, not on account of its natural grandeur but for its power facilities. Not only the street cars of Niagara Falls and Buffalo receive current from water power, but the past year has witnessed the application of such power to the railway lines of Minneapolis, St. Paul, Salt Lake City, Ogden, Tampa, Fla., Sacramento and other cities in California.

In street railway appliances the advancement has been made along lines already laid out. The generators built are larger and a little more efficient, but are the same type of multipolar 500 to 600-volt machines. The motors have increased largely in capacity, but without a corresponding increase in weight. The cars are larger and more elegant in all their appointments. The universal use of the bicycle for pleasure and business made noticeable reductions in the receipts, but even this has been turned to profit. Bicycle

racks have found wide application, and in some cities have proved quite profitable. With many companies the carrying of U. S. mail is now a factor. This can be done with little inconvenience and greatly facilitates the collection and distribution of mail. The street railway companies do not receive sufficient compensation for this service, but it has become indispensable and will receive its due reward in time.

## NEW ROADS

Nearly every city in the United States has an electric railway system, yet during the past year the increase in trackage has been no less than 1,635 miles. The actual increase has not been so great as this, as the mileage of cable lines has been decreased by 60 miles and the horse lines by 272. The greatest activity in railway building has been in the eastern states, 611 miles having been added. Illinois is the banner state, the past year showing an increase of 236 miles; but Massachusetts and Pennsylvania closely follow with 230 and 207 miles respectively. In New York 2,086 miles of street railways are in operation and in the United States, 15,718 miles. The increase has been chiefly due to the building of suburban branches as feeders to the city lines, and interurban lines.

The completion of the Union Loop in Chicago is an interesting and important event in elevated work. The trains of one steam and two electric roads now use the structure, and the Northwestern Elevated, on completion, will run over the same tracks as the Lake Street. There is very short headway during rush hours, and there are few if any railways which accommodate such heavy traffic. Since the loop was opened there has been an increase in the traffic of all the roads, being at the present time over two-thirds on the Metropolitan and South Side roads with a fair increase on the Lake Street.

The extensive conduit system, now building in New York by the Metropolitan Street Railway Company, will be the largest and most costly in the world. The previous experiments on the Lenox avenue line convinces the management of the practicability of the system. The disastrous fire in the power station of the Capital Traction Company of Washington, gave the opportunity to convert that system from cable to electric conduit, which is now being done.

Several extensive interurbans are planned, notably one from Cleveland south through the principal cities of Ohio, one from Detroit to Port Huron and one from Indianapolis through cities in the gas belt.

These long lines have produced some interesting problems in transmission; the "booster," the "special generator," the "three-wire," and the alternating current systems have been tried, but what is the best method is not yet fully determined.

Many interurbans are resulting from the combination of two street railway companies in neighboring towns and the building of a connecting track. In many cases, where one or the other of the power stations is favorably located, it can furnish current for both systems with a considerable saving in power house operation. This method is recommending itself wherever applicable, for many of the smaller roads are not on a paying basis on account of the burden of cost of management, lack of facilities for repairs and high cost of generating current.

## IN FOREIGN LANDS

Although the total mileage of electric tramways in foreign lands does not equal the past year's increase in the United States, yet there has been much comment about the awakening interest in traction affairs. America is the acknowledged authority on this subject and the experience of this country has been drawn upon in the construction of the various tramway lines in Europe. In Great Britain the railway systems of Bristol, Cork, Dublin, Brighton and the Central London have been equipped in whole or in part with apparatus of American make. One of the principal street railway companies of St. Petersburg has abandoned horses for the trolley. Berlin will soon open a combined elevated and underground railway with electricity as motive power. Barcelona and Madrid are initiating electric systems, and there is activity both in promoting and building street railways in France and Germany. This progress is by no means confined to Europe. In Kioto, Japan, electric cars are running and the government officials in Tokio will soon be enabled to take an electric car in place of the old horse cars. An American tourist starting for the pyramids will take a car in Cairo, transfer at the Kaser-el-Nil bridge across the Nile, and ride seven miles on a trolley car to the historic Sphinx. Electric traction has been very successful this year in Bangkok, Siam, where so large a portion of the population lives in house-boats on the river. The trolley system in Alexandria has been open for traffic during the past month.

## TRACK CONSTRUCTION

During 1897 by far the greater portion of the track work has been reconstruction. There has been more attention than ever before given to the effort to secure a permanent way deserving of the name. There were no "wild-cat" roads, the kind made to sell, built this year, the hard times having driven their promoters to the wall, and the smaller companies, for the most part have preferred to await a more favorable opportunity for all work that could be postponed; so the work done has been by the larger companies.

The fact that here, as elsewhere, true economy consists in buying the best, where financial conditions make it possible, is realized to a greater extent than ever before, and the policy will bring its own reward. The increased investment necessary will be offset by the decreased consumption of power, the decrease in the cost of repairs and maintenance both of the rolling stock and track, and finally in an increased value of the bonds. Another influence which has, perhaps,

in cities, had much to do with bettering the track construction, is the laying of better street pavements. This has forced a more permanent track construction, and has been, on account of this expense and the cost of the paving itself, a heavy burden on the railways—in some instances more than they could bear.

In construction details there is still to be noted an increase in the weight of the rails used; the West End, Boston, laid over 6,000 tons of 95-lb. rails in reconstruction; the Metropolitan, Kansas City, used 103-lb. rails in the new work done by it, and the Metropolitan, New York, adopted a 106-lb. girder rail as standard and is using it in relaying the 50 miles of track to be operated by the underground conduit system. In Denver, the Consolidated Tramway Company has, during the past year relaid a number of its most important lines.

Further experience in concrete work without ties shows it to be substantial and economical, and each year finds roads using trench work. There is also an increased tendency to the use of T-rails in paved streets, and where the municipal authorities can be persuaded to permit them, they have given satisfaction.

The joint problem continues to receive much consideration both from mechanical and electrical standpoints. The greatest care is given to the bonding originally and to its maintenance afterwards, and the systematic testing of the track joints continues to become more important.

## THE OUTLOOK FOR '98

It is generally believed in street railway circles that this coming year will be a period of great progress. Nearly all railway interests are on a sound financial basis under conservative management, for it has been the "survival of the fittest" during the years of financial depression, and the weaker ones have long since reached the receiver's hands. Such a strict economical policy has been pursued that, with most companies, any increase in traffic will demand new equipment. Numerous large orders late in the summer and fall indicate a prosperous season in '98, for car builders and supply dealers.

A very gratifying feature of the trade is the large export business. Foreign prejudice against the trolley is rapidly declining, the reports of the tramway committees of Birmingham, Douglas, Glasgow and elsewhere being of great educational effect, as electric traction has been unanimously endorsed. American engineers and agents have been called upon in building and equipping the new lines. Birmingham has selected an able Canadian manager to take charge of the tramways there. The most prominent railway engineer in France is a young American who is interested in street railway projects in more than 30 cities.

It is hard to believe that Europe with its 300,000,000 population will long be content with 1,000 miles of electric lines. The dawn of railway enterprise is just breaking in the Old World, and the Americans should be the most favored by it. Selling agents are in all of the chief European countries and the latest statements from the Bureau of Statistics indicate that their most sanguine expectations are being realized. During the first half of the year over \$2,000,000 worth of electrical machinery was exported, England being our largest customer.

In some departments of street railway work the application of present methods seems to have reached a limit, and 1898 promises some interesting developments. A substation of storage batteries has proven a success for one of the long lines of the Union Traction Company in Philadelphia, and the Buffalo Railway has announced its intention of putting in a very large plant of accumulators in its central station. The storage battery cars on the Englewood & Chicago have been in operation nearly a year and a good service maintained. The operators claim the station runs at good economy, and that the batteries have not shown any inherent weakness; a statement of the operating expenses alone will reveal the success or failure of this experiment. One or two magnetic contact systems have been put on the market this year, the General Electric Company having perfected one.

The South Side Elevated Company of Chicago has commenced the substitution of electricity for steam. The Sprague system is novel in many details and a practical test will be watched with interest. The success of electric traction on the N. Y., N. H. & H. R. R. has influenced many railway engineers to make a close study of the problem. The Long Island Railroad Company announces it will build a tunnel under East river and equip its suburban lines for electric traction. The number of suburban trains of this company is about 600 daily and such service is eminently fitted for the application of electricity.

The subject of electric locomotives for terminal work is engaging attention; the railroads entering Boston have already let contracts for such service there, and a similar service will undoubtedly be decided on soon for the Union Depot at St. Louis and the bridge tunnel.

Compressed air for railway work attracted a great deal of attention during the first half of the year. Three motors which were placed in service on 125th street, New York, completed a year's operation on August 2. The daily papers gave their heartiest support to the enterprise and the notices were widely copied throughout the country. The system, however, has not yet commended itself to the street railway fraternity, and we have not been advised of its adoption by any road as a result of the demonstration. The American Street Railway Association appointed no committee to report on the subject, nor was it a general subject of discussion either upon the floor of the convention or among members outside of business sessions. Compressed air, evidently, has a long road yet to travel before it reaches the point of displacing present mechanical motive powers.

Now that so many of the immediately pressing improvements in apparatus have been successfully worked out, the manager is turning his attention, as he could not do a few years ago, to a more careful study of economies in operation. He knows that his machinery and motors can be absolutely depended upon for faithful performance, and he is now taking up what were formerly considered matters of less importance, but which now combine to make a quite significant figure in the ledger balance. Leakages of the most trivial character are being ferreted out and stopped, without any impairment in the service. This feature will characterize one of the most important efforts of the coming two years. The organization of the Street Railway Accountants' Association is especially timely and is destined to greatly assist the operating department in this desirable work; in fact, a large proportion of the savings are only

possible through an intelligent division of general expense accounts.

The pleasure resort has become a permanent institution with a very large number of roads. As a rule there is less attempt to present the high priced attractions which were found too expensive, and instead a more varied, but to the general public quite as satisfactory, program has been selected.

Some interest was aroused early in the year through the promises of the gas engine men of the improvements in their machines which were to make gas engines desirable for railway power stations. But little progress has been made, however, and the year closes with the gas engine no more of a factor than it was in January. Experiments are still making, and we are promised a surprise before another New Years.

### OVERHEAD CONSTRUCTION AT BASLE.

An electric railway connecting the two railroad stations in Basle, Switzerland, has been so successful in its operation since its opening in May, 1895, that several extensions are to be made. The streets of Basle are crooked and very narrow, which necessitated some important alterations from standard construction. The gauge is about 39 in. and the distance between centers of double track is only 8 ft. 6 in. Span wire construction is employed, but the wires are gen-

STREET IN BASLE.

erally connected to rosettes attached to the houses on either side of the street. Poles are only planted at corners and at points where the rosettes cannot be used. Although a great part of the road is single track two trolley wires are strung to avoid joints and turnouts. The span wires are at intervals of 115 to 135 ft. and at the Rhine bridge, where a span of 300 ft. is necessary, auxiliary steel cables are strung across to poles at the center of the bridge. The construction work was all done under contract with Siemens & Halske of Berlin. The accompanying illustration, a view in one of the principal streets of Basle, is from the Railway World.

The daily papers have been widely circulating a story that Sioux City, Iowa, was about to purchase, and consolidate and operate the street railways in that place. Investigation shows that there is absolutely no truth in the rumor, although a consolidation of all the lines in the city is highly desirable and ought to be effected.

## THE SPRAGUE SYSTEM ON THE ALLEY L, CHICAGO.

When the tracks of the Union Loop Company were leased in part to the South Side Elevated Railroad Company it was stipulated that the motive power was to be changed from steam to electricity. While investigating the different methods of electric traction the officers of the company were much impressed with the merits of the Sprague system, and the tests carried on at Schenectady proved satisfactory to them. The system has been accepted. The passenger cars of the company are now being altered for the electric service and the five cars, which are fully equipped, are running daily on

FIG. 2.

In the reconstruction, the old trucks have been supplanted by McGuire trucks, each of which carries a G. E. 57 motor of 50 h. p. capacity. At either end of the car the portion of the platform to the right of the door is partitioned off for the motorman's vestibule as shown in Fig. 1. Only the air gage, the engineer's air-brake valve and the contact box of the controller are visible. The vestibule is very cleverly designed, the partitions on either side being doors which can readily be folded back and fastened so as not to obstruct the passageway on that side of the platform. Fig. 2 is a view of the car showing the arrangement of the vestibule.

The hood over one of the platforms has been enclosed, lined with asbestos, and three doors provided so that all parts of the electrical apparatus in this improvised box are accessible from the platform. The controller, which is of the standard K-2 type, is suspended horizontally from the roof of the vestibule. It is connected through a spring coupling and bevel gears to a  $\frac{1}{4}$ -h. p. 500-volt Sprague motor. At

FIG. 1.

the Metropolitan West Side Elevated tracks.

Although the Sprague system has received a great deal of attention, detailed information has been very jealously guarded. The essential feature is that every car is a complete unit and can be operated separately or in unison with any other number. Such a plan gives the greatest flexibility conceivable on a road where the traffic is widely different at different hours of the day. A maximum tractive effort can be secured in this way, as 60 per cent of the weight of each car with passengers rests on the driving wheels. What a valuable feature this is may be determined by the conditions of elevated service.

The first requisite is that an elevated line must give a faster service than the surface lines, or else people will not walk up and down stairs and wait for the trains. The distances between the stations are from 1,000 to 3,000 ft. and the greater part of the schedule time is taken up in accelerating and stopping the train. It is very essential that there be great tractive effort and good brakes. In the morning and evening the passenger carrying capacity must be very much increased and this should be done quickly and conveniently.

FIG. 1-A.

FIG. 3.

the other end of the controller shaft is a ratchet wheel and pawls, as in Fig. 3. The bevel gears are in the ratio of about 1 to 20 and are encased.

The spring coupling is placed in the controller shaft and takes up a portion of the motion and when the pawl reaches the top of a tooth on the ratchet wheel the springs in the coupling act, breaking the controller contact suddenly and preventing the formation of an arc.

At the outer end of the pilot motor shaft is a brake, indicated in Fig. 4. By the motion of the iron core in the solenoid, brake shoes acting on a small pulley are applied or relieved. The brake is always set except when the con-

troller is being rotated. It is very quick in action, stopping the motor within one revolution.

The contact box, or pilot motor control, is located in the vestibule, and its lever is the only part of the electrical apparatus which the motorman handles. The lever can readily be adjusted and taken off just as on an ordinary controller, except that its normal position is vertical. Fastened to the shaft, as in Fig. 5, is a spring which automatically brings the contact lever back to the zero position. Inside the box is a partition of insulating material with copper contacts, as indicated, and between this and the outer iron cover is a spring contact fastened to the shaft. The wires, leading to the relay board, pass from the contact box through a 1-in. pipe.

The reverser and relay, or throttle board, are placed under two of the side seats. The reverser is about 15 in. long, and in form is as shown in Fig. 6. It consists of a wooden cylinder, pivoted at the ends and separated into five divisions. On the cylinder in the middle division is screwed a plate to which are attached two chains extending down on either side to two plungers partially in solenoids, the windings of which are beneath the floor. On the periphery of each of the other divisions are contact pieces. Finger con-

FIG. 5.

tacts, in a vertical position, are fastened to terminals which are in the motor circuits. When the reverser is in a neutral position the circuits are broken. When the car motors are to be started in one direction the solenoid on one side of the reverser is energized, drawing the iron core down and completing the circuit to the motors. The direction of the current can be reversed by the opposite electro-magnet being energized and the reverser rotated in the opposite direction.

FIG. 6.

The throttle board, Fig. 7, has some important functions to perform. It is put in readiness for operation by closing a five-contact switch to the circuits to the five electro-magnets which govern the circuits to the controller motor. Each solenoid is in an iron case and at the lower end of the

FIG. 7.

plungers are carbon disks, as shown. By the operation of the lever on the contact box the circuits are completed to each solenoid in turn, the plungers being drawn up and the circuits to the pilot motor made by the carbon disks touching the contacts. The different circuits are for contact, series, coasting, series-parallel and parallel connections to the controller. The throttling feature comes from the action of the solenoids when an excessive current passes into the car motors. The weight of the plunger in the solenoid is carefully predetermined and figured for 100 amperes or any other desired maximum current which is to be allowed to pass into the motors. Whenever this maximum current is reached the plunger drops, breaking the contact, and brings the controller back to the zero position, but immediately it is rotated back to the point below which the excessive current passes. In this manner the control of the car motors is taken partially out of the motorman's hands, and whenever an excessive current is flowing the motors are automatically controlled.

Under the car is a 2-h. p., 500-volt motor direct connected to an air compressor. This

FIG. 8.

motor is automatically started and cut out by a regulator in which a spring acts against the pressure in the air reservoir. In this way the air is kept between two predetermined pressures. The cars are heated and lighted by electricity.

Each car is equipped with a complete set of apparatus and is entirely independent in every function. When two or more cars are in a train the air coupling is made in the usual manner and the only electrical connection is in the five circuits of No. 14 wire which are combined in one insulated coupler as shown in Fig. 8. This coupler is as easily and quickly connected as the air coupler. These five circuits connect the armatures and fields of all the pilot motors in series so that they work in synchronism. If any of them should lag the throttle board prevents the motors of that car from doing an excessive amount of work.

The train of five cars so equipped is operating satisfactorily on the Metropolitan and there is little question but that the system will be a success. The little defects always found in new apparatus are rapidly being remedied and minor changes are being made. Some very desirable results have been attained in this system although this has been accomplished at the sacrifice of simplicity.

At the meeting of the American Institute of Electrical Engineers held in July last, the discussion of Mr. Gerry's paper on "Electric Traction" brought out several remarks concerning the Sprague system.

Dr. Perrine said: "In the first place, Mr. Sprague holds that the simple question of cheapness would not be one which would entitle a heavy road, such as an elevated road, to substitute electricity as its motive power. He makes the statement that if on the elevated railroads of New York a system of power were applied which would lead to the hauling of one more passenger per car, per station, in each train, the added revenue so acquired would amount to more than saving one-half the coal bill as at present used; and, starting from this premise, what is demanded from the application of electricity to steam railroading is not so much cheapness as increased facilities. He attaches much importance to the rapid acceleration of trains, as it has been shown that rapid acceleration reduces the total amount of energy required to move between two stops a certain distance apart; and in order to accomplish this, Mr. Sprague is now attempting to control from one end of the train a series of motors all located on the separate cars; so that not only do we have the track adhesion of our locomotive car, but with any loaded train we have the track adhesion which may be given by the entire weight of the train; and particularly on grades and curves this facilitates the rapid handling of trains. It seems that too much importance cannot be attached to this question of the rapidity of acceleration, for rapid acceleration means not simply the reduction in the amount of power necessary to move a train, but means what is of still greater importance, the facility of getting trains out of the way and permitting new trains to come in. In other words it means the handling of the whole service on shorter headway, and in consequence, a greater possible number of trains, the handling of a definite amount of traffic with a less concentrated load on the structure, and also a more satisfactory service, which will induce increased travel."

President Crocker pointed out that another advantage was that the same headway could be maintained throughout the day by simply reducing the length of trains for periods of light load.

Professor Thomson said: "There is one remark to be made, however, in this connection, that complexity is introduced by having the cars all equipped with motors, and the difficulties of making connections from car to car are greatly increased, of course, in coupling; so that it may become a serious question as to whether we are not paying too much for some of the advantages; whether, in other words, we ought to extend the complexity so far as has been proposed to obtain the advantages which follow, or whether there is not some other way out of it. Each car is possessed of a controller system of its own, and that controller manipulated by some automatic mechanism. Of course this means a great deal of change of mechanism, some of which may get out of order, and a few stoppages might be of more serious import to the success of the road than the disadvantages of having a similar mechanism which did not fulfill so many conditions, although, if the mechanism on one car or two cars does get out of order, the others will carry the train right along, and by this means such a chance is largely reduced."

Press dispatches state that 3-cent fares are to blame for the troubles of the Detroit Electric.

## REPORT OF THE WEST END, BOSTON.

We present below some data from the annual report submitted to the stockholders of the West End Street Railway, of Boston, for the year ending September 30, which speak eloquently for the excellence of the management.

The gross earnings for the year were \$8,719,932 (an increase of 4.5 per cent over the previous year), the operating expenses \$6,213,709 (a decrease of nearly 2 per cent), and the net earnings \$2,505,323 (an increase of 23.6 per cent). Out of the net profits after paying taxes, interest and sinking fund charges, dividends of 8 per cent on preferred and 7.5 per cent on common stock were paid and \$16,793 carried to the surplus.

Two portions of the subway have been opened for traffic, that from the Public Garden to Park street on September 1, and that from Tremont street and Shawmut avenue to Park street on October 1; these portions are at present open from 6 a. m. till 12 midnight; there are 1,790 regular trips run through the subway per day with extra ones as the traffic demands; this gives during the busy hours of the day two to three cars per minute leaving Park street which is a severe tax upon the capacity of the station. The records show that 7 per cent of the passengers carried on the entire system are carried through the subway. Nearly 20 per cent of those taking the cars in the subway do so between the hours of 5 and 6 p. m., and 90 per cent of them at the Park street station.

During the year extensions have been made to four of the existing car houses and two new ones built making space for 355 more cars. The Harvard power house also was built this year.

The number of employes in all departments is 5,095.

The total track operated is 304.5 miles.

Traffic statistics are as follows:

|                                                |              |
|------------------------------------------------|--------------|
| Round trips, passenger cars.....               | 2,055,197    |
| Round trips, U. S. mail cars.....              | 15,454       |
| Revenue miles, passenger cars.....             | 20,450,078   |
| Revenue miles, horse cars.....                 | 335,058      |
| Revenue miles, U. S. mail cars.....            | 166,655      |
| Revenue passengers, electric cars.....         | 171,227,459  |
| Revenue passengers, horse cars.....            | 1,327,054    |
| Total revenue, passengers.....                 | 173,554,513  |
| Free transfer passengers on electric cars..... | 23,777,726   |
| Total passengers.....                          | 196,332,239  |
| Receipts from passengers.....                  | \$ 8,536,285 |
| From U. S. mail cars.....                      | 19,379       |
| Average receipts per revenue passenger.....    | 4.647 cents. |
| Average receipts per total passenger.....      | 4.348 cents. |

The increase in number of revenue passengers over the number carried the previous year is 3.4 per cent and the increase in the free transfer passengers 35.5 per cent.

Contrary to expectation the lease of the West End Street Railway Company by the Boston Elevated Railroad Company has been disapproved by the Massachusetts Railroad Commissioners whose consent was necessary to its validity. The principal reasons given for the decision are two in number: 1. The West End road would be taken out of the special class of railways that are subject at all times to special legislation 2. The term (99 years) is too long and the compensation to the West End (8 per cent on all stock) was too great a burden on the new company.

A new proposition to lease for 25 years, guaranteeing dividends on the common stock at 7 per cent, has been accepted by the West End.

**THE STREET RAILWAY SYSTEM AT NEW CASTLE, PA.**

New Castle is a small city of 12,000, its population being chiefly occupied in various iron industries. For some years electric cars have been in operation in the city, but within the past 12 months the service has been improved and a considerable sum of money spent in reconstruction and new equipment. Last spring the company purchased a large tract of land and converted it into a park. Frank M. Blaisdell, a prominent landscape gardner of Boston was engaged, and the views showing the smooth roadways, rustic bridges

and pavilions testify to his quick and careful work. The natural scenery is very beautiful and the splendid water fall gives the resort its name, "Cascade Park."

The railway lines are supplied with current from the station which furnishes the electric power and light for the city. The station was well designed and built under the supervision of Wm. Cummins, superintendent of the New Castle Traction Company. The plan shows the arrangement of the machinery in engine and boiler rooms. There are two batteries of water tubular boilers, one consisting of two 150-h. p. and the other of two 250-h. p. boilers equipped with automatic stokers. The live steam purifier and the

ALONG THE ROAD AND IN THE PARK - NEW CASTLE, PA.

CAR BARN, NEW CASTLE TRACTION COMPANY.

boiler feed pumps are of the latest design. The two engine-dynamos, nearest the boiler room, are for the railway service and consist of two 250-k. w. generators connected direct to two Buckeye cross compound condensing engines. In addition the lighting plant contains four 80-light arc machines, two 75-k. w. and one 125-k. w. alternators, belted to tandem compound condensing engines, built by the Buckeye Engine Company of Salem, O. The switchboard is at the side of the engine room near one end; the wires are all carried to it in conduits under the floor.

The plan of the car-barn and repair shop shows an arrangement well suited to the needs of such a road. Ample pit room has been provided in order that the cars may be thoroughly examined every night.

This building is of brick, 74 ft. x 150 ft. outside; the roof is iron trussed and covered with slate; the ends of the trusses rest on the tops of 13-in. I-beams built into the walls. In the rear end of the car barn are a sand room 15 ft. x 11 ft. 6 in., a room for conductors and motormen 21 ft. x 11 ft. 6 in., and a lavatory. At one side is an addition 40 ft. x 50 ft. in which is the machine shop. There are seven tracks

in the building aggregating 1,000 ft. in length; four of them are pit tracks. The tracks are 9 ft. 10 in. between centers; in the pit side of the building the rails rest on 10 x 12-in. stringers carried on and anchored to brick piers built at intervals 14 ft. 8½ in. The flooring between the pit tracks and on the other side of the building is of 2-in. oak. The pit itself is floored with brick at the level of 4 ft. 5 in. below the bottom of the track rail. At the front end are seven pairs of double doors hung to the side walls and 13-in. I-beams, and these constitute the front wall. The doors are 18 ft. high; above them the end wall is of brick, resting on two 12-in. I-beams carried on the I-beam posts.

The barn is heated throughout by steam. The repairs are simply of a general nature as the management does not consider it advisable to do any manufacturing. The machine shop is also used for making repairs for the Electric Light & Power Company and the Lawrence Gas Company, both being under the same management as the Traction Company.

In the roadbed construction, blast furnace cinders were used; the cinders have been rolled into a bed 6 in. in thick-

POWER STATION, NEW CASTLE TRACTION COMPANY.

ness. The ties were spaced 2 ft. between centers and concrete filled in between them. There are 16 miles of 80-lb., 60-ft. girder rails in the city, and four miles of 70-lb., T-rails on the private right of way to Cascade Park. The Park line was constructed at great cost in order to keep the grades below 1.5 per cent. One large cut required the removal of 70,000 cu. yds. of material and one fill had to be made 20 ft. high and 900 ft. long. The girder rails and the special work were made by the Johnson Company, and the steam road special work was constructed by the Cleveland Frog &

1,000 ft. are lightning arresters, made by the General Electric Company.

The rolling stock consists of 10 vestibule cars, with 16-ft. bodies, and 20 nine-bench open cars and five 16-ft. vestibule cars, all mounted on McGuire Columbia trucks; a sweeper and a sprinkler. The cars are equipped with Westinghouse 12 A, 30-h. p. motors and G. E. B-3 controllers; electric brakes are attached. The cars are all heated by electricity.

Although this system has not a large population from which to draw patronage, yet every detail of construction

SCENES ON THE LINE OF THE NEW CASTLE TRACTION COMPANY.

Crossing Company. White oak ties 6 x 8 in. x 7 ft., were used. The joints were staggered and bonded with two No. 0, solid copper wires to each joint. The sharpest curve on the road is of 30-ft. radius.

Side pole construction is used; white cedar poles 30 ft. in length, 8 in. top, and 40 ft. long and 7 in. top, being planted according to needs. The trolley wire, No. 0, was furnished by the John A. Roebling Sons Company. The lengths of sections of line range from 4,000 ft. to three miles, depending on the conditions of service. All the lines are independent of the others and each one is connected to a circuit breaker at the station. The feeders tap into their respective lines at the square where all the divisions center and at every fourth pole thereafter. At intervals of about

and equipment is as complete and substantial as may be found in the large cities. The officers of this enterprising company are: R. R. Quay, president; Arthur Kennedy, vice-president; DeWitt Dilworth, secretary and treasurer, and Wm. Cummins, superintendent.

The camera proved a very valuable adjunct in the defense of the Lexington Avenue Railroad Company against a \$25,000 damage suit. Helen Rovatzos, a Greek girl 17 years old, claimed that she received permanent injuries by being thrown from a car on October 10, 1896. Photographs were produced by the defense showing her hanging out clothes and rowing in Central Park. In consequence of this the suit was withdrawn.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

On the night of September 21 a large frame elevator located 70 ft. distant from the power house of the Toledo Traction Company took fire and burned to the ground. The space between the two buildings was used by the Traction Company for the storage of coal, but by keeping water constantly flowing over the pile it was prevented from igniting. Higher up the heat was intense and the power house was fully exposed, but being of fire-proof construction it was not injured. During the fire the power house was filled with a dense smoke but the operation of the plant was not interrupted. The only loss suffered by the company was a small portion of its dock which it will cost about \$100 to repair.

\* \* \*

During several months past the Franklin Institute has discussed the "smoke nuisance" in an extended manner and proposes to conclude the consideration of this subject at the stated meetings in April and May. Invitations have been extended to the inventors and manufacturers of improved furnaces and automatic stokers to present descriptions of the operation and construction of their devices and the claims of efficiency. This we think is much to be commended as it will place upon record the progress which has been made, and enable one contemplating the installation of a furnace or stoker to find in one place all the available information regarding them.

\* \* \*

The Montreal Street Railway Company has 75 miles of track and operates from 170 to 200 motor cars daily; the cars make about 7,000,000 car-miles per annum and carry 30,000,000 passengers. The speed through the streets is 7½ miles per hour and the service is kept up from 5 a. m. till 2 a. m. G. C. Cunningham, who was formerly manager and chief engineer of the road gives the following data as the average of some three years' operation of the power house:

|                                                    |                   |
|----------------------------------------------------|-------------------|
| Coal consumed per car-mile.....                    | 7lb.              |
| Coal consumed per ton-mile.....                    | 1lb.              |
| Coal consumed per electrical horse power.....      | 2.75lbs.          |
| Power consumed per motor car-mile.....             | 2,000 watt-hours. |
| Power consumed per ton-mile.....                   | 293 "             |
| Resistance to haulage per ton (draw-bar pull)..... | 147lb.            |

\* \* \*

Very few power houses are built these days without some provision for lifting heavy machinery, the traveling crane running the length of the engine and dynamo room being the most generally accepted form of apparatus. Very many substitutes for this can be found however by traveling around among power houses. The Central Railway, at Peoria, has a four legged derrick high enough and large enough to go over any of its generators. This is slid around from place to place over the floor as it is needed. Of course the manipulation of such a huge four legged affair around among the generators and supporting pillars of the room is

rather awkward but it suffices and is better than a temporary derrick, as it is always ready.

\* \* \*

### Some Notes on Cooling Tables and Towers.

The decision of the South Side Elevated Railroad, Chicago, to make use of a tower for cooling the condensing water at

the power station, now building, indicates that the economy of these devices is becoming better appreciated. We have described several such towers in these columns during the last two years and herewith illustrate another, which is known as Barnard's. In common with most cooling towers it occupies but little space and may be placed upon the roof if desired. It is preferably built of steel plate; the upper portion is filled with steel wire mats, galvanized after weaving, through which the

water percolates. The arrangement is very clearly shown in the illustration.

\* \* \*

E. J. Philip, chief engineer of the T. Eaton Company, Toronto, recently gave at the open meeting of an engineer's association the following data regarding a cooling tower for condensing water, built by his company:

The tower is a rectangular structure, 19 ft. high, with a vapor stack on the top 9 ft. in diameter and 26 ft. high, the body of the tower being 10 x 12 ft. It has an 18-in. water space at the bottom and two 5-ft. fans. The filling is 12 ft. long. The distributor is made of pipe, and works very nicely. The tower runs in conjunction with a 500-h. p. surface condenser with combined air and circulating pumps. The condenser has 800 brass tubes 8 ft. long, making over a mile of tubing, with 1,600 stuffing boxes. The water leaving the condenser has a temperature of 120° to 128°; it cools in the tower down to 68° to 80°, according to conditions. It has been cooled down to 10° below the outside atmosphere, and by supplying plenty of air this could be done at any time.

\* \* \*

The reservoir and tables for cooling condensing water which are in use at the power station of the Calumet road, Chicago, were illustrated and described in the Review for September 1896, page 546. At this plant the discharge from the condensers is at a temperature of from 110° to 130° and that at the intake from 100° to 108° F. Ever since the con-

struction of the reservoir the boiler feed has been drawn from the this source, being delivered to a Hoppe's feed water heater where the temperature is raised to 208°. In order that the initial temperature might be as high as possible the supply was taken from the condenser discharge pipe, but this method was open to objection because of the feed pumps drawing air.

General Manager Sloan has recently made a slight change in the arrangement of the condenser discharge by which this trouble is cured. A wooden box, 6 ft. square inside and 8 ft. deep, with a partition down the center extending nearly to the bottom was placed at the end of the cooling tables. The discharge from the condensers is into one side of this box, down under the partition and up the other side onto the tables, instead of onto the latter direct as formerly. The intake for the boiler feed is near the bottom of the box on the up-current side; a temperature within a degree or two of that of the discharge is secured at this point; that is, almost as high as was formerly obtained by taking the water from the pipe.

\* \* \*

The Hyde Park Thomson-Houston Company has just completed a cooling tower at its station at 53rd street, Chicago. The present equipment of the station comprises four compound engines with an aggregate capacity of 800 h. p. when running non-condensing, and the addition of another 250-h. p. unit is contemplated. The use of condensers will

INSPIRATOR JET CONDENSER.

further increase the capacity of the station about 40 per cent, making it ultimately 1,400 h. p. As the station will not be running at its maximum load all the time it was considered that a 1,000-h. p. tower would be sufficiently large.

