### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7.                      JANUARY 15, 1897.                      NO. 1

As ANNOUNCED last month, we have inaugurated a special FOREIGN EDITION of the STREET RAILWAY REVIEW, which is being mailed to every street railway in the world. It contains a large amount of matter specially prepared for foreign readers, and cannot fail to furnish most valuable information to the hundreds of foreign roads now seriously contemplating a change to electricity. As the United States leads the world in this industry, foreigners naturally look to it as the fountain head, and already large amounts of supplies and machinery have been purchased here and scattered throughout the world. It will be the special province of our FOREIGN EDITION to furnish not only a description of our best methods in operation, but to acquaint every possible buyer in the world with our American manufacturers. Letters are pouring in from abroad expressing the greatest satisfaction at our new departure.

The several fires of the month call attention to the necessity for frequent reminders to barn foremen and others to maintain strict discipline in these matters. At Janesville a spark from the generator fell upon waste, which ignited and spread to oil cans. To increase the excitement a stream of water struck the cylinder head, which blew out and maimed three people.

PROFESSIONAL agitators undertook to work up a strike among the 4,500 men on the West End road, Boston. Recognition of the union was the principal and only important issue. About 800 of the men refused to abide by the agreement of their committee with President Little to defer action on the demands one week from December 23. The effort was to force the demands by a tie-up on Christmas and the big shopping day previous. It was a dismal failure, as it deserved to be, and at no time amounted to a complete abandonment of car service an any line.

ELECTRICITY for use on suburban steam roads bids fair to make decided progress this year. The experiments and experience of the N. Y., N. H. & H. R. R. have decided its management on further electric installation; the C. H. & D. will also do some trolleying. In Chicago the C. & N. P. will spend over a million. If the steam roads are wise and progressive they will not only use electricity largely for their suburban service, on account of its advantages and economies; but also as the most effective means of preventing electrical competition by furnishing it themselves. Three cars in one hour serves the people vastly better than three cars in one train once an hour. Steam cannot afford frequent service; electricity can, and very soon will.

As PREDICTED in these columns, the hostile and selfish attitude of the steam roads in Connecticut, which has so effectually blocked interurban construction in that state, has resulted in the people waking up and taking action. The recent election worked radical changes in the state legislature, and it is conceded the trolley interests are in the majority. Judge Hall, vice-president of the New Haven system, in a recent interview shows the change of heart induced by the election returns, and now announces the steam roads admit a sphere for electric roads, but still denounces any proposition to parallel the former. The electric interests will surely ask a repeal of the general law against parallels. The steam roads will, of course, fight it bitterly, but we believe unsuccessfully.

On December 14, 1896, the Chicago city council passed an ordinance reducing the price of car fares from five to four cents. There was no public demand for the change. Even the press had not urged the measure. It originated in the council, and antedating Christmas only a few days as it did, had every appearance of a sand-bagging scheme. The four cent fare was to take effect on January 4, 1897. One week later the same council meekly reconsidered the ordinance and killed it. Their bluff did not work, but the 20,000 street railway employes in Chicago, who were promised a reduction in wages in the ratio of 5 to 4, did. It was a humiliating spectacle, and a very bitter pill to take, but these great reformers who want to be re-elected the coming spring suddenly forgot all about their alleged duties to the 1,700,000 other citizens of Chicago, pulled in their horns and marched down the hill they had

ascended with so much flourish of trumpets one week previous. Great is the glory of the Chicago alderman.

THE limited speed ordinance has been tested as far as the appellate division of the Supreme court in Brooklyn. In the justice court the city won, but was reversed in the county court. The company lost in the appellate court. The ordinance called for a speed not in excess of six and eight miles per hour in certain districts. Police-men testified to a speed of nearly fourteen miles. We have commented on the subject of limited speed so often it is hardly necessary to refer to it again. At the same time we find no occasion as the history of electric cars grow into years to alter our policy. We maintain that companies are the best judges of what is a suitable and safe speed, which is subject to local conditions. In certain hours of certain days the six miles allowed in the ordinance might be positively dangerous at certain places, while at other times twice that speed would be perfectly safe over the same rails. Where there is a clear track there can be no objection to a good speed, and where pedestrians and traffic crowd the street greater caution is necessary. No company is deliberately going to work to smash wagons and kill people, and bankrupt itself just to see the cars run fast. Speed limitations are unwise and should be unnecessary.

The REVIEW takes pleasure in announcing a movement which is one of the most important in a long time, to certain departments of street railway work. The need of a better system of accounts; but especially a standardizing, has long been felt, but has now reached a point where definite action is actually necessary. It is work which cannot successfully be done in the sessions of the American Street Railway Association, partly for lack of time, but chiefly on account of the nature of the work. We publish on another page a call for a meeting to form an Accountants' Association. The initial meeting will be held in Cleveland on March 23 and 24, at which organization will be made. Interesting papers will be read and discussed by some of the best authorities in street railway work. Forms, systems of distribution, fare accounting, are among the subjects. Committees will be appointed to report at the first regular meeting, which it is intended to hold at the same time and place as the American Street Railway Association. While the organization is a distinct one, and the nature of its work demands a separate meeting room from that occupied by the American, whose time is already more than fully occupied with operating subjects, the new organization will be in perfect harmony and prove a most valuable adjunct. The history of steam road convention work leaves no doubt as to the necessity and wisdom of this course. It takes nothing out of or away from the American Association, for the work it has to do has never been done. The large number of leading accounting officers who have urged the formation of the new work is more than a guarantee as to its need and success. The meeting point is central, the meeting will be interesting,

practical and helpful, and every company which can possibly spare its secretary, auditor or whoever is the man in charge of accounts, should not allow the opportunity to pass without representation.

## FOUR-CENT FARE FIASCO.

Business was dull in the Chicago city council. The big corporations which were accustomed to come forward with a smiling countenance and seek franchises were in seclusion. They did not seem to want anything. Christmas was coming on and the situation grew serious. If the companies did not want anything, they should not be forgotten, even if it happened to be something they didn't want.

In street railway circles things were quiet. Nothing had been heard of the "no seat—no fare" in many moons. So far as any one could discern from the usual sources of information, the dear public were joggling along in a very contented frame of mind. Certainly there was no public demand for a reduction in the price of car fares. By the time a man had ridden 12 to 15 miles with two or three transfers, for five cents, he was glad enough to be allowed to get off, or pay another fare to retain his self respect. The papers had not even been howling about a reduction in fares. This, however, made no difference, and in the aldermanic star chamber it was decided on as the surest, swiftest arrow with which to pierce the armor of the enemy. Therefore, like a stroke of lightning came the passage of an ordinance, on December 14, reducing car fares from five to four cents, the same to take effect on January 4.

But to the great surprise of the solons, the companies made no remonstrance. They did not send deputations to sue for peace, or mourn upon the streets and ask the public to help fight their battles. What they did do was to inform the 20,000 street railway employes, who are the best paid in this country, that the revenue of the companies would suffer a reduction of one-fifth on January 4, and that wages would likewise be reduced in the same proportion. As the wage item is over one-half the gross earnings, this was about an equal division of the proposed loss between the company and its men.

But while the companies appeared resigned to the new order of things, the men did not. Mass meetings were held after midnight by the men, and when the situation was understood the air grew hazy. The men were accustomed to good wages, and somehow failed to take kindly to the great reform. They did not blame the companies, who were to share an equal loss with them, but they did express themselves in no uncertain language as to the aldermen who were the cause of the disaster. And the boys "got a move" on themselves. As many as 500 or 600 in one body would march to the home of their alderman, and at any time between 2 and 4 o'clock in the morning get him out of bed to explain to his admiring constituents where he was at. And the boys had a way of making themselves understood. They lost no time in stating the case before the house, and they did it in terms that left no room for doubt. Alderman after alderman was routed out, even the mayor was waited on Sunday afternoon by several hundred. It began to look as if an entire new council would be elected this spring. So the city fathers hastened to accept light on the subject, and in just one week had repealed the four-cent fare, which no one asked for, and nobody wants.

The little bluff didn't win.

JOHN M. ROACH.

For a quarter of a century John M. Roach has devoted his time and thought to railway interests in Chicago. The reward for his faithfulness has been one promotion after another and added responsibility from year to year. After futile efforts to make a fortune in the far west, he came to Chicago in 1872 and began his street railway career by collecting fares on the North Chicago City Railroad. President Turner took notice of the ambitious young man and soon gave him the position of cashier, taking money at the barn from the conductors. He next performed the duties of purchasing agent in an acceptable manner. From this on, his rise was rapid, changes of administration not affecting his progress. He has been general manager of the north side system and the outside electric lines. One more responsible position has been added by his recent election as general manager of the West Chicago Street Railroad, thus placing the entire Yerkes railway interests under his management. The honor has been honestly earned and his many friends will take unusual pleasure in congratulating him on deserved recognition.

J. M. ROACH.

NIAGARA FALLS HYDRAULIC POWER & MANUFACTURING COMPANY.

The new power plant of the Niagara Falls Hydraulic Power & Manufacturing Company is in operation and is recognized as one of the great works in the city so rich in power facilities and developments. The erection of the plant was under the immediate supervision of Wallace C. Johnson, chief engineer of the company.

The hydraulic canal takes water from the upper Niagara river at about the lowest practical point, there being a descent of 50 feet from the entrance of the canal to the falls. The canal is 4,400 feet long, 70 feet wide, with an average depth of 11 feet, opening at its lower end into a basin parallel to the bank, 400 by 70 feet. For the installation here described a canal 16 feet wide and 20 feet deep, runs 275 feet to a forebay 180 by 30 feet and 22 feet deep. This forebay lies between the canal basin and the edge of the high bank, and over it is built the gate house, which covers the gates controlling the admission of water to the penstocks. There are also two waste gates, each 20 feet deep by 8 feet wide, by which the canal may be cleaned at any time. For handling the gates, Mr. Johnson designed apparatus in which he takes especial pride. Before each pair of gates are two cast iron cylinders about 8 feet high, with pistons. The two ends of each cylinder are connected to a pump, driven by an electric motor, by which the oil with which the cylinders are filled is pumped into either end at will, forcing the pistons to move accordingly. The piston rods are connected by an iron beam on which are hoops taking hold of pins on the gates. With this apparatus a pressure of 100,000 pounds can be exerted.

The penstock proceeds horizontally for 25 feet to clear the

NIAGARA FALLS HYDRAULIC POWER AND MANUFACTURING COMPANY.

edge of the bank and then descends for 135 feet to a solid foundation on the lower stratum of Niagara limestone (see illustration). From here it extends at an angle of 45 degrees to the power house building, under the floor of which it runs for 70 feet. The diameter of this portion is 10 feet. The penstock is of steel plate,  $\frac{5}{16}$  inch at the top and  $\frac{1}{8}$  inch at the bottom. The tail race is formed by two masonry walls 17½ feet apart.

The power house is of stone, 100 feet wide, 60 feet (to be extended to 180 feet, the work being now in progress) long and 30 feet from the floor to the eaves. The roof is supported by steel trusses, leaving the floor free from posts. The interior is served by a 26-ton traveling crane. There are now installed four water wheels of the James Leffel & Co. Niagara type, each taking water from a separate 5-foot pipe leading from the penstock. Each wheel weighs about 50 tons and stands on heavy double steel beams spanning the tailrace. The horizontal portion of the penstock is suspended from these beams by forty-eight 1½-inch square iron rods.

The wheel consists first of a vertical, circular casing of ¾-inch steel plate, double riveted to cast iron curved heads 3½ inches thick. To this case the water is admitted from the supply pipe underneath, flowing upward and surrounding the guide case, being admitted to the runner through oscillating guides which constitute the gates. The runners of the wheels are 74 inches in diameter and made of iron and bronze, the shell comprising the buckets being of bronze, and secured to an iron center. The buckets have sharp dividing diaphragms or ridges so that the entering water is split and consequently there is no end pressure on the shaft.

The gates are of the James Leffel pattern and operated by the double-ring arrangement which is controlled by a hand wheel easily operated by one person. To the hand wheel shaft is attached an automatic mechanical governor made by the Lombard Water Wheel Governor Company, of Boston. The discharge is lateral into receiving pipes, to which are connected draft pipes extending downward for 20 feet. The total head of water is about 210 feet.

Three of the turbines are direct connected by flexible couplings, each to two 560-kilowatt electrolytic Westinghouse generators, running at 250 r.p.m. and generating 2,000 amperes at 280 volts. The current from these machines is transmitted on two aluminum cables of 250 wires each, to the aluminum factory of the Pittsburgh Reduction Company.

The fourth turbine is rigidly connected to two 550-kilowatt General Electric generators and runs at 300 revolutions per minute. The generators are compound wound for railway service and are to be run in multiple. Since the completion of the plant the company has supplied the Niagara Falls & Lewiston Railroad, better known as the Gorge road, and the Lewiston & Youngstown Railway with power. For this latter service the booster (shown in our illustration) is used. The service it gives is good; the voltage at Lewiston is 580 volts, and at Youngstown, 15 miles distant, about 507.

The superintendent of the power company is F. G. Lott, who is also superintendent of the Buffalo-Niagara Falls Electric Light & Power Company, and the business head of the company is Arthur Schoellkopf, formerly president of the Niagara Falls & Suspension Bridge Street Railway Company.

NIAGARA FALLS HYDRAULIC POWER AND MANUFACTURING COMPANY—INTERIOR OF POWER HOUSE.

## ST. LOUIS OFFICE MEN'S ASSOCIATION.

The secretaries, treasurers, auditors and assistant officers of the various street railways in St. Louis, formed a local organization on December 30, and elected officers. They will meet once in three months, and after a dinner discuss questions of local interest, read papers and make these occasions the date for the clearing house work of settlement and exchange of tickets between the different roads. The first meeting was a success and proved very enjoyable. C. N. Duffy, secretary of the Citizens', was the originator of the idea.

## WEST AND NORTH CHICAGO ANNUAL MEETING.

The West Chicago Street Railroad held its annual meeting December 12. The Yerkes board was elected. J. B. Parsons who has gone to Philadelphia, and W. L. Elkins, retire from the board. Arrangements were announced for floating of \$10,000,000 consolidation bonds to retire the \$4,000,000 first mortgage bonds, \$2,700,000 other debentures and \$3,300,000 to liquidate floating debt incurred in powerhouse and new construction work.

The income from cable lines was \$1,701,306, a decrease of \$126,034, and the income from horse car lines was \$255,105, a decrease of \$987,128, while the income from electric lines was \$2,017,182, an increase of \$1,230,120; the expenses of the cable lines were \$888,539, a decrease of \$81,115; the expenses of horse car lines were \$347,284, and the expenses of electric lines \$902,554, making a decrease in the cost of operating horse and electric lines amounting to \$173,693.

The expense of operating a car a mile was 13.85 cents for the cable, 20.77 cents for horse car lines, and 10.69 cents for electric lines. The average cost per passenger was 3.87 cents.

### NORTH CHICAGO STREET RAILROAD.

The North Chicago road held its annual election January 12, re-electing the Yerkes board.

The report of the treasurer was as follows:

### INCOME.

	1896.	1895.
Passengers.....	\$2,826,800	\$2,694,359
Other sources.....	86,099	86,128
<b>Total income.....</b>	<b>\$2,913,709</b>	<b>\$2,780,487</b>
Operating expenses.....	\$1,394,387	\$1,312,107

Surplus brought forward.....	594,281	1,357,975
<b>Totals.....</b>	<b>\$1,589,372</b>	<b>\$2,354,204</b>
Regular dividends.....	758,991	659,922
Surplus balance.....	\$830,471	\$1,694,282
Deduct extra dividend January 1896.....		1,100,000
		<b>\$594,282</b>

The following are given details of operation:

	1896.	1895.
Total passengers carried.....	56,523,620	53,887,428
Total mileage.....	10,590,036	9,697,326
Percentage net earnings on capital stock.....	15.07	18.12
Percentage operating expenses to gross earnings.....		
Cable.....	47.13	39.9
Electric.....	51.23	45.2
Horse.....	90.68	91.2
Average.....	49.32	47.72

The total receipts from cable lines were \$1,535,311, and expenses, \$693,532; receipts from electric lines, \$1,192,601; expenses, \$610,893; receipts from horse car lines, \$98,887; expenses, \$89,962. The cost a car a mile was for cable, 13 cents; for electric car, 12.5 cents, and for horse car, 22 cents.

### LAKE STREET L.

President Loderback shows an average daily traffic at present of 30,208, a daily gain of about 3,000. By a reduction in operating expenses from 61.78 per cent of gross receipts to 59.16 per cent the year's deficit was only \$13,911 against \$38,148 for previous year. Steam was displaced by electricity on September 20, 1896, at a cost of \$341,813 and is to be largely credited with the reduction in operating expense and gain in traffic. Under these new conditions the road should show up nicely next year.

## CAHALL-BABCOCK & WILCOX BOILERS.

About a year ago the Aultman & Taylor Company, of Mansfield, O., began the manufacture of horizontal water-tube boilers of the Babcock & Wilcox type, which are known as the Cahall-Babcock & Wilcox boilers. Far from being antiquated in design or construction, they are of the same type as the Babcock & Wilcox boilers exhibited at the World's Fair in 1893, with several improvements in construction added. The steam drums are of open hearth flange steel, the heads being of the same material hydraulically flanged. For pressures from 150 to 250 pounds the horizontal seams are butt and double strapped joints with six rows of rivets; for lower pressures the seams are double rivetted. At each end is a Cahall swinging manhead. The flanges at the steam and safety valve openings are drop forged from flange steel plates. On the drums are cross boxes or saddles to which the tube sections are connected by nipples. These saddles differ from those in other boilers in being of cast open hearth steel or "flowed steel" which, when annealed, has the same properties as boiler plate. The headers or manifolds are of the standard sinuous type and

made of tough cast iron for pressures below 225 pounds, and of flanged steel for higher pressures. The holes into which the tubes are expanded are all reamed smooth. The fronts are made up of a steel frame work with only the door frame panels cast, giving a light and rigid construction uninjured by internal heat.

### NEW PUBLICATIONS.

The December number of Hartshorn's Roller is at hand, and proves to be as attractive as heretofore.

"Dixon's Graphite Productions" is the title of a fifty-six-page catalog, recently published by the Joseph Dixon Crucible Company, of Jersey City, N. J.

Charles A. Alden of Steelton, Pa., has issued a little book of blue prints, containing convenient formulæ for laying out and curving rails for street railway transition or spiral curves. It will be found a convenient reference pocket book for track engineers. Price, 50 cents.

Mr. St. Clair, the special correspondent of the Glasgow Herald, who visited this country last summer and furnished a series of most interesting articles on the street railway systems of our leading cities, has republished them in pamphlet form. It is extremely interesting as a glimpse of our methods by one who is entirely uninfluenced by local conditions.

"Information on the Preservation of Iron and Steel Structures" is the title of a pamphlet recently issued by the Goheen Manufacturing Company, Canton, Ohio. A pamphlet by the chief engineer of the Youngstown Bridge Company is added as an appendix. A copy will be sent free to engineers, architects, iron and steel manufacturers and contractors who will send address.

The report of the electrical commission of Baltimore to the mayor and city council on a general subway system, to be owned by the city of Baltimore, was received through the courtesy of Nicholas S. Hill, Jr., the city engineer. Mr. Hill has made this a very comprehensive work, explaining and illustrating in detail the different plans which have been considered to put the overhead wires of Baltimore underground.

In "Roentgen Rays and Phenomena of the Anode and Cathode," a book of 190 octavo pages, published by the D. Van Nostrand Co., New York, Edward P. Thompson has compiled complete and valuable data on this subject. With the exception of the concluding chapter by Professor William A. Anthony, the subject matter has been abstracted from the proceedings of scientific societies and the technical press of Europe and America. The book is illustrated by 60 diagrams and 45 half tones. List price, \$1.50.

"Auto-cars" (295 + ix pages, 12 mo., cloth, \$1.50. The Macmillan Company, 66 Fifth avenue, New York), by D. Farman, translated from the French by L. Serrallier, cannot fail to interest all readers who wish to keep abreast of the times on this subject. The opening chapters contain a very brief discussion of the principles of different motors and a short historical sketch of mechanical traction. Then follow descriptions, with illustrations and data as to performance of various types of motors for street and other auto-cars.

Petroleum motors are discussed more fully than the others. It is to be regretted that clearness has in some instances been sacrificed to brevity.

### CHAMBERS CLIPPERS.

Chambers Brothers Company, of Philadelphia, is now making a bolt and rivet clipper which is also a useful tool for use in overhead construction, especially where the larger sizes of round trolley and figure-8 wire are in use. These

clippers have head castings made of steel, and the cutters are made of the best quality of tool steel, carefully tempered. They are similar to a tool that has been made for years by this company, for bolt and rivet cutting, and which has given excellent satisfaction. The present improvement of having them open at the sides makes them applicable to wire cutting. They will take in anything up to  $\frac{3}{8}$ -inch diameter.

### THE FILER-STOWELL CORLISS.

We take pleasure in illustrating herewith an entirely new corliss engine, introduced by the Filer & Stowell Company, Milwaukee, Wis. This company, which has been in business for nearly half a century, and is enjoying an enviable reputation amongst machinery manufacturers, added a well equipped engine department to its already extensive works in 1890. A large number of its engines are now in successful operation, and experience has proven their efficiency. The company takes special pride in the design of the engine frame and in the detail construction of the valve gear and governor, which are eminently adapted for street railway and electric light work. The selection of the Filer & Stowell Company's corliss engines for the Garfield park power plant, this city, which was determined upon by the board of park commissioners, after a very careful examination, was especially pleasing to the builders, as this plant is intended to be a model of its kind, and such decision gave indisputable proof of the excellence of these engines. The plant was started up a few weeks ago, and is operating very successfully.

FILER-STOWELL CORLISS.

## STREET RAILWAY ACCOUNTANTS' ASSOCIATION.

A convention of street railway accountants will meet at the Hollenden hotel in Cleveland, Ohio, on Tuesday and Wednesday, March 23 and 24, 1897, to organize a street railway accountants' association. There can be no question that the time has come when an association of this kind is an absolute necessity. The American Street Railway Association is doing a splendid work, but the character of its work must of necessity be so largely along the lines of policy, and operation, both mechanical and electrical, as well as engineering matters, that it has no time left for the proper study of those problems which beset the accounting department. The secretaries, treasurers and auditors are less interested in electrolysis and sappy ties than they are in a model system of accounts; while the operating men would hardly care to spend three hours at a stretch studying out a perfect system of distribution of accounts. The accountants can easily occupy every minute of time now devoted to convention sessions, and still leave unfinished work. The steam roads have long ago separated their departments in convention work, and have an association for passenger agents, freight men, auditors, master mechanics, bridge superintendents, motive power, etc. While the street railways have no necessity for any such number, they do need at least one division, that of operating and accounting.

There is not one street railway in the country today but could improve in some respect its system of accounting. While we have changed our motive power from animal to mechanical means, most roads are still laboring under the heritage of much of an old system of accounts left over from the horse age. What is vitally needed is some standardizing of accounts which will admit of at least something like a comparison, one with another. The president of a large western road, who is also a director in another large road, said within the past few days to the writer, that he had given up trying to compare the two roads. While the lump sums of earnings and expenses were evident, the items which went to make up the several expense accounts were arrived at in such different ways, the results were useless for comparisons. This is generally the case; scarcely any two roads make the same distribution of expense accounts throughout.

Managers are giving much attention to economies, and it is found where such can be effected it is in items which are at present lost to sight by being assembled with other expense items. To formulate a system for a wide range of comparisons is the province of the accountants' association.

Another important reason for standardizing of accounts is found in the changed condition of the security market. A few years ago investors stood in line and crowded one another in their anxiety to buy. Now they insist on a critical examination. It is not sufficient that a road is in good physical condition and making money. They want to know how its expense accounts compare with other roads of similar size and conditions. To be able to furnish this information in satisfactory shape may mean the ability or failure to float desired securities.

There will be to be two long days of hard work for the men at the Cleveland meeting. Each will bring a set of blanks and forms he is using. They will sit around some large tables on which these forms can be grouped, and they will

take up the same work in the same systematic thorough manner in which they keep their own company's accounts.

Cleveland has been selected by the committee as a central point, and the date set at that time of the month when delegates can best leave. Some have suggested calling the association an "Auditors' Association," but the majority favor the other title, "Street Railway Accountants' Association" as more comprehensive, and including such roads as do not have a special title for the officer doing the auditing. Lest any should get a wrong impression, it may be stated the meeting is not for an exchange of figures, but of the systems of arriving at figures. If any one sees fit to seek a comparison of what his road is doing with any other present, that would be a matter between the two so desirous of comparison, though, under the present system, it is probable neither would gain much until the general standardizing is worked out.

### THE CALL.

Street railway companies in the United States and Canada are hereby invited to send a delegate to a meeting to be held at the Hollenden hotel, Cleveland, Ohio, on March 23 and 24, 1897, for the purpose of forming a "Street Railway Accountant's Association." The object of said association is to improve the present systems and methods of accounts, by an exchange of ideas among those engaged in this department of street railway work.

C. N. DUFFY,

Secretary Citizens' Street Railway, St. Louis.

FRANK R. GREENE,

Secretary Chicago City Railway.

H. C. McJILTON,

Auditor Baltimore Traction Company.

W. G. ROSS,

Act'g Comptroller Montreal Street Railway.

DANA STEVENS,

Acc't for Receiver, Belt Ry. Co., Washington, D. C.

E. D. HIBBS,

Auditor, Consolidated Traction Company, Jersey City.

### WHAT THEY SAY.

P. V. Burlington, secretary and auditor Columbus (O.) Street Railway: The project has some good points in its favor, and if carried out would undoubtedly be not only an agreeable getting together of the men who are expected to *always show good results*, but as well a profitable thing for themselves and street railway managers and owners.

T. C. Penington, secretary American Street Railway Association and treasurer Chicago City Railway: A standardizing of accounts is greatly to be desired. As it is now one company charges certain items to one account, and another road charges the same item to a different account, making comparisons valueless. The proposed plan for heads of accounting departments to meet and put under way the work of bringing about this reform, is an excellent one and I am in favor of it.

Frank R. Henry, secretary and treasurer Missouri Railroad Company, St. Louis: I am heartily in favor of the movement, but think that better results would be obtained if said association would take a wider scope and include all of the street railway office employees, and all subjects that pertain to the office be open to discussion, and that said association be made an annex to the regular American Street Rail-

## Street Railway Review

way Association, the meeting to be held in a separate hall or room, as then all that attend either association could if they desired obtain the benefits of both meetings.

A. A. Anderson, general manager Youngstown Street Railway: Answering your favor of the 15th inst., will say, I certainly would favor a movement in the direction of a Street Railway Auditor's Association. I would be glad to attend a meeting held for such purpose, and of course, Cleveland or Pittsburg, would suit my convenience better than most any other point. I think February or March would be a good time to hold such a meeting.

E. D. Hibbs, auditor Consolidated Traction Company, Jersey City: I have your favor of the 15th inst. in connection with suggested convention to be held at Cleveland. In reply I beg to say that I am strongly in favor of the arrangement and will make it a point to be there providing the scheme is successful.

H. C. McJilton, auditor Baltimore Traction Company: I beg to acknowledge receipt of your circular letter of the 15th instant with reference to the proposed Street Railway Auditors Association, and in reply beg to say that I concur with you that such an association will not only benefit the auditors of the different street railway companies, but would be very beneficial to the companies themselves.

I believe such an association, bringing together the heads of the department which is most criticised, will result in the adoption of a fixed set of accounts that will embrace every want, and place the companies in a position to exchange the cost of operation, a much needed condition.

I think if nothing else is accomplished, that alone will be worth considerable to the enterprising companies, as an interchange of percentages, cost of operation, proper forms for which can easily be arranged, would be very valuable.

The Street Railway Association has presented a set of accounts, which I think can be very much improved upon.

Your efforts in this matter should be encouraged, and any information that I can give you will be cheerfully given.

It will give me a great deal of pleasure to be present at the proposed meeting, to be held in Cleveland, but as our stockholders' meeting will be held in February, I cannot, at this writing, state positively that I can attend, but could do so were the meeting held in March.

W. G. Ross, acting comptroller Montreal Street Railway: I think the meeting of street railway auditors is a good idea and will be glad to attend.

J. P. E. Clark, general manager Binghamton Railroad Company: I believe a meeting and general conference of auditors, as suggested, would be beneficial in many ways.

A thorough discussion and interchange of ideas relative to "systems of accounts," etc., would, in my opinion, prove productive of good results to all in attendance. As to this company being represented, I could not state definitely at present writing, but think probably we would be pleased to avail ourselves of the opportunity.

H. L. Wilson, auditor West End Street Railroad, Boston; I have your favor of the 15th in reference to a meeting of the auditors of the street railway companies and think the suggestion which you have offered an extremely good one and if properly carried out, will no doubt, be of great

benefit to a large number of the street railway companies. At this time it will be impossible for me to state whether I could attend such a meeting as you suggest, but if anything further is done in relation to the matter, I will be glad to hear from you again.

Ford Starring, auditor Detroit Electric Railway: Replying to yours of the 14th, I have to say that I believe it would result beneficially to the railroads if they would encourage as much as possible the exchange of views and ideas by the heads of the various departments, not excepting auditors. Will be pleased to co-operate with you in any manner to reach the desired end.

John Hourigan, auditor Albany Railway: I am very cordially in sympathy with the idea of a gathering of street railway auditors. I believe it would be helpful to every man who would attend. I hope you will work up the idea, and if your efforts result in a meeting, I will strain more than one joint to be present. Casually, I would a little rather go to New York than Philadelphia, but if Cleveland appears to be the best for all concerned, I would be entirely satisfied. Please let me know if I can be of any service in the matter, and I will promptly respond, if possible.

Dana Stevens, accountant for receiver, Belt Railway, Washington, D. C.: I have noted contents of your circular letter of the 15th, and heartily endorse your plan. Such a meeting as you have in view would doubtless prove valuable to street railway accounting departments, and I hope your suggestion may meet with sufficient encouragement to lead to a well attended conference. Uniformity in street railway accounts would, I think, be advantageous and I think should be urged. Of course, I cannot state definitely, but know of nothing to prevent my attendance if meeting is called, and shall be pleased to meet with you.

Frank R. Greene, secretary Chicago City Railway:—I am heartily in favor of the formation of such an association and believe it could be made very valuable to both companies and officers. I expect to attend the meeting.

Russel B. Harrison, president Terre Haute Electric Railway:—The idea is an excellent one as a standardizing of accounts is greatly needed. I will attend the meeting or send a representative.

C. N. Duffy, secretary Citizens' Street Railway, St. Louis:—In my opinion if such an organization is to be formed it should be called a "Street Railway Accountants' Association," so as to embrace the head of the department doing that work whether the secretary, treasurer, auditor or whoever it is. I think the association should either be made a part of the American Association, or at least hold its annual meetings at the same place and date but in a separate room or hall. If organized along these lines I am greatly in favor of it, and will promise the attendance at the first meeting in Cleveland to organize, of six representatives from as many St. Louis roads. There is a large amount of work which should be put under way and by October the committee appointed at the Cleveland meeting can report.

Robert McCulloch, president American Street Railway Association: Am heartily in favor of organization as outlined.

The program will appear in the February REVIEW.

## SUDDEN DEATH OF COL. SINCLAIR.

Col. Wm. H. Sinclair died suddenly of apoplexy while writing letters in his room at the Powers House, Rochester, N. Y., on January 11. He was in that city to confer with gentlemen in regard to the construction of a proposed suburban road, and had parted with them at 11 o'clock in the

morning in apparently the best of health and spirits. The conference was to be resumed at 3 p. m., at which hour the party went to his room, where he was found lifeless on the floor, having fallen from his chair. Several letters and one unfinished letter were upon the table. The pen was also on the floor, having dropped as he fell. While his friends knew he had suffered from indigestion

the past few years, no one had any reason to anticipate so sudden an ending to his busy life.

Col. Sinclair was born at Akron, Ohio, October 31, 1839; was educated in Michigan, and entered the federal army in May, 1861, at the age of 21. He rapidly rose by frequent promotions, and when mustered out, which was not until 1867, he left with the rank of Colonel. He engaged in many prominent battles and sieges and twice had his horse shot from under him. He won numerous commendations from leading generals for bravery and ability, and marched with Sherman to the sea. Upon leaving the army, he decided to remain in Texas, where he became a leader in public affairs, serving in the legislature and as Speaker of the House; as collector of internal revenues and postmaster at Galveston, which has been his home. He took hold of the Galveston Street Railway in 1876 and built it up into one of the best systems in the south. About two years ago he sold out his interest at a good figure, but continued to make Galveston his home. Mrs. Sinclair, a most charming and lovable lady, died suddenly about eighteen months ago. Both were constant attendants at the annual street railway conventions.

To attempt to enumerate the sterling qualities of Col. Sinclair from a personal point of view, would be no easy task. He was generous to a fault, and above all, supremely just, universally kind, and always true, and in the highest degree possessed the esteem and honor of all who knew him. His warm hearted, genial nature quickly won its way into the hearts of others and bound them to him in ties of friendship unusually strong. Those who, like the writer, have enjoyed his confidence and friendship for many years past, will specially feel his death as a personal loss never to be replaced, and the hundreds of friends, by whom he was universally beloved, will likewise mourn the parting.

He rarely missed the annual conventions, and was present at St. Louis. He was one of the prime movers in the Texas Street Railway Association and its only president. He had also served the American Association in several official capacities.

A verdict of \$25,000 damages against the Chicago City Railway Company and the Chicago & Grand Trunk Railroad was given in favor of Isaiah C. Smith for permanent injuries received in a collision between a horse car and a Grand Trunk train, July 17, 1893. A new trial was moved.

## DEATH OF JOHN F. OSTROM.

We are pained to announce the death of John F. Ostrom, for several years past the manager of the street railway department of the Pennsylvania Steel Company. Mr. Ostrom died at Philadelphia, January 3, after an illness of five months. He was a most energetic and faithful worker, was widely and favorably known in the street railway fraternity, and highly thought of by the officers of his company.

The Alameda and Oakland (Cal.) Electric Railway has issued the decree that hereafter patrolmen and mail carriers must pay their fares when off duty.

The Western Society of Engineers gave its annual banquet at the Technical Club, January 5. Attendance was large and the event a most enjoyable one.

It is reported that the Nashville, Tenn., street railway has been sold to Chas. M. McGee, of Knoxville and New York, the consideration being in the neighborhood of \$1,000,000.

During his recent visit, the Rev. Dr. John Watson, expressed his surprise at the courtesy and intelligence of the officials and employes of the railroads and "tramways" in this country.

At the annual meeting of the Citizen's Traction Relief Association, of Pittsburg, the report of the treasurer, Charles Fitzgerald showed the following: Receipts during year, \$4,660.69; paid on deaths of members, \$900; sick benefits, \$2,592.50; miscellaneous expenses, \$212.20; balance, \$955.99; present membership, 234.

Four persons were seriously injured in a cable car collision in St. Paul. A grip car with two trailers was nearly at the top of Selby avenue hill when the gripman lost control of his car and it rapidly descended until it struck another train of three cars. The cars were demolished and it was strange that a greater number were not injured.

The Elgin (Ill.) City Railway has been spending money during the past year in improving its service and in keeping the road bed and entire system in good condition. The company bought out the Edison electric light plant and incorporated it with the railway company, and at present is doing all the electric commercial lighting of the city.

John I. McDuffee filed a petition in the United States Circuit Court against the City and Suburban Railway Company, the Traction Company, the Central Company and the City Passenger Railway Company, of Baltimore, Md., claiming that they have infringed the patent rights of an invention made by him for improvements upon electric railroads.

Mayor Fleming, of Toronto, has, after several months of negotiation, come to an agreement with the Toronto Railway Company. The street cars are to run on Sunday, tickets being sold seven for a quarter. As soon as the city builds a bridge to Toronto Island the company is to extend its lines over the island and charge only the ordinary fare from any part of the city. The council has yet to give its sanction to this but this is reasonably sure.

### SANTA CLAUS TROLLEY CAR.

The unique applications of electric cars for novel parade purposes multiply. The latest, and by no means the least interesting is a Santa Claus car, which was designed and constructed by Warren Y. Soper, of Ahearn & Soper, contracting electrical engineers, Ottawa, Canada.

The idea originated with Mr. Soper, who for some days previous caused letters to appear in the newspapers, dated

SANTA CLAUS CAR—OTTAWA.

from various points between the North Pole and Ottawa. These letters were signed "Santa Claus," and gave the information that he had decided to make a daylight visit to the city, and that he would arrive with his reindeer the day before Christmas and go through the streets of the city mounted on top of an electric car. Santa Claus intimated that his visit was made specially in the interest of the children in order that they might see him in person, and that during his trip through the city he would distribute several thousand oranges. He furnished a time table indicating the hours at which he would pass the various street corners. The result of these letters was that for some time before his announced appearance on the afternoon before Christmas the streets were thronged with men, women and child-

CROWD WATCHING THE SANTA CLAUS CAR.

ren. Promptly on time the car came in sight, covered with snow and ice and apparently just arrived from the far north. On the front vestibule were the figures "1896" and on the rear vestibule the figures "1897." The interior of the car was filled with toys of every description. Santa Claus himself was on top, seated on a toboggan and driving his reindeer. The basket on Santa Claus' back, as well as the chimney appearing through the top of the car, was overflowing with toys. The motorman and conductor were costumed as Icelanders, and beside the motorman stood an Eskimo who played on a cornet during the trip. As the car proceeded, Santa bowed in a genial way to the throngs, and from a basket in front of him distributed oranges. He was aided in the distribution by several assistants inside the car. Some four thousand oranges were thus thrown to the children. The scrambling for them furnished no end of fun.

The whole affair was carried out most successfully, and created greater interest and excitement than any event that ever occurred in Ottawa.

Our illustrations show the car, and the big crowds it occasioned.

### LENOX AVENUE CONDUIT IN A STORM.

The severe snow and sleet storm of December 16, caused a shut down on the Lenox avenue, New York, line, for several hours. Overhead trolley lines in other cities also suffered delays from the same storm. As this was the first severe storm on the line since the conduit system was installed it attracted much attention.

There was some surface accumulation of snow which drifted badly, and as the cars were not equipped with scrapers soon made a heavy track. Changes being made in the power station also cut down the supply of current to about one-half the ordinary output. In addition the conductor bars in the conduit became coated with ice, and as this was the first time the difficulty had presented itself, some time was lost locating the trouble. When discovered it was remedied by putting on some plow shares with sharp cutting edges, but this required several hours to do. The entire delay, however, was not nearly as bad as frequently occurred on overhead lines in their early days. Now that the difficulty has been solved there is no reason to expect delays in future from this cause. The fact that the company has decided to build about 40 miles more of the same conduit system is evidence that the anticipated difficulties from this source are very small.

### FULTON FOUNDRY ASSIGNS.

The Fulton Truck & Foundry Company, of Mansfield, Ohio, made an assignment for the general benefit of its creditors, without preferences, to W. S. Coppeller. Liabilities, \$30,000. Shop, machinery, tools, stock, etc., have been appraised at \$13,780, and under order of court will be offered at auction on January 30.

General Manager W. J. Hart, of the Union Street Railway Company, of Saginaw, Mich., has posted the following notice in the cars: "Union Street Railway rates of fare: single ride, all persons over eight years of age, five cents; children—one child under the age of eight, accompanied by parent or guardian, free; two children under the age of eight years, so accompanied, five cents."

## TROLLEY ATTACHMENT TO THE VAN BUREN STREET ROLLING LIFT BRIDGE.

When the Van Buren street rolling lift bridge was constructed and put in operation it presented a nice problem to the engineers of the West Chicago Street Railroad. The question was how to get a trolley connection suitable to that form of bridge. J. R. Chapman, the manager of the electrical department, was largely instrumental in solving it.

In the cut one-half of the center span of the bridge is shown, together with the trolley posts, one on the stationary

Western avenue station to the Hobbie street power house. No difficulty has been experienced with the operation of this device, and its success has made this form of bridge most suitable for street railways. With it the danger of plunging into the river when its is open is entirely eliminated.

## BRUSSELS INTERNATIONAL EXHIBITION, 1897.

The international exhibition at Brussels will be opened on April 24, and will be kept open at least six months, but the directors reserve the right to delay its closing till November 15, 1897. Brussels, next to London, is the most important tramway and railway center in Europe, as the Belgians have always held very large interests in such properties, going extensively into the installation and equipment of tramways outside of their own country. Robert W. Blackwell, 39 Victoria street, Westminster, London, who is the foreign representative of many large American supply houses, has reserved a large space at the exhibition, and will make an elaborate show of the electric railway specialties of the houses represented by him.

## BRISTOL AND ITS TRAMWAYS.

part and one on the movable portion of the bridge. We also represent an end view of the mechanism for taking care of the trolley wires for the double track. Upon shaft, A, are three drums, two of which are made of wood and receive the trolley wire, while the third supports a counter weight to revolve the shaft and hold the wire taut as the bridge is raised and lowered. A brass casting, D, receives the No. 0 trolley wire and supports the sheave, C. The wire F-G, which extends from the center to the sheave and around the drum, B, is composed of 37 strands of No. 15, and its length provides for a slack of 38 feet when the bridge is lifted. Upon the shaft A are cut screw threads, which provide for a horizontal movement sufficient to wind the wire in the grooves of the two drums. The apparatus was designed so that different weights could be used, depending on the desired tension of the wire. As the car passes the center of the bridge the current supply is changed from the

The tramway company, of Bristol, England, equipped its Kingswood line with the trolley system, and a year's trial has proved it to be satisfactory in every way. When suggestions for operating the rest of the lines by electricity were made the town council appointed a committee to investigate the subject. This committee consulted Mr. Preece, the eminent authority on submarine cables, and with his assistance a report was made. The trolley system was entirely acceptable to them, but they imposed conditions to which the tramway company would not agree. It is the option of the city when the franchise expires in twenty years to purchase the tramway. With this in view, and the fact that the city owned the lighting station, which was not paying expenses, the committee insisted that the tramway company should rent power from the city. This the company refused to do, as the city power was inadequate, and an alternating current of 2,000 volts. So Bristol will pursue its sleepy way with no speedier form of locomotion than that furnished by the ancient horse cars, unless the council relents.

TROLLEY WIRE CONNECTION AND WINDING DRUM.

PLAN FOR TROLLEY ATTACHMENT.

### TOLEDO TRACTION COMPANY'S POWER HOUSE.

The Toledo Traction Company, of which A. E. Lang is president and W. S. Jewell general manager, and whose new power house is the subject of this article, has resulted from the consolidation of various street railway and other electrical interests of Toledo. This company, in connection with the Toledo Consolidated Electric Company, a company furnishing light and power only, the current for which is supplied by the Toledo Traction Company, operates what was form-

POWER HOUSE—TOLEDO TRACTION COMPANY.

erly the Toledo Consolidated Street Railway Company, the Toledo Electric Street Railway Company, and the Western Electric Light & Power Company. During the coming year the Toledo Electric Company will also be merged with this company.

This combination of a railway and a light and power plant furnishes an almost continuous load for the station, and a high economy of operation is the result. The general arrangement is admirable, and the details have all been carefully worked out by the engineers, Sargent & Lundy, of Chicago.

Work on the power house was commenced in June, 1895, and the first fire started under the boilers in May, 1896. The building lies north of Madison street and extends from Water street to the river, having a frontage of 196 feet on Madison and 210 feet on Water. The foundations rest on piling, as will be seen in one of our illustrations. The walls are brick and quite high, it being 54 feet from the basement floor to the top of the walls. The side walls are plentifully supplied with windows, while the end walls are solid, excepting for the doors.

The boiler room is 40 feet wide, and extends the entire length of the building on the east, or river side. This portion of building has a flat roof resting on I-beams. The floor of the boiler room is 9 feet above the basement floor, which is about 2½ feet below the street grade. In the boiler room there are to be ten boilers, six 350-horse-power Heine boilers with Hawley down-draft furnaces and four 500-horse-power Stirling boilers, with McKenzie furnaces,

which were removed from the Consolidated Railway plant. Two of the Heine boilers have not been installed as yet. Our illustration shows the boiler room with the Heine boilers in place and the Stirling boilers in process of erection. Ideal arrangements are made for handling coal and ashes in this plant. The coal is delivered at the north end of the building, shoveled onto a grating, through which it drops onto an elevator that carries it up an iron chute affixed to the wall on the outside and dumps it into the storage bin. This bin is 10 feet, 8 inches wide and 39 feet, 9 inches long, having a capacity of 400 tons. In the bottom of the bin, which is 8 feet above the boiler room floor, are four hoppers, through which the coal is dropped into iron carts and hauled, after being weighed, to the boiler where it is to be burned.

Similar arrangements are made for handling the ashes. The basement under the boiler room is divided by a longitudinal wall into two nearly equal portions, of which the western one forms a single room. Hoppers, one under each furnace, receive the ashes which are from time to time dumped into an iron wagon, wet down, hauled to the north end of the room and dumped in front of the ash conveyor which delivers them to the wagons outside with but a single handling. The ash and coal conveyors are driven by electric motors, a 5-horse-power motor being used for the former and a 10-horse-power for the latter. This machinery was furnished by the John A. Mead Manufacturing Company.

The eastern portion of the basement is cut up into several rooms, one of which serves as a general store room, one as an oil room and one as a testing room. In this last is a D'Arsonval reflecting galvanometer and a 100-cell Leclanche battery used for testing insulation by the method of substitution. From tanks in the oil room oil will be supplied to the machinery by an elaborate system of piping, the oil being forced through the pipes by water from the house tank on the roof of the boiler room, the water being admitted near the bottom of the oil tanks. A Deming triplex pump with 5½ by 8-inch cylinders, driven by 15-horse-power electric motor supplies water for general purposes.

The hot gases from the boiler furnaces are conducted through a rectangular smoke flue suspended along the west side of the boiler room to a Green economizer, which is located upon a girder work construction about 20 feet above the floor, and just north of the stack, thus leaving room to

VIEW OF FOUNDATIONS.

BOILER ROOM.

install boilers underneath the economizer. The economizer is arranged to be 16 tubes wide, and the present installation is suitable for 2,000 boiler horse-power, space being left for another 1,000-horse-power to be installed later. The feed-water is heated to 250° F. in the economizer. The scrapers for keeping the tubes free from soot are operated by an electric motor. This economizer, heating the water to a high temperature, could also be used with advantage where surface condensers are used instead of jet condensers as in this plant. The feed water is measured by means of two Worthington hot-water meters located in the basement.

The stack, from the piling foundation up to the top of the building wall, 63 feet, is built of brick laid in Portland cement. On the outside it is nearly square, 18 feet on the side, the south side being part of the south wall of the building. The flue proper begins 21 feet, 6 inches above the boiler room floor, a flooring of concrete 8 inches thick, supported on 12-inch 32-pound I-beams, being laid across the stack at this point. The stack below this floor is octagonal in section, 12 feet, 6 inches in diameter, and contains a spiral stairway, thus serving as the entrance to the building. Above the walls of the building the stack is of steel, circular in section and self supporting. It is 11 feet inside diameter, the flue being lined with fire brick for the first 90 feet, and from that point to the top (206 feet, 6 inches above the grates) it is lined with tile. The draft secured is from  $\frac{3}{4}$  to 1 inch of water, depending on atmospheric conditions.

The steam pipes from the boilers all open into an 18-inch header extending along the entire length of the west wall of the building. This header is of wrought iron, lap-welded, with cast-steel flanges, and is in three sections. These sections are connected by expansion joints, consisting of copper U-tubes of somewhat smaller diameter. From the header run steam pipes to the engines, all the valves being located in the boiler-room, just in front of openings in the partition wall so that they can be easily operated from the engine room. All valves about the building are Chapman gate valves.

The engine room is 70 feet wide and about 206 feet long. The engines are located on the east side of the room. Our illustrations from photographs show a view of the switch-

INTERIOR OF ENGINE ROOM.

board as it appeared in the shops of the General Electric Company, and a view of the engine room looking north from the switch-board. The general arrangement of the machinery will be understood from the line drawings.

There are four American-Wheelock compound condensing and two Porter-Allen tandem compound condensing engines. The Wheelock engines were built by Cramp & Sons, of Philadelphia, and have cylinders 18 and 48 by 48 inches, run at 90 r. p. m. and with the normal boiler pressure of 150 pounds, will develop 1,200 horse-power when cutting off at 55 per cent of the stroke. The most economical power is 800 horse-power. Jet condensers are used and the air pumps are belted to the engine shaft. There are also two auxiliary pumps, one for the boiler feed and the other for the water of condensation from the jackets. The heads and barrel of the high pressure and the head of the low pressure cylinder are jacketed with the live steam. The valve gear for these engines was built by the Wheelock Company, of Worcester, Mass. The valves are of the gridiron type and move horizontally at right angles to the cylinders. On the low pressure cylinders there are two exhaust and two steam valves at each end. The motion of the valve stems being horizontal instead of vertical, springs instead of dash pots are used for closing the valves. Between the high and low pressure engines are located the gages, levers for operating the quick throttle valve, the primer and the drip cocks, and wheels for operating the throttle valve slowly, and the injectors.

On the shaft, which is 22 inches in diameter in the middle, 18 at the bearings, and 14 feet, 4 inches between bearings, are a 500-kilowatt G. E. 10-500-90 generator and a fly wheel. The fly wheel is 20 feet in diameter, with solid hub and built-up spokes. On the periphery are grooves for a 14-

strand rope drive by which the line shaft located in the basement of the engine room at the west side of the building is driven.

The Porter-Allen engines were built by the Southwark Machine & Foundry Company, Philadelphia. Each has cylinders 15 and 36 by 30 inches with the receiver on top. The low pressure cylinders only are jacketed. The air pumps for these engines are Blake steam pumps. Each engine will be direct connected and to two 200-kilowatt lighting generators, which are not yet in place, however. At present one of these engines is belted to a 300-kilowatt alternating current generator. The maximum power of these engines is 700 and the economical power 550 horse-power each.

The line shaft is connected to the four large engines by Hoadley rope drives, built by the New England Engineering Company, Worcester, Mass. This shaft has a total length of 198 feet, 5 inches, and is of hammered iron 6½ inches in diameter, and together with the clutches was furnished by the Hill Clutch Company, Cleveland. It is divided into four sections, 42 to 57 feet in length, which may all be connected by means of friction clutches. This shaft carries the pulleys which drive all the generators not direct connected to the engines. There is a friction clutch for each pulley on the shaft. All clutches are operated from the engine room floor by the hand wheels shown in the illustrations.

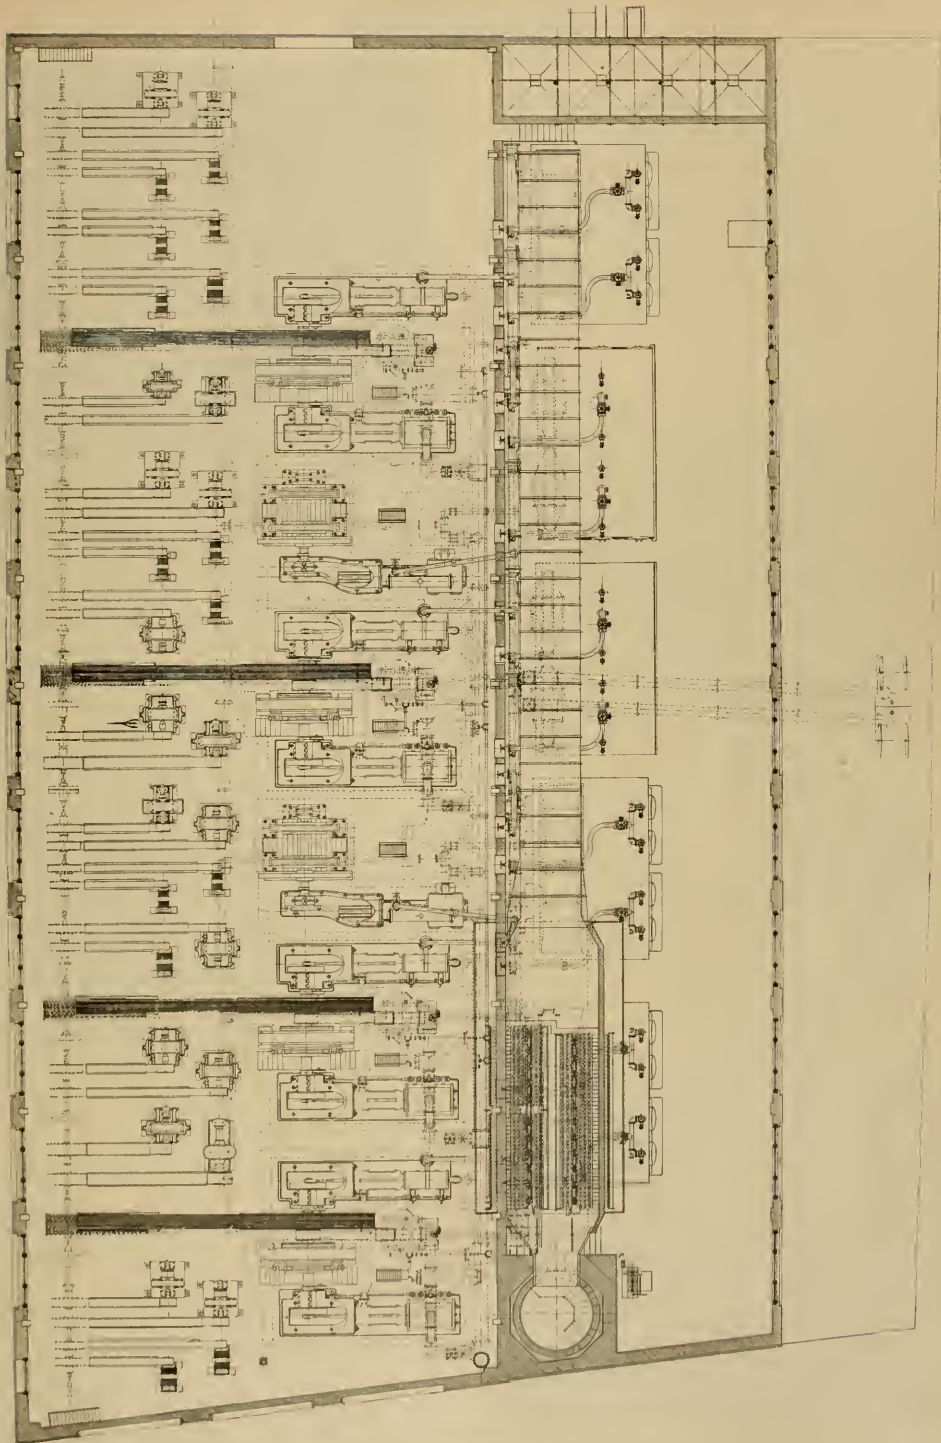

One of the novel features in this station is use of the same engines for furnishing railway and lighting current. The direct connected generators are used for railway work and the belt driven machines for lighting, all the engines being connected by the line shaft clutches. It has been found that to obtain satisfactory lighting service the railway load should

TRANSVERSE SECTION LOOKING FROM SWITCHBOARD.

PLAN SHOWING GENERAL ARRANGEMENT OF MACHINERY.

not exceed fifty per cent of the total. A Moscrop speed recorder gives a continuous record of the speed.

The engine foundations extend down to the piling as do the piers supporting the line shaft bearings. The engine room floor is of brick and cement, supported by 12-inch I-beams, spaced 45 inches between centers and resting on similar beams running at right angles and supported by the walls and engine foundations. The basement is 15 feet high in the clear and here are located the drums for tightening the rope drives, the condensers, the Jewell oil filter, and the wiring from the generators to the switch-board. Along the east side of the basement is a 24-inch exhaust header. Water for condensing is drawn from the Maumee river through two 18-inch mains.

The machines installed comprise four multi-polar 6-100-562 Edison used on the 3-wire tubing system; two 500-volt machines for power current, one an Edison 60 and the other a Thomson-Houston multi-polar 90; four 500-kilowatt G. E. 10-500-90 railway generators direct connected to the large engines; one 150-kilowatt Edison machine which has been rewound and is used as a booster in series with the railway bus bars of the Toledo & Maumee Valley road, a 24-mile loop; one 2,200-light and one 4,000-light alternating current Westinghouse; one 5,000-light G. E. type A 22-300-682; two old T-II D-62 machines rewound and used for exciters; ten 50-light Western Electric arc machines, and six 125-light Wood (Ft. Wayne Electric Corporation, Ft. Wayne, Ind.) arc machines. The arc lights, of which there are about 600, now supplied by the station are operated by the six Wood machines. The dynamos furnish 9.6 amperes at 6,250 volts and have a maximum capacity of 6,800 volts at 500 r. p. m., with an efficiency of 90 per cent. The regulating mechanism on these machines is on the same principle as the older Wood type, but remodelled, and is very sensitive in its operation so that the variation in current does not exceed  $\frac{1}{10}$  of an ampere. The armatures are of the ventilated type, smooth core. Four sparkless brushes are used.

For handling machinery there is one of the Brown Hoisting & Conveying Machinery Company's 20-ton cranes, with two carriages of 10 tons capacity each.

The switch board is of white marble and extends across the south end of the engine room, the gallery in front of it being 14 feet above the floor. On the west wall is a small

MANHOLE NO. 1—TOLEDO TRACTION COMPANY.

potential board with meters to show the drop between the station and the tubing system. Beginning at the west end, the board is divided into panels as follows: one for the 3-wire machine now installed, and one blank for the generators on the Porter-Allen engines; one panel for the 3-wire system feeders, 24 cables, with Van Fleck vertical ammeters; two panels for the power current machines; four panels for feeders, one with a recording watt-meter; four panels for the railway machines on the large engines; one panel with a 5,000-ampere recording wattmeter; ten double panels for 20 railway feeders, with a switch, ammeter and circuit breaker for each; one blank for feeders; three panels for alternating feeders; one potential panel with voltmeter and ground detector; eight panels for alternating feeders with recording wattmeters on the back of the board; and the arc board for 20 circuits and 20 machines with 4 ammeters, each of which may be connected to any one of 5 machines, and a voltmeter reading to 7,000 volts. Automatic circuit breakers are used for all except the 3-wire and the arc circuits. Behind the board are the track return cables, of which there are now four of 1,000,000 and five of 500,000 circular mils in cross section. Weston meters are used on the direct circuits and General Electric meters on all alternating and arc circuits.

All of the wiring for the 3-wire system is underground and the railway cables also leave the station underground. One of our illustrations is a view of manhole No. 1. The tubing system will supply an area about one mile square in the business portion of this city.

This station is now supplying current for 96 street cars in regular service, for 8,000 lamps on the 3-wire and alternating current systems, and for 600 arc lamps. During November, 1896, the average daily output of the station was 25,000 kilowatt-hours. During December the output has been somewhat higher, running from 30 to 38 thousand kilowatt-hours per day.

For our photographs of the station we are indebted to G. A. Cooke, assistant to the general manager.

The Chicago City Railway is being sued by Thomas T. Moran, for \$10,000, on account of the damage done his property on Wabash avenue, by the noise, smoke, cinders, soot and the vibration caused by the machinery in the new electric power house on Fifty-third street.

SWITCH BOARD.

## STREET RAILWAYS IN MEXICO.

BY FRANK HUMBOLDT CLARK.

"How often do the street cars run?"

"About every half hour, but they aren't very regular."

This conversation, which related to the street cars of Chihuahua, would apply with equal accuracy to most of the cities of Mexico, and conveys a whole volume of information regarding street railway management in our neighboring republic. The Chihuahua Railway Company, which may be taken as a fair illustration of the larger cities, for a population of 40,000 has about twenty street cars, but only

blanket-like zerape and wearing the high sugar loaf hat universally used beyond the Rio Grande, the street car driver of Mexico is as little like an American motorman as can be imagined.

The conductor goes in pairs. One man sells you a ticket for which he charges you six centavos—or more if you are particularly unsophisticated Americans, as was the case with us in Aguas Calientes. The second man comes later and collects the tickets, from which it would seem that it is cheaper to have two men instead of one man with a bell punch or register. The only exception to this rule is Monterey which is one of the most progressive cities in Mexico and boasts the proud title of the "Chicago of Mexico;"

SCENE AT GUANAJUATO.

PLAZA, VERA CRUZ.  
STREET CAR OF CHIHUAHUA.

A TANDEM TEAM, MONTEREY.  
POSTAL CAR, PUEBLA.

has four cars in regular service. The fare in a first-class car is six centavos and second-class three centavos; the longest ride is about four miles.

The trolley cars of Mexico are all donkey cars. These patient little animals are the universal motor and are driven in every style, or lack of style. Sometimes they are seen tandem as in Monterey, and frequently four, six and eight to a car, as in the steep and narrow streets of Guanajuato or Jalapa. The Mexicans are a quiet people not given to loud noises on the street, and instead of shouting, the drivers urge their donkeys on by a sharp hissing sound. The bell, as a signal, is universally supplanted by the horn. A Mexican Jehu, therefore, urges his galloping burros to greater speed by hissing at them and announces his approach by blowing what seems like a toy tin horn; wrapped in his

there, the collector, after receiving our money went to a register hanging by a strap over the dash board of the car and rang up the fares.