The tower was erected over the boiler room and is built for the most part of undressed pine lumber, making it comparatively inexpensive. In fact the entire cost of the tower, condensers, piping, tanks, iron work, etc., is probably within

\$6,000, that is \$6 per h. p. The tower rests upon two 48-in. steel girders 50 ft. long, which are supported at the ends on posts consisting of two 8-in. channels with lattice bracing. These posts are placed close to the wall on the interior of the boiler room. On top of the girders, which are suitably braced at the ends, are laid six 12 x 12-in. cross timbers and on top of these four 12 x 12-in. longitudinal timbers. On these are laid the water-tight floor of the tower which slopes slightly and delivers the water to two steel tanks, 9 ft. x 4 ft. 6 in. x 5 ft. 6 in. deep. The tower is in the form of a frustrum of a pyramid 21 x 48 ft. at the base and 13 x 41 ft. at the top and is 20 ft. high. The trays over which the water

COOLING TOWER, HYDE PARK T.-H. COMPANY.

flows are 17 in number and placed 12 in. apart; they consist of 1 x 6 in. rough pine boards laid  $\frac{1}{4}$  in. apart, the cracks being staggered. The total area of the trays is about 15,000 sq. ft. These trays rest on pieces 2 x 4 in., nailed to the posts, which are 4 x 4 in., spaced 4 ft. apart along the sides and ends of the tower. The top or distributing tray differs from the others in that the planks are laid close together; there are a sufficient number of  $\frac{3}{4}$ -in. holes that their combined area equals that of a 10-in. pipe. Around the edges of the trays are strips 3 in. high. The tower is surrounded on three sides by a wind-break 17 ft. high, the top being the same height as the distributing tray, in order that a high wind may not blow the water off of the trays. It is divided into panels of louver work, the slats being inclined inward, however, instead of outward, in order that the vapor may more readily find an exit.

The pipe which delivers the water to the top of the tower is 10 in. in diameter and branches into four 5-in. pipes, in each of which are three  $2\frac{1}{2}$ -in. openings. The main pipe also terminates in a  $2\frac{1}{2}$ -in. opening.

The condensers that have been installed at this station are of the inspirator jet type, or as they are sometimes called water jacket syphon condensers, and were furnished by Wm. Baragwanath & Son, 14 West Division street, Chicago. The

principle on which they operate and the arranging of the piping, etc., will be readily understood from an examination of the sketch, Fig. 2. The exhaust pipes are carried up so that the condenser may be placed 34 ft. above the hot well into which it delivers, this being of course to prevent the water from being carried back into the engine by reason of the vacuum formed. At the top of the exhaust pipe is a relief valve to provide an escape for the exhaust in the event of an accident causing an excessive back pressure. Above the brass nozzle in which the condensation takes place is a gate by which the supply of water is regulated according to the output of the engine; this adjustment is made at A. When starting, the two valves B and C are opened admitting the condensing water, which meets the steam in the lower part of the discharge pipe and forms a partial vacuum; the valve B is then quickly closed, and the water is drawn up through the right hand pipe to the top of the condensing tube.

### A GRADE CROSSING AT COLLEGEVILLE, PA.

The suit of the Perkiomen Railroad Company against the Collegeville (Pa.) Electric Street Railway and the Schuylkill Valley Traction Company to prevent the construction of a grade crossing, was on December 1 decided in the lower court permitting the electric road to cross at grade. The court found that "the topography favors a grade crossing, or rather makes it reasonably impracticable to avoid one." The steam road has only 13 trains per day and as the railroad station, at which nearly all the trains stop, is but 150 ft. from the proposed crossing, they would necessarily move over it at a slow speed. A good view of the tracks can be had from the highway, and a good view of the highway from the railroad tracks. Further, the grade of the highway is already too steep to permit of depressing it so as to run under the tracks, and the expense of avoiding the crossing at grade would be \$15,000, which is as much as the entire road in the borough of Collegeville (about a mile of track) would otherwise cost.

The Schuylkill Valley Traction Company, which built the

road as lessee, laid the track on August 16, though opposed by the steam road with force, and maintained its position until the court came to its rescue and caused a cessation of hostilities; now it has won the suit. While the Collegeville road itself is short it is an important link in the interurban system. General Manager R. M. Douglass is to be congratulated on the successful manner in which he handled the matter.

### IN THE EARLY DAYS.

When the Metropolitan Street Railway Company, of New York, a few weeks since celebrated the completion of its Fourth avenue electric line between Astor place and 42nd street, the new electric cars were accompanied over the route

OLD NEW YORK CAR.

by one of the horse cars used by the predecessors of the company in the early days. One of these vehicles, called by the employes a "bone-shaker," was taken out of its quarters and driven by an employe who drove it nearly 40 years ago. Several members of the Board of Aldermen were guests, but before the trip was finished they had all the enthusiasm shaken out of them.

## A CHAPTER ON BLUNDERS.

No man likes to advertise his own mistakes. They usually cost him something both in money and reputation. If some one could institute a mistake publishing bureau for collecting and publishing the blunders made in the street railway practice, taking always extreme care to conceal the identity of the victims, the industry would be much better off than it is today; for after all information is mostly obtained only by costly experience and mistakes, and the better these blunders are known the less money will be spent the country over in learning. Such a bureau will never be started for the reason hinted at in the first sentence, but rumors come to us constantly of blunders which have been and are being made and which are either too amusing or too full of useful lessons to hide under a bushel.

Our first story is about a mistake made away back in the beginnings of the electric street railway of today by one of the prominent pioneers in the field. The same mistake has been made by hundreds of lesser lights since, and it relates to electric railway return circuits. Said pioneer and his right hand man were standing beside the track near the power house one day when the right hand man averred that there was considerable resistance in the rail joints, and that the simple fish plates did not make very good electrical contact at the rail ends. The chief expressed his contempt for any such opinion and the right hand man, wishing to do a little experimenting on his own account walked over and put one foot on the end of one rail and another foot on the end of the next. This may properly be designated as one of the earliest attempts at rail bonding. But the bond was not very permanent in this case. In fact as soon as contact was established it performed several kinds of gymnastics, partly voluntary, partly involuntary, the main idea being to get out of the circuit as soon as possible. The chief was convinced that he made a mistake in relying on the electrical conductivity of the fish plates.

One of our friends had occasion recently to visit an armature winding room where an elaborate system for testing the coils and all the materials used in armature winding by the use of the high voltage breakdown test has been in use. The system is all right, and properly used will save much money by preventing poor and defective materials and coils from going into the make up of an armature. But in this case it was operated so as to be far from a money saver as the tests were made so severe that about 40 per cent of the finished armature coils broke down under test and were thrown out. That road has a fine large scrap heap of copper wire.

There was much trouble in the shop. Motors were remonstrating at having so much work put upon them and although the work they were doing was much less than that for which they were intended they were offering vigorous protests in the way of burned out armatures and commutator leads hot enough to melt anything but the hardest solder. At last an "expert" was called in, who looked over the ground and finally announced that he had discovered the whole cause of the many trials and tribulations. The "nigger in the wood pile" had been found. The field magnet collars were of malleable iron instead of brass. A grasping manufacturing corporation had been trying to save a few cents in the

manufacture of its motors. Great was the rejoicing from president down that the end of all troubles was in sight. The manager of another neighboring road who happened to have brass field collars on his motors was telephoned to in haste and asked if he could spare a few brass field collars. Said manager replied that he had nothing but malleable iron collars in the store room, but since it didn't make a particle of difference whether the field collars were brass or malleable iron and since his neighbors seemed to want some brass collars so bad, he would, to accommodate them, take some off of motors in service and put on malleable iron so that his neighbors could have the brass. This was done but it hasn't been observed that there has been any recent demand for brass field collars from the road where the great discovery was made.

Some of the most amusing blunders, to American electricians, are the attempts made by foreign manufacturing concerns when entering the electric railway field to use shunt wound generators for railway work. An American engineer who recently visited England was somewhat dumbfounded on entering one of the largest railway plants there to find immense shunt wound bipolar machines doing the work; and he was still more surprised when he learned that an extension to the station was planned on the same lines. It would be putting it mildly to say that the voltage fluctuates on that road. Even worse was the attempt once made by some German engineers to operate a small road from a motor generator in which both motor and generator were shunt wound. To make matters still worse the source of supply was a shunt wound dynamo. The voltage on the trolley varied all the way from 250 to 500.

It is all right, perhaps, sometimes to keep figures as to costs of materials, etc., a secret, but it is certainly a mistake to carry out this plan to the extent it is on one road where the heads of operating departments have great difficulty in finding out what anything costs in their own department. When the master mechanic for example turns out a piece of work that might have been bought in the open market he naturally wants to know whether it is paying the road to do this. But not an inkling can he get from the auditing department as to the cost of anything and he is obliged to "go it in the dark" or make up his own figures for his own use. It can easily be imagined how pleasant it is for department heads who are a great portion of the time studying how to reduce expenses, not to be able to know without unnecessary trouble how the present expenses run.

## CHICAGO GENERAL RAILWAY'S NEW SCHEME.

It is stated that the Chicago General Railway will seek to avoid complying with the ordinances of the city by extending its services to Hammond, Ind., and thus become an instertate line subject only to the regulations of the interstate commerce law, and the regulations of the railroad commissioners of Indiana and Illinois. The proposed route to Hammond is over leased lines, a considerable portion being those of the Chicago City Railway. It is possible that the fender and paving ordinances may be thus avoided, but it is also possible that the city may at the same time acquire the right to insist that the track be elevated at streets so as to do away with grade crossings.

## THE YERKES OBSERVATORY.

## THE PROPER SPEED OF MOTORS.

The scientific world is indebted to the munificence of a street railway man for the largest refracting telescope as yet constructed. The Yerkes Observatory, with its great telescope and the subordinate instrumental equipment, was the gift of Charles T. Yerkes to the University of Chicago. The observatory is located on an elevated tract of land 53 acres in extent, the gift of John Johnston, on the north shore of Lake Geneva, Wisconsin, some 75 miles northwest of Chicago. The air is free from smoke, there are no electric lights nearer than seven miles, the nearest railroad is a mile away, the soil is largely gravel, and the location is probably

It is only very recently that due consideration has been given to the important part that the speed for which motors are wound or geared, plays in the economy of operation of a road. Failure to consider this has caused a number of very expensive mistakes in the past few years and it is certainly high time that both operating and manufacturing companies should awake as they are doing to the fact that motors must be geared or wound for the work they have to perform and that the speed should be a matter of careful study before the purchase of an equipment.

From the abandonment of horse cars until the present

YERKES OBSERVATORY OF THE UNIVERSITY OF CHICAGO.

as favorable for astronomical work as any that could be secured in this country. Our illustrations show the building and the telescope. The building, which is in the Romanesque style with somewhat of Saracenic details, is of brown Roman brick with elaborate terra cotta ornamentation; it is in the form of a Latin cross, the long axis being east and west and 326 ft. in length. The large tower at the western end is 92 ft. in diameter, and the northeast tower 30 ft. in diameter; in the latter is the 12-in. telescope formerly in the observatory at Kenwood. The machinery for handling the instruments, movable floors, etc., and also that in the shops and laboratories, is all motor driven, the power house being located to the northeast of the observatory about 800 ft. away.

A decree of foreclosure and sale of the Mount Lowe Railway was ordered by the court in the suit brought by the Los Angeles Safe Deposit & Trust Company as trustees for the bondholders against the Pasadena & Mount Wilson Railway Company.

year the cry has constantly been for motors of higher speed and the manufacturing companies have been conforming to the demand. A few managers have found out to their sorrow that they have purchased motors that are too fast, but naturally they have not been anxious to talk about their mistakes and it is only the past few months that the best electric railway engineers have become thoroughly awake to the importance of this detail of an electric car equipment. In numerous cases which have come under the writer's notice, equipments have been purchased which were so fast that nine-tenths of the time in service it is only practicable to run at half speed or in series, the parallel notches being for various reasons too fast for the service. In some of these cases the distance between stops was so short that the motors could not be run up to full speed in parallel without taking such an enormous starting current as to require a power plant capacity much larger than that planned, and overheating the motors so that the size of the repair bills staggered the manager. In other cases the maximum speed was too high for safety.

The following table shows the comparative amount of current required to accelerate a given car up to a given speed in a given time with a motor of the same type and size under the car in each case but with different speed gearing or winding.

| Speed for which motor is wound or geared, miles per hour. | Comparative current required to accelerate cars at any given rate, amperes. |
|-----------------------------------------------------------|-----------------------------------------------------------------------------|
| 5                                                         | 10                                                                          |
| 10                                                        | 20                                                                          |
| 15                                                        | 30                                                                          |
| 20                                                        | 40                                                                          |
| 25                                                        | 50                                                                          |
| 30                                                        | 60                                                                          |

motors were wound for the maximum desired speed of 15 miles an hour, and furthermore the motors can never be allowed to attain their maximum speed. If on the other hand it is attempted to start more slowly than with the slow speed motors and make the same schedule by running up to a higher maximum speed between stops more energy must be wasted in the brake shoes when the car is stopped.

A rather inconsistent practice has been that of using the same size motors under a given weight of car, no matter whether the motor is to be run 10, 20, or 30 miles an hour maximum speed; and very often the power plant is designed on the same basis, without regard to the speed of the cars. The size of the motors should usually be increased somewhat more than directly in proportion to the maximum

THE FORTY-INCH YERKES TELESCOPE.

From this comparative table it is evident how inefficient a high speed motor is in city service where it can not attain its speed and where most of the time it is at work accelerating a car up to a lower speed than that for which it is built. For a concrete example suppose that a road is equipped with motors wound for 25 miles per hour maximum speed, but that only 15 miles an hour is allowable. The starting current used will then be 40 per cent greater than if the

speed of the cars for it is evident that the power required to maintain a car at 30 miles an hour is more than twice what it would be at 15 miles an hour, and further from the foregoing table it is seen that the energy expended in acceleration is also double. More than this as the heating of the motor windings is according to the square of the current, the motor windings of the faster motor must be somewhat more than double the capacity of the slower speed motor.

Many motors have been rewound for lower speeds in the last few years as gradually the facts above enumerated have forced themselves into the attention of electric railway engineers and there are still many running which managers would gladly reduce in speed could they do so without great expense. In many places, as said before, the motors are operated the greater part of the time in series and are rarely thrown in multiple, with the practical effect that there is no gain in economy by having the car equipped with a series-parallel controller.

This article is not intended to teach anything to electric railway engineers who have studied the subject of car speeds but is intended as a warning to those purchasing new equipment that they may not fall into the same error as many another manager. And furthermore, it may explain to some managers who have not given the matter thought why such a large power plant capacity is required to move their cars and why so many motors burn out as compared to other similar roads.

Where high speed is to be attained between frequent stops it must be done at the expense of much heavier motors and a much larger power plant than if the road were to operate on a slower schedule, and all attempts to make a high speed equipment do slow speed work or vice versa can only result in poor economy and dissatisfaction with the apparatus.

### IMPORTANT INTERURBAN VERDICT.

#### Farmer Claimed \$5,000 and Gets 6 Cents.

By an act of the Wisconsin legislature approved April 2, 1897, electric railways in that state are authorized to acquire a right of way outside of incorporated towns and cities by condemnation proceedings, and on April 14 the supreme court decided that an interurban electric railway is a commercial railroad and constitutes an additional burden on the abutting property for which compensation must be made, thus placing electric and steam roads on practically the same footing. This act and the ruling of the court may be found in the REVIEW for May, page 290. The first damage case resulting from this decision has recently been decided and cannot fail to be of great interest to railway companies. The facts are briefly as follows: James Ruan is the owner of a large farm in Milwaukee county, the land lying on both sides of the route followed by the Milwaukee, Racine & Kenosha Electric Railway Company. Mr. Ruan claimed that the construction of the road in the highway in front of his property damaged him to the extent of \$5,000 and petitioned the circuit court for the appointment of three commissioners to assess damages as provided by the statute; the commissioners appointed were three business men who viewed the premises, heard testimony and the arguments of attorneys, and awarded damages to the amount of 6 cents, all concurring.

The introduction of X-ray photographs as evidence in damage cases proved to be a novelty a short time ago, and now the fluoroscope is used to determine whether or not bones have been crushed or displaced. In the suit against the Nassau Electric Railroad Company for injury to a nine-year-old boy, the jurymen made examinations with the fluoroscope.

### MINIATURE TROLLEY CAR AT DES MOINES.

During the annual Iowa State Fair at Des Moines, the citizens of that progressive place invariably endeavor to make their city present an attractive appearance to welcome the thousands of visitors which flock to the capital to celebrate what is one of the important events of the year in that great agricultural state. The Des Moines City Rail-

A FEATURE OF THE IOWA STATE FAIR.

way fully enters into the spirit of the occasion along with the rest, and this year Superintendent W. G. Owens had constructed a trolley car one-half the size of one of the standard closed cars in use on the road, exact in every detail. It was placed on top of the company's central transfer depot and waiting room, and brilliantly illuminated with 300 colored lights. The wheels and trolley wheel were revolved by a  $\frac{1}{8}$ -h. p. motor, which also changed the color of the lights while revolving, giving a beautiful effect. It was indeed a novelty and attracted the attention it deserved.

### VESTIBULES IN NEW JERSEY.

It will be remembered that at the last session of the New Jersey legislature a law was passed which after attempting to remedy a bad blunder now reads that the street railways of that state equip their cars with vestibules for use between November 1 and March 1 of the same year. There appears to be division of opinion among the New Jersey managers as to whether the law can be enforced and at the present time but a few roads have complied with the spirit of the law. The Newark & South Orange Company, while doubting the wisdom of the act provided all its cars with the vestibules prior to November 1. The Consolidated Traction Company has decided to make a fight on the ground of the wording of the law, which it will be noticed calls for vestibules during the summer months, and will make a test case of the first conviction against it. The police of Newark and Jersey City have been very active in securing data as to the violations (a penalty of \$50 per day for each car run without a vestibule is provided) taking the number of each car and the conductor's name.

The employes of the Cleveland, Berea & Elyria Railway Company received an increase of 10 per cent in wages on December 1.

## PRACTICAL OPERATION AND MAINTENANCE OF ELECTRICAL EQUIPMENT IN THE POWER HOUSE.

BY J. D. DE GURCHY.

With a new station equipment, it would seem that little trouble should be experienced and that after the preliminary adjustments, regulations and tests, the plant ought to run in first-class order for sometime without repairs. However, there are sure to be some faults which, if not anticipated and remedied in time will lead to serious loss. It is the object of this article to present some of these troubles as they have been found to occur in the writer's experience.

In some of the older type of four pole 500-k. w. and 10 pole 750-k. w. dynamos, the terminals of the field windings of the series coil, will be found to be brought out dangerously near the brass spools, upon which the shunt and series field coils are wound.

With a ground on the field frame which is at all times possible, a very little dirt or copper dust would be sufficient to start a destructive arc, which would render necessary the taking out of the pole piece and field spool in order to repair the damaged insulation and terminal. Two or three turns of the series winding should be unwound to insure thoroughness in renewing the insulation, and to facilitate the work of putting in a new terminal. The insulation between the field spools and terminal should be kept scrupulously clean, a coat of insulac or some other good insulating paint applied, and the field frame frequently tested for grounds with a magnet or a bank of lamps. In dynamos of recent design this fault has been obviated by bringing the terminals out in the center of the field spools.

The shunt field circuit should be given a frequent and thorough overhauling; the field spool connections must be clean and tight, and the terminal connections on the rheostat firm and mechanically strong. When the shunt field wire is soldered into a terminal on an insulating block upon the field frame the wire should be run so that it will not be exposed to careless or accidental bending. The conductor might be broken, and if the insulation held it together long enough for the e. m. f. to build up, an arc would probably be formed and the circuit burnt in two. In such an event the machine switches should be immediately opened. An open circuit in the shunt field would be distinguished from any other trouble by an excessive sparking at the brushes, an abnormal increase in speed, and a falling off in the apparent circuit output indicated by the ammeter of the dynamo on which the trouble occurred. As the dynamo increases in speed, the counter e. m. f. becoming higher, the current will gradually diminish. The dynamo will not reverse in a case of this kind. It would run as a series motor, and in the same direction of rotation that it was driven as a dynamo. The fallacy of the notion that one, of two or more compound wound dynamos running in multiple, will reverse and run away in the opposite direction is evident, if the fact is considered that before the dynamo comes to a state of rest the current load, due to the low internal resistance of the armature windings would be sufficient to open the other circuit breakers, thus preventing any further trouble in that direction. No one would be so reckless as to close the machine switches of an idle dynamo, connecting it to the

main bus bars of other machines running at working pressure. The result would be practically the same.

Let us suppose that a dynamo runs in multiple with one or more others, but refuses to take its proper share of the load. Upon investigating, it is found that the dynamo is running at normal speed, all the connections tight, the commutator clean and brushes in good order. The dynamo in question has previously been working properly and the equalizing circuit of sufficiently low resistance to assure good regulation. It would now be advisable to test the shunt field coils, which can be readily accomplished in the manner illustrated in Fig. 1. Let G, H, I, J, represent coils to be tested; arrange a series of five contacts or binding posts  $A_1, B_1, C_1, D_1$  and  $E_1$  and run heavily insulated wires from  $A_1$  to  $A_2, B_1$  to  $B_2, C_1$  to  $C_2, D_1$  to  $D_2$ , and  $E_1$  to  $E_2$ . Voltmeter readings between  $A_2$  and  $B_2$  will give e. m. f. of coil G;  $B_2, C_2$  coil H;  $C_2, D_2$  coil I and  $D_2, E_2$  coil J. Trouble in any of the coils would be known by its relatively low e. m. f. and would account for the dynamo shirking its load.

It is important that the commutator brushes be kept as near to the neutral or non-sparking position, as the variations in load will permit. It is necessary with nearly all dynamos to set the lead forward or backward when the load

FIG. 1.—CONNECTIONS FOR TESTING COILS.

makes a pronounced change either increasing or decreasing. Machines should be compounded so that the load can be kept equally divided between the different units. The leads should be the same, then if a sudden load should come on or a heavy short circuit should occur, the load would not be thrown on one machine because of an excessive forward lead weakening the fields of some, and a less lead of brushes leaving the other with a stronger magnetic field. This is due to the distortion of the field, by the magnetizing effect of the current flowing in the armature.

Short circuits in commutators are caused in most instances by the pitting or burning away of the mica insulation between the segments; carbon and copper dust get in and are burned into a hard mass of sufficiently low resistance to short circuit the coil to which the segments are connected, and produce an excessive flow of current in the coil. This causes the brushes to spit and flash as the segments affected pass under them. The segments and coil being alive when leaving the brushes, destructive arcing results. If the dynamo is not soon shut down, the arcing will burn the segments low. A short circuited commutator should not be run until it becomes necessary to use a turning tool to obtain a smooth and even surface. If the short circuit were removed the commutator would still be liable to arc at that point, owing to the dirty, low and rough contact caused by the previous burning. After segments have been repaired, the

commutator should be sand-papered until smooth. All such pitting and burning of the mica between the segments, should receive prompt attention. The best and most permanent way to repair is to clean out the burned insulation and fill with mica, for all other substances and preparations are too short lived to warrant their continued use. If possible, disconnect the ends of coil from the segments and test the insulation between short circuited segments with a magnet, before filling with mica.

Very few tools are required for this work, and the necessary skill can be acquired with a little practice. Chisels for cleaning and shaping the hole can be made from  $\frac{1}{4}$ -in. tool steel. Two pieces, 6 in. long, are heated and flattened on one end of each to about the thickness of the insulation between the segments. One is ground or filed to a point as shown at A in Fig. 2, leaving the thickness of the blade a little less than the space between the segments. This tool is used to cut down to clean mica, and to square the ends of the hole preparatory to receiving the new mica, as seen at E. The other piece should be formed to the shape of a car-

FIG. 2.

pen's chisel, B, and filed thin for use in stripping off the thin flakes of mica which may adhere to the sides of the segments. If the sides of the hold are cleaned no difficulty will be experienced in driving in new mica. After the tools are finished they can be tempered, care being taken not to make them too brittle.

A pair of clamps for holding the mica to be driven, can be made of an old file  $1\frac{1}{4}$  in. wide, the file being preferable because the rough surface will hold the mica firm when being driven. After the temper is drawn, cut two pieces 3 in. long and drill 4 holes in each piece in about the positions shown at D, tap one piece for  $\frac{1}{4}$ -in. machine screws, and drill the holes in the other one sufficiently large, that the screws will not bind upon being hammered. A small hammer completes the outfit. After the hole has been prepared, cut a thin strip of mica the same size, then cut two more pieces using the first as a template, and have them thick enough to fill the space between the segments. Force these in just enough to hold them, and enter a very thin strip between the two already in the hole. This will wedge it tight. Now fasten on clamps, hammer slowly and carefully into place, cut off by drawing the keen point of a knife repeatedly across the mica and finish with fine sandpaper.

(To be Continued.)

The Metropolitan of New York, has adopted service stripes, using one blue stripe for each of the first four years, and after that one gold stripe for each five years. Some of its men have been with the company over 25 years.

## TESTING ARMATURE COILS.

In the shops of the Cincinnati, Newport & Covington Street Railway the practice is to test each coil for insulation after it is put on the armature, and just before the leads are connected up to the commutator. The voltage used is 1,000, furnished by a small rotary transformer. One lead of the transformer is connected to the armature shaft and core, and the other to the coil to be tested, and if the 1,000-volt current does not break down the insulation between the coil and core it is pronounced O. K. This is the only breaking-down test made during the assembling of an armature, as the management of the shop believes that this is all that is necessary, and that additional tests and higher voltages take more time and destroy more material than they are worth.

## NEW SOUTH WALES TRAMWAYS.

Through the courtesy of the railway commissioners for New South Wales we have received a copy of their report for the year ending June 30, 1897. The results of the working of all the tramways are given below for the last two years:

|                                                 | 1897.        | 1896.        |
|-------------------------------------------------|--------------|--------------|

| Number of passenger fares collected.....        | 72,343,812   | 68,109,264   |
| Tram-miles run.....                             | 3,088,138    | 2,736,260    |

The tramways are operated by steam, cable and electricity; the data per car-mile are not given for the electric lines alone. On the city and suburban lines the cost of working per tram-mile is 25.04 cents for the steam lines and 12.32 cents for the cable lines.

The engineer reports that during the last year  $1\frac{1}{2}$  miles of electric lines were added, and  $3\frac{1}{2}$  miles of track relaid with 60-lb. and 80-lb. T-rails. There is a considerable length now laid with 42-lb. rails that must be relaid at an early date.

## IMPORTED DUTCH TAPE FOR ARMATURES.

The Metropolitan West Side Elevated road, of Chicago, finds that for covering its armature coils, where high insulation is required in an extremely small space, an imported Dutch linen tape is by far the most reliable material yet found. Its superiority lies in the fact that it is of such close and even texture throughout. American linen tape can be found which at first sight looks the exact duplicate of the Dutch imported, but on closer inspection it will be seen that it is uneven in thickness and the threads of which it is composed are of varying size. The Metropolitan Elevated made to make special importations of this material and order months in advance, but the superior quality of the goods makes it worth the trouble and expense.

**TRANSPORTATION TO THE NASHVILLE EXPOSITION.**

The facility and satisfaction, with which the Nashville Street Railway Company handled the crowds at the Tennessee Centennial Exposition, have called forth much praise. In the first place the company improved its roadbed, laid heavier rails, put down new lines to the grounds and added 37 new cars to its equipment. Transfers were given between all lines, thus making one fare of 5 cents from any part of the city to the Exposition grounds. The schedules were at all time conveniently arranged and not a serious delay or accident occurred. The improvements are all permanent, and the citizens of Nashville feel that one good result of the Exposition is that they now have as fine a railway system as any city in the country of the size of Nashville.

**FEEDER SYSTEM AT KANSAS CITY.**

The Metropolitan Street Railway Company of Kansas City, Mo., has an extensive system, comprising 60.6 miles of cable track, 62.6 miles of trolley and 12.8 miles of horse car lines, but the latter is being or soon will be electrically equipped. To furnish power for these lines there are five stations as shown on the map. The Blue River station is equipped with two direct coupled General Electric generators of 250 and 400 k. w. capacity, respectively. Power is furnished for the Kansas City, Independence & Park line with 17 miles of track. Both cable and electric machinery are in the station at 18th and Olive streets. There are two D-62 T. H. dynamos and one 125-k. w. four pole Westinghouse generator belted to the fly-wheel of the cable engine. The D-62 dynamos are driven by high speed engines and are held in reserve, being used only at times when it is necessary to stop the cable machinery. The Vine street electric line and the 18th street cable are operated from this station. The 31st and Holmes street power house is similarly equipped, having a Westinghouse generator driven in the same manner. The Holmes street cable and the Rosedale electric are supplied from this station, the feeders of the last two stations being so arranged that both the Rosedale and Vine street lines can be operated by either or both. The Central avenue power house described in the August REVIEW has one 14 pole 1,300-k. w. generator which supplies current for the Kansas City Railway, the Armordale & Argentine line, the Quindaro boulevard, the Southwest boulevard and the Westside lines; also for a 400-h. p. motor which drives the cable machinery at the 9th and Washington street station for operating the Summit street cable. The 9th and Wyoming street station is equipped with cable machinery, also two 300-k. w. four pole General Electric and four D-62 T. H. generators. These dynamos are maintained in reserve in case of an accident to the machinery at the Central avenue station. Two of the T. H. dynamos are run from 1 a. m. to 5 a. m. to supply current for the owl car service and lights over the system.

An addition of another 1,300-k. w. generator is contemplated at the Central avenue station this year and the engines now driving the cables will be supplanted by motors. The use of alternating currents in the transmission of electricity to these motors is under consideration. The whole system has been so designed that an increase in any part can be effected from time to time when required and at minimum

cost. The average daily load is about 84 per cent of the breakfast and supper loads.

The voltage on the system varies from 500 to 550; the average maximum drop from the stations to the farthest end of the various lines is less than 50 volts. No. 0 trolley wire is used on all the lines. The feeders are calculated for a loss of 5 per cent on the positive side when carrying from 25 to 50 per cent more than the estimated maximum current, the area in circular mils per ampere varying on different lines. Some of the lines are divided into sections, but these are of no regular length, varying according to the conditions of roadbed and the number of cars; the headway ranges from 3 to 15 minutes. The length and number of feeders are governed by the same conditions; besides provision is made for the grades and the distance from the stations. All feeders on the positive side are covered with a braided weatherproof insulation and are carried on either glass or malleable iron clad insulators, depending on the length of the span and the size of feeder. Return feeders are also insulated in the same manner where they parallel or cross telegraph, telephone or electric light wires; at all other places bare copper wire is employed. The conductors consist of copper cable made up of seven strands of seven wires each. This applies to all conductors from 250,000 to 1,000,000 c. m., but the smaller feeders are solid. As a rule

the feeders follow the trolley lines and the poles are used for both trolley and feeder wires wherever practical. Connection is made from the feeder to the trolley by No. 0 stranded weatherproof copper cable used as a span wire with double globe strain insulators at the pole fastening. Soldered cars are used on the trolley wire, and a brass body sprung on the No. 0 cable with a cap screw for screwing the body and car. The No. 0 cable is tapped on the feeders the joint being well soldered and taped; the car is soldered to the trolley wire, but the brass body is not soldered to the span. The distances between the spans which are tapped to the feeders vary with the headway of the cars, the grades, the length of the section of the trolley line, and are arranged so that the feeders are tapped to the trolley on or close to the heavy grades.

There are some heavy grades on the lines, one being 9 1/2 per cent and 1,000 ft. long. The cars with 30-ft. bodies and G. E. 1,000 motors make an average speed on this grade of 5.86 miles per hour with motors in parallel. Car bodies, 16 and 18 ft. in length, equipped with Westinghouse No. 3 motors, are run over an 8 1/4 per cent grade 738 ft.

long with an average speed of 3.05 miles per hour when the motors are in series or 8.38 miles when in parallel. On some of the grades where the cars stop for taking on or letting off passengers, or other causes, the motormen are required to start up and operate the motors in series for the rest of the distance up the grade. No special provisions have been made in the feeders for supplying current on the grades other than increasing the size sufficiently for carrying the amount of current required and arranging the taps for connecting the feeders to the trolley wire on the grades.

No boosters are in service on the system. General Manager Holmes believes that it is not advisable to use more than 550 volts for a maximum at the motor terminals on grounded circuits with the present method of operation. If an efficient transmission system could be devised it would be much more desirable to lower rather than raise the voltage at the motor terminals, as it would be a saving in cost of insulation and in all electrical repairs.

### SPECIAL WORK FOR THE CHICAGO CITY.

The Indiana avenue line of the Chicago City Railway Company crosses the tracks of the Lake Shore & Michigan Southern Railroad and beneath the elevated structure of the South Side Elevated Railroad Company. The tracks of the railroad parallel the elevated at a distance of 16 ft. An ordinance requires that all trolley lines be 22 ft. 6 in. above railroad tracks. The lower part of the elevated structure is only 15 ft. 6 in. above the street; the trolley wire must then drop 7 ft. in 16 ft., but it was found impossible to keep the trolley on the wire with this inclination. To obviate the difficulty the trough shown in the figure was designed by G. W. Knox, electrician of the company. The trolley wire is clamped to the trough made of 9-in. channel iron, which is a part of the circuit. At each end the run off is so formed that the trolley wheel is guided right to the wire. The trough is supported from an oak plank  $1\frac{1}{4}$  in. thick and 6 in. wide, and is insulated from another piece of oak of the same size by five pairs of the Anderson fiber insulators. The bracing and method of suspension from the elevated structure is shown in the cut. All the work was done in the company's repair shop.

### MONTREAL STREET RAILWAY COMPANY.

The annual report of the Montreal Street Railway Company for the year ending September 30, has been received from Vice-president James Ross and it records a very prosperous year. The first financial statement is that there is a net profit resulting from the year's business of \$507,855.60, out of which two dividends of 4 per cent each and a bonus of 1 per cent were paid, beside adding \$139,522 to the surplus. During 1897 the gross receipts were \$1,342,367, an increase of 6 per cent over the preceding year; the operating expenses were \$736,428, an increase of only 3.6 per cent, and the net earnings were \$605,939; over 9 per cent more than last year. The passengers carried numbered 32,047,317. One interesting point is that since 1892 the ratio of operating expenses to car earnings has declined annually, the operating expenses being for the last six years, 83, 79, 71, 59, 56 and 55 per cent, respectively. It is readily seen that the company is on a sound financial basis, is being managed in a conservative and economical manner, and is giving a good service to its patrons.

### AMERICAN APPARATUS FOR DUBLIN.

W. M. Murphy and J. B. Concannon, of the Dublin United Tramways Company, have been on a purchasing tour in Chicago, New York and other cities in the United States, and have closed contracts to the extent of \$750,000 for apparatus to equip the street railway lines of Dublin for electric traction. Mr. Murphy stated that he was well pleased with the results of the tour, as the machinery was procured at very much less than the estimated cost, and that American manufacturers are undoubtedly leaders in street railway appliances. It is expected that \$1,500,000 more will be spent in converting the horse car lines to electric, and this will be accomplished in the next 18 months.

Electric heaters have been discarded by the Union Depot Railway Company, St. Louis, in favor of the coal stove. General Manager Scullin says the change was made because the generators could not furnish all the current needed to run the cars, to light them and to heat them.