An important branch of the street railway business in Mexico is the transportation of freight, and the miniature freight cars, both box cars and flat cars, are a common sight, especially in Vera Cruz and Zacatecas. The unique funeral cars of the City of Mexico have already been illustrated in the STREET RAILWAY REVIEW. Another branch of the business, by which we frequently had occasion to profit, is the practice of sending one or more cars marked "Especial," to meet a large party. On these special cars no passengers other than the members of the party to be accommodated are allowed, and the rate of fare is from ten to twenty-five centavos.

The Mexicans seem to have anticipated us in utilizing street cars in the postal service. In Pueblo a postal car is run to meet all mail trains and is attended by a guard of the national soldiery known as "rurales." At Pueblo we were reminded, in a manner we will not soon forget, of the good but sometimes inconvenient custom of taking a siesta from two to three o'clock. As is usual in Mexican cities, the railway station is a mile or more from the center of the city. Our special train was to stop for several hours that we might see the town. After wandering about the Plaza we went into the great Cathedral, one of the most famous on the continent. Here we lingered, allowing ourselves only time enough to reach the train at three o'clock. Upon looking for a street car, what was our consternation to find that the donkeys and cars were leisurely taking their daily siesta, the conductors and drivers were not even in sight, and there was no prospect of a ride until after three o'clock.

In Mexico the street cars go as the animals went into the ark, two by two. A first-class car, usually buff in color is closely followed by a green second class car. This is made necessary by the character of the population. There is no middle class: the people are either well to do or they belong to the wretchedly poor peon class. So common is the practice of smoking, that the men smoke their cigarettes in the first class cars as a matter of course, and women of the poor class are often seen smoking on the street.

One of the most interesting lines of the Mexican "travias," as they are called, is that which extends from Zacatecas to the well known shrine of Guadalupe, a distance of over four miles, and which is operated solely by gravity. In the expressive language of the Chinaman, "No pushee, no pullee, go like helle!" Taking on board of an accompanying flat car, the burros which are to draw you back, you start slowly and are soon whirling over bridges, past quaint flat roofed houses dropped down from the orient, by rich silver mines, through picturesque groups of natives, with magnificent views presented at every turn; in a few minutes you have completed a ride worth going a long way to enjoy, and one which located at the gate of an American city of seventy thousand souls would make the fortune of some railway manager.

Of the street railways of Mexico it may be said in general that, though their methods are primitive, they are a real accommodation to the public. The heart of a Mexican town is its plaza and at the plaza of every considerable city one can generally take a street car to the part of the city or neighboring point of interest he wishes to reach. American car builders have been liberally patronized and few enterprises are more inviting or promise better returns than the application of modern methods and equipment to the street railways of Mexico.

#### CHICAGO ELECTRICAL ASSOCIATION OFFICERS FOR 1897.

The Chicago Electrical Association elected officers for 1897 at its last meeting in December. They are as follows: S. G. McMeen, president; F. S. Hickok, vice-president; E. J. Jenness, treasurer; H. Cochrane, auditor; J. R. Cravath, secretary; W. Clyde Jones, G. W. Knox and K. B. Miller, directors. This association is constantly growing in membership and a good attendance at every semi-monthly meeting indicates a healthy interest.

#### AURORA VESTIBULES.

In last month's issue we described several of the most up-to-date forms of vestibules and gave the thoughts of several managers on the subject. We are now able to supplement that article with a description of the removable vestibule used at Aurora, where D. A. Belden is general manager. Our engraving shows a vestibule on and a vestibule off the car. It is made of ash reinforced with band iron and having angle irons at sash frame intersections. The middle window

CAR BARN—AURORA & GENEVA RAILWAY.

slides to the left. The window frames are of cherry and are fitted with extra thick glass. The vestibule leans slightly back so that the top may come under the hood of the car. The platforms are long enough so that the brake staff can be moved back 8 inches to clear the vestibule. Our engraving shows a car "before and after taking," a vestibule, and a detached vestibule.

#### CITIES MAY LIMIT SPEED.

The Brooklyn city council passed an ordinance limiting the speed of street cars to 6 miles per hour in certain down-town districts, and to 8 miles in other districts. The city recently made a test case, based on the evidence of two policemen with a stop watch, who measured a distance of 285 feet on one of the lines of the Brooklyn City & Newtown; and testified that a certain car passed at a rate of nearly 14 miles an hour. The city won in the justice court, where a fine of \$25 was rendered. The county court reversed on the ground that there was no evidence to show the action of the motorman was willful or negligent.

The appellate division of the Supreme Court sustained the ordinance and the justice. Part of the ruling is as follows: "In the case before us it appears that the motorman was in control of the car. It does not appear that any accident had occurred to the car which rendered its proper management difficult or impossible. No circumstance is shown from which it appears that the motorman could not have run the car at a speed within the rate prescribed by the ordinance. The testimony of the motorman and conductor that they did not know the car was going faster than eight miles an hour, at the most, only raised a question of fact of which the determination of the justice is conclusive."

## THE THEORY OF THE WIRING TABLE.

BY THOMAS G. GRIER.

Wires are used to form an easy and direct path for the distribution of the electric current as pipes are used for distributing gas or water to places at a distance from the source of supply. The sizes of pipes are determined upon the basis of the distance and the quantity of material sent through them. Wires, as well, must have some distinct size depending upon the circumstances governing different conditions. It is necessary to make calculations in order to ascertain the size of wire, and to shorten and to simplify this work of calculation wiring tables have been compiled. A wiring table gives at once the result in the commercial size of wire, and when the proper table is at hand no multiplying or dividing, no figuring, no application of a formula is required.

In all substances there exists some unknown obstruction to the flow of an electric current. The technical name given to this obstruction to the passage of an electric current is resistance. It is not known what causes this resistance, but by experiment the extent to which it exists in any substance can be ascertained and measured. It is known how in any substance the amount of resistance may be varied by altering the dimensions, also as to the amount of energy necessary to overcome any resistance. The theory of the wiring table is simply one of proportioning resistances.

The first point to be considered is, how is the resistance varied in any substance? The law states that the resistance of any substance varies directly as its length and inversely as its cross section. This law has been verified by experiment and is universally accepted as a law of nature. The resistance varies directly as the length of any given substance, means that if the length of a wire is doubled the resistance is doubled, and three times the length means three times as much resistance. The resistance varies inversely as the area of cross-section, means that if the area of a wire is doubled, that is, if there is just twice as much metal for a given length of wire, the resistance is decreased one-half. If the area is increased three times, the resistance is decreased to one-third. In a wire of a given substance if the length is doubled, and at the same time the area is doubled, the resistance remains the same, or if the length is increased to three times as great, and at the same time the area is increased three times, the resistance remains the same. From this application of the law already referred to, it can be seen how it is possible to vary the size of a wire so that the resistance remains constant for any length, or how the resistance may be changed to suit any condition or circumstance.

The next consideration is the action of the electric current. The pressure is measured in volts, and the flow is measured in amperes. The volts are all used up in forcing the amperes against the resistance. The resistance (if it were all in the wire) would mean a total loss of the electrical energy, because the volts would be used in doing work from which no results were obtained. It is necessary, therefore, to make the resistance of the wire which conducts the current but a proportion of the total resistance. The rest of the resistance of a circuit being that which exists in the lamps, and the other devices or apparatus which converts the electrical energy into commercial forms, as light, power or heat.

To so compile a table and calculate the sizes it is necessary to consider the relation which exists between the unit of

resistance, the ohm, the unit of pressure, the volt, and unit of current, the ampere. One ohm resistance requires the pressure of one volt to transmit one ampere. Two ohms require two volts to transmit one ampere. One volt will transmit but one half an ampere over two ohms, and 100 volts will transmit 10 amperes over 10 ohms. This is Ohm's law, which, when given in the form usually found in text books, is as follows: The flow, or current, measured in amperes is equal to the volts divided by the ohms. The volts are equal to the amperes multiplied by the ohms, and the ohms are equal to the volts divided by the current flow or amperes.

Knowing the relation of resistance to the flow of currents, and the pressure, the next point to be considered is the substance used for the wires and ascertain the amount of its resistance for a given length and size, to be used as a unit for making the calculation necessary in compiling the table. Copper commercially and physically represents the best conductor for the transmission of the electric current. A dollar's worth of copper will conduct a greater amount of electric current than any other metal of equal value with the same loss of energy. In the illustrations following, copper will be the substance considered, as the wiring tables used for ascertaining the size of wire are for copper wire. The units by which wire is measured are the circular mil and the foot. The circular mil is the area of a circle whose diameter is one one-thousandth of an inch. The foot is a unit familiar to all. The unit of wire then would be a wire one foot long, the area of which is one circular mil, and the resistance of this unit of copper wire is between 10 ohms and 11 ohms, depending upon the temperature of the wire.

Ten and six-tenths ohms may be assumed as the resistance which approximates closely to the average at ordinary temperatures. Taking this as the basis for compiling a wiring table, it is known that to send an ampere through this unit of wire would require 10.6 volts. For, as stated in Ohm's law, the volts must equal the ohms multiplied by the amperes. But in every day problems the known quantities are the volts and amperes, and the calculation is to find wires of proper resistance to suit conditions. The resistance, or the ohms, must equal the volts divided by the amperes. To solve this problem, the volts are divided by the amperes, and we have the resistance. The resistance varies as the length and inversely as the area. It is the area of a wire which is desired, and one the resistance of which will equal the resistance found by dividing the volts by the amperes. The resistance of one foot of copper wire, one circular mil in area, equals 10.6 ohms. The resistance of any wire is equal to its length multiplied by 10.6, and this divided by the area. Now it is known that the volts divided by the amperes equal the resistance, and the volts divided by the amperes are, therefore, equal to the length of the wire multiplied by 10.6 and divided by the area. In any problem of wiring we have the number of volts and amperes, also the distance the current is to be transmitted, and the only thing remaining to be found is the area. To find this we multiply 10.6 by twice the distance or the total length of wire (in multiple arc work there is one outgoing wire and the return circuit, which makes the total length of wire double the distance) and multiply this by the amperes, and divide the product by the volts used, which gives the area of the wire.

The volts used are not the total volts of the system, but the volts lost at the wire. If the problem is given so many per cent loss, it would mean a per cent of the total number of

volts. To illustrate: If the wire is to use up 2 per cent of the pressure, and the voltage of the system was 50, then you would divide by 2 per cent of 50, or one volt, or if the pressure was 100 volts you would divide by 2 per cent of 100 or 2. In compiling a table let it be assumed for a 50-volt system for a regular increase of distances of ten feet, the following method is pursued: First, the per cent loss is ascertained, let it be 2 per cent. This then would be one volt. Then one ampere will be considered, first, as the total current flow, and the following calculations would be made: 10.6 would be multiplied by 10 feet and by 2 to get the length of the wire, and this multiplied by one ampere and the product divided by volts lost, or in this case, by one which would give us an area of 212 circular mils. This would be the size of a wire necessary to allow one ampere to be transmitted 10 feet with one volt loss (or 2 per cent of 50 volts). The next calculation would be for 20 feet distance, and as the resistance of the wire must remain the same, the area first found, namely 212 circular mils, must be doubled as the distance has been doubled. For 30 feet to keep the resistance constant, the area is increased 3 times, and so on until the limit of the table, say 200 feet, is reached, when the area will be increased 20 times, as the length has been increased in that ratio. Then the same method will be continued for 2 amperes, namely multiplying 10.6 by the distance and by 2 to get the length of wire, and this multiplied by amperes and the whole divided by the volts lost. This is continued until the area for all the wires for each of the distances and for the various numbers of amperes have been determined.

As it is necessary to multiply 10.6 by the (distance multiplied by 2) in every instance, 21.2 is used instead, and the straight distance used. The whole resolves itself into the simple formula:

$$\frac{21.2 \times \text{distance} \times \text{amperes}}{\text{volts lost}} = \text{area of wire.}$$

When these areas are found the commercial sizes of wire are inserted in the table which are nearest to the size found, but always larger never smaller; that is, if the area found in the calculation came between a No. 0 wire and a No. 00 wire, the No. 00 wire would be the size used in the table.

#### A COLUMBUS (O.) PALACE CAR.

The special car "Minerva," of which we illustrate exterior and interior views, was built for the Columbus (Ohio) Central Railway Company, by the Brownell Car Company, St. Louis, Mo. The body is 21 feet long, with vestibuled platforms, 3 feet, 6 inches long, and 7 feet, 6 inches wide over posts. The vestibules are permanent and designed to form an integral part of the car, which is quite an unusual thing in car construction. All of the continuous work is bent to shape. The interior is finished in selected mahogany, with all of the cappings, moulding, etc., hand carved. Between the windows, which are of French plate glass throughout, are oval mirrors extending from the ceilings the full length of the sash. On one side one mirror gives way to an ornamental water cooler of polished bronze, designed to match the rich metal trimmings of the car. The shades are of heavy green gros-grain silk, on spring rollers, and the portieres of green silk damask with gilt figures. In summer the side sashes may be removed and storm curtains of oak-

COLUMBUS PALACE CAR.

etc, on spring rollers, substituted. Ten chairs and four divans of rattan with plush-covered hair cushions provide seats for eighteen. The floor is covered with a Wilton carpet of color and design to harmonize with the other details, and the platforms and steps are provided with thick rubber mats. Over each window is a decorative painting of appropriate design and artistic merit. The subjects of these paintings, of which there are twenty, are from the mythology of Minerva. The car is lighted by three four-burner Pintsch lamps with cut-glass globes, and heated by four "consolidated" heaters, disposed under the side risers. The ventilator sashes are filled with beveled plate glass. Electric call bells are provided throughout the car. On the vestibules are electric headlights. A movable gate of

"MINERVA"—INTERIOR.

wrought iron is also provided. The car body is painted a deep quaker green with ornamentation in gold, and mounted on Brownell's No. 3 electric motor truck, equipped with two Westinghouse No. 12 motors. This car was especially designed for use by private parties, and no expense has been spared in making it a thing of beauty that will be a joy to hundreds. Rare taste has been displayed in the decoration and furnishing, without making the very common mistake of overdoing it.

In Minnie Hall's suit against the city of Manson, Ia., for personal injury caused by falling into a hole dug in the street to lay water mains, the state supreme court decided against plaintiff, on the ground that, as the expert witnesses had disagreed, the injured limb should have been examined in open court before the jury.

## STREET RAILWAY NOTES FROM PARIS.

(From Our Own Correspondent.)

About a month since the general council of the Seine forwarded to the monopolies commission and to the public works committee, with its favorable opinion, the proposition of the General Tramways Company (late Compagnie des Tramways Sud) to substitute on the whole of its lines mechanical for animal traction. It was at this time that the company made its proposition to install a trial line from the Bastille to Charenton. Louis Puech, whose name figures in everything connected with the suppression of horses in Paris, has, in behalf of the competent commissions, prepared a report deciding upon the adoption of the transformation by the former Compagnie des Tramways Sud. It is with no small pleasure that we witness this first root of electric wire enter into Paris after the determined resistance that has been for so many years past opposed to it, for the use of it is certain to spread. This will mean much to the French company exploiting the Thomson-Houston patents; but it will also give a chance to other electric companies beside, and it is to be hoped that, for the successful working of the lines, a goodly number of orders for material will be placed with American supply companies.

Mr. Puech points out that in addition to a one-third reduction in fares, the speed will be increased. Up grades abound in Paris, necessitating a team of four horses struggling painfully in front of cars weighing six tons loaded, and making only from one to two miles per hour. The quicker service will mean less waiting at stations, where at present one frequently sees from fifty to several hundred persons waiting upwards of an hour to obtain places. The example of this company, which has the finest horses of any company in Paris, and whose term of franchise ends in 1910, is considered to be a good argument against the other two companies. These either refuse to suppress horses without special guarantees from the city on account of the expiration of the monopoly fourteen years hence, or will make the transformation only in maintaining the old rates of fares.

It may be mentioned that independently of the trial proposed for the overhead wire, the same company has agreed to fit up one of its lines with underground wires and superficial road contacts, similar to the system employed on the Place de la Republique to Romainville line in East Paris. The terminal stations of this installation will be the Boulevard St. Germain and rue Bonaparte at one end, and Clamart, a charming village under the Meudon wood, at a distance of about five miles over heavy grades, at the other. The same fares will be charged as on the Bastille-Charenton line.

Electric lighting trials are at present being made upon the compressed-air cars which work between the Gare St. Lazare and the Cours de Vincennes. Hitherto the illumination of street cars in Paris has been very insufficient—with it reading has been impossible—and as the trials are proving satisfactory, it is expected that the new illuminant will be applied to the vehicles of the more important lines this winter, but more particularly those worked by omnibuses.

Plans have been completed for the working of the Charenton, Pantin & Port d'Ivry combined street lines, a length of about nine miles, by mechanical power—steam most probably.

The accumulator electric cars running between the Opera and Saint Denis, although working most quietly and inoffensively as regards pedestrians and street traffic, have, nev-

ertheless, just been the subject of a complaint to the prefect of police, pointing out unbearable stoppages and delays and asking that the company (Compagnie des Tramways du department de la Seine) provide a better system of traction. The reply received is, that improvements now being made in the working of the motors are such as will give the public satisfaction. This will show American readers the means taken in this country by the public to obtain a better service. Competition is greatly needed.

The gas motor working a car on one of the La Villette lines, while attracting no especial comment, good or bad, was not particularly happy in a trial run it made last week, when the vehicle became ablaze through the explosion of the gas-holder. No one was hurt through the accident, which, it is to be hoped, will not prejudice the Campagnie Generale des Omnibus against this interesting motor before it has had a fair trial.

## IRON TIES AND WOOD SLEEPERS.

Jacob T. Wainwright, in the Iron Age, suggests a combination of wood sleepers and iron ties for steam railroad work, which is also applicable to street railway work. The rails are held to gage and kept from canting by an angle iron

tie-rod or bar. The rails are supported on separate lines of cross sleepers. An angle iron tie-bar with bolts for it costs 35 cents according to Mr. Wainwright so that there is an economy in first cost as compared with the ordinary tie construction, where ties cost 70 cents each. The functions of the spikes are also changed as they do not have to maintain the gage and consequently rotting wood can be used longer.

## ARABS AND THE TROLLEY.

A Cairo correspondent writing the Paris edition of the New York Herald, says: The electric trams, which are the latest acquisition to Cairo, are vastly popular with all classes. A new line was opened on Sunday near the Kasr-el-Nil bridge, and the cars are crammed daily. At the outset the cars and track had to be guarded by a posse of Egyptian police—not to protect the cars, however, but the Arabs, who with characteristic fatalism would have calmly walked in front of the vehicles and been killed in dozens. As it is, the victims number six since the institution of the new mode of transit. The Arabs are now beginning to regard the warning bell as an indication that the neighborhood of the track is unhealthful.

## J. B. PARSONS.

J. B. Parsons, who for the past 10 years has been so prominently identified with street railway interests in Chicago, has accepted the very flattering offer of the Union Traction Company, of Philadelphia, and already entered upon his duties as general manager of that road. His work in Chicago, as was his work in Philadelphia prior to coming here, has been progressive and constitutes a record of which he may well be proud.

J. B. PARSONS.

Mr. Parsons was born May 17, 1850, near Whitesville, a small village in southern Maryland. When about six years old his father, who had been a farmer, removed to Salisbury where he embarked in mercantile pursuits.

After attending the Salisbury Academy until his eighteenth year Mr. Parsons

associated himself with his father in business. He did not take kindly to a mercantile life, however, and shortly afterwards began his railroad career as assistant to the railroad agent at Salisbury.

Remaining here two years, he next moved to Philadelphia and became a clerk in the offices of the Chestnut and Walnut Street Railway Company, being soon after made division superintendent. He continued with this company until 1881, when he was elected president of the Lombard and South Streets Road. In 1886 the stockholders of this company bought a controlling interest in the Peoples' Passenger Railroad of Philadelphia, which leased several other roads, and Mr. Parsons was elected to the presidency.

In 1886 Mr. Parsons was married to Miss Katharine F. Flickinger, and in the next year removed to Chicago to accept the position of vice-president and general manager of the West Chicago Street Railroad. Since that time Mr. Parsons has been identified with this road and to him in a great measure is to be attributed the economic success achieved by it.

Our best wishes go with him in his new work in his old home.

## DYNAMOMETER CAR.

A short description of the dynamometer or dynamometer car, used by the Chicago City Railway, was embodied in the paper read by M. K. Bowen, superintendent of the road, at the St. Louis convention, reported in the STREET RAILWAY REVIEW, November, 1896. In the December issue we published illustrations from photographs showing a general view of the car and of the recording mechanism. The line drawings give the details of construction. Figures 1 and 2 show, respectively, longitudinal and cross-sections of the car, and figure 3 shows the arrangement of the recording levers and drum.

The middle axle, carrying the wheels, M, is in two pieces, a 4-inch helical spring, 9 inches long, being inserted between the inner ends of the "half-axles" and pressing them outward so that the flanges of the wheels are always tight against the rails. The spring is contained in a box made of two short pieces of gas pipe, F and D, which are screwed into blocks with conical centers fitting into corresponding holes in the axle ends. The bearings and guides for these half-axles are so arranged as to permit of both vertical and lateral motions at the wheel ends, and of lateral motion only at the inner or spring ends. To one portion, D, of the spring box, a wire cord, A, is fastened and led over a pulley fixed on the other portion, F, of the spring box to the "gage" recording lever (figure 3). It is evident that any motion of the wheels, M and M, relative to each other will be transmitted to the gage lever and recorded.

The car rests directly on the bearings of the two end axles, no springs being used, and in consequence the vertical movements of the wheels, M and M, afford an accurate measure of inequalities in the track. The movements of these wheels are transmitted through the wire cords, I and J, to the two "low-joint" recording levers of figure 3.

The difference in level between the two rails is measured by noting the motion of two wooden blocks which float in mercury contained in the two cups, G and H. The cups are connected by a pipe as shown, so that the surfaces of the mercury in the two cups may be at the same level. The wooden floats are attached to a lever supported in bearings at K, and through the vertical arm and the rod, B, a positive motion is given to the "level" lever whenever any change in the transverse level occurs. Vibration of the mercury may be checked by throttling the flow at the valve, L.

FIGURE 1, LONGITUDINAL SECTION—DYNAMOMETER CAR—FIGURE 2, TRANSVERSE SECTION.

For recording the force necessary to pull the car, a calibrated spring, Q, is placed between the ends of the two drawbars, P, P, (figure 1). A wire cord, C, is fastened to one drawbar and led over a pulley fixed on the other, to the "dynamometer" lever, the deflection of the calibrated spring being transmitted and recorded the same as is done with the lateral motion of the middle axle. Either tension or compression can be recorded by this device and as the drawbars are supported in roller bearings, there is but little loss due to friction. The car can be run in either direction, the rear drawbar being always fastened with a pin so that it constitutes the fixed point of the dynamometer.

With the exception of the "level" lever, which is operated by the rigid levers, each recording lever is provided with a spring (not shown in the cut) which is strong enough to take up the slack in the cord connections and keep the latter always taut.

The records are made on a strip of paper drawn over a drum by means of friction rollers. The speed of the paper

NEW GRIP FOR BALTIMORE.

The Baltimore City Passenger Railway is equipping its cable cars with Earll Automatic Grip. This grip is used by the Metropolitan Street Railway Company of New York and has been previously described in the REVIEW. The advantage secured by its use is the automatic release at the end of ropes and "let-go's," which make it impossible for a rope to be cut should the gripman fail to let go of the cable. Previous to the adoption of this grip the system of gripping was that employed by the Chicago City Railway, an open grip car and a closed trailer. The order is now reversed, the grip-car is a closed car, with the gripman on the front platform, and an open trailer (the old open grip car converted into a trailer). The old style of coupling has been abandoned and a solid bar substituted which obviates lost motion and the consequent jerking of the cars. Both the employes and the patrons of the road consider the new arrangement a great improvement. The gripmen are better protected and so there is now no reason for opening the forward door, the passengers are not subjected to cold drafts as formerly.

IMPROVED BRAKE HANGER.

The illustration shows an improved brake hanger support recently designed by W. G. Price, of the Chicago City Railway Company, to prevent the brake shoes "chattering" when nearing the end of a stop. The plate with a lug cast on, now used for attaching the brake hanger to the truck is replaced by the casting shown, which is made of malleable iron. It is of the same general dimensions as the old support so that no change in the hanger itself is made necessary. For the lug is substituted a box which contains two rubber cushions, A,  $\frac{3}{4}$  inch thick, and two cast iron plates, B. The bolt forming the upper part of the brake hanger is driven in between the plates, B, which serve as a

FIGURE 3 RECORDING LEVERS AND DRUM.

is proportional to the distance the car is run, the rolls being geared to one of the car axles. Light bicycle chains running over sprockets are used so that a positive drum motion is secured. As the paper must always travel in the same direction, the ordinary gear used for reversing lathes is attached to the drum motion, so that it may be thrown in when the direction of the car is reversed.

In using the car no adjustment is required except to set a stationary pencil (not shown) so that it will record a continuous zero line for the dynamometer record. The motions of the other levers being to record differences only require no zero lines for reference. In using the car it has been drawn by horses, but for future work it is intended that it shall be drawn by a motor car equipped with motors specially wound for low speeds. The speed at which the best records are obtained is about four miles per hour. In using the car with a view to determining the power lost because of low joints, it is important that the rails be clean as it has been found that a dirty rail will cause an increase in the drawbar pull of from 50 to 75 per cent in some cases.

The plaintiff in a personal injury suit against the Detroit Railway claims that running two cars close together at high speed constitutes negligence. A building at the intersection of two streets obstructed the view. After one car had passed, plaintiff, believing a second car would not be following closely, drove upon the track in time to be struck.

BRAKE HANGER SUPPORT.

bearing, compressing the rubber cushions a trifle. Any wear of plates or bolt may be easily taken up by driving a wedge under the lower cushion. The rubber being soft will not vibrate in the same period as the brake shoe and hence tends to destroy the vibrations of the latter and prevent "chattering." These hanger supports have been applied to one car, with the result that all "chattering" has been stopped, and should a further trial prove them to be satisfactory, all cars operated by the company will be so equipped.

The management of the Belle City Street Railway of Racine, Wis., will issue no more complimentary tickets to members of the city council or newspaper men.

A NOVEL TROLLEY CROSS-OVER.

An illustration of the truth of the adage, "necessity is the mother of invention," is furnished in the ingenious method by means of which the engineers of the Hingham Street Railway, of Hingham, Mass., overcame an obstacle this summer, in the form of the trolley wire of the all-powerful New York, New Haven & Hartford Railroad. The Nantasket Beach branch of the latter road is, as is well known, equipped with a trolley and current is by this means furnished at a high voltage to large motor cars. The rival street railway and trolley railroad intersect at three points of their lines. The railroad, using as an argument the difference in potential between the two trolley wires, entered into litigation which resulted in a decree of the court prohibiting the installation of any form of the many safe and admirable patent trolley crossovers commonly used at the intersection of street railways. As a result the engineers and constructors of the Hingham Street Railway, Pepper & Register, of Philadelphia, installed at Hull, Mass., the device illustrated. Similar constructions are used at the other points of intersection.

Two heavy poles are erected along the street railway, one on either side of the railroad, and as close to the tracks as is allowable. To these poles, at a distance of 18 feet above the road grade are bolted trussed iron brackets, which extend to the center line of the railway track and receive the ends of the trolley wire. This leaves unobstructed the space above the railroad tracks.

To the end of the short bracket, 5 feet 7 inches long, is pivoted a light "gate," swinging in a horizontal plane 12 inches below the railroad trolley wires, which makes the trolley wire connection for the street railway. The top member of this gate is a 2½-inch angle and the bottom member is a 1½-inch T which, when the gate is closed, receives the trolley wheel. The gate is braced diagonally by two ½-inch cables which are fastened at the outer end, run through holes in the vertical struts and secured at the butt to eye-bolts. The gate swings about a 1⅝-inch shaft, supported in roller bearings, having on its upper end an 8-inch drum. A continuous cable passes around this drum and runs back to the pole, where it is led over sheaves (not shown in the illustration) and down the pole to a second drum, fastened to the pole near the ground.

Upon the arrival of a street car at the crossing the conductor attaches a crank to the lower drum shaft and swings

the gate into position. When the car has passed, the gate is swung back into its place parallel to the railroad tracks by means of a weight or counter poise attached to one of the vertical portions of the operating cable.

Although a makeshift, and a very expensive one at that, the device is successful as far as such a roundabout method can be. In every way inferior in convenience, durability and safety to the many patent trolley crossovers on the market, the swinging trolley gate is nevertheless a very ingenious solution of a problem developed by the unfortunate circumstances attending the case.

TROLLEY ROAD MUST SHIFT ITS TRACKS.

In the superior court at Hartford, Conn., Judge Wheeler, on December 11, refused to dissolve the injunction restraining the Enfield & Longmeadow Electric Railroad Company from laying its tracks from Warehouse Point to the Massachusetts line, through the town of Enfield. Permission had been given to lay the tracks and afterwards a radical change in the location was made by the contractor and ratified by the company. The selectmen alleged that no permission had been given to make the changes, while the engineer and others of the company maintained that such permission had been received. The court held that the evidence was in favor of the selectmen and the company will be compelled to move its track and reduce the number of highway crossings from four to two.

TROLLEY CROSS-OVER AT HULL, MASS.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Construction of Elevated Railroad—Injunction by Abutting Owner Where Ordinance is Invalid.*

The erection upon a public street of an elevated railroad imposes no additional servitude where an additional use of a street has been granted by the city authorities to build and operate a street railroad an injunction will not be granted to restrain the construction or operation of the road at the suit of an abutting property owner until the resulting damages to his property are ascertained and paid, but his remedy is by action at law for such damages.

The proposition that a railroad unlawfully in a street is a public nuisance and liable as such to be abated at any time, and therefore a recovery for damages can only be had to the time of bringing the action is untenable; the injury would be a continuing and permanent one, and therefore a single recovery can be had for the whole damages, present and future. The abutting property owner having a complete remedy at law, courts of equity will not, upon his allegation that the ordinance authorizing the construction is illegal, enjoin the defendant from proceeding until the question of illegality can be litigated and determined, but will remit him to his action at law.

In delivering the opinion of the Court, Justice Wilken said:

We held in Chicago, Burlington & Quincy Railroad Company v. Street Railroad Company, 156 Ill. 255, that a street railway operated by electricity, with trolley posts on the streets, was not a new servitude of the street, and that the poles were not unwarranted obstructions in the same, as are telegraph and telephone poles, "because such erections aid and facilitate the use of the public street for the purposes of travel and transportation."

The same is true of the pillars used in constructing elevated roads. In view of the known fact that such elevated lines in large cities greatly accommodate the public by increasing the facility and safety of transit, it can scarcely be seriously contended that permitting them to be constructed and operated is to subject the streets to a new servitude or unlawful one. The right of a city to permit them is clearly recognized by the act of July 1, 1883, entitled, "An act in regard to the use of streets and alleys in incorporated cities and villages by elevated railroads and elevated ways and conveyors." (C. 114. Sections 201, 202, 203. S. C. vol. 2, 1879.)

This Court has frequently held that where an additional use of a street has been granted by the city to build and operate a street railroad, an injunction will not be granted to restrain the construction or operation of the road at the suit of an abutting property owner (*Moses v. R. R. Co.*, 21 Ill. 515; *Murphy v. the City of Chicago*, 29 Ill. 279), and that since the constitution of 1870 such owner cannot maintain a bill to enjoin the same until the resulting damages to his property are ascertained and paid, but that this remedy is by action at law for such damages. (*Stetson v. R. R. Co.*, 75 Ill. 74; *Patterson v. C. D. & V. Ry. Co.*, id., 588; *R. R. Co. v. McGinnis*, 79 Ill. 269; *Schertz v. R. R. Co.*, 84 Ill. 135; *Penn Ins. Co. v. Heiss*, 141 Ill. 35.)

The same doctrine is recognized in *Corcoran v. C. M. & N. R. R. Co.*, et al., 149 Ill. 291; *White v. Elevated Railroad Company*, 154 Ill. 620. We said in Chicago, Burlington & Quincy Railroad Company v. Street R. R. Co., 156 Ill., supra, "where the fee of the street is in the city such damages as the owner may suffer from the laying of a railroad track in the street are merely consequential, so far at least as they affect the property abutting on the street. In such

case, as there is no physical taking of the land, injunction will not lie to enjoin the taking, the remedy being an action at law for damages.

But it is insisted on behalf of complainant that on the facts set up in his bill, the ordinance must be treated as passed without the required consent of abutting owners, and therefore illegal and void, which being true the defendants should be held as proceeding with the work without any authority of law whatever, whereas in the cases referred to lawful consent of the city was shown.

The real ground upon which relief by injunction is denied in such cases is that the use of the street being within the purposes for which it is laid out, and therefore a proper use, the right to occupy is properly a question between the defendant and the municipality having the control of its streets and charged with the duty of keeping them free from unlawful obstructions, or between the defendant and the public generally, the individual being left to his action for damages for any injury resulting to his property. He has no standing in equity on account of public injury, or for the purpose of inflicting punishment upon the defendants for its wrongful acts. He can only invoke that jurisdiction in order to protect his property from threatened injury.

His injury is a depreciation of the property which is capable of being estimated in money, and recoverable in an action at law, therefore, a court of equity will not interfere by injunction.

As stated by Chief Justice Fuller in *Osborne v. Missouri Pacific Railway Company*, 147 U. S. 248. "But where there is no direct taking of the estate itself, in whole or in part, and the injury complained of is the infliction of damage in respect to the complete enjoyment thereof, a court of equity must be satisfied that the threatened damage is substantial and the remedy at law in fact inadequate before restraint will be laid upon the progress of a public work, and if the case made discloses only a legal right to recover damages rather than to demand compensation the court will decline to interfere." To the same effect is the language used in the opinion of Justice Brewer in *re Debs*, petitioner, 158 U. S., 591. In *Morris & Essex Railroad v. Pruden*, 20 N. J. Equity 530, cited in the *Debs* case, it is said: "Mere diminution of the value of the property of the party complaining by the nuisance, without irreparable mischief, will not furnish any foundation for equitable relief." *Zabriskie v. the Jersey City & Bergen R. R. Co.*, 2 Beas. 341.

It must not be overlooked that the defendants are engaged in a public work, by the completion of which the public interest will be greatly advanced. The injunction by which the progress of the work is arrested, must not only cause great injury to the defendant, but also is the occasion of great inconvenience to the public. "And again, the defendants will not occupy with the proposed track any of the complainant's lands. For the contingent and consequential damages he may suffer from any unlawful interference with his enjoyment of his property, he has his remedy by action at law whenever and as often as loss or damage ensues; and if the use of a railroad in front of his premises becomes a nuisance or the aggression proves to be a permanent injury, without an adequate remedy at law, then the court will be competent

to administer equitable relief by injunction to prevent its continuance as for its removal. But a strong case must be presented and the impending danger must be imminent to justify the issuing of an injunction as a precautionary and preventive remedy," citing *Drake v. the Hudson River R. R.*, 7 Bar., (N. Y.) 508.

\* \* \* \* \*

The principle is, that the abutting property owners having a complete remedy at law, courts of equity will not, upon his allegation that the ordinance authorizing the construction is illegal, enjoin the defendant from proceeding until the question of illegality can be litigated and determined; but but remit him to his action at law, and this, it seems to us, is a just and reasonable rule, the enforcement of which will protect the rights of all parties interested. To hold otherwise would be to render impracticable the building and operation of street car lines under our statute. While such improvements are owned and operated by private individuals or corporations, the use of the streets is public, and not private, and upon that theory alone they are permitted to be constructed in the streets, and it will not be denied that in large and populous communities they are of great public utility, if not a public necessity.

While, therefore, the private owner is entitled to have all his property rights fully protected, that right should be accorded him, if possible, by a remedy, which will not unnecessarily injure others and render impossible the construction and operation of necessary facilities for public travel.

A moment's reflection will, we think, convince anyone that if every abutting owner not consenting, may enjoin street railway companies from building their lines in streets upon the ground that the consent of the city has not been legally obtained, because of facts alleged which do not appear upon the face of the proceedings, the building and operation of all such lines will become practically impossible.

In a case like this the work would necessarily be stopped until titles to abutting property could be adjudicated and settled, the powers of agents, etc., determined and the motives which may have prompted owners to give their consent inquired into.

After this has been done, which in the ordinary course of litigation would require many months or even years of time, if the facts should be found in favor of the validity of the ordinance, the work may proceed as to the complainant, he still, being entitled to his action for damages. The decision, however, would settle the validity of the ordinance between him and the defendant and no one else. Any number of other owners may in succession procure injunctions on the same or similar grounds and prosecute them to a like final determination.

Manifestly, neither persons nor corporations would hazard capital in an enterprise subject to such uncertainty and delay. There is a certain adequate and complete remedy at the suit of the public whenever there is a threatened, or actual unlawful obstruction of streets and highways, and, as we think, an equally certain adequate and exclusive remedy to the abutting owner for all his damage present and prospective.

The contention that he cannot have such remedy by a single action we deem untenable. It is not denied that the damages which he would be entitled to recover are the same in kind as if the building of the road was lawful. But it is said that being in the street unlawfully the obstruction is a public nuisance, subject to be abated and removed at any time, and therefore the recovery could only be had for dam-

ages to the time of bringing the suit. This position is based upon the proposition that a railroad unlawfully in a street is a public nuisance and liable as such to be abated at any time, and therefore a recovery for damages can only be had to the time of bringing the action, and hence a multiplicity of suits will become necessary to give the complainants a complete remedy. The position is untenable. The injury would be a continuing and permanent one, and therefore a single recovery can be had for the whole damages, present and future. *C. & E. I. R. R. Co. v. Loeb*, 118 Ill. 204, and authorities cited. *Gault v. C. & N. W. Ry. Co.*, 157 Ill. 125.

(Supreme Court of Illinois. *John W. Doane v. Lake Street Elevated Company*, 1 Chicago Law Journal Weekly 615.)

[Note in the case of *General Electric Railway Co. v. Chicago City Railway Co.*, 1 Chicago Law Journal Weekly 451; 6 STREET RAILWAY REVIEW 535, it was held that a court of equity will not interfere to prevent the construction in the streets of a city of a public railroad to be used equally for the benefit of all the public, but will remit the parties to a court of law, and such relief as that tribunal affords.

The foregoing cases therefore, overrule the contrary opinion in *Leiter v. Union Consolidated Elevated Railway Co.*, 1 Chicago Law Journal Weekly 262; 6 STREET RAILWAY REVIEW 404.—ED.]

#### *Injury at Street Crossing—Failure of Car to Stop When Passing Standing Car—Duty to Look and Listen—Care Required of Child.*

1. A street railway company propelling its cars by electricity along the public streets of a city owes a duty to the public which requires it to so regulate the movements of its cars at the intersection of such streets, when receiving or discharging passengers from a standing car, as not to unnecessarily expose pedestrians to the danger of collision with a passing car on the opposite track.

2. While a car of such a company was stopping at a street crossing to receive and discharge passengers, a boy of the age of seven years and eight months, who was walking across the street from behind the standing car was struck and killed by another of its cars passing from the opposite direction; the evidence tended to prove that the boy's view of the approaching car was obstructed until he had passed the standing car, that no bell or gong was sounding by the approaching car, which was going at the rate of six miles an hour, that the boy did not look for an approaching car before entering upon the track, where he was struck almost immediately upon stepping upon it, and carried a distance of thirty or forty feet before the car could be stopped, upon the trial of an action for damages against the company for negligently causing the death, the trial judge refused motions to nonsuit and to direct a verdict on the alleged grounds that there was no proof of negligence on the part of the company, and that contributory negligence was established on the part of the plaintiff's intestate, and ruled that the questions of negligence and contributory negligence were for the jury; held, that the judge committed no error in so ruling.

3. It was also held to be no error in the judge to refuse to charge that it was not the duty of the moving car to stop before passing the standing car, the judge having already charged the jury that it was for them to say under all the circumstances whether it was negligence upon the part of the motorman to run past that standing car at that time and place or not.

4. The rule requiring one to look and listen before crossing a steam railway, in order to be in the exercise of due care, does not apply with equal force to one crossing the

track of a street railway in a city street where the company and the public stand on an equal footing in the use of the highway, and it was held that it was not negligence per se in the plaintiff's intestate under the circumstances, in going upon the defendants' track without first looking for an approaching car, and the judge's refusal to so charge was sustained, he having fairly submitted the question of contributory negligence as a matter of fact for the jury to determine upon the facts in evidence.

5. When a child has reached the age of discretion and is considered sui juris as a matter of law, the degree of care and caution required of him will be no higher than such as is usually exercised by persons of similar age, judgment and experience, and whether that degree of care and caution has been exercised by the child in a given case is generally, if not always, a question for the jury.

(Court of Errors and Appeals New Jersey, Consolidated Traction Co. v. Scott, 13 National Corporation Reporter 105.)

*Injury to Boy "Hitching" on Car—Forced to Leave Car by Conductor—Struck by Car Coming in Opposite Direction.*

This was a suit by appellant to recover for personal injury sustained by him. At the conclusion of the plaintiff's case the court took the case from the jury by a peremptory instruction to find for the defendant, and a verdict being so returned and judgment rendered thereon, this appeal is prosecuted. The facts shown are that the plaintiff, then twelve or thirteen years of age, when returning from school jumped upon a projection from the rear end of a street car, and while hanging on, as he testified, rode about the length of the car, when the conductor came up and spit at him and "made a punch at his face," whereupon he jumped off, and at that instant another car drawn by horses on a parallel track, was approaching from the opposite direction to that in which the car upon which he was riding was going, and as he jumped off he staggered and run upon the other track, or close to it, and was struck by the approaching horses, knocked down and most severely hurt. It was an instance of what boys call "hitching," and it is not denied that appellant was a trespasser when upon the car.

Appellee insists that the evidence in behalf of appellant shows that the injury was attributable to the contributory negligence of appellant to such an extent as to preclude a recovery. The question of whether there was contributory negligence by the person injured is, as in the question of whether the one doing the injury was guilty of negligence, one of fact for the jury and not one of law for the court.

Of course, if the case as made by the plaintiff, showed such a degree of contributory negligence by him as would require the court to set aside any verdict which it might discover, then it would be proper to take the case from the jury. But a careful consideration of the testimony makes it quite clear that there was evidence tending to establish due care on the part of the plaintiff.

A person in the presence of imminent danger to his person is not required to act with all due care and caution that need reasonably be required of him under ordinary circumstances, and it remains for the jury to say whether he acted with undue rashness in attempting to escape from the known peril that came in front of him. Dunham T. W. Co. v. Dandelin, 143 Ill. 409; West Ch. St. Ry. Co. v. McNulty, 64 Ill. App. 519.

We do not discover in appellee's brief that any serious question is made, but that there was evidence tending to establish negligence on the part of appellee.

On the question of whether, under the proved facts, appellee was guilty of negligence we refer to North Ch. St. Ry. Co. v. Gasdka, 128 Ill. 613, which is almost precisely in point.

The judgment of the Superior court is reversed.

(Appellate Court of Illinois, first district. Hagestrom v. West Chicago Street Railway Co., 29 Chicago Legal News, 87.)

**BICYCLE-HOLDER ON STREET CARS.**

In order to accommodate cyclists who wish to reach the parks or ferry landings without riding their wheels through the business districts, the San Francisco street car companies have been experimenting with bicycle-holders. The illustration shows the holder recently tried on the Mission street line. It is attached to the back of the rear dashboard, and

BICYCLE HOLDER ON STREET CARS.

designed to carry two bicycles. Two swinging arms of wrought iron, each about a foot long, are secured to the upper edge of the dashboard, about two feet apart; from these depend leather lined hooks to receive the top bars of the frames. To the lower portion of the dashboard are attached two swing rests, to which the wheels are secured by straps across the rims. A single fare is charged for each bicycle carried.

**LORAIN FOUNDRY COMPANY.**

The Lorain Foundry Company, organized within the last year, at Lorain, O., has recently completed a plant which is a model of its kind. This company manufactures ingot molds, rolls and heavy castings up to 75,000 pounds, making a specialty of castings for rolling mill and blast furnace work. The main building is divided into three bays, the center one having a clear floor space of 10,000 square feet available for the molding and pouring of heavy castings. This bay is served by a 35-ton electric traveling crane. The side bays have each about half the floor area of the large one, one side being devoted to light molding and casting, the other containing the cupola, air furnaces and core ovens. The smaller bays are also provided with electric cranes, and every arrangement is made for the convenient charging of the furnaces and pouring of the metal. The officers of the company are Max M. Suppes, president; F. A. Smythe, vice-president; W. F. Saltmarsh, treasurer; Hugh H. Davis, superintendent.

By Robt. Kunstman.

To the visitor of a manufacturing town or district in our country, so rapidly leading others in enterprise and industry, a fine, tall and well proportioned chimney, rising in the midst, or on the flank of an extensive power house building, studded with glittering windows, ornamented with a symmetrical and imposing entablature and crowned with a flat or moderately rising roof, will be an appearance invariably giving delight and wonder with much cause for reflection.

The beauties of charming and classic architecture are here but rarely displayed, but the fascinating impressions which the observer nevertheless receives and will experience from such a structure, are more a feeling of admiration and respect for the wonderful industrial achievements which are marked by these monuments of our nineteenth century.

Gently escaping white clouds that may surround the uppermost crown of this modern obelisk make the whole appearance of the plant pleasingly complete and characteristic, and give us to understand that at the bottom of all is the precious black diamond which gives life and activity to hundreds of cars on many miles of track.

But alas! if instead of this, dense, black smoke is, with swift and apparent violence, bursting out of this elongated circular volcano, and is rolling far and far away over the country, indications then are at hand and before us, that nature's bountiful gifts and benefits are evidently not appreciated there, and are deplorably misused.

Here we discover that something must be radically wrong, repulsive to more than one of our senses and detrimental to economic principles, with a violation of the laws which scientific researches and exertions have discovered and established during recent years of advancement in perfecting the natural forces which are to serve mankind.

The one indication in our power house picture is, that therein a good and complete combustion of the available fuel for steam generation is achieved, while in the other all appearance points to the fact that an imperfect combustion, a careless and wasteful use of coal for the production of motive power for this plant, are the order of the day.

Both sights demonstrate at a glance the functions of the chimney which shall be the object of our consideration. We will therefore deal with:

1. The functions of the power house chimney as a means to effect good and economic combustion.
2. The use of the chimney as a conveyor of surplus products of combustion and obnoxious gases to the outer air.
3. The construction of a serviceable chimney in brick or iron.

As it cannot be the object of this article to deal with the

scientific rules that underlie the entire process of combustion in all its different stages and relations, as to evolution and complete combination of all the combustible elements of the different kinds of fuel for the purpose of producing heat and steam in an entire steam generating plant, we take only the chimney into consideration, as the second, an auxiliary, though highly important part of such a well constructed furnace, where the process of combustion is really performed, we will necessarily have to adopt and introduce many data given by experts and authorities that have already dealt specially and exhaustively with the subject.

Coal when thrown into a fireplace evolves among others the two principal combustibles, namely carbon and hydrogen, which uniting with the oxygen of the air produce heat. Oxygen, therefore is the indispensable element of combustion, its proper supply is the first important question for economic use of fuel and it can only be the oxygen of the air that surrounds us, which has to supply our wants for this yet somewhat complicated chemical problem.

In addition to oxygen, our surrounding atmospheric air contains also nitrogen, in the proportion of 1 pound of oxygen to  $3\frac{1}{2}$  pounds of nitrogen, or, by volume, 1 cubic foot of oxygen to 4 cubic feet of nitrogen, the latter being a neutral gas, so far as combustion is concerned, and is simply present as a diluent, for every cubic foot of oxygen required in combustion, five cubic feet of air must therefore be supplied.

We know that 160 cubic feet of air and weighing about 13 pounds, are necessary for the combustion of 1 pound of coal, though bituminous coal demands more air in proportion, according to the excess in volatile constituents, than anthracite; but it is necessary to admit a greater quantity of air than is chemically consumed, so that each particle of gaseous combustible matter should have its due equivalent of oxygen, and therefore close on 300 cubic feet or 24 pounds of air will be required to provide for the consumption of one pound of coal.

This means that we have to supply or draw a surplus of air through the furnace, which costs us about 10 per cent of the calorific value of every pound of coal.

The drawing in of this air and forcing it through the furnace is one of the principal functions of the chimney; the expression "draft" means the movement of a column of the outer and heavier (because colder) air, at say 62 degrees F., to the place where the lighter and heated gases emanating from the furnace leave for the chimney at a temperature of say 500 degrees F. The temperature of the products of combustion at the moment of their formation and after their service of generating steam, naturally varies with the quantity of air in dilution and with their more or less perfect utilization under the steam boiler.

The movement of draft is generally measured in inches of water pressure. Let a cubic foot of water at 62 degrees F. weigh 62.32 pounds, or in other words a column of water 12 inches high is exerting a pressure per square foot at its base of 62.32 pounds. One inch of water consequently means a pressure of 5.193 pounds on one square foot or 0.577 ounces on one square inch.

When one cubic foot of outer atmospheric air at a temperature of 62 degrees F. and weighing 0.075 pounds displaces hot gasses at 500 degrees F. of 0.04 pounds weight per cubic foot, a difference exists here of 0.035 pounds, which represents the upwards rising force or "draft" at the bottom of the chimney where the connection with the furnace is made. Let, for instance, the chimney be 150 feet high. We then get for every square foot of its cross section a draft pressure of 5.25 pounds or 0.81 inches expressed in water pressure.

The rising of a balloon filled with heated air is probably the simplest verification of this indisputable fact that heated air exerts a measureable force of rising beyond the cooler atmospheric air.

This result in our chimney, however, is not entirely true, and requires correction and modification on account of the gases within the chimney not being of the same specific gravity as the atmospheric air. The gases after leaving the furnace (still with the presumption that complete combustion took place) are a mixture of gaseous steam, nitrogen and carbonic acid gas, all of different specific gravity, and instead of dealing with gases of 500 degrees F. of 0.04 pounds weight per cubic foot, we have different weights in our component parts which will naturally cause variation in draft in a chimney of certain height, and supposing even that the temperatures are the same, the variation in the amounts of constituents of different coals will likewise influence the draft of the chimney.

To what extent the effect of different constituents of various kinds of coal exists may be seen when we quote from reliable investigations the analyses of two very different kinds of coal.

	Anthracite Coal.	Average Soft Bitu- minous Coal.
Fixed carbon.....	86.75	45.50
Volatile matter.....	6.20	37.25
Ash.....	5.25	10.75
Moisture.....	1.80	6.50

For 100 pounds coal burnt, the amount of air required for complete combustion is respectively as follows: 1374 and 1443 and the weight per cubic foot of chimney gases at 500 degrees F. would be for the one 0.0137 and 0.0116 for the other.

From this difference in weights of gases of combustion, different draft power of a chimney of say 100 feet high is the result even when the temperature of the gases and that of the atmospheric air is the same, but as the latter also depends upon the season, with prevailing cold or warm weather ranging from an average of say 0 degrees F. to 102 degrees F. the effect on the draft of chimney must also in this respect be taken into consideration and we learn that it is not infrequently to the amount of 50 per cent or even more.

For instance, with gases of combustion of the respective weights per cubic foot as previously stated, we quote the interesting results from "Helios," published by the Heine Safety Boiler Company.

FOR ANTHRACITE COAL.

	Draft power in inches.
Weight of 1 cubic foot air at.... 0 degrees F.....	0.086.....0.822
Weight of 1 cubic foot air at.... 62 degrees F.....	0.076.....0.624
Weight of 1 cubic foot air at.... 102 degrees F.....	0.070.....0.520

FOR AVERAGE SOFT, BITUMINOUS, COAL.

	Draft power in inches.
Weight of 1 cubic foot air at.... 0 degrees F.....	0.086.....0.863
Weight of 1 cubic foot air at.... 62 degrees F.....	0.076.....0.664
Weight of 1 cubic foot air at.... 102 degrees F.....	0.070.....0.560

More draft is required for anthracite than for soft coal.

The supply of the correct quantity of air is in practice a matter of considerable importance. Insufficiency of air results in an imperfect combustion and causes waste and loss of the volatile portion of the fuel, more carbonic oxide is then produced and only 8 parts of oxygen instead of 16 parts have united with six parts of carbon and too much carbon is passing off in a fine, unconsumed, state. By the color of the escaping smoke no doubt is left to the observer of the presence of plenty of matter that is still combustible, products of an incomplete combustion.

On the other hand in cases of too much surplus air having been admitted, the heat of the furnace is not only reduced but inactive quantities of air and a greater volume of gases are carried through the chimney. The efficiency of the chimney is thereby diminished through the reduced difference between the chimney temperature and the outside air; this may reach a condition when it will take too much fuel to heat the surplus air to the right temperature of the furnace and chimney gases; and great loss is also here to be expected.

To obtain the results of the velocity of the movement of gases per second within the chimney, various formulas are applied. All will more or less depend upon the difference of the height and weight of an enclosed column of the hot chimney gases and the weight of the outside air, its temperature and entrance velocity at the grate.

The former, as we have shown, can be expressed in inches of water, with a factor that varies according to the constituents and compositions of the gases from various coals.

In practice it will be found that much depends upon the construction of the boiler and flues, and upon the careful method of firing, or whether the bed of fuel in kept regular, as much draft will be expended in overcoming the friction and impediment to the velocity of entering air under the grate. This velocity should not fall below 10 to 20 feet per second, nor should the velocity of escaping chimney gases be less than 9 to 25 feet per second, so that with allowing for chimney friction we will have a draft power of from 0.4 to 0.6 inches water.

With the increase of the temperature of the chimney gases, say up to 800 degrees or 900 degrees, which means an accelerated process of firing, and consuming more coal with a quicker and hotter escape of gases, the velocity of draft can be increased, but this would certainly be done at much greater cost.

It is quite probable that while a chimney of 100 feet, with 500 degrees chimney gases required for the full work of drawing in the air and expelling it, 12 to 15 per cent of fuel was consumed, whereas at 900 degrees it required 25 per cent, with a loss or waste of 10 per cent. In such a case the remedy is to lengthen the chimney, as it was not high enough for the work expected from it.

How far, with the height of chimney as a constant, but with changes in temperature of chimney gases, a deviation in

the capacity takes place, is shown in the following comparison;

Temperature of chimney gases at.....	500° F. at 900° F.
Showing a draft pressure in inches.....	0.67    0.91
Percentage of fuel to secure this draft....	13%    25%
At 500° F. for same draft the height.....	100 ft.    140 ft.

The exact relation between area and height of a power house chimney are still a matter of much speculation, and the difficulties which exist to determine the one as well as the other from formulas, will yet remain on account of the absence of more exhaustive tests on the amount of the friction of air passing through grate and fuel bed, through boilers and flues, and on account of the different kinds and qualities of coal and the uncertain and irregular methods of firing.

Modern conditions have altered in recent years, the constants on which the results of such formulas have been depending; 50 per cent air space of grates has replaced that of 20 per cent to 30 per cent, a consumption of 10 pounds coal per hour per square foot is superseded by one of 20 to 40 pounds of coal.

Local circumstances and surrounding conditions will, in nearly all cases, to a great extent, determine the height of the chimney; it is quite obvious that the draft of a chimney will be seriously impaired if the wind comes from the direction of higher buildings or hills existing in the near vicinity.

For settling upon the area of a chimney a principal factor will always be the quantity of fuel consumed per hour indicating the horse-power capacity of engine or boiler. We will quote two formulas for determining area and height, namely, those of Kent and Gale, as they are considered the best, and give dimensions which are more suited to modern conditions and practice in the construction of a good steam producing plant. Still it is at all times necessary to consider the relation between height and area only as to certain limits and restrictions dictated by practical considerations. The two formulas are as follows:

<p>KENT.</p> $A = \frac{0.06 F}{\sqrt{h}}$ $h = \left( \frac{0.06 F}{A} \right)^2$	<p>GALE.</p> $A = 0.07 F \cdot \frac{3}{4}$ $h = \frac{180}{T} \left( \frac{F}{G} \right)^2$
--	--

Here is A = area, h = height of chimney in feet, F = pounds of coal burnt per hour, T = temperature of chimney, G = grate area. It must be remembered that for Kent's formula A represents only the effective area, therefore, a ring, 2 inches wide, is to be added all round to correct the obtained result as no friction of gases with the sides is brought into consideration.

From the authority of J. J. deKinder, M. E., we learn that a height of 75 feet is a suitable one for a chimney for most free burning bituminous coals, 115 feet for slow burning bituminous, and from 125 to 150 feet for anthracite coals. According to the same authority 0.75 inches to 0.88 inches for anthracite is given as necessary draft pressure. He gives 20 to 25 pounds per hour as minimum rates of combustion and 40 per cent air space in grates for anthracite and 50 per cent for soft coal.

We will now introduce a table principally derived from this most excellent compilation of valuable information on the subject, namely from "Helios," showing to what extent capacity of a chimney may be obtained for horse-power

according to different heights with varying areas and diameters.

Height of Chimney in Feet.	Capacity for Horse-Power Ranging		With Area in Square Feet.		Diameter in Inches.	
	From	To	From	To	From	To
75	75	90	3.14	3.69	24	26
80	75	120	4.28	4.91	24	30
85	90	160	3.70	6.30	26	34
90	130	180	4.00	7.07	30	36
95	150	287	5.59	10.56	32	44
100	176	445	6.31	15.00	34	54
110	208	577	7.07	19.63	36	60
120	267	1,173	8.73	34.48	40	81
130	337	2,058	10.56	63.62	44	108
140	413	2,596	12.57	78.54	48	120
150	672	2,693	19.63	78.54	60	120
175	1,044	2,904	28.27	78.54	72	120
200	1,983	3,100	50.27	78.54	96	120

The length of flues from the furnace to the chimney in so far as this depends upon constructive and local conditions, will influence the drawing power of the chimney to a considerable extent and it is stated that flues from grate to inlet at base of chimney extending from 100 to 2000 feet, which latter may be found in some chemical and smelting works, will diminish the draft power of the chimney fully to the amount of 10 to 60 per cent.

It is obviously certain that deviations from the straight direction of flues through curves, angles or any downward directions should be avoided, otherwise sufficient allowance must be made for it in the height of chimney.

According to the statement previously made, another function of the chimney is to convey obnoxious gases which may be in the mixture of products of combustion, beyond the sphere of doing injury to human beings or vegetation, and this is of considerable importance when such chimneys are in connection with chemical works or metallurgical establishments.

The height in such cases depends chiefly upon the surroundings. To what height such lofty structures may become necessary can be seen from the following: The Townsend shaft, Port Dundas, Glasgow, reaches 468 feet, with a diameter of 32 feet at base; the Pollux shaft, Glasgow, 455 feet, 6 inches, the Fall River Manufacturing Company's shaft, Fall River, 341 feet, and Clark Company's shaft, Newark, N. J., 320 feet.

#### ON THE CONSTRUCTION OF A CHIMNEY IN IRON OR BRICK.

When the right locality and dimensions of the chimney are once determined, it is for the engineer to solve the problem of erecting it in connection with the furnace and in harmony with the buildings, for which its functions are to be put into requisition. Architectural embellishments are admissible only when the buildings are treated in such a character as will warrant putting it in harmony with them; plain and well proportioned outlines are the most appropriate and suitable features of a good chimney.

Nature's own works teach us the best lesson in a straight, gracefully erect and tall Californian or Norfolk pine tree, what the right relations and proportions between diameter and elongation have to be, in order to stand the side pressure of wind force.

The condition of the ground which will have to bear the structure exerting a pressure of from 1 to 2 or even 5 tons per square foot will next require the greatest care and consideration, while the construction of the foundation with best material and good workmanship only can secure unailing stability and permanency of the superstructure.

Iron chimneys are appropriate and useful up to certain heights and moderate diameters; chimneys of that description are made of boiler plate or steel plate on brick pedestals on solid stone foundations. A cast iron socket is to hold the flue. The former is bolted down with long, strong anchor bolts, reaching through brick pedestal and foundation. Such a chimney is easy to erect and requires no guy rods to hold the shaft upright. See sketch.

Iron chimneys of greater length and diameter may be also

constructed of steel plates and will then reach with extended and widened base, direct to the foundation.

A circular lining with firebrick, or ordinary well burnt segmental shaped brick, can be inserted inside from the bottom to top.

Brick chimneys are made square, hexagonal or octagonal and very frequently round. The latter kind is the best and strongest as to stability and the most economical with regard to material contained in its sectional area.

Round Brick Chimney with side lining

Round iron chimney with cast socket and pedestal of brick without guy rods

We give a sketch plan of a round stack built of brick of a height of say 154 feet and inside diameter of 7 feet of flue at grade and 7 feet diameter of flue at the mouth. This chimney will require from 450,000 to 500,000 brick on a foundation of steel beams and concrete. The pressure exerted upon the ground is about  $1\frac{3}{4}$  tons per square foot.