SPECIAL OVERHEAD WORK—CHICAGO CITY RAILWAY.

## PROTECTION FROM LIGHTNING.

The disastrous effects of lightning were experienced soon after the introduction of electrical apparatus for street railway service, and it was evident that some means must be taken to preserve the armatures of generators and motors from damages by electric storms. The first types were quite simple, consisting simply of two serrated surfaces with a short air gap. The air gap was not of proper length and the arresters were not placed as they should be, consequently they were ineffective. A number of designs were evolved for station, car and line service. With the air gap it was found that after a stroke of lightning the arc was maintained by the dynamo current; to prevent this a fuse was introduced into the earth circuit. As soon as the fuse would blow the arrester was useless, and when another discharge quickly followed the first, as is often the case, the apparatus was unprotected. The air gap was employed in preference to other resistance, as it is a good insulator under ordinary circumstances, but offers very much less impedance to the

coil is placed in the circuit and connection is made to the water into which the discharge passes. The objection to this form is that there is a constant consumption of energy. The high resistance arrester consists of a series of iron and mica washers. The high potential of a discharge will bridge the insulating washers and pass to earth, but in so doing it is liable to fuse a little of the iron and a metal contact is made with the iron washer below and soon the circuit is complete to earth. The next step was to not only provide a discharge path, but also

FIG. 2.—LIGHTNING ARRESTER CONNECTIONS.

to blow out the arc. This was accomplished in the mechanical magnet and the magnetic blow out arresters.

The Thomson-Houston magnetic blow out arrester is perhaps the best known of any of that type, a modification and outgrowth being the type MD line and car arrester made by the General Electric Company.

Fig. 1 represents the arrester in a box with a cover so arranged as to be convenient for inspection and repair. The air gap between the two spark terminals is .025 in., which permits a discharge at 2,000 volts. In series with the spark gap is a non-inductive resistance of 100 ohms, through which the generator current passes in following the lightning discharge to the ground. The resistance permits a current of about five amperes to pass the air gap and the blow out magnet coil instantly ruptures the arc. To eliminate reactance in the magnet winding, it is connected in parallel with a part of the non-inductive resistance. As shown in Fig. 2 a reactance coil is placed in the circuit between the arrester and the apparatus to be protected. The reactance of the coil reinforces the insulation of the machine, and thus the discharge passes across the air gap and to the earth, that being the path of least resistance.

Another type is the non-arcing arrester made by the Westinghouse Electric Company. Between the spark terminals are blocks of charred lignum vite, having grooves  $\frac{1}{32}$  in. deep. The carbon offers too great a resistance for the passage of dynamo current, but is low enough for the high potential of the lightning discharge. With the use of carbon, no metallic vapors are formed to sustain the arc.

Fig. 4 represents the Garton lightning arrester with iron case for pole use. This arrester is of the magnetic blow out

FIG. 1.—G. E. TYPE MD ARRESTER.

passage of a stroke of lightning than any other kind of insulation, and is instantly restored to normal.

The oscillatory character and the disruptive discharges of lightning give rise to complicated phenomena and make absolute immunity from danger almost impossible. The line may receive a direct stroke, or excessive current may be induced from a primary discharge quite apart from the line. After the line has received the discharge there are what are known as "nodal" points, or points which, because of the oscillatory character of the lightning, are at a very much lower potential than other parts of the line. For this reason arresters must be distributed at intervals. The successful operation depends largely upon the systematic arrangement of the arresters and choke coils, and also the installing of short and straight earth connections. The number of pulsations of a lightning discharge is so great that a few turns in the circuit over which it passes induce a very high self-induction, and this offers great impedance to the flow of current. This is made use of by introducing a solenoid of wire or choke coil between the lightning arrester and the apparatus to be protected. This offers a greater resistance to the discharge, which consequently passes to earth through the arrester circuit.

Among the first types were the high resistance and "tank" arresters. In this type each feeder passes over a metal lined tank which is connected to the water mains. A

FIG. 3.—WESTINGHOUSE NON-ARCING ARRESTER.

type and is extensively used in street railway service. The spark gap is of such length that its resistance is considerably below that of the insulation resistance of the motor fields and armature. The lightning arrester circuit should offer less resistance to the discharge than any other, to be a reliable protection to the apparatus.

It would seem that after so much time had been spent in studying the conditions and in developing such excellent safe-guards against damage by lightning that little trouble would be experienced on street railway lines. Recently in one of the large eastern cities one road lost 40 motor armatures during a severe electric storm. An official of a small western railway wrote the REVIEW, saying: "We have arresters on cars, also kicking coils and pole arresters every mile, and still our armateurs go. We are beginning to think that the only safe way is to pull the trolley down and lie still until the storm is over, which is unbusinesslike even in a small city." It was evident that the question of protection from lightning is a very live one with some railways at least, and further inquiry was made.

On the Canton-Massillon electric lines the Wirt's non-arcing and the Keystone arresters are employed on the cars, but none on the lines, as all that have been tried have given trouble by getting grounded and short circuiting the whole system. As there is a considerable number of motor armatures lost, the company thinks it would be very advantageous to put a reliable arrester on the lines. It has been the experience of this company that the armatures on the suburban lines are in greater danger than those operating in the city, because the cars being farther apart, there is a more violent discharge at one time. After every storm each arrester is inspected.

The Springfield (O.) Railway Company has little trouble from lightning, having lost only two motor fields. The cars are protected by the Westinghouse and General Electric arresters with kicking coils, and the lines have one Garton or Wirt arrester every mile. After each storm the arresters are inspected and cleaned, and they are repaired frequently, which probably accounts for the immunity from damage on this road.

Elgin, Ill., has had 21 storms during the past three years, and the railway company has passed through a rather trying experience. On the suburban lines Westinghouse and General Electric arresters are placed at intervals of one-half mile. Each feeder running to the bus bar has a lightning arrester, and there is also one in each dynamo circuit. In the city, barbed wire is stretched over the feeders and grounded every second pole, and still armatures are lost.

FIG. 4.—GARTON ARRESTER.

studying the conditions and in developing such excellent safe-guards against damage by lightning that little trouble would be experienced on street railway lines. Recently in one of the large eastern cities one road lost 40 motor armatures during a severe electric storm. An official of a small western railway wrote the REVIEW, saying: "We have arresters on cars, also kicking coils and pole arresters every mile, and still our armateurs go. We

FIG. 5.—CONNECTIONS FROM BUS BAR TO TANK.

Last year the bus bar was divided as shown in Fig. 5 and three choking coils of three coils each were put between the bars and these connected to three carbon rods by plug switches and the rods dipped into a tank of running water. As soon as there is a storm in sight or one reported the plugs are inserted, making a direct ground connection through the water resistance. This has been a protection so far, but there is a loss of from 10 to 15 amperes while connections are made. To further protect the machine armatures the series fields have all been changed to the positive side to act as choking coils. In case a discharge did reach the machine the fields would be lost, but these are easier to replace than the armature coils.

The Wirts non-arcing arresters with no kicking coils are in use in the cars of the Urbana & Champaign Railway and on the lines at intervals of a mile or less. The line arresters are grounded to the rails and also to damp earth. Twice a year they are inspected, cleaned, repaired and tested. No armatures have been lost in four years, and this is thought to be due to the fact that the later types of railway motors and multipolar generators offer a greater resistance to lightning than the old types.

On the lines of the Akron, Bedford & Cleveland, Garton arresters are placed every half mile, Wirts are used on the cars, and tank arresters are in the stations. The tank arresters are grounded to the rails and to the water pipes. On the cars, the arresters are connected to the trucks and to the motor ground wire. They are inspected after each storm and are repaired and cleaned whenever burned out or taken out for renewals. Choke coils are provided in all the cars and good connections are made from the line arresters to the rails, and there is little damage due to lightning.

The Akron & Cuyahoga Falls Rapid Transit Company has arresters on the cars only, and these are the General Electric make with choke coils. As there have been few storms in that vicinity, few armatures have been lost.

At Aurora, Ill., the Garton and General Electric arresters are in service on the lines and cars, being one mile apart on the line; on the cars choke coils are also used. After each storm the arresters are inspected, but are not cleaned or repaired at any specified times. Occasionally an armature is lost, but not often. There is more danger on the suburban lines, as they are longer and catch more storms.

The arresters on the cars of the Detroit Electric Railway consist of carbon combs made from old brushes, and in the same circuit is a fuse which breaks the circuit after a discharge. The fuse is easily replaced. On the lines, according to the apparent needs, are placed the Garton, Wirts, and Ajax arresters, with choke coils. These are connected through the earth to the rail by a bare copper wire. After each severe storm the arresters are inspected, cleaned and repaired. No armatures have been lost on this road on account of lightning.

At Grand Rapids none of the lightning arresters tried were satisfactory, so the electrician designed the one shown

FIG. 6.—HOME MADE LIGHTNING ARRESTER.

in sketch Fig. 6. There are about 100 of these in service, and during one storm they worked successfully 150 times. Whenever the fuse is blown it is replaced and the arrester is cleaned and inspected. The only difficulty is that if a second stroke quickly follows the first the armature is not protected; otherwise none of the car apparatus has been damaged by lightning.

It seems from the experience of railway electricians that if care is taken in installing and keeping in repair the lightning arresters there should be comparative safety. On city lines two arresters should be placed to the mile and in the suburban districts four to the mile, and these should have good electrical connection to the track. On the cars great care must be taken in making as good connections to the truck as the motor ground. The arresters should be inspected the same as the motors and trucks and always kept clean and in good repair.

**TO SECURE DATA ON MUNICIPAL OWNERSHIP.**

The United States Commissioner of Labor has undertaken the collection of statistics regarding the gas, electric light and water works of the country, both private and municipal, with the object of securing such data as will serve as a reliable basis for estimates as to the cost of such service. This work should receive the hearty co-operation of all parties interested whether favoring or opposing municipal ownership, which so many believe to be the panacea. Allen R. Foote, well known as one of the authors of "The Law of Incorporated Companies Operating under Municipal Franchises," in an able paper before the League of American Municipalities, in September last, lays down as the proper basis for comparisons of the relative advantages of private and municipal ownership, the "cost of service to the users and taxpayers." This is, indeed, a most proper and equitable basis, but one which the most radical of our socialistic friends who do not believe in profit-taking will probably not accept, in the event of the verdict going against them.

If the cost to the public is to be the basis of comparison we believe that the private corporations have nothing to fear when the truth is told, but let it be the whole truth. The argument is commonly made that public management is necessarily more expensive than private management, and the proposition is as vehemently denied as affirmed. We believe in the affirmative; first, because in the present advanced state of civilization in this country, public management means partisan political management; second, because a strong executive head is necessary to the economical conduct of a business, and our multi-headed boards with divided responsibility do not furnish this.

Below are presented some data concerning the lighting of the city of Chicago. The report of the Comptroller for 1895 gives the capital invested in the plants and apparatus of the electric light department as \$766,446.97 and the report of the Department of Public Works for 1896 gives the amount expended for construction in the electric light department for 1896 as \$31,676.32 making the total capital invested \$798,123.29. During the year 1896 the average number of lamps maintained and operated was 1,140 and the cost of such operation and maintenance was \$96.40 per

lamp. There is no mention made of any fixed charges, so we must add:

Interest, at 5 per cent on capital invested (\$700.11 per lamp)... \$35.00  
 Depreciation, 10 per cent on machinery, 5 per cent on poles, cables and conduits, (depreciation of buildings is supposed to be compensated for by appreciation of lots)..... 40.60

making the total cost per lamp \$172.00. These lamps burn all night, from dusk to daylight, every night in the year. The city rents 517 2,000-c. p. lamps from private companies and these are required to burn the same number of hours as the city lamps. The total cost for the year was \$56,996.41; cost per lamp, \$110.24. From this it appears that the city could rent all its lamps and thereby save \$70,406.40 per annum, and we will add, get better light for many of the city lamps do not furnish even half the candle power called for.

The following is an extract from the report of a committee appointed by the city council of Lafayette, Ind., to investigate the subject of electric lighting for that city:

The committee \* \* \* finds that the cost of establishing a first-class plant, capable and suitable for the requirements and needs of the city of Lafayette and the people thereof, will cost approximately \$100,000; that the cost of maintenance, not estimating the additional costs for commercial purposes, making the estimate on the basis of 300 street lights, will be approximately \$63.57 per street light. This estimate does not include any interest on the money invested.

The city subsequently made a contract with private companies for lights at the rate \$76.80 and \$67.20 per year.

In this connection might be mentioned the recent decision of the city council of Philadelphia to lease the gas works in that city, for the last 50 years operated by the municipality, to a private corporation; the surprising thing is not that the venture was a costly failure as managed by the city, but that the council could be prevailed upon to acknowledge it and take steps to remedy it.

**PROGRESS IN SOUTH NORWALK, CONN.**

It is difficult to predict just what a city council will do; as a rule we know that it will be foolish, but the degree of idiocy we cannot know in advance. In South Norwalk, Conn., the Norwalk Tramway Company has always sprinkled the principal streets through which its lines run. The council thought that the company should be required to

sprinkle all the streets where tracks were laid, and passed an ordinance to that effect, providing that in the event the streets were not so sprinkled the speed of cars should not exceed one mile per hour, in order that there might be no dust raised. The company is chartered by the legislature, and of course paid no attention to the ordinance which would in effect be a repeal of the charter. As the press and the public also only laughed at the council's action, the absurdity of it was soon realized and within a week it was repealed. The illustration is from the Bridgeport Herald.

## SURFACE CONTACT STREET RAILWAY SYSTEM.

The demand for a commercially practical system of surface contact electric traction, has existed since electric traction was first introduced, but such a system had to come to its appointed place after the overhead and underground contact systems. Various schemes have been evolved in the past which have either been discarded as impracticable or have appeared before the demand for them has become acute enough to encourage their development. Today the demand for a surface contact system exists and peculiarly enough, this demand comes from Europe. In a European city, the first practical surface contact electric railway is already far advanced towards completion.

The experiments at Schenectady have been carried out upon a stretch of the track which forms part of the extensive factory tramway system of the General Electric Company's works. The addition to the roadbed between the rails of the track, consists simply in two parallel rows of iron

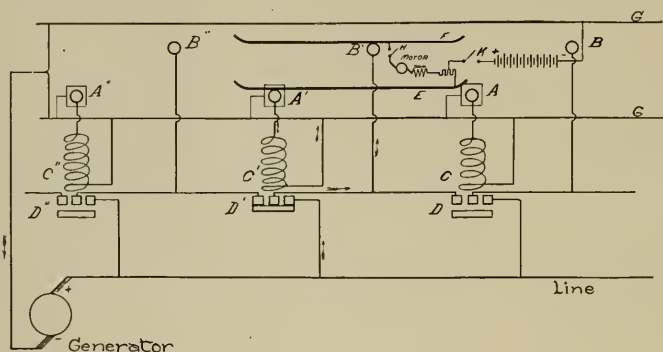

FIG. 1.

disks, elevated to a height of about one inch above the level of the rail. The General Electric Company is now engaged in changing over to the surface contact system the entire trolley tramway system in the yards.

The main requirements in a surface contact system are four: Low cost of installation and maintenance; absolute absence of current from all disks not covered by the car; freedom from leakage of current, and reliability under all possible conditions of weather, service and location. It is the attempt to meet simultaneously all those requirements that has rendered the problem one of considerable difficulty, demanding long study and costly experiments to overcome.

The only live portions of the General Electric surface contact system on the street surface are the contact plates immediately beneath the car. This is true whatever the position of the car and whatever the speed—each plate in turn communicating current to the motors and becoming inert as the contact shoe on the car leaves its surface; these contact plates are placed in parallel rows between the two rails of the track and staggered. Each positive contact plate is made alive by the operation of an automatic magnetic switch, which, instead of being placed in immediate juxtaposition with its plate or opposite it outside the track, is placed in a manhole with a large number of others each connected to its own respective plate. Through each negative plate is performed the double duty of closing the contact in the switch,

which "cuts in" the positive plate and of receiving the return current from the motors. Fig. 1 shows the arrangement of the plates on the street surface.

The operation of this system will be understood from the diagram Fig. 2; A, A', A'' are the negative plates B, B', and B'', the positive contact plates, placed equal distances apart, a little less than one-half the total length of the shoe; C, C', C'' represent the automatic magnetic switches and D, D', D'' their armatures or contact makers. F is the positive or collective shoe, E the negative or return shoe and C the track return; H and K are switches which form part of the controller, the latter connecting in, or cutting out, the cells of a small storage battery, which is used only to energize the coil of the first switch through the plate over which the car passes in starting. After the armature of the first switch has been raised into contact and the line current has completed its circuit, the battery is cut out by the forward movement of the controller handle. In the diagram the bar is to move to the right and all the magnetic switches are open.

The handle of the controller is turned to the first notch and switches H and K closed. Current from the battery flows through a small portion of the motor resistance to the shoe, thence to contact plate A and the coil C', completing the circuit to the ground. The coil C' thus energized raises the armature D', closes the circuit through the automatic switch and the line circuit completes its path through the motors and through the greater part of the motor starting resistance, shown by the arrows through the positive plate B and shoe F. Part of the return circuit goes to the storage cells, which are kept continually charged, and part through shoe F, negative contact plate A', and coil C' to ground, keeping the latter energized and the automatic switch closed so long as

the shoe E remains on contact plate A'. Moving the controller handle forward from the first notch to the second notch opens the switch K, cuts out the battery and sends all the return current through the coil C'. The shoes E and F in the diagram are a little longer than the distance between contact plates. Thus, when the car moves forward slightly, the shoe F will be in contact with the two contact plates A and A' and the return circuit will divide, half going through coil C' and half through coil C, energizing both, and closing the armatures in the switches D' and D. The car moves forward and the shoe E passes beyond the contact plate A'. The circuit in the coil C' is broken, the armature D' drops, cutting out entirely positive plate B', leaving it dead, but allowing B' still to receive current through the closed switch at D. Shoe F moving forward then makes contact with plate B before it leaves plate B' and the current is uninterrupted in its flow.

The automatic magnetic switch is the heart of this system. It has been designed to endure under the severest strains and to act with such uninterrupted precision that the working of the system may not be impaired. The development of this automatic magnetic switch marks a decided step forward. Mechanically the switch is simple, strong and durable, with all chances of derangement reduced to a minimum. In the course of the experiments this switch has been subjected to the roughest possible usage and has withstood it unharmed.

If the leakage is great an arc is likely to form when the armature of the switch drops, and so long as this is held the contact plate in the street will remain alive, while the arc would burn the switch. It is not practicable to allow the armature to drop far enough to break the arc, and, to extinguish it, the magnetic blow out principle is brought into play. By the use of this, retention of this arc is impossible. But there is also the possibility of another arc forming in case of accidental ground on one of the leads to the positive contact plate or if the forward switch fails to close when the handle of the controller is on the first notch, giving a path to ground through the battery. This is also taken care of by the magnetic blow out. All surface contact systems have similar conditions to meet, but none have incorporated the magnetic blow out principle.

The form of the contact plates is shown in Fig. 1. They are first set in iron boxes and then surrounded by insulation. The contact plates consist of two parts, a wearing piece screwed into a support and held by a spring washer. This wearing piece can be removed readily without disturbing the support. The standard shoe is about 13 ft. long, the ends

FIG. 2.

being curved upward slightly to prevent catching. The shoes are supported from the axles and have a slight upward and downward movement to allow for any irregularities in the height of the contact plates. The amount of drop in the shoe is regulated by a set screw.

The automatic magnetic switches are grouped in manholes where inspection can be readily effected. Each manhole will contain about 20 switches, and the wires from the contact plates to them will be protected in similar manner to underground wires for any other purpose.

The battery on a car consists of 10 cells with normal capacity of 50 ampere-hours at 5 amperes. It is equal to all emergencies, being called into requisition only momentarily, while being in charge the balance of the time the controller handle is on the first notch.

A close examination of the design and operation of this system will show that it possesses many striking advantages. The operation of the automatic switches is perfect under all conditions as the full line voltage can be secured to close them and they open by gravity. There is no possible chance of the contact remaining electrified after the car has passed, as by the use of the blow out on the switch and the

switch itself, which opens as soon as the current is shut off, all danger and trouble due to live contacts is eliminated.

Grouping the switches in manholes renders the working part of the system easily accessible for inspection.

In the city of Monte Carlo, in the principality of Monaco, this system is being laid down by the Thomson-Houston Company over a distance of about 3 miles. It is expected that this will be in operation very shortly.

## SUBSTANTIAL RECOGNITION OF LONG SERVICE.

W. F. Kelly, general superintendent of the Columbus Street Railway has announced a schedule of substantial recognition of long time employes, and took advantage of Thanksgiving day to post the bulletin which came as a pleasant surprise to the men. The notice reads as follows:

"At this season of the year when others are rejoicing in the pleasures of the home festival, we wish to express our pleasure and appreciation of your labors during the year now drawing to a close. During many weeks of heavy travel and crowded streets you have operated your cars skillfully with the result that serious accidents have been few and personal complaints rare. While all engaged in this service are entitled to their full share of credit and we fully appreciate their skill and ability, we desire especially to remember in a substantial way those who may fairly be termed "veterans" in the service. To this end we will each year present to motormen and conductors, inspectors and foremen who have been five years in the service of this company, one complete uniform suit and to those who have been in such service ten or more years two uniform suits, all of which will be made to order.

"As a badge of merit, indicating faithful and satisfactory services, the coat sleeve of each five year man will be decorated with one gold stripe, each ten year man with two stripes and so on, adding a stripe for each five years' employment.

"It is earnestly hoped that this testimonial of our good will may be received in the same spirit in which it is given, and that all may take a just pride in maintaining a high stand-

ard of efficiency and the good name and good character of all our employes.

"Following is a list, as shown by our books, of those who have been five or more years in the employment of this company. If there are any errors or omissions we will be glad to make corrections. Those whose names appear in the list please call at my office and receive order for suit.

"Wishing you all a joyful Thanksgiving, I am, very truly yours,  
"W. F. KELLY,  
"General Superintendent."

Columbus, Ohio, November 25, 1897.

In the 10-year list are 18 men, and in the 5-year service are 64 men.

The Staten Island Electric and the Staten Island Midland railroad companies waged a legal contest during the past year for the possession of South street in the village of St. George. After the vacating of the injunction which had been secured the Staten Island Electric put several hundred men to work and built 500 ft. of track in a day. Another injunction was obtained and the village trustees had the tracks torn up. The men who tore up the rails were arrested but released on bail. The situation is now just as it was originally.

## THE MEN WHO MANAGE THE METROPOLITAN OF WASHINGTON.

At the annual election of officers of the Metropolitan Railroad Company of Washington, D. C., held July 14, 1897, Robert D. Weaver was elected president. Mr. Weaver has long been identified with the Metropolitan Railroad Company as a director and vice-president, and this long association with the affairs of the company has amply qualified him for the position to which he was elected. The election of Mr. Weaver was most gratifying to a large majority of the stockholders, representing as he does the largest interest in the road, the stockholders felt that in looking after his own theirs would be well cared for. Mr. Weaver was educated in the schools of Washington, leaving them, however, at an early age to engage in business with his father. By his energy and business acumen he soon accumulated a fortune, and to-

ROBERT C. WEAVER.

day at the age of 40 years, is reckoned one of the solid men of his native city. No enterprise of large magnitude is complete without his presence, and his personality is shown in them all. He is progressive, energetic and at the same time prudent, and under his management the Metropolitan Railroad Company will be kept abreast of the times.

Griffin B. Coleman is secretary and general manager and his name is almost synonymous with that of the Metropolitan Railroad Company, he having entered its service as a bookkeeper when quite a boy. By his integrity, ability and industry he has advanced step by step to his present position. Upon the retirement of Samuel L. Phillips from the presidency of the company in October, 1896, Mr. Coleman, who was then secretary, was elected general manager in order that his scope of usefulness might be enlarged. At the annual election of the officers held July 14, 1897, Mr. Coleman was elected for a second term as secretary and general manager, his administration of affairs having been so eminently successful. To his energy and ability is largely due the success of the company, which stands today preeminently one of the best equipped street railroads in the United States, if not in the world. While the road is managed with due regard to economy, still no expense is spared to keep the equipment in the best possible condition, and by his liberal management and uniformly courteous personality, Mr. Coleman has won many friends for the company and its advanced street railroad methods. The stockholders of the company are highly pleased over the success which has attended his control, and at the last meeting elected him a director.

G. B. COLEMAN.

## DENVER OBSERVATION CAR.

The Denver Consolidated Tramway Company has given the very appropriate name "Seeing Denver" to its observation car. During the past summer the car has been leased by the Mayham Investment Company and two trips were arranged daily. Framed notices were put up in the hotels and drug stores advertising the car. At 9 a. m. and at 2 p. m. each day the car started at the Brown Palace Hotel and made a circuit past the other principal hotels for passengers. A trip, of about 40 miles requiring 2½ hours, was then taken on the lines of the different railway com-

DENVER OBSERVATION CAR.

panies in the city. A neat souvenir, illustrating the interesting features of the city and state, was given to each passenger. A guide, who was thoroughly posted, accompanied the party to explain the various sights and buildings about the city, as well as to give general information regarding the resources of Denver and Colorado. The fare for each trip was 25 cents. The car comfortably seats 80 passengers. The scheme was liberally patronized, and the Mayham company made money out of the venture as well as advertising its investments.

## TROLLEY FIGHT IN NEW JERSEY.

The Brunswick Traction Company, fearing injunction proceedings, worked during the early morning hours on November 1 and succeeded in laying a track across the Albany street bridge in New Brunswick, N. J. There is a sharp fight between this company and the New York & Philadelphia Company, the former having secured an injunction restraining the latter from operating a line recently constructed by it in Bridgewater township, Somerset county.

## VANDALS AT ITHACA.

The Ithaca (N. Y.) Street Railway Company has offered \$100 reward for information which will lead to the arrest of miscreants, who on two occasions recently, have endangered its property and the lives of passengers. The chief engineer of the company noticed some emery on the engines while examining the machinery before starting up, and investigation revealed that the oil cups were filled with emery. A short time afterwards a motor car in turning the curve at the Cascadilla shot down the incline at dangerous speed in spite of the brakes. It was found that the rails at this point had been greased. A detective has been placed on the case and if the guilty parties are found they will be vigorously prosecuted.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Rights of Transfer Passenger — Insufficient Accommodations.*

John Hanna was a passenger on one of the lines of the Nassau Electric Railroad Company on Bergen street, in Brooklyn, N. Y. When the car reached the intersection of Fifth avenue he got a transfer slip entitling him to continue his journey on the line upon that avenue. When a car came along he boarded it by the front platform. He surrendered his transfer ticket, after which he was directed by officials of the road who were riding on the front platform, to enter the car. Finding this to be impossible, he refused to leave the platform, and was then ejected from the car by force. The Second Appellate Division, in affirming judgment secured by Hanna in his suit against the company for assault, held that the court properly charged the jury that if the plaintiff's ticket had been taken from him by the conductor, and there was not sufficient room in the body of the car to permit him to enter, his ejection was illegal; but that, if there was room in the car, he was bound to enter it, his removal from the car was lawful, and the defendant was entitled to a verdict, unless excessive force was employed. A railroad corporation which has accepted a passenger's transfer ticket can not, the court said, remove him from its car until it has either returned, or tendered a return, of the ticket to him. A transfer passenger has not necessarily, it was held, the right to board the first car that approaches him on the line, regardless of whether there is accommodation for him, and to force himself into a dangerous or improper position upon the car; his duty is to wait until a car approaches in proper condition to receive him, and should no such car appear, he can maintain an action against the corporation for its breach of contract to carry him.

(Supreme Court of New York, *Hanna v. Nassau Electric Railroad Company*, 45 New York, supplement 437.)

*Nonuser of Street Railway Franchise.*

The nonuser of a street railway franchise for more than four years in a period of great industrial depression and extraordinary financial difficulties on the part of its owners, during which the street is paved with wooden blocks at the expense of the adjoining property owners, and the old rails and ties taken up with the knowledge and consent of the company when they were substantially worthless, but electric poles and wires, except a trolley wire, remain in place, does not constitute such an abandonment or nonuser as to raise a presumption of the surrender of the franchise, and entitle property owners to enjoin the relaying of the track, when the company has given assurance of its intention to resume operation of the road and no proceedings have been taken to declare a forfeiture.

By the acceptance of the terms of the ordinance, the railroad company assumed a public trust. It undertook to serve the public by affording it rapid transit; and it became its duty to continue that service, not simply because it had contracted so to do, but because it had become charged with such duty by legislative grant. It could not lay down the burden when it chose, nor emancipate itself by merely ceasing to operate its cars. In case of an attempt on its part to so shirk its duty as to a part of its road, it could doubtless be compelled, in proper proceedings, to resume its operation, and carry out the public duty which it voluntarily assumed. *Atty. Gen. v. West Wisconsin R. Co.*, 30 Wis. 100-107.

Certainly in such case, action could be brought under section 3,241, Rev. Stat., by the state, to forfeit its franchises and vacate its charter, for failure to exercise its public powers and perform its duties.

Coming now to the question whether the franchise has been extinguished in the case before us, it is quite apparent that there are only four ways in which it can be claimed that such extinguishment could take place, viz.: (1) by operation of some self-executing forfeiture clause in the grant; (2) by surrender of the franchise, and acceptance of such surrender on the part of the state; (3) by the decree of a court of competent jurisdiction, in an action brought for the purpose; (4) by abandonment or nonuser for so long a period that a surrender and acceptance will be presumed. There are no facts in the case upon which it can be claimed that the franchise has been extinguished in either of the first three ways above mentioned. There was no self-acting forfeiture clause in the ordinance which granted the franchise. There has been no surrender thereof and acceptance of such surrender by the state, and no action has been brought to declare and enforce the forfeiture. There remains, then, for consideration, only the question whether it has been wiped out by a nonuser for more than four years. It is argued that from this fact an abandonment of the franchise has resulted. It is evident that the term "abandonment," as applied to a corporate franchise, 36 L. R. A., of this kind, is a misnomer. A mere privilege of right may, perhaps, be properly said to be abandoned in a proper case, although even in that case there must be something more than mere nonuser to constitute such abandonment. There must be also an act clearly indicating an intention to abandon. *Washb. Easem.*, 3d ed., p. 661. But while a mere easement or right may be abandoned, the word is plainly inapplicable to a duty owing to the state. A public duty is not to be laid down at will. In the case of a mere easement there is but one party interested, and he may voluntarily abandon his right; but in a case of a public duty there are two parties beneficially interested, i. e., the party who owes the duty, and the state to which the duty is owing. The necessary results must be that, in order to extinguish the duty, there must be concurrence on the part of the state. It has been held that a total nonuser of the franchises of a corporation may exist for so long a period and under such circumstances that a surrender of its franchises by the corporation, and acceptance of such surrender on the part of the state, will be presumed. The cases holding this doctrine are cited in *Combes v. Keyes*, 89 Wis. 297, 27 L. R. A. 369; and *Mylrea v. Superior & St. C. R. Co.* (Wis.) 67 N. W. 1138. The doctrine cannot be said to have been adopted by this court, however. In *Combes v. Keyes*, which approaches nearest to it, there had been complete nonuser for 26 years, and legislative acts impliedly accepting the surrender, and it was held that the corporation had passed out of existence. Similar is the case of *Henderson v. Central Pass. R. Co.*, 21 Fed. Rep. 358, where nonuser of a street-car franchise for 10 years, followed by a repeal of the franchise, and a legislative grant of the same right to another company, was held to extinguish the first franchise. The present case, however, is not such a case. The period of nonuse here was

about four years and eight months. It was a period of great industrial depression, and of extraordinary financial difficulties on the part of the various corporations which successively owned the franchise. The old track became, by reason of the change in means of locomotion, practically worthless, and its entire reconstruction a necessity. It appears by affidavits of officials of the roads that it was always the intention to resume operation of these two blocks as soon as the financial atmosphere cleared. An ordinance declaring this franchise, with others, forfeited, was introduced in the common council; but, upon representation by the company that it was the intention of the new company to operate the road over these blocks in the near future, the clause forfeiting the franchise on the two blocks in question was stricken out. The only fact which can be claimed to indicate an intention to abandon the franchise, is the fact that in 1892 the street was paved with wooden blocks, at the expense of the adjoining property owners, and that the old rails and ties were taken up, with the knowledge and consent of the company. This fact, however, loses much of its apparent significance, in view of the changes in roadbed made necessary by the introduction of electricity, and in view, also, of the other facts just referred to.

This, then, is the situation: There has been no cesser to use, accompanied by any act clearly indicating an intention to abandon the right. Even if it could be said that there was any such act, there has been no consent on the part of the public to such abandonment, nor acceptance of a surrender. The nonuse has not existed for such a length of time, nor under such circumstances, that a surrender and acceptance of the franchise can be presumed. It follows that, when the plaintiffs commenced their action, the franchise was still in existence, and consequently the injunctive order was erroneous.

(Supreme Court of Wisconsin, *Wright v. Milwaukee Electric Railway & Light Co.*, 36 Lawyer's Reports, Annotated, 47.)

[NOTE: Relaying of street railway tracks after nonuser of the street for nearly five years where the franchise was properly granted by the city, and has not been surrendered, or any action taken to forfeit it, and cannot be prevented by the city, in an action in equity where the state has not granted to the city any power to forfeit the franchise but as provided for an action by the attorney general to assert such forfeiture. *Milwaukee Electric Railway & Light Co. vs. City of Milwaukee*, 36 Lawyer's Reports Annotated, 45. The power of a city to make a condition of its assent to a street railway that it shall be forfeited unless the road is completed within a specified time to a certain point outside of the city, is denied in *Galveston & Western Railway Company*, 38 Lawyer's Reports, Annotated, 33, where the legislature has given the right to use the streets if the city consents.—E.D.]

#### *Injury to Lineman by Falling of Electric Pole—Notice of Latent Defect.*

The lineman of the defendant company, in the discharge of his duty, was ordered to take down a guy wire from an electric pole and guy tree. The pole had not been securely planted. It fell on the lineman, inflicting injuries of which he died. The vice of construction was latent and concealed. The officers of a preceding board of management had been notified of the defect. The company is not relieved under the plea of want of notice, although the present general manager has not been notified, but the preceding manager or superintendent.

(Supreme Court of Louisiana, *Bland v. Shreveport Belt Railway Company*, 36 Lawyer's Reports Annotated, 114.)