An inside lining or inner shell of two thicknesses of brick with air spaces behind is introduced over two thirds of the entire length. The inner shell or lining is built perfectly independent of the outer shell or shaft, the air spaces acting as the best nonconductors of heat to the outside and preventing equally well a chilling influence of low and cold temperature on the inner higher temperature of the heated air.

Such a chimney may be entirely built from inside without the use and erection of an outside scaffold; the correct dimensions are generally set out on flat ground in strings and from it straight edges are prepared to indicate the exact batter of the exterior face with plumb lines attached to it or used separately.

The chapter is made comparatively light and capped with a cast iron ring plate carefully secured with anchor bolts.

In a future issue we will treat more particularly upon the construction of power-house chimneys.

### WHELOCK'S HILL CLIMBING DEVICE.

F. H. Wheelock, of St. Paul, Minn., has applied for letters patent on the unique hill-climbing device for street cars which is shown in the illustration. It is designed for use on roads which have pieces of track so steep that auxiliaries in the way of racks or other devices are required. An eight or ten-inch timber is laid inside of each rail on the heavy grades so that the wheel flanges will clear it. On top of this sleeper

WHELOCK'S HILL CLIMBING DEVICE.

is laid a rail E and a rack D. The gear, B, is keyed on the axle close to the car wheels and gears with the rack. Just inside this gear the car axle carries a flanged wheel, A, of small diameter, on which the car is supported while on the incline, the rail E being placed at such a height that the large wheel, C, is lifted clear of the surface track. It is seen that this device not only provides a rack on the steep grades, but also gears down the motors so that the tractive force is greatly increased.

The New London, Conn., Street Railway, during the fiscal year just ended, earned \$52,661, from 1,136,548 passengers, at an expense of \$30,013. Net earnings were \$22,648, and dividends \$11,550.

### COMBINED SURFACE AND UNDERGROUND SYSTEM.

Our illustration, for which we are indebted to Engineering News, shows the scheme of a rapid transit system designed by Walton I. Aims, C. E., of 35 Broadway, New York. The system comprises a double surface line and a double line laid in a tunnel just below the pavement, with the tracks directly below those on the surface. The surface lines would convey passengers to stations, between which rapid

COMBINED SURFACE AND UNDERGROUND SYSTEM.

transit would be secured by express trains running underground.

Both lines would be operated by electricity, the surface cars taking current from conductors laid in a conduit opening directly into the subway and the underground cars by the overhead trolley system. The conduit being open at the bottom would be effectually drained and at the same time the slots in the conduits would serve to ventilate the tunnel. Should local conditions prevent the construction illustrated, the underground construction may be modified by depressing the subways, laying the track in circular shield tunnels if necessary.

This system furnishes a means of securing local and express service on parallel tracks, one of the requisites for satisfactory service in large cities, but has the disadvantage of running its local trains on the streets where they are subject to all sorts of delays. In addition, the surface cars are liable to be crowded with passengers who do not wish to use the express service, to the obvious disadvantage of those who do. It is apparent that both tracks must be operated by the same company in order to secure good results, and this may prove an obstacle to the introduction of the system where the streets are already occupied by surface roads.

### FINED FOR NICKELING.

The Bridgeport Traction Company has made an example of several conductors who had been several times inspected and reported on unfavorably. The case was brought in the city court, where the judge imposed a fine of \$5 and costs.

An appeal was taken from the decisions, though it is not expected the appeal cases will ever be brought to a hearing.

## ACRES OF BARN.

In August 1895 the Cottage Grove Avenue car barns of the Chicago City Railway Company were destroyed by fire, inflicting a loss of over a quarter of a million of dollars. The company has recently completed a new barn, several views of which we publish, together with line drawings showing the arrangement and some details of construction. The company owns a lot of  $3\frac{1}{2}$  acres fronting on Cottage Grove avenue between 38th and 39th streets, and the new car barn extends to the lot line everywhere except on the northwest corner, where on a triangle of about 3,000 square feet in area a stable has been erected for thirty or more horses.

located where it will be accessible at all times, for use in case of emergency.

In the southeast corner of bay No. 3 is the employes' club room, 23 by 50 feet, which, together with light and heat, is furnished by the company. Next to this is a room 18 by 28 feet in which are quartered the wreck wagon and its team of horses. The equipment of this room is all in the most approved fire department style. To the north of the wreck wagon is the office and conductors' room. Here lockers for the men are provided. The oil and lamp room 8 by 39 feet lies just south of the club room, with a small coal room in the rear. Oil is delivered to the storage tanks, which are below the floor level, through a hatchway in the sidewalk.

NEW CAR HOUSE, CHICAGO CITY RAILWAY.

The new barn is but one story in height with a frontage of 242 feet on Cottage Grove avenue. The front which is of red pressed brick with terra cotta trimmings is shown in one of our illustrations. The best idea of the extent of the building is to be had from the view of the roof. The general arrangement is shown by the floor plan. Two longitudinal brick walls divide the barn into three bays, which are in communication only at the transfer track, which extends clear across the barn about midway of its length. These openings in the dividing walls are each provided with two pairs of fire doors so that the bays may be isolated from each other. These doors roll upon inclined ways so that when released they will close of themselves. It is intended to arrange tripping devices with lead wires to a single lever,

The Pintsch gas which is used for lighting the cars is delivered to storage tanks located under the sidewalk by a pipe line from the gas plant of the Pintsch Company.

The entrance tracks are in the center of the second bay and between them is the train dispatcher's tower, the lower story of which serves as the sand reservoir. From his tower the train dispatcher has a clear view both ways on Cottage Grove avenue and also of the barn for its full length. In front are the levers controlling the semaphore signals and on the floor at one side the levers for throwing the track switches. The tower is connected by telephone or speaking tube with the office and the transfer track.

Cars run into the barn under their own momentum, but horses are required to take them out onto the tracks again.

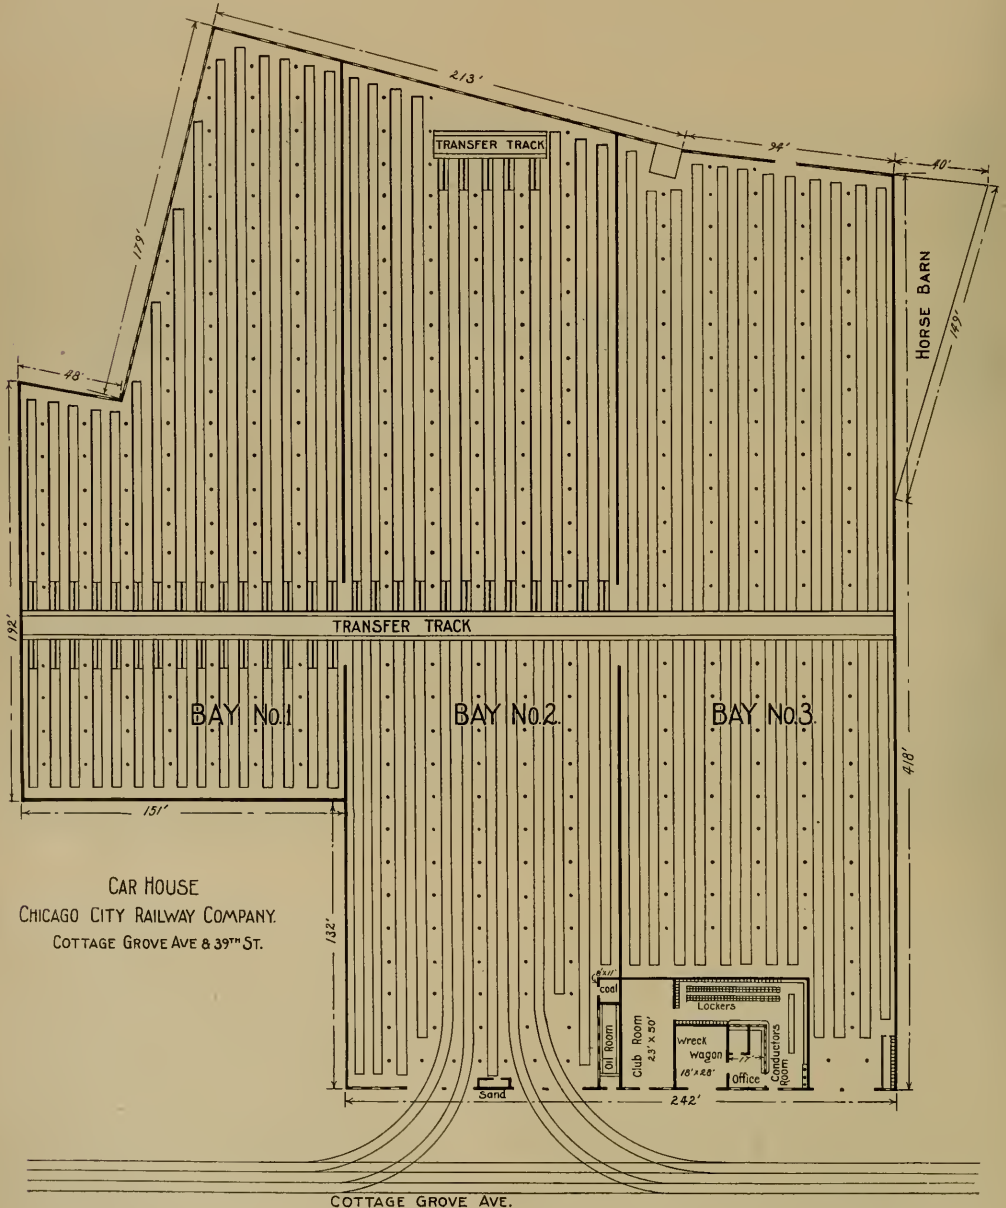

# Street Railway Review

The barn tracks are all level so that the cars are easily moved about and transferred to different tracks. The transfer tables are of wood and mounted on 30-inch wheels.

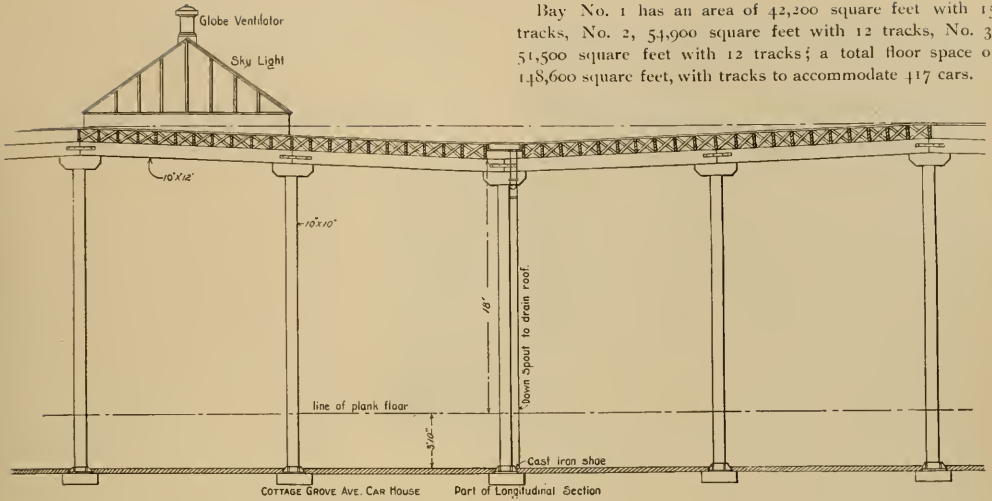

In bays 1 and 2, the earth has been excavated to a depth of about 4 feet below the tops of the rails, and a cement floor laid. Throughout bay 1, and in that portion of bay 2 back of the transfer track, only the spaces between the tracks are floored over, the space between the two rails of each track being open, except for a few feet on either side of

the transfer track. Over the pits thus formed the trucks may be easily examined and cleaned. Water connections are provided every 50 feet along each of these pits, with drains in the cement floor at the same intervals, furnishing the best facilities for washing cars. It is intended at some future time to excavate and put in a cement floor in bay 3, also.

The roof is supported on timber posts 10 inches square, spaced 15 feet apart lengthwise and 20 feet crosswise of the

Bay No. 1 has an area of 42,200 square feet with 15 tracks, No. 2, 54,900 square feet with 12 tracks, No. 3, 51,500 square feet with 12 tracks; a total floor space of 148,600 square feet, with tracks to accommodate 417 cars.

barn. The roof is divided for drainage into sections, 40 by 60 feet, sloping to the center, and each section provided with a drain pipe running down beside one of the supporting posts to a sewer connection. Each 40 by 60 foot section of the roof has a skylight 14 by 20 feet. In the rear of bay No. 1 are blacksmith and carpenter shops for making light repairs; also a crane for handling the grips when they are to be taken out or put into the cars.

The stack shown in the floor plan and in the photograph of the roof is that of the old barn, and is not now used for any purpose. As it was not injured in the fire it has been allowed to stand. No steam plant is now required as there are no elevators as in the old two-story barn, and the building with the exception of the offices, where stoves are used, is not heated. The cars are heated by their stoves, in which fire is kept up all night in cold weather, thus insuring comfortably heated cars even on the first trip out.

## AN IMPORTANT CASE.

Suit is brought against the Milwaukee Electric Railway & Light Company to restrain it from relaying its tracks on Washington avenue.

President Cromwell and Attorney George P. Miller will appear for the company, and maintain that as the rest of the road has been in constant operation, the franchise grants it the privilege of using the two squares in question.

It is claimed that the operation of a part is the operation of the whole, and if abandonment of a part means the abandonment of the whole, the franchise must be declared invalidated.

There are many interesting points that will arise in the argument, bearing upon the right of the city to control its streets where franchises have been granted to other parties.

CHICAGO CITY RAILWAY COTTAGE GROVE AVENUE CAR HOUSE.

## FOX RIVER INTERURBANS.

### The Joining of Chicago's Prosperous Outer Belt Towns.

For several years schemes have been on foot to build an interurban electric line to join the towns of Elgin, Geneva and Aurora (and incidentally a number of smaller towns lying near and between), but not until this year were these long-cherished plans carried out. These towns are all situated in the Fox river valley, about forty miles west of Chicago, and form a kind of outer belt line around that metropolis. The valley is thickly populated, and gave promise of a good paying traffic for an interurban electric line, which promise has been made good since the roads have been built.

There are two separate roads, owned and operated by different companies. That at the southern end, covering the territory between Aurora and Geneva, is owned by the Aurora & Geneva Railway. This line is not entirely completed, however, but will be the coming spring. Running north from Aurora this road first

touches North Aurora, with a population of 500. Seven miles from Aurora is Batavia, with a population of 5,000, which is the present terminus. Two and a half miles further north is Geneva (population, 2,500), which is the objective terminus. The line is built on the easterly side of the highway, between Batavia and Aurora, which highway follows the west bank of the river. The track is placed on a grade uniformly higher than the wagon road, and is gravel ballasted throughout. The rails are 60-pound T in 60-foot lengths, with six-bolt joints. The "horseshoe" rail bond is used. Oak and cedar hewn ties, 2,640 to the mile, were put in. It will be seen from this that the builders spared no money on good construction material. One of the bridges is shown in the engravings. It consists of two plate girders 50 feet long, with ties resting on the lower flange. The safe carrying capacity of this bridge is 50 tons moving load. It was made by the Wrought Iron Bridge Company, of Canton, O. The maximum grade is 2½ per cent, which occurs in four places, but only for a few hundred feet. There are about two miles

D. A. BELDEN.

SCENE ALONG FOX RIVER.  
CULVERT AND CAR AT SULLIVAN'S CREEK, TWO MILES FROM AURORA.

STREET IN BATAVIA.  
BRIDGE AT MILL CREEK, THREE AND ONE-HALF MILES NORTH.

of level track and four miles of very light grades. Abrupt changes of grade are avoided. The line is free from bad curves. The shortest curve radius is 1,000 and the usual radius 2,000 to 3,000 feet. There is considerable masonry in the way of culverts, the largest being shown in one of the engravings. The pole line is flexible bracket construction except within the city limits of Aurora and Batavia. Round cedar poles, painted white, and Creaghead brackets were used, with a No. 00 round trolley wire. There are two No. 0000 feeders, one running about 1½ miles from the power house, and the other about 5 miles. These serve to keep the drop on average loads as low as 10 per cent at the end of the line. It is a single track road with turnouts 2½ miles apart.

The equipment at present consists of two 26-foot body, cross seat cars, with G. E. 1,000 motors. The cars seat 36 people, and are comfortably heated with National electric heaters. At present writing an hourly service is being given. The cars leave the Aurora terminus on the hour and the Batavia terminus on the half hour. The business has exceeded the company's expectations. The line was opened

DIRECT CONNECTED UNIT IN ELGIN POWER STATION.

SCENE ON MILL CREEK ON AURORA LINE.

for business October 21, and since that time one car on the interurban has earned more than any four cars on the Aurora Street Railway city lines, while costing no more to operate. A 10-cent fare is charged for the seven miles from Aurora to Batavia. This is just one-half the regular fare of the Chicago & Northwestern Railroad, which has of late been running trains almost as frequently as the electric road runs its cars. Next spring, in addition to building 2½ miles further, to Geneva, it is expected to obtain control of 100 acres of ground three and a half miles out of Aurora, at a beautiful spot where Mill creek empties into the Fox river. The winter travel of the road has so far exceeded expectations that it is believed the summer travel will be something remarkable. The Fox river is noted for its beauty, and in the summer there is much travel, not only by picnic parties, but by campers thickly scattered along the banks of this attractive river.

The officers of the Aurora & Geneva railway are William Palmestock, of New York, president; Robert B. Dodson, of New York, vice-president; and D. A. Belden, the well-known and able general manager of the Aurora Street Railway, secretary and general manager. Mr. Belden deserves

great credit for his persistent efforts in pushing through and securing capital for this undertaking, and the soundness of his judgment has already been demonstrated by the traffic.

The interurban route north of Geneva is owned by the Carpentersville, Elgin & Aurora Railway, of which the officers are J. B. Lane, president; D. B. Sherwood, secretary; and E. D. Waldron, treasurer. It was built last spring, and enjoys a fine traffic. There are practically two divisions of the road, one extending north from Elgin to Dundee and Carpentersville three miles, the other extending south to South Elgin, Coleman, St. Charles and Geneva, twelve miles.

STANDARD BOILERS IN ELGIN POWER STATION.

making in all fifteen miles of valley supplied by the road. It is a single track road, gravel ballasted and laid with T-rails. Side pole construction is employed. Through Elgin the tracks of the Elgin City Railway are used. Upon completion of the Aurora & Geneva Railway to Geneva, next spring, there will be started a through baggage and express service, for which there will be specially built equipments.

The thing of greatest mechanical interest in connection with the equipment of this road is the Ball Engine Company's vertical cross compound direct connected engine in the power house. Its dimensions are 17 and 30 inches by 16-inch stroke, and it runs at 200 revolutions. Its rated horsepower when condensing, is 400. The shaft is extended out on each side to two outboard bearings, and on each end is a 225-kilowatt General Electric railway generator. The engine is 14 ft. feet high, 17 feet long and 9½ feet wide. The aim

## THE CONNECTICUT PARALLEL.

For many years the steam railroads have controlled the state legislature of Connecticut; hence there was little surprise, though much public dissatisfaction, when the railroad interest throttled electric interurbans. At first the fight was made at crossing points, where electric lines were obliged to cross the right of way of the steam lines. But failing here, the legislature was appealed to, in the effort to prevent this new and vigorous competition which was becoming stronger each year. In 1893 the famous statute against paralleling was passed, which reads "No street railway shall hereafter be built or extended from one town to another town in the public highways so as to parallel any other street railway or steam railroad, unless authorized by special charter prior to January 1, 1893, until

ELEVATION BALL ENGINE—CARPENTERSVILLE, ELGIN & AURORA RAILWAY.

of the designers of this engine was to build a high speed upright engine, with enclosed housings, double acting steam cylinders and easily accessible shaft boxing, a combination which would make a very desirable engine. The introduction of the shaft into this engine is accomplished by arranging the shaft boxes in a large jaw cutting into one side of the housing deep enough to bring the center of the shaft in a plane with the center of the housing, finished spots being provided to meet corresponding finished surfaces on the cast iron boxes. These boxes consist of one bottom, two quarter and one top box for each journal. Each of these are provided with removable babbit metal shells, upon which the journals bear. These shaft box jaws in the housing are closed by the use of heavy struts. As shown by the drawing these struts fit into V-shaped grooves, so that when bolted in tight the jaw is firmly closed and the mechanical circuit of the housing completed. These are but a few of the many good points of this engine which is worthy the special attention of all power house designers and engineers.

the company shall have applied to the superior court or any judge thereof, and shall have obtained a finding that public convenience and necessity require the construction of such street railway."

Under this statute the steam lines have practically had things their own way, for naturally the very centers of population which an electric line could profitably connect, were already united by a steam road; as for instance, Hartford and New Britain.

The steam roads in their opposition loudly wept for their own stockholders who were to be made penniless, and for those other stockholders who were likewise to put their faith and money in new electric enterprises which could never pay. The position was one which vigorously begged the question. Another claim for sympathy was based on a sort of 'auld lang syne,' in that the steam roads had been doing business so many years at the old stand, and it was cruel to try to part such old friends as the roads and their patrons of a generation.

But the people somehow could not see it that way. They saw in the new electric interurbans a more frequent service and lower rates than the steam roads could or did give, and where an electric line did squeeze in it immediately became popular with the public, who saw and appreciated its possibilities, and so it came to pass when the people wearied of a legislature devoted solely to the interests of the steam roads, that they gathered themselves together, held a caucus and elected a new legislature which will soon meet, and when it does the people will be likely to get a lot of trolley roads,

## PROGRESSING BACKWARDS.

Several years ago a charter was granted to a company to put down and operate street railway lines in Orlando, Florida. The road was built and afterward sold to a New England man, who made some improvements and additions. It proved to be a financial failure and has been abandoned for more than a year. The city council ordered the marshal to remove the tracks, as they had been permitted through neglect to become a nuisance.

VIEWS ON THE CARPENTERSVILLE, ELGIN & AURORA RAILWAY.

and if the steam roads in the nutmeg state want to do the local business they will have to do as steam roads in other states have had to do, and that is increase the service and reduce the rates. If the steam roads cannot do both, then where is their argument against the electric lines which have demonstrated that they can? The public are playing a winning game with nothing to lose, and in these days of progress and improvement the electric line, city and suburban, is destined to prove the most important factor in modern life.

A verdict for \$12,000 was given Ann McCormack recently against the Nassau Electric Railroad, Brooklyn, for the death of her husband, who was killed by one of the company's cars.

The Buffalo & Niagara Falls Electric Railway reports for the quarter ended September 30, 1896, gross earnings, \$51,527; operating expenses, \$18,591; fixed charges, \$13,323; net income, \$22,612.

## HOLYOKE STREET RAILWAY RELIEF ASSOCIATION.

For some time past whenever one of the employes of the Holyoke Street Railway Company would be sick, a collection would be taken up for him. The men felt the need of a definite plan and a firmer organization and a committee was appointed to draft by-laws for the association. Officers have been chosen and the organization will soon be on a firm basis.

The York (Pa.) Street Railway has suffered the loss of 600 feet of trolley wire and 400 pounds of bond wire by theft. The line will be protected by keeping the current on at night.

The Norwich Street Railway Company, Norwich, Conn., reports gross earnings of \$84,711 for the year. Operating expenses were \$55,359, dividends, \$12,500; car miles, 297,265; passengers, 1,987,519.

## THE LATEST AIR-BRAKE APPARATUS.

The Standard Air-Brake Company does not rest upon its laurels, but is always to be found in the van. Fully appreciating the great changes in rolling stock called for by electric traction, it has been earnestly working in order to meet every possible condition in which air-brakes will be required. While the company is making very large sales of its axle-driven compressor type of air-brake, it has recently brought out its motor-driven type to meet those cases in which it is not possible to find room on car axles, by reason of the motors taking all the space.

The latest apparatus of this company, which we illustrate herewith, solves the problem of furnishing an air compressor which is independent of the axle of a car. The 1-horse-power type occupies a space 22 inches long, 13 inches wide, and 17 inches high. The combined motor and compressor is exceedingly compact. The motor is iron-clad and securely protected against dust and moisture. It is of the slow-speed, series, multi-polar type. The brushes are easily accessible for inspection and renewal. The armature can be readily withdrawn by removing front head of motor. The motor frame is made of steel, which combines lightness with maximum capacity. The motor is insulated with extreme care to guard against possible grounding or breaking down of insulation. The armature is of the well-known drum type with the sections made separately and bedded in slots in the face of core. Damaged sections can be renewed in case of injury as is common in car motor armatures. The motor is guaranteed to develop a power above its rated capacity. The motor is protected against the ingress of oil from bearings and compressor.

The compressor is of the single-acting type, with double cylinders. These are placed vertical with trunk pistons connected directly to eccentrics in crank case. Pistons are carefully balanced to insure freedom from vibration and noise. The eccentrics are effectively lubricated by revolving in a closed chamber partly filled with oil, which is kept at such a height as to be always in contact with the sliding surfaces. The openings for intake and discharge are of ample capacity, and thereby the usual noise due to induction and discharge is effectively prevented. The compressor is bolted centrally with the motor and the shaft of compressor is a prolongation of the armature shaft, but it is not a part thereof. Bearings are made of phosphor bronze, and can be readily renewed without dismantling compressor. Pistons are made air tight in cylinders by the use of two piston rings of cast iron, with overlapping joints. Any vibration of compressor and motor is taken up by the rubber cushions which are interposed between motor-compressor and base, which latter is arranged in the form of a tray to catch any oil which may escape from bearings. Oil cups are suitably arranged, which, with occasional filling, maintain a regular height of oil in crank case.

Recognizing the fact that it is most undesirable to compel a motorman to use a hand rheostat in order to make a motor-compressor operate, the company sometime since patented here and abroad, the apparatus shown in the cut. The

CONTROLLER.

automatic controller automatically maintains a practically uniform pressure in the air storage reservoirs under cars or elsewhere. By its use when the air supplied to reservoirs reaches a predetermined limit, the motor-compressor is entirely stopped. As long as air pressure in the reservoirs remains within eight or ten pounds (or any other adjustable limits) of the required maximum, the motor-compressor remains inoperative. Should pressure however be reduced below the minimum limit, the motor-compressor is immediately started (slowly at first and gradually increasing as the resistance is automatically removed from circuit) and continues operating until the maximum limit is reached, when it again immediately stops as before.

The motor is series-wound and when starting with empty reservoirs, would naturally "run-away"; but under such conditions, the resistance remains in the circuit and is only

STANDARD AIR BRAKE MOTOR-PUMP.

cut out as the pressure increases. The apparatus is equally applicable to a shunt-wound motor. The speed of motor-compressor is at all times automatically controlled by the amount of work required.

While the motor-compressor is in operation, if for any reason the line circuit should be interrupted, or if the trolley leaves the wire, or if the conductor changes the trolley, the resistance is thrown in circuit with motor-compressor simultaneously with the stopping of motor-car. When the current is again restored the motor-compressor resumes operation, gradually increasing speed in the way above indicated. The automatic controller not only controls this air-brake

motor-compressor, but is applicable to various forms of motor and power control, such as in electric and other elevator practice, hydraulic and other pumping, handling cranes, bridges, etc. It may be used in all places where it is desirable to start or stop motors, which, without its aid, would be well nigh inaccessible. For example; freight or passenger elevators may be operated from any one of the several landings by simply pressing one button for starting and another button for stopping.

The entire outfit only occupies a space of 9 by 10 by 14 inches. It is furnished with lock and key to be retained by proper custodian, so that tampering may be prevented. The company is to be commended for its foresight in thus meeting every situation.

STANDARD AIR BRAKE AUTOMATIC REGULATOR.

John Gorman, convicted of stealing wire from the Washington, Arlington & Falls Church Railway Company, was, on second trial, sentenced to two months in jail.

## BALL SIDE CRANK MEDIUM SPEED ENGINE.

The Ball Engine Company, Erie, Pa., has recently placed on the market the engine which we illustrate. It is designed to meet the demand of many railways for engines direct connected to generators, and in view of the severe conditions of electric railway service all the parts have been made of liberal proportions and every refinement in adjustment and manipulation incorporated. The bed is symmetrical and an example of good designing. Toward the upper end the bed becomes a round hollow column, having on the top and bottom sides the guide surfaces which are bored at the same time that the casting is bored and faced for the reception of the cylinders. Elliptical openings at the sides render access to the crosshead easy. The crosshead is of the double plate pocket type, having taper shoes of cast iron with the rubbing surfaces spotted with genuine habbit metal. The shaft boxes are arranged in a deep jaw in the engine frame, good

BALL SIDE CRANK MEDIUM SPEED ENGINE.

bearing being secured by providing finished surfaces on the boxes and in the jaw. There are four boxes to the bearing, all of them being adjusted by means of wedges and set screws. The crank shaft is of 40-carbon open hearth steel, solid from end to end, forged and ground to a smooth running surface. The connecting rod is also of forged steel with the ends cut out to receive crank and crosshead boxes. The boxes on both ends are adjusted by wedges moved by set screws placed in the top of the rod. Both wedges move in the same direction so the length of the rod is not changed. The high pressure valve is of the double-face telescopic type, receiving the boiler pressure on the inside. The low pressure valve is of the common "D" type with a round relief area on the back. The outboard bearing has the same form of boxes and the same adjustments as the main bearing. Crucible steel is used for the piston rods, valve stem, rocker shafts and crank pins. The governor of the engine shown is in the fly wheel and is quiet and quick in action, and especially adapted to give good regulation under sudden changes in load.

## LAW AGAINST SPITTING.

The very unpleasant subject of expectorating in street cars has been referred to several times. It seems to have been a practice which was tolerated in the early horse car days, before the advent of heated cars, and when the floors were covered with hay, which was changed every day. At any rate, in these days, there seems to have been little attempt at reform in this direction. With modern cars, the disgusting practice is even more objectionable than before, though probably no less dangerous to health. With a view to eradicating the evil, many roads carry placards in all winter cars, couched in language, both persuasive and mandatory, forbidding spitting in cars. In New York city the health department took steps, last year, to put a stop to the evil in surface and elevated cars and ferries.

Now, the Chicago commissioner of health, proposes to try his hand, and bases his plans on an ordinance which reads: "Any person who shall commit any indecent, lewd or

filthy act, in any place in the city, shall be deemed a disorderly person, and upon conviction shall be fined \$5 or imprisoned in the house of correction six months, or both."

The Civic Federation and the Woman's Club promise their support, and a police order will be requested to enforce the law.

The movement is certainly a most commendable one. Our observation is that steady headway is being made in this direction, for in a number of places the street railways have succeeded in almost stamping out the practice.

## COMPRESSED AIR IN CHICAGO.

We are informed that the General Railway Company has arranged with the Illinois Compressed Air Company for tests of cars operated by the Hardie compressed air motor on the Kedzie street line. The compressor is in place, two cars have been built and are awaiting shipment, and as soon as the piping is installed the trial will be commenced. It is expected that the cars will begin running within sixty days.

SPECIAL CARS IN WILMINGTON.

The Jackson & Sharp Company, of Wilmington, Del., has recently built some special cars of beautiful design and having several novel features. C. F. Hutchings, superintendent of the Wilmington City Railway Company, has placed upon his roads some of these cars, which are used for ordinary traffic, but can be readily converted into party cars. The seats, lambrequins and trimmings can be quickly removed and the car fitted up as a special as shown by the accompanying engraving. The interior finish is of mahogany and the decoration, upholstery, draperies and carpet all combine to make the appearance very attractive. No sash is used for the window glass, which is of polished plate, and is imbedded with rubber between the posts in the woodwork surrounding the window opening. In this way any rattling, which would result from ordinary sash, is avoided. The curtains are made of Pantasote and fitted with Forsythe fixtures, and these, as well as the lambrequins, were furnished by the McKay Curtain Company. Comfortable rattan chairs of various styles and sizes are furnished, some of which have tufted hair cushions covered with plush. Special cars of suitable design and finish have been so costly in

SIDE SEATS REMOVED FOR "SPECIAL."

proportion to the limited demand that their use has been confined to comparatively few roads. This objection has been overcome as this car does not cost a great deal in excess of regular first-class cars and its earning capacity is much increased by its use both as a regular and a special.

The Steinway trolley road of Flushing, L. I., made a Christmas present of \$25 to each conductor and motorman who had handled their cars for a year without accident.

## INCLINED RAILWAYS.

At the November meeting of the Engineers' Society of Western Pennsylvania, an interesting paper on "Inclined Plane Railways" was read by Samuel Diescher. He said in part:

"The oldest type in use is the 'gravity incline' found in mines and quarries situated at altitudes much higher than the point where the products are to be delivered for consumption or further transportation. This type is used only for lowering the load, the weight of the material transported furnishing the motive power.

"The range of employment of cable railways with gripping devices is confined to grades on which the resistance from car and load does not exceed the friction in the grip and should further be confined to grades on which in case of emergency the car may depend upon its brakes.

"Recently another type was introduced which is a compromise between a gravity incline and an electric railway. It is built with single track as well as with double track. In street railway parlance it is known as the 'balance system.' It came into existence since the general adoption of electricity as motive power for street cars. So far as it has been used for transportation of electric street cars on grades too steep to be surmounted in the ordinary way. This type has no power plant of its own, but the operation is performed by the motor of the ascending car. To accomplish this the car is counterbalanced to the extent of its dead weight; in a single track plant this is attained by a properly balanced iron dummy car, traveling simultaneously with the motor car but in opposite direction. In case of a double track line, the necessary balance is established by another car traveling in opposite direction. The accord in travel between the one car and the dummy, or the two cars, is accomplished by the employment of a rope extending from one car to the other by way of a sheave located at the head of the incline. In the case of a double track the cars are temporarily connected with the opposite ends of the rope which they both drop upon their arrival at the respective terminals of the incline. With a single track and dummy one end of the rope is permanently connected with the latter and the other is picked up by the car when it enters the plane and is dropped again when it arrives at the point whence it can dispense with the help from the rope. As a matter of course, in the double track plant, schedules must be closely observed, else the travel will be very irregular and unsatisfactory to patrons. It is obvious that the operating expense of such an inclined plane is very small, and were it not for its limitations by length and grade, its applicability would be very extensive. It is also limited by the condition that the tractive effort that can be secured with the loaded car must exceed the resistance due to gravity. Inclined planes of this type are in successful operation at Seattle, Wash., Portland, Ore., San Francisco, Providence, Easton, Pa., and Beaver Falls, Pa."

One statement was made which needs correction, viz., that "the steepest grade on which an electric car can travel without auxiliaries, \* \* \* and to advantage, is 9 per cent." Many roads have much heavier grades; one in San Francisco, for instance, is 13 per cent, and we have there ridden on a car, loaded to the steps, and equipped with only two ordinary motors. With this load a speed on this grade of between four and five miles an hour was easily maintained and the operation has been continued.

### TUSCARAWUS RAILROAD COMPANY.

The Tuscarawus Railroad Company, of New Philadelphia, O., is perhaps the only street railway company which mines its own coal. This company operates 8½ miles of single track between New Philadelphia, a town of 6,000, and Urichsville with 4,500 inhabitants. This line connects at Urichsville with the United Electric Company's road to Dennison (4,500) two miles distant, and at New Philadelphia with the Tuscarawus Electric Company's street railway to Canal Dover (4,500) 3½ miles away. On the line are two smaller towns, Barnhill and Midvale. At Midvale which is the half-way point are located the car barn and power house shown in our illustration. To the rear of the power house is seen the opening of the company's coal mine. Coal (run of the mine) is delivered to the boiler room at an average cost of 40 cents per long ton, a low price for fuel. The power house is equipped with a 250-horse-power Erie-Ball

with electricity and the remainder in building extensions. Naugle, Holcomb & Co. have the work in charge, and are pushing it rapidly. George Weston is the engineer and superintendent.

A line will be built in Harrison street, running west from 48th street, where it connects with the Metropolitan Elevated to Harlem. Also a line beginning at Robinson avenue and Harrison street, running south on Robinson to 22nd street, west on 22nd to Harlem avenue, south on Harlem to 26th street, thence through Riverside, crossing the Desplains river north of the Chicago, Burlington & Quincy tracks, and thence in a westerly direction through Grossdale to Lagrange, comprising some 17 miles of double track in addition to the 13 miles of railroad leased from the Northern Pacific.

Later the line will be extended to Hinsdale in DuPage county. The overhead trolley will be used. There is already constructed track in Harrison street running from Harlem as

POWER HOUSE OF THE TUSCARAWUS RAILROAD COMPANY AT MIDVALE, O.

engine and four D-62 Thomson-Houston generators. The company owns five cars, built by the G. C. Kuhlman Company, of Cleveland, each equipped with two 30-horse-power Westinghouse 12-A motors and G. E. type K controllers. The line was opened for traffic on September 10, cars running on 60 minutes headway. Since cold weather a skating park with hand stand, etc., has been built on the open ground at the right of the car barn, which acts as a stimulant for traffic. The officers of the company are, president, William Christy, of Akron; vice-president and superintendent, C. E. Mitchner, of New Philadelphia; secretary and treasurer, C. H. Howland.

### CHICAGO SUBURBAN RAILWAY COMPANY.

The Suburban Railway Company, which has leased the Chicago, Harlem & Batavia and the Chicago & Southwestern divisions of the Chicago & Northern Pacific Railroad, on December 15, executed a \$3,000,000 mortgage; \$1,250,000 will be spent in equipping the Northern Pacific

far east as Central avenue, 1½ miles on Robinson avenue and 2½ miles running east from Lagrange.

The contract for the power house building was let to Scoullar & Bierwirth in the early part of this month, and ground was broken a week ago. The power house will be located on the northwest corner of Harlem avenue and 22nd street, with a frontage of 108 feet on Harlem and 96 feet on 22nd. The stack and building have been designed for a 2,000-horse-power plant, but the first installation will comprise only three 250-horse-power Stirling boilers and two tandem compound condensing Green engines, one of 560 and one of 210-horse-power. The stack is to be of steel, 96 inches in diameter and 150 feet high above the grates. A well will supply the condensing water, which will be cooled for re-use by means of a cooling tower or of an open pool and cooling troughs.

The Hornellsville, N. Y., Electric Railway was robbed of \$100 which was taken from a box in which the conductors on the late runs deposit their days receipts.

## CONCRETE WORK IN DETROIT.

By F. A. Little, Chief Engineer, The Detroit Railway.

When the Detroit Railway was granted a franchise to build and operate an electric railway in the streets of Detroit, Mich., it accepted, among many other things, that portion of the general street railway paving ordinance, which we will now quote:

"And the foundation for the pavement shall be constructed in the following manner, to wit: The roadway shall be excavated to a sufficient depth below the grade of the pavement to permit of the construction of a concrete foundation to a depth of six inches below the ties, and said foundation shall be composed of cement, sand and broken stone in the proportions and manner specified for pavements when a street is paved with a concrete foundation in the city of Detroit; upon this foundation the ties shall be placed and concreted in with the same kind of concrete to their full depth, and to such a height above their top surface as may be necessary to meet the cushion provided in the street paving specifications of the city of Detroit for the class or kind of service paving material to be used under this ordinance.

"Provided, that owing to the projecting of the ties beyond the lines of the outer rails of the track the street railway company operating such railway, shall maintain, until the repavement of the street, the pavement for a space of eighteen inches outside of the outer rails on either side to the satisfaction of the board of public works, against any damage thereto caused by the depression of the tracks or the movement of the ties or rails resulting from the operation of cars or trains thereon."

Also among the requirements was the provision that there should be one inch of sand under the tie, to form a cushion, and to better enable the track men to surface the track.

Before we enter into the discussion of the subject matter, we wish to say that whatever facts we shall present to you in this article are based on the construction of nearly fifty miles of track on a concrete foundation in the city of Detroit, and the figures that are given are the average as taken from prices of labor and material in Detroit.

The first thing that enters into the preparation of a road-bed is

### GRADATION.

According to the terms of our franchise, by using a 7-inch rail and a tie 5 inches in depth and 7 feet long, 1 inch of sand under the tie, 6 inches of concrete for the foundation, it is necessary to excavate 7 feet wide and 19 inches below the surface grade of the pavement or grade established by the city engineer.

The average cost of excavation through streets paved with cedar blocks laid on sand or plank, is 8 cents per lineal foot, and through streets with concrete foundation under the cedar block, it is from 12 to 15 cents.

### CONCRETE.

The concrete is usually laid in two courses, in order to facilitate construction. The first course is laid 6 inches deep and 7 feet wide. When it has set from five to seven days the track is laid, lifted and lined, and the second course of concrete is laid.

The second course of concrete varies in depth according to the kind of pavement that is to be used, as follows: With cedar block 7½ inches, brick, 8½ inches and asphalt

10½ inches. All 7 feet wide. For computation of quantities the space occupied by the ties is to be subtracted.

The composition, as required by the board of public works is as follows: "All concrete laid in the streets of the city of Detroit shall consist of Louisville cement one part, clean sand two parts and crushed stone four parts," or rather the formula that is used is,

- 2½ sacks of Louisville cement—(1¼ barrel or 2 barrows).
- 4 barrows clean sand.
- 8 barrows crushed stone, (a little over one cubic yard).

For one cubic yard of concrete it takes 1.616 cubic yards of the above proportion, or one cubic yard of crushed stone to 1.08 cubic yards of concrete.

In preparing for the first course of concrete, there are two men that go ahead and set small stakes with the top of the stake at grade for the upper surface of the first course of concrete. Then on a mixing board 10 to 12 feet square, the sand and cement are mixed quite thin with water, after which add the crushed stone (which should have been previously wet) and mix this compound thoroughly, but do not let it get thin enough to run, then shovel into the trench or excavation that has been prepared to receive it, keeping two men known as surface graders tamping the concrete to grade with wooden tampers 12 inches square.

When it comes to laying the second course of concrete, it has to be tamped under the ties and rail and for this tampers with 2 by 6 inch iron faces are used.

The second course is laid to a grade that meets the requirements of the kind of pavement that is to be used.

The labor may be itemized as follows:

1 foreman at \$2.00 per day.....	\$ 2.00
2 stake setters at \$1.50 per day.....	3.00
8 men on board at \$1.50 per day.....	12.00
3 men on stone at 1.50 per day.....	4.50
1 man on sand at \$1.50 per day.....	1.50
1 man on cement at \$1.50 per day.....	1.50
2 surface graders at \$1.65 per day.....	3.30
1 man from fire department to turn on water from fire department hydrant at \$1.75 per day.....	1.75
Total.....	\$29.55

The above men will lay an average of 400 lineal feet of concrete 7 feet wide and 6 inches deep, or 51.85 cubic yards per day of 10 hours. Equal to \$0.57 per cubic yard.

The cost of concrete per mile of single track for cedar block pavement may be summed up in this manner, viz:

1,540 barrels Louisville cement at 60 cents per barrel.....	\$ 924.00
630 cubic yards sand at 65 cents per cubic yard.....	409.50
1,260 cubic yards crushed stone at \$1.25 per cubic yard.....	1,575.00
Labor at \$1.50 per day.....	780.00
City inspection.....	40.00
Total.....	\$3,728.50
	or 70 cents per lineal foot,
and for brick pavement, 76 " " " " "	
" " asphalt " 88 " " " "	

### TRACK LAYING.

The ties used are No. 1 white oak, sawed from live white oak and are 7 feet long, 5 inches deep and 8 inches wide, and are not to vary over 2 inches in length.

The rail is the "Cambria" grooved, section \$14, 85 lbs. per yard, 7 inches high and 30 feet long. The special work is made from 7-inch Cambria & Wharton 90 lbs. per yard, with 3-inch tram to which is bolted a guard.

The ties are laid on the first course of concrete 2½ feet centers (although we have laid about 15 miles with 2 feet centers.)

The rail is laid and spiked, using 5 by  $\frac{9}{16}$ -inch spikes. After spiking, sand is tamped under the ties and the track brought to grade and lined. After this is done it is ready for the second course of concrete previously described. If the weather is at all warm it will be necessary to have a few men go just ahead of the concrete boards and keep the track in line.

### PAVEMENT.

Cedar block is the leading pavement in Detroit, but brick, asphalt, Medina and cobble stone are used. The Detroit Railway has laid between its tracks within the city, and all on concrete, about 117,000 square yards of cedar block, 13,000 yards of brick, 1,100 yards of asphalt, and 140 yards of Medina block, and about 36,000 yards of cobble stone pavement on its suburban lines, the average cost per square yard being as follows:

Cedar block (with concrete laid).....	\$ .52 to \$ .55	per square yard
Brick " " " .....	1.15 to 1.20	" " "
Asphalt " " " .....	1.90 to 2.00	" " "
Medina block " " " .....	2.70 to 3.00	" " "
Cobble stone (no concrete used).....	.28 to .30	" " "

While cedar block does not make a lasting pavement, it is recommended as cheap pavement where the travel is not very heavy, lasts from five to seven years and is easy to keep in repair. The interest on the difference between the first cost of that and either asphalt or Medina block keeping it in repair. The itemized cost of it being:

Cedar block, at \$15 to \$20 per cord, sawed and culled, and 70 square yards per cord.....	.28 cents to 30 cents	per square yard
Gravel at \$1.15 per cubic yard.....	4 cents to 5	" " "
Tar at \$17.50 per ton.....	11 cents to 12	" " "
Labor at \$1.50 per day.....	9 cents to 10	" " "
Total.....	.52 cents to 57	" " "

We have not had occasion to use "headers" in unpaved streets, except in a very few instances, and then we used second-hand curb stones that cost us 20 cents per foot.

The rolling of the pavement, which is included in the above figures, costs about 1 cent per square yard.

Do not attempt to lay cedar block pavement without using either tie rods or tie plates, because the swelling of the blocks and the tamping of the gravel between the blocks will throw your tracks all out of gauge.

(See Fig. 1 for cross-section of track laid on concrete foundation.)

### RAIL JOINTS.

So far we have used nothing but the 36-inch ten-hole splices, with two rows of holes, with six on the lower and four on the upper row, using 1 by  $3\frac{1}{2}$ -inch bolts. When we are doing construction work we keep one man doing nothing else but inspecting the bolting, and in that way we are able to have every bolt drawn up tight, drawing the splice up so that the center of the arch is about  $\frac{1}{8}$  to  $\frac{3}{16}$  inch distant from the web of the rail. By having this inspection we are able to have the bolting done evenly, and so far we have not found any indication of low joints where the track has been laid on concrete foundation in paved streets.

We have had some experience with hot riveted and electric welded joints. Hot riveting gives fair satisfaction where it has been used on the Cleveland City Railway, Cleveland, Ohio. Although we think that the additional life of the joint is not great enough to warrant the extra expense. The electric weld seems to give the best all-around results where the breakage of joints is at a minimum, but the great cost of welding with the present methods, cause most companies to hesitate about trying it.

### BONDING.

Benedict & Burnham No. 00 bonds were used in most of our construction, although last year we used Chicago No. 0000 bonds of the "U" pattern, and bonded to the base of the rail. We have made no electrical tests of these bonds, but from tests made by others we think that the Chicago No. 0000 bond is among the best of the copper bonds that are in the market today.

However, we consider that the electric welded joint is the only bond that approximates perfection.

We are indebted to C. B. King, electrical superintendent of construction of the Detroit Citizens' Street Railway Company, for the following information in regard to their experience with the electric weld on Jefferson avenue.

He says that they consider the electrically welded joint the "ideal," it giving a perfect joint for the return current.

In four miles of this track 38 joints pulled apart last winter, but no others have been reported broken since.

No loss of current was apparent after these breaks, which is attributed to the fact that metal ties were used, and at intervals of about 500 feet, the rails were cross-bonded with a 1  $\frac{1}{2}$ -inch square bar of iron.

Last spring these breaks were repaired by using a special splice that fitted around the broken weld. Then bonding around the break with from four to six Chicago No. 0000 bonds.

He also says that the conductivity of this rail is perfect,

no greater loss of current can be detected at the joints than at the center of the rail. And a further test shows that the stray currents in the earth and from the water and gas pipes (which are connected at the power house with the negative pole of the dynamo) are all towards the rail, while that which is bonded with the best copper bonds, the current is towards the water and gas pipes, showing conclusively that the resistance in the electric weld joint is practically nil.

The cost per lineal feet of single track, concrete foundation, which includes the cost of excavation, laying, lifting and lining of track, cost of concrete and labor of mixing and tamping, and cost of pavement, may be summed up as follows:

Excavation, 10 inches deep by 7 feet wide.....	\$.80	per lineal foot
Track laying, lifting and lining.....	.10	" " "
Concrete, (cedar block).....	.70	" " "
Pavement, cedar block.....	.42	" " "
Total cost with cedar block pavement.....	\$1.30	" " "
" " " brick.....	1.80	" " "
" " " asphalt.....	2.45	" " "
" " " medina, or granite.....	3.20	" " "

## TRENCH WORK.

There is one other matter to which we wish to give some attention, and that is, construction on a concrete foundation, without ties, or as we call it "trench work."

When our work of construction began in streets paved with brick and asphalt laid on 6 inches of concrete, and our managers realized the great expense that would be attached to construction with ties, they began to look over the field for a cheaper method and decided on "trench work" without ties.

Before beginning this work it is necessary to have the line of the tracks run very carefully with a transit, giving "points" about every 50 feet.

From this line the gauge line of the tracks can be located, then with a chalk line, chalk a line 6 inches on either side of the gauge line. (This precision is to save cost of pavement and concrete that might be torn out by careless workmen); then the trench is excavated to a depth of 15 inches for a 7-inch rail and 12 inches wide, (see Fig. 2) using, to cut through asphalt, two-edged axes made by our blacksmith, and "stone" picks to get through the concrete.

the width of the channel corresponding to the width of the base of the rail, and the rail placed in the channel. Great care is taken to see that the track is to proper grade and line.

This completed, the track is ready for the grouting, or the second course of concrete. The composition of the grouting (see "A" in Fig. 2) being one part best Portland cement, one part clean sand, and three parts of fine gravel, thoroughly mixed with water, and then carefully tamped about the rail, bringing the grouting up to the proper height to meet the cushion for the pavement. The men are cautioned not to disturb the alignment of the track in any manner.

After this is allowed to set from eight to ten days it is ready for paving. If it is asphalt pavement we let it out by contract, but the brick paving we do ourselves. Instead of using tar for cement between brick, we use grouting composed of one part of Portland cement to three or four parts of clean sand, mixed thin with water, so that it will run readily. This is poured over the brick, and worked between the joints of the brick with a wire broom. This grouting permeates the sand cushion under the brick, and when once set, forms one solid mass of brick and concrete, shedding all

Sections of track laid in trenches without ties in streets paved with asphalt and brick on concrete foundation

Fig. 2.

Fig. 3.

Fig. 4.

The first, or foundation course (see "B" Fig. 2) is prepared, using the regular concrete proportion of one, two and four, and adding one-fourth of one part of Portland cement. This is tamped into the bottom of the trench and should be allowed to set seven days.

The rails are then suspended over the trenches, the splices put on, the final bolting is done, and the rail dropped into the trench, laying with "broken" joints. The tie-rods (round, for asphalt and flat for brick) are put on every ten feet, and with tie-rod at every joint.

Where the tie-rods cross between rails a trench is cut about 4 inches wide and deep enough to allow the rod to go in and connect the rails without having any weight borne by it.

The rails are then drawn to gauge, the track lifted, or blocked up to grade, using oak "shims" for blocking. A plate 24 inches by 6 inches by 3/8 inch is placed under each joint (see Fig. 3) to give extra support, or what has given better satisfaction is channel iron, with a one inch flanges

water and holding the track in a vise which we believe will be as lasting as the rail.

We have used this construction on 90° curves, by making the trench 15 inches wide and laying the concrete so as to make a brace for the rail, and the curves appear to be as perfect today as they were on the day that they were laid.

In one or two instances we have noticed small depressions in the track where the street was paved with asphalt, caused by soft soil under the concrete and because the concrete under the asphalt did not support the foundation under the rail. We think that this can be remedied in future work by watching the character of the soil, and where it is soft excavate a little deeper and broaden the base (as shown in dotted lines "C" in Fig. 2) and tamp in crushed stone until a solid foundation is formed, and in fact we think that under a great many conditions a broader base is advisable in this kind of construction to insure a greater degree of stability.

The cost of construction with this method is much cheaper as the following comparison will show.

	Trench work per lineal foot.	With ties per lineal foot.
Excavation.....	\$0.10	\$0.15
Concrete (foundation course).....	.11	.35
Track laying, lifting and lining.....	.08	.10
Grouting, or second course.....	.18	.53
Paving with asphalt.....	.55	1.55
Ties and spikes, 2½ C. to C.....	.....	.17
Channel iron, "shims" etc.....	.03	.....
<b>Total</b>	<b>\$1.05</b>	<b>\$2.85</b>

A difference of \$1.80 per lineal foot in favor of "trench work."

The largest saving is in pavement and concrete as is shown in Fig. 4. While this track has only been laid for one and one-half years and consequently we are not prepared to give the life of it, yet our experience with it justifies us in recommending it to the consideration of all street railway managers who have roads to build in streets paved with brick or asphalt and on a concrete foundation.

In conclusion we wish to say that we are well satisfied with our methods of construction on concrete foundation in paved streets, but do not advise its use in streets that are not paved outside of tracks, because where we have tried it, unless we had the most perfect drainage, the winter's frost of this northern latitude was sure to heave and break the concrete to such an extent that the tracks needed to be soon repaired.

## AN ELECTRIC ROAD UP MT. TOM.

The project to build an electric road up Mt. Tom, Massachusetts, has taken definite form. The last state legislature granted a charter for the formation of a company which should operate such a road. It has been incorporated under the name of the Mount Tom Railroad Company.

The altitude of the mountain is 1,250 feet, and it is expected that the length of the road will be a little over a mile, with a grade from 14 to 24 per cent.

The equipment and construction of the road will be similar to that up Lookout Mountain, at Chattanooga, Tenn.

There will be two cars on the incline, one running up while the other is going down, and they will be connected by a cable which will pass over large drums at either end of the route.

There will be telephonic communication between the two cars to avoid trouble in starting and stopping, so that when the bell of one car rings the other one is also sounded. The electric motors on the cars furnish all the power, and it is estimated that, with this cable connection, the power required to take the cars up to the summit is not much greater than to move them on the level.

Motors of 75 or 100 horse-power will be used. Power will be furnished by the Holyoke Company. This road will make the mountain accessible to 150,000 people by street car ride. It is expected that \$100,000 will be spent before the road is completed next June.

President Loomis, of the Holyoke Company, is also the president of the Mt. Tom Company, W. R. Hill is treasurer of both concerns, and with one exception, the directors are the same.

Each of the married men, employed upon the Northeast Electric road of Kansas City, received a Christmas present of a large, fat turkey. Each of the single men received a silver dollar, with which he could buy a turkey or spend otherwise, as he saw fit.

## NEW ELECTRIC LINES.

A new interurban electric line running through the oil country and connecting with Toledo is contemplated. C. T. Geddes who recently resigned his position as general manager of the Toledo, Bowling Green & Fremont Railroad Company, is the practical railroad man in the scheme. The

route is shown in our sketch. Lines from Tiffin and from Findlay meet a few miles south of Bowling Green and thence run via Bowling Green to Waterville on the Maumee river and down the west bank of the Maumee to Toledo. The territory through which the road will run is full of oil wells and it should prove a paying one.

Another line in which Mr. Geddes is interested is one to be built from Monroe Piers at the mouth of the Raisin river

to Tecumseh, Mich., via Monroe and Petersburg, with a possible connection from Monroe to Toledo. One of the features of this road will be its freight traffic, transporting the fine white sand which is found in abundance near Petersburg and is so desirable for glassmaking.

## FEED WIRE THIEVES.

The Traction Company, of Baltimore, Md., lost 1,200 feet of feed wire last August. After cutting down the line the robbers burned off the insulation and sold the wire for old copper. The expressman who carted away the wire was found and gave what information he could. Recently he notified the detectives that the same men had bargained with him again to haul some wire. Plans were carefully made and the two thieves arrested and now await trial in the criminal court. It is thought that they have been engaged in similar operations in Pennsylvania, Delaware and New Jersey.

## THE WARNER CAR HEATER.

The Ohio Brass Company, of Mansfield, O., has recently issued a catalogue describing a new electric heater for street cars. Either four or six heaters are used in each car, two adjustments being possible in the first case and three in the second.

The construction is simple and strong, two malleable iron castings being used for the casing. One supports the wires and is provided with lugs to fasten the heater in position, while the other protects the coils and is so formed as to insure a draft of air over the wires. A special grade of wire

is used, whose resistance does not vary even with high temperatures and is not readily oxidized. In a set of four heaters alternate sections are connected in series and by means of two switches the circuits are controlled independently. With one circuit in operation, 3 amperes are taken from a 500 volt circuit and with the two in parallel, 6 amperes are used.

When six heaters are in a set, the sections are so divided that one carries twice as much current as the other, and in this way, either 3, 6 or 9 amperes of current are consumed. The temperature of the car can be closely regulated and sufficient heat is generated even for the coldest weather.

Each heater is tested and guaranteed for two years, new coils being furnished to replace any that may be defective.

## BLIZZARD IN THE EAST.

A severe wind and snow storm, December 16, seriously interfered with all kinds of traffic in New York, Boston and cities along the New England coast. The trolley roads made a gallant fight to keep their tracks clear and generally succeeded by the vigorous use of their snow plows. In Brooklyn the mail cars were delayed for several hours. The underground trolley system was seriously affected by the snow drifting into the conduit and blocking the cars. On some of the suburban lines the wind piled the snow in drifts of from three to twelve feet deep. In one or two of the cities some short-sighted business men objected to the street car companies clearing their tracks, and threatened to shovel the snow back between the rails.

The Marietta Street Railway suspended operations because of the cost of street paving and the near approach of electric competition. It will be several weeks before the horse cars are superseded by the trolley.

## NEW OFFICIALS.

W. E. Hepperle, of Harrisburg, has recently been appointed superintendent of the Hagerstown Railway Company.

F. M. Talcott, of Richmond, Va., has taken the management of the Consolidated Street Railway, Dallas, Texas, in place of C. M. Ward, who has resigned.

E. W. Courtney, assistant electrician of the Washington, Alexandria and Mount Vernon Electric Railroad, has resigned to accept the position of general superintendent of the electric railroad in Frederick, Md.

Joseph T. Jones, of Buffalo, N. Y., was elected president of the Niagara Falls electric road, to succeed Colonel Gaskill. The new directors of the company are J. T. Jones, Charles A. Sweet, George L. Lewis, Harlow C. Curtis, William B. Rankine, Adelbert Moot, William H. Johnson, A. J. Porter and Charles B. Hill.

At the annual meeting of the Sherbrooke, Quebec, Street Railway Company, John W. Burke, of New York; J. E. Flood, of Sandy Hill, N. Y.; Wm. Morris, of Lennoxville; Walter Blue and F. J. Griffith were elected directors. At a subsequent meeting, John W. Burke was chosen president and F. J. Griffith secretary-treasurer.

At the last meeting of the Baltimore City Passenger Railway Company, Gabriel D. Clarke, Jr., was elected director to fill the vacancy caused by the recent death of his father. The present board of directors consists of Bernard Cohn, Austin L. Jenkins, O. A. Kirkland, Alexander Shaw, Walter S. Franklin, John W. Hale and Gabriel D. Clarke, Jr.

William J. Fransioli, who had been acting general manager of the Manhattan Elevated Railroad since the death of Colonel F. K. Hain, has been appointed permanent manager by the board of directors. Mr. Fransioli, though a young man, has been with the elevated company for sixteen years, the last five of which he has been Colonel Hains' assistant.

The Hamilton, Ontario, Street Railway Company held its annual meeting and elected Wm. Gibson, M. P., to succeed B. E. Charlton as president. The directors are: President Wm. Gibson, B. E. Charlton, E. Martin, Vice-President Isaiah Beer, W. J. Harris, F. W. Fearman, John A. Bruce, and J. B. Griffith, who continues to act as secretary and manager.

The annual meeting of the stockholders of the Washington & Great Falls Electric Railway was held, and the following directors elected: J. P. Clark, S. T. G. Morsell, Lee Hutchins, J. V. N. Huyck, Frank B. Clark, W. E. Lewis and E. C. Clark. The board then met and chose J. P. Clark for president, S. T. G. Morsell, vice-president and Lee Hutchins secretary and treasurer.

At a called meeting of the stockholders of the Chattanooga Electric Railway Company, the resignation of Captain C. A. Lyerly as president was accepted and the following officers elected: President, J. H. Warner; vice-president, Percy Warner; secretary and treasurer, E. D. Lilly. The new board of directors is composed of J. H. Warner, Percy Warner, Edwin Warner, W. T. Adams, C. A. Lyerly, T. D. Young and G. W. Meade.

## FIRE LOSSES DURING THE MONTH.

### BROOKLYN.

The car sheds and repair shops of the Brooklyn Heights Railway Company were damaged to the extent of \$40,000. The fire was supposed to have originated from a defective electric wire. The prompt action of the car employes saved all but fourteen of the two hundred cars stored in the barn. The loss is fully covered by insurance.

About a dozen cars were burned and the car sheds of the Nassau Electric Railroad damaged to the extent of \$35,000. One of the cars was turned in with a burnt out motor box and it is presumed that the fire was started by some of the wood work igniting from the heat of this box.

### JANESVILLE, WIS.

The Janesville Street Railway Company's power-house was destroyed by fire, the loss being \$12,000, partially covered by insurance. It is supposed that sparks from the generator ignited some waste and the fire was communicated to the oil cans in the engine room. When a stream of cold water struck the engine, the cylinder head blew out, injuring three persons.

### NEW BRUNSWICK.

Allens Theatre Building, containing the offices of the Brunswick Traction Company, was destroyed by fire. Loss \$300,000.

### AKRON, OHIO.

The Wooster avenue barns of the Akron Street Railway & Illuminating Company, with thirteen cars, were destroyed by fire. Loss \$10,000; insurance \$8,000.

### DUBUQUE, IOWA.

The quick response of the fire department prevented a very threatening fire in the power-house of the Light and Traction Company. The fire was beneath the engine and dynamo floor and was extinguished by cutting away the floor and using the "cellar nozzle." The only loss was the damage to the floor.

## FLEXIBLE TROLLEY SUSPENSION.

A new trolley suspension has recently been placed upon the market by Fletcher & Stone, of St. Louis. Great flexibility is claimed for this device when used either with the bracket or span wire styles of suspension. Difficulty has been experienced by the trolley pounding the line when running under a rigid car. This suspension obviates this difficulty, for it permits both vertical and transverse vibra-

tions, and in this way provides for the oscillation of the car and the pressure of the trolley. In case the trolley jumps the wire, the force of the blow given to the span wire is not transmitted to the line, and in this way many fractures of the wire are prevented. Being suspended in this way, the trolley wire is pliant throughout its length, and is free to permit any vibrations to pass. The Suburban Street Railway, of St. Louis, has adopted this suspension on the Locust street line.

## T. E. HUGHES.

T. E. Hughes is perhaps as well known to the street railway profession as any of our readers. For fifteen years he gave his attention to the manufacture and operation of street railway cables and of late years, since the advent of electrical traction, has made a study of the electric transmission of

T. A. HUGHES.

power for railways. After ten years' service as manager of the Washburn & Moen Manufacturing Company's warehouse at Pittsburg, he has accepted an offer of the Standard Underground Cable Company, of Pittsburg, to take charge of the sale of its insulated wires (other than lead covered cables) in the eastern states. Mr. Hughes will have headquarters at room 18, Times building, New York, where he will be glad to greet his friends, the old as

well as the new ones, which he has the faculty of making so easily. Geo. L. Wiley, who has been the manager of the New York office of this company, will continue in that capacity, giving special attention to lead covered cables, underground conduits and accessories.

## CALUMET BONDS CAUSE BANK FAILURE.

The National Bank of Illinois, this city, is in the hands of the national bank examiner. The bank had loaned \$2,400,000 on Calumet Electric Railway bonds, taking the bonds as collateral at 90 cents on the dollar. Some of the directors in the road are directors in the bank. Some people believe it is a step on the part of the Chicago City Railway to secure the Calumet.

## OBITUARY.

Daniel Moran, superintendent of the car house of the Quincy, Mass., Street Railway, died December 11. Mr. Moran had been sick but two days, a rush of blood to the brain causing his death.

Albert Maetzcke, of St. Louis, who invented a street car fender, committed suicide while mentally deranged. He was a man of fine education, but brooded over the alleged theft of one of his inventions until his mind gave way.

Benjamin F. Wallis, of Fitchburg, Mass., who was treasurer of the Fitchburg & Leominster Street Railway from 1886 to 1894, is dead. Two sons, William B. Wallis, of Boston and Robert N. Wallis, of Fitchburg, survive him.

Elias S. Ward, a director of the Bridgeport Traction Company and formerly its vice-president, died suddenly at his home in Newark, December 23. He was the owner of a large patent-leather tannery in Newark, a stockholder in the Prudential Insurance Company, the Newark & South Orange Street Railway. He was widely known for his charities and his kind, genial disposition. Mr Ward was about 50 years of age and leaves a widow and two sons,

### REVOLUTION INDICATOR.

We illustrate herewith a revolution indicator recently placed on the market by the Electro-Dynamic Company, of Philadelphia. The working of this indicator is electrical and is based on the principle that the voltage of the current generated by the revolution of an armature in a constant magnetic field is directly proportional to the speed. Figure 1 shows the generator, which is a magneto machine differing from a dynamo in having permanent magnets for the fields. This generator is belted to the shaft, or if extreme accuracy is desired it may be geared, whose speed is to be indicated. From it wires lead to the indicator dial, figure 2, which is a simple voltmeter with the scale graduated in revolutions per minute or miles per hour or whatever else may be the unit desired. It is evident that further additions may readily be made to the recording apparatus to suit peculiar conditions such as providing a dial and clock for a continuous record, or an alarm to attract attention when the maximum allowable speed is exceeded. There is no limit to the number of dials which may be connected with one generator and this feature makes the indicator well adapted for large plants, where the superintendent as well as the engineer will wish to keep in touch with the engine room. The apparatus is installed on the ships of the American line and numerous yachts, dials being placed in the chief engineer's room and on the bridge.

On twin-screw ships a reliable speed indicator enables the two engines to be kept quite near the same speed, permitting the rudder to be carried amidships and avoiding the drag which occurs when it is kept at an angle. One of the "greyhounds" reports a gain of two hours by its use. For railway work its advantage over the Boyer recorder with its complicated connections to the dial is evident.

This indicator shows the direction as well as the speed, since a reversal of the direction of motion of the armature

FIGURE 1—REVOLUTION INDICATOR MAGNETO MACHINE.

will reverse the current. The dial is graduated both ways from zero as is shown in the cut. In order that the voltage produced by the generator may be proportional to the speed the field must be of constant strength. To accomplish this a special grade of steel is used. The armature is of the

iron clad type and acts to some extent as a keeper for the fields. Should variation in the magnetism occur it may be corrected by an adjustable shunt in the air gap. Dial indi-

FIGURE 2—REVOLUTION INDICATOR—DIAL.

cators may also be easily adjusted. To standardize the instrument it is only necessary to compare the readings with an ordinary revolution counter.

### THE HUNT AIR BRAKE APPARATUS.

The Hunt Air-Brake Company, having its works at New Kensington, Pa., is making marked strides in the way of improvements and the orders and testimonials received are evidence that the Hunt air-brakes give satisfactory results in any service in connection with electric, elevated or cable roads. To be able to promptly fill orders the company has recently ordered sixty-four motors. The air pump and three-way valve used with the apparatus are eminently satisfactory in their working and trials in service show that with a fair voltage the air pressure may be raised from zero to seventy pounds in two minutes. This is an important factor, as the air pressure is raised so quickly that should the trolley jump the line after being on only a moment, the motorman would have sufficient air at his command to make several stops.

Among the recent improvements deserving of especial mention is the use of aluminum in the manufacture of the air brake equipment. Objection was made to the first design on the score of weight (the motor and pump being combined in one piece of apparatus), but in its present form the apparatus may be carried on the platform of almost any well built car. The aluminum is the product of the Pittsburgh Reduction Company with works at Niagara Falls and at New Kensington, adjoining the works of the Hunt Company. The manufacture of this metal has been so developed that its use for the brake castings is now practicable. All parts of the apparatus, other than the pump and motor castings, are of aluminum, the result being a handsome piece of machinery which is an ornament to the car,

Another improvement is the small compound combined pump-motor brake, specially designed for short cars and which can be carried under the seat or under the car. This type is of aluminum throughout except such parts as of necessity are made of brass or iron, and is very light. The space occupied is 32 inches long by 12 inches wide and 15 inches high.

Both of these combined motor brakes are controlled by a new automatic controller which is also of aluminum throughout except the points of contact. The casing is of aluminum with a glass face and occupies a space 14 by 7 $\frac{1}{4}$  by 3 $\frac{1}{2}$  inches. By this device the pump is absolutely automatically controlled, the maximum pressure being set, say, at 70 pounds and the minimum at 40 pounds. Should the trolley jump the wire the pump is automatically stopped until the trolley is readjusted and the car started. The motorman has no care of the apparatus and merely handles the air by means of the three-way cock which is directly in front of him. To avoid the possibility of an accident to the brake equipment by reason of excess current there is provided a "midget" cut-out by which the excess current is discharged. Every precaution has been taken to protect the apparatus from injury and to insure to the purchaser a reliable air brake. By attaching a hose to the combined motor-pump air may be used for cleaning the motors, controllers, seat cushions, etc.

The Hunt Air Brake Company now has its axle connected brake in successful operation on the Cleveland & Elyria, the Akron, Bedford & Cleveland, the Pottsville Electric Railway, the Norfolk & Ocean View, and the Binghamton Electric Railway. Orders are being filled for combined motor brakes for the Norfolk & Ocean View, the Cleveland & Elyria, the Elyria & Lorain, the Mt. Clemens Fast Line, the Saginaw & Bay City, and the Akron, Bedford & Cleveland. The new cars of the Wilkesbarre & Northern Railway have been equipped with the Hunt trail brakes and the company has orders from several roads in Pittsburgh, Buffalo and elsewhere for these brakes. The company is also furnishing some roads with combined motor-pumps for use in the power house for cleaning purposes. The pump may be mounted on wheels so as to be carried about the plant and connected up where most convenient.

## NEW MANAGEMENT FOR THE CINCINNATI, NEWPORT & COVINGTON RAILWAY.

The temporary embarrassment of the Cincinnati, Newport & Covington Railway has been relieved by the issue of \$500,000 of second mortgage bonds, which will be sufficient to enable it to meet all obligations. The new board of directors, elected from the members of the syndicate whose bid was accepted, has taken possession of the business affairs. The advisory board will consist of the president, James C. Ernst, and four directors, Charles Fleischmann, Henry Pogue, Charles E. Orr and H. P. Eells. It is believed that this change will put the road on a paying basis, and as a result its stock has taken an upward turn.

At Allentown, Pa., a collision between a trolley car and a passenger train on the Central Railroad, of New Jersey, was caused by a broken switch and resulted in the motorman being killed and five passengers injured.

## SOME FURTHER NOTES ON THE ELECTRIC RAILWAY RETURN.

By H. S. Newton, Electric Engineer Syracuse Rapid Transit Railway Company.

I am encouraged by a fellow feeling which I invariably have aroused after reading accounts by others of the difficulties in railroad construction, to chronicle for the REVIEW the experience we have had in Syracuse in the matter of rail-bonds. This in its primary details has been so similar to the tribulations of Mr. Knox, in Chicago, that I am satisfied the trouble with riveted, upset and simple con-

THE UNDER FISH PLATE BOND.

tact bonds cannot be confined to any one place but must be of common occurrence everywhere.

During the last two and a half years we have laid some thirty odd miles of double track nine inch girder and have passed through all the stages of bond practice from no bonds at all to the latest development in that line which we have worked out and which gives every indication of filling the bill. Previous to the installation of the heavy iron, and in fact on portions of our line at present, horse car rail of the flat "L" variety with iron plates at the joints does service with not a suspicion of a bond, occasional taps being made to a track feeder overhead. This is with a serious loss in the return, however, and is somewhat more to be condemned even than the use of the poor bond connections which we have used on other parts.

My attention was directed to the condition of the first bonds used in our new construction about six months after they were put in place on the occasion of our uncovering some track for paving purposes. The first bonds taken off revealed a mass of verdigris or oxide, which it was hard to realize could have collected in so short a time. Further research developed no improvement in the condition of the

UNDER THE FISH PLATE BOND ON RAIL.

bonds elsewhere and it was determined that a change to another bond or to some other method of taking back the return current was decidedly necessary.

To find a better bond was by no means an easy matter. The one we had been using was selected after careful inspection of the various devices on the market, had been approved by the superintendent and engineer of the water depart-

ment as proof against the productions of electrolysis in the water pipes and was supposed to be in all respects a superior article. The use of supplementary under ground wires, my own previous experience had proven to be a wasteful throwing away of good copper from the fact that the life of such wires was limited to a very few years.

Our first step in a new direction was to improve the bond we were using, an attempt which was only successful to a limited extent; our next was the trial and speedy adoption of an entirely new departure, a bond which solders fast to the rail. This bond we are using to-day, the last order having been for some seven thousand to be used two at a joint on sixty-foot rails. Our success with it has been so remarkable that I cannot refrain from explaining somewhat in detail its construction and the manner of putting it on, especially as by its simplicity and permanency it seems to me to have entirely solved the problem of obtaining a good return.

The process of soldering strips or small pieces of metal to a large mass of metal like a rail seems to have been looked upon by a great many engineers and mechanics as impracticable. The idea has seemed to prevail that it was necessary to get the whole of the greater mass as well as the smaller pieces to a temperature equal to that of the melted solder before it was possible to make them unite, whereas, as a matter of fact, if the immediate surfaces to which it is desired to have the solder adhere are only brought to the right heat the result is accomplished without trouble. To this fact the bond we are now using owes its success. The bond itself and the surface of the rail in immediate proximity to the bond and against which it is brought in contact are elevated to the temperature of melted solder. The solder which is left on the bond faces by the manufacturer in process of construction is interposed between the two faces and the joint is formed, a steady pressure on the bond at the same time prevents too thick a layer of solder forming, by squeezing the superfluous metal out at the sides of the contact plates.

The bond is manufactured in two forms, one placed around the fish plates, in plain sight when the track is

AROUND THE FISH PLATE BOND ON RAIL.

taken up for repairs; the other designed to be placed under the fish plate out of the way. The former has the advantage of being easy to inspect and well-designed for special work while the latter is the cheaper in cost, is a somewhat better conductor because shorter and is doubly secured by the fish plate bolts which reinforce the solder in holding it to place. The short bond consists of a single piece of metal, the long bond of a No. 0000 copper wire tipped at each end with contact plates.

The contact ends on both bonds are ground down perfectly true on a surface grinder and tinned before leaving the factory. In performing the latter operation care is taken to first carefully clean the surfaces with soldering salts

and then to dip them in the melted solder in such a way that the superfluous metal will run down and settle on the surface where the plate meets the steel of the rail.

Preparing the rail to receive the bond we have found to be a very simple matter. When the short bond is used a plug is inserted in the facer made for the purpose which fits the fish plate bolt holes. By the help of a ratchet drill stock, a space is then faced off clean around the last holes in the end of each rail. Some soldering salts are applied to these surfaces, the bonds are clamped in place and the gaso-

SOLDERING ON A BOND.

line torch used for the purpose applied. A moment's application of the heat completes the process. With the nine-inch rail we have found it thoroughly practicable to use as high as four bonds at each joint.

When we first began using the soldered bond a pair of ordinary lineman's torches were used for soldering. These we found got out of order easily, however, necessitating a considerable outlay of time and money for repairs. An improvement in this line was then looked for and found in a large brazier's furnace, which is provided with adjustable torches and holds five gallons of gasoline. With this instrument a man can solder on a bond in one minute's time, making a perfect joint.

The results of this kind of bonding are easy to see on all the track where the bond has been used. No difference of potential between rail and water pipes with the positive terminal of the voltmeter on the rail is observable. The bugbear of electrolysis in water and gas pipes I feel sure is killed, with nothing to fear for the future. We are approaching the period where the practice of neglecting the ground return in figuring power distribution may be followed with a little more chance of obtaining correct results. Our bonds are all tight. The number of loose ones found by the inspector when work was in progress this summer and fall was not more than one-half of one per cent. The short bonds when loose are exposed the moment the clamps are taken off, the long ones on taking a turn or two with a wrench. To correct the evil the rail must be faced again and the heat applied. With thoroughly trustworthy men we never find any loose bonds, however, and under any conditions the cost of rebonding is so slight as to be insignificant. The work can be done at a profit for ten cents a bond where delays are not necessary and for twelve where all hindrances are considered.

The Wilmington, Pa., City Railway Company has covered the safety gates on the platforms of the cars with canvas, thereby protecting the motormen's legs and feet,

## ELECTRIC LIGHT FROM THE CAR AXLE.

### Moskowitz System of Car Lighting.

A most satisfactory arrangement of providing electric light in railway coaches has been offered by the National Electric Car Lighting Company, of New York. The conception and construction of the whole apparatus is very ingenious.

A four pole, iron-clad differential shunt and series wound dynamo, weighing about 350 pounds, is suspended from the truck of the coach.

A hard wood, split pulley on the car axle, drives a spring cushioned counter shaft which absorbs all the violent jarring.

The dynamo is belted to the counter shaft and makes  $3\frac{1}{2}$  revolutions to one of the car axle.

The commutator is quite large and the current is taken from it by two pairs of self lubricating carbon brushes.

The dynamo is designed to give from 35 to 40 volts with a current output of 25 to 30 amperes. The dynamo does not begin to operate until the speed is 250 r. p. m., or a train velocity of 8 miles an hour, and the differential winding prevents an excessive flow of current.

Two storage batteries of 32 cells each are placed under the car and absorb all the output of the dynamo which does not go to operate the lights.

When the dynamo is not running, the lights are supplied with current from the batteries, which have a capacity of 175 ampere hours.

The batteries are of the Plante type, but are credited with much longer life than ordinary cells, the positive plates lasting nearly three years.

All the wiring centers in a neat and compact switch board placed under lock and key in a little closet at one end of the car.

A small ammeter, a dimmer, switches to the lamp and dynamo circuits, and one regulating the storage batteries, are on the upper part of the board. Beneath are automatic electro-magnetic switches controlling the charging of the batteries and the reversal of current. The car is brilliantly lighted by twelve 16-candle-power lamps on the inside, with four lamps in the closets and vestibules.

The Pennsylvania Railroad Company has adopted this system for lighting some of its cars, and the Santa Fe is giving it a thorough trial at their own expense.

Messrs. Max E. Schmidt and Morris Moskowitz, who are representing the western interests, are confident that it will prove a great success.

## COMPRESSED AIR MOTORS.

Compressed air motors are still running in New York city. In some respects they are doing much better than was generally expected. The motor on 123rd street has run 17,373 miles and carried 107,529 passengers up to December 25, and the operators claim without delays or the expenditure of a cent for repairs. On the 3rd avenue system several motors are running steadily. These are all being operated by the American Air Power Company.

What is known as Whitney's company has incorporated for \$1,000,000, with one-half paid in, under the title of the Compressed Air Power Company. The directors named are: William C. Whitney, Thomas J. Ryan, Frederick S. Pearson, William W. Cook and William L. Elkins.

### "L" ROADS IN HARD LINES.

The cable in New York and the trolley in Brooklyn have played havoc with the "L" roads. The latter have been deferring action from month to month, vainly hoping for better earnings. There is now no alternative for them but to equip electrically. The comparison of passengers carried tells the story in a few words:

NEW YORK CITY.			
	1896.	1895.	1894.
Elevated roads.....	184,703,636	187,614,085	202,751,532

## WEST END STRIKE A FAILURE.

The West End, Boston, employes failed in their attempted strike, which was to force a recognition of the union. It was plainly the work of professional agitators, and the great majority of the men had little heart in it. On December 23, the president of the union issued an ultimatum to President Little, saying that a strike would be declared if the agreement presented by the men was not signed by 3 o'clock. President Little sent for the union officials and persuaded them to give him one week to consult the directors. In violation of this, 800 of the men went out on a strike the next morning. The officers of the road immediately took steps to supply the places of the strikers, and on Christmas day all the cars were running. Some of the old men were allowed to return.

People's Street Railway Company of Luzerne county, Pa., is granted permission by the court to change its name to "Scranton Railway Company."

The Baltimore City Passenger Railway Company declared a semi-annual dividend of five per cent, payable on or after January 2. This makes ten per cent paid during the year which has been a very successful one under the management of Col. Walter S. Franklin.

## DORNER &amp; DUTTON FAILURE.

The Dorner & Dutton Manufacturing Company and the Dorner Foundry Company, of Cleveland, have failed. On January 2 judgments aggregating \$85,000 were entered. There was a big scramble among the attorneys, of whom thirty were in court at one time. On January 7, E. E. Strong was appointed receiver. The failure is a bad one, and the percentage likely to be paid to creditors is very small. When George A. Arthur entered the Manufacturing Company early last year, as vice-president and secretary, it was understood he would put additional capital into the business. It appears now the new money was chiefly used in the Foundry Company. Business depression, the management and the ruinous prices at which some lines of goods were sold, united to bring about the failure. There is a good deal of resentment among recent creditors, who now assert the company must have certainly known, fully two months prior to the crash that it could not possibly hope to pull out, but notwithstanding this went on and incurred further liabilities. What the salvage on the wreck will be, will largely be determined by the policy of the receiver. If a sale of the machinery of which there is considerable, and much of it, especially the gear cutters, comparatively new, should be forced, it would not bring much more than old iron. The Foundry Company is largely to blame for the failure.

## TRACK LAYOUT AT PULLMAN.

Our engraving shows the track layout recently installed in the yards of Pullman's Palace Car Company, at Pullman, Ill., by the Paige Iron Works, of Chicago. In order to furnish a means of transporting trucks and material between the truck shop and the machine shop, a distance of about 525 feet, the tracks shown were laid. Sixty-pound T-rails are used. The special feature about the construction is the use of street railway switches throughout, with a consequent great saving of space that would otherwise be required for the switch stands, throw rods, etc. There is also a saving of time because the switches may be thrown by the man pushing the truck. While the switches are all constructed for car wheels the curves are so sharp that only trucks or short four wheeled cars can be used. On the lead track, however, with its longer curves, locomotives and cars are used.

## A NEW ROAD.

Repeated calls upon the representatives of the Chicago Electric Street Railway Company have developed the fact that they are too much occupied to furnish any information as to their plans, and that they have even forgotten who are the financial backers of the concern. The company was, on January 9, enjoined from proceeding with the work of purchasing frontage consents. The information in chancery filed by the attorney-general alleges that none of the stockholders of the company have any money, and that their object is merely to speculate in articles of incorporation and force existing lines to buy them up.

## BIG STERLING CONTRACT.

The Sterling Supply & Manufacturing Co., New York, are to equip the 150 open cars now building at the Stephenson works for the Metropolitan Traction Co., New York city, with Sterling registers, Sterling sand boxes, Sterling fenders and Sterling safety brakes. These brakes are the same as already in use on the Broadway cable as their standard. The Metropolitan Traction has also ordered 600 Sterling sand boxes for cars now running on its lines. President Carson, of the Sterling Company, is evidently one of those prophets who are honored in their own country, and as the devices have been previously in use on the Metropolitan, the order is all the more pleasing to him as evidence of satisfactory performance on one of the best known roads in the world.

## DETROIT CITIZENS' CONTROLS BELLE ISLE.

Tom L. Johnson, Albert Pack and Henry A. Everett have purchased the Fort Wayne & Belle Isle Railway, for \$1,100,000, being par for nine-tenths of the bonds and \$175 per share for nine-tenths of the stock. Fares have been raised from eight tickets for a quarter to six for a quarter, with transfers to other lines.

The Camden (N. J.) & Suburban Railway Company, distributed \$500 among its conductors and motormen, Christmas, as a token of appreciation of exemplary conduct during the past three months.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances, are expected to give their views and experiences on subjects within the range of the department.

## Union Loop Power House.

We publish herewith the plans of the power-house of the Union Elevated Railroad Company, of Chicago. The tracks to be operated by power from this plant comprise the entire union loop. The volume of traffic will be very great. The number of trains now on the three elevated lines in operation is about 1,000 per day, and with the addition of trains from the north side it is probable that the number will not be less than 1,500. This station will be the most important one in the city, as all the elevated roads will receive a portion of the power from it, and will have a capacity of 10,000 horse-power. It is expected that it will be in operation about July 1.

The power-house is on Market street, about 300 feet south of Van Buren street and extends to the river. The frontage is 141 feet on Market street and 63 feet on the river, the north lot line being 164 feet long. The building is two stories with a basement, the street front, which we show, being of pressed brick with stone trimmings. Up as far as the boiler room floor the walls are laid with Portland cement.

This is the only modern street railway power-house west of Philadelphia built on the double-deck plan. This type of construction was only adopted by force of necessity. It was originally intended to build a station with engines and boilers both on the ground floor, but it was found practically impossible to get any more land at that place and there seemed to be no other good location available, for suitable power-house sites are not easy to find in the heart of the business district of Chicago.

In the basement, which is 6 feet, 5 inches below the street grade, will be the condensers and circulating pumps. Wheeler surface condensers will be used. The large hatchways shown in the plan make the basement lighter and afford a ready access to the machinery. For handling the pumps and condensers an 8-ton post crane is provided at each hatchway.

Along the north side of the engine room, which is 8 feet, 7 inches above grade, are to be the engines. Provision is made for four horizontal corliss cross-compound condensing engines with cylinders 30 and 60 by 60 inches, running at 75 r. p. m.; three only will be installed at first, however. The fly wheels are 25 feet in diameter, with 100,000 pounds in the rim. The engines will be built by the George H. Corliss Company, of Providence, and each direct-connected to a 1,500 kilowatt generator built by the Siemens & Halske Company of America. The engine room will be served by a traveling crane with a span of 50 feet, 8 inches.

The boiler room floor is 48 feet, 3 inches above the engine room floor. The boilers rest on box girders  $41\frac{5}{8}$  inches deep, and these are carried by other girders of about the same depth, supported at intervals of 18 feet, 3 inches by columns. Twelve feet, 3 inches below the boiler room floor is a second floor of arched cement which forms the ceiling of the engine room. Between these two floors are the conveyors for handling the ashes. The boiler plant comprises sixteen 400-horse-power Babcock & Wilcox boilers, furnishing steam at 160 pounds pressure. Acme mechanical stokers made by the Falls Rivet & Machine Company will be used.

FRONT ELEVATION—ELECTRIC POWER HOUSE UNION ELEVATED RAILROAD, CHICAGO—LONGITUDINAL SECTION.

## PERSONAL.

Edwin L. Watson, president of the Worcester & Suburban Railway, has lately returned from an extended wedding tour.

T. R. Hull, superintendent of the Centerville (Conn.) Electric Road, was presented with a gold watch and chain by the directors of the company.

S. J. Wick, of the Electric Railway Equipment Company, Cincinnati, spent several days in Chicago last week, calling on his many friends in the trade.

O. M. Hubbard, of the Bradford Belting Company, Cincinnati, spent several days in Chicago last week. He reports business as good and improving.

Superintendent John Bushy, of the Wyandotte & Detroit River Electric Railway, was presented with a handsome cane chair for Christmas by the employes.

S. H. Bennett, secretary and treasurer of the Atlanta Railway Company, Atlanta, Ga., was given a very handsome umbrella on Christmas by his employes.

W. A. Satterlee, purchasing agent for the Metropolitan Street Railway, of Kansas City, has recently been to Florida looking after an orange grove, of which he is the possessor.

J. B. McClary, who has served so acceptably as superintendent of the Birmingham (Ala.) Railway & Electric Company, was also made general manager at the recent annual election. Our congratulations on deserved recognition.

Henry J. Davies, assistant secretary and treasurer of the Big Consolidated, Cleveland, O., was tendered a surprise party at his home recently, the occasion being the return from his bridal trip. A silver water service was presented to him.

E. Kessler, superintendent of the Richmond (Ind.) Traction Company, was on Christmas eve presented with a gold watch by the employes of the road. The gift was offered as a testimonial of the fair treatment which they had always received at his hands.

Wm. H. Ryan, who has heretofore been the western manager of the Engineering Magazine, with headquarters in the Modanock block, Chicago, will shortly remove to New York to take the position of business manager. The best wishes of his many friends go with him.

N. S. Wells, president, and W. S. Dimmock, superintendent of the Omaha & Council Bluffs Railway & Bridge Company, have returned from an inspection trip. The present intention is to erect a new plant before the opening of the Trans-Mississippi exposition, which will be held in Omaha in 1895.

Edward Caldwell, formerly with the Electrical World and the Street Railway Gazette, and for the past two years business manager of the Street Railway Journal, has accepted the position of manager of the Railway Advertising Company, of New York, which controls the privileges on the

Metropolitan system of that city, the Consolidated, of New Jersey, and the Union Traction Company, of Providence.

William P. Deppe, who held a responsible position as representative of the bondholders in the Cincinnati, Covington & Newport Street Railway, having completed his work, has accepted a desirable place as chief clerk in the office of the passenger traffic manager of the Big Four railroad. His many friends will wish him continued success.

The two sons of Eugene F. Phillips, president of the American Electrical Works, Phillipsdale, R. I., are now taking an active part in the management of the business; F. N. Phillips having assumed the position of treasurer, made vacant by the resignation of W. A. Hathaway, and E. Rowland Phillips having been appointed superintendent of the works.

## ELECTRIC TRACTION IN GLASGOW.

Another indication of the awakened interest in rapid transit throughout the cities in Great Britain was the recent visit to this country of J. Young, general manager, and W. Clark, engineer of the Tramway Department, of Glasgow, Scotland. They sailed from Liverpool, September 19, and in their seven weeks' trip, investigated the street railway systems of New York, Brooklyn, Jersey City, Staten Island, Philadelphia, Baltimore, Washington, Pittsburg, Cincinnati, Chicago, Detroit, Cleveland, Buffalo, Niagara, Toronto, Montreal and Boston. They made an exhaustive report, taking up every form of transit. They briefly considered the storage battery, oil and gas motors, compressed air and electromagnetic systems and found them wanting. Electric open conduit installations are so expensive as to be prohibitive and the cable system is too rigid and cumbersome in its operation besides being unsuited to suburban service.

The trolley system is then discussed at length and reported upon favorably. They take the testimony of railway men of America and conclude that all objections due to electrolysis in gas and water pipes and danger of rapid transit may be overcome. Speaking of the disfigurement of the streets by trolley poles they say, "Civilization demands that the aesthetic give place in many instances to the useful. When the four separate burghs now served by our tramway system are included, we have a population of 841,000 persons on an area of 14,661 acres, which gives 36,480 to the square mile. No one wishes our citizens to continue so closely packed together as they now are. In our humble opinion, and judging from what we have been privileged to see in America, the most powerful instrument which lies in the hand of the municipality for effecting this purpose is the best and cheapest possible tramway service radiating from the center of the city outwards in every direction."

The city owns its own tramways and is very conservative in making any alterations. The rate of fare is from one to five cents according to the distance traveled. The horse cars will be superseded by the trolley only on one line at first and future extensions will depend on its success on this line.

The Richmond (Ind.) Traction Company has for years made a practice of remembering its employes at Christmas by giving each one a present in cash or a turkey dinner, with the result of promoting good feeling between the employes and the management.

### THE CAST-WELD JOINT AS A CONDUCTOR.

"Verily, verily, I say unto you, he that tooteth not his own horn, the same shall not be tooted."

I was thrice amused in reading Harold P. Brown's article in the REVIEW of December 15, on the cast-weld joint.

First. Because he says "the joints were magnificent mechanically, making the smoothest riding track I have ever seen." This is a very frank admission.

Second. Because he claims the plastic alloy plug he sells will make the cast-weld joint absolutely perfect electrically. We shall see.

Third. Because he attempts to prove his assertions by showing pictures of defective joints, and acknowledges at the same time he is doing so.

We will quote Mr. Brown: "At Newark, N. J., the mechanical performance of the joints has been excellent. *It is hard to find the joints.* It is evident that there is sufficient clearance between rail and cast iron to allow for expansion and contraction, for very few of the joints have broken in winter, while during the heat of last summer \* \* \* these rails showed no signs of twisting." This is certainly strange—a condition both positive and negative, and opens a field for speculation and experiment.

He claims there is contraction and expansion and no open joints and, according to his argument, rails will shrink but not show it on the ends even where they have the opportunity of sliding in the joint, for he will not admit the contraction sometimes pulls the cast-weld joint apart. Perfectly nonsensical.

But look at Mr. Brown's reasoning: "The reason for this is plain. When the molten iron is poured around the steel the latter expands; as it is in the center it is the last to cool, and therefore remains expanded until the cast iron has set. When it resumes its former size there is a minute clearance left, through which water soon finds its way, leaving a high resistance coating of iron oxide which grows thicker as time passes."

If Mr. Brown had looked into the subject he would have found that the rail becomes heated to a welding point, during the pouring of the metal, and that a perfect cast-weld must take place, if the rail ends have been properly cleaned; of course it sometimes happens that imperfect joints are made, but these are few and are soon found out and broken off to be used for experimental purposes by competitors. By reason of contraction the rail will pull in a bad joint and in this way they are detected.

Mr. Brown should also know that the shrinkage of the joint begins from the outside and adds considerable inward pressure against the rail and as the welding has taken place there is no opportunity for the rail to leave the "sufficient clearance."

He says, " \* \* \* I found several broken joints that were being removed from the track and failed to discover any trace of 'welding.'" This may be true, for that is a good reason for removing them, but it is doubtful, as one of the engravings shown by him (Figure 1) shows a corner of the rail still attached to the joint, beyond a question welded. Considerable more than a "trace."

Again, he saw, "Joint of 78-pound rail taken from track of Missouri Railroad Company, after one and one-half days use, on account of breakage of rail through contraction."

Now, if Mr. Brown is truthful and correct and there is "sufficient clearance between rail and cast iron to allow for expansion and contraction," why did this rail break?

It is really too bad he did not begin his article with the

last paragraph, and add the price of the plug, for then the reader would readily understand his motive in condemning the Falk cast-weld joint as an electrical conductor and his engravings of defective joints would make more apparent his position; that rails will contract and expand in the cast-weld joint, that the plastic alloy plug will add to the conductivity of the joint; although the plug must necessarily follow one or the other end of the rails and thus break this beautiful brown connection. It is unjust, unfair and decidedly unprofessional for Mr. Brown to attempt to toot his own horn, at the expense of anyone but himself, and he who reads the article carefully to the end will see whose toot it is and Mr. Brown's reputation, as an engineer, will suffer.

Allow me to compare one of Mr. Brown's experiments "the result of this inexpensive bonding" (his plug) with one made by O. N. Rau, E. E. of the Milwaukee City Railway Company.

For electrical conductivity at the joint (cast-welded):

With the plug, 700 amperes, .012 volts drop; without the plug, 760 amperes, .0107 volts drop; while in the rail alone the drop was .0117 volts and the latter joint in question had been exposed to the weather for three years.

In conclusion, I desire to call Mr. Brown's attention to one or two extracts from undisputed authority.

M. K. Bowen, superintendent Chicago City Railway: "It is strong and substantial, as has been proved by its holding under the extreme changes in temperature for which Chicago is noted. Seventeen thousand joints were put in in 1895, and of these only 154 joints were lost. The joint in comparative tests has been shown to be far stronger than the rail itself, and such breakages as have occurred were due to a flaw in the metal. The metal cast around the joint has eight times the cross section area that the rail has. Hence, considering steel as four times as strong as cast iron, the joint is twice as strong as the rail. The metal in contact with the mold begins to cool and forms a crust while the interior remains molten. This crust continues to cool and at the same time contracts, forcing the molten metal strongly towards the center, which makes a solid and rigid joint. When the joints parts, it is for two or three inches, so that you can see them readily. If there is any oxidation between the joint and the rail, I hardly imagine it would do any harm unless it was sufficient to loosen the cast iron from the rail proper. In that case it would come apart three inches, due to the contraction of four or five blocks of steel."

Robt. McCulloch, general manager National Railway, St. Louis: "We have one piece of track which is thirteen miles long and all welded together, the most of it being sixty-foot rail. We have not an ounce of copper nor a bond of any kind on the entire track. We have made tests of all sorts, with delicate instruments, graded to the thousandth part of a volt, tested as long and short lengths as possible, sometimes a mile and sometimes a single joint, and have found in most instances that the carrying capacity of the joint was greater than that of the rail at any other place. We have found no necessity for bonding; our contact is perfect at the extreme ends of the rail; and I do not believe it is necessary to bond a welded track."

G. W. Knox, E. E., Chicago City Railway: "I wish to say before leaving the subject of the cast-weld joint, that with all the joints which I have tested I have found no appreciable drop across their parts. \* \* \*"

If more testimony is wanted to convince Mr. Brown that he has made a mistake, I can assure him it will be forthcoming.

HENRY R. KING.

## FOREIGN FACTS.

An inclined electric railway up Mont Blanc is talked of.

Dundalk, Ireland, has approved a scheme for an electric railway.

Marseilles Tramway Company is considering the adoption of electric traction.

The municipality of Braila, Roumania, will build an electric railway to Lacul Sarat.

Manchester's Carriage & Tramways Company will apply for the right to extend its line in Pendlebury.

Reading's Tramway Company invited the town council to inspect the electric railway at Bristol, England.

An electric railway in Hastings, Eng., is being promoted by Mr. Chadwell, C. E., of Richmond Chambers, Blackburn.

The Belfast council favors the equipment of the Belfast Tramway with the overhead trolley, as proposed by the company.

Application will be made to Parliament to empower a company to construct an electric railway between Cardiff and Penarth, Wales.

Right to construct a light electric railway between Cheltenham and Winchcombe, Eng., is asked by Mr. Nevins, of County Wexford, Ireland.

Yarmouth, Eng., is considering an electric railway project, promoted by H. Chamberlin, representing the British Thomson-Houston Company.

Whittaker Brothers, of Flamborough, England, are said to be interested in a proposed light electric railway between Bridlington and Flamborough.

A syndicate proposes to bore two 11-foot tunnels from Hammersmith, Broadway to Carmon street, London, a distance of six miles, for an electric railway.

Storage battery cars have been placed in operation on the steam railway at Paris, operated by the Compagnie des Tramways de Paris et du Department de la Seine.

Longton town council has approved the agreement of the British Electric Traction Company to build and operate a light railway from Longton to Trentham and Blyth Bridge.

Gustave Michelet, president of the Permanent International Tramway Union, died at Brussels, Belgium, November 4, after a long and painful illness. He was 59 years of age.

Tenders for permanent way construction of the Hartlepool Electric Railway are being received by J. Vincent Ketchener, London, for the British Electric Traction Company.

Electric traction will be installed on the steam railways of Charleroi, Belgium, bids for the work having been received by the Societe Nationale des Chemins de Fer Vicinaux, of Brussels.

The Imperial Tramways Company, of Middlesbrough, England, proposes to expend \$500,000 upon the conversion of its lines to electricity, their extension and the construction of five new lines.

Eight miles of electric railway is to be constructed in the city and county of Cork, Ireland, the scheme having received the approval of the Cork corporation, the Grand Jury and the Cork Harbor Board.

A trial is to be made in Paris, France, of the Westinghouse electric street railway system, with contacts on the level of pavement. The experimental line of about a third of a mile in length will be laid in the Rue Maubenge, starting from the Carrefour Chatsandun.

The London United Tramways Company will again apply for Parliamentary powers to substitute electric for horse traction on the lines from Hammersmith to Kew and Richmond, and from Uxbridge Road Station to Acton. It is believed the county council is now more favorable to the overhead trolley.

The British Electric Traction Company has been formed to succeed the Pioneer Company, which is closing its first year of successful working. At the special meeting of stockholders held to authorize the change, Sir C. Rivers Wilson, who presided, said that electric traction in England was entirely in its infancy, but they looked forward with satisfaction to the enormous field before them. He did not think it was to be regretted that so little had been done in this country, because they would be able to profit by the experience of other countries.

## HILLTOP RAILROAD OF PITTSBURG.

The Hilltop line, which is a branch of the Pittsburg & Birmingham Traction Company, has recently been opened. It connects the old city of Pittsburg with the districts situated on the southern shore of the Monongahela river. It crosses the river over the Smithfield street bridge and goes up a grade of 15 per cent on Brownsville avenue. By this road the suburb of Knoxville is brought into communication with the city. The line has been in great demand, as it now affords a rapid transit to about 50,000 people who have been dependent upon the inclines and such walking as unpaved streets afford. The Birmingham Traction Company operates on this line twenty-two cars, each equipped with two 50-horse-power Westinghouse motors and controllers. To provide for this increased demand for power the company has remodeled its station on 31st and Carson streets and put in an equipment of three 700-kilowatt Westinghouse generators.

## TOOK THE HINT.

When a crowd of people boarded the street car, the conductor took a large rag and assiduously cleaned the large sign at the end of the car.

He turned and smiled at an acquaintance, saying, "That's the only way I can get 'em."

Every one watched him, and as he stepped aside, read, "Gentlemen will please not spit upon the floor of this car."

It worked like a charm.

## MILWAUKEE MATTERS.

The Milwaukee Electric Railway & Lighting Company has purchased the Pabst power and lighting plants in Milwaukee and Wauwatosa and the Milwaukee-Wauwatosa electric line. Henry C. Payne remains as vice-president, and has appointed the following officers, separating, so far as operation is concerned, the railway and lighting departments:

## The Official Circular.

The Board of Directors has this day made the following appointments in the Railway, Lighting and Accounting departments of the company, viz:

General Superintendent of Railway Department—Thomas E. Mitten.

General Superintendent of Lighting Department.—W. L. Church.

## ACCOUNTING DEPARTMENT.

Comptroller and Auditor.—W. L. Mason.

Assistant Treasurer.—George O. Wheatcroft.

Cashier.—H. F. Boggis.

Chief Engineer of Power Plants.—W. H. Crawford.

Chief Electrician.—O. M. Rau.

Superintendent of Construction and Maintenance of Way.—A. W. Lynn.

Superintendent of Transportation.—George M. Kuemmerlein.

Superintendent of Maintenance of Rolling Stock.—E. W. Oulds.

Assistant Superintendent of Lighting Department.—S. G. Coleman.

Claim Agent.—E. R. Manhardt.

Storekeeper.—Charles P. Evans.

The office of purchasing agent is abolished. Mr. Vandenberg assigned to duty in the general manager's office.

All said officials will report to the general manager, except superintendents, who will report to the general superintendents of their departments.

Until the office of general manager is filled, such reports shall be made to the vice-president.

H. C. PAYNE, Vice-president.

The Pabst properties are acquired under the title of a new company, the Milwaukee Light, Heat & Traction Company, with Mr. Payne as vice-president, and the same board as the big company.

## AUTOMATIC WIRE CONNECTOR.

The cut shows a new wire connector that has some original features worthy of mention. Inside of the shell is slipped a toothed spring and when the connector is shoved over the wire the teeth prevent its withdrawal. If the connector is to be taken off a small pin is inserted in the hole back of the spring which releases the spring and the wire is withdrawn. The connections can be instantly made with-

out the aid of a tool, and it can be taken down without injury to the wire or coupler. The Bradford Belting Company, of Cincinnati, is introducing the connector, which especially recommends itself for emergency work. The absence of solder, the good contact afforded, and the unquestioned strength of the device will at once suggest themselves as qualities particularly desirable. The spring can be removed, if desirable, but cannot fall out.

## THIRD AVENUE, NEW YORK, CONTRACTS.

The White-Crosby Company, 29 Broadway, New York City, will let contracts for equipment for the Kingsbridge extension of the Third Avenue railway of New York City.

The General Electric Company received the original contract and sub-let it to the White-Crosby Company who will purchase generators and motors of the General Electric Company. The road is to be  $3\frac{1}{2}$  miles double track, commencing at 162nd street and following Kingsbridge road to Spuyten Duyvil creek.

The Johnson Company are to furnish the rails which are to be 60 feet long, 106 $\frac{1}{2}$ -lb. girder of the Tribby pattern. All frogs, switches, crossings, etc., are to be Johnson's guaranteed special work.

Over-head wire is to be No. 0 hard drawn trolley wire.

Feeders and electric light wires are to be laid in conduits.

Center poles with ornamental pole tops are to be used and every other pole will support one 2,000-candle power electric light.

The generators will be built by the General Electric Company and will consist of one 800, one 500 and one 300-kilowatt. The General Electric Company will also furnish two 125-light Brush dynamos.

The power house is to be furnished with six water tube boilers in batteries of 2 each, of 500-horse-power for each battery.

Three of the generators are to be direct connected to the engines which will be horizontal cross compound condensing.

The lighting machines are to be direct coupled to high speed engines.

The power plant will be equipped with separators, heaters, economizers, condensing plant and a compressed air oiling system.

Joints are to be the Falk cast weld with bonds furnished by the White-Crosby Company.

## CORRESPONDENCE.

NORWAY, ME., Dec. 23, 1896.

EDITOR STREET RAILWAY REVIEW:

I think I can throw some light on the subject of wheel wear. Most of the trucks manufactured are not bolted together so as to be sufficiently rigid, and as a consequence the majority of them are out of square when put under the cars. I have remarked this with most of the standard trucks, and with the prevailing manner of putting them under cars it is unavoidable. If a square were placed on the trucks that go under our cars 75 per cent of them would be found out of line. One side of the truck should be clamped and the other side jacked into line, and the holes in the car body laid off from this position. The car springs will not then be continually forcing the truck to one side of the track, producing cars that are "hoodoos," running slow and causing excessive wheel wear, and every once in a while getting off the track in a mysterious manner. In testing cars I have found some as much as two inches out of line. In that case on one side the flanges would be found thin and on the other double grooves. If the trucks were squared up and braced before leaving the factory, and then after being put in place had the bracing removed, we should hear less of one-sided wheels.

F. B. LEE,

Superintendent Norway & Paris Street Railroad.

The Metropolitan Electric Company, of Chicago, reports a good demand for linemen's tools of which it carries a large stock.

The American Electrical Works, Providence, R. I., makers of bare and insulated wire, have issued a calendar with a view of their plant printed in colors.

The Mitchell Tempered Copper Company, Corry, Pa., is sending to its street railway friends a copper cow paper weight which is a very unique and novel affair.

McIntosh, Seymour & Company, Auburn, N. Y., report that their business has been good during 1896, and that the prospects for engine sales in 1897 are very good.

The Arnold Electric Power Station Company is completing the Englewood & Chicago storage battery plant and will have the station in operation in the near future.

The A. Mertes Manufacturing Company, Allegheny, Pa., calls the attention of the trade to its motor gears and pinions through a business card, to which is affixed a neat thermometer.

The R. D. Nuttall Company of Allegheny, Pa., has sent out a neatly designed calendar to remind its friends that the gears, bearings and machine work of this firm are as reliable as ever.

Wendell & McDuff, New York agents for the Taunton Locomotive Manufacturing Company, of Taunton, Mass., have moved into larger offices on the fifth floor of the Havemeyer building.

The Mica Insulator Company, of London, New York and Chicago, has removed its western headquarters to 117-119 Lake street, and is in a position to promptly fill all orders for micanite specialties.

H. B. Coho & Company, 203 Broadway, New York, handling light, heat and power machinery, report that they have been very busy with regular work and feel quite confident of good trade for 1897.

The Cutter Electrical & Manufacturing Company, Philadelphia, sends greeting to the trade and calls attention to its switches and circuit breakers by means of a calendar which bears an I-T-E circuit breaker, "proper."

The American Electrical Works of Providence, R. I., comes to the front and sustains its reputation for novelties, by extending Christmas greetings and calling attention to its bare and insulated wires in a Christmas pudding.

Wm. Wharton, Jr., & Co., of Philadelphia, and the Pennsylvania Steel Company, have been awarded the contract to supply rails for the conduit electric railway to be built in New York by the Metropolitan Street Railway Company.

Eugene Munsel & Co., miners and importers of mica, Chicago, have moved into new quarters at 117-119 Lake street, and will be enabled to carry larger stocks of mica and drop forged copper segments.

A. O. Schoonmaker, of New York, has lately opened a Chicago office at 1563 Monadnock building, in charge of John Child. A full stock of mica, uncut, cut to size, segments and rings for standard railway motors, will be kept on hand.

The Safety Car Heating & Lighting Company, of New York, has been given the contract to equip 150 cars for the Broadway Cable Road with its Pintsch gas light. The cars are being built by the John Stephenson Company, of the same city.

Jos. Dixon Crucible Company of Jersey City, N. J. has received many complimentary testimonials for its silica-graphite paint, which has been used extensively for telegraph and trolley poles, boiler front and all kinds of wood and metal work.

The Paige Iron Works, which make a practice of issuing bulletins illustrating work recently done by the company, will shortly send out to the trade leaflets showing the track layouts installed for Terre Haute, Ind., and North Chicago street railways.

The Hunt Air Brake Company, Pittsburg, has placed an order with the Story Motor & Tool Company, of Philadelphia, for 50 motors for its combined motor brake, which, with the previous order within a month, makes a total of 64 motors ordered.

Creditors of the Reliable Manufacturing Company hold their fourth meeting at Boston, Mass., January 15, to present their claims to the Court of Insolvency. Assignee Louis W. Hodges, of Foxboro, presents his final account at the same meeting.

The Bibber-White Company, 49 Federal street, Boston, announces to the trade that it has succeeded to the business of Bibber, White & Company, and of the New England Electric Supply Company and will carry a complete line of electrical supplies.

The Binghamton (N. Y.) Railroad Company recently received from the Laclede Car Company, of St. Louis, three new electric cars. They are furnished with vestibule fronts and sashes and doors of the latest pattern and are very handsome in appearance.

J. B. Walker has resigned the management of the Sioux City Traction Company to accept a very flattering offer from the Suburban Railroad of Chicago. The construction of the Suburban offers a splendid field for the exercise of Mr. Walker's well known ability as a practical electrician and street railway manager.

T. C. Rafferty, who is very well known in the electrical supply business, is now associated with the Metropolitan Electric Company, of Chicago, having disposed of all his other electrical interests. We wish him every success in his new work, and congratulate the Metropolitan Electric Company on their foresight in securing his services.

During the first week of the new year the the General Electric Company closed a contract with the Metropolitan Traction Company, of New York, for seven direct current 850-kilowatt generators and 600 motors, and contracts with the Third Avenue Railway, of New York, and with the St. Anthony Falls Power Company, of Minneapolis.

The Indiana Rubber & Insulated Wire Company, Jonesboro, Ind., has, during the past year, been running its factory on full time and has a nice list of orders to begin 1897 with. During 1896 the company has been making a specialty of telephone and telegraph cables, and at present is making a number of large cables to go to the Pacific coast.

The Clonbrock Steam Boiler Company, of Brooklyn, N. Y., have scored a victory for its Morrin Climax boiler over all others, in securing the entire boiler contract for the Tennessee Centennial Exposition to be held the first of May next. This is quite a triumph for the Climax boiler considering the merits of the boilers offered in competition.

The Western Electric Company, of Chicago, has been given the agency for the Lundell motors, and will keep on hand a full stock for prompt delivery. The Lundell is one of the best of the enclosed type of power motors for many uses requiring from one-sixteenth horse-power up. Prices and full information may be had on application.

J. P. Johnson, for some years with the Babcock & Wilcox Company, in its main office, and later salesman in the Pittsburgh office, on January 1 took charge of the Cleveland office for the Cahall sales department for the sale of Cahall vertical and Cahall-Babcock & Wilcox boilers, manufactured by the Aultman & Taylor Machinery Company, Mansfield, Ohio.

The Joseph Dixon Crucible Company, Jersey City, N. J., in a circular letter to the trade states that the volume of its business was not very much less for 1896 than for the previous year, and in some lines showed an increase. Collections are reported as good, and business prospects for 1897 as encouraging to manufacturers for both home and export trade.

The R. D. Nuttall Company, Allegheny, Pa., reports the general gear trade to be larger than ever before in its experience, and from the correspondence now being received, anticipates a very heavy trade during the coming year. During the dull season the company has laid in a good supply of standard gears and pinions, and is well prepared to promptly fill orders.

The Compressed Air Power Company has been incorporated in New York City, to introduce the Hoadley system of street car propulsion. The capital stock is \$1,000,000; and the directors are Joseph H. Hoadley, president, Almeric Hugh Paget, secretary, William C. Whitney, Thomas F. Ryan, William W. Cook, W. L. Elkins and Frederick S. Perkins.

Foreign agencies have been established by General Manager Wessels, of the Standard Air Brake Company, as follows: The Bergische Stahl-Industrie, Berlin and Remscheid, Germany, agents for continent of Europe.; Noyes Brothers, Sydney and Melbourne, Australia, agents for Australia; Lamar Lyndon, Yokohama, Japan, agent for Japan and China.

The Safford & Moore Railway Jack Company, of Chicago, has been reorganized, Mr. Safford being succeeded by J. M. Williams, and the company will now be known as the Williams & Moore Railway Jack Company. It is intended to place a new self-feeding railway drill upon the market within the next thirty days. Prospects are reported as extraordinarily good.

The Edison flexible solder-on unsoldered copper contacts, on bus bars, cable junctions, instrument terminals and for steel and copper contacts on rail bonds, rail feeders, pipe feeders, cable terminals for loops around switches, crossings and special work have been furnished and will be sent to the Edison Company of Philadelphia, the Chicago City Railway Company and others.

Geo. M. Boyd, 612 No. 225 Dearborn street, Chicago, represents wealthy planters who will shortly erect mills on their property, and build ten miles of single track electric road to cross their plantations and make a short cut between two steam roads. Freight and passengers will be carried. A fine water power is available for the generation of current for the road and mills.

Harold P. Brown sends information that the demand for the Edison-Brown plastic rail bond has been so great that the factory at Montclair, N. J., has been running at full capacity. During the winter, orders have been received from La Capital Tramways Company, of Buenos Ayres, two roads in New South Wales, the Fairmount Park Railway of Philadelphia and the Consolidated Traction Company of Newark.

Edward P. Sharp, of Buffalo, N. Y., says that his sale of railway motors and generators has been satisfactory for the past year. Although few orders have been received in December, the number of recent inquiries indicate a good trade in this line of material for the coming year. A large number of orders have been taken for the Macallen section and sheet mica strain insulators, the former having been adopted as standard by the Consolidated Traction Company and other roads in Pittsburg.

The Taunton Locomotive Manufacturing Company has introduced a street railway sprinkler which will wet down a single track or a 100-foot boulevard without the use of out rigging. This is accomplished by means of a direct current motor, running 1,100 revolutions, connected by a speed-reducing device to a pump shaft which runs 200 revolutions per minute. The outfit is placed on the platform of the tank car and the stream directed from a nozzle. The track is sprinkled by the usual perforated iron pipe in front and at the side of the car.

The Phoenix Iron Works Company, Meadville, Pa., reports a good prospect for 1897. This company has recently installed a pair of 125-horse-power simple engines at the bureau of engraving and printing, Washington; a pair of 125-horse-power compound engines at the state asylum, Polk, Pa.; and three 300-horse-power Strong boilers in the Great Northern building, Chicago. Orders have been received for direct connected engines for Chippewa Falls, Wis., and for Delavan, Wis., and an engine and boiler for Yokohama, Japan.

Kennedy Park, for ten years in the erecting department of the Babcock & Wilcox Company, of New York, and for the past five years superintendent of the New England erecting department for that company, has severed his connection with them and gone with the Aultman & Taylor Machinery Company, to take charge of the erecting department for Cahall vertical and Cahall-Babcock & Wilcox boilers in New England. Mr. Park's connection in the New England district for some years past has made for him many strong friends, who will be glad to know of his new position.

The executive committee of the National Association of Manufacturers met in Philadelphia on December 18, to make preparations for the annual convention to be held in that city January 26, 27 and 28, 1897. The following resolution was adopted by the committee:

"RESOLVED, That it is the sense of this executive committee that the tariff laws should be revised at the earliest possible moment, in order that uncertainty be removed, confidence restored, and business permitted to revive.

"That rates of duties should be made as low as possible, consistent with the fair protection of our industries and the labor they employ."

The Murray Iron Works Company, of Burlington, Iowa, which has been in business at that place for the past twenty-seven years, is of late making a specialty of high grade corliss engines for electric railways and light and power stations. The company is also giving particular attention to the building of high pressure steel boilers to engineers' specifications. The plant includes a large and finely equipped foundry, two complete machine shops—one of which is entirely devoted to the building of corliss engines and a modern boiler shop with hydraulic riveters, pneumatic appliances, etc.

F. E. Huntress and George C. Ewing have joined forces for the sale of electric railway equipment, and have opened an office at 8 Oliver street, Boston, for the purpose. They will deal in motors, both new and second-hand, and all lines of street railway supplies, iron, steel and general castings, and will also represent the Walker Company in New England. They will also contract for railway and lighting plants. Mr. Huntress remains president of the Neal Head-light Company and Mr. Ewing as secretary. Mr. Huntress was honored at the recent election by being elected to a seat in the house of representatives in Massachusetts.

A. H. Hackerman, general manager of the Fuel Economy Company, of Matteawan, N. Y., has this to say about business prospects for 1897. "We do not think that there will be any quick improvement for some time, but before the end of the year we believe that all the factories will be running on full time. Our conclusions about this are drawn from our own business as we are always late in feeling a revival of business. We feel that from the inquiries with the orders that our coming in, business must be reviving in other lines. Until, however, the finances of the government are set upon a more substantial basis than they are now, business will not be as good as we all wish."

The eighteen air brakes sold over eight months ago by the Standard Air Brake Company to the Washington, Alexandria & Mount Vernon Railroad Company have had a remarkably successful career. As many of our readers know, the road is a fast line. Recently four cars were run

as a train by superintendent of motive power, J. Colvin. A speed of over 60 miles per hour was made, and the Standard geared compressor type air brake worked perfectly. It is interesting to note that at that speed the pinion of compressor made 845 revolutions per minute, as the car wheel was but 24 inches in diameter. Nearly 15 revolutions per second is service that only a well constructed machine can stand.

J. S. Bradley, secretary of the New Haven Register Company, on being asked what was new, replied: "We are getting out a new single register, which is intended for all classes of trade which want a good reliable register at a very low figure, and while it does not contain all the features of the 'New Haven' register it does contain all the desirable features of all other registers on the market and is gotten up in elegant shape with enameled case in imitation of mahogany, with antique copper sash. As to the more prominent sales within the past few weeks, we have closed deals with two fine systems for our double machines and have several other large contracts for these under negotiation both in this and foreign countries."

During the month of December, 1896, the American Engine Company, Bound Brook, N. J., shipped 60-horse-power American-Ball engines to the Albany Journal and the Scranton Truth and motors and dynamos as follows: Western Newspaper Union, 50 and 12-horse-power motors; Chattanooga Daily News, one 100-light dynamo; Gazette Publishing Company, one 5-horse-power motor; Toledo Blade, one 12-horse-power motor; W. D. Boyce Company, one 12-horse-power motor; Age Herald Publishing Company, one 9-kilowatt dynamo; Dayton Journal, one 9-kilowatt dynamo; Indianapolis Sun, one 3-horse-power motor; Inquirer Company, one 75-kilowatt dynamo; Harrisburg Telegram, one 3-horse-power motor; Jarecki Manufacturing Company, one 9-kilowatt dynamo; Boston Herald, one 100-horse-power motor.

T. W. Meachem, president of the New Process Raw Hide Company, Syracuse, N. Y., on being questioned as to the new year said to a REVIEW representative: "Having, in the face of general business depression, increased our annual output 30 per cent during 1896, we naturally look forward to 1897 with serene confidence. We are getting out nothing new in the street railway line, but we are convincing street railway managers, one after another, that we already have something that it is to their interest to adopt, and the number using our pinions is larger than ever before. That business generally will steadily improve all during the coming year we think no one can doubt. We expect to profit especially from such improvement, for the reason that when times are hard the buyer is more apt to be influenced by first cost rather than intrinsic value."

The Ball Engine Company, Erie, Pa., reports it has been running its works until ten o'clock ever night since October 1. Among the engines it is just completing are a 450-horse-power vertical cross-compound engine direct connected to a Siemens-Halske generator to go to Russia, one of the same size and arrangement for the Schoenberger Steel Company, Pittsburg, Pa., one of 150 horse-power for the same company, and one 100-horse-power vertical tandem compound and four 200-horse-power vertical cross-compound engines, each direct connected to two General Electric generators, for

the Chicago Public Library. The company is also building a 350-horse-power vertical cross-compound direct connected to a G. E. alternating machine for the Apollo Iron & Steel Works, Vandergrift, Pa., and a 350-horse-power horizontal cross-compound for the Wilmington (N. C.) Electric Light Company.

The Standard Air-Brake Company has begun the new year well, as the first order it received was from Germany, through its general representative, the Bergische Stahl-Industrie, of Berlin and Remscheid, for air-brake equipments for 30 double-truck motor cars for the Oberschlesische Dampfstrassenbahn. The company's motor-compressor type will be furnished, and in addition to the 30 outfits there is another order for 30 more to follow, making 60 cars in all. The significance of this order is apparent, as this road has been a steam road all along, but is about to be electrified. The company's foreign business is very active, and within the past few days requests have been received for some three hundred additional equipments, for which it is expected contracts will be closed within a very short time. The company has not only increased its force, but has enlarged its facilities to meet the increased business.

The McGuire Manufacturing Company of this city reports a very satisfactory business during 1896, the sales showing an increase of 25 per cent over the previous year. The year was an especially good one in snow sweeper and stove lines. The published results of tests of coal v. electricity in car heating, and the fact that the Columbia heater is standard on many large and coaservative roads, has proven decidedly advantageous to the McGuire Company, and the stove department has been pushed to the limit, and even at this late date is running full force. The season in the sweeper department has been exceptionally good, and shows an increase over last year's business. Twenty-eight railroads already have the sweeper in use. The company has received its share of the truck orders the past year, and this department has been running steadily. The list of sales of its patented ratchet handles is assurance that they are being largely adopted.