## A TROLLEY WAGON.

A trolley road wagon for running on country roads has been built and tested by W. G. Caffrey of Reno, Nevada, and satisfactory results obtained. Two No. 0 trolley wires are held by insulators 18 in. apart on poles which are placed at intervals of 125 ft. The two wires are about 17 ft. from the ground. The trolley consists of a metallic frame having two overrunning wheels and underneath two locking wheels which prevent the top wheels from leaving the wire, and for the lower wire a similar device is used. The two trol-

A TROLLEY WAGON IN NEVADA.

leys are connected by an insulated pantagraph with guides to provide for unequal tensions on the two wires. The trolley cables to the wagon run on an automatic reel in the wagon, and this arrangement permits the wagon to run 200 ft. from the pole line. The rear wheels are attached to a shaft geared to a 2-h. p. Westinghouse motor, suspended on springs. Rheostat control is used and the wagon has a suitable steering device. It is stated that with a load of 2,500 lbs. the wagon reached a speed of 15 miles an hour. This trolley wagon was designed for localities with good roads, heavy traffic in farming produce and where cheap power can be obtained. This data and illustration were furnished by the *Scientific American*.

## THANKSGIVING AT A SOUTHERN PLEASURE RESORT.

J. B. McClary, general manager of the Birmingham, Ala., lines, sends us a copy of the program he laid out for Thanksgiving day, at the company's pleasure resort. Other roads may find in it a suggestion for next year. The principal features were two foot ball games, with such other amusements as 100-yd. foot race, bicycle races, half-mile foot race, old men's race, throwing hammer, quoit contest, three-legged race, hurdle race, and several foot races for boys under 16 years. The event was a great success and called out a big crowd. The prizes other than the cash prizes were donated by local merchants.

## FUNERAL CARS IN SAN FRANCISCO.

The principal cemeteries of San Francisco are located in San Mateo county, about 12 miles distant from the ferries. Although many interments are still made within the city limits, persistent agitation against further burials and for the removal of the cemeteries which are now being gradually surrounded by the city, has caused the development of several beautiful cemeteries, sufficiently removed from the metropolis to ensure the eternal rest of those laid there.

The main line of the San Francisco & San Mateo Electric Railway Company passes the gateways of five cemeteries, and into one of which Cypress Lawn, and probably the most beautiful west of the Mississippi river, the company owns a spur track, the rails of which barely show through

faction on the part of the public and all the high class undertakers who have used the car has amply demonstrated the fact that it is strictly in line with modern ideas and progress. The charge for this service is \$15 while the cost of an equal service by hearse and carriages is \$70 a fact keenly appreciated by many who find other burdensome charges at a time when they are frequently least prepared to meet them.

The average time required in making the round trip is about  $2\frac{1}{2}$  hours which includes the lay-over at the cemeteries, whereas fully double that length of time is required by carriage. The car is called for principally through the agency of undertakers who maintain regular monthly accounts with the company and at whose service the car is held whenever desired.

Upwards of 250 funerals have been conducted with this car the greater portion being within the past year.

FUNERAL CAR AT SAN FRANCISCO.

the velvety green lawn. The funeral car "Cypress Lawn" owned by the company, has now been in use about three years. It is a substantially built double truck car of the passenger coach type, the interior being finished throughout in black walnut and is carpeted and upholstered in harmonious colors. One end of the car, completely separated from the remainder, is set apart for the reception of the casket and family of the deceased while the other portion is fitted out similar to the regulation Pullman cars.

For many reasons when the car was first introduced it was cautiously received by the public and there was but little call for it; but notwithstanding this fact, the present era has witnessed the destruction of many old time ideas and customs, and in San Francisco at least, the electric funeral car has become a well established institution which appeals alike to the reason and common sense of the public. True, the funeral car is still regarded with an evil eye by hackmen and certain classes of undertakers as an invasion of their time honored rights which, of itself is a good reason for its existence. The invariable expression of satis-

The construction of an additional car will be necessary in the near future as the company is unable at times to meet all the demands with a single car.

The experience in San Francisco is directly in line with what has been advocated by the REVIEW for many years; and in cities where the location of the cemeteries is at all distant and adjacent to company's lines we firmly believe the funeral car services' will be found both acceptable to the public and remunerative to the company.

## FLOODED CONDUIT AT WASHINGTON.

As a result of a recent rain storm the electric conduit of the Metropolitan Traction Company was completely flooded for 150 feet along F street in Washington. The cars were operated on this line during the two hours the conduit was flooded, the load increasing from the normal, 300 amperes, to 600 amperes. This has occurred a number of times and is conclusive evidence that the General Electric open conduit is not short circuited by rain water.

### A SUCCESSFUL FREIGHT LINE.

The management of the Lewiston & Youngstown Frontier Railroad Company has found the freight business an important factor as an income earner on that road. This road is familiarly styled "The Old Fort Route." It runs between the villages of Lewiston & Youngstown in Niagara county, N. Y.

Before the road was built Youngstown and Fort Niagara

LOADING FREIGHT.

had no rail connections of any kind. In the summer time the river boats carried freight between Lewiston and Youngstown, and during the winter a time-worn stage was the only regular means of communication. Therefore it was necessary to team much of the freight and express from Lewiston, where it was brought by the New York Central. When the electric road was built connection was made with the Central tracks at Lewiston, and now freight cars are regularly transferred from the Central tracks to those of the electric road. During the past summer and fall this service has been greatly appreciated by the farming community along the electric road. Especially was this true in peach and apple time, when refrigerator cars were taken down the trolley line to the four specified points of loading. During peach time the scene at these points was instructive in the extreme, showing quite well how a trolley line aids a farming section. Long lines of wagons could

FREIGHT TRAIN ON THE "OLD FORT ROUTE."

be seen, each waiting its turn to get up to the cars to unload in order to hurry back to the orchards for more fruit. The close presence of the freight cars saved the long haul to Lewiston, and was quite an economical factor in handling the crop. In previous years the trip to Lewiston consumed time, took more men and teams, thus creating expense. Furthermore, the crop reached the markets quite a few

hours earlier, owing to the rapidity with which it was handled at the loading point.

In anticipation of a heavy freight traffic the Lewiston & Youngstown Company ordered a motor car especially designed for freight business, and it proved to be a very valuable part of the road's equipment. The extreme length of the car is 20 ft., the box being 14 ft. long. From the top of the rail to the top of the car the height is 10 ft. 8 ins. It rests on a single truck of very strong pattern, the wheel base being 7 ft. Heavy oak timber was used in its construction, its weight being 7 tons. A Gould automatic coupler and a radial draw bar are provided so that it can be coupled to freight cars or trolley car trailers, this latter feature being valuable during the picnic season. The car is equipped with two General Electric four turn motors, wound in such a way as to exert a high tractive effect for a given amount of power. While these motors are not rated at any specified horse power they are practically 50 h. p. each. On level grades the car will pull 10 loaded freight cars with ease. It is equipped with a snow plow and track scrapers in order that it may be used during the winter in keeping the road open.

One day as many as 19 cars of freight were turned over to the Central from this electric road, Lewiston, as stated, being the transfer point. The average during August and September was nine cars, and during October it was five cars a day. The rate the electric road charged for peaches was 1 cent per basket, and from 750 to 1,100 baskets were put in a car, the average weight being about 20 lbs. to a basket. The crew of the motor car consists of a motorman and a conductor, the latter being the all-around man. Superintendent W. A. Heller speaks very highly of the work and value of the motor car.

### CONTROLLER NOTCHES AND RESISTANCE DIVISION.

Increasing attention is being given by manufacturing companies to the proper adjustment and subdivision of resistance in connection with controllers. The tendency is to put more points on the controller and provide plenty of terminals on the resistance frame, so that the amount of resistance on each notch can be adjusted to the weight of the car. The mistakes of the past have been either that too much has been cut out at a step, or that the successive steps have not been even. On one class of motor car equipment put in use several years ago the resistance on the first controller points is made so as to start the car smoothly with the heaviest trailer load it is ever called on to pull. The result is that with a light load the car starts off with a jerk. It would have been a very simple matter to put in enough resistance on the first point to start the light load smoothly, and with a heavy load the motorman could pass over the first notch without stopping.

A. E. Lewis, a Montreal man interested in a street railway deal in St. Louis Du Mile End, has mysteriously disappeared and a reward of \$1,000 has been offered for information as to his whereabouts. It is suspected that he has been foully dealt with on account of the railway project as it was unpopular in some quarters.

# CROSSINGS OF STEAM RAILROADS AND STREET RAILWAYS.

PART II.

Many, if not all the states, have passed laws regulating the construction and operation of grade crossings with two objects in view, the protection of the senior franchise, and the protection of the public from injury. Also, most states have delegated more or less authority to regulate crossings to the municipal corporations within which the crossings are located, and the result is that in nearly every city and town there are ordinances limiting the speed at which crossings may be run, and ordinances providing for flagmen or gates at such crossings.

To protect the senior franchise it is usually provided that when one road is crossed by another the crossing shall be made in a manner that shall interfere as little as possible with the operation of the one first on the ground. The cost of installing the crossing was placed upon the junior road, but the cost of maintenance and of flagmen, etc., borne jointly. At the present time, however, the tendency is to throw the cost of maintenance entirely upon the road seeking to cross.

As a district becomes more thickly populated the danger of serious accidents at grade crossings becomes proportionately greater, and as the number of accidents increases, the measures adopted by the state for their prevention become more drastic. In several states in the east the policy of abolishing grade crossings wherever it is at all practicable to do so has been adopted, while some farther west have provided for the protection of crossings by interlocking or other safety devices.

The courts are continually rendering decisions in crossing cases which are of great interest, and without attempting to cover the subject fully, we shall endeavor to give a general idea of the laws at present obtaining and some recent decisions of the courts.

In Alabama street railways may cross steam tracks at grade, but they must do so in such a manner as not to interfere with the steam road and must make arrangements satisfactory to the latter. In the different cities there are special ordinances as to the watchmen, etc., at particular crossings.

Georgia has no law prohibiting grade crossings and they are therefore made at grade. The railroad which is crossed may, however, select such a crossing as will in its judgment be safe, and it is installed at the expense of the company desiring to cross. City ordinances vary as to the speed permitted at crossings; for the most part no flagmen are required.

Iowa follows the general rule that street railways do not constitute an additional burden on the abutting property, unless the motive power be steam. And a company having franchises from the city may extend its tracks beyond the city in highways 100 feet or more in width, and by permission of the supervisors, for two miles in 60-foot roads, in order to reach a state institution. In this state, cities are in general empowered to regulate the crossings of

railway tracks, to regulate the running of engines, cars and trucks within the city limits, and to make rules and restrictions for the purpose of preventing accidents at crossings. The street railways and the steam roads in this state usually manage to settle all the questions arising between them in an amicable manner and therein furnish an example that many of their brethren would do well to follow.

In Kansas cities of the first class are authorized to regulate the crossings of railroad and street railway tracks, and provide precautions and prescribe rules regulating the same, and to require railroad companies to erect viaducts at street crossings. The cost of constructing and maintaining crossings is borne by the junior road which in practice submits an agreement to construct the crossing and maintain it in such a manner as not to impair or abridge the full and free use of the tracks crossed.

In Michigan the question of permitting crossings, the apportionment of their cost, and in fact the whole matter is placed in the hands of the state railroad commissioner. City ordinances regulate the stopping of cars at crossings; where two street roads cross, the cars of the senior company have the right of way.

The city of Duluth, Minn., has an ordinance on the protection of grade crossings which is as follows:

Whenever so required by the resolution of the common council it shall be the duty of every railroad company, whose track crosses any street or road in the city limits, to keep and employ a flagman at such particular street or road crossing, as the common council may direct and such flagman shall give the necessary warning of the approach of all locomotives, trains or cars, to avoid danger to persons and property.

In this city all the grade crossings of the street railway system are bunched on one street, where there are 16 grade crossings within a distance of about 10 squares; 10 of these are in a group, all lying within a distance of two squares. At this point, in addition to the flagman required by the ordinance quoted to be provided by the steam railroad companies, the street railway voluntarily employs a flagman of its own.

The city is at present attempting to have a viaduct built over the bunch of crossings at the expense of the steam roads.

In Wisconsin there are no statutes regulating the crossings of railroads. In the case of the Milwaukee, Racine & Kenosha Electric Railway against the Chicago & Northwestern Railway, the supreme court in a decision rendered April 11, 1897, held that an electric railway is a commercial railway, and in consequence an electric road imposes a new burden upon abutting property and can not claim the right to cross at grade because the highway in which it is laid crosses a steam road at grade. The crossing which was in dispute in this case was effected by building a subway at a cost of \$25,000. By ordinance of the city of Milwaukee street cars must stop 20 ft. from the crossing and the con-

ductor must advance to ascertain whether the crossing be clear before the car is again started. We believe that this is a precaution observed by nearly all roads whether required to do so or not.

In Texas the municipalities have full control over the streets, and the grant to lay tracks on a street carries with it the right to make all necessary crossings. The regulations for safety of crossings vary in different cities as regards the use of flagmen, gates, etc. In most instances mutual agreement between the two classes of roads have proved to be satisfactory. The cost of maintenance of the crossings is equally divided between the two roads.

In Tennessee steam roads are required to flag all street crossings, and roads crossing must maintain the track at joint expense.

In Montana street railways may cross steam roads by making safe and satisfactory crossings.

Rhode Island has no law prohibiting grade crossings.

#### MISSOURI.

In this state all public and quasi public corporations may exercise the right of eminent domain, but in case the land so desired is held by any other corporation the junior one can not make such use of it as will materially interfere with the "uses to which by law the corporations holding the same are authorized to put said lands." By a law passed in 1895 all street railways operating by electricity are required to construct their wires not less than 20 ft. above the top of any railroad track that they may cross, and the wires must be so guarded that they shall be prevented from coming in contact with cars, track or telegraph line. At crossings street cars must come to a full stop not less than 10 ft. nor more than 20 ft. from the tracks of steam roads, and the conductor or other employe go forward to see that the track is clear.

In Kansas City the municipal authorities have passed special ordinances relating to special crossings but no general ordinance. In most cases where such action has been taken regarding the construction of tunnels or viaducts at street road crossings the cost has fallen upon the street railway. Such viaducts and tunnels are open to the public.

The Metropolitan road in that city has built three viaducts of 500, 1,000 and 3,000 ft. in length, and in addition five steel bridges over railroad tracks, these latter costing \$95,000.

#### PENNSYLVANIA.

In Pennsylvania railway companies may acquire exclusive rights in streets as against other companies, the first one entering upon the street having the exclusive right, and the right to cross tracks at grade is an important one. By a law passed in 1889 it is provided that any corporation incorporated under that act shall have the right in its construction to cross at grade, diagonally or transversely, any railroad operated by steam or otherwise, now or hereafter built. This has been held to mean, however, that the crossing must be so made as not to violate the rights of the senior companies. And also, this act must be construed in connection with an earlier one (1871) by which the courts of equity are empowered to impose such regulations as may be necessary to make the use of the crossing less dangerous to life and property.

In the Pennsylvania case decided in 1897 mentioned in the former article on this subject the supreme court says:

"The act of 1889 gives the right to cross at grade, but then we are met by the act of 1871 which says that the court shall, by its process, prevent it, if an overhead crossing be reasonably practicable. This leaves only for the court the physical problem to be solved by the influence warranted from the character of the two roads, the business done upon them, the topography of the territory, and like facts."

Street railways have not the power of eminent domain in Pennsylvania and our understanding is that the tendency of the courts is to require electric roads to comply with the terms of their charters in all respects. As the steam roads own their rights of way in fee they can throw considerable difficulties in the way of interurban lines by withholding consents.

The regulations in regard to the maintenance of watchmen at crossings are quite various and depend largely upon the temper of the city council in the particular place. The railways usually settle the matter amicably, having due regard to the special circumstances surrounding each case.

In the case of the Pennsylvania Railroad against the Greensburg, Jeannette & Pittsburgh Street Railway Company, the supreme court held that a railroad is not such an abutting property owner that it can contest the right of a street railway to use a bridge over the railroad tracks.

#### MAINE.

In Maine the street railways are subject to the supervision of the state board of railroad commissioners. The commissioners have power to determine, subject to the review of the supreme court, all disputes between companies regarding crossings and connections. The customary procedure is for the road desiring to cross to secure a decree from the commissioners. The law provides that the junior road shall bear the expense of the installation and maintenance; if a flagman is considered necessary the wages are usually assessed against the two roads in equal portions.

When grade crossings are prohibited the cost of viaducts is assessed according to the discretion of the commissioners on the street railway, the steam road and the city or town. When built such viaducts are used by the public.

#### MASSACHUSETTS.

In this state the only regulations governing crossings of steam railroads and street railways are by statute. The operation of cars over steam railroad tracks and the construction of tracks over the same are practically synonymous with respect to regulations. Prior to 1894 all the older companies could cross steam railroad tracks at grade by obtaining a location upon the street or highway from the local authorities. At that time, however, an act was passed which prohibited the construction of street railway tracks across the tracks of steam railroads without the consent of the board of railroad commissioners.

The board examines each case and gives or refuses consent, but looks with great disfavor on grade crossings and its policy is against granting permission when it can be avoided. In giving consent it usually apportions the expense of flagmen in about equal proportions, but where the use of flagmen is created because of the construction of street railway tracks the greater portion of the expense is usually put upon the street railway company. The law with respect to crossings is the same regardless of the location.

It is a question whether it is possible under the laws of Massachusetts for a street railway company to build even a

viaduct or tunnel over or under the tracks of a steam railroad without the consent of the railroad. The whole expense in such a case, however, is borne by the street railway company. There are instances where the railroad commissioners have seen where a viaduct would be beneficial, and the consent of the steam railroad has been obtained, but should a steam railroad refuse absolutely, it is not possible to cross without a special act of the legislature. There are instances where the railroad commissioners have refused consent and the street railways have obtained special legislation.

Where viaducts or tunnels are constructed it depends entirely upon the circumstances whether the public may make use of them. If the street railway should join with the local authorities for the purpose of discontinuing an old crossing and constructing a viaduct or tunnel the way thus created is open to all the public, otherwise it is private. There are no regulations for viaducts other than the general regulations which apply to the street or highway at each end of the tunnel or viaduct.

The railroad commissioners in their last annual report to the legislature recommended that the street railways be permitted to purchase or condemn land for the purpose of avoiding a grade crossing, subject to the approval of the local authorities. A bill looking to that end was introduced in the legislature, but was "hung up." Under the general street railway law of the state no street railway company can take land and operate cars thereon. The operation of cars must be upon a public way which is under the jurisdiction of the local authorities.

#### DELAWARE.

Delaware is a small state in which there are but three street railways, all in Wilmington, or directly connected with the Wilmington system. The Wilmington & New Castle Electric Railway Company is the only one not entirely owned or controlled by the Wilmington City Railway Company. The charter of the latter company permits it to cross at grade any steam or other road within six miles of the city of Wilmington. The rights of the company under the charter have been recognized, but notwithstanding this the Philadelphia, Wilmington & Baltimore Railroad sought to prevent the building of a crossing which was necessary to bring the cars of the Wilmington & New Castle road into the city under a traffic agreement with the Wilmington City. The case was decided in May last and the chancellor said in summing up:

"After carefully considering and weighing these affidavits, I am satisfied that it does not clearly appear from them that the crossing under the trolley system at this point would be more dangerous and a greater menace to the complainant's traffic than would the crossing by horse power, against which no injunction is asked, so that even should it be granted that these allegations are relevant and material to this application, yet as the evidence before me leaves the relative danger to a railroad crossing of the two systems an unsettled question, they cannot avail the complainant, since in the application for a preliminary injunction the complainant's case must be clearly made out.

"As has been seen already, the complainant does not claim any property rights as abutter or owner in fee which will be affected by the proposed crossing of its right of way by the respondent under the trolley system, and does not claim to be in danger of receiving any damages other than those already considered, it is therefore manifest that it has no standing in this court for its application for a preliminary injunction, and that for the purpose of this motion it is not open to the court to consider the question whether the respondent railway company has or has not power or authority, under its charter

or under the laws of the state of Delaware, to use electricity as a motive power for the propulsion of its cars in the said city of Wilmington."

There is no specific statute in regard to grade crossings, but the steam roads have the first right of way and can compel the street railways to conform to specifications as to how the crossings shall be made. The Philadelphia, Wilmington & Baltimore in one case compelled the Wilmington & New Castle to build a bridge 100 ft. long over a single track.

There are no regulations, state or municipal, as to flagmen, gates, etc.

Where viaducts are necessary the question as to which party shall bear the cost is an open one to be passed upon by the courts.

#### FREIGHT SERVICE IN DETROIT.

At the session of the Michigan Legislature last winter an act was passed authorizing any suburban or interurban street railway to carry light freight, but no freight cars can be run within the corporate limits of any city or village between 8 a. m. and 8 p. m., without the consent of the municipal authorities. The Detroit & Pontiac Railway Company has taken advantage of this amendment and has established a

CAR ON THE DETROIT AND PONTIAC.

freight service between the two cities. An old suburban car has been rebuilt as shown in the sketch. Each day the car leaves Pontiac at 6:10 a. m., stops at Royal Oak, Bloomfield and Birmingham for farm and dairy produce, and arrives in Detroit at 7:50. The return trip commences at 8 p. m., and requires an hour and 40 minutes. The load generally consists of purchases made in the city, trunks, grips, and dry goods, etc., which the wholesale merchants send to the country stores. This is a most convenient service for those living on the line of the road and is a source of considerable income to the railway company.

#### A ROAD THAT FAILED.

A correspondent in the west writes us of the stockholders of the road in his town as follows:

"They know all they wish to know about street railways. They have quit—liquidated and retired. The tracks are torn up; the cars moved into shady yards and converted into summer houses where stockholders may enjoy the only successful trips the cars have ever made. It is a run to oblivion over smooth tracks without a jolt or a jar from flat wheels or flat-headed councilmen; with no monthly deficit to be met, no franchise to hold, no mules to feed; and is a happy dream that ends the nightmare of unsuccessful operation."

## GEAR MAKING AND CUTTING.

It is estimated that there are about 100,000 street car motors in use, and to supply these motors with gears demands an output of 20,000 to 30,000 per annum. The cast iron gear and the gun-metal pinion have been replaced by gears of cast steel and pinions of raw hide or hammered steel. This change has reduced the weight 60 or 70 lbs.

FIG. 1.

and the life of the gears has been lengthened to an average of two years. The teeth of the old cast iron gears were frequently broken but this breakage is practically unknown with steel gears. At the River Works, Lynn, Mass., the General Electric Company makes all its pinions and gears. The foundry is equipped with every modern appliance for the manufacture of steel castings of the highest grade. In the gear cutting shop there are milling and key-seating machines and special drill presses, these being designed for

FIG. 2.

very accurate work. Fig. 1 shows the pinion forging, the pinion blank, milled, bored and seated, ready for the teeth to be cut, and the finished pinion. Fig. 2 represents a steel gear, bolted together and machined, with part of the teeth cut. Recent tests have shown that a worn gear and pinion require about 400 watts more power to operate than a new pair, and from these results the question between the extreme life and the proper economic life has come up for consideration.

## ELECTRICITY ON TRUNK LINES.

"The Engineering Side of the Application of Electricity to Standard Railroadings" was discussed at the October meeting of the New York Railroad Club. Among those present was Dr. Cary T. Hutchinson, who made the following remarks:

"Something has been said about electricity, but nothing regarding trunk line conditions. I am of the opinion that the latter is by far the more important side of the question, and if electricity is ever applied to trunk lines it will be due chiefly to changes made in the conditions of the trunk line service and very little to improvements in electrical machinery. Although the electric locomotives which are built today are as far superior to the one shown on the board as is New York Central 'No. 999' to the first 'Rocket,' yet I think that the application of electricity to trunk line service is no nearer than it was at the time this locomotive of Mr. Edison's was built. The electrical appliances have improved steadily, but the trunk line conditions have become worse, from an electrical point of view; that is to say, freight trains are heavier, express trains run faster and are more numerous, and the entire tendency has been away from conditions favorable to electricity.

"The chief condition for economical electrical service is that the train service shall be frequent; that is to say, that the machinery, including the copper feeders, be always kept loaded, doing work to its full capacity, nearly all the time, instead of two or three minutes out of the hour, as would be the case were an attempt made to run the present trunk line service with electricity.

"The only place in the country where there is anything approximating to the application of electricity to trunk line service is at Baltimore, and here the reasons leading to this application were not primarily those of economy. Incidentally the change has proved economical, but the cause for this application was the comfort and convenience of the passengers, rather than any saving in the operation. The locomotives here, as you may know, weigh about 200,000 lbs., and have given on test a drawbar pull of 65,000 lbs., probably as heavy duty as any steam locomotive has ever given.

"This question is not changed materially in my opinion by the use of alternating currents in any form; it is purely and simply a question of keeping the machinery at work all the time and of supplying sufficient track facilities.

"I wish to disabuse your minds of the impression that probably prevails that the work at the New York, New Haven & Hartford on its third rail system has advanced in any degree this application of electricity to trunk line conditions. The service given by the N. Y., N. H. & H. is nothing more than trolley service on a large scale, with heavier cars and higher speeds, and with the trolley wire put on the ground in the form of a third rail. Engineering difficulties have, of course, been met with and overcome, but there is no relation between this work and the topic under discussion. I think a great deal of harm has been done by the indiscriminate laudation of this third rail system, much of it coming from the N. Y., N. H. & H. officials. It has created an impression on the minds of the public generally that electricity is applicable to any kind of a steam line. In one case particularly that I know of this loose talk was the cause of a loss of nearly \$150,000. The people in question had gone to the expense of developing a water power plant for operating an electric road under conditions that were utterly unsuitable for electric service. I was sent out to examine it, and advised them to discard all their electrical machinery and use steam locomotives. The head of the enterprise told me that he had been led to the adoption of electricity by the fact that the N. Y., N. H. & H. road was using it."

To us it appears that the man deserving of adverse criticism in the last paragraph of the foregoing is he who spent the \$150,000 without using his head, and not the N. Y., N. H. & H. people, who so far as we know, devote themselves to managing their own business. When the chicken emulates the swimming powers of the duck and comes to grief, do not blame the duck.

The Western Electric Company is mailing to its customers a handsome 11x14 half-tone engraving of a lion, reproduced from nature,

## TWO CASES OF ELECTROLYSIS.

Periodically the bug-a-boo of electrolysis appears to the newspapers, the water companies and the city officials. A pipe pitted by the action of electricity is discovered, and then the newspapers begin to calculate how many million dollars damage has been done to the water and gas pipes all along the trolley lines. Electrolysis has been discussed and remedies suggested in these columns before. The only excuse for introducing the subject again is that in several places, notably Chicago, Cleveland and Salt Lake City, there is at present some agitation about the damage done by the current in seeking a return circuit to the station.

F. C. Kelsey, city engineer of Salt Lake City, to whom we are indebted for photographs, sent this report to the city council and Figs. 1 and 2 are from the photographs taken of the pipes described:

In September, 1895, a break occurred in the 6-in. water main on the north side of Second South street, near the end of the street car track, between Fifth and Sixth West streets. This pipe was laid in 1891. Upon examination it was found that the pipe where the break occurred was badly affected by electrolytic corrosion, the action being more marked along a longitudinal crack in the side of the pipe. This would appear to indicate that it had been cracked for sometime and that the greater part of the current flowed from the pipe along this crack where the water oozing from the pipe had moistened the ground.

On February 10, 1897, a second break occurred in this line about 80 ft. west of the first one; the pipe at this point was nearly destroyed, the shell in some places being less than 3-16 in. thick. Some portions of the pipe where corroded resembled graphite and the iron could be easily cut with a knife.

I have examined the pipe for some distance on each side of where the break occurred and also the length put in in 1895, to replace the one destroyed, and find it to be corroded. Measurements taken with a voltmeter show that the pipe in this locality is positive to the ground and consequently there is a flow of electric current from it, with the resulting electrolytic action. There is no doubt but what the

prevent it. The present condition of the street railways in this city as regards return conductors is as follows:

Salt Lake City Railway: I am informed by Superintendent Read: "That the rails within the paved district are well bonded and in addition a supplemental bare copper wire is laid between the rails and connected with the bonds every 200 ft. Outside the paved district the only return conductor provided beside the rails is an insulated overhead wire on Second East street, extending from the power house and having one connection each with the tracks where it crosses them on Second, Third and Fifth South streets. Outside the paved district the rails are bonded with No. 4 copper wire fastened to the flange of the rails with rivets."

Salt Lake Rapid Transit Railway: President J. S. Cameron states: "That the only return conductor beside the rails provided for the system is an overhead No. 0000 wire extending from the power house

FIG. 1.

to the intersection of State and Seventh South streets; at this point it connects with two No. 0 wires, one running north on State street to the intersection of First South street, the other following the Calder's Park line to the intersection of Ninth East and Tenth South streets. These conductors are connected with the rails at intervals of from 200 to 400 ft. Inside the paved district the rails are bonded with No. 0 bare copper wires fastened to the rails with 3/4-in. rivets. Outside of this district the rails are bonded with two strands of No. 12 or three strands of No. 16 bare copper wire riveted to the flange of the rail. When the lines were constructed connections were made at several points on each line between the rails and the fire hydrants and also a connection was made with the water pipe in front of the power house."

FIG. 2.—WATER MAINS IN SALT LAKE CITY.

corrosion in this case was caused by the return currents of the electric railways, accelerated by the soluble salts contained in the ground around the pipes.

The results in brief of the investigations and tests made by electrical engineers to determine the cause and remedy for electrolysis are:

That on all single trolley railways where the current leaves the rails for the ground it will flow to and along the underground pipes and wherever it leaves them corrosion is sure to result.

That ample metallic return conductors provided by thoroughly bonding the rails and connecting them every two or three hundred feet with overhead or underground conductors extending to the power house will reduce the action to a great extent but will not entirely

These statements show that the street railways in this city are not provided with ample return conductors. The rails outside of the paved district are not sufficiently well bonded and the return wires are a protection to the pipes only in the district which they cover.

Before making any recommendation as to a general plan for protecting the pipes I respectfully ask that I be authorized to purchase a low reading voltmeter and make a complete electrical survey of the pipe system to determine the location and extent of the pipes that are in danger. If, however, you decide not to authorize the survey, I would recommend that the pipe on each side of where the breaks occurred on Second South street, be uncovered as far as there is any indication of corrosion, carefully examined, and where badly corroded so that there is any danger of bursting, that the pipe be

removed. For the protection of this pipe in the future an overhead return conductor of sufficient size should be put in, extending from the power house to and along Second South street to the intersection of Eighth West street and connecting at this point with the rails of the Lake Breeze line. This conductor should be connected with the rails on Second South street every 200 ft. If, after this is done, the pipe at this point is still positive to the ground, an insulated conductor should be laid along the pipe that is in danger connecting with it every 100 ft., and extending to and connecting with the overhead return conductor.

In Chicago E. B. Ellicott, superintendent of city telegraph, made the following report to L. E. McGann, Commissioner of Public Works, after the readings as shown in Fig. 3 was taken:

I have had an examination made of the ground return of the street railway company operating an electric railroad line on South State street with the following results: At the corner of 51st and State streets a test was made between a 30-in. gas pipe and the rails of the street railway company. It showed that there was a current of 25 amperes flowing from the pipes to the rails at a point where this large main was intersected with a 6-in. gas pipe at 51st street. In the block between 50th and 51st streets there was found to be a difference of potential of three volts between the hydrant and the rails, and a current flow of 16 to 20 amperes. Between 51st and 52nd streets, near which latter street is located the power house of the street railway company, there is a gradual decrease in current flow, which shows that the ground return at a point on 51st street and State street is very poor.

The railway company should be required to run the proper return wires from this point in order to decrease the flow of current from the pipe to the rails. The 6-in. gas pipe which was removed was found to be very badly pitted from the action of the current, and it is no doubt affecting the water mains in this vicinity and at other points along the line which have not as yet been tested.

The difference of potential between the rails and the gas and water pipes should be reduced to practically nothing in order to prevent the deterioration of the pipes. I do not know of any other way of securing this result except to run the proper-sized copper return cables

I would suggest that a competent man be detailed for this work and the tests be made at an early date in order that the railway companies may have an opportunity to correct the defects before winter. The test above referred to was made with a representative of the Chicago City Railway Company present, and his reports will probably show the same results as above given.

In the Salt Lake City report it seems evident that there has been damage from the action of the current although the soluble salts in the earth may be a large factor in the results.

The Chicago report is based on the readings taken in the locality shown by Fig. 3. The railway company was instrumental in making the tests in order to determine whether or not the return circuit was in good condition. It is the policy

FIG. 4.

of the company to have adequate returns, for it costs many times the amount to generate power to force the current through the earth and water pipes than any damage that might result from electrolysis. In order that any current which may be in the pipes may have a good return circuit and no electrolytic action result a strip around the circumference of the pipe is filed and a copper band is bolted firmly in place and connected by an equalizing wire to the rails. The faults in this locality, shown in the map, will soon be removed and it is improbable that there is another place in the whole system where such results can be found.

It cannot be denied that there is danger of electrolytic action to any underground pipes or metal conduits in the vicinity of electric railway tracks if proper care is not taken with the construction and maintenance of the return circuit. With the track rails well-bonded and the conductivity supplemented by return feeders or copper wires in the middle of the track and connected to each rail, which is the usual practice, there is little reason to believe the current will overcome the high resistance of the earth and flow along an iron pipe, every joint of which is a poor electrical connection. The current takes the path of least resistance and in a good return circuit this may amount to a fraction of an ohm. When current is flowing in the gas or water pipes the danger points are the places where the current leaves the pipes to return to the station or at the joints where electrical contact is poor.

To obviate the danger copper bands are placed around the pipes at the points where the current is likely to leave them to return to the generators, and connected to the rails.

General manager M. R. McAdoo of the Paterson, (N. J.) Railway Company, has had some experience in this line. About a year ago the water pipes within a radius of a half mile of the power station were found pitted by the action of the current, and electrical experts were engaged to make a survey. All the tracks in this area were thoroughly re-bonded and more feeders were strung to the station and connected to the water mains. Since that time the number of breaks has been less frequent. It is the opinion of the general manager that the question of electrolysis may be solved by having a good return circuit and connecting the water mains in the neighborhood of the station to the return circuit.

Oftentimes the tests made by city authorities are uninten-

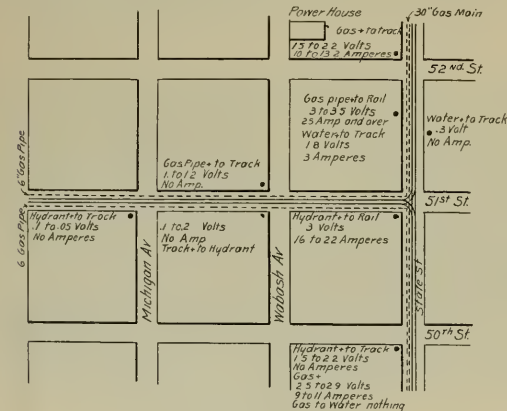

FIG. 3.

and make connections to the rails at such points that it will prevent the flow of current between the pipes and the rails; or to connect the pipe to the rails at different points along the line and give the current a path to the rails through a good connection.

I would not want to recommend the latter method without first making some very careful and extended tests. There is no doubt that within the next year or two it will be necessary to replace many of the water mains, owing to their being affected by carrying the street railway return current, and I am of the opinion that a complete test should be made of all the street railway lines which parallel water mains with a view of determining where the dangerous points are, and that the railway companies be required to remedy the defects in the return conductors.

tionally misleading and grossly wrong conclusions are drawn. Perhaps a test is made with a millivoltmeter and the current flowing from the tracks to the pipes calculated. Such readings as these may be found in localities where the trolley lines are unknown, and a difference of potential exists between gas and water mains regardless of the fact that there may not be a trolley line within miles of them. Not infrequently when the pipes are uncovered the metal has been reduced to a mere film or even perforated. Such a pipe is shown in Fig. 4 and its emaciated condition might easily be ascribed to trolley currents, but fortunately the reverse can be proved. This piece of gas pipe was taken out of a lamp service at the corner of Ogden avenue and Polk street, in Chicago, being accidentally broken in the setting of a railway pole. No electricity had been used on the west side of the river at that time. Had it been discovered a few months afterwards when the electric cars were in operation the gas company would undoubtedly have claimed that the entire service was being jeopardized by the current. Such evidence as this is not even reliable and the street railway companies would do well to fully investigate every phase of the case before accepting such proofs.

**NEW REPAIR SHOP FOR THE ALLEY L.**

The repair shops and yards of the South Side Elevated Railroad Company between 61st and 63rd streets in Chicago present a scene of great activity. The work of altering the cars and assembling the electrical apparatus for the Sprague equipment is now in progress. There are 20 cars near completion and ready to take the place of the steam locomotives. The steam service will have to continue until the completion of the power station at 39th street, which will

FIG. 1.—CROSS SECTION.

require at least two months. It is probable that some of the cars equipped with motors will have to be recalled into service for trailers, but this can be readily done by removing the pinions and the contact shoes. The vestibules are very compact and only occupy the portion of the platforms to one side of the door.

The present repair shops are provided with facilities for keeping the locomotives and passenger coaches in order. It was found necessary to construct another building to care for the motor cars. This will be done by extending the elevated structure north to 61st street and using the building now occupied by the lighting plant. This is of brick, two stories high, about 50 ft. square; on the first floor are the engines and dynamos which furnish the light for the elevated stations, and the second floor is used for office purposes. The electric lighting machinery will be removed and sold. As shown in Fig. 1 the structure is supported on piers and iron columns and provides for seven tracks.

The girders and columns were in stock, having been left from the World's Fair. Light brick walls will be built around the iron frame work.

On the first floor will be the carpenter and tin shop, large store rooms, waiting and toilet rooms for the employes and the repair shop for small parts. An elevator of sufficient capacity to elevate the trucks from the first to the second

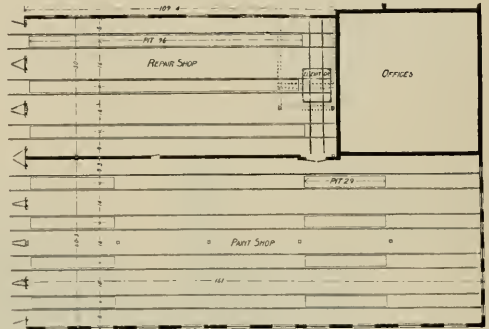

FIG. 2.—FLOOR PLAN.

floor will be installed, but the car bodies will remain on the second floor on a level with the elevated tracks. In the paint shop there will be eight pits located as shown in the floor plan, Fig. 2.

The old machines to be removed into the new shop consist of a wheel lathe, a 52-in. double headed lathe, two engine lathes, one a 15-in. and one a 21-in., a bolt cutter, an 18-in. shaper and a drill press. Other machinery necessary to repair the electrical equipment will be procured later.

**MORE NIAGARA POWER FOR BUFFALO.**

The demand for electric power in Buffalo has been so great in the last few months that it is necessary to add a new circuit of three wires to the transmission line. The Niagara Falls Power Company has placed an order with the General Electric Company for seven new 1,250-h. p. step-up transformers of the air-blast type. The voltage will be raised from 2,200 to 11,000, but ultimately to 22,000, and the current is changed from a two phase to a three phase. From the step-down transformers of the Cataract Power & Conduit Company, which controls the general distribution of the current in Buffalo, three phase circuits will run to a number of induction motors which are being installed in the grain elevators. The Buffalo Railway Company is also increasing its step-down transformer and rotary converter capacity in its Niagara street power station. In addition to the two 500-h. p. converters in operation two more of similar size are being constructed by the General Electric Company. Three 275-k. w. step-down transformers will also be added. These transformers reduce the voltage of the three phase current from about 10,500 to 375 volts and the rotary converter delivers a direct current of 550 volts to the bus bars of the station switchboard.

The Metropolitan road, Kansas City, Mo., has installed a motor to drive its machine shop at 12th and Charlotte streets.

### NEW FEATURES OF THE BALL ENGINE.

The illustration shows one of the engines manufactured by the Ball Engine Company of Erie, Pa., whose work is well known in electric railway plants. The engine shown is equipped with the Rites governor and automatic lubricating system. This governor was described in our September issue, page 593. The lubrication is accomplished by a gravity system of supply to sight feeders distributed at necessary points over the engine. By means of a pump driven continuously from the valve motion the oil is delivered back to the supply tank after use, making the system automatic. A direct pressure may be established on the oil

the introduction of a gas capable of combining with them. The new process insures a perfection of vacuum not obtainable in lamps exhausted in groups.

For street car purposes it is essential that the lamps have mechanical strength, uniformity in current consumption and long life without a decrease in brilliancy. A long life lamp can be secured which gives a dim light but these are not economical as there is little return for the current consumption. The Edison lamp has an efficiency of 4 watts per candle power. The lamps being in series it is important that they be uniform, so the railway lamps are made in three different classes—for 500, 550 and 600-volt circuits. The filament of cellulose with a hard graphite carbon coat-

THE BALL ENGINE.

supply pipes to remove any obstructions in them. The oil after leaving the bearings runs down to the bottom of the frame and from there to a receiving tank near the floor level, where screens remove some of the foreign matter; the oil is pumped up to the supply tank in greater quantities than necessary for the engine and the overflow runs back to the lower tank. Such a gravity system supplies the oil free from bubbles which are so great a cause of annoyance with direct systems.

### INCANDESCENT LAMPS FOR STREET CARS.

At the lamp works of the General Electric Company the output of incandescent lamps is 6,500,000 yearly. For two years or more experiments have been in progress to perfect a new exhaustion process, which would do away with the mercury pumps. This has been accomplished by means of a small mechanical pump which exhausts one lamp at a time. The natural residual gases, which are always a source of much trouble, are thoroughly removed from the lamps by

ing is so shaped and anchored as to be free from injury from vibration. In this lamp the anchor is set in the stem and this combination checks the vibrations rather than holds the filament rigid.

### ELECTRICITY ON LONG ISLAND.

The management of the Long Island Railroad announces that a considerable portion of its suburban system is to be equipped for electric traction, and does so without any qualifying statements as to the equipment being experimental. The officers of the company say that they are confident that electricity will do the work better than it is now done by steam locomotives. The reason for the change is the construction of a tunnel under East river to connect the present Flatbush avenue terminal in Brooklyn with the business center of New York, which could scarcely be used with steam for motive power. The preliminary steps for the building of the tunnel are now in progress and it is estimated that two and one-half years will be required for its completion. The change to electricity will not be made until that time.

### Alabama.

**BIRMINGHAM, ALA.**—Bids will be received by the Birmingham Traction Company until December 15 on 6.5 miles of track, 60 and 56-lb. rail, 12 crossings, 12 switches, 8 curves, bonds, furnishing and stringing No. 0 trolley wire, furnishing and stringing No. 0000 feeder wire, two 125-k. w. generators and switchboard, engines, boilers and traveling crane; 4 cars, 4 trucks, motor equipments for 4 new and 2 old cars. George H. Clark is engineer and G. M. Williams, general manager.

### California.

**SAN LUIS OBISPO, CAL.**—R. E. Jack has been granted a franchise to build a car line in Higuera street.

**OAKLAND, CAL.**—The Piedmont & Mountain View Railroad has been practically absorbed by the Realty Syndicate.

**SAN FRANCISCO, CAL.**—It is said that Spreckles will ask the supervisors for a franchise to build an electric railway in Bush street.

**SAN DIEGO, CAL.**—Receiver A. E. Dodson offered the road of the Citizens' Traction Company for sale by auction November 18, at the minimum price of \$40,000, but no bidders appeared.

**REDLANDS, CAL.**—To promote the construction of an electric railway the Redlands Orange Grove & Water Company offers to take \$2,000 of the bonds of any company formed for such purpose. A horse car line is now operated.

### Chicago.

**CHICAGO.**—Consents for the long-desired trolley line on Evanston avenue have been obtained by the North Chicago Street Railroad Company.

**CHICAGO.**—Charles T. Yerkes has declared his intention of equipping North and West Chicago Street Railroad cars with fenders in compliance with the ordinance.

**CHICAGO.**—Charles T. Yerkes, it is said, has succeeded in financing the Northwestern Elevated Railroad, and it is expected that construction will be resumed the coming year. The Northwestern was projected in 1892. Two years later work was begun and continued until 1896 with an outlay of \$5,200,000. Nearly all of the concrete foundations have been laid, rendering it possible to erect the iron superstructure in a very short time. A suitable location for the power house has been acquired, with an ample supply of pure lake water for condensing.

**CHICAGO.**—The Englewood & Chicago Electric Street Railway Company will equip its cars with fenders in compliance with the city fender ordinance. The Chicago Electric Transit Company, a Yerkes corporation, has obtained frontage consents for the construction of four miles of road on which work will begin immediately. The North Chicago Street Railroad has obtained frontage consents for a trolley line in Dearborn avenue. Right of way for an electric railroad along the Illinois and Michigan Canal is asked by a syndicate of Chicago, Ottawa and Streator men. Among those interested are W. H. Holcomb and H. D. Judson of Chicago.

### Colorado.

**DENVER, COL.**—President George H. Holt says the Denver City Cable Company will discard the rope and put in an electric system with a view to reducing the heavy operating expenses.

### Connecticut.

**SHELTON, CONN.**—It is said the Shelton Street Railway will be extended along the river to Paradise Green.

### Delaware.

**WILMINGTON, DEL.**—The Wilmington City Railway Company contemplates an extension across the Washington bridge.

**WILMINGTON, DEL.**—Jacobs & Vandegrift, of Philadelphia, have begun work on their contract to build the Wilmington & Brandywine Springs Railway.

**WILMINGTON, DEL.**—The Elsmere & Wilmington Electric Railway, 1.5 miles in length, was formally placed in operation recently. D. W. Taylor is president of the company.

**NEWPORT, DEL.**—The Newport, New Castle & Wilmington Railway Company has been organized with Thomas Holcom of New Castle president, and J. A. Cranston of Newport secretary. An electric road will be built from Newport to Wilmington, via New Castle

### Georgia.

**ATLANTA, GA.**—The Consolidated Street Railway Company has decided to equip its cars with the Security fender.

**SAVANNAH, GA.**—The council has granted radical changes in the routes of Savannah's street railway, adding many miles of double track.

### Illinois.

**ROCK ISLAND, ILL.**—Contracts have not been let for the new machinery for the Tri-City Company's power station.

**ELGIN, ILL.**—The Elgin City Railway Company has filed a mortgage to David S. Wegg, securing an issue of \$200,000 of bonds.

**FREEMONT, ILL.**—The management of the electric car line is figuring on extending to Beebe's wood and converting it into a pleasure resort.

**QUINCY, ILL.**—Business men are reviving the project to build an electric railway from Quincy south through Payson, Plainville and other points in Pike county.

**PEORIA, ILL.**—The Central Railway Company plans an extension of its lines north to connect with its recent acquisition, the Glen Oak & Prospect Heights Street Railway.

**SALEM, ILL.**—The Illinois & Southern Construction Company has been incorporated to build an electric railway. Capital stock \$2,500; incorporators, C. H. Neff, W. C. Irwin and A. N. Rooks.

**EAST ST. LOUIS, ILL.**—John F. Day, one of the promoters of the East St. Louis & Belleville Electric Railway, says that the grading of the roadway will begin before the end of the year. Condemnation proceedings cause the delay.

**SALEM, ILL.**—The Wabash & Mississippi Construction Company has been incorporated to build and operate an electric railroad from East St. Louis through the counties of St. Clair, Madison, Clinton, Clay, Richland and Lawrence. Capital stock, \$2,500; incorporators, C. H. Neff, W. C. Irwin and A. N. Rooks.

**ROCKFORD, ILL.**—James S. Ticknor has sold his interest in the Rock River Electric Railway project. E. M. Hopkins of Chicago is to be the president, J. S. Ticknor, Rockford, the secretary, and Mayor Schuelder of Oregon the treasurer of the new company. The company is now completing the right of way.

**EAST ST. LOUIS, ILL.**—An electric railway 11 miles in length will be built by the St. Clair Turnpike Company. D. P. Alexander, a director of the company, represents capitalists who have acquired control of the stock, and who have ample capital to build the road at once. Surveyors are laying out the route.

**AURORA, ILL.**—Promoters of the Aurora, Yorkville & Morris Electric Railway are awaiting with interest the decision of the court in the condemnation suits brought by the Aurora & Geneva Railway. If it is decided that companies organized under the horse and dummy act can not condemn land they will incorporate under the general railroad law.

**JOLIET, ILL.**—Col. John Lambert, manager of the Consolidated Steel & Wire Company, is the principal backer of a company which is getting the consents of the property owners to build an electric railway, taking in the principal business streets not already used by the Joliet Street Railway, and branching out to Rockdale, three miles southwest.

**EAST ST. LOUIS, ILL.**—The St. Louis & Belleville Suburban Railroad Company has been incorporated to build a line over the St. Clair Turnpike. Capital stock \$350,000; incorporators, George Townsend and William T. Reed, general contractors, of Chicago, Wilber N. Horner, attorney, of Chicago, ex-Judge Alonzo S. Wilderman, of Belleville, and John Niemes, contractor and mason, of East St. Louis.

**PEORIA, ILL.**—Stockholders of the Glen Oak & Prospect Heights Electric Railway met November 26 and authorized President Monroe Seiberling to sell the property to Walter Barker, president of the Central Railway. A few minutes later a deed was filed for record and Mr. Barker took possession. The Central now controls all lines in the city and is better prepared to fight the new Peoria & Pekin Traction Company, which is making great headway.

### Indiana.

**ANDERSON, IND.**—Noah J. Clodfelter has obtained for his Indiana Traction Company an extension to July, 1898, from the Fairmount council.

**JEFFERSONVILLE, IND.**—Storage batteries will be placed on the street cars as an experiment by the new owner, Capt. Edward J. Howard.

**HUNTINGTON, IND.**—The Huntington Street Railway Company, which expects to build eight miles of track, was granted a franchise November 24.

**TERRE HAUTE, IND.**—Receiver Jump's petition to the court for authority to borrow \$25,000 to buy boilers and enlarge the capacity of the street railway and electric lighting plant has been allowed.

**JEFFERSONVILLE, IND.**—Captain Edward J. Howard of the Howard Shipyards in Jeffersonville will take possession of the Jefferson City Street railway at once and equip the cars with electric motors. The dynamos supplying current will be set up at the shipyard planing mills, where he has ample power.

### Iowa.

**DES MOINES, IA.**—The Des Moines Street Railway Company contemplates extending its system two miles, to Valley Junction.

**BOONE, IA.**—The Boone Electric Street Railway went into operation November 15. President L. W. Reynolds expects to extend the line next spring to Incline, and to establish a pleasure resort.

**COUNCIL BLUFFS, IA.**—A special election will be held December 1 to vote on the question of extending the lines and franchise of the Council Bluffs, Lake Manawa & East Omaha Construction Company.

**MASON CITY, IA.**—The success of the Mason City & Clear Lake Traction Company's freight and passenger line is causing the promotion of similar roads. One of these is to run northwest through Fertile to Lake Mills, also southeast through Coldwater to Rockford. Another line is to run from Charles City to Hampton and from Clear Lake to Belmont.

### Kansas.

**PITTSBURG, KAN.**—Work is soon to begin on the extension of the Pittsburg, Frontenac & Suburban Electric Railway from Chicopee to Weir City and Columbus. Weir City has granted a franchise to the Pittsburg & Columbus Railway Company.

**FORT SCOTT, KAN.**—The Citizens' Railway Company has been incorporated to operate an electric road and power plant in Fort Scott. Capital stock, \$50,000; directors, W. B. Hurst, W. H. Frost, H. C. Post, C. B. McDonald, W. D. Lowry, D. P. Thomas, Grant Hornaday, W. C. Perry and John H. Crain, all of Ft. Scott.

### Kentucky.

**ASHLAND, KY.**—The Ashland Improvement Company, largely interested in the Ashland & Catlettsburg Street Railway, has made an assignment to Willis L. Ringo, general manager of the railway.

### Maryland.

**BALTIMORE, MD.**—The Central Railway Company has installed 265 cells of storage battery to equalize the load on the Preston street power house.

**BELAIR, MD.**—Water power will be used by the Belair & Havre de Grace Electric Railway Company to generate electricity. The turbines and generators will be located on Deer Creek.

**BALTIMORE, MD.**—The Garrison Avenue Railroad Company has been incorporated to build a line. Capital stock, \$100,000; incorporators, Nelson Perin, W. A. House and Mr. Offutt.

**SANFORD, ME.**—C. A. Bodwell, superintendent of the Mousam River Railroad, says that everything is favorable to the construction of the new road in the spring. The line will extend a distance of 20 miles from Sanford to Cape Porpoise.

**BALTIMORE, MD.**—The Central Railway Company has begun work to connect its Canton extension with the Canton, Sparrows Point & North Point Railway. Fifteen closed cars are being built by the City Passenger Railway Company for the Green line.

**BALTIMORE, MD.**—A mortgage to cover an issue of \$1,250,000 of bonds has been given by the Baltimore & Northern Railway Company, which is a consolidation of the Falls Road Electric Railway Company and the Pikesville, Reistertown & Emory Grove Railroad Company.

**BALTIMORE, MD.**—The petition of the Baltimore, North Point & Bear Creek Railway Company for permission to lay track on the Mount Carmel road has been taken under advisement by the Baltimore county commissioners. The application is opposed by the East Baltimore & North Point Railroad.

**BALTIMORE, MD.**—It is said that the Columbia & Maryland Railway has passed into the control of John E. Searles' railroad and steamboat syndicate, William L. Elkins and P. A. B. Widener of Philadelphia selling their interests. David M. Newbold and Robert S. Carswell of Baltimore retain their large holdings.

**BELAIR, MD.**—W. P. Husband of the Havre de Grace & Belair Electric Railway Company has applied to the county commissioners for right of way between Belair and Aberdeen. Seventeen miles of single track is to be laid through Fountain Green, Fulford, Churchville, Carson's Run and Aberdeen to Havre de Grace, thus penetrating the most thickly populated districts of the county. Freight will be carried as well as passengers.

### Massachusetts.

**MARSHFIELD, MASS.**—An electric street railway is to be built from Marshfield depot to Brant Rock.

**NEWTON, MASS.**—The Newton Street Railway Company is said to be planning a new power station and car house.

**FITCHBURG, MASS.**—The Fitchburg & Suburban Railroad Company has been granted a franchise over the route asked.

**SPRINGFIELD, MASS.**—The ties distributed along the route of the Springfield & Southwestern Electric Railway have been attached on claims for transportation, etc.

**NEWBURYPORT, MASS.**—Right to extend to Groveland has been granted to the People's Street Railway Company. The capital stock will be increased \$200,000 to provide the funds.

**NORFOLK, MASS.**—Permission to establish a pleasure resort half way between Dedham and Norwood has been granted to the Norfolk Central Street Railway Company by the Railroad Commissioners.

**NATICK, MASS.**—The Needham selectmen have granted a franchise to the Natick & Cochituate Street Railway Company for an electric railroad through Needham from the Wellesley line to the Dedham line.

**BOSTON, MASS.**—The state railroad commissioners have refused to ratify the lease of the West End Street Railway to the Boston Elevated Railroad Company on the ground that a lease would be against public policy.

**MILTON, MASS.**—The petition of the Boston, Milton & Brockton Street Railroad Company for a franchise has been given a hearing by the Milton selectmen. The petition of the Quincy & Boston Street Railway Company was also heard.

**PALMER, MASS.**—The directors of the Palmer & Monson Electric Railroad Company have chosen C. F. Grosvenor, president; E. G. Hastings, vice-president, and Rufus Flynt, secretary and treasurer. It was voted to accept the franchise granted by the town of Palmer.

**WEBSTER, MASS.**—Directors of the Webster & Dudley Electric Railway Company have voted not to accept the franchise and to dissolve the company. Edgar S. Hill is making arrangements with the New England Railroad Company to have an extra track put in from Webster station to Elliott's Shore and run electric cars during the summer.

**MARSHFIELD, MASS.**—The Brant Rock & Duxbury Beach Electric Railroad Company has been organized to build six miles of road from Marshfield station to Brant Rock and Duxbury. Work is to begin at once. Capital stock, \$50,000; I. L. Currier, 105 Main street, Worcester, president and treasurer; Bradley S. Bryant, secretary; George H. Thomas, Charles J. Sprague, Henry C. Phillips, Charles Atwood and Walter Peterson of Brant Rock, directors.

**NORFOLK, MASS.**—The Norfolk Southern Street Railway Company has been incorporated with a capital of \$150,000. The board of directors are John C. Lane, Norwood, Robert S. Gray, Walpole, Joseph J. Feeley, Walpole, Edward E. Draper, Boston, George S. Forbush, Brookline, Frederick S. Lane, Foxboro, and Aaron R. Sanderson Boston. The road will be seventeen miles in length, starting at the junction of Washington street and Railroad avenue, in Norwood and extending through Walpole and Foxboro to the railroad station in Mansfield.

## Michigan.

**THREE RIVERS, MICH.**—The proposed electric railway from Three Rivers to Leonidas is being actively promoted.

**DETROIT, MICH.**—Dearborn township has granted a franchise to the Detroit, Ann Arbor & Ypsilanti Street Railway Company.

**ESCANABA, MICH.**—The Escanaba Electric Street Railway has ceased operation, President J. Lillie having found it a losing venture.

**LANSING, MICH.**—The scheme to build an electric railway from Lansing north through St. Johns, Ithaca and St. Louis is still being agitated.

**ADRIAN, MICH.**—Once more has the sale of the Adrian Street Railway been postponed, as it is doubtful whether Judge Chester will confirm the best bid of \$625.

**DETROIT, MICH.**—Springwells township has granted a franchise for an electric road over Michigan avenue to the Detroit & Ann Arbor Electric Railway Company, in which John A. Russell is interested.

**MONROE, MICH.**—The council has granted a street railway franchise to A. E. Kiopelle, C. W. O'Brien and Leopold Freud, who will give a bond as an evidence of good faith, and construct a steel bridge over the River Raisin.

**LANSING, MICH.**—A company is being organized by Judge Montgomery and Senator F. L. Dodge of Lansing; Senator E. Mudge of Maple Rapids; George W. Stone of Ithaca, and C. C. Vaughan of St. Johns, to build the long-talked-of electric railway between those places.

**DETROIT, MICH.**—Col. Seymour Brownell, of 28 High street, West, has succeeded in interesting Detroit capitalists in his scheme to build an electric railway. His associates have purchased a controlling interest in the capital stock of the Detroit & Howell Plank Road Company.

**GRAND RAPIDS, MICH.**—A new franchise is asked by the Consolidated Street Railway Company on the ground that it cannot do business under the present burdens. In return for more liberal provisions the company promises to make extensions and improvements costing \$100,000.

**FLINT, MICH.**—The council has voted a franchise to Hon. Samuel W. Smith and Joseph E. Sawyer of Pontiac and George E. Taylor of Flint for the proposed electric railway from Pontiac to Flint. A survey of the road has just been completed. Mr. Taylor says work will be begun by May 1, 1898, and cars will be running before November, 1899.

**DETROIT, MICH.**—The Detroit & Northern Railway Company has been incorporated to construct an electric line between Mt. Clemens and Marine City, 32 miles in length. Right of way has been obtained and construction is expected shortly to begin. Capital stock, \$350,000; incorporators, Fred Woodbourne, St. Paul; Luther S. Cushing, St. Paul; John Townsend, St. Paul; Arthur P. Lothrop, St. Paul; George E. Smith, Detroit; Clarence A. Lightner, Detroit, and Edwin Denby, Detroit.

**DETROIT, MICH.**—The old power house of the Fort Wayne & Belle Isle Railway, at Detroit, which has been out of use since the consolidation of the street railway companies has been purchased by the Detroit, Ypsilanti & Ann Arbor Suburban Railway Company. The property will be removed to Wayne to furnish power for the new line that will connect Detroit with Ypsilanti and Ann Arbor. The work of removing the power house will be started within two weeks. It is thought that cars will be running over the new line by January 1.

**DETROIT, MICH.**—The Detroit, Ann Arbor & Ypsilanti Electric Railway Company has been incorporated. Capital stock \$100,000; incorporators, James D. Hawks, president of the Detroit & Mackinac Railway, S. F. Angus, John C. Liggett, Obadiah Bingham and M. J. Griffin of Detroit. The road will be 43 miles in length, extending from the terminus of the Detroit Electric Railway to a connection with the Ann Arbor & Ypsilanti Motor Road at the city limits of Ypsilanti. M. J. Griffin, as contractor, will immediately begin work in Springwells.

## Minnesota.

**ST. CLOUD, MINN.**—Receiver Clark of the car line has been given leave by the bondholders to expend \$3,500 for new motors, etc. The road is now said to be paying expenses.

## Missouri.

**KANSAS CITY, MO.**—W. C. Weaver, superintendent, is buying material with which to improve the Northeast Electric Railway.

**ST. LOUIS, MO.**—Construction is soon to begin on the Lindell Railway Company's 14-mile extension to Creve Coeur Lake. Specifications are being prepared.

**ST. LOUIS, MO.**—The Russell Place & Oak Hill Railway Company has been incorporated with \$2,000 capital stock by G. W. Parker, T. G. Russell and C. G. Russell.

**ST. LOUIS, MO.**—The North & South Railway bill, granting unknown persons right to construct 100 miles of street railroad, has passed the house of delegates.

**KANSAS CITY, MO.**—A franchise has been granted the East Side Electric Railway Company by the lower house of the city council. It is said Mayor Jones will veto the ordinance.

SHELBY, MO.—Orville G. Wales, 1509 Chemical building, St. Louis, is promoting an electric railway between Shelby and Shelbyville. Interested in the project are Dr. McCully, W. H. Warren, and T. F. Hughes of Shelby.

### Nebraska.

LINCOLN, NEB.—Ernest C. Ames, master in chancery, will sell the Lincoln Street Railway December 17, by order of the United States court, on petition of the New York Security & Trust Company.

### New Hampshire.

PORTSMOUTH, N. H.—The Portsmouth, Kittery & York Electric Railway will be extended through Newcastle and Rye to Hampton as soon as conditions will permit in the spring.

### New Jersey.

NEW BRUNSWICK, N. J.—The Brunswick Traction Company has received permission from the Piscataway township committee to extend its line from Bound Brook to Dunellen.

MOUNT VERNON, N. J.—John H. Starin, owner of Glen Island, and others have applied for a franchise to build an electric railway from the railway station to the Glen Island dock.

HACKENSACK, N. J.—The Bergen County Traction Company, operating between Fort Lee and Englewood, it is said, will apply for a franchise next spring for a line through Hackensack.

SOUTH ORANGE, N. J.—The South Orange & Maplewood Traction Company has been incorporated to construct a line. Capital stock, \$100,000, with \$25,000 paid in; incorporators, Henry A. Page, South Orange; Edward D. Page, New York, and Frank Brewer, West Orange.

MORRISTOWN, N. J.—The Speedwell Lake Railroad Company has been incorporated to build and operate a line from the terminus of the Rockaway Valley Railway to Speedwell avenue, Morristown. Capital stock, \$50,000; incorporators, Frederick H. De Coster, Richard B. Moriarty, Mahlon Pitney, Frederick V. Pitney and Frederick S. Smith of Morristown, Byron K. and George W. Stickle of Rockaway, N. J.

### New York.

SCHENECTADY, N. Y.—The Schenectady Railway Company, it is said, will make extensions.

NYACK, N. Y.—The Nyack Traction Company has applied for permission to construct an electric street railway.

ROCKAWAY, N. Y.—The Rockaway Village Railway, has been purchased, it is said, by the Long Island Railroad Company.

WESTFIELD, N. Y.—The Princess Bay Electric Railway Company has been granted a franchise by the Westfield highway commissioners.

BUFFALO, N. Y.—The Buffalo Traction Company has given a bond of \$200,000 to guarantee the construction of its lines as provided in its franchise.

NYACK, N. Y.—George F. Kissam of New York, is president of the new Nyack Traction Company. A. B. Wilgus of New York, is also interested.

BUFFALO, N. Y.—East Aurora has granted a franchise to the Buffalo, Hamburg & Aurora Electric Railway Company for a line along Main street.

BROOKLYN, N. Y.—The Sea View Elevated Railroad has been purchased and will be equipped with electricity by the Brooklyn Heights Railroad Company.

PATCHOGUE, N. Y.—The Patchogue & Port Jefferson Traction Company will decline the franchise granted by Patchogue, hoping to obtain a more liberal one.

STATEN ISLAND, N. Y.—The Princess Bay Railroad Company, which was recently incorporated to build 1.5 miles of electric road, has received its franchise.

BROOKLYN, N. Y.—The Brooklyn Heights Railroad Company will apply to the aldermen for the privilege of building from Flatbush to Bath Beach and Bensonhurst.

MARCELLUS, N. Y.—The Marcellus Electric Railroad Company has filed its consents for the construction of an electric road from Marcellus to Marcellus Station.

NEW YORK, N. Y.—The state railroad commissioners have given the Metropolitan Street Railway Company permission to change from horses to electric conduit on the 86th, 106th and 125th street lines.

WHITEHALL, N. Y.—G. S. Leavenworth has made preliminary surveys of the 20 miles of road to be built between Whitehall and West Paulet, Vt., by the Whitehall & Granville Electric Railway Company.

NEW YORK, N. Y.—The Fulton, Wall & Cortlandt Street Ferries Railroad Company's property was sold December 2 by L. J. Phillips & Co., under foreclosure of mortgage instituted by the Central Trust Company.

ALBANY, N. Y.—T. D. Welch of Ravena, N. Y., has taken the contract to build the electric railway from Nassau village to Brainard Station, a distance of seven miles. Several teams and 100 men are at work grading.

PATCHOGUE, N. Y.—An amended franchise has been granted the Patchogue & Port Jefferson Traction Company, of which J. B. Swezey is secretary. Sixty days are given in which to accept or decline the franchise.

NEW YORK, N. Y.—Electric cars were placed in service November 4, on the Fourth and Madison avenue lines of the Metropolitan Street Railway. By January 1 the company will have installed electricity on 40 miles of track.

NEW YORK, N. Y.—Permission to construct a horse car line in Wall, Pine, Liberty, Cortlandt, and William streets is asked by the Fulton, Wall & Cortlandt Street Ferries Railroad Company, under franchises granted in 1885.

JAMAICA, N. Y.—The Long Island Electric Railway Company has been given more time in which to complete the construction of its line on South and Hay streets. The company also asks a franchise to run its cars on Fulton street.

ALBANY, N. Y.—The Greenbush & Nassau Electric Railway Company has contracted with the Columbia Power Company for 300 horse power, thereby postponing the construction of its own power plant. Cars are expected to be running by February 1.

PELHAM MANOR, N. Y.—The Pelham Park Railroad Company has petitioned the board of aldermen for a franchise to construct two extensions of the horse car line from Bartow Station to City Island, with a branch to the city limits at Pelham Manor.

SARATOGA, N. Y.—Civil Engineer Robert E. Dunston, Samuel J. Mott and W. S. Winchester of Saratoga Springs are making a survey of the projected electric railroad between Saratoga and Ballston, which is being promoted by the Saratoga Traction Company.

ALBANY, N. Y.—Laborers working on the Greenbush & Nassau Electric Railway are murmuring because their pay is not forthcoming. It is said Belden & James have not succeeded in floating the \$180,000 of bonds which they took to New York with that object.

WATERTOWN, N. Y.—The Consolidated Watertown and the Watertown & Brownsville Street Railways were sold November 27 under foreclosure of mortgage held by the Central Trust Company. Mayer Lebkuecher of Newark, N. J., and C. T. Cornell of New York bought the roads for \$28,000 above the incumbrances.

LITTLE FALLS, N. Y.—The trustees of Frankford village have granted a franchise for an electric railway to Clinton Beckwith of Herkimer and John V. Quackenbush of Mohawk, N. Y. Col. Beck-

with says the franchise will not be accepted on account of the provision requiring the company to pay the village 2 per cent of the gross earnings.

**BROOKLYN, N. Y.**—The Brooklyn Rapid Transit Company has obtained nearly all the consents required for the 16th avenue line, which is to be built next spring to connect the Eastern District and New Utrecht. For the 12 months ending October 31 the company earned a surplus of \$89,529, against a deficit of \$78,753 for the same period preceding.

**SIDNEY, N. Y.**—The Delaware Terminal Railroad Company has been incorporated to build 15 miles of electric railroad from Sidney to Franklin. Capital stock, \$150,000; incorporators, Charles L. Burgess, Sigmund T. Meyer, David S. Meyer, John Neff and H. S. Meyer of New York, Louis F. Raymond of Franklin, and Edmund R. Halsey of Newark, N. J.