The Weston Engine Company, Painted Post, N. Y., is again in full working order after the disastrous fire last summer. The new works were occupied about November 15, but were not fairly under way until December. The company is now working about 100 men, running the shops both night and day in order to fill orders which have been received within the last two months. Some of the prominent sales made are as follows: Presbyterian Board of Publication, Witherspoon building, Philadelphia, two 14 by 14 and one 12 by 12 Imperial engines arranged for direct connection to Siemens-Halske generators; Star Theatre, Philadelphia, one 12 by 12 Imperial engine, belted; J. W. Jackson, Philadelphia, one 13 by 14 Imperial engine, belted. The above was sold by representatives, the Reynolds-Lalor Company, 41 North 7th street Philadelphia. Other sales are, City of Brooklyn, one 7 by 8 Imperial engine, direct connected to Excelsior generator; New Amsterdam Hotel, New York City, one 9 by 10 Imperial engine, direct connected to General Electric generator; Meltzer Bros., brewers, Brooklyn, one 7 by 8 Imperial engine, belted; Hendey Machine Company, Torrington, Conn., one 11 by 12 Imperial engine; Brooklyn Music Hall, Brooklyn, one 12 by 12 Imperial

engine, belted; all sold by the New York managers. J. K. Fyfer, Centralia, Mo., has ordered one 11 by 12 Imperial, belted. Other orders include engines for small power, and sales of the standard Weston.

Clement C. Smith, superintendent of the Falk Manufacturing Company, Milwaukee, reports a contract for cast-welding the Third avenue line, New York, on which work will begin at once. The work at Lyons, France, is progressing satisfactorily, and arousing much interest abroad. In the way of special track work the company is getting out all the special work for the new line at Peoria, some for the West Chicago Street Railroad, and for Memphis. Mr. Smith adds: "As to our ideas of the prospects for 1897, we believe that our business in all departments will be much larger than ever. The success of the cast-welded joint has now been so indisputably demonstrated, and was so thoroughly discussed at the St. Louis convention and in the various street railway and electrical papers, that the demand for the joint this season will be very heavy. Our special work business is developing very nicely and as many of the roads have been holding back on expenses for the past year, or to anticipate election, they will now be forced to renew a good deal of their old work, and we shall receive our share of this business."

Eugene Munsell & Co., Chicago and New York, are naturally gratified at the following unsolicited letter from H. S. Cooper, superintendent of the Schenectady (N. Y.) Railway, under date of December 21, 1896: "In March, 1894, you put a full body and slot insulation of micanite on one of our Edison No. 16 street car armatures, and the same was wound at once and put in service, and has been pretty steadily running ever since, the car having made over 50,000 miles. The armature has never given us any trouble in 'body grounds' since it started, although it is of the 'ring' type, and is not protected by the motor frame, it being open to snow, slush or water from the wheels. The wiring on this armature has just been burned out by a severe and continued overload, so heavy as to not only char the insulation of the wire, but to melt some of the wires themselves. On stripping off the wires we were surprised to find the insulation of body and slots in apparently good order, and after fully stripping and testing, we find it absolutely perfect, mechanically and electrically, and are now rewinding it, having done nothing to the insulation but to give it a coat of varnish and bake it. We consider this so remarkable a record that we think it only justice to you to inform you of it. While the full micanite body insulation costs several times more than our previous method of cloth, mica and paper, the results in freedom from armature 'body grounds,' and the ability to re-use the insulation indefinitely, are points that will make us consider the use of micanite as essential in all our work for the future."

#### "BIG FOUR" INTERCHANGEABLE MILEAGE.

The interchangeable 1,000-mile tickets of the "Big Four Route" are indispensable to all business firms and commercial travelers. The lines of the "Big Four" penetrate all the big cities of Ohio, Indiana and Illinois, and a ticket which can be used to reach these cities as well as cities on principal connecting lines, is invaluable.

### Alabama.

MOBILE, ALA.—Ground has been broken for the Dauphin street extension of the Mobile Street Railway.

### Arkansas.

LITTLE ROCK, ARK.—Judgment in default for \$22,582 against the City Electric Street Railway was given, January 4, in favor of the Thomson-Houston Electric Company. The suit has been pending six years.

PINE BLUFF, ARK.—The Pine Bluff Power & Transit Company has been incorporated with a capital stock of \$100,000, for the purpose of operating water works, electric, steam or horse power street car lines. The officers and directors are W. H. Langford, president; J. B. Trulock, vice-president; D. C. Bell, secretary; W. L. DeWoody, treasurer; J. B. York, Simon Bloom, J. W. Withers, R. M. Galbraith and M. A. Austin.

### California.

LAKEPORT, CAL.—E. P. Clendenin asks an electric railway franchise.

SAN DIEGO, CAL.—Stockholders of the San Diego Electric Railway Company meet January 15, to authorize a \$400,000 mortgage.

SAN FRANCISCO, CAL.—It is said Behrend Joost proposes to redeem the San Francisco & San Mateo Street Railway, which was sold by a receiver.

SALINAS, CAL.—An electric railway company is organizing to build a line. The directors are J. D. Carr, William Vanderhurst, F. H. Lang, J. H. Menke, H. Corey, Henry Bardin and J. B. Iverson.

SANTA ANA, CAL.—The Santa Ana & Orange Motor Company has been incorporated to build five miles of road. Capital stock, \$20,000; incorporators, W. B. Henry, E. P. Nickey, M. A. Menges and D. H. Thomas.

SANTA CRUZ, CAL.—The Big Creek Company has contracted to supply power to the electric railway. It is said the Big Creek Company has already purchased a water wheel, generator and fifty-two miles of wire.

LOS ANGELES, CAL.—Citizens desire the conversion of the Glendale division of the Terminal Railway from steam to electricity, and have chosen W. G. Watson, W. S. Bullis and F. R. Warren, a committee to receive subscriptions to the subsidy required by the company.

### Chicago.

CHICAGO.—The petition of the Southwestern Street Railway Company for a franchise has been referred to a committee.

CHICAGO.—The Illinois & Michigan Canal Commissioners are said to have rescinded their grant of a franchise for an electric road on the towpath.

CHICAGO.—The Chicago & South Side Rapid Transit Elevated Railroad Company is making estimates of the cost of electrically equipping the Alley L.

CHICAGO.—The Suburban Electric Railroad Company has given a mortgage to secure \$3,000,000 of bonds, of which \$1,250,000 will be issued at present to cover the cost of construction.

CHICAGO.—The Suburban Electric Railroad Company, which is building a line, has been reorganized. The new directors are, Charles H. Crosette, president; H. K. Galpin, secretary; S. B. Shope, David B. Lyman and Herbert Hulcomb.

CHICAGO.—The Chicago, Lemont & Joliet Electric Railway Company has been incorporated to build and operate an electric road. Capital stock \$300,000; incorporators, E. H. Heilbroun, S. T. Hart, E. D. Hopkins, G. Lawrence Taylor and D. C. Baldwin.

### Connecticut.

EAST BERLIN, CONN.—Citizens are forming a company to build a trolley line to Berlin.

HARTFORD, CONN.—The Hartford Street Railway Company will apply for an amendment to its charter permitting extensions of its lines.

SOUTHINGTON, CONN.—An amendment to its charter permitting various extensions will be asked by the Southington & Plantsville Tramway Company.

BRISTOL, CONN.—The Bristol & Plainville Tramway Company will apply for the right to extend its tracks through Terryville to Plymouth and Thomaston.

SHELTON, CONN.—Franchises to build and operate in Bridgeport, Stratford, Trumbull and Huntington have been applied for by the Shelton Street Railway Company.

GREENWICH, CONN.—The Greenwich Tramway Company will apply for an amendment of its charter permitting extensions to Port Chester, N. Y., and Stamford, Conn.

NEW HAVEN, CONN.—Many extensions of its lines will be constructed by the New Haven Street Railway as soon as authority can be obtained from the State Assembly.

NEW HAVEN, CONN.—The New York, New Haven & Hartford Railroad is about to let contracts for two 850-kilowatt generators and other equipment for its power plant at Berlin, Conn.

PORTLAND, CONN.—John H. Sage and others, have petitioned for the incorporation of the Portland & East Hampton Street Railway Company, to build and operate through the towns of Portland and Chatham.

MILFORD, CONN.—J. D. Brown and others are forming the Milford Traction Company and will soon incorporate to build from Milford to Stratford, through Woodmont to Derby and through Orange to New Haven.

ROCKVILLE, CONN.—The franchise granted recently to the Rockville & Ellington Street Railway Company has been amended by striking out three streets. Windsor avenue was given the Hartford, Manchester & Rockville Tramway Company for its line to Talcottville.

NEW HAVEN, CONN.—A big electric railway scheme is backed by Morris F. Tyler, Dr. Thomas R. Russell, Dwight N. Clark, Robert Payne, Stiles Williams, Charles F. Walker, Rollin C. Newton, and Nathan P. Merwin. The line is to run from Westville, through Woodbridge and Seymour, to Naugatuck.

NEW HAVEN, CONN.—A lease of the New Haven & Centerville Electric Railway to the Fair Haven & Westville Street Railway Company, is being negotiated. Contracts have already been signed for the operation of the Centerville Company's cars with current from the Fair Haven Company's power station.

NORFOLK, CONN.—Samuel P. Williams, of Waterbury; Walter S. Judd, of Litchfield; John H. Wadhams, of Goshen, and T. H. McKenzie and others, are organizing a company to build 27 miles of electric railway from Watertown to Norfolk, by way of Morris, West Morris, Bantam, Litchfield, Goshen and South Norfolk.

DANBURY, CONN.—The old project of connecting Danbury with the Harlem road at Golden's Bridge has been revived with some prospects of a successful issue. Walsh & Purdy, attorneys, will petition the legislature for the incorporation of the Danbury & Golden's Bridge Street Railway Company. The road is to be 15 miles in length, with a power plant located centrally at North Salem. F. S. Wardwell, one of those interested, states that the capital has been subscribed, and the right of way given by property owners along the whole route.

### Delaware.

WILMINGTON, DEL.—John N. Carswell has been appointed receiver of the proposed Chester & Wilmington Electric Railway.

### District of Columbia.

WASHINGTON, D. C.—The Washington & Gettysburg Railway Company asks a charter to build and operate a trolley line to carry passengers and light freight. Incorporators, George W. Cissel, Charles Jacobson, Edgar P. Berry, John H. Gheen, George W. Harvey and James S. McIlhenny, of the District of Columbia, and Asa M. Stabler, John Miller, J. Enos Ray, Albert Gleason, R. G. Israel, N. W. Williams, Frank C. Drane, Ashley M. Gould, S. D. Waters, Francis Thomas, Rert H. Miller and O. A. Homer, of the State of Maryland, and T. William Harris, of the State of New York

### Georgia.

SAVANNAH, GA.—Herman Myers, of Savannah, and J. H. Fall, of Nashville, representing bondholders, bought the Electric Railway at auction, January 5, for \$210,000. When reorganized the company will purchase new equipment.

### Illinois.

ALTON, ILL.—An extension in Sixth street is contemplated by the Alton Railway & Illuminating Company.

OTTAWA, ILL.—Boston men are corresponding with R. C. Jordan with a view to taking hold of the Ottawa Street Railway.

EAST ST. LOUIS, ILL.—The ordinance granting the St. Louis Rapid Transit Company right of way for an electric road, from the Eads Bridge to Belleville, has been favorably reported on.

LAKE BLUFF, ILL.—C. E. Loss, the electric railway builder, of Chicago, has been granted a franchise for six miles of road in Lake Bluff, to connect with his line in Waukegan. Cars are required to be in operation by June 1.

WAUKEGAN, ILL.—The Bluff City Electric Street Railway Company has amended its charter "to construct, locate, maintain and operate electric street railroads in the several townships, cities and villages in the counties of Lake and Cook, in Illinois."

OSWEGO, ILL.—An electric railway scheme is quietly making progress. The prime mover is Hon. Fay P. Winslow, and he has associated with him U. P. Hord. Power will be supplied by the Oswego Water Power Company, which was recently purchased by Mr. Winslow. The line will carry freight and passengers between Aurora and a large district east and south of Oswego and Yorkville, besides catering to pleasure riders who would visit the most beautiful section of the Fox river.

### Indiana.

ANDERSON, IND.—Noah Clodfelter has had his electric railway franchise extended, after showing he had backing.

### Iowa.

OSKALOOSA, IA.—An election will be held to vote for or against electric cars.

BURLINGTON, IA.—Suit to foreclose \$300,000 first mortgage bonds of the Burlington Electric Street Railway has been brought by the American Loan & Trust Company, of New York.

BURLINGTON, IA.—The Burlington Railway & Light Company has been incorporated to purchase, own and operate the electric railway. Capital stock, \$1,250,000; incorporators, C. H. Walsh, J. J. Ransom and Col. George H. Higbee.

### Kansas.

LAWRENCE, KAN.—The receiver will sell the Lawrence Street Railway by order of court.

### Kentucky.

BOWLING GREEN, KY.—James H. Wilkerson is the receiver appointed for the Park City Railway.

COVINGTON, KY.—The South Covington & Cincinnati Street Railway has changed hands. The new officers are: president, J. C. Ernst, of Covington; vice president, Charles E. Orr, of Pittsburg; treasurer, H. P. Eells, of Cleveland; secretary, James H. Hoyt, of Cleveland.

### Louisiana.

NEW ORLEANS, LA.—The right to construct an electric railway in Napoleon avenue will be sold by auction by the city.

### Maine.

CALAIS, ME.—President George A. Curran contemplates extending the Calais Street Railway along the St. Croix river bank to Red Beach. The new line would be very attractive to pleasure riders.

BANGOR, ME.—Extensions of its electric lines to Eddington, Clifton, Holden, Dedham and Orrington and the construction of a great bridge over the Penobscot river are contemplated by the Bangor Public Works Company.

BANGOR, ME.—The Penobscot Central Railroad Company has applied to the railroad commissioners for an approval of their plan to build and operate an electric street railway from Bangor to Gardland by way of Glenburn, Kenduskeag, Levant, Corinth, Exeter and Charleston. Freight will be carried as well as passengers. Capital stock, \$250,000; incorporators, F. O. Beal, of Bangor; I. C. Libby, of Waterville; A. L. Gerald, Harrison T. Gould, of Kenduskeag, and C. E. Edmunds, of Corinth.

### Maryland.

BALTIMORE, MD.—The Central Railway and the City & Suburban Companies are both asking additional right of way.

BALTIMORE, MD.—Judge Dennis has decided that the City Passenger Railway Company has the right to install electricity on North Charles Street and the Blue Line Cable.

### Massachusetts.

BROCKTON, MASS.—The Brockton Street Railway Company asks the right to extend four lines.

MILLBURY, MASS.—The franchise of the Blackstone Valley Street Railway Company has been extended to December, 1897.

MILFORD, MASS.—The Milford, Holliston & Framingham Street Railway will probably accept the franchise recently granted.

NORTHAMPTON, MASS.—The Northampton Street Railway Company will extend its lines and add several cars to its equipment.

BOSTON, MASS.—The West End Street Railway Company has leased the Subway at a rental of 4% per cent on the cost of \$7,000,000.

BOSTON, MASS.—President W. B. Ferguson denies the report that the Gloucester, Essex & Beverly Street Railway had been sold to the West End Company.

HOLYOKE, MASS.—Directors of the Holyoke Street Railway have approved a lease of the Mt. Tom Railroad. The construction will be done by the latter company.

HOLYOKE, MASS.—The selectmen of South Hadley Falls have granted the franchise asked by the Holyoke Street Railway Company. Work will begin immediately.

HOLYOKE, MASS.—Directors of the Holyoke Street Railway have instructed President Loomis to ask a franchise in Chicopee, if the building of the road would be warranted.

**MANSFIELD, MASS.**—A portion of the capital stock of the Foxboro Union Street Railway Company has been subscribed. The line is to run between Foxboro and Mansfield.

**BOSTON, MASS.**—The Safety Electric Railway Company asks a charter to build an elevated railway in Boston and suburbs. Incorporators, Myron J. Ferren, Walter S. Keen, Frank E. Orcutt and A. W. Barrett.

**WORCESTER, MASS.**—Creditors of the Massachusetts Car Company held their second meeting January 5, at Worcester, to prove their claims. The assignees are George S. Forbush and W. G. Wheildon, 53 State street, Boston.

**MARLBORO, MASS.**—The Framingham, Southboro & Marlboro Street Railway Company has been organized to build nine miles of road. Capital stock, \$100,000; directors, S. H. Howe, of Marlboro; F. D. Newton and C. B. Sawin, of Southboro; J. R. Entwistle, of Framingham; W. B. Ferguson, of Malden; C. E. Barnes, of Plymouth, and C. E. Bresser, of Leominster. The stockholders include the above and M. F. Maher, of Framingham; C. W. Shippee, of Milford; W. S. Reed, of Leominster; Albert Stetson, of New York; J. M. Cunningham, of Chelsea; Frank E. Lowe, of Greenfield; A. B. Turner & Brother, of Boston; W. H. Gilman, of Boston.

## Michigan.

**DETROIT, MICH.**—Erin has granted John B. Dyar a franchise for his Detroit-Port Huron interurban.

**ST. CLAIR, MICH.**—John B. Dyar has been granted a franchise in St. Clair, making another link in his proposed Detroit-Port Huron interurban.

**MONROE, MICH.**—Another extension of the franchise of the Monroe, Dundee & Lake Erie Railway has been granted. President W. H. Cowles, who has deposited \$500 forfeit, claims that men with capital are interested. He expects to have the road to the lake completed by June 15.

**MUSKEGON, MICH.**—The Muskegon Street Railway, including 14 miles of line, power plant and pleasure resort, was sold under foreclosure of second mortgage, January 5, to Herbert Payson, of Portland, Me.; John Crosby, of Bangor, Me.; and Weston Thompson, of Brunswick, Me., who represent also the first mortgage bondholders. Receipts in 1896 were \$25,000 less than in 1892 and \$2,000 less than for the previous year. The road was well equipped and well managed, but its fixed charges were too heavy to be met by the decreasing earnings. The company will be reorganized on a paying basis.

**KALAMAZOO, MICH.**—The Michigan Traction Company has been incorporated with \$500,000 capital stock, by L. N. Downs, F. N. Rowley, E. E. Downs, of Kalamazoo, and George J. Kobusch and Otto Von Schrader, of St. Louis, Mo. The company will probably acquire the Citizens' Street Railway, of Kalamazoo, and build an interurban road 23 miles in length to connect with the Battle Creek Railway. Incorporators of the new company control the car lines of both cities. Franchises have been applied for in the intervening towns and villages, and arrangements are being made to commence construction early in the spring. It is expected the new road will be open for business about July 1.

## Minnesota.

**STILLWATER, MINN.**—Judge Williston has refused August Jesse's highest bid of \$2,300 for the street railway.

**MINNEAPOLIS, MINN.**—A. M. Allen's petition for an electric railway franchise to Lake Minnetonka has been denied by the county commissioners.

## Mississippi.

**MISSISSIPPI CITY, MISS.**—The application of George W. Pierce, Jr., for a street railway franchise, has been filed until March, when the original franchise expires.

## Missouri.

**ST. LOUIS, MO.**—The Suburban Electric Railway Company expects to have its Kirkwood extension in operation by April 15.

**ST. LOUIS, MO.**—Eugene H. Benoist, Breckenridge Jones, Fred E. Allen and Frederick Vierling are interested in a street railway project for which a franchise is asked.

**PEIRCE CITY, MO.**—The City Council has granted a franchise to the Peirce City & Monett Electric Railway Company, which is said to be backed by ex-Governor Fishback, of Arkansas.

**ST. LOUIS, MO.**—J. D. Houseman has taken possession of his line, the St. Louis & Kirkwood Electric Railroad, on a decision of the Supreme Court setting aside the appointment of a receiver.

**JOPLIN, MO.**—Judge George F. Davis, of Sarcoxie, who is interested in the proposed electric road between Sarcoxie and Joplin, has been corresponding with Little Rock, Ark., men who may furnish the capital.

**ST. LOUIS, MO.**—The People's Consolidated Railroad Company asks permission to acquire the People's Railroad, and the Fourth Street & Arsenal Railroad, and the right to construct lines on many streets.

**ST. LOUIS, MO.**—Farmers propose to construct an electric railway to convey their produce to the city. The route is from a point on the St. Louis & Kirkwood line, near Brentwood, through Des Peres, Manchester, Ballwin and Ellisville.

## Montana.

**BUTTE, MONT.**—The Butte Consolidated Railway Company writes that quotations are wanted on a car load of car wheels—about 300 to 330 pounds each, 30 inches diameter, 2¼-inch tread. Quote lowest cash price, f. o. b., Butte.

## New Hampshire.

**NEW LONDON, N. H.**—The New London & Potter Place Electric Railway Company will be incorporated.

**CHESTER, N. H.**—Those interested in the Chester & Derry Electric Railroad will apply for a charter to build a line connecting Chester and Exeter via Brentwood.

**PORTSMOUTH, N. H.**—Massachusetts men have purchased the franchise of the Kittery, Kittery Point & York Beach Electric Railroad Company and expect to begin construction very soon.

## New Jersey.

**BRIDGETON, N. J.**—The South Jersey Traction Company's property will be sold under foreclosure of mortgage.

**PLAINFIELD, N. J.**—Chandler Riker, of Newark, and capitalists of the city, plan a trolley line from Plainfield up Watchung Mountain.

**NEWARK, N. J.**—The South Orange & Maplewood Street Railroad Company has applied for right to extend.

## New York.

**BUFFALO, N. Y.**—The Buffalo Railway Company has issued \$1,000,000 bonds for betterments.

**BROOKLYN, N. Y.**—Fire, December 27, destroyed the Bushwick repair shops of the Brooklyn Heights Railroad.

**JEFFERSONVILLE, N. Y.**—Frank Loebler is promoting an electric railway between Jefferson and Liberty to cost \$115,000.

**HUDSON, N. Y.**—A receiver is asked for the Hudson Electric Railroad. Liabilities are estimated at \$90,000; and assets, \$70,000.

**ROME, N. Y.**—The Rome City Street Railway Company will soon consider a proposition to extend its line four miles to Lindale.

SYRACUSE, N. Y.—Plans and specifications are being prepared for bidders for the construction of the Syracuse & Suburban Railroad.

PORT RICHMOND, N. Y.—The plans of the Staten Island Electric Railroad Company for a trolley line in Richmond avenue have been approved.

TROY, N. Y.—The application of the Greenwich & Schuylerville Electric Railroad Company for permission to build has been granted by the state commissioners.

BROOKLYN, N. Y.—Fire broke out at 1:30 A. M., December 18, in the Rockaway avenue car sheds of the Nassau Electric Railroad. Nine open cars were burned. Loss, \$30,000.

CORTLAND, N. Y.—The Cortland & Homer Traction Company expects to make a survey for an extension of its line from McGrawville through Solon, Willet, Taylor, Pitcher and Cincinnati.

GARDINER, N. Y.—Charles E. Johnston, 43 John street, Kingston, is forming a company to build a trolley line between Pancake Hollow and Jenkintown, passing through Gahow, Tutletown and Ireland Corners.

NEW YORK, N. Y.—William G. E. See has been appointed receiver of the Fulton Construction Company, which built the Twenty-eighth & Twenty-ninth Streets Railroad. Mr. See will sell the assets, consisting principally of a number of street railway franchises.

NEW PALTZ, N. Y.—Promoter B. Van Steengber has sold his franchise for an electric railway between New Paltz and Highland, to Ferdinand McKeige, a capitalist of New York, who has engaged Attorney C. W. H. Arnold, of Poughkeepsie, to form a company to construct and operate the road. The sale includes the incomplete power station at Lloyd.

BUFFALO, N. Y.—The Buffalo, Kenmore & Tonawanda Electric Railroad Company will construct a line in Elmwood avenue to connect its road with that of the Buffalo Railway. The company's finances have improved recently. The road was built three years ago at a cost of \$153,000, of which \$63,000 remained unpaid when the Buffalo Traction Company obtained control. To clear the indebtedness, at a meeting December 21, the original stockholders subscribed \$20,200 and the Traction people \$42,800. A large pleasure traffic is expected the coming summer from visitors to the company's resort, the Kenmore Palace Park, where it is proposed to give summer operas at 10 cents admission.

GREENBUSH, N. Y.—Those interested in the proposed electric railway between Greenbush and Brainerds, a distance of 17 miles, have drawn up articles of incorporation of the Greenbush & Nassau Electric Railway & Power Company. The following directors have been chosen: William H. Nichols, John F. Lape, Fred Carr and Bradford Lansing, of Greenbush; Joel T. Morey, Gardner Morey and Thomas James, Nassau; James Gray, East Albany; C. J. Smith, Bath; W. D. Barnes, Brainerds; J. H. Finnerty and Dr. S. C. Curran, East Greenbush. The directors elected: William H. Nichols, president; Thomas E. James, vice-president; Dr. Curran, secretary; Fred Carr, treasurer John F. Lape, general manager, and John F. Lape, Thomas James and W. D. Barnes, executive committee.

### North Carolina.

RALEIGH, N. C.—Fire on the night of December 31 destroyed the power house and car shed of the Raleigh Electric Company. Loss, \$25,000; insurance, \$12,500. The plant will be rebuilt.

### Ohio.

DEFIANCE, OHIO.—W. R. Taben is the receiver appointed for the Defiance Light & Railway Company.

NILES, O.—The Mineral Ridge & Niles Electric Railroad Company has been incorporated with \$50,000 capital stock.

MARIETTA, O.—The Marietta Electric Company has absorbed the Marietta Street Railway with a view to equipping for electricity.

CINCINNATI, O.—Wyoming village has granted a franchise for another link in the Cincinnati, Middletown & Dayton Traction Company's line.

TOLEDO, O.—Bowling Green has finally granted the franchise asked by the Toledo, Bowling Green & Fremont Electric Railroad Company.

CINCINNATI, O.—The Mt. Auburn Electric Railway Company has accepted its franchise for a line to Reading, and received a bonus from the citizens.

YOUNGSTOWN, O.—The Mahoning Valley Electric Railway Company has given a mortgage for \$1,200,000 to the Central Trust Company, New York.

WARREN, O.—Motor equipments will be purchased very soon by the Trumbull Electric Street Railway. Next spring three new 46-foot cars will be added.

YOUNGSTOWN, O.—The Trumbull Electric Railway, of Warren, and the Youngstown Street Railroad have been consolidated as the Mahoning Valley Railway.

AKRON, O.—The Wooster avenue barns of the Akron Street Railway were burned at 2 o'clock on the morning of December 15, together with 13 cars. Loss, \$10,000; insurance \$8,000.

WESTERVILLE, O.—W. E. Hoyer and C. E. Burr, who are interested in the Worthington & Westerville Street Railway, have obtained an extension of time in which to complete the road.

CINCINNATI, O.—Contracts have been let by the Cincinnati & Miami Valley Traction Company for the erection of power houses at Franklin and Busenbark's station and a car barn at Middletown.

CINCINNATI, O.—The new Cincinnati, Hamilton & Dayton Traction Company has elected D. G. Edwards, president; C. G. Waldo, general manager; G. R. Balch, secretary, and F. H. Short, treasurer.

CLEVELAND, O.—The car barn and repair shop of the Cleveland, Painesville & Eastern Electric Railroad Company, at Willoughby, were burned on the evening of December 26. Loss, \$50,000; insured.

SANDUSKY, O.—A syndicate of New Yorkers is negotiating the purchase of the Sandusky, Milan & Norwalk Electric Railway, with a view to constructing a line connecting with the Cleveland road running to Elyria.

CINCINNATI, O.—The Cincinnati, Hamilton & Dayton Traction Company has been incorporated to construct a very extensive electric railway system. Incorporators, C. G. Waldo, D. G. Edwards, George R. Balch, R. P. Rifenberick and C. A. Wilson.

CHILLICOTHE, O.—Smiley Caldwell, president of the Highland Park Inn Company, who is interested in the electric road to Hillsboro, says it is expected to have the line completed by July 1. A party of surveyors, headed by H. M. Redd, is in the field.

CLEVELAND, O.—The completion of the Cleveland & Chagrin Falls line to the latter place will be pushed as fast as the weather will permit. Among those interested are R. L. Palmer, of Cleveland; L. M. Coe, F. D. Carpenter, and A. Hilliard, of Berea.

ASHLEY, O.—A. S. Shoemaker, of Ashley, is promoting an electric road between Mt. Vernon, Knox County, and Richwood, Marion County, passing through Sparta, Marengo, Ashley and Prospect. Forty business men of Ashley have agreed to pay for a survey of the route.

LIMA, O.—The Dayton Northern Railway Company has been incorporated to build a railroad, to be operated by steam or electricity, from Franklin to Lima. Incorporators, Walter B. Ritchie, J. E. Townsend, F. N. Haskell, E. R. Thomas, W. C. Brown and J. R. Mergue.

**MARIETTA, O.**—The Marietta & Western Bridge Company has been incorporated at Allegheny, Pa., to construct an electric railway and bridge between Marietta and Parkersburg, W. Va. The line will be twelve miles long. Capital stock, \$400,000; incorporators, William C. Jutte, August Jutte, C. M. Buchanan and C. Cramer, of Marietta.

**CLEVELAND, O.**—The franchise of the Cleveland, Wadsworth & Southern Electric Railway Company has been forfeited for non-compliance with conditions. The county commissioners have given a franchise over the same territory to the Cleveland & Southeastern Electric Railway Company. From Cleveland the line is to run to Wadsworth via Parma, Royalton, West Richfield, Bath, Ghent and Akron.

## Oregon.

**PORTLAND, ORE.**—C. E. Smith and others have been granted an extension of their franchise to build an electric road on First street.

## Pennsylvania.

**YORK, PA.**—Captain William H. Lanus has in contemplation the construction of five electric railroads, aggregating thirty-seven miles in length.

**BRADDOCK, PA.**—A bond for \$5,000 in acceptance of the Talbot avenue franchise has been filed by the Braddock & Homestead Street Railway Company.

**ALLEGHENY, PA.**—The Northside Traction Company has changed its plans for power supply, and now contemplates building a large power plant on the river bank. The company will relay with heavier rails and equip with new cars.

**MEDIA, PA.**—The Media, Middletown & Aston Electric Railway project, formed two years ago, is being revived. John B. Robinson, John E. Burnley and Samuel L. Kent have been appointed a committee to place the stock, if possible.

**PITTSBURG, PA.**—The Pittsburg & Mt. Washington Electric Street Railway Company has been incorporated to construct four miles of railway. Capital stock, \$24,000; president, Samuel Garrison; directors, W. C. Jutte, A. Jutte, George F. Williams, Pittsburg; Charles Cramer, Wilkinsburg.

**NEWTOWN, PA.**—The Newtown Electric Railway Company has been incorporated to build four miles of road. Capital stock, \$100,000; incorporators, Thomas P. Chambers, George C. Worstell, James C. Hutchison, Alexander Chambers, Ashbel W. Watson, Edward H. Buckman, George C. Blackfan, and Thaddeus S. Kenderline, all of Newtown, Bucks county; Henry Palmer, Henry Lovett, M. D., William B. Parry, Harvey H. Gillam, Harry W. Watson, all of Langhorne, Bucks county.

**SCRANTON, PA.**—A consolidation of the Scranton Traction Company, Valley Passenger Railway Company, Scranton Passenger Railway Company, Dunmore Street Railway Company and Scranton Suburban Railway Company, has been effected under the name of the Scranton Railway Company. Capital stock, \$2,500,000. Directors, Clarence M. Clark, president; J. P. Ilsley, vice-president; C. Ford Stevens, secretary and treasurer; E. W. Clark, Jr., Timothy Burke, Frank Silliman, Jr., and Horace E. Hand. All of the officers, with the exception of the last three, are Philadelphians.

**WEST CHESTER, PA.**—The Chester County Central Railroad Company has been incorporated to build a single track electric line for milk, produce and passengers. The charter was obtained under the steam railroad act, and the company will use the right of eminent domain, thereby conferring, to condemn a straight route between Philadelphia and West Chester. Capital stock, \$600,000; president, William S. Kirk, West Chester; secretary, John S. Love, Jr., and treasurer, A. Aylsworth Kite. The stockholders have organized the Columbia Construction Company to build the road.

## South Dakota.

**MADISON, S. D.**—A. L. Fuller has purchased the Madison motor line of Receiver Thompson, with the object of repairing and operating.

## Tennessee.

**CHATTANOOGA, TENN.**—The cable power house of the Lookout Mountain & Lula Lake Incline Railway was burned December 12.

**NASHVILLE, TENN.**—C. M. McGhee, of New York, has purchased the interest of Inman, Swan & Co., in the Nashville Street Railway.

**CHATTANOOGA, TENN.**—The reorganized Chattanooga Electric Railway Company has elected J. H. Warner, Edwin Warner, Percy Warner, W. T. Adams, T. D. Young, C. A. Lyster and George W. Meade, of Brooklyn, N. V., directors.

## Vermont.

**BENNINGTON, VT.**—A. B. Valentine, of Bennington, is interested in the proposed electric road to North Bennington.

**BELLOWS FALLS, VT.**—F. C. Kennedy, J. S. Pierson, John J. Flynn, A. O. Humphrey and Joel H. Holton, of Burlington, are negotiating for the franchise of the Bellows Falls & Saxton's River Electric Railway with a view to its immediate construction.

## Washington.

**WHATCOM, WASH.**—Affairs of the Fairhaven & New Whatcom Street Railway Company have been straightened out, and the receiver will be discharged.

**TACOMA, WASH.**—The foreclosure suit of the New York Guaranty & Indemnity Company against the Tacoma Railway & Motor Company has been decided in favor of plaintiff. The property is ordered sold.

**TACOMA, WASH.**—The Aman Lake Railroad, which was to have been equipped with electricity, has been torn up by the owners of the rails. It is expected that Robert Wiingate and John S. Baker, who hold the franchises, will nevertheless carry out the plan for electric equipment.

## West Virginia.

**BENWOOD, W. VA.**—The Benwood & Moundsville Street Railway Company has opened its line to Moundsville.

## Wisconsin.

**OSHKOSH, WIS.**—The Oshkosh Street Railroad Company has given a mortgage for \$50,000.

**JANESVILLE, WIS.**—The burned power house of the Janesville Street Railway will be rebuilt in time for the summer traffic. The owner is George W. Blabon, of Philadelphia.

**APPLETON, WIS.**—F. C. Rutan, of the Interurban Electric Railway, has again bobbed up. It is claimed the road will be built between Neenah and Appleton before July, 1897.

**MARINETTE, WIS.**—It is proposed to develop the water power of the Menomonee River, 7 miles above Marinette. The Marinette Gas, Electric Light & Street Railway Company is said to be interested.

**OSHKOSH, WIS.**—The Winnebago Construction Company has been incorporated to build the electric road for the Citizens' Traction Company. The capital stock is \$90,000. A site for a power house on the river front has been purchased.

**JANESVILLE, WIS.**—Fire, December 23, destroyed the power plant of the Janesville Street Railway. The flames spread with such rapidity that the engineer did not have time to save his coat, which hung almost within reach. Superintendent Cummins and Assistant Reader were both painfully burned in trying to save the office desk. Loss, \$15,000; insurance, \$5,000.

## Canada

**ROSSLAND, B. C.**—An electric mine railway is to be built at Red Mountain by the recently incorporated British Columbia Tunnelling & Developing Company.

MONTREAL, QUE.—The Temple Investment & Loan Company has been organized to build and operate street railways and lighting plants. Incorporators, S. A. Cox and J. W. Flavelle, of Toronto, and John Torrance and James McBride, of Montreal.

**Mexico.**

TAMPICO, MEX.—L. Goodman, of Nuevo Laredo, Mex., has been granted a franchise to build and operate street railway in Tampico, and is expected to be in the market for supplies.

**West Indies.**

KINGSTON, JAMAICA.—The Jamaica Street Car Company's application for a franchise has been denied. Offers from others will be considered by the Privy Council until April 15, 1897.

**THE EFFECT OF HARDENING PLASTIC RAIL BONDS.**

December 22, 1896.

Editor STREET RAILWAY REVIEW:

Dear Sir:—I have heard it recently stated as an objection to the Edison plastic rail bond that the amalgam would sometimes harden. As I had a very long experience with the earlier forms of this alloy designed by Mr. Edison, I wish to say that on a road in Orange the bonds were mixed so as to harden and had four or five years successful use.

If a connection jarred loose from any cause the heat produced by increased resistance quickly softened the amalgam and re-established the contact. In designing the more modern forms of this bond, it was decided to put in a slight excess of mercury and to allow sufficient room in the receptacle holding the alloy, to prevent its being put under pressure. This alloy when properly used, will remain plastic for years, as I can testify from long experience. If this alloy is put under pressure and the excess of mercury is forced out, it leaves a brilliant white metal of great density and of better conductivity than the plastic form. It readily softens under heat and will not be blackened by an arc. Roads whose joints are well maintained need not worry about contact if their plastic alloy is found hardened.

Very truly yours,

LAKE ONTARIO & RIVERSIDE RAILWAY COMPANY,  
F. H. Tidman, Recr.

**FINEST TRAINS SOUTH.**

Queen & Crescent route, Florida limited. Solid trains from Cincinnati to Jacksonville with modern high back coaches, Pullman sleepers, cafe, parlor and observation cars. W. A. Beckler, Northern Passenger Agent, 111 Adams street, Chicago.

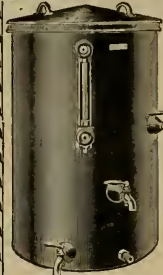

The cable railway up Highgate Hill, London, has been purchased by the Exploiters & Investors Syndicate, of Old Broad street, which proposes to place it in condition for operation.

**WANTED.**

SCRAP COPPER WIRE, SCRAP BRASS and PLATINUM.  
We buy any quantity of Scrap Metals at Highest Market Values for Cash or in Exchange for our High Grade Babbit. Cotton Waste, etc. Correspondence solicited. Write for Illustrated Catalogue.

**SWARTZ METAL REFINING CO.,**

Main Office: 120-122 W. LAKE ST., CHICAGO, ILL.  
ESTABLISHED 1885.

**Profit and Loss**

At the end of each year you ought to look up the amount spent for lubricating oil and charge half of it to "Profit and Loss Account" on the "Loss" side. In using oil less than half is consumed, the remainder is thrown away as waste oil. Our filter makes this oil as good as new and it can be used over and over again. That means something, and is worth considering. We send the filter on trial to be kept or returned at your option.

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. FEBRUARY 15, 1897. NO. 2

As a result of that returning confidence, no doubt, the street railway managers who office in the House and Senate have now permitted the lines in Washington to speed up to 12 miles an hour.

THE annual report of the railroad commissioners of Connecticut, for the fiscal year ending September 30, 1896, is out, and contains some interesting and valuable figures. The report deals in totals but we have reduced these figures to expenses per car mile, putting it into shape for serviceable use for our readers. The article on Connecticut roads appears elsewhere in this issue.

THE article by James R. Chapman on current consumption with low potentials, presents some interesting points. The data shows that a street car motor will operate with less current at low voltage than at normal potential, a sacrifice in the speed of the car resulting. It is calculated that less energy is expended in running a car mile with low than high voltage. The saving amounts to 22 per cent in a reduction from 520 to 320 volts. However, other considerations, the speed of the cars, and the power transmission are to be taken into account, but Mr. Chapman's article offers food for thought to electrical railway men.

THE account in another column of the twelve years history of the Mutual Benefit Association in operation on the Washington-Georgetown road, offers food for thought. During that time the association has paid \$18,000 in sick claims and \$4,000 on deaths, and has to-day to its credit \$88,000. The cost per capita per year is a mere trifle and the good work is most commendable. The plan should commend itself to many other roads.

ONE of Pingree's underlings who rejoices in the strikingly American name of Petrowski, has introduced a bill in the Michigan legislature to provide for a street car service of not more than five minutes headway in all cities of 150,000 or more. This is a gentle compliment of Pingree to the city of which he is still mayor. There is one other little improvement which Petrowski seems to have overlooked and that is the bill should have provided that each passenger should be entitled to an entire car for his or her exclusive use on the payment of one cash fare.

THE attempt made by certain interested parties to have the franchise annulled for one of the lines in Milwaukee, on account of the temporary abandonment of two blocks of track which the company built but had not used for four years, was defeated in the Supreme Court. Recently the company desired to build the balance of the line which had been commenced but not used all the time since. Property owners first took an injunction and followed this up with a prayer to have the franchise annulled, as stated. The result is as important as it is interesting. The text of the decision will be found in this issue.

THE severe grades which can be easily surmounted by electric cars in these days, would hardly have been considered possible in the earlier days, although Leo Daft as long ago as 1888 operated on a 15 per cent grade in Pittsburg by means of a rack auxiliary. Grades that would make steam road construction practically impossible are becoming numerous in electric engineering, and without employing any auxiliary means. On another page we describe a 13 per cent grade 1,000 feet in length on which the electric cars operate without any trouble whatever. On another portion of the same road is an open cut grade on a sharp curve. This ability to climb and descend heavy grades is a most important feature in construction cost and means electric lines where steam roads cannot afford to build. Interurbans are, in point of numbers, only in their infancy, and the next five years will witness the construction of hundreds of miles of these lines.

THE daily press of the entire country with one accord has been repeating, until the statement has become a stereotyped one, "The price of everything except street car fares, has been reduced." Strangely, too, the public which has the fares to pay, neither originated the demand for lower fares or even joined in a protest

against the universal five cent fare. It has been the daily press and members of city councils, which have raised the cry. A bushel of corn today is practically just the same as a bushel of corn in 1887; a ton of rails weighs no more now than then, though admittedly of better quality; a ton of coal has not changed in quality or measure and a pound of sugar contained quite as much saccharine matter ten years ago, as now. The market price of all these commodities has fallen during that period. The argument then, that street car fares should be less to-day than in 1887 is in many respects a sound one, in which we fully concur. There is this vital difference, however, in the comparison; that while invention has greatly cheapened the cost of production of a ton of rails and a pound of sugar, there are no more ounces in a pound, or pounds in a ton now than there were then. On the other hand, while companies have made a reduction in the one item of power necessary to move a car, they have assumed large interest charges on the greatly increased investment made necessary to erect power houses, furnish better cars and lay the more expensive tracks required to carry these new cars. Where a 45-pound rail was sufficient in 1887, now a 60, a 70 or even a 100-pound rail must be laid. Wages have been very largely increased, and scores of repair accounts opened, which had no existence then. It is evident, therefore, that in furnishing a ride to-day, of as great length as that of ten years ago, the quality and quantity of service now rendered has so advanced as to be worth more money than was charged then, and yet the price has not been increased. Were there nothing further to offer as an explanation of why car fares remain at the five cent unit, the case is clear that the increased value now given for the old price is alone a reduction in price, fully equal to that of any other commodity. But our case does not rest here. The tables printed on another page, compiled from data gathered from every portion of the country, present results which will astonish even street railway experts. An average of all the cities tabulated shows the street car ride for five cents in 1897 to be an increase of 237.5 per cent over that of 1887; or in other words if companies were charging now on the basis of 1887 they should receive 16.85 cents where they are only charging 5 cents; a difference of almost 12 cents. And yet we hear that "The price of everything but street car fares, has been reduced."

THE call for a meeting of Street Railway Accountants, to be held in Cleveland, March 23-24, as published in our last issue has met with a most hearty and gratifying response. Upwards of 50 roads have already signified their intention to send delegates, while half as many more are in favor of the meeting and its purposes, and hope to be represented but could not promise definitely until a little later. In some cases an impression was had that this initial meeting was simply for the purpose of forming an organization and that the first practical work would not be taken up until the first annual meeting, which will be held at the same time and place as that of

the American Street Railway Association. While an organization will be a part of the object of the meeting, it will be seen by a glance at the program published elsewhere (and not yet fully complete) that there is a lot of very valuable work to be done at the Cleveland meeting. Committees also will be appointed to report on standardization and other matters at the October meeting, and will have the intervening months in which to work. No gathering of the men devoted to this important department of street railway work has ever been assembled as yet, and the need is urgent and pressing for immediately commencing the improvement of accounting. In the operating department, electric and mechanical engineers who have had experience on many roads have been called in to assist in the erection, installation and putting in working order of power houses and equipments. These experts have imparted their knowledge and experience to the operating department which takes the property when finished; and in many ways the operating department has had the benefit of what a large number of roads have done and are doing. All this time, and while most radical changes have been taking place in methods of operation, which mean corresponding changes in account keeping, the accountant has been practically neglected. Nobody ever seemed to think of him, or that he had any new problems; and as for going outside the office to see what others were doing was an unknown quantity. Now the accountants are going to help themselves. They will do as the operating departments have had to do; get together with others engaged in the same work, and by a general and mutual exchange of experiences and improvements, better and simplify their own work. The purpose is a most highly commendable one and deserves the support and representation of every road in the country.

#### GOOD IN AN OLD LAW.

About a year ago one John Werder was injured by a trolley car in Jersey City, and entered into a contract with a professional claim adjuster named Stanford, by which he agreed to do nothing without the consent of the latter, who was to advance funds for Werder's maintenance pending settlement, and receive one-half of the amount collected from the company. Werder effected a settlement without the knowledge of Stanford and the latter sued him for \$189.50 which had been advanced. Werder's defense was that the contract was void because it was "barratrous, champertous, for maintenance, and against public policy." The judge took the same view of it and Stanford was non-suited.

#### JOEL HURT REMAINS.

Joel Hurt, who has served, under protest, several terms as president of the Atlanta Consolidated Street Railway Company consented to accept the office again and was elected at the annual meeting of the board held January 20. The other officers were also continued for the coming year. The company has done a good business during 1896 and a dividend of 2 per cent was declared, payable April and October. This is the first dividend the company has earned.

CONCRETE WORK IN TRACK CONSTRUCTION.

When electric traction was adopted on our street railways an era of reconstruction was entered upon as a matter of necessity, and nowhere was reconstruction more imperative than in track work. The new motive power permitted higher speeds and economic operation compelled heavier cars; better service stimulated traffic and longer trains run on shorter headway resulted. The tracks which were built in the days of animal traction did not stand under the severe service, and a more permanent way became a necessity. Thus, track building became a matter for serious consideration, and continues to be so as the work of rebuilding lines and rectifying mistakes proceeds.

The first requisite for economic operation is that the rail shall present a good rolling surface to the wheel. This means the rail must be sufficiently heavy to prevent local deformation under load, and so well supported that it will not deflect by reason of the foundation settling. The heavy and deep rails now used are sufficiently strong as girders when supported at short intervals only, and no difficulty is experienced with tie construction where the roadbed has been properly tamped.

With pavements to be kept up, however, especially if the street traffic is heavy, a problem of no less importance is that of properly supporting the pavement. The advantage of solidity in track and pavement was perhaps as well appreciated in this country as abroad, but it was adopted first in England. The reasons for this are not far to seek. The

longitudinal) in the world with a minimum expense for maintenance.

A substratum of concrete is ideal for supporting the pavement, and hence, as the track must have as good or better foundation than the adjoining pavement, a large proportion of the newer track is put in on concrete foundation.

In the REVIEW for January F. A. Little presented the figures on cost of concrete foundations, based on the construction of nearly fifty miles of track in Detroit. In that article Mr. Little pointed out the advantage in cost which trench work has over the construction with ties, the difference in labor, paving, etc., when track is laid in a street

FIG. 1—TRENCH WORK—TWIN CITY RAPID TRANSIT COMPANY.

already paved with asphalt being \$1.05 as against \$2.85, a saving of 63.5 per cent.

By the courtesy of W. J. Hield, general manager of the Twin City Rapid Transit Company of Minneapolis, we are enabled to give some data on the cost of trench work in that city. Fig. 1 shows a section with dimensions and Fig. 2 a view from a photograph of a section of the track. The rails used are of the American Society of Civil Engineers' standard, weighing 80 lbs. to the yard and in 60 foot lengths, with the joints cast-welded. In Fig. 2 the section is taken through one of the joints. The flange way is formed by

FIG. 2—SECTION OF TRENCH WORK—TWIN CITY RAPID TRANSIT COMPANY.

roads and pavements in England were better built than here, and the street railway is an American institution. We have had to try all kinds of experimental construction in order to determine what was best suited to our needs, and often when we knew that it was poor, yet it was good enough for an ill-paved street. On the other hand, the Briton had good roads and well-paved streets, and with his proverbial conservatism and distrust of all that is new, he was very adverse to having his pavements torn up. Franchises were difficult to secure, and when the tracks were laid repairs were expensive to make; as a consequence only the best construction could be afforded. That this is really the cheapest is well shown in Liverpool, where tracks and pavement have endured what is, perhaps, the heaviest traffic (both cross and

granite blocks 4 to 4½ inches deep laid against a wooden form 1 inch thick. After the cement has set, the form is removed and the spaces between the rails and the granite blocks filled to within an inch of the top with asphalt.

The city ordinances of Minneapolis provide that the railway company shall pave between the rails and between the lines of double track. The paving was done by contract and in settling with the contractor it was agreed that the company should pay the price of asphalt pavement from outside rail to outside rail, the granite stretchers being furnished by the contractor and figured at the same price and no allowance made for the space occupied by the rails. The pavement is laid on domestic concrete which was included in contract price of \$2.45 per square yard.

The following extract from the paving ordinance will explain the method of mixing and laying:

"Upon the sub-grade will be evenly spread a layer of hydraulic cement concrete six inches in thickness to be made as follows:

"One measure of hydraulic cement and two of clean sharp sand, will be thoroughly mixed dry and then made into mortar with the least possible amount of water. Crushed rock of a quality to be accepted by the city engineer and of such dimensions that the various stones will not exceed two and one-half inches in any direction, clean from dust and dirt, drenched with water, but containing no loose water in the heap, will be incorporated immediately with the mortar in such quantity as will give a surplus of mortar when rammed. This proportion, when ascertained, will be regulated by measure.

"Each batch of concrete will be thoroughly mixed. The mixing will be continued until each piece of stone is completely coated with mortar, it will then be spread and at once thoroughly compacted until free mortar appears upon the surface. The whole operation of mixing and laying each batch will be performed as expeditiously as possible and with the use of sufficient number of skilled men. The upper surface will be made exactly parallel with the surface of the pavement to be laid, and when in place, all wheeling, working or walking on it must be prevented until sufficiently set."

The Portland cement for the beams is composed of two and one-half parts sand to one of cement. As much stone is used as this will cover, and the concrete is mixed and laid in the manner described for domestic concrete. Like the paving the trench work was done by contract, so that in the statement below, the concrete and labor of excavating are not to be separated. It is the experience of Mr. Hield that liberal allowance for contingencies must be made in estimating the item of labor, because of the fact that city employes, sub-contractors, plumbers, gas fitters, telegraph and telephone companies, and others, are all working in the street at the same time, and delays which cannot be anticipated, are bound to occur.

The cost of a mile of single track is itemized as follows:

	Per Mile.	Per Foot.
Rails, 125.71 tons at \$32.00.....	\$ 4,022.72	\$ .762
Cast-welded joints, 176 at \$2.84.....	499.84	.095
Concrete beams.....	2,640.00	.500
Labor.....	2,640.00	.500
Tie bars (every 12 feet), spikes, ties and copper cross bonds (every 150 feet).....	325.00	.043
Paving, asphalt on 6-inch American concrete.....	10,869.84	2.059
Total.....	\$20,897.40	\$ 3.959

Deducting the rails and joints we have for the cost of single track, \$3.10 per linear foot, which shows that where the railway company is required to put in the pavement there is but little difference in first cost between tie work and trench work on concrete foundations.

As before stated, if the street is already paved with asphalt there is a great saving by the use of trench work. And when the track is to be rebuilt the economy of trench work is apparent. There are no ties to be dug up and replaced, and consequently the sub-grade need not be disturbed, it only being necessary to remove the pavement and the domestic concrete about the base of the rails and lay the new rails upon the old Portland concrete beams.

## A NEW ELECTRIC LINE FOR CARRYING FREIGHT.

Surveys and plans have been completed for the construction of the Oxford (Me.) Central Railway, and active operations will begin about the first of April. The road with three branches will be 31 miles in length, and will connect Oxford, Norway, Waterford, Harrison, Bisbee Town, North Waterford, Lynchville, East Stoneham, and other settlements and villages in this locality. This country is heavily timbered, and it is expected that the saw mills will furnish much of the traffic for the line. Already 30,000 tons of freight business per year have been guaranteed by 26 different firms. The power house will be located at Rice's Junction, where the road branches. The equipment will consist of 2 large passenger cars, 8 wheels, 45 feet over all; 4 G. E. 50 motors speeded to 50 miles an hour; 4 observation cars, carrying 100 to 125 passengers, and several 36-foot freight cars. The guaranteed business of the road is now \$42,810, and with an estimated operating expense of \$16,792, this will leave a fair profit on the investment of \$260,000, which the road will cost.

## THE CALUMET ELECTRIC STREET RAILWAY.

It has been rumored that the South Chicago City Railway was to absorb the Calumet Electric, but this has been strenuously denied by the officials, who say that no negotiations of any kind are pending. The fact that the company has been reorganized indicates that no sale is imminent. John Farson has been re-elected president and H. M. Sloan general manager. The National Bank of Illinois now has a controlling influence in the board of directors. George C. Prussing, John C. McKeon, James R. Mann and George E. Adams have been chosen to fill the vacancies left by F. W. Leach, Carl Moll, Robert Berger and H. B. White. It is believed that with proper management much can be accomplished. The road operates 70 miles of track and touches many of the suburbs and small towns south of Chicago. It is well equipped, and in the summer time the capacity of the road is taxed to the utmost.

## ST. LOUIS STOPS AT FAR CROSSING.

One by one the several cities which inaugurated the near crossing stop to receive and discharge passengers have returned to the time honored system of stopping at the far crossing. St. Louis has now returned to the old way as did Baltimore, Chicago, Cleveland and the others. We have never been able to see any advantage in the near stop while the disadvantages are many and evident. The annoyance of either alighting in the street 20 feet from crossing or curb, or else passing out through the front door and motor-man's platform, is great, particularly in stormy weather. Strangers accustomed to the far stop at home usually miss a car in learning the exception to the general rule, when in other cities. Much time is lost also in allowing teams on cross streets to pull in ahead of the car.

Ostend and Middlekerke, Belgium, will be connected by electric railway, the executors of the late Col. North having determined to carry out his plans.

## THE REDUCTION IN STREET CAR FARES.

The daily press from the Atlantic to the Pacific, in daily, weekly, Sunday and extras, has shouted itself hoarse in the assertion that everything has been cheapened in price, but street car fares alone remain the same.

The reader would naturally suppose from the decided and authoritative declaration so often made, that the daily press had studied the question carefully, and based its assertions on evidence which can be put in figures. But if one analyzes the problem he will find quite the contrary to be the fact.

Very much of what goes to produce one ride in a street car has "not decreased in price." Certainly the car itself has not cheapened. Any boy could answer that after one glance at the old bobtail and two-horse cars, and the present type of rolling stock. In replacing the narrow platforms with capacious ones; in substituting electric and hard coal heaters for the damp hay which formerly covered the floor; in brilliantly lighting the modern car like a drawing room, where once a little foul smelling oil lamp hid in a box at one end of the car leaked oil on the passenger below:—in none of these respects has the cost of producing a car ride cheapened. The old time tracks which were used until reduced to little more than a streak of rust, would not carry the modern electric car a single block. The new and heavy and easy riding equipment requires tracks which are heavy and strong and smooth, and which costs from two to three times as much to build as in the old horse days. The car windows must be large and of good quality glass; the car must be warm; it must be kept clean; while the old style wooden seats with sometimes a bit of thin carpet tacked on, would hardly meet the fastidious demand of a public which has been cushioned on plush and springs. The wages paid the motormen and conductors are certainly no less than was paid in ante-electric days; with scarcely an exception the wages now paid are very much higher. Where then is the "great reduction in the prices of everything" of which we hear so much?

But taking the question as first stated, that car fares alone have not suffered in the general slump in values of the past ten years, let us see what are facts and what is history. The statement, undoubtedly, has been generally accepted without question because there has not been the same opportunity to deny it.

We assert now, as we have previously, that the price of car fares not only has been reduced, but that no other article of as common use has been as greatly reduced in price. The position of the street railway of today is very like that of a tailor, who ten years ago, made the clothes for a boy, and who today, the boy grown to manhood, is still making the suit for the same person, only of vastly better quality and workmanship, for the same price he received then. The riding public has demanded better cars, longer cars, faster cars, more frequent cars, earlier cars, later cars, all night cars; all these have been given but with no advance in the price of a ride. The public has asked each year to have the ride lengthened a little, with no similar elongation in fares, until in many instances the increased ride is now longer than the original haul. All this the street railway companies have done. Then the public wanted free transfers to other lines where ten years ago an extra fare was cheerfully paid, and all over the country, wherever it was possible to do so this privilege has been granted. It is even possible in one

city under the (too) liberal transfer system for a passenger to ride 100 miles in one day on a 5-cent fare.

And yet we hear it said "prices of everything but car fares have been reduced."

Thus far the reader has simply our assertion for the above statements, though it is but fair to presume our statements regarding the industry to which this magazine is devoted are reliable. But we propose to submit specific cases, selected at random from all parts of the country, from the Atlantic to the Pacific, and we believe even street railway managers will be surprised to see what has been the increase in service rendered, without any increase in compensation; indeed, not a few roads which were getting 10 cents for a given ride 10 years ago, are now hauling over the same route with increased distance added, for one five cent fare.

We have selected both large and small cities, without any previous specific knowledge whatever as to what was their increase in ride, and the results are simply astounding.

These 28 cities show an average increase in the length of a 5-cent ride in 1897 as against the ride in 1887, of 237.5 per cent. Another way of stating the same thing is that on the basis of charge then, the company should now receive 16.85 cents instead of the five cents it does receive. There is no other commodity of general use which begins to show the reduction in price that car fares show.

We shall not attempt now to elaborate on the financial benefits which have accrued to individual property owners; to city revenues through increased taxation resulting from enhanced value of real estate, and the new life which came to slow towns with the advent of electric cars. These advantages alone should entitle the street railways to great consideration, for no other element was ever introduced in metropolitan life which has had so extensive and beneficial an effect. This time we shall deal simply with the abstract proposition that the street car fares have been reduced, and reduced to an extent which would bankrupt any manufacturer to meet in producing the necessities of life.

The reduction in price has been in three ways: First, by making a straight 5-cent fare over single routes where formerly 10 cents was charged, (5 cents on each division). Second, by extensions of old lines by which in many cases the haul was doubled and even trebled, but making the entire haul at the old fare rate. Third, by issuing free transfers which gives the passenger a ride on one or more connecting lines at the price formerly charged on each of those lines. A single illustration of this latter concession will illustrate. The Chicago City Railway, which has a very liberal transfer system, issues daily an average of 290,000 transfers. If on changing cars the passenger paid his fare in cash instead of with the transfer ticket, the company would receive \$1,500 per day more than it now does. Of course there is a small per cent of pleasure and visiting riding, which it would not receive but for the transfer system, for people would not go as often on unnecessary errands where the round trip was 20 cents per passenger instead of 10 cents; but the proportion which comes under this head is only a small fraction.

It may also be urged that the free transfer is used to compete with steam roads, but that does not alter the fact that the public receives extra return without any additional expense, nor that were there no street railways there would be no competition. There is no dodging the fact that street car rides have been enormously enlarged, but the price remains the same, or is even less than before.

# Street Railway Review

The first case we will examine is an abnormal one, and tells where we can ride

100 MILES FOR 5 CENTS.

T. J. Minary, general manager of the Louisville Railway Company, advises us as follows:

"We have more than doubled the number of transfers we made in '87, thus giving the public the benefit of six or seven continuous routes, where one can ride from seven to nine miles; in 1887 we only had two. We adopted a universal transfer system, making it at all points where the public would be benefitted, having about ninety different transfers

In Bay City, Mich., the fare was straight 5 cents as far as the center on each of the lines shown up to 1892. Now, for a single fare one may ride from the end of any line to the end of any other, the maximum ride being 189 per cent of what it was prior to 1892.

In Atlanta, Ga., the Consolidated Street Railway Company, in addition to extending all of its lines as shown in the diagram, making them on an average 147 per cent longer than in 1887, has reduced the fare on the Atlanta & Decatur line from 10 cents to 5 cents.

The combined effect of extensions and transfers is well shown in the case of the National Railway lines of St.

Twenty-five per cent of our passengers take advantage of the transfer system, and you may know this is liberal, when I say they can, by going a little out of the way, repeat the transfers with us, and if they so desire, can ride all day, or 100 miles for five cents."

In all of the diagrams the full lines represent the road in 1887 and the dotted lines the extensions made since that time.

Louis. In comparing the conditions of ten years ago and today, General Manager McCulloch says; "1887—speed 6 miles per hour, small cars, rough track, cars not warmed and no transfers; 1897—speed 12 miles per hour, large cars, smooth track, cars heated and a transfer system, doubling and trebling the present increased length of roads. Fare five cents including transfer." This makes the 5-cent ride 257 per cent of what it was in 1887.