**BROOKLYN, N. Y.**—The Brooklyn & Jamaica Turnpike Company has been incorporated by the backers of the recently incorporated Cross Country Railroad Company. The road will connect Brooklyn and Jamaica with Flushing and the north shore of Long Island. It is said that the franchise for a trolley line from Rockaway Park to Wave Crest is owned by the same men.

**COLLEGE POINT, N. Y.**—The Cross Country Railroad Company has been incorporated to construct 15 miles of electric road in Kings and Queens counties from Flushing Bay to Liberty avenue, Brooklyn. Capital stock, \$250,000; incorporators, Joseph McLean, Andrew A. Halsey, Theodore Bernard, Charles H. Kelby, James Crowley Francis Bacon, James Erwin and Charles Brandon of Brooklyn.

**SYRACUSE, N. Y.**—The chamber of commerce held a meeting recently to promote the electric railroad. As surveyed, the road would extend a distance of 41 miles, to Solvay, via Oswego, Mandana, Skaneateles, Marcellus, Camillus and Fairmount. The survey has just been completed, under the direction of J. W. Ackerman, chief engineer of the Lehigh Valley Railroad. To build the line there has been incorporated the Syracuse, Skaneateles & Moravia Railroad Company with \$1,000,000 capital stock. Wing T. Parker of Moravia is president; Henry J. Hubbard of Skaneateles, vice-president; Joseph Parker of Moravia, secretary, and Thomas W. Downing of Moravia, treasurer. Heavy freight is to be carried as well as passengers.

### North Carolina.

**SALISBURY, N. C.**—D. L. Risley of Philadelphia, Pa., is said to be interested in the Salisbury Street Railway & Electric Company, which has been organized to build a trolley road.

### Ohio.

**TORONTO, O.**—Edward McElvaine, the Pittsburg capitalist, is said to be promoting an electric railway to connect Toronto with East Liverpool and Steubenville.

**SANDUSKY, O.**—J. W. Flowers of Toledo has been getting right of way for the electric line to be built by the Cleveland, Fremont & Toledo Electric Railway Company.

**YOUNGSTOWN, O.**—The application of the Mahoning Valley & Southeastern Electric Railway Company for right to build a line has been granted by the county commissioners.

**TIFFIN, O.**—A large quantity of rails, iron poles and trolley wire has been received for the Tiffin-Fostoria Electric Railway, construction of which is being rapidly pushed by Manager A. F. Kaup.

**KENTON, O.**—A scheme is on foot to build an electric railway through the Scioto marsh. From Kenton the road would extend through Foraker, McGuffey and Alger to Ada. It is said that Calvin S. Brice is interested.

**DELAWARE, O.**—W. A. Hall asks the court to appoint a receiver for the Delaware Street Railway. Mr. Hall is director of the Deposit Banking Company which recently got judgment for \$2,000. A reorganization will be attempted.

**CINCINNATI, O.**—John Martin and the Ohio Turnpike Company are about to construct an electric railway from the terminus of the East End Electric Railway to Bethel, Clermont county, passing through California, Mt. Washington, Fruit Hill and Williamsville.

**LIMA, O.**—Promoters of the Lima & Huntsville Electric Railway are active. Right of way is fast being obtained. The car house will be located at Huntsville. Another project is on foot for the construction of an electric road from Huntsville to West Liberty, DeGraff and Quincy.

**DAYTON, O.**—The Dayton, Spring Valley & Wilmington Transit Company has been incorporated to build the electric railway noted in DAILY BULLETIN from time to time. Capital stock, \$50,000; incorporators, J. M. Wilson, Wallace Berryhill, J. H. Racer, George Truman, and Frank E. Robbins.

### Oregon.

**SALEM, ORE.**—F. R. Anson, receiver of the Salem Electric Street Railway, is taking bids on 1,000 ties for renewals.

### Pennsylvania.

**PITTSBURG, PA.**—The United Traction Company has taken out a permit in Allegheny for the erection of a pumping station.

**HARRISBURG, PA.**—The Tower city council has granted the Lykens & Williams Valley Electric Railway Company right of way through the town.

**MEADVILLE, PA.**—Isaac A. Walker & Son, who have the contract for the construction of the Meadville Street Railway, have reorganized and are proceeding with the work.

**ROYERSFORD, PA.**—The Royersford & Trappe Electric Railway Company is being formed to build a line connecting with the Schuylkill Traction Company at Collyerville.

**READING, PA.**—Holders of the Reading & Southwestern Railroad securities are asked to vote a lease to the United Traction Company for 99 years on a guarantee of 5 per cent.

**NORRISTOWN, PA.**—Thomas Butcher, S. Powell Childs and Chalky Styer have been appointed a committee to obtain right of way for the proposed trolley line from Norristown to Ambler.

**PITTSBURG, PA.**—Negotiations have been closed whereby the control of the United Traction Company is acquired by a syndicate represented by Alexander Brown & Sons, bankers, of Baltimore.

**TAMAQUA, PA.**—The Tamaqua & Lansford Electric Railway, 8.5 miles in length, has been placed in operation. It is said the Lehigh Navigation Company will equip the "Switchback" for a trolley road.

**MEADVILLE, PA.**—John W. Shryock, president of the Meadville & Edinboro Electric Street Railway Company is negotiating with the Erie Electric Motor Company for track privileges at the Erie terminus.

**PHILADELPHIA, PA.**—A banking firm has disposed of its controlling interest in the Hestonville, Mantua & Fairmount Electric Railway to parties closely identified with the management of the Union Traction Company.

**MECHANICSBURG, PA.**—The Susquehanna & Western Railway Company has been incorporated to build six miles of road from Wormleysburg to Mechanicsburg. Capital stock, \$50,000; president, B. F. Myers of Harrisburg.

**DOYLESTOWN, PA.**—The Doylestown & Willow Grove Traction Company has been incorporated with \$10,000 capital stock by D. N. Walmsley, Carroll R. Williams and Joseph Jones of Philadelphia, and Samuel Steckel and G. P. Brock of Doylestown.

**ASHLAND, PA.**—The Ashland-Centralia Electric Railway Company has been granted the right of way to construct a road two miles in

length, connecting with the Shamokin-Mt. Carmel Railway at Centralia and the Shamokin-Mahanoy City Trolley Line at Ashland.

**PITTSBURG, PA.**—The West End Traction Company has been incorporated to consolidate a number of small roads running to Carnegie, Crafton and other places southwest of the city. Capital stock, \$15,000; incorporators, J. C. Reilly, W. J. Burns, Thomas S. Bigelow, J. D. Callery and W. V. Callery.

**CONSHOHOCKEN, PA.**—The Stoke-Pogis Railway Company has been incorporated to build 3.5 miles of electric railway from Rosemont to West Conshohocken. Capital stock, \$50,000; incorporators, Frederick Phillips, president, Clinton Gage, J. M. Whitham, William M. Kerr, George C. Schoff, Henry C. Landis and J. N. Kerr, all of Philadelphia.

**WHITE HAVEN, PA.**—The Wyoming & Pond Creek Railway Company has been incorporated to build six miles of electric road from White Haven to Sandy Run Junction. Capital stock, \$60,000; incorporators, A. J. Lathrop and S. J. Lathrop, Pittston; D. F. McCollins and A. M. Freas, Wilkesbarre; C. L. Hoover, Sandy Run; L. L. Rogers, M. G. Lathrop and L. C. Bacon, New York.

### Rhode Island.

**NEWPORT, R. I.**—The Middletown and Portsmouth Railroad Company has been incorporated to build an electric line through Middletown, Portsmouth and Tivertown, connecting with roads in Newport and Fall River. Capital stock, \$300,000; Melville Bull, president; W. A. Tucker, Charles Peirce and Mr. Saltonstall of Boston, directors. The construction is in charge of the Tucker-Anthony Company of Boston.

### South Dakota.

**YANKTON, S. D.**—The Yankton Street Railway will take up its track on Douglas avenue and surrender its charter.

### Tennessee.

**KNOXVILLE, TENN.**—The Knoxville Street Railway Company has accepted its franchises.

**OBION, TENN.**—The Obion & Tiptonville Rapid Transit Company has been organized to build a line between the two towns. The incorporators are G. B. Morris, W. M. Wilson, R. S. Lyons, T. J. Ogilvie, J. H. McDowell and T. C. Wilson.

### Texas.

**BEAUMONT, TEX.**—J. A. Hanson, one of the incorporators of the electric railway company, says a bond will be filed immediately and the construction of the road begun.

**GALVESTON, TEX.**—On application of the Guaranty Trust Company of New York, R. B. Baer has been appointed receiver of the Gulf City Street Railway, which was absorbed by the Galveston City Railway Company some years ago.

**SHERMAN, TEX.**—J. McGeagh, representing an eastern syndicate, has acquired the Sherman City Street Railroad, the Electric Belt Railway of Sherman, and the Denison Street & Electric Railway. A double track connection between Sherman and Denison will be built by the new company known as the Sherman & Denison Twin City Electric Rapid Transit Company. Mr. McGeagh has bought 200 acres of land on which will be established county fair grounds, race tracks and pleasure parks. The contemplated extensions will increase the mileage from 14 to 27.

### Vermont.

**BENNINGTON, VT.**—The Bennington Electric Railroad Company and the Hoosick Railway Company have filed with the secretary of state a certificate of consolidation as the Bennington & Hoosick Valley Railway Company. Capital stock, \$160,000.

### Virginia.

**NORFOLK, VA.**—John L. Williams of Richmond is at the head of a syndicate which expects to acquire all the street railway lines of Norfolk.

### Washington.

**MYERS FALLS, WASH.**—W. B. Aris of Myers Falls and A. J. Ross, vice-president of the Exchange National Bank, Spokane, are said to be interested in a project to build an electric railway nine miles in length from Myers Falls to the Columbia river, using water power.

### West Virginia.

**PARKERSBURG, W. VA.**—Brown & Hazlett of Wheeling have been retained as consulting engineers for the new electric railway.

**PARKERSBURG, W. VA.**—Howard and Edward Hazlett, brokers of Wheeling, contemplate building a street car system in Parkersburg. They expect to organize a company to obtain franchises and put in the road.

**CHARLESTON, W. VA.**—The Capital City Electric Railway Company has taken possession of the Charleston Horse Railway, which was purchased some time ago at receiver's sale. Besides equipping with electricity the new owners will extend the line three miles, and have all in operation before January 1.

**PARKERSBURG, W. VA.**—As predicted in the DAILY BULLETIN of November 10, the promoters of the new electric railway have purchased the Park City Street Railway. The deal was closed November 24, and transfers the franchises, real estate and 500 ft. of 60-lb. rails. The new company was represented by W. N. Chancellor, C. H. Shattuck, John Busch, George A. Burt and their attorney, W. W. Van Winkle. Howard and Edward Hazlett, brokers and bankers of Wheeling, represent outside parties who are putting money into the road.

### Wisconsin.

**OSHKOSH, WIS.**—The Citizens' Traction Company has been granted right to lay additional tracks.

**RACINE, WIS.**—Citizens of Racine talk of building an electric railway to Waterford via Union Grove and Burlington.

**OCONOMOWOC, WIS.**—An electric street railroad scheme is promoted by the Oconomowoc Advancement Association.

**OSHKOSH, WIS.**—The Citizens' Traction Company's new ordinance is of doubtful legality, having been vetoed by the mayor and approved by the acting mayor.

**MILWAUKEE, WIS.**—A private telephone system including 100 miles of line and costing \$10,000 is being erected by the Milwaukee Electric Railway & Light Company.

**MILWAUKEE, WIS.**—It is said that the apparently defunct Citizens' Street Railway scheme has been taken up by parties interested in the Falk Manufacturing Company, and that the road will be put through if a liberal franchise is granted.

**MILWAUKEE, WIS.**—The council has indefinitely postponed the ordinance to extend the franchise of the Milwaukee & Waukesha Company. The project is believed to be dead. A coal storage and handling plant will be installed by the Milwaukee Electric Railway & Light Company.

**MADISON, WIS.**—The Madison City Railway was sold under foreclosure December 1, for \$110,000, being bid in by Trustee Newcomb for the bondholders. The bonds and interest due aggregate \$174,412. The plant, which is now a paying property, has been in the receiver's hands a year and a half.

### Canada

**STRATFORD, ONT.**—The city council has decided to call for tenders for a street railway franchise.

**VICTORIA, B. C.**—An extension of two years' time in which to complete its works is asked by the British Columbia Electric Railway Company.

## THE NIAGARA FALLS POWER COMPANY.

In the REVIEW for October brief mention was made of the work in progress of enlarging the plant of the Niagara Falls Power Company and a view of the new wheel pit was shown. The illustrations herewith show the building as

POWER HOUSE.

now extended to cover the entire pit and a later view of the new section of the wheel pit. The new section is 294 ft. long, making the total length 434 ft. The depth is 179 ft. The average width is 20 ft., which is increased at the top to make room for masonry walls 6 ft. wide, the distance

THE NEW WHEEL PIT.

between the walls being 21 ft. The new portion of the pit is to be lined with brick throughout, and it is the intention of the company to eventually so line the original pit also.

In the new section several important changes have been made in the details of construction. In the first installation the girders were built into the walls; in the new portion,

they rest on castings built into the brick work. Also the new turbines and the lower penstock elbows instead of resting on the girders built in the walls are to be provided with lugs and rest on castings in the brick work.

There will be four turbines placed in the new wheel pit to operate four exciters, thus providing an absolutely independent source of power for the exciters for the large generators.

## THE AMERICAN INVASION OF ENGLAND.

(As seen by an English Engineer.)

English engineers and those interested in the adoption of electric tramways are much exercised at the present moment on the subject of the equipment of tramway systems. It is held by many that the methods which have been so pre-eminently successful in the United States are not fitted for English conditions, and it is this opinion which forms the basis to the opposition to American plants. The question has become acute during the past few weeks, from the fact that the Central London Railway has placed its electrical equipment in the hands of American firms and that Glasgow has likewise determined upon adopting an American plant for working the experimental line. It is not difficult, however, to explain the reason why American interests are somewhat dominant in English traction tramway matters at the present moment. It has been the practice for some years when advocating the claims, the advantages and the economies of the over-head system of electric traction to quote largely from American experience and it will be within the recollection of many American engineers that it was quite a customary part of the proceedings, when considering electric tramways in England, to send a deputation to America to examine and report upon the latest practice that prevailed there; nor has this custom yet completely died out.

There is hardly a report published in this country by any of the authorities that is not in a great measure based upon the results that have been achieved in the United States. When a municipal corporation or a tramway company, therefore, proposes to equip its tramway lines for electrical working, it is not surprising that there should be a distinct leaning towards American methods. Moreover, it must not be forgotten that the most active exponents of electric tramway principles in England at the present moment are of American origin or have gained their experience in the United States. Speaking without any bias in the matter, the writer affirms with the greatest confidence that a great deal of gratitude is due to Americans, whether manufacturers or consulting engineers, for it is to their pioneering efforts that the progress we have already made is due. The most successful of the modern electric systems at present working in this country are American throughout and it would be idle to deny the usefulness as object lessons of the Dublin, Bristol, Dover and other systems which are built on American lines. It is claimed that there are numerous English contractors who are ready and willing to completely equip a tramway for electrical working if they are only given a chance, but there is nothing unpatriotic in being businesslike and it is obvious if an American house can offer a complete scheme in competition with an English house which may lack experience, it ought not to be surprising that any company or municipality which is doing the best it can for itself should hesitate to adopt an English system. It is a little

curious, also, to note that in some of the systems in this country that are reputed to be English throughout how many of the details in line construction are of American origin.

In the opinion of the writer, there will be in the near future considerable extension of American work in this country, and it is also equally clear that as soon as English engineering houses put themselves into a position to compete with Americans and will be disposed to copy the best American practice, there will be an adjustment in the market, and the Americans may find it difficult to beat us on our own ground. History will repeat itself. In the early days of electric lighting Americans showed the way in this country, and no doubt there were considerable heart-burnings on the part of English contractors, that they were frequently left out, but directly they began to improve their electrical work, it soon became apparent that home-made machinery could be made as well and as cheaply as American; there was practically no extension of American systems. There is this difference, however, that when electric lighting was first commenced in this country, there was not a great deal done in America; but in tramways you have a tremendous start; your systems have been worked out with exceeding care and precision. Various parts of the system have become standardized, and with the results of great experience at your disposal, it is natural to assume that you have acquired the very latest and the best methods. Not only does the practice seem to have been worked out with great precision, but the theory of the subject has been set forth with great skill. It would be foolish if English people refused to avail themselves of American experiments and experience.

There is, and probably always will be, more disposition to experiment with a view to effecting improvements than is generally the case in this country, and as Professor Ayrton pointed out a few days ago, "America is the laboratory of the world." In this country there must always be in electrical matters a limit to experimenting, for obviously a tramway company which is responsible to a body of shareholders would not be permitted to carry on extensive and costly trials, and the law of the country would absolutely prohibit any municipality embarking upon any scheme that had not been well tried and had become established practice. Having regard to these things, any one who approaches the subject in an unprejudiced spirit can not help the conclusion that it is to Americans we must look for much of the development of tramways.

There has been a disposition on the part of English engineers to criticise the details of American tramway practice. It is claimed that it is needless for us to go to America to buy engines. No one for a moment could and no one seeks to deny the splendid work carried out by English engine makers and they can rightfully boast of turning out an engine that has no superior in the world; but how many can claim to have made engines for tramway practice? It is said however that the conditions arising in electric traction do not differ materially from those which occur in lighting and mill work, but it seems to the writer that half an hour inside a tramway power house ought to convince one that the conditions are totally different from what is met with, for instance, in lighting work. The best known engine in this country for electric lighting, and it is in all respects a splendid piece of mechanism, was totally unable to meet with satisfaction the conditions arising in one of the most quoted

electric tramway power houses in this country and it became necessary to adopt the horizontal compound type of engine. Having regard to this experience, it is not surprising that the Tramway Company should send to the States for engines that had proved their worth for tramway purposes.

Quite recently, in a discussion on tramway matters, there was a tendency among the speakers to sneer at American engines and it was denied that a fly-wheel had the usefulness that seems to have become established by American experience. To an ordinary person who has some cognizance of the engineering ability and experience of American engineers, it seems somewhat absurd to think that on such an important matter as fly-wheels the Americans are hopelessly wrong. A further criticism on American methods is that there is too much tendency to change practice in tramway matters, but that is a most curious objection to bring forward, because the changes that have been made in lighting systems in this country are very remarkable and although the uniformity of English electric lighting stations is constantly dwelt upon, it would not be difficult to select several stations where three or four types of plant are in existence. There must of necessity be a process of evolution and it seems futile to object to American methods merely because their experience suggests occasional alterations of their practice.

It may be a matter of some interest to show the tramway undertakings that have been completed and are about to commence operations in this country for the purpose of showing how far American methods are being adopted.

Lines equipped, or to be equipped, by American contractors:

|                               |             |
|-------------------------------|-------------|
| Bristol.....                  | £ 27,249    |
| Central London Railway.....   | 3,244,000   |
| Coventry.....                 | 40,000      |
| Douglas Southern Tramway..... | 41,000      |
| Dublin.....                   | 120,000     |
| Glasgow.....                  | 20,000      |
| Dover.....                    | 27,000      |
| Middlesborough.....           | 143,000     |
| Plymouth.....                 | 3,683       |
|                               | <hr/>       |
|                               | £ 3,665,332 |

Lines equipped or to be equipped by English Contractors:

|                               |             |
|-------------------------------|-------------|
| Bessbrook & Newry.....        | £ 10,000    |
| Blackpool & Fleetwood.....    | 156,500     |
| Brighton & Rottingdean.....   | 20,000      |
| City & South London.....      | 958,149     |
| Giant's Causeway.....         | 45,087      |
| Guernsey.....                 | 22,686      |
| Hartlepool.....               | 12,000      |
| Isle of Man.....              | 188,462     |
| Kiddeminster & Stourport..... | 50,000      |
| Liverpool Overhead.....       | 707,829     |
| South Staffordshire.....      | 266,346     |
| Waterloo & City.....          | 80,079      |
| Leeds.....                    | 80,000      |
| Plymouth.....                 | 2,171       |
|                               | <hr/>       |
|                               | £ 2,580,309 |

The foregoing figures do not in every case show the value of the electrical equipment; for instance, in the Central London Railway, the figures represent the total amount of the contracts and the same applies to the Liverpool Overhead and the City & South London Railway; in all the other cases, however, the figures practically show the value of the electrical equipment.

London, Dec. 1, 1897.

## WHAT THE STARTER SAID.

The Bertillon Transfer — Baltimore Tired of Near Crossing Stops — Saengerfest in Columbus X-ray a Boomerang — A Cow Case.

"Let 'er go", sang out the starter, while at the same instant two bells were accompanied by the last day car gliding away into the gray fog. Then he filled his pipe, and the boys gathered around for the evening chat.

Did you notice that eastern paper I had here yesterday? Well, there was a story in it, hatched up by some reporter. Seems he got hold of one of those transfers as has the faces pictured out with beards and mustache and the old woman on, so as to punch the kind of passenger you give it to. Now he wasn't satisfied with marking a man by his Burnsides or bald head, but wants the repertoire extended to include whether the hair is red or black; and if his clothes is hand-me-downs or custom tailor; and a punch for the lady with store teeth, and so on. Guess he must have tried to ride on one as was punched fer the man with brains, and the con wouldn't take it.

\* \* \*

I hear the folks in Baltimore have got good and tired of stopping at the near crossing, and wading ashore in the mud. Now the women have raised a howl and the fellow who got the ordinance passed wishes he was at Klondike. It was just the same way in Brooklyn and Cleveland, and a lot more places. I told you it wouldn't last long. You can't run the nose of your car over the crosswalk, and so everybody has to land in the street. And the passengers tries to crowd out the front door and gets fouled in the baskets and kits of tools and things, and the dickens is to pay generally. Then they blames the motorman for wearing a storm coat and taking up so much room; and by the time you gets your bell there is a procession of teams headed across your track like an industrial parade, and you has to wait; and by the time a man has run a mile down town he's away off his schedule. No, sir; the old way at the far crossing is the correct thing.

\* \* \*

One of the Columbus boys was along here yesterday and he gave me a good one. Seems the superintendent, George Scranton is his name, rooms in a tony apartment house, and as he stays down until the last car is in for the night he likes to sleep late in the morning. Things went all right for a while, until some young ladies as came to town to study music, took the room next to his'n. About 7:30 a. m. they would begin at the piano and kept it up until they went to the school, at nine. The first few days he says nothing, but after a while it got tiresome. He sent in a polite report of his case, but the next morning they began earlier than ever, and when one was tired the other would spell her. Bang, thump, bang! scales and all kinds of musical pieces without any tunes. Then this Scranton gets weary and complains to the owners, and they tell him as how they was awful sorry, and the like of that, but it was a free country and they couldn't do nothing.

Scranton says, "Anybody got a right to play all they wanter round the premises?"

And the man says, "Yes, as long as it is in their own room."

Well, he didn't do a thing to 'em. He goes out to the company's park, and unpacks the biggest barrel organ you ever see. It was one as belongs to the merry-go-round. He gets some of the boys to fetch her down on the last car, and it took six of them to get her up the stairs. Then he rigs a motor from the light wire and was ready for 'em.

The next morning the musicians opened up the ball bright and early. Scranton was tired, 'cause he staid up late connecting things up, and when they woke him up he just turns over and sets the controller in the fourth notch. The machine got her headway quick, and "White Wings" and "Sweet Violets" could be heard six blocks. It roared and ripped, and you'd a thought the heartstrings of a cyclone was being torn out. Of course the girls made a miss, and when the music factory had run about 15 minutes he shut her off. Then he gets up and dresses, but the last thing when he leaves is to throw her on again. All day long it played and played, over and over again, until the neighbors was all out in the street, and all the tenants had served notice on the agent that they were going to move out.

The agent couldn't find Mr. Scranton until most dark. Said he was out testing the suburban line for leaks on the bond wires. The agent was crazy, but Scranton reminds him as how he said tenants had a right to music so as it was in their own room.

The fellow tumbled.

"How long do you intend to keep her there!" says the agent, sort of friendly like.

"Wall, as I am very found of music," says Scranton, says he, "I calculate I wouldn't open the park before June 1, and I might just as well have the good of the organ; and besides the folks as made it says as it is better for it not to stay idle out in the park. Might get rusty."

Well, the agent fixed the girls, and now nobody in the plant dares play so much as a jewsharp while Scranton is asleep.

\* \* \*

I've noticed where the companies has been exposing fraud hurts by putting the folks under the X-ray and showing as how the bones they claimed was cracked was as straight as a die. But did you see how a woman got \$10,000 on the Elgin City Railway the same way? She claims she was hurted, and, the company thought as how it wasn't so. But she up and has a X-ray picture made of the inside of her hip and there they was, just like her doctor said all the time. Still there is a good deal of doubt as who was to blame, the company or her, and the case has got to be tried all over. Seems to me, though, it would be a good scheme for the company to get these X-ray landscapes before it got into court, and maybe sometimes it would be cheaper to settle than law it.

\* \* \*

Some folks wants the hull earth. The other day the interurban which is building down to Peory, and runs through some farms, had a cow case. Seems some fellow left a gate open on the right of way, and a cow gets out, and into a orchard and eat so many apples she foundered. The farmer sends for the old man, who viewed the remains, and couldn't deny as how the cow was dead and as big around as a generator; so, rather than have any row, he pays the old hayseed \$35, and throws in the carcass. Now, they say every dried up old heifer in that hull section is being fed on dried apples and warm water, and driven on the right of

way to swell up and die and get damages. The old man had to hire boys to go out and pick all the apples off the ground for half a mile wide and four miles long, so they wouldn't have a case on him."

"Well, the owl's waiting, and I'll go home."

THE STARTER.

### PERSONALS.

E. D. Du Bois, superintendent of the Citizens' road, Muncie, Ind., was among the REVIEW callers.

Frank J. Jones, vice-president of the Citizens road, Memphis, visited Chicago for several days early this month.

C. D. Wyman, general manager of the New Orleans Traction Company, made the REVIEW a pleasant call on his recent trip north.

D. W. Pugh, whose name is synonymous with the Stephenson Car Company, New York, called on many of his western friends in Chicago, last week.

George W. Hommel, who was for some years general superintendent of the Milwaukee City Street Railway Company, has removed to New York.

Asa W. Field, cashier of the Union Street Railway Company, Saginaw, Mich., was presented with a gold-headed cane by the employes of the road.

A. L. Young, president of the Central Railway & Electric Company, New Britain, Conn., and the board of directors were re-elected at the annual meeting.

W. A. Smith, general manager of the Omaha Street Railway, spent several days in Chicago, during his December trip east, where he went to inspect several roads.

Captain Robert McCulloch, general manager the citizens road, St. Louis, and Richard McCulloch, electrical engineer, were REVIEW visitors when in Chicago early this month.

A. E. Lang, president of the American Street Railway Association, and president of the Toledo Traction Company, has been quite seriously ill, but is much improved and able to be out again.

S. F. Hazelrigg, superintendent of the Atlantic Coast Electric Railroad Company, has left Asbury Park, N. J., for a voyage to Rio Janeiro, Brazil, which will necessitate his absence for several months.

R. Semmes, general manager of the Mobile Street Railway, was one of the last victims of yellow fever, which he contracted late in November. After quite a hard siege he pulled through and is recovering.

H. C. Mackey, formerly assistant auditor of the Minneapolis Street Railway Company, has been appointed auditor of the Milwaukee Electric Railway & Light Company and will assume his new duties January 1.

L. S. Wright, general manager of the Schuylkill Electric Railway Company, has resigned on account of failing health. The employes at Pottsville, Pa., presented him with a gold-headed cane as a token of their esteem.

At the recent meeting of the board of directors of the Leavenworth Electric Railroad Company, E. E. Coombs, auditor and cashier, was selected to fill the position of general manager left vacant by the resignation of L. M. Erb.

On December 2, M. B. Dunham, of Warren, Pa., president of the Titusville Traction Company was badly hurt by the explosion of the boiler of a dinkey locomotive used on the line. Three of the men were also injured, two of them fatally.

Ira Bishop, who has been superintendent of the Piedmont division of the Alameda, Oakland & Piedmont (Cal.) Electric Railroad, has been appointed general superintendent, succeeding B. H. Fisher. The change is due to a change in the ownership of the road.

E. H. Mather, superintendent of the New Haven (Conn.) Street Railway, entered upon his duties as superintendent of the Central Railway & Electric Company of New Britain on November 22. At the annual meeting of the latter company he was elected treasurer also.

M. K. Bowen, general manager, and W. B. Walker representing one of the largest stockholders of the Chicago City Railway, were elected directors to fill resignations of E. M. Phelps and James C. King. Other changes in the board are announced for the annual meeting, January 15.

George R. Folds, of the Twin City Rapid Transit Company, was the recipient of a very flattering offer by the Nassau road, Brooklyn, to become its claim agent. The Twin City, however, made it an object for Mr. Folds to remain and continue the service in which he has done such excellent and satisfactory work.

Thomas H. McLean, president and general manager of the street railway system in the City of Mexico, is taking a few weeks' rest and visiting his railway friends in the States. He is in excellent health, and has won a high place in the esteem of the people and officials of Mexico City, and has revolutionized the service. He expects to commence on the work of changing to electricity during the coming year.

Richard E. Danforth has been appointed superintendent of the Buffalo Railway Company and the Crosstown Railroad Company, succeeding P. C. Deming, who has resigned. Mr. Danforth has been connected with the Buffalo street railways for several years and leaves the position of superintendent of the Buffalo, Bellevue & Lancaster; this position is now filled by F. D. Jackson recently with the Niagara Power Company.

On October 1, E. G. Johnson, who has been superintendent of the Brigantine Transportation Company of Brigantine Beach, N. J., was appointed superintendent of the Philadelphia & Brigantine Railroad and will henceforth manage both roads. Mr. Johnson has succeeded where others failed, and the new appointment indicates that his work is appreciated. It is understood that the Brigantine Transportation Company will make extensive improvements in the spring.

### OBITUARY.

Dwight S. Smith, one of the builders and owners of the Jackson (Mich.) Street Railway Company, died at his home on the morning of November 24, after a short illness.

John Savage, superintendent of the Detroit & Oakwoods suburban, was instantly killed in a wreck on his road, December 4. Mr. Savage had been in railway work in Detroit constantly for the past 16 years, and was highly thought of by officials, the men, and the public.

We regret to note the death of Ross Mackenzie, which was announced a few weeks ago in a dispatch from Nelson, B. C. Mr. Mackenzie was born in New York, but removed at an early age to Toronto. For years he has been engaged in railroad and street railway work. Shortly after the completion of the Niagara Falls Park & River Railway, he was offered the management, which he held until a year ago, when he resigned to accept a position with the Crow's Nest Pass Railway.

An electric car on the Oregon City line was held up by two robbers and \$90 was secured from the 35 passengers aboard. When the car was stopped the conductor thoughtfully turned out the lights and enabled the passengers to hide some of their valuables and money. As soon as the car arrived in Portland the police were notified and detectives were sent in pursuit of the robbers.

## A CHEAP AND PRACTICAL VESTIBULE.

Each year adds to the number of states which by statute have made it compulsory to equip street cars with vestibules and managers in those states who have for the first time to comply with such a law can not fail to be interested in the device here illustrated. This cheap and practical vestibule was designed by S. P. Baird, superintendent of the Portsmouth Street Railroad & Light Company, Portsmouth, O., to whom we are indebted for the illustrations and data. This description is offered in the hope that it may prove of advantage to some road which finds it difficult to make both ends meet.

The line drawing shows a horizontal cross-section of the vestibule in place on the car and makes clear the details of construction of the top and bottom portions of the frame. The supports of the vestibule are two rods of  $\frac{7}{8}$ -in. round iron extending from the platform floor to the hood. The front sash are from old horse cars that were condemned.

THE PORTSMOUTH VESTIBULE.

The side sash are transom sash; in these the glass is in three pieces, so that in event of accidental breakage the cost of replacing the glass will be less.

The four photographs reproduced were taken at intervals of four minutes and make evident how quickly the vestibule may be put on the car. The first is car No. 17 ready to

years, being removed in the spring and replaced in the fall. They were built in the company's shops at a cost of \$8 per car, including, of course, two vestibules.

## STORAGE BATTERY FOR THE BUFFALO RAILWAY.

General Manager H. H. Littell advises us that the Buffalo Railway Company is about to install a storage battery plant in connection with the Niagara street power house. The size of this plant will make it a special object of interest to railway engineers and its success, which is confidently predicted, will mark advancement in power station practice. The contract for the battery has already been awarded and when it is completed and installed, which will be some time in March next, it will be operated in connection with the steam and converter plant now used by the company. The battery will be charged from the converters. Should there be a sur-

plus of power from the Niagara transmission at any time, or if the steam plant is not worked to its capacity during the day, the battery will store the surplus current until such time as it is needed. The current thus accumulated will be available whenever the demand is more than ordinarily heavy, or possibly, when some part of the present plant is out of repair temporarily. The greatest demand for power is at 6 p. m. and this is supplied by starting up an extra engine and dynamo but the charged battery is to furnish the current at such times.

The battery will have a capacity of 1,200 h. p.-hours and will have 290 cells, each weighing 1,200 lbs. The iron tanks will occupy a floor space of 2,800 sq. ft. A new fire proof building, with a frontage of 10 ft. and 70 ft. deep, will be erected for the battery adjoining the Niagara street power station. Work on it will commence at once.

This move has been made only after careful investigation, and the railway company has such faith in its success that the tanks, in which the cells are placed, will be made much larger than necessary to meet present requirements. At any time desired more plates can be added, without enlarging

PLAN OF BOTTOM.

receive the vestibule; No. 2 shows the vestibule on the sidewalk ready to be placed in position; No. 3 shows the men at work; No. 4 is the car ready to run; time, 12 minutes.

Vestibules of this pattern have been in use for three

the tanks, so as to increase the capacity of the battery two-thirds.

The Niagara Falls Power Company supplies the Cataract Power & Conduit Company with a 24-hour service. As the street railway lines are not operated all night, there will be much surplus power for charging the battery which will be discharged during the times of heavy loads, morning and evening. The adoption of the storage battery for this work is quite in keeping with the progressive spirit of the company.