The chart represents the hauls on the different lines of the City & Suburban Railway Company of Baltimore. All the companies give free transfers good on any line operated by the company within the city limits, which practically doubles the service given for 5 cents. J. F. Heyward, general manager of this company writes: "I can testify that the Baltimore companies are giving a great deal more to the public than formerly, and would state that on summer evenings we carry passengers a distance of 16 miles for a single city fare. This only went into effect last year and is one more concession added to the many received by the public. There can be no argument made to hold the position that prices of everything except car fares have been reduced in the past few years."

The layout of the Third avenue line and its connections is such that it is difficult to make it clear without a map of the city. The cut however, shows in a diagrammatic way the mileage of the original line which runs from Broadway and Park Row to 131st street, and of the connecting lines. The 43rd street, Manhattanville & St. Nicholas avenue system

with 12 miles of tracks, intersects 3rd avenue at 42nd street and 110th street, giving two cross lines and two lines running by different routes between 42nd street and Manhattanville. From 125th street and 3rd avenue the 125th street and Amsterdam avenue line runs north to 216th street. The Kingsbridge extension, now building, will have 10 miles of track and runs from 116th street north. In the down town districts, between the city hall and 18th street, the 3rd avenue line is intersected by several lines of the Central Cross-town and the Dry Dock Railway Companies, with an aggregate of 16 miles of track. All track mileage is of double track.

In the diagram, all other lines are shown as connecting with the 3rd avenue line at its northern terminus, which is not the case. This arrangement is adopted to bring out the better facilities now afforded to patrons. Prior to 1895 no transfers were given, so that the original 8 miles on 3rd avenue was the 5-cent ride at that time. In that year the present system of transfers was inaugurated on the lines

shown and the 5-cent ride has now a maximum length of 18 miles as opposed to 8 miles two years ago, with the additional advantage to patrons that it may commence almost any

place and end any other place, the maximum ride for 5 cents being 225 per cent of what it was in 1894.

The diagram shows the track extensions of the South Covington & Cincinnati Street Railway since 1887, the present maximum haul being 4½ times what it then was. In 1887 the fare was uniformly 10 cents with no transfers, now it is 5 cents with transfers, giving the patrons 9 times as much for the same money as was done 10 years ago. In addition electricity has replaced horses as motive power.

Springfield, Mass., is another city that has received the

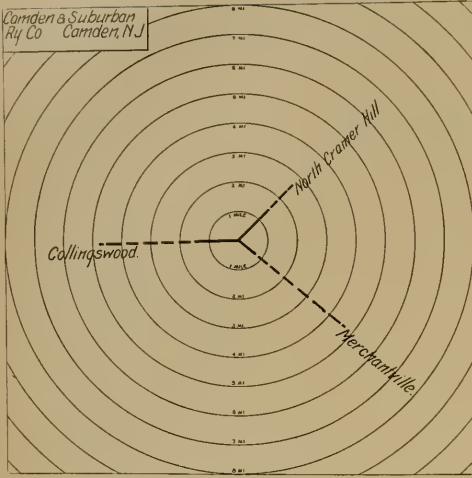

advantages of a reduced fare as well as a longer haul for one fare. In 1887 the fare on the Springfield Street Railway was 6 cents, and the greatest distance that a pas-

# Street Railway Review

sions, as shown on the diagram, the Camden & Suburban Railway Company has 5 lines which run by different routes to the same points, with free transfers over all lines. The fare to any point is 5 cents. The longest haul now is three times what it was ten years ago.

In San Francisco the Market Street Railway Company

senger could ride for one fare was about 3 miles, including transfer. At the present time the fare is 5 cents and the greatest distance for one fare, including transfer, is about 17 miles, or  $5\frac{1}{2}$  times as much ride for one fare. When, to

has succeeded to thirteen other transportation companies, and has increased the length of haul by extending lines, by introducing a transfer system and in addition has reduced the fare from 10 to 5 cents. The longest haul today is 14 miles, as compared with  $5\frac{1}{2}$  miles ten years ago, and this is given for one-half the money.

The relative length of street car rides for a single fare in Brooklyn is partially shown by the diagram, in which the dotted lines show four of the hauls made at the present time over the lines operated by the Brooklyn Heights Railroad Company, and the full lines show four of the long hauls

revert to the terms made so familiar to us during the past year, the purchasing power is considered, the patron gets 6.8 times as much for his money.

In addition to increasing the track mileage on the divi-

# Street Railway Review

made in 1887. In connection with this diagram President Rossiter says: "Further than shown, a man by our system of transfers from one route to another may ride for the period of his natural life, if he bring his food with him."

On the Union Depot Railroad (St. Louis) Company's lines, in addition to the extensions shown there is a system of transfers by which the passenger may ride for 22 miles

largely due to the transfer privilege which is being extended every year. In 1897 the maximum ride for 5 cents is 243 per cent of what it was in 1887 when transfers were unknown.

On the Paterson (N. J.) Railway the present maximum is four times as long as in 1887.

The Lindell Railway Company of St. Louis gives a haul that is 280 per cent of what it was in 1887 and in addition gives transfers at almost all intersections.

C. F. Hutchings, superintendent of the Wilmington (Del.) City Railway Company, writes:

"We originally had two lines in the town and no transfers, so the longest ride for 5 cents was the length of one line which was 1.89 miles. All the lines are now run by one company with full privilege of transfers which gives the longest ride 5 miles for five cents."

The diagrams for railways in 17 cities which are shown in pages 79, 80 and 81 scarcely need any detailed comment. For the purposes of comparison the ratio between longest 5-cent ride in 1897 and in 1887 has been computed for the 30 roads for which sufficient data was furnished, and the results shown graphically in the diagram.

There are instances in which the comparison between the longest rides in 1887 and 1897 fails to convey an adequate idea of the improvement in transportation facilities that has really been effected. Such, for instance, is the case in Providence, R. I., where the length of the longest line is now

in one direction for a single 5-cent fare. In 1887 there were no transfers.

Several roads have submitted diagrams of their lines showing the maximum hauls only, and these have been brought together in the accompanying figure.

In Rochester, N. Y., the increased length of haul is

\* Not including the transfers which are allowed on all times  
 \*\* Fare in 1887 was 10 cents  
 † Fare in 1887 was 6 cents

only 20 per cent more than that of the longest line in 1887. However, there are now 22 lines with an average length of 4.58 miles, and then there were 18 lines with an average length of but 2.76 miles.

Also in Columbus, O., ten years ago, there were 8 lines, average length 2.63 miles with very limited transfers, while in 1897 there are 7 lines, average length 5.06 miles, with universal transfer system.

It will be remarked that in the foregoing diagram there is no definite relation between the population and the increase in length of haulage; New York and Philadelphia are among the low ones and Chicago and Brooklyn near the top. In a single instance only is the 5-cent ride less than twice as long as it was ten years ago, and the average for the 30 roads shows it to be just 33 3/4 times as great. If one were to make allowance for the continuous trips as provided for on the Brooklyn and Louisville roads this latter figure might be indefinitely increased.

Having shown what the street railway companies are now furnishing for 5 cents and how it compares with the service rendered in the good old days, we shall conclude with a com-

parison between the power of money to purchase street car rides and some of the other necessities of the patrons and also of the car companies, which is self explanatory.

Labor was not included in the foregoing table for the reason that complete statistics for the roads shown were not at hand. Such incomplete data as we have, indicate that labor has not shared in the general decline but, that wages are higher, absolutely, than ten years ago. On one of the large Chicago lines the trainmen's wages have been increased 80 per cent since 1887. Labor, however, is the most important item in the expenses of street railways as will be seen by examining the reports of the Connecticut street railways shown on another page, where the item of wages is on an average 37.9 per cent of the total operating expenses which amount to 70.4 per cent of the gross receipts. Be it well understood that the item wages does not include salaries, the latter being for the Connecticut roads 9 per cent of the operating expenses.

### ACCOUNTANTS' ASSOCIATION NEXT MONTH.

The indications are for a large attendance at the meeting of the street railway accountants in Cleveland, March 23-24. Acceptances from upwards of 50 roads are already received, with 20 more which hope to send delegates but cannot absolutely promise so far ahead. The letters from officials are with one single exception very urgently in favor of the new work. The one road in question considers its system perfect and could not expect to learn anything new by coming, which latter statement is undoubtedly true in the case of the person who holds such views.

The meeting is an assured success and will prove one of the most helpful and interesting assemblages of street railway men ever held. Among the subjects for papers are the following:

#### FROM HORSE CAR TO ELECTRIC ACCOUNTS.

Showing the almost entire transformation brought about by change in power.

#### STATISTICAL REPORTS IN A NUTSHELL.

Showing time and manner of making complete, yet condensed, weekly, monthly and annual reports, requiring but a few minutes time of the busy officer or stockholder to get at the cream.

#### USEFUL AND USELESS CLASSIFICATIONS.

Showing how little division of accounts may be used to accomplish excellent results, and how much has and can be done to wear out the patience of the auditing department and owners of the property to get at what is wanted.

#### MONTHLY CLOSING OF ACCOUNTS.

Showing how creditors may be required to present bills promptly when material or labor is furnished and present statement of account on the first of each month; how bills may be certified to by heads of department when received and turn same over to auditor; and all other matters relative to the month's business.

#### EARNINGS; HANDLING AND ACCOUNTING.

The care and handling of the fares received from passengers from the time they are collected by the conductor until they are deposited by the treasurer. This paper to embrace the registration and recording of fares and depositing of same by conductors, the form of trip card, the making up of the

daily receipts on the books in the office, the method of counting and checking same with forms of register records, cash balance sheets, short lists, etc., etc.

#### STANDARDIZING ACCOUNTS.

A standard system of accounts; classification of operation expense accounts, and form of report that will admit of comparison and diffuse information between companies.

#### NAMING AND STANDARDIZING APPARATUS.

The necessity of, and assistance to the accounting department, of the naming and standardizing of apparatus and appliances used in the operating department.

#### TRANSFER TICKETS.

From the time they are printed until they are destroyed; keeping in stock; issuing to conductors; collections; checking with trip reports; records.

#### INTER-URBAN ACCOUNTING.

A system of accounts for interurban lines; differential rates of fare; pro-rating fares with city lines used; keeping record of mileage run on city lines used; registering or receipting fares.

There will be one or two trolley rides about the city with probably a run out on one of the several interesting interurbans for which Cleveland is famous.

Officers who intend being present are requested to make notes of such points as they especially desire discussed and hand them in the first day. It is suggested also that each one bring a complete set of his forms and blanks for comparison and study. There can be no question that at this meeting many a tough problem which has caused endless worry and study will be found to have been successfully worked out by some one.

The Hollenden hotel will be headquarters, and a spacious room, well lighted, has been placed at the disposal of the association for its sessions. The accountant who fails to attend this meeting will miss something he cannot afford to lose.

### TOO LOW A FARE IN BROOKLYN.

The Nassau Electric Railroad Company of Brooklyn, has been enjoined from carrying passengers from the Brooklyn Bridge to Coney Island for five cents, and may have to charge to cents. The restraining order was issued by Judge Dickey of the Supreme Court, at the instance of the Brooklyn Elevated Railroad Company, which complained that in reducing the fare the Nassau Company had violated an agreement and in consequence the elevated road had suffered a reduction of \$15,000 in receipts. The court ordered the Nassau Company to pay this amount. The company will appeal the case.

### MIGHT TRY WIND NOW.

The Oswego, N. Y., electric lines are in grief. In October the road went into the hands of a receiver, has been losing money since, as before, and is behind in its pay roll over \$1,600. The reserve engine at the power plant was wrecked by an accident and the water power which has furnished power most of the time failed by reason of the water in the hydraulic canal being drawn off to permit the annual repairs. Fire and water having failed there seems but one of nature's forces left untried, and we mildly suggest trying a wind-mill.

## CONDUCTOR'S RECORDS IN MILWAUKEE.

A set of blanks and a system by which conductors can conveniently keep trip accounts and records of accidents is absolutely essential to a railway of any magnitude, and the more complete the records can be made the more valuable will they be to the auditing and claim departments. The

blanks, which we illustrate, are those used by the Milwaukee Street Railway Company. They were adopted several months ago and have been found to serve the intended purpose, without imposing too much clerical work on the conductors.

Each conductor is provided with a cloth portfolio, 9 inches long by 4¼ inches wide, in which are carried three forms; the trip record blank of which Fig. 1 shows the front and Fig. 2 the back, a defect card and an "accident" form. The

trip record and the defect card are each about 4 by 9 inches, the latter red in color, and the accident form is 8 by 9 inches and folded.

The trip record as shown in Figs. 1 and 2 provides for a record of the time and fares collected on one side, and for register readings and transfers issued on the other. One side of the portfolio when opened shows a sample trip record slip properly filled in for the instruction of the conductor. On the other side are instructions

### WHAT TO DO IN CASE OF ACCIDENT.

The motorman will: Stop the car. Go to the assistance of the injured person. Secure his name and address.

The conductor will: Secure names and addresses of all available witnesses whether passengers or bystanders. If accident is serious, notify telephone No. —.

If property has been damaged: The motorman will assist conductor in securing name and address of owner. Name and address of witnesses. The extent of the damage. Also in making out report. Notify inspector as soon as possible.

Form #1  
Milwaukee Street Railway Co.

**ACCIDENT NO.** .....

Name of Injured Person: .....

Address of same: .....

Property damaged: .....

Name of Owner: .....

Address of Owner: .....

Car No. ....

Line .....

Report Filed .....

City Agent .....

HOW THE ACCIDENT OCCURRED.

I certify that the above is a true statement of the occurrence.

Conductor .....

189

To Superintendent  
Dear Sir:—I have to report the following accident which took place in connection with my car this day, as follows:

Car No. .... Line .....

Conductor .....

Exact Place .....

Car Going .....

Badge No. ....

Motorman .....

Exact Time .....

Sped .....

NAME	ADDRESS	NATURE OF INJURY OR DAMAGE

NAME OF WITNESS	ADDRESS	WHERE STANDING AT TIME OF ACCIDENT

FIGURE 3—FORM FOR REPORT OF ACCIDENT—FIGURE 4.

The conductor will report on accident blank: Injury to person or property occurring in connection with or caused by his car. Falling of passenger when taking or leaving car, no matter how slight the injury. Ejection of passengers. Turn over report to station master before going off duty.

Wire down. When first car arrives at break, motorman will immediately take charge of the prostrate wire, warning all persons away from it, until relieved by another representative of the company. The conductor will run to the nearest telephone and notify No. ——. When necessary to pay toll it will be returned upon application to the station master.

The instructions above given serve to fully explain the accident form, shown in Figs. 3 and 4.

The defect card is a printed form on which is to be reported any damages sustained by the car. The back of this form is to be filled in by the inspector who investigates the case and when the superintendent has passed upon it the card bears a complete record of the case.

## ELECTRIC TRACTION IN LYONS.

BY EMANUEL KUHNE.

The introduction of electric traction on the street railways of Lyons is due to the energy and progressive spirit of Monsieur Bonnet, director of la Compagnie des Omnibus et Tramways de Lyon, through whose efforts the Oullins line of this company was equipped with electricity in the early part of 1894, the French Thomson-Houston company having charge of the installation. Because of the excellent results obtained with the new motive power, a second line, the Lyon-St. Fons-Venissieux, was also changed from horses, the transformation being completed in August, 1895. Each of these lines is about 5½ miles long and has its separate power plant.

All the old tracks in Lyons, as throughout France, are laid with what is known as the "Marsillon" rail which, as is shown in the illustrations, comprises two rails, the rail proper and the guard rail. The rails are about 4 inches high and together weigh but 60 pounds per yard. The running rail is of the same dimensions as the guard rail except that the head is 1¾ in. wide instead of 1 in., thus making it really about a 35-pound rail that is used. These rails are supported in chairs 6½ in. deep, bolted to cross ties placed 4 ft. apart. The distance between the rail and the guard is 1½ in., which

is maintained by bolts and filler pieces spaced about 2 ft. apart.

As might have been expected the new service proved too severe for the old tracks and the joints were so bad at the

JOINT, BROKEN TO SHOW WELD; THE FINISHED JOINT.

end of a month that the company decided not to equip its other lines electrically until financial conditions should permit the rebuilding of the tracks and the substitution of a heavier rail, which appeared to be in the far future. Fortunately a satisfactory substitute for rebuilding was found in the cast-welded joint, which has proved to be so efficient in

MOLDS TO FORM FLANGE WAY.

America. The work of cast-welding the joints on the lines already electrified was begun in December last under the supervision of Mr. Hoffman of the Falk Manufacturing Company of Milwaukee, U. S. A. Since commencing, the joints have been cast at the rate of from 70 to 80 per night, for all the work is done at night so as not to interfere with traffic. One of the illustrations shows the cupola and the pouring of a joint. Because of the narrow streets the screen, which is seen in the foreground, is placed in front of the joint as it is poured to protect passers by from the possible splashing metal. The views of the finished joints will serve to give a better idea of the rails which were previously described. Notwithstanding the rails have been laid for years no difficulty is experienced in securing a perfect weld, the joint being stronger than the rail.

The cast-welded joints proved to be so efficient that when three miles of track had been welded, the Falk company was awarded the contract for welding all the track of the Compagnie des Omnibus et Tramways de Lyon, about 33 miles. This is to be equipped electrically and the company expects to have it so operated by the fall of 1897.

The new central power station, now building, about 1½ miles from the center of the city, is well under way. The generating plant will comprise four 400-k-w Thomson-Houston (of Paris) generators, direct connected to horizon-

POURING A JOINT.

A CONDENSING TANK.

tal steam engines, by Piguët of Lyons. Steam will be furnished by semi-tubular boilers. Water for condensing the steam is supplied by two large wells. The method of condensing in tanks so common in France is shown in one of the illustrations. The walls of the building are of concrete consisting of two parts cinders and one part cement. The photographs show exterior and interior views of the boiler house.

Current will be conveyed to the cars by an overhead trolley wire except for about three-fourths of a mile in the heart of the city where a system of surface contacts will be used. The trolley wire is to be supported on ornamental poles available for street lamps. As several of the lines of the company are distant from the central station it is necessary to use heavy feeders. These are the ordinary armored cables and are laid in the ground, no tile or other conduit being used. To protect the cables from accident when excavating in the street at any time in the future, a strip of wire netting is laid a few inches above the cable, so that when it is reached the men may know that the cable is near and avoid injuring it.

The rolling stock will consist of 150 cars, 50 of them the old double-decked horse cars transformed, and 100 new ones of the type shown; all will be equipped with the G. E. 800 motors by the Thomson-Houston company of Paris. The old cars seat 60 and the new ones 50 passengers each. Municipal regulations require that each car have a speed indicator, and a simple one designed by Monsieur Abdank, directeur of the Volta laboratory, has been adopted.

Other tramway companies in France have been awaiting

the outcome of the Lyons experiment and as a result the Falk Manufacturing Company is now building five cupolas which are to be used in Paris, Marseilles and other cities contemplating a change in tractive power, and there is no doubt but that during the current year there will be an enor-

VIEWS OF POWER STATION, NOW BUILDING.

CAR USED AT LYONS.

mous increase in the use of electricity as a tractive power in Europe.

Mr. Hoffman, who is now in the United States will return about the middle of March and in addition to the Falk company will represent several large American supply houses. This field is now much more promising than in America.

"Cahall-Babcock & Wilcox Boilers" is the title of a very handsomely illustrated sixteen-page pamphlet, issued by the Cahall sales department, Pittsburg, Pa., describing this type of boiler. Accompanying it is the report of efficiency and capacity tests of these boilers made by J. M. Whitman, of Philadelphia, which show excellent results to have been obtained.

## DOUBLE GRIP POLE JOINT.

A pole joint is being exploited by John Spencer, of Wadnesbury, England, for use in building up tubular electric railway poles. It consists simply of a sleeve upset at the

ends to prevent telescoping. Some large contracts are being filled with this device. The inner tube is hung upon the outer one and all are shrunk together, making a compact and rigid joint.

## CURRENT CONSUMPTION OF MOTOR CARS UNDER VARIOUS POTENTIALS.

By James R. Chapman, Manager Electrical Department North and West Chicago Street Railroads.

Having observed that operating men generally believe that as the potential on a line decreases the amperes used by motor cars increase, some experiments were made with a view to ascertaining the relation between the two measures of energy in terms of car-miles. The results are tabulated below and show plainly that, at low voltage, the ordinary street car motor consumes less volume of current than when operated at normal potential. Further, that the energy required to move a car a mile—as measured by watt-minutes—is less at low potential than at normal, while the ampere minutes per car-mile increased as the potential drops. The natural deduction is that cars can be operated more cheaply with a 500-volt station potential than with 550, provided of course that the slight loss in speed does not require more cars to be operated to maintain the same schedule.

It is of course understood that slightly different results might be obtained in commercial service, but the experimental method adopted is the only one wherein the same results can be obtained twice in succession under precisely the same conditions. It is possible that some manager having a switch-board watt-meter will take this matter up and give average results between operating his station at 500 volts for a period and then at 550, watching weather and all such governing conditions, so as to give fair results in both cases.

Many 500-volt stations, built six or seven years ago, have been speeded up so as to run at a switch-board potential of 550 volts. Unless the operating schedule has been changed so as to increase the number of miles per car per day, it would seem as if this higher potential were a mistake, as viewed from the standpoint of fuel per car-mile.

### GENERAL DATA.

Date.	December 16, 1896.
Kind of Car.	Twenty-one-foot body. Thirty feet over all
Truck.	Four 33-inch wheels, 8 feet, 6 inches base.
Motors.	G. E. 800. K 2 Controllers.
Instruments.	Weston, round pattern, fixtures in the car.
Watt-meter.	Thompson Recording, 150-ampere capacity, portable pattern.
Length of Run.	2.01 miles.
Character of Track.	Level, straight.
Rail.	86-lb., surface dry, some little dust.

### NOTES.

In each case run was made without stop, on 8th point of controller (loop not used). Special track was encountered twice in each run, requiring current to be cut off and speed checked to about eight miles per hour.

All calculations based on 10-second reading of indicating instruments; comparison, however, was made at the end of each run with recording watt-meter, the rate of variation being practically the same for each run, and the watt-meter always lower than the product of the volt ampere readings.

The low potential was obtained after regular operating hours by bringing current from a distant power house, via a circuitous feeder route, and switching on car heaters in barns along the route until the desired potential was obtained.

Average Run.	Average Voltage.	Average Amperes.	Time Used.	Total Watt-Minutes.	Watt-Minutes per mile.	Total Ampere-Minutes.	Ampere-Minutes per mile.
1.	521.37	29.59	6 min. 40 sec.	102,847	51,168	197.27	89.14
2.	509.74	31.75	6 min. 30 sec.	105,196	52,336	206.37	102.67
3.	493.83	29.66	7 min.	102,520	51,009	207.62	103.29
4.	401.85	27.37	7 min. 30 sec.	82,490	41,039	222.45	110.67

## WIRE THIEVES IN TROUBLE.

The Chicago City Railway had indictments for malicious mischief and grand larceny brought against the four men who attempted to steal a thousand feet of copper cable. Between 11 and 1 o'clock at night these men cut the line which forms the return circuit to the new power house on 47th street and Oakley avenue. They climbed a telegraph post, adjoining the street railway lines, and by means of two old saws and a hammer, severed the cable. Cutting it into 100 foot lengths they dragged it across the fields to the railroad. Here they coiled it up and hid the wire expecting to remove it at their leisure and sell it for old copper. It was insulated cable of 49 strands of No. 16 wire and worth about 16 cents a foot. The employes soon discovered the theft and detectives were put on the track of the guilty parties. They were soon captured and tools found in their possession which indicated that the men made a regular business of stealing car brasses, bearings, etc., and selling them for scrap. It is the intention of the company to make an example of these men and prosecute them to the full limit of the law.

## CARE OF MOTOR CARS.

It has been the policy of the West Chicago Street Railway to prohibit the motormen and conductors from tampering with the electrical machinery. The superintendent believes that a "little knowledge is a dangerous thing" and so has not given a course in electricity to his motormen. A motorman has only to manipulate his controller and replace a blown fuse. A thorough system of inspection is carried on, each motor being overhauled, cleaned and painted every 90 days. Few accidents have occurred and the number of burnt out fields and armatures is surprisingly small. One winder, working two days a week, is able to keep 100 motor cars in perfect order. This result seems to justify this system.

Glasgow's street railway committee has voted to send the manager and engineer-in-chief of the city lines to the United States to learn the latest and best electric railway practice.

## PRACTICE IN ELECTRIC RAILWAY POWER DISTRIBUTION IN EASTERN MASSACHUSETTS.

Considerable has been written in the past on the theory of power distribution for electric railways. The arrangement of feed lines for various requirements and the possible uses of boosters, three wire systems and alternating current transmissions have been enlarged on until there is little need to tell the well posted railway electrician what the possibilities are.

The present article is intended only to deal with work that has actually been done on some of the extensive network of lines covering the entire eastern part of the state of Massachusetts. In the locality mentioned nearly every variety of problem in electric railway feeding presents itself, and the solutions adopted by the progressive electrical engineers of those roads will no doubt be of interest to others. Moreover there may be those who are hesitating about trying some of the experiments that have there been tried and a knowledge of the success of these experiments will enable such to go ahead confidently with the improvements contemplated. Eastern Massachusetts has electric roads of all varieties, from the crowded city lines of the West End Street Railway of Boston, to the long interurban lines of light traffic owned by other companies in the surrounding region. We will take up first the peculiar features in the feeding system of the

### LYNN & BOSTON RAILROAD,

which operates an extensive interurban trackage as well as the city lines in several municipalities. E. C. Foster is general manager and the electrical problems have been worked out by the company's very progressive electrical engineer, Maurice Hoopes, who is we believe the originator of several important innovations in electric railway feeding practice.

This road was one of the pioneers in adopting the plan of connecting its power stations in regular operation for the purpose of equalizing the load between them. This plan is one which was looked upon as a doubtful experiment by many outsiders when it was first tried but it has never given any trouble and is a decided advantage in several respects. The way this connecting together is accomplished is by simply taking out or "jumping" the section insulators between adjacent sections formerly fed from two different stations.

This plan is shown conventionally in Figure 1, which represents a straight line of road of a length requiring it to be fed by two power stations 1 and 2. It is divided into sections a, b, c and d. When the common plan is employed of

FIGURE 1.

operating the two power plants entirely independent of each other, section b is fed from station 1 and section c from station 2. To connect the stations together to operate successfully it is only necessary to put a "jumper" over the section insulator at x. The practical result is that when the load on section b is light and that on c heavy, station 1 helps station 2 pull the load on section c. In other words the neutral point between the stations is constantly shifting according to the location of the heavy loads.

The value of this arrangement from the standpoint of economy and reliability lies in two facts, one of which relates to the economy of operation and the other to reliability and to the investment necessary to secure reliability. It tends to improve the economy of the stations so connected because the load is not so fluctuating on any one station, and the more constant the load the greater the economy of the steam plant. To take an extreme example, suppose on the road indicated in Figure 1 the cars become bunched on sections a and b, leaving none on c and d. If the stations are not connected to help each other, station 1 will have an enormous overload and station 2 no load whatever. But if they are connected at x, station 2 can take a good proportion of the load and both stations will work economically and without undue strain. In such a case as that just assumed station 2 would not naturally take half the total load, because of the greater resistance of the feeders between it and the sections where the load was, but by raising its voltage sufficiently above that of station 1 its load could be made equal to that on station 1.

Another economical advantage will be spoken of in connection with the West End system. The second advantage, that of reliability with a minimum investment, is readily apparent when it is seen that reserve apparatus at one station is available to help the other station or stations in case of breakdown. Thus, when there are a number of stations tied together there need be but one reserve unit in one of the stations, whereas if they were operating independently, each station would have to have its reserve unit to say nothing of the fact that each station would have to be provided with apparatus to take care of a greater maximum load because it could not receive help from the other stations. It is a well known and understood fact that two machines running in multiple can take care of more cars on a road than the same two machines operating independently. It is but a logical carrying out of this that two power stations in multiple can pull more cars than the same power stations operating independently. It is desirable though, not absolutely necessary to have direct telephone communication between stations when such an arrangement is to be practiced.

One of the first questions that the practical station operator will ask about such a plan is regarding the current for which the circuit breakers are set on the feeders that are supplied from both stations. It is the custom on the Lynn & Boston road to set the circuit breakers on sections which are common to both stations so that they will only go out on a very heavy current a little less than the current required to open the generator circuit breakers of the entire station. Of course this means that it will require a very heavy short circuit on the line to open the breakers, but that is but a slight objection and weighs little beside the advantages of the system.

The accompanying map, Figure 2, shows the Lynn & Boston system. It will be seen by reference to the key that quite an extensive network of lines is connected to both the Lynn and Chelsea stations. This network really constitutes one big section common to the two stations and is made by connecting together four regular sections. Each of these four sections has its individual feeders and the connection between sections is made by long stretches of No. 0 trolley wire over single track. This arrangement makes possible a rather peculiar practice which is resorted to in order to keep cars moving in case of short circuit on one of the sections.

In event of trouble on one of the four connected sections its feeder switch in the station is left open and the resistance of the trolley wire connecting that section with the others is such that it is possible to keep in the circuit breakers on the other feeders and operate the other sections. This compensates for the disadvantages of having so large a mileage of trolley wire connected together.

Much use of boosters and high voltage feeders is made on this system. One part of the network fed by both Chelsea and Lynn stations is fed by a booster in the Chelsea station as indicated on the map. The practicability of feeding part of a network by booster and part by direct 550-volts, has been questioned, but it is working with perfect success.

two posts on this board. One of the field connections is connected to one end of the shunt. The other is attached to a clamp that can be fastened at any point desired along the german silver strip. This booster, which has a rated capacity of 550 amperes as a generator, is adjusted to give 30 volts for every 100 amperes passing through it, or 165 volts when its rated current is flowing through it. However, as high as 900 amperes are sometimes temporarily passed through it, giving 270 volts rise—a total pressure at the power house on the booster feeder of 800 volts.

As previously mentioned, this road also adopted the plan in a few cases of running some feeders at a higher voltage than others. What is of special interest regarding this plan

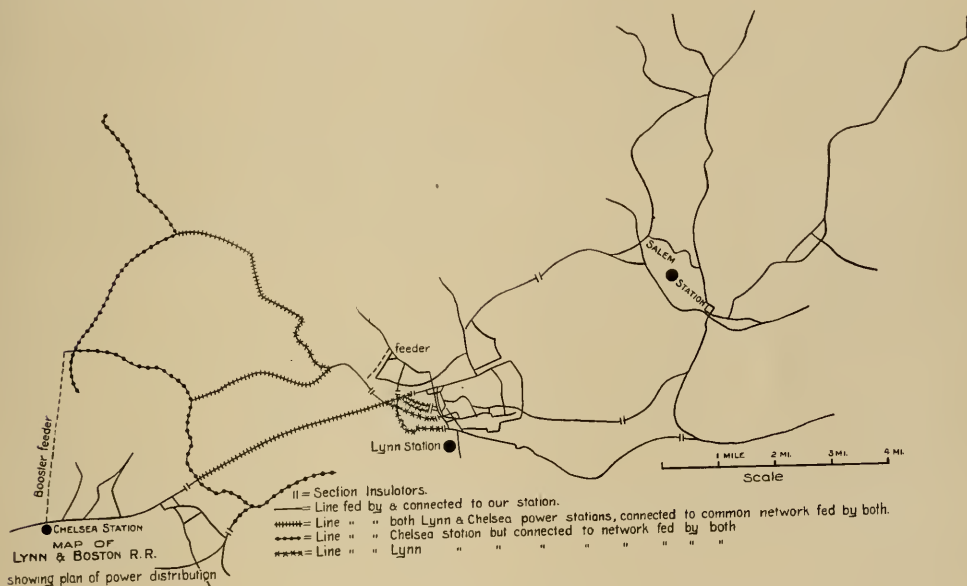

FIGURE 2.

The booster feeder is 4 miles long and the position of the road which it feeds reaches a point  $9\frac{1}{2}$  miles from the power house.

The booster used is a regular m. p. 300 kilowatt railway generator with the shunt field dead and a german silver shunt around the series field. It was found that this machine when run as a booster with the full series fields as used for the ordinary railway work would give as high as 400 volts, with the total rated current of the machine flowing through it, and consequently it was necessary to put a shunt across the series fields to keep the voltage down to the desired amount. The high voltage produced by the series field when working alone as compared with the comparatively small rise in voltage it gives when run as a compound winding when the shunt field coils are in action, is accounted for by the fact that the current in the series coils of a generator with the shunt field excited act on field magnets that are brought nearly up to saturation already by the shunt coils and consequently their effect is small. The german silver shunt around the series coils is mounted on a board fastened to the machine. The german silver conductor is stretched between

as used here is that some of these high voltage feeders feed into the same sections that are fed by the regular 550 volts at points nearer the station. This plan has given no trouble whatever as there is no possibility of the high voltage machines feeding back into the power station and running the lower voltage generators as motors except when there is no load on the line—in which case the high voltage is not needed.

Some of the schemes used for connecting up boosters and high voltage machines to the switchboard will be of interest to those contemplating similar work. It is a simple matter to design an entirely new board to take care of such things compared to what it is to plan desirable ways of accomplishing the same results temporarily or with the existing switchboards. Figure 3 shows the method used for connecting in any machine desired as a booster without altering the permanent switchboard connections. It leaves the booster free to be used as an ordinary generator any time desired. Two feeder panels of the ordinary type are shown, including single pole switch, ammeter and circuit breaker. One generator panel is also shown with a three pole switch and the

connections of the generator to the switch. The other connections on the generator panel are not given as they are not used when the generator is run as a booster and, the three pole switch being open, they are entirely out of circuit. The

FIGURE 3.

generator with its series field is shown, as is also the adjustable german silver shunt around the series field. To connect the machine in as a booster, flexible cables are used, which have terminals on their ends that fit in between the jaws of the switches on the board. These cables are indicated by the dotted lines, and of course are run in front of the board. It would be possible of course to run these connections back of the board, but as there would then be nothing to indicate that such connections were made there would be more liability of a mismove on the part of the switchboard attendant that would result in a bad short circuit. With the present arrangement the switches can not be closed to make the ordinary connections without removing the booster connections. The same arrangement can be made with any modern type of switchboard as the equalizer connection is left open.

The board at the Lynn power station is being changed over so that any generator can be run on the high voltage bus bar at 650 volts or on the low voltage at 550 volts. The board is of the early panel type put out by the General Electric Company, having the equalizer run behind the panels. Figure 4a shows the generator connections to the switchboard as they now exist, and Figure 4b shows the

FIGURE 4A.

FIGURE 4B.

connections after the change is made. In the final outcome what was formerly the equalizer bus on the switchboard is changed to the high voltage bus and the equalizer is not brought to the switchboard but is simply run along the row

of generators. Of course with the new arrangement two equalizers are necessary, one for high voltage, the other for low. At each machine a double throw equalizer switch is provided so that it can be connected to either equalizer at pleasure. The negative connections of the machine to the switchboard remains the same. Instead of a three pole main switch three single pole switches are put in. The equalizer wire to the generator is taken out and what was formerly the equalizer terminal from the generator is connected as indicated to the positive terminal so that there are practically two positive switches on the board. One of these however is for use when the generator is running at 550 volts, the other for 650 volts. The equalizer bus on the board being now a high voltage bus the middle of the three single pole switches on each panel is closed to connect the generator if it is to be run on high voltage, and the right hand switch as indicated in the diagram to connect it for low voltage.

Voltmeter plugs are being put in all the feeder panels on this road for the purpose of quickly testing the insulation resistance of each feeder before shutting down at night and before turning on current in the morning. There are two of these plugs and they are connected in as shown in Figure 5, where  $P_1$  represents one plug receptacle and  $P_2$  the other. By plugging the voltmeter in  $P_1$  before the feeder switch is closed and when current is on the other sections next to the

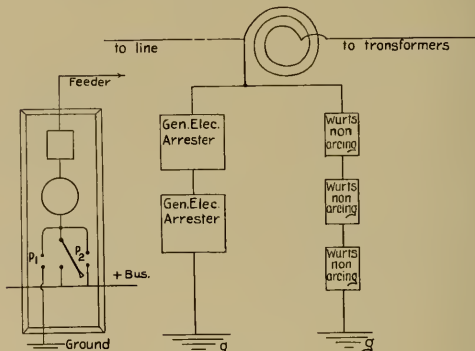

FIGURE 5.

FIGURE 6.

section under consideration the insulation resistance of the section insulators and other insulating devices between it and the other surrounding sections and feeders is determined. By plugging the voltmeter in at  $P_2$  when the feeder switch is open and the positive bus alive the insulation resistance between the feeder and trolley section and ground is determined. The formula for calculating insulation resistance in ohms from such voltmeter tests can be found on page 4 of our January, 1896, issue.

### THE LOWELL & SUBURBAN RAILWAY,

of which P. F. Sullivan is general manager, has attracted national interest among street railway men and electrical engineers in general, because of its rather bold move in putting in a three phase transmission at 5,000 volts to transmit power from its steam driven power station at Lowell to Nashua for running the road in and near the latter city. The main features of the scheme as originally carried out were as follows: In the power station at Lowell were placed three generators, which were similar in construction to a rotary

converter. At one end they gave a three phase 375-volt alternating current, and at the other direct current at 500 volts. The latter was used for exciting the fields and for helping the station when needed. These generators were rated at 120 kilowatts each. The alternating current was transformed up to 5,000 volts, and conducted over three No. 00 wires to a sub-station ten miles away, where it was transformed down again to 375 volts, and by rotary converters changed to a 500-volt direct current. Five miles further on was another sub-station with a similar equipment of static transformers and rotary converters, with the exception that the transformers were wound for a slightly different ratio of conversion to compensate for the additional line drop between it and the other sub-station, for both sub-stations were fed from the same mains. Transformers were connected delta fashion between the three mains, and six are ordinarily used (two groups of three in parallel), but twelve can be switched in if desired.

Since the alternating plant was first put in some changes have been made, and practical experience has taught lessons that theory could not foresee, although considering the novelty of the installation, it has been remarkably successful and free from trouble. Owing to light traffic the sub-station farthest from Lowell is not now being used, as it is found cheaper to supply the territory all from one sub-station and do away with the labor expense of the other. Should traffic require it, the abandoned sub-station would be again started. But the most important change made is in the generating machinery. After much trial it has been found impracticable on account of armature reaction or allied phenomena to run a self-exciting three phase generator, because the voltage will not hold up under heavy load, and the machines originally installed, which gave both direct and alternating current, are being replaced by larger separately excited machines which give nothing but three phase alternating current.

Lightning has in times past wrought considerable havoc among the high voltage static transformers, but that difficulty has now been conquered. As soon as one transformer is burned out by lightning, it short circuits all the others in the bank and they are soon ruined also. This is made possible by the fact that there are no fuses whatever in the high pressure side of the circuit and the low pressure side is very heavily fused. Fuses on the high pressure side are not considered practicable. The lightning difficulty has been overcome by a very thorough system of lightning arresters. Arresters are placed at three places: at the power station, the sub-station and about midway between. They are not placed oftener because an effective bank of lightning arresters for a high voltage circuit of this kind is an imposing array of apparatus and requires a building. On each of the three wires is connected a combination as indicated in Figure 6. There are practically two sets of arresters. One set is composed of two General Electric arresters in series and the other set of three non-arcing Wurts in series. A choke coil is placed between the arresters and transformers.

As stated before there are no fuses in the 5,000-volt circuits, and the high pressure circuit is never opened when there is current on it owing to the enormous arc that would take place. All the switch jaws and terminals on the high pressure circuits are placed on hard rubber pillars which elevate them from the surface of the slate switch board. All the necessary switching is done on the low pressure side of the transformers, but even there the circuit is not opened

with the load on except when absolutely necessary, because the inductive effects are liable to produce a bad arc. Consequently nearly all the control is accomplished in the field exciter circuits. Of course the alternating generators are run in parallel.

While the change of generators was being made in the power station recently a very interesting makeshift was employed to run the lines ordinarily supplied by the 5,000-

volt transmission. It was nothing less than a booster to raise the direct current to 1,000 volts. This enormous "boost" in voltage was made necessary by the fact that the feeding had to be done over the transmission line which was designed for 5,000 volts. Of course direct feeding run at 1,000 volts would have been impracticable at any time except when the traffic was light. The booster is a 300-ampere multipolar General Electric railway generator with the shunt fields cut out and enough added to the series field coils so that it will give 500 volts at 300 amperes. The insulation around the booster and its switchboard, of course, has to be very good. It goes without saying that a booster to compensate for 100 per cent drop in voltage is not an economical apparatus, but to tide over an emergency in this case it proved very useful.

The three wire system is used on this road in summer to take care of a distant portion of the line on which the pleasure traffic is very heavy. The section so fed consists of a double track line two miles long. The distance from the power house to the middle of the three wire section is five miles. The line is sectioned so as to make half of each track positive and half of each track negative as indicated in Figure 7. The line work for the three wire system is carried out in a substantial manner and a strain insulator is put in the middle of each span wire as in Figure 8 to help insulate against the 1,000 volts between the trolley wires. The usual strain insulators at the ends are also used.

At the station switchboard connections are made so that one generator can be put on the negative side of the three wire service if desired and the switches arranged so that the three wire system can be started up or discontinued at a moment's notice. It is not used during the winter. The plan used in connecting a generator on the negative side of the three wire system is to disconnect its positive from the station bus bar and its equalizer from the station equalizer

and then reverse its field connections with a special switch provided for the purpose. Its polarity being thereby reversed, its former positive pole, which becomes negative by reversing the fields is connected to the negative feeder on the three wire system. The negative side of the generator becoming positive is connected to the negative station bus (which is the neutral of the three wire system) by simply closing the switch on the generator panel. Switches for mak-

## CHICAGO CITY RAILWAY IN 1896.

ing these connections are put on a special panel. This special panel is used and the field connections reversed instead of employing a double throw main switch on the regular generator panel, because the special panel obviates the use of two bus bars near together with 1,000 volts between them and nothing but proverbially leaky slate to keep up the insulation.

## THE WEST END STREET RAILWAY

of Boston, also has adopted the practice of operating all of its power stations in multiple. This plan is of even more importance on an immense city system of this kind than on an interurban. That some idea may be had of the scale on which this scheme is operated the following enumeration of the power stations of the road is given:

Central Power Station; six 1,200-k-w, two 1,500-k-w, and 40 D-62 generators.

East Cambridge Power Station; seven 500-k-w generators.

Charlestown Power Station; two 800-k-w generators. Dorchester Power Station; two 1,000-k-w generators.

Allston Power Station; twelve 62-k-w generators. East Boston Power Station; three 250-k-w generators.

All these power stations are connected together through the medium of "jumped" section insulators. All stations are in direct telephonic communication with the Central power station and the operation of all the stations is superintended by the chief at the Central station. This plan of operating is of great importance in the economy of the West End road. In the first place it makes it possible to work the apparatus in all the power stations at somewhere near a full and economical load. Every power house engineer operating large units knows that there are often times when, for example, it is necessary to run two machines underloaded, because there is just a little too much for one. If, however, the plant is being run in multiple with others, it can give away a small portion of its load to the others and run one unit on a full and economical load. Where there are a large number of stations, as at Boston, it is a simple matter for the chief at the central plant to order the running of such machines as will distribute the load properly among the stations and at the same time keep what machines there are loaded fully. Then too, during the latter part of the night, the whole road can be run from the central station. C. F. Baker, master mechanic of the road, made the statement to the writer that were it not for this plan of running stations in multiple, the company would be obliged to build another power station. In this case therefore, the plan not only means economy in operating, but a great saving in investment, due to the fact that the surplus power house investment at one point can help at points where there is a temporary shortage of power instead of confining its operation rigidly to its own immediate territory.

Johannesburg, South Africa, has granted a concession for a complete electric railway system with branches to populous suburbs.

Workmen's cars, with 2 cents fare for 4 miles ride, have been running over the Kingswood line of the Bristol Tramway Company. Where two cars sufficed at the beginning, seven are now in use. Electricity, with its low operating expense, has made it possible to place a ride within the means of a great many men who formerly walked.

The annual meeting of the Chicago City Railway resulted in a re-election of old directors and officers, and furnishes some interesting figures. The road earned from passengers, \$4,761,945; from mail cars, \$1,139; and from other sources, chiefly advertising in cars, \$45,781; a total of \$4,808,866. The operating expenses for all systems, including insurance and taxes, were, \$2,977,208, or 62.52 per cent of passenger earnings.

The revenue car-miles run aggregated 24,552,000, a net increase of 2,611,000 miles, divided as follows: Cable, 13,908,190, (decrease, 964,390); electric, 10,018,020, (increase, 4,491,260); horse, 626,690, (decrease, 915,870). On all lines 95,238,915 revenue passengers were carried; 46,435,411 on cable lines, (48.76 per cent); on horse lines 2,874,631, (3.02 per cent); and on electric, 45,928,873, (48.22 per cent). The electric lines show an increase of over 17,000,000, while the cable decreased 6,924,000, and the horse lines decreased 4,043,985 passengers. These figures are for cash passengers, and do not include the extra transfer rides, which amount probably to 40 per cent more. The decrease on horse and cable lines is due to the substitution of electricity, for the daily receipts, which were \$13,010, show an increase of \$845 per day over '95. Operating expenses were \$8,134, an increase of \$442 per day. The horse lines, including owl cars, show a net loss on the year of \$18,510, a decrease in loss, however, over '95 of \$103,731.

Operating expenses in cents, per car-mile, were:

	1895.	1896.
Cable lines.....	10.240	10.540
Horse lines.....	30.550	25.889
Electric lines.....	14.776	13.467
All.....	12.796	12.126

Present trackage is, cable, 34.92 miles; electric, 141.76 miles; horse, 7.54 miles: a total of 184 miles single track measure. The passenger equipment numbers 1,735 cars--grip, motor and trailers. The company has only 231 horses, of which 136 are on teaming work, as against some 3,000 head a few years ago.

During the year 13,477 of the Falk cast-welded joints were laid, on which the breakage was only  $\frac{1}{8}$  of one per cent.

After paying 12 per cent dividends on \$10,750,000 of stock, and 4½ per cent interest on \$4,619,500 of bonds, there was a surplus of \$152,425. Altogether the showing, both in the aggregate and in detail, is a very creditable one.

## THIS BREAD WAS WATERLOGGED.

Undoubtedly more of human nature, the real genuine article, can be found and studied on a street car than anywhere in the world. Judge B. is one of the presiding judges in an Ohio city, and also a stockholder in the street railway there. His good wife makes frequent pilgrimages to a charitable institution, going in the street cars. Recently returning from her errand of mercy, she discovered on boarding the car that in her generosity she had not left so much as one stray nickel. So she inquired of the gentleman sitting next to her, if he knew the judge. Of course he did, for everybody knows the judge; so she said she was judge's wife, temporarily without funds, and borrowed the needful nickel. She took his address, and the following

day the judge called on him, expressed his thanks and returned the loan. A few days later the party called at the judge's office, and said he was down without funds and asked the loan of a dollar. But the dollar never came back.

Moral: Ladies when riding in a street car, and finding themselves without funds, should allow some gallant to pay, but don't take his address.

### A VISIT FROM A FRENCH STREET RAILWAY ENGINEER.

Charles Le Blanc, chief engineer of the Compagnie Generale de Traction & d'Electricite of Paris, spent a day in Chicago recently in search of street railway ideas. Mr. Le Blanc, in spite of his name and prominence in French companies, is of American extraction. After completing his education at Washington, D. C., he was placed in charge of the electric plant on the cruiser Atlanta. Resigning this position he took up street railway work with the Sprague Company and installed the first electric road in Boston. Later he was employed by the Edison and General Electric companies, becoming chief engineer for the latter in Pittsburg. In May of 1893, his labors in foreign fields commenced and the French companies received the benefit of his varied experience in operating electric roads in Boston, St. Paul, Minneapolis, Portland and other American cities. He is now chief engineer of the largest electric construction company in France, and consulting engineer for several others.

At the present time, street railway work is receiving a great impetus in France, in fact, all over Europe, for the people are becoming awakened to the blessings of rapid transit. The Compagnie Generale de Traction & d'Electricite alone has 31 franchises granted in as many cities in France, with a number of others pending.

It is the policy of this company to build and equip the railways and either guarantee the operating expenses or run the roads for the profit derived from them. American methods have been carefully studied and every detail of power house and railway economy worked out. The guarantee is 5 cents per car-kilometer and some of the roads have gone as low as 3.6 cents. Condensers are used in all cases, cooling tanks catching the water, sprayed by centrifugal pumps and used over and over again in the boilers. In a 900-ft station in Paris only 5 to 6 cubic meters, or about 500 gallons of water are consumed per day. Coal costs \$4.50 a ton and every device is used to make its consumption economical.

Many regulations and restrictions are placed upon the street railway companies by the government authorities. The trolley poles and street construction are made ornamental, the speed of the cars are regulated to 15 kilometers per hour in the city, and such precautions are taken in running, that very seldom an accident occurs. A car run averages about 175 kilometers per day.

Compressed air is recognized as a failure in Paris, the cars being too cumbersome and the machinery requiring constant attention and repairs. The operating expense is about 17 cents per kilometer and there is little profit for the companies. Electricity is coming into favor for rapid transit. One line of surface contact, seven miles in length, runs between the Place de la Republique and Romainville, and has given satisfaction.

Another company has been authorized to construct a trolley road for trial. The tendency at the present time is to adopt the mixed system, using the trolley in the suburbs and the accumulators in the densely settled portion of the city. Hamburg, Dresden and one or two other cities in Germany have adopted this system. When the car is running, lightly loaded, in the outskirts of the city, the accumulators are being charged and are ready for operating the motors when the end of the trolley line is reached. Feeders to the line are unnecessary, for if the voltage drops or power is inadequate for a steep grade, the storage batteries are automatically thrown into the circuit and help drive the motors. The accumulators on one car weigh about 2,000 pounds and run the car for 14 miles without difficulty.

The problem that brought Mr. Le Blanc on his flying trip to America, was the rule in some of the French cities that there should not be a drop from the end of the track to the station of over 5 volts. Believing that this requirement could be met by the three wire direct current system he has been to St. Louis to study operation there, and is going to Bangor, Me., in search of further facts. During his journey he left an order for 40 tons of trolley wire, part of which is to be used in the Brussels street railway, running to the Exposition. There will be 8 miles of double track upon which 40 cars will operate.

The Thomson-Houston Company has furnished the electrical machinery for fourteen roads, including those at Havre and Rouen. American machinery is receiving just recognition and favor, especially the street car motors, which are not equalled by those of any European make.

Mr. Le Blanc, after a visit to Boston, sailed from New York, February 6 for Paris and Brussels. Thence he will go to Alexandria, Egypt, to attend to street railway interests.

### RELATION OF TEMPERATURE TO POWER.

C. S. Sergeant, general manager of the West End system of Boston, has to show some very interesting records on the relation of power output to the temperature of the weather. It is found that there is a direct relation between power and temperature, and that it takes more power to run a given number of cars in proportion to the coldness of the weather. This is not due to passenger travel, because travel is less on a cold day. The cause of this increase of power is probably to be explained by the presence of frozen mud on the track (which fact makes itself very evident to the car); by the decreased conductivity of the earth, and by the stiffness of the grease in all journal boxes. The electrical economy of the generators, motors and feeders is, of course, higher in cold weather than in warm, and that the lower mechanical efficiency more than overcomes this in cold weather goes to show that there must be a decided drop in mechanical efficiency in cold weather. Mr. Sergeant thinks that enough allowance has not usually been made in the past for the increased power that cold weather requires. His conclusions are based on careful daily records of several months duration.

The officials of the St. Helens, Eng., tramways are contemplating asking the corporation to supply them electrical power on the basis of 6 cents per kilowatt hour. As now operated by steam engines the operating expenses of the tramways are 77.4 per cent of the gross receipts.

## THE AKRON, BEDFORD & CLEVELAND.

Through the courtesy of Wm. Christy, general manager, and Frank J. J. Sloat, superintendent, we are enabled to present some views from photographs taken along the line of the Akron, Bedford & Cleveland Railroad, the road that has a 40-mile an hour record. This road was built in the summer of 1895, and opened for traffic on September 1 of that year. The main line is 27 miles long, extending from Newburg Station to Cuyahoga Falls, passing through Bedford and Northfield. From Newburg Station the cars are run over the lines of the Cleveland Electric Railway to the public square in Cleveland, a distance of 6 miles. From Cuyahoga Falls the southern terminus of the A., B. & C., the tracks of the Akron Street Railway are used to connect with Akron, the county seat of Summit County, 5½ miles away.

There are two power houses, one located at Cuyahoga Falls and the other at Bedford, 18 miles distant. At Cuyahoga Falls are installed four 250-horse-power Stirling boilers, supplying steam at 120 pounds pressure, to two 28 by 42-inch simple non-condensing Allis-Corliss engines. The boiler plant is equipped with Rose shaking grates and a Berryman feed-water heater. The stack is of steel plate, self-supporting and 120 feet high above the grates. The engines run at 82 revolutions per minute and are belted to Tesla-Schmid, double-end type, d. c., a. c., 250-kilowatt generators, built by the Westinghouse Company. At present the current is taken from the commutators, but it is intended at some future time to centralize the power plant at the Cuyahoga Falls station and use alternating current with a transformer station at Bedford. The engine fly-wheels are 17 feet in diameter and weigh 20

SCENES ON THE AKRON, BEDFORD & CLEVELAND.

The main line is laid with 60-pound T-rails on white oak ties spaced 20 inches between centers and ballasted with gravel. It is difficult to detect low joints when riding over the road. The line is single track with switches about four miles apart. The trolley wire is of No. 0000 hard drawn copper, suspended from iron pipe brackets. There are three feeders, two of 300,000 circular mils, and one of 200,000 circular mils, whose aggregate length is nearly 26 miles. The track is bonded with the Benedict & Burnham bond, one to each joint, with 300,000 circular mil cables at switches etc., two such cables being used at all broken connections.

The route is through a rolling country and it was necessary to do considerable cutting and filling to bring the grades down to something within reason. On the main line the maximum grade is 6½ per cent, but on the line of the Akron connection there is one grade of 13 per cent, 1,000 feet long, and another of 8 per cent on a sharp curve. The outer rail is elevated at all curves and a guard rail laid so that the curves may be safely taken at a 30 mile speed.

The belts are double, short lap, and 32 inch wide. From center of engine shaft to generator shaft is 36 feet. The plant at Bedford differs from this one only in having three instead of four 250-horse-power boilers. During the year that these stations have been in operation not the slightest trouble has been experienced with the machinery, which is an enviable record for any power plant.

The company owns twenty-one cars, all of its standard type, 41 feet over all, seating 42 people, mounted on two trucks, and equipped with two Westinghouse 38-A 50-horse-power motors with G. E. special controller. The cars are from the Jackson & Sharp Company, and on Jackson & Sharp and Dornier & Dutton trucks. The cars are designed to run in one direction only and the front platform is protected by a permanent vestibule. With a view to securing greater adhesion when the car is heavily loaded and also of providing a pilot truck for the car, both motors are mounted on the rear truck. For turning the cars Y's are provided at

Newburg, Bedford, Cuyahoga Falls and Akron; at Cleveland the car runs around a loop.

All cars are equipped with air brakes, eleven having the Standard Air Brake Company's geared compressor; and ten the Hunt eccentric compressor.

At the present season only eight cars are kept on the road, the schedule time from Newburg to Cuyahoga Falls, 26 miles, being 70 minutes, or from Cleveland to Akron, 37½ miles, 2 hours and 15 minutes. The last trip at night is scheduled for 1 hour and 50 minutes. Along the line stations are built at all cross-roads, which afford shelter to patrons in bad weather. At each switch is a telephone box, so that the conductor can readily communicate with the train dispatcher who has his office at Cuyahoga Falls. When trains are running regularly the conductor only calls up the dispatcher's office when at the half-way point, but in case of delay he must do so at every switch, and thus keep the dispatcher informed as to his location. Trains carry signal flags by day and lamps by night.

At Cuyahoga Falls are located the shops of the company,

INTERIOR OF CUYAHOGA FALLS POWER HOUSE—A., B. & C. R. R.

where all repairs are made, and in addition the wheel work of the Cleveland Electric Railway. The company has just completed a large double-truck snow plow equipped with four 50-horse-power motors, which will serve as a switch engine for transferring coal, etc. In summer this plow will be used as a locomotive to transfer excursion trains on the Cleveland, Akron & Columbus Railroad to Silver Lake, one of the most noted resorts in northern Ohio, a distance of ¾-mile via the Akron, Bedford & Cleveland.

The Imperial Tramway's Company, of Stockton, Eng., has applied to the Board of Trade for Parliamentary sanction to build a trolley road. It is proposed to make the gauge 3 feet, 6 inches, in order to offer as little obstruction as possible in narrow streets. The council considered the petition and imposed some conditions upon the granting of a franchise. The trolley poles are to be constructed so that they can be used for lighting purposes; the streets are to be paved at the expense of the company; when the franchise expires the corporation will have the option of buying the system.

## ELECTRIC HEATER CONTROL AT SOUTH CHICAGO.

B. J. Jones, superintendent of the South Chicago City Railway, has adopted the plan of having the inspectors that travel on the road regulate the electric heaters on the various cars. That is, the controlling switch which changes the connections of the heaters so as to give varying degrees of heat is locked up so as to be accessible only to the inspectors.

There are two reasons for this practice. One is that the conductors are liable to be poor judges of what is the right temperature for a car, or often careless about seeing that the right temperature is maintained. The other reason is, that in turning the ordinary heater controller switch a conductor with little knowledge of electricity or the knack of breaking arcs, is liable to turn the switch so as to draw an arc that will ruin it. Consequently the control of these switches is put entirely in the hands of the inspectors. There is, however, a main switch in the heater circuit whereby the conductors can shut off the heaters entirely. A switch suitable for the

purpose of breaking 12 amperes at 500 volts must be of different construction from the ordinary run of switches, but one has been found that answers the requirements.

## CABLE CARS FOR EDINBURGH.

Work was commenced last September and has been progressing through the winter months, changing most of the horse tramways in Edinburgh to the cable system. Ultimately 37 miles of cable track will be constructed which will give the city a modern and complete system of street railways. This alteration is being made so that it does not interfere with the daily traffic. Sections of about 300 yards of track and conduit are laid at a time and the horse cars continue operations. From the suburbs, Gorgie, Newington, Morningside and Murrayfield, progress is being made to the center of the city. It is expected that the work will be completed by the latter part of this year.

Electricity is proposed as a substitute for steam on the railways connecting Turin with Gassino and Moncalieri, Italy.

## OPERATING EXPENSES OF CONNECTICUT ROADS IN 1896.

The Railroad Commissioners of Connecticut have made their annual report of the earnings and expenses of all street railways in the state, for the fiscal year ending September 30, 1896.

The past year has been a very quiet one with the Connecticut railways and few additions have been made either to track mileage or equipment. With one exception all the roads paid operating expenses. Twenty-seven companies reported, two more than the previous year. The entire cost of the 351.92 miles of tracks has been \$16,538,223 and of the equipment, \$2,047,937. The gross earnings, for last year, amounted to \$2,589,619, being \$.2056 per car-mile and the operating expenses \$1,704,725 or \$.1353 per car-mile. An average dividend of 3.7 per cent was earned. From the tables, it appears that the large roads have not a great advantage over the small ones in expenses and earnings per car-mile. The greatest earning was reported from a road 4.7 miles in length, while the Bridgeport Company has the smallest expense account per car-mile. The following tables indicate the itemized operating expense account in dollars per car-mile. In all cases figures given below referring to miles of track are for the number of miles of single track.

### BRIDGEPORT RAILWAY COMPANY.

Length of railway, measured as single track is 48.6 miles with 1.2 miles of sidings and switches. The company owns 45 closed, 71 open cars, 7 snow plows, 2 sweepers and 1 sprinkler; employs 200 men and carried 6,383,503 passengers with a car mileage of 1,721,147. The expense items were:

## OVERHEAD TROLLEY IN ELEVATED RAILWAY SHOPS.

Considerable trouble has been experienced in the shops of the Lake Street Elevated, in this city, in handling the cars for repair work. The third rail, which carries the current, was a constant menace to the workmen and a source of trouble from short circuits by some one dropping iron tools

TROLLEY ATTACHMENT.

upon the rails. To obviate this difficulty, Mr. Tabbot, the electrician, designed a very ingenious trolley device which is now in operation.

The accompanying cut shows the arrangement of trolley and how it is applied. The overhead wires are about ten inches apart and both of the same potential. The cable is joined to the trolley carriage by a universal joint. At the

ICE BRUSH ON THIRD RAIL.

other end connection is made by a male and female joint to the motors by means of the line which is usually used to carry the current to heat the cars. This connection can be quickly and easily made or broken and the cars can be moved from place to place without danger or difficulty.

A simple contrivance has been put upon the elevated cars to free the third rail from ice or dirt. A small wire brush is fastened on the box in front of the contact shoe by means of a hinge. Whenever there is need of its use, it is let down upon the rail and held in place by a set screw as shown in the illustration.

## ELECTRIC TRACTION.

"Electric Traction" was the subject of a paper read by Edward Barrington before the Western Society of Engineers, at Chicago. In it some interesting figures are given on the cost, mileage, traffic and equipment of the railways of the country. The trolley system receives much attention and some adverse criticism. Favorable comment is made upon the storage battery and conduit lines, the "button" and "Tesla" systems of the Westinghouse company.

The use of electric traction by the Baltimore & Ohio, the New York & New Haven Railroads, the design of the Baldwin-Westinghouse electric locomotives and several other examples of electricity applied to steam roads were given. This part of the paper was especially singled out for a target in the discussion and the points brought out were of much value and interest. In regard to the use of electricity instead of steam for handling modern or suburban traffic, John F. Wallace said: "Treating the question of the substitution of one power for the other, while electric power may be deemed more desirable for various reasons that can not be demonstrated by dollars and cents, still the main underlying feature must, after all, be that of economy. The problem which the railroad manager has to face in considering the matter is, will the interest on the cost of construction of the new application, plus operating and maintenance charges, be less than the cost of steam power plus operation and maintenance expenses. In considering any individual application, while the question might be answered in favor of electricity on a new installation, the problem is complicated by the difficulty of making satisfactory disposition of the existing steam plants with which suburban railroad lines are now equipped. When it comes to sacrificing

the value of the present property, the cost of an electrical application is much enhanced.

"I do not understand that any application has been long enough in use to determine all the elements of cost that enter into the adoption of electric traction, in order that careful comparisons may be made with the well-known elements of cost surrounding the use of steam. Sufficient data also have not been obtained to enable railroad men to arrive at a definite opinion as to what system of electric transportation is best; whether it is better to use large, powerful, independent motors hauling trailers, or whether it is better to use combination motor and passenger cars with a large number of transportation units. While on lines of light and regular traffic, motor cars which carry from 75 to 100 passengers and leave at frequent intervals may fulfill the requirements of that business, on the other hand this business may be so heavy and irregular that units of this character running even one minute apart may not be able to properly take care of it; or, the requirements of speed may be such that it would not be safe to run the small units of transportation so close together. Therefore the use of transportation units that would enable from 500 to 1,000 passengers to be carried on each train, leaving at slightly longer intervals during the busy hours of the day, might be absolutely essential.

"A number of railroads having a large suburban business have been watching the development of electric traction for years, and there is but little question that they would be willing to substitute this power for steam if the questions that suggest themselves to railroad managers could be accurately and satisfactorily answered.

"In reference to special applications, probably the railroad most favorably situated for the adoption of electric power for handling its heavy suburban traffic, is the Illinois Central Railroad.

"The writer of the original paper hinted at a few foundation principles which may be formulated in the general proposition that the field for electric power lies where the service to be performed consists of small and frequent units of transportation moved over short distances, and that steam is more desirable for large and heavy units of transportation, moved infrequently over long distances and at high speeds."

Mr. Brinckerhoff said in part:

"I think an examination of the third rail system of the Metropolitan will show that we have handled the question of continuous contact in as complicated track layouts as occur in any surface work. I do not pretend to say that just as it stands this would make the ideal surface equipment, but I cannot see why we should feel that having gone so far successfully, we need fear that surface railroad conditions will introduce complications that are beyond the ingenuity of man to overcome.

"As to the system of automatic block signals, that is a serious matter. I can say, however, that we are operating at present a continuous block signal system with an independent wire circuit which does not conflict with our track return. These signals make about 35,000 movements per day and are giving satisfactory service. The question of practicability of handling the suburban passenger service of some of the largest steam railroads coming into Chicago, is really not doubted by railway engineers, and many of them would admit, if they felt it policy to do so, that they could operate cheaper with such an equipment. The most of them are, I should judge, in this position—they have now a large and expensive steam equipment which they would be

obliged to discard, and until this must be renewed or they are forced to make a change by the competition of competing lines, they do not feel justified to go into such large expense. To my mind this question has ceased to be one of engineering; it is rather in the hands of the business managers; when they say the word, the engineers I think can attend to the details without any very great departure from present methods.

"We have demonstrated to the other elevated roads in Chicago that we are making a very considerable saving over steam. They have either changed or are contemplating changing their motive power."

After mentioning the cost of cable and electric systems and observing that an electrical engineer could accomplish almost anything in power transmission if allowed unlimited means, Mr. Summers spoke as follows:

"The New York, New Haven & Hartford Railroad on its Nantasket Beach division in the summer of '95 equipped the division with electricity; it ran an average of 150 trains per day. It made, at that time, something of a radical departure in substituting the Figure 8 trolley wire, which has since been frequently used, the idea being to prevent any jumping of the trolley, which is one of the principal difficulties in high speed trolley service. The fact is, quite significant that when the service was extended the third rail system was used the rail being put in the center of the track; it cleared the pilots about 2½ inches. It was found occasionally an engine would go over the road with some part hanging low, and the result was the electric trains stopped until the steam engine got off the section. In order that the short circuits occurring on this division should not affect the rest of the system a separate feeder system was used, equipped with magnetic circuit breakers. The third rail was discontinued at crossings and the current carried on by means of an insulated cable, the trains being carried over by momentum. There have been many suggestions made as to carrying a connection through the train and keeping one contact until the next is made. The third rail service system is entirely experimental, and I do not think there is any evidence to show that it is as yet practicable."

Mr. Lundie: "Traction in its very nature is mechanical, and I simply make this remark to lead on to the fact that this whole question is one of transmission of energy from a central power station. In a central power station by using large units you can get out of a pound of coal a great many more foot-pounds of energy than you get out of the same amount of coal out on the road in a locomotive. Mr. Barrington gives an illustration of a central station where 2.89 pounds of coal were required per electrical horse-power-hour when the engines were running condensing as designed. When they were operating non-condensing, owing to the lack of water, they required 3.93 pounds of coal to produce the same energy. Say then, that the average of 3.4 pounds of coal are required to develop an electrical horse-power-hour. This would probably be equivalent to 5 pounds of this coal out on the road per brake horse-power-hour. Now, then, let me quote from Mr. Goss' experiments on his locomotive at Purdue. These are probably as reliable experiments as we have. Mr. Goss, out of a series of twenty tests, gives an average of 5.3 pounds coal actually used per indicated horse-power-hour. We may then figure on 6½ pounds of coal developing a horse-power-hour at the rim of the wheel, so that you have 5 pounds in one case and 6½ in another, or 1½ pounds saving in favor of the central sta-

tion. Against this pound and a half you have to consider the capital invested in the power house, and the transmission system. You must also take into account the depreciation in the transmission system."

Mr. Coster, manager of the Chicago office of the Westinghouse Electric & Manufacturing Company: "I only wish to say a few words. I am not going to discuss Mr. Barrington's paper, but I am desirous of giving a few facts which I just penciled out while listening to some of the discussions. I think you are right, Mr. President, in your opening remarks when you said that if the electric companies could prove to the railway companies that there was economy in installing an electric plant to take the place of the steam plant, they would do so. Now let us take, for instance, the Illinois Central Railroad, which is very near to our hearts, as we all use it very often. It has a very excellent locomotive equipment for the suburban service. This equipment, I suppose, cost a good deal of money; if it were to do away with this equipment and replace it by electric power, I suppose the locomotives could not be used for the cross-country service. In that case the electric companies would be at a disadvantage, and I do not blame the Illinois Central for not substituting electric traction at the present time, for it would not pay it as long as it had these elegant locomotives. They will have to be worn out first. If, on the other hand, the Illinois Central Railroad equipping its roads afresh today, I am sure that several companies could demonstrate to its satisfaction that it could operate the road cheaper by electricity than by steam. That is, not the entire road, but only the suburban traffic of the road."

Mr. Arnold: "The question which, it seems to me, the steam railroads must meet, is not a question of whether they can operate cheaper than electric roads can, but whether they can hold their present traffic in competition with electric roads which have already paralleled them in many instances, and will continue to do so, although they may not parallel them for great distances for some time to come. They will parallel them, however, for suburban service and between county seats, as in the case mentioned by the chairman, where there are a number of cities of from three to five or six thousand people, varying from six to twenty miles apart. This affects a certain portion of the steam railroad traffic, or draws from it, but for through traffic lines I am not of the opinion that the electric motor for heavy traffic can at present compete with the steam locomotive for economy, if it is judged entirely from the standpoint of fuel consumption where the interest on the investment is considered. The figures given here tonight we have seen check out very closely. The electric advocate gives the cost per horse-power-hour as .2 of a cent at the power station; the locomotive man gives it as .26 of a cent at the locomotive, with a simple engine, while with a compound engine he gives it 20 per cent better; that brings it to pretty nearly to .2 of a cent per horse power hour delivered at the locomotive. This being the case, you cannot expect to produce a horse-power-hour in a power station at .2 of a cent and deliver it to an electric locomotive some miles away for .26 of a cent, and effect a saving, for the reason that the difference of .06 of a cent per horse power hour must pay the interest on the extra cost of the electrical equipment of a road over its present cost as operated by steam, which I do not think it can do on roads operating few and heavy trains at long intervals, in accordance with the present standard system of railroading.

This is the comparison that it gives with a heavy freight or passenger service, but when you come to the condition of handling small trains at short intervals, I think that the electric trains will supersede the steam trains in almost every instance, and the prominent case that we have in mind is the Illinois Central right here near us. I understand by reading over the discussion which took place here a week ago that the officials of the road are willing, or rather have expressed an indication that they might adopt electricity if they could be convinced of the economy of it. If I read the figures correctly which were handed me a couple of hours ago of the operating expenses of the Illinois Central road, and the estimated cost of operating it by electricity made by their own engineers, I figure out a saving of something like \$250 per day from their own figures. If that is the case, the question, it seems to me, is decided in favor of electricity. These figures include interest against the cost of both locomotive equipment and the electrical equipment, and therefore take in the whole question."

#### CHARLES BRYANT FAIRCHILD.

The extensive experience and knowledge of street railway affairs of Mr. Fairchild will, hereafter, be used to promote the interests of the Standard Air Brake Company.

Mr. Fairchild was born at Monterey, Mass., January 4, 1842. His early education was received at the public schools near Binghamton, N. Y., where his family had removed, and Susquehanna Seminary.

His course was brought to an abrupt close by the opening of the war. He enlisted in the twenty-seventh regiment of New York volunteers, was captured and confined in rebel prisons for nearly a year. After his release, he received the commission of first lieutenant and assigned to duty in the Kanawha Valley, W. Va.

When the war closed a course of study was taken up at the State Normal School at Brookport, N. Y., and soon after his graduation here, he took the degree of A. M. from Amherst College. A professorship was tendered him in the Normal school and he held this position until January, 1871. His health having failed he engaged in horticulture and farming pursuits near Raleigh, N. C., for nine years. He then removed to New York city where he taught in the grammar schools.

Not until 1885 was his attention given to street railway work. Then a cable railway scheme was invented but did not prove to be a great success. The Street Railway Journal secured his services in 1889, first as associate editor and one year after, as editor.

Two books, "History of the Twenty-seventh Regiment, N. Y. Volunteers" and "Street Railways," are the products of his pen.

In 1895 his editorial duties ended and his attention was given to the development of an emergency pavement brake for street railways. On December 4, 1896, Mr. Fairchild entered the service of the Standard Air-Brake Company and his brake will be manufactured by this concern.

C. B. FAIRCHILD.

## SUCCESSFUL BENEFIT ASSOCIATION.

**In Existence 12 Years—Has Now a Trust Fund of \$88,000—  
\$22,000 Paid Death and Sick Claims.**

Nearly twelve years ago there was formed in this city one of the best benefit societies today existing in America. When the twelve hour law relating to street railroads went into effect, May, 1886, the conductors and drivers of the Washington & Georgetown Railroad Company, now the Capital Traction Company, celebrated the happy event by decorating their horses and cars with flags and bunting. At the same time Mr. Hurt, the then president of the company, congratulated his subordinates on their success by presenting them with his personal check for \$500. On being asked the best disposition to make of this money Mr. Hurt suggested the formation of a relief association, a proposition that at once met with the approval of all parties interested. A constitution and by-laws were drafted by Mr. Hurt, and after a few preliminary meetings a permanent organization was effected August 2, the same year. John Larowe and Mr. Hurt were elected president and secretary respectively. The society was barely organized when the Washington & Georgetown Company came to its assistance with the substantial donation of \$5,000.

Only employes of the road are eligible for membership and when they leave the service of the company their membership ceases.

The prime object of the Washington & Georgetown Railroad Employes' Relief Association is the immediate payment of sick and death benefits to members. As it now exists the association is similar to no other organization in the world, but embodies the features of many. It may very properly be termed a savings bank, life insurance company, mutual benefit association and is not unlike a building society. It is necessarily more prosperous today than ever, and during its existence, by safe and judicious investment, now has a capital of \$88,283. On January 1, of this year, there was on hand in cash, \$3,853 and secured outstanding notes for \$84,430. The total charge against each account for the same time was \$6.58 which was offset by \$4.22 received for interest, leaving a net individual expense of \$2.36. The average annual expense to each member is not more than \$2. Up to January 1, 1897, there has been paid in sick benefits \$18,030 and \$4,000 on account of deaths.

The monthly dues are \$1.00 and on the death of a member an assessment of 50 cents is levied. The decease of a member's wife calls for an assessment of 25 cents. During sickness or other disability \$6 a week is paid during illness. There is no limit to the amount of the latter and one member who is yet drawing this weekly stipend received on the same account last year \$137. On the demise of a member his family receives \$100. The death of a member's wife entitles him to \$50, although no monthly dues have been paid for her. The advantage of the organization was practically demonstrated not long after its inception, on the death of a young Englishman employed on the road. He had no friends in this country. Had he not been a member of the association it is not difficult to say what disposition would have been made of his body. Probably Potter's field would have kept it for a few hours and subsequently a dissecting table. As it is his remains now peacefully rest in Oak Hill cemetery on the banks of picturesque Rock Creek,

for which the railroad company is responsible, are safely invested at six per cent. This interest is semi-annually credited each member pro rata. At a low rate members can borrow from the association on good security. Many members make deposits and get six per cent. In some instances their savings represent a snug sum. On withdrawal a member receives his dividend. One such who entered the association at its birth left the service of the company this month. He had paid in a total of \$120, and had enjoyed several sick benefits. On his severance he drew out \$110.67. In another case a member had paid in \$11.63, received \$11.00 in sick benefits and leaving the road drew out \$8.50. And yet there are men in the employ of the company who are not members of the association. On more than one occasion such men have been buried by the generosity of their associates. It is not necessary to state that such charity is not naturally extended with that free heartedness that would obtain under other circumstances.

Every month the secretary of the association prepares a balance sheet that is conspicuously posted in the office for the benefit of members. The books of the society are at all times open for inspection, and the officers serve without compensation. The current expenses for 1896 were \$196.39. January 1, 1897, the membership amounted to 475, in which is included officers and directors of the road.

Much credit is due Mr. Hurt for the admirable success of the association, of which he is practically the father.

## A CLEARANCE DETERMINER FOR GENERAL ELECTRIC MOTORS.

It has always been somewhat of a problem to determine satisfactorily the clearance between armature and fields in the G. E. 800 motor. Indeed, some prefer to relin the armature bearings much more frequently than is necessary rather than run the risk that attaches to depending on available methods of measurement. A little device that originated

on the Lyon & Boston system solves this problem as satisfactorily as any, and with it the measurement of clearance is made very easy. It is simply an L-shaped gage of the general form as shown in the accompanying engraving. The dimensions of course are varied to suit the motor equipment, and the thinness to which it is thought desirable to wear the bearings. This gage is thrust down into the grease cup and a dangerously small clearance is discovered by entering the lower shank of the L into the groove that is cut lengthwise of the bearing for grease. This groove being always the same depth the clearance is accurately found.

A locomotive of the N. Y., N. H. & H. R. R. collided with an electric car at Broad Cove Crossing, Somerset, Mass. The electric car was smashed into splinters and the locomotive, together with two coaches, was derailed, but miraculously no one was seriously injured. A snow storm was raging at the time which prevented the motorman and conductor from seeing the train until it was upon them and they jumped, saving their lives.

### THE REPAIR SHOPS OF THE NORTH CHICAGO STREET RAILROAD.

The North Chicago Street Railroad has well equipped its repair shop and inaugurated a system of daily inspection, so that a defective part in any machine receives immediate attention. About 16 men attend to 200 motor cars, besides looking after the shop repairs of the cable grips, road, track and power house. The shop is under the management of Mr. Lynch, who is constantly making improvements and adding labor saving devices.

Our illustration, furnished by the Paige Iron Works, represents a part of the shop. In the foreground is an emery wheel for grinding flattened car wheels. The axle

ing, and to swing them around to the lathe at the rear or transfer them from the track to the traveling crane overhead. On this lathe a hammered steel shaft is bored out and cut off with proper dimensions for the motor pinions. The teeth are then cut on a planer from which the head stock has been removed and a special device fitted for holding the cutter. In this way 6 pinions or 10 gears can be cut at one time.

Whenever it is necessary to take out the axles and wheels the car is run on a track over the pits and a removable piece of track is taken out. The wheels are let down on a truck which runs along an 18-inch tramway on the floor of the pit.

The whole shop is conducted in an able manner and is a model of its kind.

WHEEL GRINDER—NORTH CHICAGO STREET RAILWAY SHOPS.

and wheels, as shown, are removed from the truck, but this is unnecessary for the operation of the machine. A car is transferred to the track, jacked up, the axle placed in the centres, the gear case removed and the pinion of the grinding machine thrown in the motor gear as indicated. The two cup shaped emery wheels are adjusted by a screw to the proper height and so as to slightly cone the tread of the wheels, then operations begin. A large belt drives a jack shaft under the floor which runs the vertical shafts bearing the emery wheels at 850 r. p. m. The speed of the pinion is such that the wheels are turned around about five times a minute. The machine requires from 1 to 10 hours to put a set of flat wheels in proper condition.

The two curved pipes in the back ground of the cut are used as cranes to hold armatures or other parts needing turn-

### WILL NOT USE CONDUCTORS.

A few months ago we published a list of conductorless roads. In most cases it had become a physical impossibility to continue operations without cutting out this expense. The report on each case showed that it was possible to do this and still not increase the accident account.

The Petersburg, Va., Electric Railway has now dropped its conductors. An ordinance has been introduced at Pueblo, Col., to allow the company to operate without conductors. Dover, N. H., lines are now operating with cars in charge of the motormen.

The Leeds Corporation Tramway's Committee has decided to renew the rails on three of the tramway routes.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Negligence in Boarding Moving Electric Car.*

It is not negligence per se to board or alight from an electric car while in motion, and in an action for injuries sustained thereby the questions of negligence and contributory negligence are for the jury.

The doctrine of comparative negligence does not now exist in Illinois.

In its opinion the Court said:

The courts of other states have adopted the same rule, that it is negligence for a passenger to alight from a moving train of cars, the motive power of which is steam. The rule as applicable to steam railways is relaxed when applied to horse cars or street railways. *Railroad Co. v. Buck*, 96 Ind. 346; *Stoner v. Pennsylvania Co.*, 98 Ind. 384. *Beach on Contributory Negligence* (section 90) says: "It is well settled that it is not contributory negligence per se for one to alight from or to board a moving street car, and here, again, we find the severity of the rule as applicable to steam railways essentially relaxed." *Booth on Street Railway Law* (section 336) lays down the same rule in the following language: "Although the act of boarding a car while in motion is always attended with some risks, the rules applicable to persons entering cars operated by steam are not usually applied with the same strictness to street railways operated by horse power. It is a general rule, established by numerous decisions, that if a person who has the free use of his faculties and limbs has given proper notice of his desire to be taken up, and the speed of the car has been slackened in the usual manner, it is not negligence per se to attempt to get on while it is moving slowly, and that, if a person is injured under such circumstances, the question of his contributory negligence is ordinarily one of fact for the jury."

The doctrine is established in nearly all of the states where the question has arisen, that it is not negligence per se for a passenger to board or alight from a street car operated by horse power, and the question of contributory negligence is one of fact for the jury. *McDonough v. Railroad Co.*, 137 Mass. 210, 21 Am. & Eng. Cas. 354; *Eppendorf v. Railroad Co.*, 69 N. Y. 195; *Ganiard v. Railroad Co.*, 50 Hun. (N. Y.) 22; *Morrison v. Railroad Co.*, 130 N. Y. 166; *Railway Co. v. Green*, 56 Md. 84; *Railway Co. v. Williams*, 140 Ill. 275. In the case of *Sahlgaard v. Railway Co.*, 48 Minn. 232, where the motive power of the car was a cable, the same rule as above stated was held also to be applicable. In large and populous cities, where many cars are passing, and constantly receiving and discharging passengers at crossings, it is a well known fact that many of such passengers board cars and alight therefrom before the car has come to a full stop, and that they do so usually with perfect safety. It is well known, also, that street car companies tacitly invite many passengers to board and alight from their cars by checking up to a slow rate of speed and immediately starting up at a greater speed when the passenger is safely aboard or has alighted. It would be impossible for a court to lay down the rules as to what particular rate of speed would be sufficient notice to a passenger that, if he attempted to get on or off, he would be held guilty of contributory negligence. It would also be a great hardship, and unjust to lay down a general rule that a passenger attempting to

board any street car while in motion at all should be held in contributory negligence. Every person is supposed to know that the boarding of a moving train or car is attended with the danger of a misstep or fall, and a fall beside a moving car is liable to bring some part of the body or limbs in danger of being crushed. It is the duty of those having control and management of cars designated for traffic on the public streets to bring such cars to a full stop at such places as are convenient and necessary for the purpose of discharging and receiving passengers, and it is no less the duty of passengers in getting off such cars to observe due precaution for their own safety. We cannot say, however, that it is inconsistent with ordinary care and caution for a person to board a street car while in motion. Whether one has not exercised due care or caution in so doing is to be determined by the particular circumstances in each case, and is, therefore, a question of fact to be submitted to the jury.

The cases heretofore cited in which it has been held that it is not negligence per se for a person to board or alight from a street car while in motion, have reference in a great degree to horse cars. As we have stated, there is a wide distinction in cases of such motive power, as the act is not in itself negligence, while in cars propelled by steam it is negligence to do so. Where the motive power is electricity, a question not entirely free from difficulty is presented. The modern progress of methods of transportation, the recent discoveries of the possibilities of electricity as a motive power, and the perfection which it has within a few years developed and attained, have demonstrated a power popular as a method of transit. The purpose to which a power of this character is applied must to some extent be considered. Where horses were formerly used, electricity has now in a measure superseded. The same style and often the same cars are used, the same streets are traveled, and a like number of stops, and in like places, are made, to receive and deliver passengers. Electricity as a motive power, while stronger and more powerful and with possibilities of a greater speed, is at the same time more nearly under the control of the person in charge than horse power. The strict rule in force regarding the negligence of a person alighting or boarding an ordinary train of steam cars had for it many good and sufficient reasons, which are not applicable to the electric car as in general use. In the latter case stops are frequent, and opportunity for great speed is not presented. Steps for passengers are near the ground, and the chances of a misstep or fall are not so great as in steam cars as constructed. Streets on such lines are generally paved, and in that respect passengers may safely depart or board such cars in one place as another, whereas, in the case of steam cars, platforms are generally provided. While in electric cars the possibilities of speed are greater than in the case of horse cars, yet the general operation and management of such cars so nearly approaches to that of horse cars that it must be held that the same rule of law which, in the cases cited and a long line of other cases, holds that it is not negligence per se to board or depart from such cars while in motion is also applicable to electric cars.

(Supreme Court of Illinois, *Cicero & Proviso Street Railway Company vs. Meixner*, 4 American and English Railroad Cases (N. S.) 246; 160 Illinois Reports 320.)

(NOTE. In *Omaha Street Railway Company vs. Martin*, 4 American & English Railroad Cases (N. S.) 1, the Supreme Court of Nebraska reached the same conclusion holding that whether the act of a person in attempting to board a moving street car is negligence or not, is generally a fact to be determined by the jury taking into consideration all the circumstances in evidence in the case.—E.D.)

*Riding Bicycle on Cable Car Track—Injury by Car Approaching From Behind.*

There was evidence that plaintiff was riding on a bicycle upon the "slot" between the rails of a cable car track, and was knocked down by a car that approached from behind, without warning, by sounding of the gong, or otherwise. *Held*, that he was lawfully upon the track; that although, being in a place of danger, he was bound to exercise corresponding care, he was not under a duty as matter of law to look behind, and that there was enough to go to the jury on the questions of the cause of the accident, defendant's negligence and plaintiff's freedom from contributory negligence.

(Supreme Court of New York. *James H. Rooks vs. the Houston, West Street & Pavonia Ferry Railroad Company*; 29 Chicago Legal News 118.)

*Injury to Persons Driving Upon Track—Rights of Street Railway Company in Street—Duty of Motorman and of Persons in the Street—Greater Speed Than Permitted by Ordinance.*

Plaintiff emerged from an alley way, driving his team into an open street, upon which defendant ran its car. Immediately after leaving the alley, he looked in the direction from which the car came, and in consequence of trees and poles, saw none, and then approached the track. Before crossing it he made no particular effort to see whether a car was coming, and it was possible that the poles might have obstructed the view between him and the car. The car was running at the rate of 25 or 30 miles an hour, and no gong was sounded until just before the collision occurred in which plaintiff was injured. *Held*, that a nonsuit was improperly granted.

A street railway company has no superior right on a public street to that of the public at large, except the right to lay its track and operate cars; and if it adopts a dangerous propelling power it must be held to a degree of care proportionate to the increase of danger to the public.

A street car has the right of way in case of meeting a person or vehicle, but each party, in order to avoid accident, must exercise ordinary care and such reasonable prudence as the surrounding circumstances require; and what may be considered ordinary care in one case may amount to culpable negligence in another. The existence of negligence in each case must depend on the circumstances peculiar to it.

It is the duty of a motorman to notice whether or not the track is clear when he approaches a public crossing, and to sound the gong as warning.

While some courts hold that, where the speed is greater than that permitted by the ordinance, it is negligence per se, yet the better rule appears to be that it is a circumstance from which negligence may be inferred, and is always proper to be considered by the jury.

Persons traveling on a public street, along or across a street, are not held to the exercise of the same degree of care as when traveling along, or upon, or across, an ordinary steam railroad.

When the injured party was negligent in the first instance, such negligence will not defeat his action, if it be shown

that the defendant might have avoided the injury by the exercise of ordinary care and reasonable prudence.

As to whose negligence was the proximate cause of the accident is a question of fact for the jury.

Supreme Court of Utah. *Hall vs. Ogden City Street Railway Company*, 1 American and English Railway cases (N. S.) 77.

*Failure to Plead Improper Remarks of Counsel—Setting Aside Verdict—Verdict of Fifty Thousand Dollars.*

In a court of record the plaintiff, for the validity of his judgment, must see to it that the defendant is brought, or comes into court, and also that there are written pleadings showing a cause of action over which the court has jurisdiction. Thus, jurisdiction over the person and subject matter is made to appear.

The defendant is not called upon to do anything to show jurisdiction. If he is brought or comes into court, jurisdiction over him is obtained; his plea confers no jurisdiction, and his failure to plead deprives the court of no right; on the contrary it confers a right to enter his default, or, to speak more accurately, he has deprived himself of a right he otherwise had.

Proceeding to trial as if an issue had been made up, when there has been a failure to make an issue, is a waiver of the formal issue, and the trial will be treated as though an issue by plea had been formally tendered.

When verdict will be set aside therefor.—Under our system of practice there is, practically nothing which the court can do to remove the poison engendered by a maliciously unfair and unjust statement of counsel, save to grant a new trial. Whether the court will for such cause grant a new trial, is a matter of discretion. If, from all that was done, as well as from the verdict, the court is of the opinion that the jury were not thus improperly influenced, and that the verdict is, in no measure, the result of such unfair means, and that the parties have had the trial by jury which, under the constitution and law of this state is their right, the verdict should not, for the misconduct of counsel be set aside.

The very large and most unusual verdict rendered in this case was the result, in some measure, of the inflammatory and improper address of counsel. So believing, the court feel compelled to set aside the judgment.

(Appellate Court of Illinois, First District, *West Chicago Street Railway Company vs. Jesse Krueger*, 29 Chicago Legal News, 179.)

(NOTE.—In a similar case the same court, speaking by Shepherd J., of the improper remarks of counsel said: The effectual and perhaps only practicable remedy in ordinary cases, is for trial judges to impose the penalty of a new trial upon counsel who attempt to subvert justice by appeals to the sympathies and prejudices of a jury, in trials where such feelings may be easily aroused, and trial courts should not hesitate to use that authority in this regard.)

(North Chicago Street Railroad vs. Leonard, 29 Chicago Legal News 181. Ed.)

*Snow Piled on Side of Street by Street Car Company—Injury Caused Thereby to Conveyance on Street.*

1. In an action for damages, caused for personal injuries sustained by plaintiff through defendant's negligence, an averment in the petition, "that he was exercising due care in driving along said street, and but for the existence of said mass of snow so piled in said street, could have controlled and stopped his team, and his buggy would not have been overturned or any injury sustained by him," states facts suffi-

ciently to justify a submission to a jury of the question as to whether, under all the circumstances, the mass of hardened snow negligently piled upon the highway, was not the legal cause of the accident, which resulted in an injury to the plaintiff.

2. A street railway company, which, in removing the snow from its tracks, piles it up in the part of the street outside such tracks, and suffers it to remain there in masses, which constitutes an obstruction to travel, in violation of its general duty and of a local ordinance, is responsible for the injuries suffered by a traveler on the street whose carriage is upset by coming in contact with such mass of snow before he was able to regain control of the horses.

3. It is not, in itself, negligence to start an electric street car in the ordinary manner, and in the ordinary course of the operation of such car, while a team of horses, which manifest no symptoms of fright, is being driven past it.

(United States Circuit Court of Appeals, Sixth Circuit, McDonald v. Toledo Consolidated Street Railway Company, 29 Chicago Legal News 35.)

### MECHANICAL TRACTION IN PARIS.

(From Our Own Correspondent.)

Among the best known systems for street car traction in Paris the Rowan is first in popularity. The cars are the most comfortable and smooth in movement, and in winter the ample supply of hot water from the condensers heats them so admirably that it is no surprise to find them always crowded. Also they are very quick to start and speedy on the road, and in all respects far more agreeable to the public than the awkward trail cars drawn by the Mekarski six-wheeled compressed-air locomotives over the same line from the Louvre to Auteuil.

As will be seen by the description which follows, the

FIGURE 1—SINGLE BOILER ROWAN MOTOR.

boiler and motor, though apparently built in the car, in no way communicate any vibration to the vehicle, as is so uncomfortably noticeable in other forms of auto-cars (save electric) used in Paris. These cars are thus a luxury for the public, which has, after all, some claim to consideration as well as the shareholders.

There are two types of boilers in regular use with these cars—single vertical and twin vertical. Figure 1 shows the single boiler type of motor. The inner shell of the boiler is made square for a distance above the fire box, and has horizontal water tubes extending across it in both directions. These tubes are of different diameters, the largest being in

FIGURE 2—TWIN-BOILER ROWAN MOTOR—LONGITUDINAL SECTION.

the bottom row. Above this square chamber the inner shell of the boiler is conical and contains a worm in which the steam is superheated. The superheating coil is, by its position, protected from cold air currents. The upper portion of the boiler is bolted to the fire box-shell by means of flanges on both, so that the water tubes are readily accessible for cleaning and examination.

The cylinders and moving parts are perfectly protected from dust and mud by a casing which is not shown in the illustration. The motor is placed at the front end of the truck, where it will be under the driver's eye, and the truck balanced at the other end by a feed water tank.

In Figures 2, 3 and 4 are shown a longitudinal section, a plan and a transverse section of the twin-boiler motor. The boiler is similar to two single boilers coupled by a transverse trunk. When it is desired to inspect the tubes the outer shells, with the trunk, may be lifted clear of the lower parts of the boilers as with the single boiler.

As the public-way regulations often prescribe the width of the frames and outside cylinders are not always easy to restrict within the given limits, it becomes necessary to place the cylinders within the frame. This is the arrangement on the Paris city cars, and, as will be seen from the illustrations, all of the motor is comprised between the axles and the fire-boxes and the steel case which excludes mud and dust and serves as the frame. It also carries a feed water tank which is placed at the end opposite to the motor. Instead of entering their guides from the bottom, as is usually the case, the axle boxes slide in from the top. Doors in the upper side only, enable the driver to readily inspect the moving parts from his usual position on the foot plate. Upon each side of the frame, equidistant from the two axles, is riveted a channeled plate bent to the arc of a circle with the center of the truck as its center (see Figures 3 and 6). The forward

end of the car is carried on two leaf springs which have at their extremities shoes sliding in the semicircular channels. By this means free movement of the forward truck is allowed on the sharpest curves, of which there are some of 48 feet radius. It is a matter of but a few minutes to lift the car body, draw out the motor truck and put another in its place, if it is not desired to have the car lie idle while cleaning or repairing the motor. The construction of the

FIGURE 3—TWIN-BOILER ROWAN MOTOR—PLAN.

pony truck at the rear end of the car will be understood from Fig. 5.

The motor shown in Figures 2, 3 and 4 weighs 13,000 pounds empty, can evaporate 1,830 pounds of water per hour and exerts a tractive effort of 2,200 pounds. The adhesion of the drivers being augmented by the weight on the front bearings of the car body, is sufficient for such a draw-bar pull, even on muddy rails. An auto-car motor has the advantage that it may be made 2½ times lighter than an independent locomotive.

The surface condensers, placed upon the car roof, consist of a series of chambers formed by two thin sheets of cor-

FIGURE 4—TWIN-BOILER ROWAN MOTOR—TRANSVERSE SECTION.

rugated copper riveted together, forming thus cavities ¾-inch in diameter. These chambers, placed side by side and hidden by the name board on the roof, are connected together at one end by the exhaust steam pipe, and at the other by a

collecting tube, which receives the water of condensation and leads it to the tanks underneath the car body. A rubber hose connects these tanks with the feed water tank in the engine frame and keeps the latter always supplied. The injector and pumps are contained in this latter tank.

In addition to the economy effected in the cost of heating the cars during the winter months, these condensing cars save in fuel from 2¾ to 3½ pounds of coke per mile run, or about \$200 per year, reckoning the annual mileage at 22,500 and coke at \$6 per ton of 2,240 pounds. Besides this economy there is the usual advantage of condensation, pure water and little boiler incrustation. In case the condensing water becomes highly heated and the engine is working at full power on an up grade, all of the steam may not be condensed. In this event it is led from the condenser into the upper part of the fire box, and there becoming super-heated escapes invisible into the outer atmosphere. The

FIGURE 5 AND 6—THE ROWAN CAR.

double boilers have but one water gage and one pressure gage, and the car is easily managed by one driver in the most crowded streets.

Since the introduction of the Serpollet cars and the Romainville electric cars there has been more claim to elegance of appearance in Paris street cars, but until now the Rowan bogie cars remain the most handsome of any employed. The "galloping" movement of the first named, and of others, is entirely absent in the latter, because of the long wheel base. These cars haul a trailer with seats for 50 with ease, and can run a whole day without need of taking water. They burn about 6½ pounds of coke per mile run. The coke is carried in a number of little buckets at the driver's hand. With a full load of 50 passengers the car weighs about 28,000 pounds.

Friends of J. M. Atkinson, this city, will regret to learn of the death of his sister, who died in Chicago. He went east with the remains, for burial at Richmond, Va.

Albert M. King, superintendent of the Jackson & Sharp Company's car works, at Wilmington, Del., died January 1, of heart disease. He was 48 years of age. During his 18 years' service as superintendent Mr. King was brought into contact with many railroad men who will remember him with pleasure and regret his sad and sudden death.

## THE STREET RAILWAYS HAVE TO CONTEND WITH SNOW STORMS.

Street railway companies have learned that snow storms are very troublesome and costly experiences. The delay or stoppage of regular traffic causes not only a loss in fares but also of public prestige. So that much attention has been given to plows, brushes and sweepers and all companies are now more or less thoroughly prepared for such emergencies. These appliances have received a severe test during the past month for snow or sleet storms and intense cold weather have prevailed almost throughout the country. One source of trouble has been the packing of dry snow and dirt on the rails and the consequent damage to commutators and armature by careless use of the controllers. In the cities the frequent passage of cars together with a liberal use of salt and sand kept the rails in fair condition. The suburban and interurban lines had to contend with heavy drifts which in some cuts reached a depth of 6 feet. In Chicago, the roads were very successful in keeping the tracks clear even in the outlying districts. On one branch of the Calumet Electric the deep drifts and sunken rails prevented the operation of the line for half a day.

In New York City, Col. Waring entered into an agreement with the Metropolitan, the Third avenue, the Forty second street, Manhattanville & St. Nicholas avenue, the Dry Dock, the East Broadway & Battery, the Second avenue, the Central Crosstown, the Union railways, and all lines controlled by them. The arrangement was that each company should assume responsibility for a certain street area, from curb to curb, instead of only on its own tracks, while the city street cleaning department clears the snow from the remainder of the streets through which the companies' tracks pass. This has worked with satisfaction both to the public and the companies, the snow being removed so quickly that neither the street nor railway traffic was obstructed.

In New Britain, Conn., considerable difficulty was experienced from the snow being packed on and between the rails of the East Main street line by cabs which had taken guests home from entertainments the night before. The snow plows were supplemented by force of 30 men and 10 teams. It cost the Central Railway about \$600 to keep the system in operation and the effort called forth favorable comment from the press.

At Springfield, Mass., the snow storm gave employment to upwards of 500 idle men, which cost the city and street railway company about \$1,500. The work of removing snow was carried on with vigor and little inconvenience to patrons resulted.

The New Utrecht & Gravesend (N. Y.) trolley line was unable to cope with the big drifts on the tracks and traffic was suspended for nearly two days. Four cars and a plough were stalled in the snow banks on the West End line at Coney Island, causing great inconvenience to the patrons.

The Omaha Street Railway Company placed all the sweepers on the tracks as soon as the snow began to fall and kept the cars running at frequent intervals, a very effective method.

At Westchester, Pa., ice on the trolley wire and rails caused no end of trouble especially on the grades where the wheels would spin on the slippery tracks.

## GOOD RECORD FOR A CABLE.

The Melbourne Tramway & Omnibus Company, Melbourne, Australia, on December 10, 1896, replaced a wire cable on the Collins street line, which had been in use since December 8, 1895, 52 weeks and 4 days, running at 10 miles per hour. This cable was manufactured by George Cradock & Company, Wakefield, England, and was between 17,000 and 18,000 feet in length and  $3\frac{3}{4}$  inches in circumference. The railway company was well satisfied with this Cradock cable, as the average life of the last three ropes, all by other makers, used on this line was but 16 weeks and  $\frac{1}{3}$  day.

## NEW LINE IN CANADA.

A company known as the Brantford, Port Dover & Galt Electric Radial Railway Company has been organized at Brantford, Ont. As shown on the map the line will run south from Brantford to Port Dover on Lake Erie via Mt. Pleasant, Boston, Waterford and Simcoe, with about 40 miles of track, and in a northwesterly direction from Brantford to Paris and thence to Gault or Ayr, about 25 miles. It has not yet been definitely decided whether Gault or Ayr will be

made the northern terminus. The company will carry passengers and light freight, and should the demand justify it a heavy freight service will be added. This line will run through a very rich agricultural country and connect a large number of small towns, to which such a service as that contemplated will be very advantageous, and there is every indication that the venture will be a paying one. It is intended that the roadbed and equipment shall be up to the standard for interurban lines.

## PENNSYLVANIA STREET RAILWAYS.

The total number of miles of street railway in operation in this state is 1,562, being an increase for the year of 253 miles. There are 3,319 motor cars in service, of which the Union Traction Company of Philadelphia owns 1,153. The men employed number 8,394, but this is believed to be considerably short of the actual figures, as many of the companies failed to report the exact number of their employes. The railways carried 376,502,551 passengers, the receipts being \$18,791,553, leaving for dividends \$3,518,053. The capitalization per mile of road averages about \$112,000.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

The West End Street Railway of Boston, is adopting a plan long advocated by the REVIEW, viz., electrical driving for its boiler feed water pumps in its largest power station at Albany street. The arrangement is a very simple and economical one. Two old D62 generators have been set up to operate as motors and are belted to a line shaft. Either one of these machines is large enough to operate all the pumps, so that one is held as a reserve. To the line shaft are belted six quadruple cylinder feed pumps. The line shaft runs at 160 r. p. m. and the pumps at 30. The pumps have fast and loose belt pulleys for starting and stopping independently, and are provided with fly wheels. The pumps are all alike, each having four single acting cylinders, 6 inches in diameter by 6 inch stroke. As many pumps will be run at a time as the load of the station requires. The plant has a maximum rated output of over 13,000 horse-power. It is expected that the new plan will be a decided economy over the old one of feeding by wasteful direct acting steam pumps, not only in the way of fuel but in repairs and attendance. A direct acting steam pump that makes no use of the expansion of the steam it uses, and gives an indicator diagram resembling the cross section of a dry goods box, is not a very difficult thing to beat in the way of economy even through the medium of a dynamo and motor. It might be argued that a steam engine driving the line shaft which drives the pumps would be more economical than the more roundabout power transmission employing an electric motor. But this is not likely to be the case, for the poor economy of the small steam engine as compared with the large compound condensing corliss engines with which the direct connected generators are driven will compensate for the transformation of power from steam to electricity. Then too, the steam engine would require more attention and repair than the motor, to say nothing of the fact that the motor being scrap machinery cost the company nothing, while a steam engine would have had to be purchased. The adoption of this plan by the largest power station in the country will, we trust, induce other companies to throw aside conservatism in this matter and follow the example already set by several English railway power stations.

\* \* \*

In view of the power plant performance tests that have previously appeared in this department the results of a test made in the South Chicago City Railway power station the past fall, furnished us through the courtesy of B. J. Jones, superintendent, are of interest. The test was made to determine the working efficiency of a new direct connected cross-compound condensing corliss, but included the whole plant from coal pile to switchboard. The showing is a splendid one for the general efficiency of the plant and is nearly equal to the best of the twenty electric railway power plant performances summarized in our April 1896 issue. The test lasted 24

hours, from 5 a. m. to the same time the following morning. The results are as follows:

Total watt-hours.....	5,260,000
Total pounds of coal used.....	27,100
Total pounds of water used.....	145,700
Water evaporated per pound of coal (actual condition.) lbs.....	5.37
Water per kilowatt-hour, lbs.....	27.69
Water per electrical horse-power-hour.....	20.65
Coal per kilowatt-hour.....	5.15
Coal per electrical horse-power-hour.....	3.84
Cost of fuel per day.....	\$ 12.87
Cost of fuel per ton.....	.95
Cost of fuel per kilowatt-hour.....	.0024
Cost of fuel per electrical horse-power hour.....	.0018
Cost of evaporating 1,000 pounds of water (actual conditions).....	.0883

The boilers are the Stirling water tube type and Green economizers are employed.

\* \* \*

The want of accuracy in water meters is proverbial and few power plant engineers that have any regard for the truth depend on them for keeping record of the evaporative efficiency of their boilers. The only sure way is to actually weigh or measure the water used for feeding. To measure the water in any quantity requires a large tank, but unless the plant is very much crowded such a tank is usually desirable, not only because it affords an accurate means of measuring water but because it affords water storage to tide over any brief shutting off of the source of supply. The Lynn & Boston Railroad, at its Lynn station, has an iron tank, the capacity of which is accurately calculated from its dimensions. This tank stands on waste land back of the station and contains when full about enough for a day's supply. It is filled every day from the city mains, and the amount of water used is determined by a gauge showing the height of water in the tank. If it becomes necessary to use more water than a tankfull in a day, more is run in and account of it is kept by a water meter. The amount so measured is so small a part of the whole usually, that a considerable error in the meter could cause only a small per cent of error in the total result. However the water meter is calibrated every day by running water through it to fill the tank so that even this small error is eliminated.

\* \* \*

For some years the West End road of Boston, has been hampered in getting coal to its largest power station because the power house is on the opposite side of a public street from the coal docks where fuel is landed. Up to this winter the method has been to load the coal into one horse dump carts and haul it across the street, where after much fuss and backing and slipping on grades it was finally landed in front of the boilers. Conveyers have not been put in as at the other plants of this company because permission could not be obtained to cross the street with conveyors either overhead or underground. Recently, however, the great expense for

### PYROTECHNIC DISPLAY BY THE LAKE STREET ELEVATED.

During the recent snow storm in Chicago, the rails of the elevated roads were covered with sleet and snow. More than the usual amount of arcing and sparking was caused. Whenever a train of cars passed it left a shower of sparks.

These descended to the street or on the tops of the surface cars. People looked upon the spectacle with wonder and suspicion and gave the incandescent particles a wide berth. However it proved to be perfectly harmless, possible small particles of iron and dirt being the cause. Neither the rails nor contact shoes showed any evil effect from the illumination. The flashes were almost continuous and could be seen for blocks, and hundreds watched the display.

### A SELF-FEEDING RAIL DRILL.

The Williams & Moore Railway Jack Company, 90 East Ohio street, Chicago, has recently put on the market the self-feeding rail drill which we illustrate herewith. In it, the inventor, Mr. Moore, has developed a mechanically efficient drill which is compact in form and easily manipulated. The

FIG. 1—MOORE'S SELF FEEDING RAIL DRILL.

illustrations which we publish show the construction. Fig. 1 is a plan and Fig. 2 an elevation of the drill when in position.

Rotary motion is transmitted to the drill through the four bevel gears, which are supported in the principal casting A, and operated by the hand lever B, a double ratchet, which engages the wheel C on the forward stroke and

D on the return, thus giving a continuous application of power to the drill. The thrust of the drill is transmitted from the lower bevel gear, the shaft of which serves to hold the drill, through an inner frame E (which is not very clearly shown) and is finally received on the steel nut F, carried on the screw as shown. Ball bearings are provided between the gears and the inner frame E, and also where the outer gear bears on the nut F (this latter ball bearing is shown by dotted lines in Fig. 1) and by this means the friction due to thrust is cut down to a minimum.

The screw is firmly set in the yoke G, as are the guides H I L, which serve to keep the main casting A in line. The arrangement of the side straps and the hooks which grip the rail is readily seen. By lifting the lever I, the side straps are thrust forward and the hooks pushed out so that they may be thrown back and permit a train to pass without moving the drill. It should be mentioned that the hooks may be adjusted so as to pass under the rail as well as over it.

The automatic feed is secured by means of the split collar K, which is fastened to and turns with the shaft of the outer gear. When the thumb screw J is loosened the nut F remains stationary and the feed is by hand, but when the thumb screw is tightened the collar bears on the lower portion of the nut (shown dotted) and causes the latter to turn, giving an automatic feed. As the only connection

FIG. 2—ELEVATION.

between the collar and the nut is through friction the speed of the feed depends upon how tightly the nut is gripped.

The drill is 11 inches wide by 24 inches long and  $6\frac{3}{4}$  inches high. When in position it rests upon a foot piece P, and the shield S, which protects the gears from contact with the ground.

### THE NEW ORLEANS TRACTION COMPANY.

The New Orleans Traction Company, which has heretofore rented its power from the Louisiana Light & Power Company, has purchased from the latter company one-half of its plant, comprising eighteen boilers, three large engines and generators. Several improvements in the plant are contemplated, and the capacity will be increased by adding a 1,000-h-p. cross-compound Allis engine direct connected to an 800-k-w generator. The company has made arrangements for the summer season at its West End resort. Among the attractions is Phinney's United States band of Chicago, which has been secured for two months. It will be remembered that it is this company which recently secured the able services of C. D. Wyman, late of Milwaukee, as general manager.

The Tramways Committee of Dover, England, has decided to make some improvements. A new car shed is to be constructed, new rails laid, the road-bed improved and additions made to the equipment.

## BAD MONEY.

## How It Comes to Street Railways and What is Done With It.

Whenever a man finds that some one has passed a counterfeit nickel, dime or quarter on him, he has a very vindictive feeling. However honest he may be, it is a great temptation to either drop the bad coin in the collection box or give it to some unsuspecting street car conductor. Most of the street railway companies have had to make rules in regard to receiving this kind of coin, leaving the conductors to bear the responsibility of such dishonesty. Perhaps their stories would be of more interest than those from the treasurers of the companies. While pursuing this investigation the writer had a practical example of how this matter is treated. Some evil disposed person left a poor sample of a counterfeit half dollar with a Chicago conductor. No doubt the conductor felt that there were two parties involved, himself and the public and he was the injured one. Retribution was his right and he slipped the counterfeit into the hand of the next unsophisticated person needing change. This is the every day method of solving the problem.

However, in spite of vigilance, the companies find themselves in the possession of some bad money. A short time ago the Citizens Street Railroad Company of Indianapolis, turned over to the United States treasury agent about three years accumulation of counterfeit money which was forwarded to Washington to be destroyed. The coins are mostly of small denomination, but one very poor counterfeit of a \$5 gold piece was among them. It was made of composition metal, imperfectly stamped and gold plated. Two \$3 silver certificates, known as Windom-head notes were also sent to Washington. The rest of the collection was made up of 28 dollars, mostly cast and of poor quality, 18 half dollars, 46 quarters, 384 dimes, 936 nickels and 1,390 coppers. We have received numerous letters from street railway treasurers who make the following reports:

The Consolidated Traction Company, of Jersey City, says: "Our receivers have orders not to accept any mutilated or counterfeit coins. If they do so, they are obliged to make good the amount."

The Chicago City Railway Company says: "In regard to bad money, will make the following answers: We accept only current money from conductors. About twenty dollars slips through all hands annually. That we do get, we destroy. We find that dollars predominate in counterfeits."

The Tri-City Railway Company of Davenport, Iowa, answers: "We do not accept it from conductors. They must stand any loss from this source. Receivers report counterfeit silver dollars occasionally and some plugged nickels. Very little trouble from this source."

Denver Consolidated Tramway Company says: "We accept no counterfeits. If a bad coin is turned in, it is held back and given to the secret service agent. The conductor must pay a good coin in its place. For 1896, about \$20.80 was received which is about the average. The counterfeits are mostly dollar and half dollar pieces. Conductors have the privilege of going to secret service agents and finding out about all new counterfeits. Notices of new counterfeits are often sent to conductors."

The New Orleans Traction Company has this to say: "Touching bad money, counterfeit coins received from conductors are retained by us, and the value they were intended to represent, collected from the conductor. We receive

monthly an average of about \$12.00 counterfeit money. By request of the special agent of the Treasury, counterfeit coins are turned over to the Government monthly, and a receipt taken for the amount. The denominations usually received are dollars and quarters, principally quarters."

The West End Street Railway Company of Boston, says: "Replying to yours of the 13th would say that our rule regarding counterfeit currency, is to charge it to the conductor turning it in. We keep no account of the total amount turned in but I should say that in round numbers it amounts to \$1,000 per annum out of gross receipts of some \$8,000,000. Quarters and halves predominate in amount but nickels are received in the greater number. The Government compels us to keep the counterfeit currency until it is called for by an inspector and it is then carried away by him in the lump. Under the laws we are held liable as issuers of counterfeit money, if any is returned by the company to the conductors turning it in."

Twin City Rapid Transit Company, of Minneapolis, says: "Previous to 1894, our conductors deposited the receipts in an envelope at the end of each trip. Under this system there was received fully \$100 per year bad money, and about \$600 in mutilated coin. The bad money was charged up to the conductors, and turned over to the United States Government Agent who collected it once a month. The mutilated coin was returned to the conductor to be redeemed by them. Our experience has been that the spurious coin predominates in the dollar, and the mutilated coin in the subsidiary coin. Under our present system our conductors settle at the close of each day with the settling clerks at the stations, and any bad or mutilated coin is not accepted in settlement. The bulk of our silver is shipped direct to the Sub-Treasury in Chicago, and they are very particular regarding mutilated coins, and coin that passes current here, or at any of the banks, is refused by them. We get back from these Sub-Treasuries not over \$50 a year. We can sell our mutilated coin in open market at 40 cents on the dollar. There is, however, a party in Chicago who calls here once a month and pays us 50 cents on the dollar. Just what disposition he makes of it, I do not know."

## THE VESTIBULE QUESTION ON THE COVINGTON &amp; NEWPORT LINES.

Superintendent T. M. Jenkins, of the South Covington and Cincinnati systems, thinks that his scheme of caring for his motormen during the cold weather is better than those generally in vogue and disposes of the vestibule problem which has recently been agitated there. Extra men are put on the cars to take the place of the regular motormen at every other trip across the suspension and Newport Central bridges. Not only is this done but a supply of hot coffee and substantial lunch is on hand at the different bridges and waiting stations where the men make their shifts. This is served free to the motormen and conductors. None of the men relieved have deductions made in their wages for the time spent off their cars.

Mr. Jenkins maintains that this plan is not a matter of economy but that it is most satisfactory and has been in operation for three years. There are also fewer accidents for there are no vestibules to obstruct the sight and hearing of the motormen.

THE LONDON TRAMWAYS.

"The London Tramways" was the subject of a lecture delivered by J. Allen Baker, in connection with the London Reform Union, on November 26. The extreme poverty of London in regard to this cheap and efficient mode of transportation was well presented in the following table, in which comparisons are made with other cities in Great Britain, on the Continent, and in America:

TOWN.	Population.	Length of Tramways.	Miles in London if there was the same Proportion.
Glasgow ... ..	750,000	40 miles ... ..	280
Leeds ... ..	400,000	24 miles ... ..	300
Dublin and Kingstown ...	300,000	40 miles ... ..	400
Huddersfield ... ..	100,000	20 miles ... ..	1,000
Hamburg (Germany) ...	650,000	60 miles ... ..	480
Hanover (Germany) ...	166,000	40 miles ... ..	1,200
New York ... ..	2,000,000	{ Street miles, say 250 800 single miles	625
Brooklyn ... ..	1,000,000	{ Street miles, 200 600 miles track	1,000
Boston (suburbs) ...	900,000	{ Street miles, 250 Track miles, 428	1,875
Philadelphia (suburbs) ...	1,200,000	{ Street miles, 280 Track miles, 470	1,120
Washington ... ..	250,000	{ Street miles, 75 Track miles, 144	1,500
Chicago ... ..	1,900,000	{ Street miles, 450 Track miles, 780 Electric, 680 Cable, 85 Horse, 17	1,300
St. Louis ... ..	645,000	{ Street miles, 175 Track miles, 335	1,300

London, with a population of from four and a half to five millions has but 141 street miles of track of which one quarter is single.

In London, wages are lower and horses and fodder higher than elsewhere, and because of these conditions mechanical traction would give correspondingly higher profits, or what is perhaps of more importance to patrons, more extended, better and cheaper service with no diminution of the profits of the companies. As it is, London imports horses from Canada, a country which, of 462 miles of street railway, has but 12 operated by animal traction.

ELECTRICITY ON THE NEW YORK, NEW HAVEN & HARTFORD RAILROAD.

N. H. Heft, chief of the electrical department of this road, writes us that the work on the power house at Berlin, Conn., is progressing favorably. This station will furnish current to the Berlin branch of the New England railroad between New Britain and Hartford. The third rail conductor to be used is similar to that employed on the Nantasket Beach road which has been described in a former issue. The station is to be equipped with 10 horizontal tubular boilers, made by Edward Kendall & Sons of Cambridgeport, Mass., 2 cross-compound condensing engines of the improved Green type, made by the Providence Steam Engine Company, and 2 direct connected generators of 850 K-W capacity each.

The street car lines of Christiania, Norway, have passed into the hands of a German syndicate, the Berliner Gesellschaft fuer Electricische Unternehmungen. The new proprietors, no doubt, contemplate displacing the horse with the electric motor.

ALLEY "L" OFFICERS.

The reorganization of the Alley "L," under the title of the South Side Elevated Railroad, was effected in the latter part of January, and the new company assumed control in the early part of this month. The company has made a provisional contract with the Union Loop Company and will pay 1/2 cent for every passenger carried with a minimum charge of \$62,500 per annum. The officers are Leslie Carter, president; William Flemming, vice-president; Marcellus Hopkins, late the receiver, general manager; John H. Glade, secretary and treasurer.

ANOTHER ACCIDENT FRAUD.

A short time ago a man fell off a White line car in Baltimore and seemed to be badly injured. He pretended to be in great pain and was removed to the city hospital, but refused to permit a physician to examine him. Later two witnesses turned up and the company compromised with him for \$60. Not long afterwards another man went through the same performance on the same line. The manager of the street car company became suspicious and set a detective to work. The man finally confessed that he was not hurt and made his escape as soon as the detective left him.

BALL AT BINGHAMTON.

On February 4, the members of the Employees Aid Association of the Binghamton Railroad Company, entertained their friends at the second annual ball of the association, which was held at Bennet Hall, and proved a most enjoyable entertainment. The bulletin board called for two trips with a lay-off of 60 minutes when supper was served at the Delmon'co. After the signal of "All right—go ahead," the program commenced with a waltz, "Get your fairs ready, please," "A regular armature winder," and "Step lively, please, we're late" were later ones and the last dance was "All out here."

INTERURBAN FARES ON THE LOWELL, LAWRENCE & HAVERHILL.

The Lowell, Lawrence & Haverhill Street Railway has a very simple plan of collecting fares on its lines and one which seems to be as secure as any. On the line from Lowell to Lawrence through cars are run and the fare for the whole trip is 15 cents. The line is divided into three divisions on each of which a 5-cent fare is charged. When a passenger gets on at one end of the line and pays the full fare of 15 cents to the other end the conductor rings it up as a 5-cent fare and hands the passenger two tickets or checks good for a 5-cent ride each. When the next section of the road is reached the conductor goes through the car again, collecting a fare from every one in it. The passengers having checks turn them in, of course, as fares, and the conductor rings them up as such. The same operation is gone through with on the third division of the road. The conductor must therefore at all times be able to show cash for the fares he has rung up and the checks he has issued. The plan amounts to a collection of cash fares on each division, except that through passengers are given change in the shape of checks instead of cash.

## TEMPORARY ABANDONMENT OF TRACKS DOES NOT WORK FORFEITURE.

The Milwaukee Electric Railway & Light Company won a notable victory in the suit brought by the 27th street property owners to restrain it from laying its tracks. It was claimed that abandonment of certain tracks annulled the franchise, but the decision of the Supreme Court as delivered by Justice Winslow does not sustain the stand. It further settles all questions as to a franchise being a contract and asserts that it is granted by the state through the medium of the city and any action affecting it must be brought by the attorney-general, after obtaining the consent of the Supreme Court. Justice Winslow further says:

"By the acceptance of the terms of the ordinance the railroad company assumed a public trust; it undertook to serve the public by affording it rapid transit and it became its duty to continue that service not simply because it had contracted so to do, but because it had become charged with such duty by legislative grant. It could not lay down the burden when it chose nor emancipate itself by merely ceasing to operate its cars. In case of an attempt on its part to so shirk its duty as to a part of its road it could doubtless be compelled in proper proceeding to resume its operation and carry out the public duty which it voluntarily assumed. (*Attorney-general v. West Wis. Railroad Company*, 36 Wis. 466, 497). Certainly in such case action could be brought by the state to forfeit its franchises and vacate its charter for failure to exercise its public powers and perform its duties.

"Coming now to the question whether the franchise has been extinguished in the case before us it is quite apparent that there are only four ways in which it can be claimed that such extinguishment could take place, viz: First, by operation of some self-executing forfeiture clause in the grant; second, by surrender of the franchise and acceptance of such surrender on the part of the state; third, by the decree of a court of competent jurisdiction on an action brought for the purpose; fourth, by abandonment or non-user for so long a period that a surrender and acceptance will be presumed. There are no facts in the case upon which it can be claimed that the franchise has been extinguished in either of the first three ways above mentioned. There was no self-acting forfeiture clause in the ordinance which granted the franchise; there has been no surrender thereof and acceptance of such surrender by the state, and no action has been brought to declare and enforce the forfeiture. There remains then for consideration only the question whether it has been wiped out by nonuser for more than four years. It is argued that from this fact an abandonment of the franchise has resulted. It is evident that the term abandonment as applied to a corporate franchise of this kind is a misnomer. A mere privilege or right may perhaps be properly said to be abandoned in a proper case, although even in that case there must be something more than mere nonuser to constitute such abandonment; there must also be an act clearly indicating an intention to abandon. (*Washburne on Easements*, 3d ed. p. 661.)

"But while a mere easement or right may be abandoned, the word is plainly applicable to a duty owing to the state. A public duty is not to be laid down at will. In the case of a mere easement there is but one party interested and he may voluntarily abandon his right, but in case of a public duty there are two parties beneficially interested, i. e., the

party who owes the duty and the state to which the duty is owing. The necessary result must be that, in order to extinguish the duty, there must be concurrence on the part of the state.