### BAD COLLISION AT BALTIMORE.

During the heavy fog which prevailed on the morning of November 21, two cars on the suburban road of Baltimore, the Baltimore Northern Electric, met head on, the accident resulting in the death of both motormen and the very serious injury of some of the passengers. The accident occurred on a curve at the foot of a grade, down which one car was coming rapidly, and to mount which the other car had turned on full current. One motorman was instantly killed, nearly every bone in his body being broken. The other lost a leg, was terribly crushed and died in a few minutes after removal from the wreck. One conductor was cut in the face by broken glass until he was scarcely recognizable and lost the entire lower part of one side of his face. Both motormen leave families; one of them a pair of twins only three days old; the other a child of three weeks, making the case an unusually pathetic one.

The cars were demolished, one telescoping the other past the middle. The coroner's jury found that one car crew disobeyed orders, by not taking a switch and waiting for the other car to pass.

### CHIEF ENGINEER FOR ALLEY L.

A. L. Hadin has been appointed chief engineer of the power plant of the South Side Elevated, Chicago, and is now engaged in superintending the erection of the machinery. The selection of Mr. Hadin is an excellent one as he has had a very extensive experience in the management of steam and electrical machinery. For the last six years he has been chief engineer of the Aurora (Ill.) Street Railway, and during this time remodeled the power plant, and by his careful management and the design and construction of many labor and money saving devices brought it to a high state of efficiency. Prior to taking this position Mr. Hadin was for seven years in charge of the plant of the Hutchinson (Kan.) Water, Light & Power Company.

### EMPLOYEES' EXAMINATION IN ST. LOUIS.

Superintendent George W. Baumhoff, of the Lindell Railway, St. Louis, invited all the motormen and conductors on his road who could be spared from duty to report at the general offices on Saturday night, November 27, and had there a little surprise in the shape of a list of 50 questions chosen with a view to testing the competency of the men for the positions which they hold. The time allowed was 70 minutes, and nearly all succeeded in completing their papers in less than that time. Prizes of \$25, \$15 and \$10 were awarded for the three best papers.

### A MUNICIPAL LIGHTING PLANT IN CALIFORNIA.

The "Argus" of Alameda, Cal., says: "This city spent more than \$42,000 on its light plant last year, \$22,000 the year before, \$27,000 the year before that and is likely to spend more than \$20,000 this year. The municipality could buy all the light it uses for \$10,000 a year at the outside. The light it sells is undoubtedly sold at a loss. As a business venture Alameda's experiment is a rank and wretched failure."

### A NEW WAY OF FIGHTING.

The North Hudson County Electric Railway in extending its lines to Jersey City was opposed by one of the property owners along the line, Mrs. Christiana Parrott, who sought to prevent the company from setting a pole in front of her lot by the novel method of getting into the hole herself. She held the enemy at bay for a time but growing tired of standing placed a board across the hole and sat with her feet in it. The men finally decided to put the pole in anyhow and when it came to the point the woman gave way fearing injury.

### NEW PUBLICATIONS.

The University of Wisconsin has published as one of the Bulletins the thesis of George Henry Trautmann on "A Comparative Test of Steam Injectors." Nine injectors of different makes were tested according to a definite system so that they can be accurately compared in all particulars.

The Electrical Review, London, with its issue of November 12, 1897, celebrated its twenty-fifth birthday, and took advantage of the occasion to give a general review of the progress in all the several lines of electrical work during the past quarter of a century. The special articles were contributed by men high in their respective branches of the electrical industry, and constitute a most valuable and interesting history. Advertisers also availed themselves of the special features and large edition to occupy a generous amount of space; and both the editorial and business departments of this excellent weekly are deserving of much credit for their good work in this number.

"Russell's Convention Dates" published at Newark, N. J., is a paper which can not fail to prove of great value to street railway managers who wish to know in advance of trolley parties and sight-seeing trips to be taken by conventions scheduled to meet in their own or neighboring towns. The paper is a weekly now completing its first year and its success shows that there was a field for it. It is a list tabulated alphabetically according to states and towns of the places of meeting, giving the name of the organization, the date of meeting, name and address of the secretary, and the class of the meeting, whether district, state, or national. It covers Canada and British America as well as the United States. All announcements are kept standing until after the date of the meeting.

The "Power Catechism" has just been issued from the press by the Power Publishing Company, 146 World building, New York. Cloth, \$2.00. It comprises, including the index and tables, 226 pages, and consists of correct answers to direct questions covering the main principles of steam engineering and the transmission of power, and in accordance with our latest knowledge, compiled from the regular issues of Power, after revision and extension. This work is to be highly recommended to those who are seeking specific information on the subjects treated as the answers given are direct and as complete as they could well be made in a book of this kind, glittering generalities being carefully avoided. The index and the table of contents have been carefully prepared and enable one to find the subject sought very readily. The catechism was prepared under the direction of F. R. Low, editor of Power.

COMPRESSED AIR IN NEW YORK.

On August 3, 1896, three cars equipped with the Hardie system of compressed air motors went into regular service on the 125th street line, New York. The cars were run in between other cars and had their own schedule. The demonstration was continued until August 2, 1897, when the air cars were withdrawn. The daily press throughout the country lent its columns and influence to the experiment and few features of street railway work have ever been better cared for in this respect. The cars maintained good running time and the service was generally satisfactory to the public; notwithstanding the favorable conditions, the year's demonstration had closed without a contract for a continuation of the compressed air car service, or its adoption by any other road in this country.

On August 17th last a test was made on the Manhattan Elevated, a specially constructed locomotive having been built for the purpose. The air power people labored under some disadvantage on account of the overweight of their engines, which on arrival had to be reduced from 46,150 lbs. to 44,730 lbs. This necessitated the removal of five bottles reducing the air storage from 193 cu. ft. to 163 cu. ft. The tests were made with trains of three, five and four cars; one trip on each of three nights. The pressure with the four-car train fell from 2,360 lbs. at the start to 180 lbs. at the finish. The train made the usual station stops and carried passengers. Henry C. Cooke, general manager of the American Air Power Company, in his report to the president, says of this performance: "The motor hauled all the various loads and performed all the tasks it was set to do, never having failed in hauling any load, but lost eight minutes time over the schedule when the first trial with five cars (each loaded with 14,000 lbs. of dead weight, and speed around curves limited to six miles an hour) was made. This was due to various causes, principally to inexperience in handling the engine, unfamiliarity with the road, restricting speed on curves to six miles per hour, and tardiness in starting from stations, due to smallness of starting pipes and valves, all of which can be corrected, and this trial must not be considered conclusive."

Theoretically compressed air undoubtedly possesses desirable features although we have yet to be convinced that a "self contained" car of whatever system, can ever be as economically operated on a line of any magnitude, as the car which is always in connection with the central source of power, where that power can be made at lowest cost and drawn on for much or little as the demand requires. The question is still an open one, almost as much so as it was in August 3, 1896.

At that time, we stated, that in our judgment, no two or three cars would ever solve the problem, but that the operation of a much larger number, say 20 cars on a line for a full year, would give some data of consequence. It by no means follows that a 20-car line will show the same cost per car per year as is shown by one car on a two or three car line. The trouble with the air system is that so much of vital importance is still an open question and General Manager Cooke in his report admits this when he says, "The records show that the 125th street cars use 100 to 450 cu. ft. of free air per mile traveled, which the Ingersoll Sergeant Drill Company estimates can be furnished at a cost of 2.8 cents per 1,000 cu. ft. of free air, compressed to 2,000 lbs.

which, including re-heating, is equal to 1.33 cents per car-mile."

The actual cost for any considerable service apparently is still contingent on the correctness of the estimate of a concern having air compressing machinery to sell. The year has not been without progress for the American Air Power Company, as it has effected the sale of the English patents to a strong English syndicate composed of well-known and influential men. These gentlemen have incorporated a company with \$750,000 capital for the purpose of promoting the business; first in the city of London and later throughout Great Britain. Interest has also been aroused and important contracts are stated to be pending for Germany and other foreign countries.

McLEAN'S GOOD WORK IN MEXICO.

When Thos. H. McLean assumed the presidency and management of the street railway lines in the city of Mexico, he found abundant opportunity for the introduction of modern American methods of operation. The owners and the public and the government considered they had a finely managed road, and would have been satisfied with simply a continuation of the former methods. The needed improvement, however, which at once became apparent to Mr. McLean, was something which he discerned would have to be worked out gradually.

The accounts for the first complete year under his management have just been made up, and the showing is as pleasing to the stockholders as it is to Mr. McLean's friends. The earnings have been increased nearly \$95,000, and the entire increase carried into the net earnings. After paying a 6 per cent dividend of \$482,000, a surplus of \$37,000 remains towards an extra dividend in 1898. Following is the statement:

|              | EARNINGS.   | EXPENSES.   | NET.      |
|--------------|-------------|-------------|-----------|
| 1897.....    | \$1,614,575 | \$1,004,680 | \$510,804 |
| 1896.....    | 1,519,519   | 1,095,012   | 424,507   |
| Increase.... | \$ 94,056   | (decrease)  | \$ 95,387 |

The winter months of December, January and February are those of poorest earnings. The gain in the net is further emphasized by the fact that all kinds of fodder during 1897 have been unusually high in cost, and with much lower prices in sight for the coming year, even better gains are confidently expected. The motive power is mules, which, of course, does not admit of the created travel possible in an electric or cable system.

INDIANAPOLIS 3-CENT FARE CASE.

On November 20 the motion to dismiss the Indianapolis 3-cent fare case was argued in the United States Circuit Court of Appeals. December to the decision of the court was handed down by Judge Woods, the appeal being dismissed on the ground of want of jurisdiction. The court says: "There is a distinct assertion that there is a contract right which has been impaired, and unless the contrary is clear it makes a case of which this court cannot take jurisdiction. There is too much foundation for the contention to admit of the inference that it is made in bad faith, and that being so, the question is one for the supreme court and not for this court."

Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.

The Akron Street Railway & Illuminating Company has purchased for \$400,000 the line of the Akron & Cuyahoga Falls Rapid Transit Company, extending a distance of 20 miles between Kent and Barberton, O.

The Portsmouth Street Railway Advertising Company has been incorporated at Portsmouth, Va. The capital stock is \$5,000, and the officers are W. H. Triol of Philadelphia, president; and William E. Stoakes of Philadelphia secretary and treasurer.

The Williams & Moore Railway Jack Company of Chicago made an assignment November 18 to Lucian M. Williams. The assets are estimated at \$5,700 and the liabilities at \$13,000. The company will be reorganized and the business, which has been good, continued as before.

W. A. Shirley, secretary of the Wheeling (W. Va.) Railway Company, writes us his company has applied for a charter for a park for pleasure resort purposes at the north end of Wheeling Island, and intends to have a first class track for horse and bicycle racing, base ball and other amusements.

The Union Electric Construction Company has been incorporated at Des Moines, Ia., to build and equip electric railways and manufacture street railway appliances. The capital stock is \$5,000,000, and the incorporators are William B. Purvis, Halsey J. Tibbals, B. F. Taylor and John S. Carter.

The Skinner Electric Brake Company has been incorporated at New York, commencing with \$5,000 capital stock. The incorporators are James D. Ganner, Brookline, Mass.; Frank L. Pashaw, Canton, Mass.; E. S. Shepherd, Attleboro, Mass.; Benjamin Pope, Boston, and A. F. Copeland, Newton, Mass.

November 22 the following named gentlemen were re-elected directors of the West End, Boston: G. T. W. Braman, T. Jefferson Coolidge, William Hooper, Albert C. Houghton, Samuel Little, Joseph B. Russell, Richard M. Saltonstall, Samuel Spencer, Walter S. Swan, Stephen M. Weld, Moses Williams and Alfred Winsor.

The receiver of the Newark & Granville Electric Street Railway Company, Newark, O., has been authorized by the court to issue fare tickets, to be styled labor tickets, and sold at the rate of 10 for 25 cents, to be good when presented by laborers before 7 a. m. and between 5 and 7 p. m.; also tickets for school children at the rate of eight for 25 cents.

At a meeting of the board of directors of the Market Street Railway Company, San Francisco, W. J. Adams who has long had a place on the board resigned and was succeeded by I. W. Hellman, president of the Nevada Bank, who recently acquired a large block of the stock. Will H. Crocker also retired and Henry T. Scott was elected in his place. The board as now constituted is as follows: H. E.

Huntington, F. S. Douty, Charles Holbrook, C. G. Lathrop, N. T. Smith, Alvinza Heyward, J. L. Willcutt, I. W. Hellman and Henry T. Scott.

The last competitor of the Union Traction Company, of Philadelphia, the Hestonville, Mantau & Fairmount Passenger Railway has passed into the control of the larger company through the purchase of a majority of the stock by individuals interested in the Union Traction. The Hestonville Company operated 24 miles of track and 150 cars.

The Cleveland 3-cent fare ordinance has been temporarily defeated. It was lost on the first ballot and the motion to reconsider was lost on a tie vote. Councilman Hopkins, father of the defeated measure, states that another one, having the same purpose, will be introduced at the next meeting. It is directed especially against the Woodlawn avenue line of the Cleveland City Railway Company.

A recent circular of the General Electric Company of Berlin gives the electric roads for which apparatus was furnished by that company as follows: In operation, 28 roads with an aggregate length of 476.4 kilometers of single track, 841 motor cars and 566 trail cars. In construction, 21 roads with an aggregate length of 288.7 kilometers of single track, 425 motor cars and 156 trail cars. And in addition the company is preparing plans for 17 new roads or extensions to old ones.

The girls employed by the Western Electric Company formed the Occident Club for literary and social purposes about two years ago. It is self-supporting and managed entirely by the employees. The company has now provided two large rooms and furnished one as a library and reading room which may also be used for entertainments and has a seating capacity of 500; the other room is fitted up with a kitchen and lunch counters. The entertainments have been meritorious and well attended.

The report of President Nagle of the Chicago City Railway Employees' Mutual Aid Association for the year ending September 30, shows the association to be in a prosperous condition. The membership increased during the year from 1,884 to 2,021 and the insurance in force from \$942,000 to \$1,010,500. There were 12 deaths; the losses were paid by six assessments of 50 cents each, making the average cost per death 25 cents to each member; in 1896 the average cost per death was 34 cents; in 1895, 50 cents.

C. D. Wyman, general manager of the New Orleans Traction Company, writes us under date of December 1, that business through the South and especially in the city is very rapidly picking up, and that there is no more talk of the fever which has been exterminated. "You may tell all your friends that they are absolutely safe in visiting our city. If there has been any good worked by the scourge, it has been the general cleaning up of everything so we have on our best clothes now, and we were never in finer array to welcome our friends from all parts of the country. Just say for me in the next issue of the REVIEW, that they can all come; we will greet them warmly, treat them nicely, and send them away at the end of their visit, sound in body, refreshed in mind, and with a calm and equable conscience."

At the 24th annual meeting of the directors of the Melbourne Tramway & Omnibus Company, F. B. Clapp, managing director, presented a report which made a very favorable showing for the past year. The traffic receipts amounted to \$1,794,575 and the operating expenses were \$1,023,720. The total assets of the company are \$4,129,960 and the paid up capital stock is \$2,400,000. There is a reserve account for tramway renewal which amounts to \$1,000,000. During the past year there has been a very satisfactory increase in traffic and the prospects for the coming year are unusually bright. A dividend of 2 per cent was paid in January and one of 3 per cent was proposed in the annual report.

### BIRMINGHAM STREET RAILWAYS.

If the city of Birmingham does not soon follow up the report of its tramway committee by adopting electric traction it will lose its vaunted reputation of the most progressive city in England. Although it has a population greater than Boston and suburbs, its traction facilities would not be

TRAIN ON THE BIRMINGHAM TRAMWAY.

considered up to date in a country town in Massachusetts. The people of Birmingham have to ride behind noisy, dirty, puffing steam locomotives going to and from their homes. The illustration represents the locomotive, which is entirely encased, and a double deck trailer on one of the principal streets of Birmingham.

### SMITH AND HIS LAMPS.

"Smith of New York," who is so well known no other address is really necessary to reach him, is reaping the results of several decades of well conducted business, augmented by the successful effort to always be in the lead, and to produce goods which will make the user want more of the same kind. While the concern manufactures all kinds of lighting apparatus, it is best known to our readers for its car lights, both interior and for the dash. Some time ago when the other headlight makers went into a combination, Smith persistently refused to join them, saying he intended to be free and independent in his position to make and sell his goods to the mutual advantage of the buyer and himself. Special pressure was brought to bear to bring him into the fold, and after friendly overtures failed, the effort was made

to force matters by bringing suit on some of his patents. All these failed, however, and Smith of New York won out beautifully, and the only result was more attention was directed to his goods. He is furnishing every kind of headlight desired; through the dash, in front of the dash or on top, according to order. His lights are standard on hundreds of roads.

### GENERATORS IN THE UNION LOOP STATION.

The illustration represents the armature and commutator of one of the Siemens & Halske 1,500-k. w. generators now being installed in the Union Loop power house in Chicago. The arrangement of the armature winding and the connections to the commutator are clearly shown. This construction has all the advantages of internal fields; great radiating surface and maximum magnetic effect are to be found. The commutator is on the armature spider, and its construction and insulation are for large current capacity and long life. The armature winding is such as to give good ventilation. The poles will be 16 in number.

The armature was entirely assembled at the company's works and had to be transported on a special car, on account of its great size and weight. For such service the com-

1,500-K. W. SIEMENS-HALSKE ARMATURE.

pany has designed and built two or three flat cars, with two out-board bearings, on either side of the car near the middle. The armature shaft rests on these bearings and part of the armature projects beneath the car floor, but far enough above the roadbed to prevent any damage from obstructions there. By this means armatures of very large diameter can be transported and come beneath the limit of height prescribed by the railroad companies. This armature had to be moved for some distance through the streets, from the tracks of the Chicago & Northern Pacific to the station. The trucks were removed from under the car body and it was let down on skids and pulled along on rollers by means of a capstan. The rest of the machine is so divided as to be easily handled.

This is the first of three machines to be installed in a short time, and the work on the station is being pushed as rapidly as possible.

## MR. WESSELS' WITHDRAWAL.

It is with keen regret that we announce the early withdrawal from the air brake business of Edward J. Wes- sels who has resigned his position as managing director of the Standard Air Brake Company to take effect on March 1. Mr. Wes- sels needs no introduction to our readers for he is known the world over as the "apostle of street railway air-braking." For the past three and a half years he has been an incessant toiler in this field. He was called

E. J. WESSELS.

upon to take hold of the old Jenett Air-Brake Company, which at that time had not made much headway and was in fact unknown. As soon as he took hold, the trade realized that the business had passed into competent hands. Realizing that the business could not be successfully worked at long range he sold the Chicago factory and transferred operations to the east. His sale of the factory on advantageous terms, in the teeth of bad times,

at once arrested attention. Before long he had evolved a successful axle compressor. He then went abroad and appointed agents. In a few months he sold hundreds of air brakes in England, Belgium and Germany. Then he developed business in far distant lands and before long shipped hundreds of brakes as far away as Australia. Meantime he and the company's engineer invented and patented the first independent motor compressor for braking cars and trains. Automatic current control next claimed attention and soon apparatus was patented which has relieved motormen from responsibility. They only need to use the interlocking controlling handle in order to have command of the car or train. Mr. Wes- sels was no less successful as a salesman. He had no one to assist him and depended largely on judicious advertising to make sales. Every "ad." was written by him and his invariable rule was never to let an advertisement appear a second time and always to use a full page. His example was followed by many. Printers Ink pronounced his "ads." the very best that had appeared. He also advocated the use of air brakes, in graceful and accurate style, and his articles in the technical press always commanded attention. Members of the American Street Railway Association will recall his admirable papers in Atlanta and Montreal. His motto was "This one thing I do" and into the development of the air brake he threw his great energy, versatility and ability. For these reasons we are sorry to record his early departure from the field. It is safe to state that no enterprise in which he sees fit to embark will ever suffer from dry rot and wherever he goes there will be scores of friends who will give him a welcome.

The Brooklyn Rapid Transit Company has recently issued 100,000 copies of a little book entitled "Where and How to Go" which is full of information regarding schedules, places of amusement, suburban towns, etc. It is illustrated with 55 half tone views and a large map of Brooklyn and vicinity. It is very artistic and indicates that General Passenger Agent Kennedy is up-to-date in every way. Presumably the advertising in the book pays for its publication.

## THE MOORE RAIL DRILL.

A new rail drill, herewith illustrated, was designed by M. M. Moore, 88 East Ohio street, Chicago. It was the purpose to build a drill that could be easily operated by hand, readily attached to the rail and quickly removed so as not to impede traffic. The drill frame is clamped to a bar, permitting a side movement of 2 1/2 in. and a vertical adjustment. At the end of the spindle there is a ball bearing which makes the drill operate very easily. The drill is self-feeding. The frame is less than 5 in. in

FIG. 1.

FIG. 2.

height so that it can be left in place while the cars are running over the track, and permits its use between the rails. The frame is substantially built and does not spring while in use. A 1 1/8-in. hole has been put through a 7/8-in. web by one man in 1 minute and 20 seconds without springing the frame. Fig. 1 shows the drill in position and Fig. 2 with the top removed which operation can be done in two seconds. To illustrate how easily and quickly the drill can be used, one man using one hand drilled a 7/8-in. hole through a 7/8-in web in 45 seconds.

## ADVERTISING AT COLUMBUS, O.

The Columbus Street Railway Company last summer distributed some handsomely illustrated folders; one is devoted to the attractions at Olentangy Park and another has an outline map of all the lines and gives directions for reaching every part of the city by means of the street cars. Secretary P. V. Burlington says that these folders have been distributed to nearly all the towns within a radius of 50 miles and are handed to the incoming strangers at the Union Station of the steam roads. By making these folders so attractive it is found that fully 95 per cent are preserved. Besides these, programs are issued whenever there are special musical and kinetoscope entertainments at the park. During the season there were a McKinley night, a labor day celebration, Franklin Centennial, a convention of stationary engineers and another of insurance men, all of which were commemorated in a fitting way by programs at the park.

As is usual during the winter season the street cars in Cheboygan, Mich., have been removed from the trucks and placed on runners and will be operated as sleighs.

**NEW WEST END POWER STATION,  
BOSTON.**

The West End Street Railway Company, of Boston, has recently completed the new power station needed to provide for its Cambridge traffic. It is known as the Harvard Power Station and was built for an ultimate capacity of 7,200 k. w.; work was begun May 10, 1897. The building is of selected hard burned brick with free-stone trimmings and in general appearance resembles the company's Dorchester station; it has a frontage of 126 ft. on Boylston street and is 172 ft. deep. The roofs of both engine and boiler rooms are iron trussed, tile arched and covered with composition.

The engine room lying next to the Cambridge Parkway has a capacity for four and contains at the present time three 1,800-h. p. horizontal, cross-compound, Allis engines with independent jet condensers, direct connected to three 1,200-k. w. multipolar General Electric generators, designed to run at 80 r. p. m. At one end is a blank wall to provide for further extension. The floor of the engine room is 12 ft. above that of the boiler room which is at the street level.

On the basement floor under the engine room, on the same level as the floor of the boiler room are the condensers, air pumps and feed pumps, the engine room floor being cut away so as to place the apparatus in full view of the engineer at all times. The feed pumps comprise one steam pump 14 in. and 8½ in. x 10 in. capable of supplying water for 6,000 h. p. of boilers, and three pumps driven by electric motors through a counter shaft, each with a capacity of 5,000 gallons of water per hour at a speed of 30 r. p. m.

In the boiler room are six 500-h. p. water tube boilers with extension furnaces designed to carry a working pressure of 180 lbs., and arranged in three batteries of two each.

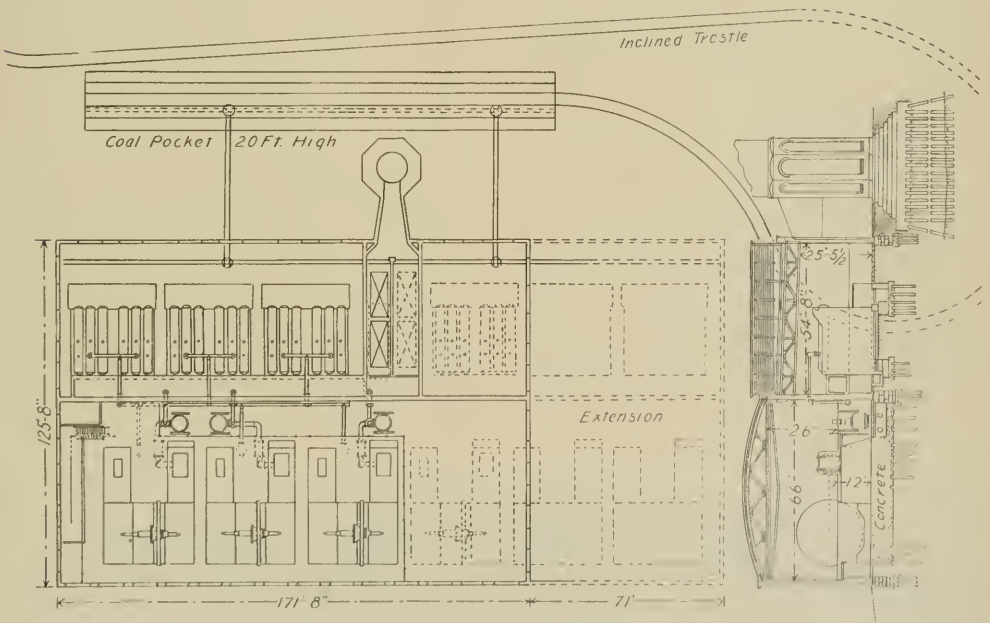

There are three feed water heaters of 800 h. p. each. The smoke flue is carried to and around the Green economizer, space being provided for another economizer of the same capacity. Under each section is a by-pass. On the roof above the economizer is a structure, shown in the illustration, to facilitate the removal of economizer tubes.

The stack is of brick and 226 ft. high; the inside is lined with fire brick and is 11 ft. in diameter; the stack is of ample size to take care of the contemplated ultimate boiler power, 6,000 h. p. It rests on piles which are covered with concrete to a depth of 5 ft., with a capping of granite 8 ft. 6 in. thick made up in five courses.

As shown by the illustration, the engines and boilers are placed back to back with all the piping in the engine room beneath the floor so that there is no obstruction to the use of the traveling crane. The crane is of seven tons capacity and is worked by hand.

The switchboard is at the north end of the engine room on a platform 8 ft. above the floor, commanding a full view of the engines and generators; the switchboard has the usual complement of meters, circuit breakers and switches. Leading from this platform is the office of the chief engineer where are a recording voltmeter, a recording steam gage and a telephone. Under the office on the basement floor is the test room equipped with instruments for testing the underground cables. These cables are carried from the station in a conduit through which the wires also return.

Coal will be handled at this station by a trestle and coal pocket adjacent to and in the rear of the building. From this pocket, through chutes leading from the bottom, it will be loaded into the coal or charging cars, which will run into the boiler room on a narrow gage track. Ashes will be removed over the same track.

HARVARD POWER STATION, WEST END STREET RAILWAY, BOSTON.

### QUICK-BREAK SWITCHES FOR RAILWAY WORK.

The General Electric Company has designed a line of quick-break, 500-volt switches which are especially adapted for street railway service. As may be seen in the illustration, the switch blade contact consists of two pieces connected to a common hinge and by a pair of helical springs, one on each side. In opening the switch the outer section of the blade, to which the insulated handle is attached, is withdrawn to an angle of  $30^\circ$  before the inner section

QUICK-BREAK SWITCH.

moves. The inner half of the blade is then forced from the clip by positive action and is drawn sharply to the outer half by the tension springs. This results in an extremely quick break and a wide gap, over which an arc cannot hold. Switches of this type are made for both single and double throw, with or without bases, and with either front or back connections.

### AN AUTOMATIC CAR FENDER.

The accompanying cut represents an automatic car fender designed by Obe. Cullison. It is attached to the wheel truck, is simple in construction, does not extend far in front of the car and is automatic in action. When striking an object the two coil springs are released and the fender shoots out about 3 ft., or this result may be effected by the motorman striking a foot lever attachment. A contact roller is at the front of the fender but there is little oscillation as the fender is attached to the truck. The fender can readily be changed from one end to the other of the car.

FENDER IN ACTION.

THE CULLISON AUTOMATIC CAR FENDER.

FENDER READY FOR ACTION.

### THE PROPER CONSTRUCTION AND USE OF ECONOMIZERS.

Henry G. Brinckerhoff, of Boston, presented a paper on this subject before the meeting of the New England Cotton Manufacturers Association held at Philadelphia in October and we give below a brief abstract.

The practice of heating the feed water in a separate vessel using the heat in the waste gases to do so and leaving the boiler to supply chiefly the heat necessary for the latent heat of the steam is one that has been extensively adopted by large steam users in all parts of the world. Such flue heaters are usually called economizers. A great many makers have constructed pipe heaters and with a few exceptions they have failed. These failures are to be attributed to three causes: 1. Not being of cast iron, the only practical metal to withstand the corrosive action of sulphurous gases. 2. Lack of capacity, it requiring time for the transmission of heat. 3. Lack of automatic cleaning of the pipes. The late Edward Green was the first to develop a flue heater embodying these essential features, whose absence in others was the cause of failure.

Important details of construction are: 1. The absence of all packed joints inside the brick work. 2. Easy accessibility to all parts of the internal surface. 3. The vertical pipes should be forced into the top and bottom headers by hydraulic pressure making metal to metal joints. 4. Each section should be tested to 350 lbs. per sq. in.

A well constructed economizer built under these specifications should last 20 years under ordinary care and attention. The care required consists in blowing off daily at the same time as the boilers. Every three months the soot should be cleaned out of the chamber below. Once a year the caps should be taken off and the interior of the pipes inspected; if the water is bad this should be done oftener.

### TROLLEY GETS STEAM ROAD PASSENGERS.

The traffic on the four-mile extension recently built by the Woonsocket (R. I.) Street Railway Company to Slatersville and Forestdale, is very gratifying to the company. The street railway is now a competitor of the New England Railroad for this business and the comparative conditions are as follows: The electric cars run at intervals of 30 minutes and carry passengers from any part of Woonsocket to Slaterville or Forestdale for 5 cents. The steam road runs from three to five trains per day, lands passengers at a point remote from the center of Slaterville and charges 10 cents, or 9 cents on 10-ride tickets. The result is that the electric line gets nearly all the passengers.

**THE SARGENT BRAKE SHOE TESTS.**

The Sargent Company, of Chicago, has since introducing its new "Diamond S" brake shoe made extensive service and laboratory tests and secured interesting data concerning this shoe. The "Diamond S" brake shoe consists of expanded steel and cast iron; a bundle of the expanded steel strips each of the same width and length as the brake shoe is placed in the mold and the cast iron poured about it, filling the open spaces in the steel core. Such a shoe is evidently strong and therefore safe against breakage, and uniformity can be secured by care in the manufacture. The service tests were made to determine the durability of the shoe and its effect on the tire.

"DIAMOND S" SHOE.

These tests were made on different railroads, the usual method being to equip one truck of the car with the "Diamond S" shoes and the other with the shoes to be compared with it; where two cars were always run together, one car would have shoes all of one kind. The service tests showed these shoes

to wear slightly longer than chilled iron, and about four times as long as the ordinary cast iron shoes. No cutting of tires was reported.

The laboratory tests to determine the frictional qualities of the shoe were made on the Master Car Builders' testing machine at the works of the Westinghouse Air-Brake Company, Wilmerding, Pa., by J. C. Whitridge, who worked with the machine under the direction of the M. C. B. Committee in 1896, and these tests are directly comparable with those made by the Committee.

Four shoes were tested: No. 2, soft "Diamond S"; No. 4, plain cast iron, cast at the same time and from the same metal as No. 2; No. 6, hard "Diamond S"; No. 7, plain cast iron cast at the same time as No. 6. Nos. 2 and 6 were tested at initial speeds of 65 and 40 miles per hour and at braking pressures of 10,733 lbs., 6,750 lbs. and 2,798 lbs., representing the pressures in heavy passenger service, medium passenger service and ordinary freight service, respectively. Three or more tests were made under each set of conditions.

Judging from the time required to grind the shoes to a bearing on the test wheel the "soft" shoes tested are thought to be approximately of the same hardness as the "hard" cast iron shoes tested by the M. C. B. Committee. A comparison of the results shows that the coefficients of friction of the "Diamond S" shoes are about the same or slightly higher than that for the hard cast iron of the M. C. B. tests, which is more nearly the hardness of cast iron shoes in general use than the "soft" cast iron taken as the standard by the Committee.

The experiments on steel-tired and chilled wheels show that practically the same coefficients of friction may be expected with the "Diamond S" shoe on the two wheels. The report concludes: "The steel appears to increase somewhat the frictional qualities of very hard cast iron brake shoes, but when soft cast iron is so used the addition of the

expanded steel does not materially affect the friction, the results not showing a uniform tendency either to raise or to lower the mean coefficient."

The coefficients of friction being considered the same, it is evident that the longer life of the "Diamond S" shoe gives it a marked advantage.

**WIDENER'S GIFT TO PHILADELPHIA.**

On November 25, P. A. B. Widener, who is so well known to our readers because of his extensive interests in electric railways in different parts of the country, and particularly as former president of the Union Traction Company, of Philadelphia, announced his intention of presenting

MR. WIDENER'S RESIDENCE.

his residence to the city for use as a branch of the free library. This is not the first instance of his munificence to the city, as a short time ago he promised his collection of paintings, estimated to be worth \$750,000, to the city in the event of the construction of a suitable building to accommodate them. The appropriation for this building was provided for in the recent loan bill passed by the popular vote.

**ILLINOIS STATE ASSOCIATION.**

The preliminary work of organizing an association among the Illinois street railways has been placed in charge of President Patterson, of the Bloomington City Railway, who has addressed the following letter to those concerned.

"It has been suggested by several street railway managers that a Street Railway Association be formed in this state, and I have been requested to write the different companies in this state to ascertain their views on the subject of forming such an Association, and I would suggest that a meeting of representatives of the different companies be held at the Great Northern Hotel, Chicago, on Thursday, January 5, 1898."

**RAE'S MOTOR CARRIAGE.**

Frank B. Rae, of Chicago, has designed a carriage to be operated from storage batteries. One motor is employed and this is geared to the rear wheels and is controlled so as to give four speeds. The carriage with passengers weighs nearly 2,000 lbs., and the battery capacity is sufficient to make a continuous run of 60 miles. Mr. Rae's long experience in electric railway and elevator work gives assurance of thoroughness and efficiency in the design of the electrical apparatus.

## KEYWAY CUTTER.

We illustrate herewith an ingenious and labor saving machine for cutting keyways on railway axles. This machine has two traveling beds for carrying axles, in each of which a deep "V" center is cut for holding the axle in place. By this means any sized axle from 1-in. to 6-in. in diameter, on being placed in the "V" receptacle, immediately assumes a proper position in the machine, that is, in an exact center line with the cutting device. This not only obviates the tedious necessity of lining up the axle with the machine, but renders it impossible to cut the keyway in any but a correct manner.

These traveling beds are worked by an independent crank movement, and the feed stroke is easily adjusted to any length of keyway, from 1-in. to 12-in. Each bed is entirely independent of the other, and the machine will cut one or two axles at a time as may be desired. The cutters are end millers with a continuous feed, which is worked by a single ratchet with two dogs. When making any stroke, the dog not in use simply slips back into proper position for feeding the cutter when its time comes. This machine will cut

MCGUIRE KEYSEATING MACHINE.

keyways 12 in. long, 1 in. wide and  $\frac{1}{2}$  in. deep in from 35 to 40 axles per day, with accuracy and ease. It is used, among others by the Terre Haute Car & Manufacturing Company, Terre Haute, Ind.; Jones & Laughlin, Ltd., Pittsburgh, Pa.; McGuire Manufacturing Company, Chicago. It is designed, made, and sold by the latter company, to which all inquiries should be sent.

In a recent Texas case the power of a city to make a condition that the franchise of a street railway shall be forfeited unless the line be completed to a certain point without the city within a given time is denied, the legislature having given the right to use the streets of the city subject to the consent of the city.

## FOURTEEN-FOOT CAR FOR MEXICO.

Through the courtesy of the Jackson & Sharp Company we have received photographs and description of a novelty in tram cars just built by that company. The car was ordered through a New York broker and even the manufacturer knows nothing as to its owner or its use except that it was shipped to Mexico. It is painted a bright yel-

THE YELLOW KID.

low and in the shop went by the name of the "Yellow Kid."

The length of the body is 9 ft. 10 in.; the length over all, 14 ft. 6 in.; the width at the sills, 5 ft. and the gauge 600 millimeters ( $23\frac{5}{8}$  in.). The closed compartment measures 5 ft. 5 in. and has two facing seats that will hold three people each; the open end is 4 ft.  $2\frac{1}{2}$  in. long and has two seats for three each. The platforms measure 2 ft. each. The wheels are 20 in. in diameter.

## HOLD-UP IN KANSAS CITY.

The street car hold-up is not confined to Chicago, the latest one reported being from Kansas City, Mo. At 10:30 p. m. on November 20, while the grip car was being shifted at the terminus of the 18th street cable line, the conductor was attacked by a negro, and on refusing to surrender the money in his care was shot in the side. The bullet was deflected by his pass-book so that it inflicted only a flesh wound. The gripman came to the rescue with a coupling pin and received a bullet in the thigh. The negro escaped.

## ATTORNEY BLODGETT, OF THE GENERAL ELECTRIC, MURDERED.

George R. Blodgett of Schenectady, the well known patent attorney of the General Electric, was shot during the night in an encounter with a burglar who had broken into his residence. He died the following morning from the wound. He was a man of marked ability and highly thought of by friends and professional associates. The company immediately offered a reward of \$5,000 for the arrest of the murderer, who it is said was trying to secure certain valuable papers of record which Mr. Blodgett had taken home to work on during the evening.

The street railway at Janesville, Wis., did not pay and on November 30, operations ceased for the winter.

Force Bain, consulting engineer of Chicago, has been busy with expert patent work for some time.

The Corning Brake Shoe Company has opened an eastern office at 35 Nassau street, New York, for the sale of the Corning brake shoe.

F. T. Ley & Co., of Springfield, Mass., have received the contract to build the Palmer & Monson (Mass.) Electric Railway, a short line connecting the two towns.

The Ball Engine Company of Erie, Pa., has mailed to the trade an illustrated pamphlet descriptive of its new governor which was recently described in the REVIEW.

The General Electric Company during the months of June, July and August, received orders for 278 generators, aggregating nearly 1,000 k. w., for lighting purposes alone.

S. C. Strock, dealer in poles, piling, ties and timber, 11 Broadway, New York, reports a very good year considering the unsettled state of business, and that the outlook for 1898 is splendid.

The Missouri Car & Foundry Company of St. Louis has acquired the Madison Car Works at Madison, Ill., which have stood idle a year, and will operate the plant in connection with its own works.

The Cincinnati Manufacturing Company states that it has found that the sales of conductor's punches for use on street railways very satisfactory and growing steadily. The management looks forward to a much larger trade in punches during 1898.

The Fuel Economizer Company, Matteawan, N. Y., reports that the year's business has, on the whole, been satisfactory. The prospects are much brighter and the company looks forward to a large increase of business immediately after the new year.

The Rooke Register Company has been incorporated at Peoria, Ill., to manufacture street car fare registers. The capital stock is \$10,000; and the incorporators are George F. Rooke, C. A. Jamison, James Danley, L. H. Seltzer, Arthur Keithley and others.

The Cravath Manufacturing Company, 825 Monadnock building, has come into existence during the past year and has done much pioneer work in the way of showing railway managers the advantages of current recording instruments on each car. It expects to reap the benefits of these efforts the coming year.

The Joseph Dixon Crucible Company has within a few months placed on the market two products of great importance to metal workers, the anti-flux known as "brazing

graphite" for liquid brazing and a brazing crucible for use with this process. The latest crucible is of a form particularly adapted for bicycle manufacturers.

Meysenburg & Badt of Chicago are the representatives of the Weston Electrical Instrument Company, the Helios Electric Company, the Excelsior Electric Company and other concerns manufacturing electrical machinery and appliances. This firm also does a brokerage and contracting business for electrical construction, including power houses and railways.

Frank J. Sprague of New York has received the contract to equip 120 electric motor cars for the South Side Elevated Railroad, Chicago. As Mr. Sprague's system of train control is a new departure in electric railroading the directors hesitated to award the \$275,000 contract until a 17-days' practical test had demonstrated its efficiency and safety to their entire satisfaction.

The American Engine Company, Bound Brook, N. J., writes: We are glad to say that the year's business has been quite satisfactory to us, and we look forward hopefully to the coming year expecting business to steadily improve. We have completed our full line of direct connected generators and American Ball engines, and find a very satisfactory trade in these.

The Electric Railway Equipment Company writes: Our business for the year 1897 has been excellent. We have had a very heavy demand for our steel tubular poles; and during the year we have brought out several specialties which have met with marked success. We are now figuring on considerable work for construction in the early part of 1898 and anticipate a good year.

The Wells & French Company, Chicago, has the Price momentum brake on street cars in different parts of the country for trial and very favorable reports of their operation have been received. The Citizens' Street Railroad Company, of Memphis, has ordered momentum brakes for seven large double truck cars. Inquiries and orders in hand indicate a prosperous season in 1898.

The Morden Frog & Crossing Works, Chicago, writes: We are pleased to report a marked increase for this year in our street railway business, and from present indications, it will be better in 1898. During the present year we have added another engineer to our staff, assigning him specially to street railway work, and have also added to our machinery so as to insure prompt filling of orders.

The Taunton Locomotive Manufacturing Company, Taunton, Mass., writes: We think we have reason to look forward to a good business for our street railway department for the year 1898. We have sold 32 snow plows this season which is in excess of any previous result. There has been no change in the personnel of our firm. We have appointed J. M. Denniston, Chicago, as our western representative.

S. D. Merton, formerly secretary of the Heine Boiler Company, has organized the firm of S. D. Merton & Co., with headquarters at 317 Security building, St. Louis, and

is prepared to design and build heavy machinery foundations, boiler walls, etc., such work as any mason can do after a fashion, but very few are able to do properly and yet keep the cost within bounds. Mr. Merton's experience is a sufficient guarantee as to his ability.

The Forest City Electric Company advises us as follows: The outlook for the coming year is most encouraging, and we fully expect to do twice as much business in the coming twelve months as we have done in those just passed. The foreign trade is taking an impetus and continued inquiries regarding our roll drop, drop forged commutator bars and protected rail bonds, lead us to believe that there are prospects for a large field in that direction.

Eugene Munsell & Co., and the Mica Insulator Company, of 218 Water street, New York, and 117-119 Lake street, Chicago, carry a large stock of mica, Micanite and M. I. C. Compound, ready for prompt delivery. Orders are promptly filled by their local agents, the Cuyahoga Supply Company, Cleveland, O.; Arthur S. Partridge, St. Louis, Mo.; Sinclair Randall, Cincinnati, O.; and the Brooks-Follis Electric Company, San Francisco, Cal.

The New Haven Car Register Company reports that the field for its registers is constantly widening and the company has recently received a large number of letters from roads using them in which is expressed the great satisfaction given by them in service. In addition to the full line of fare registers the company is manufacturing a ballot box which has been adopted by Boston and a number of other cities in New England and which is attracting a great deal of attention.

"The Wainwright Steam Appliances" is the title of a new catalog issued by the Taunton Locomotive Manufacturing Company of Taunton, Mass., and illustrates and describes different types of water tube heaters. In these heaters the transmitting surface consists of corrugated copper tubes, and the increased tube surface reduces the volume necessary for a heater of given power, while the flexibility of the tubes prevents straining at the joints and the consequent leaking.

Mayer & Englund, Philadelphia, representing the International Register Company of Chicago, have secured the contract for supplying registers to the Capital Traction Company of Washington, D. C. Each car will be equipped with two single type machines, one to register the tickets and the other the cash fares. This contract was let only after a thorough investigation, and the result is considered strong testimony as to the excellence of the International "iron clad" register.

The New Process Raw Hide Company, Syracuse, N. Y., says of its business: We are about closing up a very satisfactory year's business and feel fully assured from the present outlook that our next year's trade will be greater than we have ever had. The improved condition of the street railway companies as a whole would seem to warrant this prediction. Our foreign trade increases year by year until it has become an important factor in our business, and the outlook in this direction is also very flattering. We hope we may be able to verify the above predictions at the end of 1898.

The Crane Company, Chicago, advises us as follows: Business during 1897, taken as a whole, has been quite satisfactory. We have been particularly successful in placing large quantities of our highest grade of steam piping material, valves, fittings, etc., in street railway plants throughout the country, besides closing contracts for the complete piping equipment of the London Central Underground Railway, London, England, and the Dublin United Tramways Company, of Dublin, Ireland.

The Sargent Company, Chicago, writes: We have had a gratifying increase in business during the past year over the previous one, and are looking forward to even a more favorable year in 1898. The output has been increased in both our crucible and open hearth steel departments, and we now have orders enough to keep us busy for some time to come. Our new "Diamond S" brake shoe for steam and street railways is making great strides into favor, and we expect a considerable increase in our business from this one source alone.

The Cambria Iron Company, Philadelphia, reports: We are continuing to furnish for street and electric use, our various sections of girder, guard and high T-rails, and also ordinary T-rails (the same as we furnish steam roads), of all of which we have a full line of sections. We are altering our mill to enable us to change rolls more rapidly, so that we can give better satisfaction to our customers in filling small orders promptly. We look for the general prosperity now obtaining in the whole country to cause a large street rail business next year.

The John Stephenson Company writes: The year which is rapidly drawing to its close has been a very satisfactory one, as compared to its immediate predecessor. While there has been no decided "boom" we have been kept fairly busy, and the general tone seems to promise better things for the future. Foreign countries, especially European, are being stirred up by the success of the leading cable and electric roads on this side of the Atlantic, and doubtless a great revolution along this line will transpire within the next few years, in which American skill and progress ought to bear an important part.

Gustave Fischer, in his official capacity as engineer of Government Tramways of New South Wales, tested the plastic alloy which is employed in the manufacture of the Edison-Brown plastic rail bond. One side of a polished steel plate was amalgamated, covered with the plastic alloy and immersed in dilute sulphuric acid for three months. A sample joint was made up of standard rails and angle plates with a pair of plastic bonds and left under the water in Sidney harbor for the same length of time. In both cases the unprotected steel was deeply corroded while the amalgamated spots were bright and shining.

The Bates Machine Company, Joliet, Ill., says: We are pleased to advise you that we have noticed a decided increase in the last three weeks in both business secured and inquiries, and the outlook for trade in the near future is very flattering. Our works at the present time are running night and day, and among the orders booked in the last 15 days we note the following for engines: one 100-h. p., Portland, Me.; two 250-h. p., Philadelphia; one 150-h. p., Richmond,

Va.; one 125-h. p., Kansas City, Mo.; one 200-h. p. and one 1,000-h. p., Canal Dover, Ohio; one 150-h. p., Tacoma, Wash.; one 100-h. p., San Francisco.

The Western Electric Company has furnished a room 18 x 18 ft. in the rear of its store as a show room for fixtures. Numerous chandeliers and brackets have been placed in this room and these have been wired up with 2-point, 3-point, 4-point and combination switches in order to show the methods by which lights in private houses may be controlled. A large variety of beautiful shades is shown on the fixtures. Five of the Western Electric enclosed arc lamps are also exhibited. Another improvement is the introduction of a pneumatic carrier system connecting the sales department with the store rooms and order department.

The Strass Electrical Engineering Company, 29 Liberty street, New York, has this to say: We are experiencing a marked improvement, not alone in the quantity of work passing through our offices, since the end of June, '97, but what is more important, we find that the prices obtained both on competitive work, as well as on the regular work furnished our clientele, are far more satisfactory. We believe that the advent of a solid and settled condition of trade is casting its shadow before, and have no doubt but that "increasing business" and "better prices," will be reported from all quarters during the coming year.

The Ohio Brass Company has recently made a valuable acquisition to its engineering department in the shape of a special testing set from which graduated voltages as high as 10,000 can be obtained. This set will be used in testing insulating materials and will be put to a two-fold use; first, for experimental purposes, such as determining the quantity of insulation required in connection with any device of new design which may be composed of insulating material, either in whole or in part; second, in connection with the electrical tests to which every stock piece of insulating material which this company manufactures will be subjected before being shipped from the factory.

Our attention has been called to the "New Columbia" street car heater in use on the Chicago City and North Chicago roads. It is certainly interesting to street railway managers to see a very ornamental, self-feeding, coal stove in operation on a street car, which is entirely free from ashes or dirt of any kind, carrying its fuel for 18 hours without the use of a shovel or poker, and not a door to be opened nor any ashes to be removed throughout the whole day, and still capable of heating the largest street car. Such is the "New Columbia" and we congratulate the McGuire Manufacturing Company on its latest contribution to the comfort of street railway travel.

The International Register Company, Chicago, manufacturers of stationary and portable fare registers, writes: We can report a very great improvement in our business during the year. When we removed to our present location last February, we supposed that in doubling the space previously occupied by our factory, that sufficient provision had been made for increase in the business for sometime to come, but the volume of the business has increased so rapidly in the intervening months that further additions to the shop room have been recently made necessary. We have work for

several months ahead with our largely increased force, and the prospects for 1898 are such that an additional enlargement in the capacity of our plant will probably soon be required.

The Ball Engine Company, Erie, Pa., advises us of the receipt of the following letter from Julian Kennedy, the eminent steel works engineer of Pittsburg, which refers to a 400-h. p. vertical engine direct connected to a Siemens-Halske generator: "I am in receipt of a letter from H. S. Loud, general manager of the Nicopol-Maripol Mining & Metallurgical Company's works in South Russia, in which he says: 'The electrical plant is working beautifully. You would be doing an almost obligatory service in thanking both the Siemens-Halske and the Ball Engine people for me for the very great satisfaction which their machinery has given this company. The Ball Engine people were especially gracious in the prints, etc., sent, and their workmanship is magnificent.'"

H. F. J. Porter, general sales agent of the Bethlehem Iron Company with headquarters at 1433 Marquette building, Chicago, has during the past six months been located at the works in South Bethlehem, Pa., during the absence in Europe of R. W. Davenport, second vice-president. Mr. Porter is spending a few days at his office in Chicago and reports that there is a decided improvement in the steel forging business in the east, and that there are evidences that business will pick up rapidly in the west. He will return to the works and have his headquarters there during the winter. His western office will be in charge of his assistant Erwin Nelson, who will be glad to answer all correspondence and give information on matters relating to steel forgings of all descriptions.

The J. G. Brill Company says: The business for 1897 has been quite a satisfactory one for us. We have had the shops fairly well crowded from the beginning of February up to the present writing and have run during the entire time with our full force. We find many of the roads in this country are increasing their rolling stock equipment to meet the demands of increased travel, and consider this a very satisfactory and steady growth. Further, there have been projected quite a few new enterprises which have required rolling stock and we are glad to say in each particular case where we have been interested, the project has been on a sound basis. We consider the year's business, (1897) more satisfactory than 1896 and look forward to increased trade in 1898.

Among the highly prized compliments held in the files of the Central Electric Company, the following from W. E. Brice, president and general manager of the Mason City & Clear Lake Traction Company, is self-explanatory. The letter is dated July 9, 1897, and is as follows: "We have just completed 18 miles of electric railway using your material for the entire overhead construction. We have found everything to be first-class, and can recommend your materials for the purposes for which we used them. The shipments have all been made very promptly."

The attention which this road has attracted on account of its splendid success makes this voluntary testimonial to the high standard of the material furnished by the Central Electric, specially noteworthy.

The Q. & C. Company, Chicago, has issued to the trade an attractive pamphlet containing answers to questions often asked regarding Servis tie plates which puts the matter in a very accessible form. This company advises us of a marked improvement in general business and says: In the street railway line, the use of the Servis tie plates where cross ties are used, is becoming much more general, and we believe there will be a large demand for these. In our sawing machines for cutting rails, the regular sale of the small hand machines has now been added to by the demand made for power machines, with which frogs and switches and all other work can be made at a very small expense. Our present orders, together with inquiries, certainly warrant us in looking for a much larger business for 1898.

The Sampson Cordage Works, 115 Congress street, Boston, writes: We have been obliged to put in extra machinery for the special finish that we apply to our first quality trolley cord. The war between first quality cord and low priced cord is waged back and forth, sometimes with success for one and sometimes for the other, though so far the first quality goods have the advantage. We believe, ourselves, that it pays in the long run to use the first grade, but many buyers are attracted by the low prices of these lower grades. We are prepared to furnish either, and as we do a larger business in this particular line than any other manufacturer, are able to supply this cord to the best advantage. The prospects for improved business today are much brighter than for a year or two back, as there seems to be no limit to the increase in mileage of street railways all over the country.

The McGuire Manufacturing Company is closing the year full of business. For the month of December it expects to complete the order for 120 Alley "L" trucks, deliver 52 A1 suspension trucks to the Consolidated Traction Company, Pittsburg, and also a number of smaller truck orders. It also has for delivery orders for 27 of the combination snow plow and sweepers and the orders for "New Columbia" heaters to be delivered in this closing month, aggregate 470. The business of the entire year winds up very satisfactorily, but the last four months of the year are to be credited with this result, the first eight being anything but flattering. The company anticipates an immense business for 1898, indeed the orders in sight are enough for the present capacity until next June, and it has in contemplation an addition to the present works, a building 116 x 160 ft., three stories and basement.

The Westinghouse Electric & Manufacturing Company has some important contracts for electric apparatus to be installed by the large companies at Niagara Falls. Shipment has commenced on the five 5,000-h. p. generators for the Cataract Construction Company, and work is progressing on the exciters, aggregating 675 h. p., together with the switchboard appliances necessary for these machines. Six 300-volt, 750-h. p. generators are under way for the Niagara Falls Hydraulic Power & Manufacturing Company. The Niagara Electro-Chemical Company has contracted for a large increase in the transformer plant and 800 h. p. in air-cooled oil converters. Two 1,000-h. p. oil converters are building for the Acetylene Light & Power Company and the Mathieson Alkali Company has recently been furnished with 11 165-h. p. rotary transformers, several induction motors and 28 oil converters.

The Monarch Stove & Manufacturing Company, Mansfield, O., advises us: Having just begun the manufacture of the "Monarch" Track Cleaner, our year's business could not be summed up to make a very flattering showing. Suffice it to say, however, that such introduction as has already been made among the railway people of the "Monarch" cleaner has been attended with very flattering success. We have had a sufficient amount of business to justify us in feeling that we are on the right track. We have only to keep ourselves before the trade in the proper manner, and the business will be a very satisfactory one. The quality of our work will be such as to bring us additional business without question. Agencies have recently been established as follows: New England, C. N. Wood, 31 State street, Boston, and New York and New Jersey, J. Dolph & Co., 126 Liberty street, New York; the western business is handled from the factory at Mansfield.

The Standard Paint Company, 81 John street, New York, writes: The outlook for business in the street railway field in 1898 for us is exceedingly good. In fact, we may say that the boom has already struck us. The P. & B. compounds, tape and armature varnish, are in far greater demand this year than they have been for some years previous. As already noted in the columns of the REVIEW, we have found it necessary to establish a plant abroad to take care of our foreign business, this business having already assumed proportions which render it impossible for our American factory to manufacture P. & B. products sufficient to supply both continents. Our branch factory located in Hamburg, Germany, is now virtually ready to begin operations, and we hope and feel assured that when it is started up our works in this country will be sufficiently relieved of the pressure to enable them to turn out our products rapidly enough to supply the domestic demand.

D. W. Phelan, 280 Broadway, New York, dealer in ties and wooden poles, writes us as follows: I have had more large orders during the past two months than during any similar period within the past three years. I control several thousand acres of oak and chestnut timber and am cutting it up into ties and poles. I have recently delivered to one customer alone within five weeks from the receipt of the order over 3,000 chestnut poles, all of which were cut specially for this particular order and delivered without interfering in any way with regular orders which were very heavy. I also control the output of six southern mills making a specialty of octagonal yellow pine poles and trolley ties and carrying a general assortment of poles in stock, which enables me to ship promptly on receipt of orders. I have filled many of the largest octagonal pole orders that have been placed during the past year, so that I am more than satisfied with the year's business and the outlook for 1898 is full of encouragement. I expect to be strictly in it next year.

W. W. Wharton, secretary of the Electric Mutual Casualty Company, Philadelphia, advises us as follows: The Association has grown steadily during the past year and we are in every way satisfied with its progress. While the number of electric railway applicants for casualty insurance has been large, we have been compelled to reject many of them as not reaching the proper standard of excellence either in equipment, management or financial condition, as main-

tained by our Association. However, we have accepted during the year, 18 new members, swelling our total to 51 and increasing the advance premium income of the Association to over \$65,000 annually. As a result of this care in the selection of our members, our losses have not increased in proportion to the growth of the organization, and consequently our surplus has grown very rapidly. With the success of our plan for casualty insurance on electric railways assured, the future prospects of the Association are very bright and our organization will continue to increase its membership gradually by the addition of only the most acceptable risks.

The Columbia Machine Works of Brooklyn, N. Y., a firm composed of John G. Buchler and Frank H. Platt, manufacturers of supplies pertaining to a street railway system, and specialties of various kinds is an example of "Young America." About four years ago it began business, occupying one floor in a moderate sized factory. Today it fills to overflowing, two large five story, and three two story factories besides two lots used for foundry purposes. The endeavor of the firm is to have nothing go out that is not first class in material and workmanship, believing an inferior article even at lower prices works an injury to all business enterprise. In the year now closing they have customers in nearly every state in the Union, also in Canada, England, France, Germany and Spain. For 1898 they are prepared for a banner year being especially equipped for armature winding, commutators, new, refilled or assembled segments, with their own drop forged pure copper commutator bars, drop forgings, brass, malleable iron or iron cast-

ings, sand boxes, adjustable brake and controller handles, also machine work in all its branches. They make it a feature to perfect new inventions, cheerfully estimating on anything that can be made.

The Joseph Dixon Crucible Company, Jersey City, N. J., attributes its prosperity to the probable cause and writes: There has been no change whatsoever in the personnel of the Dixon Company. There have been no additions to buildings during 1897 simply because we have not had time to formulate any plans or look after the erection of any buildings. We have a large plot of ground adjacent to our factory which we shall endeavor to cover with buildings sometime during 1898; at the present time every available corner of our factories has been utilized for business purposes. We are behind in filling our orders for the simple reason that orders have come to us in unheard of numbers. Although we have made no additions in any way during 1897 we have nevertheless by working over-time been enabled to put out more goods than we thought we had capacity for and still we are behind in filling our orders. It may be that this condition of things is due to the fact that the Dixon Company during the dull times did not withdraw or drop a single advertisement anywhere. All of our advertisements not only were run, but they were frequently changed and we whooped it up as lively as we could without ever thinking of dull times, and we are now probably receiving our reward.

The Weston Engine Company, Painted Post, N. Y., writes as follows: Our business for the year 1897 has exceeded by far our expectations as we have built and deliv-

ered more than double the number of engines built in any previous year, and the prospects for 1898 are exceedingly bright at the present time. We now have on hand orders for more than thirty engines of the "Imperial" type, and many more are in sight. We have been obliged within the last month to refuse two large orders owing to the fact that we could not make satisfactory delivery. We find our present plant although practically a new one, entirely inadequate to take care of our business, and now contemplate erecting another large shop immediately, or early in the spring. We have recently purchased a large amount of new machinery and are now making several changes in our plant, the most notable being the installation of one of our 12 x 12-in. Imperial engines direct connected to a 50-k. w. Westinghouse generator, for the furnishing of electric light and power for our plant, in place of the belted outfit which we are taking out. The contemplated addition will more than double our present capacity, and it is our opinion at the present time that even with this addition our plant will be inadequate to take care of the business.

The Swarts Metal Refining Company, Chicago, writes us as follows: The past year which we are about to end has been somewhat more satisfactory than the previous year; orders have been placed more freely, prices have advanced and the general feeling has been somewhat encouraging all through the year, with the exception of a considerable falling off of trade in the past two or three weeks. This we can attribute only to the fact that inventory begins very soon and the desire to reduce supplies on hand. We are, however, looking for a revival in trade, and we believe the prospect in store for the coming year is as bright, or brighter, than for some time past. In regard to our own business would say the only change is our removal to larger and more spacious quarters on May 1, last. Since removing to our new establishment our business has more than doubled. We have been very successful in keeping our plant running. While our trade with the electrical railways is but a small branch of our business, yet we find it a very profitable and desirable trade. We will use our best efforts in the future—as we have in the past, to supply the trade with our strictly high grade motor metal and other supplies, and shall also use our best efforts to keep up the standard of our goods in the future as we have in the past.

The H. W. Johns Manufacturing Company writes us that the electrical department has had a prosperous year, the aggregate sales exceeding those during any similar period. The company secured its share of the current contracts for trolley insulating material and greatly increased its foreign business. The toggle-clamp, self-fastening feed-wire insulator met with a wide sale and the year's experience adds its testimony to the value of moulded mica as a most reliable and desirable insulation. The season for electric heaters opened later than usual, but the business done has been gratifying. The Johns Company believes that for the best results in properly heating a car, the heaters must have large radiating surfaces properly distributed and not depend upon the heating and distribution of air, and states that it has found the public quick to notice the greater comfort afforded by the "H. W. J." heaters. The sales of "vulcabeston" repair parts, such as motor bushings, commutator rings, and controller parts have increased, while the orders from the

manufacturers of electrical apparatus, who have been among the largest consumers of this heat-proof material, have reflected the quiet condition of the trade in some lines compared with more active years. The Johns Company anticipates a good business during 1898 and expects to book its proportion.

Harold P. Brown, manager of the Edison-Brown Plastic Rail Bond Company, writes us that the past year has registered a series of triumphs for the plastic bond, and says: Many prominent roads have reported tests after two and three years' service, showing the bonds to be as good as new, while copper bonds installed at same time have dropped to 10 or 15 per cent their original conductivity. One of the Brooklyn roads after trying electric-welded rails, "cast-weld" joints, copper bonds welded to rails and all modern types of ordinary and flexible copper bonds, has found the plastic bonds unequalled not only for rails but for switch board contacts, where hot switches and shunt connections have been permanently cured by the treatment with the contact alloys. The principal roads constructed during the year in Europe, South America and Australia have used the plastic bond and the factory is still running on full time with foreign orders. Engineers are learning in all parts of the world that the rails cannot be bonded to full conductivity with any amount of copper, as proved by the following letter from the Western Electrical Instrument Company, Newark, to Mr. Brown: "We recently had occasion to adjust milli-voltmeters to rail sections as shunt for 1,500 amperes. In attempting to do this we found that the contact resistance between the current terminals and the rails could not be made of low enough resistance to allow sufficient current to pass through the rails from our low potential battery (4 volts). After we used your plastic alloy between the rails and the current terminals, we found that the contact resistance was reduced to almost nil, and we had no further difficulty in drawing sufficient current out of the batteries to make the required adjustment of the instruments. Thinking that this statement of facts may be of interest to you, we beg to remain, etc." For the spring trade a single road has contracted for over 45,000 plastic bonds and the outlook for the year's trade is excellent.

From the Cahal Sales Department, we have received the following letter: "We beg to state that in our line of business the year just closing shows a most remarkable advance in the volume of business over 1896, our business for 1897 being more than double that of the preceding year. The increase in volume of business during the last 90 days has been especially remarkable. Prior to 1897 the biggest year's business done by any one water tube boiler concern in the United States was 162,500 h. p. in 1892-3. From present indications we have every reason to believe that our business for the year 1897-8 will largely exceed this figure. On the 19th of November our orders received on the single day were for over 13,000 h. p., which is unprecedented in the water tube boiler business. Among those to whom we have furnished large quantities of boiler power during the year 1897 are, the Carnegie Steel Company, Pittsburg; the Illinois Steel Company, Chicago, and the Shenango Valley Steel Company, New Castle, Pa., all of them representative firms in their line. In the electrical field, we have built boilers for the Brooklyn Edison Company, the Brooklyn Heights Railroad Company, the Union Traction Company, Philadelphia, and the Capitol Traction Company, Washing-

ton, D. C., which are also representative concerns in the electrical field. Our aim is and always has been to secure the large orders wherever possible and in this we have succeeded to a most flattering degree, the Carnegie Steel Company and the Shenango Valley Steel Company having given us this year orders aggregating nearly 25,000 h. p. We are also building 6,000 h. p. of boilers for the new sugar refinery now building by the New York Sugar Refining Company. Our sales are generally distributed between the two principal types of boilers we manufacture in the following proportions: 60 per cent Cahall vertical water tube, 40 per cent Cahall-Babcock & Wilcox type. Our factories have at the present time ample facilities for turning out 300,000 h. p. a year and they are at this writing crowded with work, our business since October 1st being beyond the capacity of our factories. It is of course almost impossible to estimate on future condition of business, but from the reports that we receive from our various branch offices of projects contemplated for the ensuing year, we feel very safe in prophesying that our next year's business will be very much larger than the present one."

The Consolidated Car Fender Company writes as follows: Our business has been larger the past year than the total business of the two previous years. More than 4,000 cars have been equipped by this company, on 45 electric roads, in 56 cities and towns. We are at this time equipping cars for the Metropolitan Street Railway Company of New York, the Troy City Railway Company of Troy, N. Y., the Utica Belt Line Street Railway Company, Utica, N. Y., the Consolidated Traction Company, Jersey City, N. J., the Cleveland, Painesville & Eastern Railroad Company, Cleveland, O., and the Dover Electric Street Railway Company, Dover, England. More "Providence" car fenders have been attached to electric cars in the United States during the past year than all of the other projecting fenders combined. This statement is true, notwithstanding the fact that the "Providence" fender costs more than double that of any projecting car fender now made. So far as our experience will show electric roads pay their bills promptly, and not one poor account has been made by us, or a single dollar lost, since we began to deal with them three years ago. The few competitors we have complain "that we are ruining the fender business by asking and receiving high prices for our goods." We may be ruining the business for them, but are certainly not doing so for ourselves. The demand for our fenders the past few months has been so great that we have found it necessary to carry in stock not less than 500 full equipments of our regular pattern. From the present outlook we feel confident that we will equip during the next year not less than 5,000 cars. It has been demonstrated beyond a question that a car fender made of tempered spring steel, with the best quality of malleable iron fittings, is cheaper in the end for electric roads to buy than a fender made of gas pipe, angle iron and rope netting, with common gray iron attachments. Hence the demand for the "Providence" fender.

A cartridge on the tracks of the Kedzie avenue line of the West Chicago Street Railroad, exploded with great force and raised the front of a motor car off the rails. One lady was thrown into the street and severely bruised, but the other passengers were more scared than hurt. It is thought that some mischievous boys placed the cartridge on the rail.

**CLODFELTER STILL IN THE RING.**

Receiver James L. Bradford sold the Indianapolis, Anderson & Marion Electric Railway, November 17, to Noah J. Clodfelter for \$5,000. Arrangements were made for the settlement of \$80,000 worth of claims by the issue of stock in the new company, which is capitalized at \$500,000. The property consists of franchises, right of way, grading, and 2.5 miles of track, with partial power plant equipment. From Marion, Ind., the line will run to Indianapolis by way of Gas City, Fairmount, Alexandria, Elwood, Noblesville and Broad Ripple. Interested with President Clodfelter in the new Indiana Traction Company are Major L. N. Downs, Battle Creek, Mich.; C. S. Cleaver, and R. A. Davidson, Chicago; W. R. Pierson, Fairmount, Ind.; Frank Maus and Judge Bartholomew, Indianapolis; Judge J. B. Tuttle and H. M. and E. F. Loud, Au Sable, Mich.

wagons of the neighboring farmers as trailers. In order that the wagons may keep the track a second pair of rails is laid inside the running rails and slightly above the latter. The advantages of such a scheme are the saving in horse-flesh and time.

**SPEED REGULATION IN DETROIT.**

On October 9 the Detroit city council passed, in great haste, an ordinance limiting the speed of street cars throughout the city to 10 miles per hour. So much opposition to this developed, the citizens of Detroit fully appreciating the advantages of a rapid service, that the council subsequently reconsidered its action and referred the ordinance to a committee which reported in favor of one limiting the speed to 10 miles within one-half mile of the city hall, 15 miles between the half-mile circle and the boulevard which surrounds the city at an average distance of three miles from the city hall, and 20 miles elsewhere, which ordinance was passed.

By the purchase of the stock and part of the bonds of the Sea Beach and of all the stock and bonds of the Sea View road the Brooklyn Rapid Transit Company secures a through connection to Coney Island both by way of the

Brooklyn Bridge and by boat from Bay Ridge. The cost of the securities is placed at about \$750,000. It is announced that both roads will be equipped with electricity.