"The period of nonuse was about four years and eight months. It was a period of great industrial depression and of extraordinary financial difficulties on the part of the various corporations which successively owned the franchise; the old track became by reason of the change in means of locomotion, practically worthless, and its entire reconstruction a necessity, it appears by affidavits of officials of the roads that it was always the intention to resume operation of these two blocks as soon as the financial atmosphere cleared.

"This then is the situation: There has been no cesser to use accompanied by any act clearly indicating an intention to abandon the right; even if it could be said that there was any such act there has been no consent on the part of the public to such abandonment nor acceptance of a surrender; the nonuse has not existed for such a length of time nor under such circumstances that a surrender and acceptance of the franchise can be presumed.

"It follows that when the plaintiffs commenced their action the franchise was still in existence and consequently the injunctive order was erroneous.

"By the court: Order reversed and action remanded for further proceedings according to law."

## NEW TRACTION ON THE CINCINNATI, HAMILTON & DAYTON.

The Cincinnati, Hamilton & Dayton Railroad Company had decided to adopt some other tractive power than steam on its branch line between Middletown and Hamilton and is considering propositions from several electric companies and also one from the American Air Power Company of New York for a system of compressed air. John W. Hill, consulting engineer, has been retained by the company to advise it as to the practicability of using compressed air. If it is possible to do so this system will be adopted, in order that the overhead installation incident to electricity may be avoided. The track on this division is in exceptionally fine shape and no changes will be made in it. The car equipment will be of the best and designed especially for interurban service. This line of steam road is to be operated in connection with the Middletown Street Railway, making together 26 miles of track.

## "ELECTRIC GRASS."

One of our electrical friends who operates a road in a swamp country was surprised one day last summer on finding that there was an appreciable difference of potential between the different parts of the lawn in front of the power station. Thus, if a rod was stuck into the sod at one spot on the lawn and another rod at another point, a deflection could be obtained on a low reading voltmeter connected between them. This was a somewhat startling discovery even to the electrician himself, but when one of the clerks learned of the fact he (the clerk) seemed to have a great light dawn upon him. "I've noticed," he said, "that the grass on that lawn seemed to grow remarkably well. Don't you suppose that the electricity helps it grow. You know they have been making plants grow by electric light recently."

## THE STREET RAILWAY AT ATHENS, GA.

### Water Power Replaces Steam—An Interesting Plant.

Two and a half years ago the present owners of the street railway of Athens, Georgia, purchased the plant from the receiver who had operated it for eight months under the orders of the Superior Court. The outfit consisted of the steam generating plant, six miles of track, four or five second hand cars with old fashioned electrical equipment and a twelve acre park. The business grew amazingly from the start and improvements were made as rapidly as the receipts would allow.

After a year's ownership, about 18 months ago, the company took up the question of running the railway by water power, and finally determined to purchase the shoals and property of the Oconee Mills Company, which had for a half century operated a grist mill on the Middle Oconee river, two and a half miles from Athens.

The development of this power gave the company a surplus beyond their need for the railway, and as a consequence, it was determined to install a light and power plant to operate in connection with the railway. A contract was made with the Stilwell-Bierce & Smith-Vaile Company of Dayton, Ohio, for an equipment of one pair of 39-inch horizon-

RACE AND GATES.

tal wheels and one 33-inch horizontal wheel, together with the flume and gate work for another 33-inch wheel to be put in at a later date if necessary.

Much preliminary work was necessary in the building of the dam, a timber structure 400 feet long, the blasting out of the head and tail races and wheel pit and the necessary masonry for the foundations and race walls; all of which were built in the most substantial and lasting manner.

The head race, protected by massive pine gates, is 175 ft. long, 33 ft. wide and 12 ft. deep, and the wall on the river side and the abutments are built of rock, laid in the best Portland cement, 13 ft. thick at the base and 5 ft. thick at the top. After escaping from the wheel pit, the waste water is carried through a practically natural canal 500 ft. long to a point on the shoals 6 ft. below the level of the river at the station, from which for 100 ft. the race is separated by a dam of timber covered with loose rock.

Upon the completion of the foundations, the Stilwell-Bierce & Smith-Vaile Company sent its representative,

W. B. Reynolds, to install the wheel work and in 30 days this portion of the work was completed in a most satisfactory manner and the construction of the building begun.

STATION AND TAIL RACE.

The most important feature of the whole work, perhaps, was the Giesler governor, upon which depended the success of the installation and the completion of the contract and guarantee.

The condition under which the railway governor works are unusually trying, owing to the fact that the two lines of the system meet at a junction point, and all cars stop and practically start at the same time, making the changes from no load to full load and vice versa, frequent. Under these conditions the governor regulates very satisfactorily.

The 33-inch wheel is belted direct on the railway generator, which was removed from the old steam plant. In the center of the generator floor, the General Electric Company installed one of the latest improved 250 k-w. mono-cyclic generators belted by a 34-inch belt from the shaft of the 39-inch wheel with a handsome marble switch board and all

RAILWAY WHEEL AND GOVERNOR.

necessary instruments. From this machine three wires are carried to the center of distribution in the city, two of them for lighting and the third, a teaser, being called in play for motors of the induction type.

This, being almost the first mono-cyclic installation in the south, has attracted great attention and interest throughout this and neighboring states, where water-powers abound and have for years, run to waste; and its success, which is practically assured, points to the development of many similar powers and the growth of small and large industries under the fostering care of cheap power.

On November the first, the company secured the city lighting and moved to its station the two 50-light T-II arc machines owned by the city. These are driven from the shaft of the 39-inch wheels by Medart clutch pulleys, and the steadiness of the city lights has caused unusual comment and expressions of satisfaction from the city fathers.

The building, covering the wheels and generators, is 75 by 52 ft., built of stone and brick with metal covered roof. The generator floor is raised 8 ft. above the floor of the wheel room, in order to avoid any possibility of danger from high water, and an engine room has been built and engine and boilers installed for use in case of emergency. From the station to the center of distribution the wires are carried in almost an air line on heavy cedar poles, and from the center, four circuits radiate to different portions of the city, giving the best possible effect and an unvarying voltage

GENERATOR FLOOR.

in the secondary lines. The new type H transformer of the General Electric Company has been installed and has proved very efficient. The railway equipment of the company has been greatly improved by new cars and equipment and during this winter the electrical heating of the cars has been tried and proved a paying investment to the company and an appreciated comfort to its patrons. An extension of the plant is contemplated to the Seaboard Air Line and North Eastern Railway stations and eventually to the power station, where the company owns sufficient land for a large park and an attractive stretch of water for boating and sailing.

When this plan is carried out, the chute and other attractions would be moved from the present park in the city and a very enticing pleasure resort laid out. The officers of the company are; W. S. Holman, president; J. Y. Carithers, vice-president; W. T. Bryan, secretary and treasurer, and C. D. Flanigen, superintendent and purchasing agent. These officers with A. P. Dearing, form the board of directors.

## THE CHICAGO METROPOLITAN ELEVATED.

Plans for reorganizing the company have been formulated by Walter G. Oakman, Samuel Thorne and Frederic P. Olcott. It is intended that one-half of the \$15,000,000 of bonds be converted into preferred stock. The fixed charges then on \$7,500,000 of bonds would be \$375,000 which is \$55,000 more than the net earnings in 1896. About 53,000 passengers were carried a day in January. It is expected that with the Union Loop in operation the traffic will greatly increase and the earnings will be sufficient to cover the full fixed charges. Robert E. Jenkins is president and William E. Baker has been elected vice-president and general manager. The road is being operated under the receivership of Dickinson MacAllister.

## HOT WATER ON STEAM ROAD.

Not having a legislature which would give it an "anti-electric law" such as obtains in Connecticut, the Chicago & Northwestern Railroad found it necessary to resort to hot water as a preventive. This road had obtained an injunction to prevent the Milwaukee, Racine & Kenosha Electric Company crossing its tracks at South Milwaukee, which was dissolved on January 9, and the electric company at once proceeded to attempt to lay the crossing. In addition to sending its men to guard the track, stealing the tools of the rival company and running a switch engine back and forth over the crossing, the Northwestern people attached a hose to the boiler and threw hot water on the street railway men. As a result of this latter President Slush, of the Milwaukee, Racine & Kenosha has brought a personal injury suit against the Railroad Company.

## ELECTRIC RAILWAYS IN EUROPE.

The Journal des Transports has published some statistics showing the rapid development of electric street railways in Europe during 1896, the number having increased from 70 to 111, with a total length now of 561 miles as against 437½ a year ago. The trolley, in spite of the many objections we hear urged against it by property owners and in some cases by public authorities, is so far in the lead that there can scarcely be said to be a second. Of the 111 lines 91 are operated on the overhead trolley system, 9 have a central rail, 8 accumulators, and 3 an underground current. The geographical distribution of the lines is as follows: Germany, 255 miles and 857 motor cars; France, 82½ miles and 233 cars; England, 67 miles and 168 cars; Switzerland 29½ miles and 86 cars. Bulgaria and Denmark are the only countries which have no line worked by electricity.

The Blackburn, Eng., Tramways Company has voted to equip with electricity those portions of its lines now operated with horses. The city has offered to build the plant and furnish current at 6 cents per car-mile.

The rewards for the competitive designs of the Jungfrau Railway have been given, the Swiss and German firms receiving the major share. One American and one English concern submitted plans and received prizes.

## NEW RAILWAYS IN JAPAN.

In the adoption of modern methods of manufacture and transportation Japan is not neglecting the street railway. We learn that among the lines recently proposed are the three following, with an aggregate capital of about three and one-half million dollars. The Fushimi Electric Railway, with a capital of 900,000 yen and promoted by Okubo Yoshio of Tokio and others, is a line  $28\frac{1}{2}$  miles long running from Fushimi to Nishinomiya, via Nasso, Todaiji, Koriyama and Itami. A company with 33,000 yen capital proposes a tramway  $5\frac{1}{2}$  miles long between Inamimachi and Demachi in Tomachi district, Toyama-Ken. The Tokio Circuit Tramway, with a capital of 2,500,000 yen will build a line  $44\frac{1}{2}$  miles long in Tokio.

## ANNUAL REPORT OF THE COLUMBUS, (O.) STREET RAILWAY COMPANY.

President Emerson McMillin has presented a report for the fiscal year ending December 31, 1896. The road has felt the effects of business depression, but good management and harmonious relations between the officers and employes of the company have combined to make operating expenses very low. A great deal of extra patronage was received by the opening of Olentangy Park, which is an amusement ground.

The number of passengers carried in 1896 was 13,810,455, which is about 30,000 less than the previous year. Car-miles run in 1896, 3,860,540; 1895, 3,592,333. Earnings per car mile in 1896, 16.2 cents; 1895, 17.4 cents. Expenses per car mile in 1896, 8 cents; 1895, 8.7 cents. Operating expenses in 1896 were 49.2 per cent of total receipts; in 1895, 49.7 per cent.

Dover, England, proposes to employ automobile vehicles for street scavenging in place of the present horse-drawn carts.

Vienna engineers have been granted a franchise to construct an electric railway between Arnau and Koniginhof, Austria.

Manchester local authorities have been asked to permit the construction of electric railways. The promoters are represented by Andrews & Butterworth, surveyors, and Joseph Sampson, solicitor.

Electric locomotives will be tried on the lines running from St. Petersburg to Moscow and Warsaw, Russia. The experiment is said to be in charge of the Ministry of Ways and Communications.

The Oberschlesische Dampfstrassenbahn Company will soon be supplied with air brakes from the Standard Air Brake Company, New York. The order is for equipping 30 double truck motor cars.

It seems probable that Barcelona, Spain, will soon enjoy the blessings of electric traction. Plans have been laid before the Commission of Public Works to construct an electric tramway and these have been accepted with certain conditions. The speed of the cars is regulated to  $7\frac{1}{2}$  miles an hour when carrying passengers and  $9\frac{1}{2}$  miles when empty.

## REDUCED STREET CAR FARES.

By J. P. E. Clark, General Manager Binghamton Railway.

There has been a marked disposition of late on the part of municipal and state legislators throughout the country to enforce a lower standard rate of street car fare than now exists. They have been warmly seconded in their efforts in this direction by the press.

The sole arguments advanced in favor of the proposed reduction is "prices of everything except car fares have been reduced in the past few years." Conceding the truth of the common argument, there are innumerable advantages and privileges afforded the street car rider of the present day that have evidently been overlooked by our friends, the legislators and the press, and when carefully considered will offset the argument advanced and demonstrate beyond question that, notwithstanding the standard 5-cent fare has not been reduced, the increased length of ride and general efficiency of service of the present day afford largely enhanced facilities and conveniences and much better returns for the nickel expended than in days of old, when horses and mules were the propelling power of street surface railroads and the numerous improvements of the present day were unknown.

In nearly every city and large town throughout the United States the street car lines have been extended and new divisions added and with the general system of free transfer almost universally adopted in the past few years.

In many cities where several roads have been merged into one, the companies could, under their original charters, charge double fares, but have waived their privilege, establishing a universal 5-cent fare, with free transfers to all parts of the city.

The demands made of a street railroad company today are greatly in excess of those of a few years ago. The cars must be new and up to date, thoroughly cleaned, heated and in charge of competent well dressed crews. All modern appliances for heating and the comfort of passengers are expected as soon as invented and their practicability demonstrated, and cars must be operated more frequently. To accomplish all this means much larger investments than in the old horse car days and largely increased expense of operation and maintenance. Of course receipts are greater; were they not, the street railroad organizations could not pay operating expenses, to say nothing of interest or profit. The increased liability of accident to persons and property under the present system of electric and cable service is an important item of expense manifest to all street railroad officials, but apparently lost sight of by the legislators and press.

When taking into consideration that in many of the larger cities a person, by the use of the transfer system, can spend almost an entire day on a street car upon the payment of a nickel, and in smaller cities reach any point he may desire for 5 cents, boarding a large, airy, well appointed car at his convenience, and comparing the same with the stuffy, foul smelling old horse car of a few years ago, to say nothing in relation to the rapid transit and saving of time thereby, the people of the present day should be eminently satisfied with a 5-cent fare.

Upon looking at the increased facilities and advantages furnished under the improved system of street railway service of the present day, the street car rider should pay his 5-cent piece cheerfully and thank his lucky stars that he lives in a progressive age.

### Arkansas.

EUREKA SPRINGS, ARK.—Local men have subscribed enough stock, it is said, to insure the construction of the Berryville & Eureka Springs Electric Railroad.

### California.

OAKLAND, CAL.—J. J. Lamping has petitioned for a street railway franchise.

SAN DIEGO, CAL.—The Citizens' Traction Company has been attached by the Risdon Iron Works for \$2,400 for material supplied.

OAKLAND, CAL.—A consolidation of all Oakland car lines is being engineered by William Henshaw, manager of the Union Savings Bank.

SANTA ANA, CAL.—The city trustees consented to the transfer of the motor railway franchise from E. I. Tolle to the Santa Ana and Orange Motor Company.

SAN FRANCISCO, CAL.—The Market Street Railway Company petitioned the board of supervisors for a 50-year franchise to run a single or double track railway along Masonic avenue and other streets.

SAN DIEGO, CAL.—A. D. Norman has been appointed receiver of the Citizen's Traction Company upon petition of the Union Savings Bank and Trust Company of Cincinnati; mortgage indebtedness amounts to \$80,000 and a floating indebtedness of \$20,000, monthly receipts, \$16,000. The road will continue operations.

### Chicago.

CHICAGO.—The Inter-Ocean Electric Railway Company has amended its charter to decrease capital stock.

CHICAGO.—The General Electric Railway Company has been granted right to construct conduit roads on thirty miles of south side streets.

CHICAGO.—Negotiations are pending for a reorganization of the Calumet Electric Street Railway, its consolidation with the South Chicago City Railway, and the construction of additional lines.

CHICAGO.—The Chicago General Street Railway and the West Chicago Street Railroad have buried the hatchet. The Chicago General is given right to operate over the West Chicago's right of way to the stock yards at a rental of \$200 monthly.

CHICAGO.—Dickinson MacAllister has been appointed receiver of the Metropolitan Elevated Railroad. The line is a new one, 16 miles in length and cost \$14,000,000 to build. On this investment there has been issued \$15,000,000 of bonds and about the same sum in stock. After paying operating expenses of \$500,000 annually, the road has only \$400,000 with which to meet fixed charges of \$750,000.

CHICAGO, ILL.—Judge Showalter entered an order extending the receivership of G. H. Condict, of the Englewood & Chicago Electric Street Railway to a bill for foreclosure. The bill was filed by Stephen D. Bayer, who bought the creditor's bill upon which the receiver was appointed two weeks ago. It is the intention to have the court issue receivers' certificates, equip it with storage battery cars and then sell it.

CHICAGO.—The South Side Elevated Railroad Company has been incorporated to acquire the reorganized Alley Elevated Railroad, build extensions and equip electrically. Capital stock, \$10,323,800; directors, Byron L. Smith, W. B. Walker, A. O. Slaughter, Joseph Leiter, L. J. Gage, George E. Adams, Chauncey J. Blair, E. L. Lobbell, T. J. Lefens, E. Buckingham, William Fleming, and Leslie Carter.

### Connecticut.

FARMINGTON, CONN.—An electric line connecting Farmington and Torrington is being surveyed by T. H. McKenzie, 38 Ballerstein building, Hartford.

EAST WINDSOR, CONN.—The East Windsor Electric Railway has been incorporated to build a connection of the Hartford Street Railway and the Enfield Street Railway. Incorporators, J. H. Simonds, C. G. Harrison, S. D. Rockwell, L. B. Griffin, C. E. Woodward, G. A. Ellis, E. F. Thompson, John Mason and G. S. Phelps.

TORRINGTON, CONN.—Among the incorporators of the proposed electric road to Harwinton are the following: From Farmington—Senator Erastus Gay, A. R. Wadsworth and E. C. Ayer; Burlington—John A. Reeve (judge of probate and town clerk), Adrian Moses, Lester A. Lowrey and Edwin N. Gillett. Harwinton—Lewis Catlin, Sylvanus Smith, Albert G. Wilson, Elijah G. Gibbs, A. E. Bartholomew and Charles S. Birge. Torrington—D. W. Clark, W. V. Barber and H. M. White.

### District of Columbia.

WASHINGTON, D. C.—The district commissioners propose to sell the Anacostia Railroad on claims for paving.

WASHINGTON, D. C.—Right to erect a trolley line along the Anacostia Railway is asked by President A. E. Randle of the Capital Railway Company.

### Georgia.

ATLANTA, GA.—The Consolidated Street Railway will relay 100 tons of 70-pound rail on creosoted ties.

ATLANTA, GA.—The Consolidated Street Railway Company is considering the extension and improvement of its suburban lines.

ATLANTA, GA.—It is practically settled that the Chattahoochee River Electric Railway will be extended to Marietta by the Collins Park & Belt Railway Company, C. J. Simmons, president.

SAVANNAH, GA.—The Savannah Traction Company has been incorporated by the purchasers of the electric railway. Herman Myers of Savannah, paid \$211,000 for the road at the recent judicial sale. His associates will expend \$75,000 to 100,000 additional to equip the power plant for commercial lighting as well as railway work.

### Illinois.

LINCOLN, ILL.—W. H. Traner has been appointed receiver of the Lincoln Electric Street Railway.

WAUKEGAN, ILL.—A franchise through Highland Park has been granted the Bluff City Street Railway.

EAST ST. LOUIS, ILL.—The council has granted a franchise for 14 miles of electric railway connecting East St. Louis and Belleville.

PARIS, ILL.—Capt. M. Evinger, of Terre Haute, Ind., is interested in the Enterprise Electric Railway Company, organized to build a line in Paris.

LINCOLN, ILL.—The Lincoln Street Railway, of which W. H. Patterson is president, has suspended operation owing to inability to pay for labor.

OTTAWA, ILL.—A franchise was granted by the council to the Ottawa Street Railway Company. The management expects to build lines along the frontage petitioned for and rebuild.

PARIS, ILL.—The stockholders of the Enterprise Electric Railway Company elected Morris S. Evinger, of Terre Haute, Ind., president. The 100 shares of \$100,000 stock was delivered at the office in Terre Haute. A franchise will be asked to operate a line here.

OTTAWA, ILL.—The Ottawa Electric Street Railway Company has been reorganized by George J. Paul, of Chicago. The capital stock of the new company is \$100,000, and the officers are W. P. Ellis, of Boston, president; M. T. Moloney, of Ottawa, vice-president; George J. Paul, secretary and general manager, and Al. F. Schoch, of Ottawa, treasurer.

### Indiana.

MARION, IND.—Superintendent C. W. McWhinney says the Marion City Railway will be extended to Fairmont as soon as the weather will permit.

COLUMBUS, IND.—John S. Crump's electric car line and lighting plant has suspended operation owing to dull business, and the doubling of the insurance rate on all buildings lighted from the trolley circuit.

MARION, IND.—David Overman and John McDonnell have revived their Marion, Hackleman & Independence Electric Railway scheme, which has been slumbering for 2 years. They are getting farmers' consents.

HARTFORD CITY, IND.—The scheme to connect a number of small towns in the vicinity by electric railroad is being revived by Muncie, Hartford City and Monepelier capitalists. R. H. Howe, of Indianapolis, is consulting with the parties interested and is making an effort to furnish the rolling stock.

### Iowa.

COLESBURG, IOWA.—Hon. F. A. Grimes, of Colesburg, is promoting an electric railway to connect with Manchester.

### Kentucky.

FRANKFORT, KY.—Special Commissioner T. N. Lindsey will sell the Capital City Street Railway at an upset price of \$12,000, by order of Judge Barr.

OWENSBORO, KY.—The barns of the Owensboro City Railroad were burned at 10 o'clock a. m., January 5, together with four open cars valued at \$7,200; four trail cars valued at \$2,000; one mule car, valued at \$250; repair supplies valued at \$500, and four motor equipments valued at \$1,600. The total loss is \$12,150, and the insurance \$3,000. Owing to excessive premiums the company had reduced its line of insurance. Operation continues as usual, and orders will be placed very soon for new summer cars in place of those burned.

### Maine.

KITTERY, ME.—The Kittery & Eliot Street Railway Company has been incorporated with \$300,000 capital stock by Frank E. Rowell, Horace Mitchell and others.

SANFORD, ME.—The Mousam River Railroad (electric) may be extended to Kennebunkport and Cape Porpoise by Boston men who are negotiating a purchase of the property.

NORWAY, ME.—The Oxford Central Electric Railway Company proposes to build 31 miles of road, connecting Waterford, Norway, Stoneham, Harrison and Bridgeton. Among those interested are E. W. Eastman, of Auburn; John D. Clifford, of Lewiston, and L. H. Burnham, of Albany.

### Maryland.

BALTIMORE, MD.—The Baltimore Traction Company has obtained control of the Windsor Heights Line, which will probably be extended to Wetheredville.

BALTIMORE, MD.—The Maryland Traction Company has been incorporated with \$1,000,000 capital, by George R. Week, R. Harry Cox, Wallace King and John Cowan.

BALTIMORE, M. D.—The Falls Road Electric Railway Company was granted permission to extend its tracks on Lafayette avenue, and also to extend proposed line in the annex between Woodberry and Mt. Washington.

HAGERSTOWN, MD.—Receipts of the Hagerstown Railway during the first five months of its operation have averaged \$85 daily, or more

than enough to pay expenses and interest on bonds. Their judgment having been vindicated, the officers will now go ahead with the proposed extension to Funkstown.

MYERSVILLE, MD.—The Myersville & Catoctin Railway Company has been formed to build 8 miles of electric road, connecting with, but independent of the Frederick & Middletown Electric Railway. Capital stock, \$100,000; incorporators, Col. David C. Winebreuer, of Frederick, president; Reno S. Harp, of Frederick, secretary; George W. Wachtel, of Myersville, treasurer; Cyrus F. Flook, of Frederick; Maurice E. Brightbill, of Annville, Pa.; and John C. Leatherman and George D. Toms, of Myersville.

### Massachusetts.

SCITUATE, MASS.—The Norwell & Scituate Street Railway Company has accepted its franchises.

HANOVER, MASS.—The Hanover Street Railway Company will begin work this spring on a 10-mile extension to Scituate.

MILFORD, MASS.—A Boston syndicate petitions for a franchise to connect Milford with Upton and Farnumville by electric railway.

BEVERLY, MASS.—The Lynn & Boston Street Railway Company has been granted a franchise to install electricity on the Cove branch.

BOSTON, MASS.—Tucker, Anthony & Company, of Boston, are taking bids on material for the construction of the street railway at Shrewsbury.

BROOKFIELD, MASS.—Superintendent C. A. Jeffs, of the Warren Brookfield & Spencer Street Railway, writes that he wants a filter for boiler feed water.

BRIDGEWATER, MASS.—The Bridgewater, Whitman & Rockland Street Railway Company proposes to build an extension of the Hanover Street Railway.

FITCHBURG, MASS.—It is stated that the franchise for the electric railway, Westminster, has been accepted and work will begin as soon as the weather will permit.

ORANGE, MASS.—Senator J. B. Farley is interested in a plan to build an electric road to Millers Falls, by way of Wendell Depot, Erving and Farley, a distance of 10 miles.

BOSTON, MASS.—The West End Street Railway Company has let contracts for the electrical installation of the Boston subway and work will commence in 10 days under the direction of E. K. Turner.

BARNSTABLE, MASS.—The Barnstable County Street Railway has been organized, and A. D. Makepeace, of West Barnstable, chosen president; Willard Howland, of Boston, secretary; E. C. Perkins, of Boston, treasurer.

NORTHAMPTON, MASS.—The Northampton Street Railway Company has an option on several acres for a pleasure resort to be equipped with merry-go-round, etc. Permission to purchase is asked of the railroad commission.

BOSTON, MASS.—The contract for the electrical equipment and apparatus for the Worcester & Marlboro road, amounting to \$50,000, has been given to the General Electric Company. The company will erect an 800-horse-power-house at Northboro.

BARRE, MASS.—The Barre Street Railway Company has been incorporated to build and operate a street railway to carry freight and passengers and supply electric light. Capital stock, \$50,000; incorporators, George W. Cook, Charles H. Follansby, Charles F. Atwood, F. A. Rich and Dr. George A. Brown.

CAMBRIDGE, MASS.—The Citizens of Cambridge intend to form a corporation with a capital stock of \$50,000 to construct five miles of street railway extending from Mount Auburn, Cambridge, to Belmont and Waverly. Among those interested are A. O. Davidson, Watertown; E. C. Benton, Belmont; Edward B. Stearns, Cambridge; Thomas L. Sauter, Watertown; John C. Watson, Cambridge; Frank Chandler, Belmont, and Ashley Watson, Cambridge.

WORCESTER, MASS.—Charles A. Richardson, president of the Worcester Construction Company signed a contract with Tucker, Anthony & Co., of Boston, agreeing to do the work of constructing the electric road between Worcester and Marlboro. This includes the building of the power house and the company is negotiating for supplies of the new road which will be 20 miles long and will use 45,000 ties, 7 feet long with 6-inch face and thickness, and 1,000 poles 28 feet long with 7-inch tops.

## Michigan.

DETROIT, MICH.—Gus F. Smith, of Detroit, asks a street railway franchise.

DETROIT, MICH.—A franchise through Monguagon is asked by the Detroit & Toledo Electric Railway Company.

BENTON HARBOR MICH.—The Benton Harbor & Eastern Electric Railway & Transit Company has been incorporated to build to Sister Lakes and Dowagiac.

PONTIAC, MICH.—Directors of the Pontiac & Sylvan Lake Railway are considering whether an extension of a mile to Cass Lake would not convert their line into a paying enterprise.

CARLETON, MICH.—A franchise is asked for a line in Carleton to connect with the Detroit & Toledo Electric. Those interested in the Carleton division are: G. F. Smith, George M. Hendrie, W. C. Sterling, of Monroe, Mich., Cameron Currie, J. L. Carleton, S. Hendrie, F. T. Lodge, T. Newberry.

HOLLAND, MICH.—Chas. W. Humphrey, of Ironwood, Mich., presented to the council a petition asking for a franchise from the Chicago & West Michigan Railroad, crossing west on Main street to the river. The harbor shore will be followed 6 miles to Macatawa Park and the Lake Michigan shore 7 miles to Saugatuck.

KALAMAZOO, MICH.—The Michigan Traction Company has been granted right of way through Charleston and Augusta. The report that the road would connect with Lansing is said by General Manager E. E. Downs to be entirely groundless. The proposed road is 23 miles long, with a loop of 2 miles, taking in Gull Lake.

MUSKEGON, MICH.—The Muskegon Railway, recently foreclosed, has been reorganized as the Muskegon Street Railway Company, with John L. Crosby, of Bangor, Me., president; Weston Thompson, of Brunswick, vice-president; Herbert Payson, Portland, Me., treasurer, and F. A. Nims, of Muskegon, secretary and managing director. Improvements of various kinds are planned for Lake Michigan Park, which is owned by the company and which will make this one of the leading summer resorts.

## Minnesota.

MINNEAPOLIS, MINN.—Fire at Robbinsdale, January 14, destroyed two gasoline motor cars and car shed owned by A. B. Robbins. New gasoline motors will be secured at once. Loss, \$4,000; partly insured.

## Mississippi.

VICKSBURG, MISS.—Jos. Hirsch and J. J. Hays are interested in getting the citizens to subscribe \$20,000 of the \$100,000 stock that will likely be issued to build a street railway system in this city.

## Missouri.

WARRENSBURG, MO.—The street railway has been sold for scrap iron.

SHELBYNA, MO.—Dr. J. M. McCully, president of the Shelby County Electric Railway Company, has placed his proposition before eastern men who expect to furnish three-fourths of the capital for construction. The road would cost \$60,000.

KANSAS CITY, MO.—The American Railway Construction Company of Chicago has been awarded the contract for building the Wyandotte street electric line by the West Side Railway Company. The road will be a fine example of modern railway construction, 103-pound rail will be laid in cement and cast welded. The contract price is \$110,000.

ST. LOUIS, MO.—The North St. Louis Improvement Association decided to organize a company to build a street car line on North Market street, connecting the wharf with all other lines by transfer. Messrs. Gundlach, Cummings, Weneker, St. Clair, Kolmer, Rubelman, Lucas, Mannist and Burghoff subscribed for stock in the new company.

KANSAS CITY, MO.—The Metropolitan Street Railway has let the contract for the electrical equipment of the Rosedale line, costing \$70,000, to the Electrical Insulation Company, of Chicago, the work beginning March 1 and ending May 1. About 350,000 pounds of copper will be used in the overhead work. This same company has received the contract of the West Side Railway Company to equip the Wyandotte street line.

## New Hampshire.

PORTSMOUTH, N. H.—I. C. Libby, of Waterville, Me., and A. F. Gerald, of Fairfield, Me., have purchased the franchise of the Portsmouth Electric Railway. The same parties recently acquired the charter of the Kittery & York Beach Electric Railroad. Work on the latter will begin immediately, piles having to be driven to cross a marsh a mile wide. At the Portsmouth end the material will be placed in readiness to begin construction as soon as the frost leaves the ground. The line will be 25 miles long and equipped in the best style.

HAVERHILL, N. H.—Thomas Sanders, of Haverhill, asks the incorporation by the New Hampshire legislature of four companies to build various lines which, when connected, would form one continuous electric railway from Massachusetts to Canada. One charter is for the Nashua, Salem & Haverhill Street Railway, to have a capital stock of \$200,000 and to run from Nashua south through Hudson, Windham, Derry and Salem to the boundary line between Massachusetts and New Hampshire; a second to incorporate the Nashua, Manchester & Concord Electric Street Railway, with a capital stock of \$600,000, to run from Nashua to Concord through the towns of Hudson, Litchfield, Merrimac, Londonderry, Bedford, Manchester, Hooksett, Suncook, Allenstown and Bow; the third to incorporate the Manchester, Chester & Haverhill Street Railway, capital stock not to exceed \$400,000, to run from Manchester through Auburn, Chester, Sandown, Hampstead and Plaistow to the Massachusetts line; the fourth to incorporate the Merrimac Valley & St. Lawrence Street Railway, with a capital stock of \$900,000, to run from Concord through Canterbury, Boscawan, Northfield, Franklin, Sanbornton, Hill, Tilton, Alexandria, Bristol, New Hampton, Bridgewater, Plymouth, Ashland, Holderness, Campton, Center Harbor, Moultonboro, Sandwich, Meredith, Thornton, Woodstock, Lincoln, Franconia, Bethlehem, Carroll, Low and Burbank's Grant, Jefferson, Randolph, Berlin, Kilkenny, Milan, Stark, Dummer, Odell, Millsfield, Dixville, Clarksville, Carlisle, Webster, Hubbard and Pittsburg, to the boundary line between the United States and the Dominion of Canada.

## New Jersey.

EATONTOWN, N. J.—Joseph Johnson's mill property is to be converted into a power plant for the Long Branch electric road.

NEWARK, N. J.—Belleville township has granted a franchise to the Passaic & Newark Electric Railway Company to operate a double track line.

BOUND BROOK, N. J.—A franchise for a line between Bound Brook and New Brunswick is asked by the Philadelphia & New York Traction Company.

LONG BRANCH, N. J.—The Atlantic Highlands, Red Bank & Long Branch Electric Railway Company is asking consents with a view to renewing its application for a franchise.

ATLANTIC CITY, N. J.—Receiver C. D. V. Joline sold the line and steamboats of the Brigantine Trolley Company, February 5. It will require \$20,000 to repair the damage wrought by recent storms to the piers and roadbeds.

SOMERSET, N. J.—The County Board of Freeholders granted a permit to the New York & Philadelphia Traction Company to enter this town, assurances being given that the line between this place and Bound Brook will be in operation by May 1.

ELIZABETH, N. J.—The Elizabeth & Westfield Railway Company will be incorporated with about \$200,000 capital stock to construct a trolley line. Back of the company are Bernard M. Shanley, of Newark; John D. Crimmins, of New York; Chandler W. Riker, of Newark, and Col. E. W. Hine, of Orange.

DOVER, N. J.—The proposed electrical equipment of their High Bridge branch from Rockaway to Port Oram, is viewed with favor by the officials of the Jersey Central Railroad. The matter was brought to the attention of the company by the Dover Electric Light Company, which has power to spare to operate twenty or more cars.

### New York.

BUFFALO, N. Y.—A repair shop may be built by the Buffalo Railway on a site just purchased.

LASALLE, N. Y.—George P. Smith is getting additional consents for his electric railway project.

LONG ISLAND, CITY, N. Y.—The Steinyard Railroad is considering an extension of its trolley line to Whitestone.

MECHANICSVILLE, N. Y.—J. A. Powers is at the head of an electric railway enterprise. Lansingburgh is one terminus.

BUFFALO, N. Y.—The Buffalo, Gardenville & Ebenezer Street Railway Company proposes to extend its line on Seneca street and Union road.

PORT CHESTER, N. Y.—A bond for \$10,000 has been given the village trustees by the Port Chester Electric Railway Company to guarantee the construction and operation of the road as provided in the franchise recently granted.

WOODHULL, N. Y.—It is stated that the bonus subscription of \$10,000 has been raised and the work on the electric road from this town to Branchport will be commenced.

BUFFALO, N. Y.—The Crosstown Street Railway Company applied for a franchise in new streets, and its application will be heard on the 19th of this month by the committee on streets.

BUFFALO, N. Y.—Depew and Blasdell, two suburbs, are to be connected by electric railway. Messrs. Vanderbilt, Depew and Webb, large holders of real estate, will build the line.

SENECA FALLS, N. Y.—N. H. Becker and W. C. Gray, of Seneca Falls, are interested in the proposed electric road to Auburn. An iron bridge will be built across Cayuga Lake.

BUFFALO, N. Y.—The Niagara Falls, Clifton & Drummondville Street Railway, which runs from Clifton to Lundy's Lane in Canada, has changed hands and will be electrically equipped with an anticipated extension to Fort Erie.

ADDISON, N. Y.—Postmaster John Hinman, of Addison, and J. S. Sargent, E. Chatfield and Dr. F. H. Van Orsdale, of Jasper, are interested in the proposed electric railway to connect Addison, Jasper and Woodhull, a distance of 12 miles.

BUFFALO, N. Y.—The Buffalo Traction Company is now ready to begin building 15 miles of track on the east side of the city. The Erie Construction Company will do the work and have opened offices on the seventh floor of Ellicott Square.

BROOKLYN, N. Y.—Permission has been granted by Justice Dickey of the Supreme Court, to the Kings County Electric Railroad and the Long Island Electric Railroad, to connect and extend the two systems. The incline will be built in Liberty avenue at the city line, and the works will cost about \$35,000.

ADDISON, N. Y.—An electric road is to be built between Addison, Tuscarora, Woodhull and Jasper. Among those interested are G. H. Brewster, John Hinman, W. O. Feenaughty, D. M. Darrin, H. D. Baldwin, R. P. Brown, E. M. Welles, F. H. Wheaton, B. G. Winton, O. B. Stratton and C. O. Shockey.

FALLSBURG, N. Y.—The incorporators of the Fallsburg & Monticello Railroad, already noted in DAILY BULLETIN, are B. Van Steenberg, J. H. Devoe, C. B. Harris, and William Dean, of 53 Broadway, New York city; John A. Cartledge, J. H. Van Steenberg, W. A. Lester Rock, of New York. The company's principal office will be in New York city.

CATSKILL, N. Y.—The Catskill Electric Railway Company has been incorporated to operate an electric street surface line, two miles long, from Catskill to Jefferson, Greene county, with a capital of \$30,000. The directors are Charles S. Williamson, M. D., William S. Roberts, Louis E. Roberts, Michael W. Conway, W. C. Courtney, W. C. Wood, Howard A. Mock, Daniel W. Sharpe, and Schuyler W. Mattison.

NEW PALTZ, N. Y.—The New Paltz & Walkill Valley Railroad Company has been incorporated to construct 0 miles of electric railway from Highland to New Paltz. Capital stock, \$150,000; directors, Hugh H. Douglass, G. H. Harmon, Paul Shiffer, Charles G. M. Thomas, James F. Reed, Joseph H. Devoe, George E. Woods, Henry M. Brundage and William G. Hoyt. The backer is Ferdinand McKeige, of New York.

AUBURN, N. Y.—The Auburn & Western Railway Company has been incorporated to build eleven miles of electric road between Auburn and Seneca Falls. Capital stock, \$300,000; directors, Robert Wetherill, of Chester, Pa.; William C. Gray, Jr., and Norman H. Becker, of Seneca Falls; George B. Longstreet, of Auburn; George B. Leonard, William P. Goodelle, W. A. Holden, Hiram W. Plumb, and C. D. Beebe, of Syracuse.

### North Carolina.

RALEIGH, N. C.—Charles C. Johnson, secretary, writes that the Raleigh Electric Company will rebuild its burned plant at an early date. A first-class building will be erected and equipped with the latest machinery, the type of which has not as yet been decided upon.

### Ohio.

MARIETTA, O.—The Marietta Electric Company made its initial trip February 3.

SANDUSKY, O.—Clark Rude has been appointed receiver of the Sandusky Electric Railway on application of stockholders.

SANDUSKY, O.—Rumor has it that the abandoned grade of the Sandusky, Ashland & Coshocton Railroad will be used by a new electric line.

STEUBENVILLE, O.—The Steubenville Traction Company is negotiating a lease of the Steubenville branch of the Wheeling & Lake Erie Railroad.

FOSTORIA, O.—C. C. Conroy, an oil man, and C. T. Geddes, are at the head of a project to build an electric railway between Fostoria and Waterville.

FRANKLIN, O.—The council has granted to the Cincinnati & Miami Valley Traction Company, permission to build and operate an electric car line in this village.

CINCINNATI, O.—The Cincinnati & Miami Valley Traction Company has given a mortgage of \$650,000 to the Finance Company of Pennsylvania for construction purposes.

CANTON, O.—William A. Lynch, president of the Canton & Massillon Electric Railway, says that the Akron-Canton Street Railway Company will begin work as soon as the weather permits.

CLEVELAND, O.—The Cleveland & Eastern Electric Railway Company has been incorporated to build a line terminating at Orwell. The incorporators are D. H. Tilden, R. M. Lee, C. E. Fish, G. H. Hopper and C. H. Taylor.

EAST LIVERPOOL, O.—The East Liverpool and Wellsville Electric Street Railway Company will be sold in one month at sheriff's sale. The Union Trust Company of Cleveland, O., foreclosed the mortgage securing \$300,000 of bonds.

MIDDLETOWN, O.—An ordinance has been passed granting the Cincinnati & Miami Valley Traction Company the right to construct and operate a street railway through Middletown which shall be commenced within six months and completed in a year.

MANSFIELD, O.—The town council of Shelby granted to Reid Carpenter a franchise for an electric road between Mansfield and Shelby. Application is also made to the board of county commissioners by the same party for right of way along country roads and nothing will be done until the decision is given.

DAYTON, O.—The Dayton, Johnsville & Eaton Traction Company has been incorporated to build an electric road from Dayton to Eaton by way of New Lebanon, Johnsville and West Alexandria. Capital stock, \$50,000; incorporators, Henry B. Pruden, Alfred G. Feight, J. Elliot Beirce, Joseph Weil, and Barry P. Murphy.

TOLEDO, O.—Contracts for the construction of the line between Toledo and Monroe Piers, 22 miles in length, have been let to J. N. Bick, of Toledo. Wm. C. and Wm. M. Johnson and P. N. Jacobson, Detroit parties, are backing the enterprise. The cost of construction and equipment will be about \$300,000, and the road to be complete by August 1.

TROY, O.—The T., T., D. & E. Electric Railway project is booming. The officers are: President, Judge Theodore Sullivan; vice-president, George W. Scott; secretary, Dr. W. H. Thompson; assistant secretary, F. J. Gates; treasurer, John T. Knoop; superintendent, F. M. Sterritt; assistant superintendent, Frank T. Worman; superintendent of construction, Colonel Jeff Miller; attorney, George T. Long.

CINCINNATI, O.—A bond for \$10,000 has been filed by President C. T. McCrea, of the Cincinnati & Hamilton Electric Street Railway guaranteeing that construction will be under way by May 1. From the terminus of the Cincinnati Consolidated at College Hill, the line will run over the Hamilton pike to the county seat of Butler County, passing through Mt. Healthy, Pleasant Run and Symmes Corner. The line will be 12 miles long.

## Pennsylvania.

NANTICOKE, PA.—The Nanticoke & Newport Railroad Company which was formed to build a street railway, has been dissolved.

NEW HOPE, PA.—The East Pennsylvania Traction Company has applied for a franchise. The road will cross the Delaware between New Hope and Lambertville, N. J.

QUAKERTOWN, PA.—It is proposed to extend the Quakertown & Springtown Electric Railway, now in course of construction, to Argus, Trumbauersville, Tylersport, Schlichtersville, Sellersville and Perkasie.

NEW CASTLE, PA.—The New Castle Traction Company has been incorporated. Capital stock, \$500,000; incorporators, H. W. Mitchell, M. L. Merwin, Pittsburg; C. F. Patterson, E. L. Allen, and William Beal, of Alleghany.

WEST NEWTON, PA.—A charter was granted to the West Newton Northern Street Railway Company to connect West Newton with Herminie. The directors are James E. Bell, cashier of the First National Bank of West Newton, and T. F. Vankirk and F. M. Null.

HARRISBURG, PA.—The Sewickley Valley Electric Passenger Railroad, capital \$15,000, was chartered to build 2½ miles of road between Osborn and the Beaver pond. James D. Callery, Pittsburg, is president; directors, J. D. Callery, W. H. Keech, J. C. Reilly, Geo. C. Wilson, Pittsburg; J. M. Tate, Jr., Sewickley.

PITTSBURG, PA.—The Citizens' Monongahela Electric Railroad Company has been incorporated to build four miles of road on Mt. Washington, for which franchises are asked. Capital stock, \$24,000; president is James M. Bailey; directors, John Paul, Joseph G. Walter, William Halpin, William H. Minnick, of Pittsburg.

ALLENSTOWN, PA.—A. S. Cadwallader of Philadelphia, is president of the East Penn Traction Company, just incorporated to build through Lehigh county, beginning at the Bucks county line, on the road leading to South Bethlehem, thence to Coopersburg, Centre Valley, Friedensville and Colesville to the Northampton county line.

TITUSVILLE, PA.—The Titusville Electric Traction Company has been incorporated to build 15 miles of road beginning at Pleasantville and running through Crawford, Venango and Warren to the Titusville city limits. Capital stock, \$100,000; president, M. B. Dunham, of Warren; directors, George H. Dunham, R. D. Stoilzing, Pleasantville; T. F. Lemassena, Newark, N. J.; A. J. Hazeltine, Warren.

PITTSBURG, PA.—Stockholders of the Mt. Troy & Reserve Township Traction Company have decided to commence the construction in the spring of their line running for three miles in Allegheny city and Reserve township. Jacob Beckert is president; C. Beckert, vice-president; August Beckert, secretary and treasurer; Florence Wohleber, John Habermehl, Chas. Beckert, John F. Havekotte, William Eberhardt, G. H. Beckert and John P. Ober are directors.

## Rhode Island.

PROVIDENCE, R. I.—The United Traction Company will extend its Pawtuxet Valley line to Natick.

## South Carolina.

AIKEN, S. C.—The Aiken & Augusta Railroad Company has been incorporated to build an electric railroad 18 miles in length. Philadelphia capital is interested.

CHARLESTON, S. C.—The Charleston Street Railway Company has purchased the controlling interest in the enterprise Railroad, owned by Cuyler, Morgan & Co., of New York, and is negotiating for the outstanding interest. Both lines will be electrically equipped and operated as one system.

## South Dakota.

EDGEMONT, S. D.—An electric road to connect its mines may be built by the Edgemont & Union Hill Smelting Company.

## Tennessee.

CHATTANOOGA, TENN.—The Chattanooga Rapid Transit Company will be incorporated to build Samuel W. Divine's proposed electric road between Rossville and Chicamauga, Ga. Capital stock, \$150,000; incorporators, Samuel W. Divine, W. B. Royster, Charles T. Divine, John W. Wyatt, J. P. Pemberton, James R. Reid and James R. McFarland.

## Texas.

DALLAS, TEX.—The Dallas City Street Railway Company began work this week putting down new track and this, it is thought, is the first step in the proposition to put the lines on an electric basis.

SAN ANTONIO, TEX.—A mule car line is to be built to Von Ormy, 12 miles distant, by the Von Ormy-Medina Railway Company, of which F. Villereal is president; J. B. Bywaters, vice-president, and Edward Krause, manager.

DALLAS, TEX.—The Dallas & Fort Worth Company has been formed to build 30 miles of steam or electric road between the two cities. Capital stock, \$500,000. Back of the project is the Dallas Terminal Railway & Union Depot Company.

## Vermont.

STOWE, VT.—A bonus is offered any one who will build an electric road to Waterbury. Address J. F. McMahon.

BURLINGTON, VT.—Subscriptions are being received for the stock of the Grand Isle Railway Company, which plans to build an electric road from Burlington through Colchester, Milton South Hero and Grand Isle.

## Washington.

TACOMA, WASH.—Additional franchises have been petitioned for by the Tacoma Railway & Motor Company.

SEATTLE, WASH.—The Seattle Traction Company has been incorporated. Capital stock, \$1,000,000; incorporators, Jacob Furth, George B. Blanchard, Manson F. Backus, William A. Walthew, John W. Catbcat, John R. Walthew, Maurice C. Cheal.

## West Virginia.

PARKERSBURG, W. VA.—S. Darrow, C. W. Daly and William Caskey have petitioned for right to construct a double track electric road between Parkersburg and Williamstown.

MORGANTOWN, W. VA.—Theodore L. Swan, C. L. Brown and T. H. Wilson, of New York, have been granted the privilege of constructing and operating an electric railway from Grafton to Pruntytown.

WHEELING, W. VA.—Arrangements have been made to extend the Wheeling & Suburban Railway from Tridelpia to West Alexander. Pa. Capitalists of Washington, Pa., wish the line extended to their town also.

## Wisconsin.

KENOSHA, WIS.—The Milwaukee, Racine & Kenosha Electric Railway Company, it is said, will renew its application for a franchise in Kenosha.

OSHKOSH, WIS.—The Council granted F. H. Josslyn, representing the Citizens' Traction Company, permission to build a track on River street. It is expected that the road will be in operation in 60 days.

DELANAV, WIS.—A 20 year franchise has been asked and will be granted to the Delavan Light & Fuel Company to build 12 to 15 miles of electric road from this city to the several parks around the lake in this vicinity. Local capitalists only are interested.

GREEN BAY, WIS.—Sealed proposals for furnishing and placing an electric motor and other apparatus for swinging the Main street bridge will be received up to January 22. Specifications and plans may be obtained by addressing E. L. Shaw, Marinette, Wis.

OSHKOSH, WIS.—Although the Winnebago Construction Company contemplates putting in an electric railway from Oshkosh to Kaukauna, it is doing nothing on the line at present, but is confining its attention to the electric street railway of Oshkosh, which it is hoped to have in operation by June 1.

RACINE, WIS.—Although Hiram J. Smith has been made receiver of the Belle City Street Railway, Jackson I. Case, the former manager, will continue as superintendent. The liabilities, outside of the bonded indebtedness of \$300,000, will not amount to \$12,000. The bonds are distributed as follows: Charles B. Hathaway, of Cleveland, \$50,000; Case estate, \$50,000; Mr. McNair, of St. Louis, \$50,000; Jackson I. Case, \$60,000. No other changes have been made, and it is expected the affairs of the company will soon be straightened out.

## Canada

FORT ERIE, ONT.—The Fort Erie Ferry Company contemplates building an electric line to Chippewa, 15 miles distant.

BRANTFORD, ONT.—Mayor Elliott states that his company proposes to build an electric road from Brantford to Port Dover.

BERLIN, ONT.—The owners of the Berlin Electric Railway are negotiating for the purchase of the St. Thomas Street Railway, with a view to equipping for electricity.

WINNIPEG, MANITOBA.—The Fort Frances & Pacific Railway will be chartered to build an electric railway in the Rainy Lake gold country, connecting with the Canadian Pacific Railway at Wabigoon.

ROSSLAND, B. C.—Mr. Heinze, owner of the Columbia & Western Railway, is estimating the cost of changing its motive power from steam to electricity.

## REPORT OF THE TORONTO STREET RAILWAY.

The report which was submitted to the shareholders of the Toronto Street Railway Company on January 20, made an exceedingly satisfactory showing when the severe depression in business during the past year is taken into consideration. After paying fixed charges and a dividend of  $3\frac{1}{2}$  per cent on \$6,000,000 capital stock there was a surplus of \$12,026. The operating expenses increased over those of 1895, but the increase is explained to be due to the repairs of motors. During the spring the city permitted large quantities of water to accumulate in the streets and many cars were damaged in consequence, on some days as many as 35 or 40.

The following statement exhibits the totals for the last two years:

	1896	1895
Gross earnings.....	\$997,273.28	\$992,800.80
Operating expenses.....	597,760.31	489,814.76
Net earnings.....	489,512.97	502,886.04
Passengers carried.....	23,537,911	23,355,228
Transfers.....	7,354,895	7,257,572
Percentage of operating expenses to earnings in 1896, 59.9; in 1895, 49.3.		

There are a number of questions between the city and the company that have been in dispute and arrangements have been made to settle them by an amicable suit, the result of which will be final. Negotiations for a Sunday car service are progressing favorably and the company is confident of bringing them to a satisfactory conclusion.

No changes were made in the officers of the company, but F. L. Wanklyn was appointed manager, an office newly established. Mr. Wanklyn has had an extensive experience, having been for several years works manager for the Grand Trunk Railway.

## SAVANNAH COMPANY AGAIN ON ITS FEET.

On January 17 the receivers of the Electric Railway Co. turned over the property to the new company known as the Savannah Traction, and after the election of directors, Herman Myers was chosen president; J. H. Fall, vice president; J. G. Reid, secretary and treasurer; and J. S. Collins, managing director. No stock has been issued as yet, but the amount will probably be \$500,000. After the late experience of the company, the stockholders are of the opinion that the bonded indebtedness should be kept as small as possible. A new power house is soon to be built and the road will be put in first class shape.

## JOINT USE OF TRACK IN CALIFORNIA.

A bill was railroaded through the California legislature several years ago, at the instance of an electric line in Los Angeles, which wanted to get into valuable territory already occupied by cable tracks. The bill provided that under certain conditions of rental one company could run its cars over not more than five consecutive blocks of another company. A bill is now pending to amend the law by changing the word five to ten, and omitting "consecutive."

W. G. Seevers has succeeded his brother, Paul, as manager of the Muscatine (Ia.) Electric Railway.

## BREAKING THE SNOWBANK.

BY GEORGE E. STEPHENS.

"Of the falling of snow there is no end."

More than one street railway in this country has had reason to declare the truth of this statement during the past few seasons. In fact on some occasions the truth has been enforced by a snow bank piled mountain high on each side of the street car track and many a poor superintendent, compelled to drag himself out of a good warm bed to take his place on the elevated seat of a road scraper, with the wind blowing forty knots an hour and the mercury hugging the zero notch, can testify to the need of a well designed snow plow. The winter so far in Galesburg has not been a hard one but the management believes in making hay while the sun shines.

As the result of the plans laid by E. P. Baum, chief engineer and electrician of the Galesburg Electric Motor & Power Company, the snow plow which is shown in the accompanying cut was built and on its first run was proven a success. The work has been accomplished within a few weeks from the start and now the officials of the company are ready for the fray. A description of the car as completed will give one a good idea of its size and the work it is expected to do. The car is 16 feet long and 6 feet, 13 $\frac{1}{2}$  inches wide and rises 7 feet from the rail to the top of the roof. The frame work is of heavy oak timber and the heavy stresses of the plows come on sills 5 by 8 inches in

SNOW PLOW, GALESBURG, ILL.

size. The body of the car is finished in pine and made light as possible, there being enough weight in the frame, truck and plows. The plow is mounted on a McGuire Columbian truck and equipped with Westinghouse No. 3 motors with type D controllers. The converters and connecting wires are all placed inside the car leaving only the motor connections beneath.

The main features of the machine, of course, are the plows, one in front and one at the rear, and the whole car is constructed with a view to the best workings of these. They are made of quarter-inch steel; are 1 feet high and run 8 feet and 1 inches from the point of the nose to the heel. They are raised and lowered in guides by a ratchet lever and screw inside the car. The plows are so constructed that they run back to a point close to the truck, doing away with the up and down motion common to cars using single trucks. On either side of the plow at the rear and hedging, close onto the truck, is a very convenient part, consisting of

a 16-inch wing worked by levers inside the car. The principal use of the wings is in bucking large drifts. When the nose is poked into a big heap and the car sticks fast the wings are brought into the side and the car may be easily backed.

By means of the levers in the car the plows may be raised and lowered at will, from a distance of a half inch to 8 inches. This lift is needed because Galesburg is well provided with brick pavements and the operator who should be so unfortunate as to plow up some feet of bricks would likely be brought before the common council. Inside the car are two sand boxes with a rotating sand valve which allows of three different sized flows. Each box is independent of the other and can be worked from either end of the car. A draw bar is arranged through the plow so that passenger cars may be attached. The car has two headlights and is lighted inside by three lamps. On the right side of the car is placed a door, 2 feet, 3 inches wide and 6 and one-half feet high. There are 5 windows in each end giving a full view of the street. The steel plows were made at the shops of the Frost Manufacturing Company.

## SECOND AVENUE RAILROAD, N. Y., SOLD.

A majority of the stock of the Second Avenue Railroad, N. Y., has been purchased by William C. Whitney. While Mr. Whitney bought the stock as an individual it is his intention to have the road incorporated with the Metropolitan system and operated by electricity or compressed air. The Second avenue company owns 13.5 miles of double track and operates 3.38 miles under leases, using animal traction. There is \$1,862,000 of capital stock, on which a dividend of 5 per cent was paid last year, and \$1,900,000 of bonds bearing 5 per cent interest. After meeting fixed charges and paying the dividends the surplus in 1896 was \$21. With mechanical traction substituted this road can not fail to make a paying addition to the Metropolitan system.

## PRESIDENT BILLINGS DEAD.

A. M. Billings, of this city, and president and owner of the street railway system of Memphis, Tenn., died suddenly of heart disease on February 7. He was one of Chicago's old settlers, and worth from \$10,000,000 to \$20,000,000. He became interested in the Memphis road about 6 years ago and later was practically its only stockholder. He spent about \$12,000,000 there, transforming to electricity and extending lines, etc. His interests in Chicago gas are well known, and he was also president of two banks. Although 83 years of age at the time of his death he was actively engaged in the management of large affairs, and one of the best known and respected men in the city.

## WAUKEGAN-CHICAGO LINE.

The Bluff City Electric Street Railway Company expects to sell through tickets from Waukegan to Chicago for 30 cents which is 75 cents less than is charged by the Northwestern railroad. There are about fifteen growing towns and villages between these two cities which will furnish much local travel. There will be 29 miles of track built to connect the Waukegan line with Chicago at Evanston. The cost of the road will be about \$500,000.

"EVERY INCH A KING."

I read with great interest the very able and courteous article in the January number of the Street Railway Review, over Mr. Henry R. King's signature and feel that I have not lived in vain, since to me is due the discovery of the Kipling of Conductivity, the Genius of Joints.

My joy is increased by the fact that throughout my small circle of electrical and railway acquaintance, I can find no previous trace or hint of the scientist and poet whom I have unwittingly unveiled to an admiring world. Though none can tell what happy clime has hitherto shielded him from universal homage, it is evident from his inspired words that he proudly retains an ancient prerogative of his royal name for things that were not so, promptly become so because he states that they must be so. At his command, cast scrap iron assumes the tensile strength of rolled steel and acquires the conductivity of hammered silver; iron oxide loses its insulating properties, while the expansion co-efficient of steel rails shrinks modestly to zero!

I once thought that the hundreds of copper-bonded "cast-weld" joints which I had personally measured in Newark and elsewhere had three to five times the resistance of the same length of rail between joints; the rails are still in the streets where any one can test them to my confusion. But this is needless; the King has spoken. Selah!

The resistance of the joint is less than the rail as per advertisement; let it be so! I must bow before the royal mandate and believe, or tremble lest his veiled threats materialize into a thunderbolt and blast my reputation. The King speaks of a St. Louis road; does he not know that the officials of the Missouri Railroad Company actually dare to think heavy copper bonding necessary to help out their "cast-weld" joints? Why not blast them just a little for their infidelity? Then they probably have the same two unused joints from the "cast-weld" exhibit which were tested in their power house and found wanting; why not repeat my tests and consign me to a dungeon for inaccuracy? The King quotes from Mr. Bowen, of the Chicago City Railway in merited praise of the mechanical stability of the joint.

Surely he must have heard that Mr. Bowen's road uses on its "cast-weld" joints even heavier copper bonds than most angle-plated roads put in. And furthermore, Mr. G. W. Knox, Electrical Engineer of the same road, has had the audacity to recommend the use of the Edison Plastic Alloy on the terminals of the big copper bonds he uses to help out the "perfect conductivity" of the "cast-weld" joints!

Evidently I shall have plenty of good company when the royal blasting apparatus gets under headway. But when the King tackles mathematics, I fear he gets outside his jurisdiction. He tells of a marvellous "cast-weld" joint whose dimensions he does not give. This joint has never been used, but he says it has been *exposed to the weather for three years!* Of course such exposure is more trying to the joint than actual service! He says this joint has a drop of .0107 volts with 760 amperes and that in "the rail alone the drop was .0117 volts;" (length and section of rail not stated.)

While, with Brown's plug, (depth, diameter and method of application not given,) the drop with 700 amperes is said to be .012 volts.

Here occurs a dramatic pause in which the blasting of Brown is supposed to commence. But figures are queer

things for Kings to fumble with. For purposes of comparison, I will assume that the rail weighed 90 lbs. to the yard; that the "cast-weld" joint had eight times its section; that the voltmeter terminals were properly attached to the rails at the same points in each case, and that the "plug" was  $\frac{7}{8}$  of an inch in diameter and  $\frac{3}{4}$  of an inch deep, applied so that half was in each rail. All the sample "cast-weld" joints I have seen exhibited have had the rail ends closely pressed together. There are therefore two paths for the testing current, connected in parallel with each other; one directly through the rail ends, and the other from the sides and bottom of the rails through the metal of joint; the latter is of cast iron having one-half the conductivity of steel per square inch, but with 8 times its section. It thus has 4 times the actual conductivity per lineal inch. Therefore if there should be *contacts of no resistance* through the rail ends and between the rails and the iron the iron would carry 4.5 of the current and the rails 1.5. The actual section of the joint at junction is 81 square inches, 9 of which are steel and 72 are iron. The latter are equal to 36 square inches of steel and the joint to .41 of steel. The figures quoted by his majesty now give us common mortals a means of getting the resistance of each of the two paths. The hole would affect only the path through the rail ends; if it were drilled with oil and the Plastic Alloy inserted *without* removing the same and *without* properly amalgamating the steel surfaces, the plug might just as well be made of insulating material, *for it could carry no current.* For convenience in calculation, I will assume that the voltmeter wires were attached in line with the outer edges of hole. Now this hole has taken from the contact area of the rail ends a piece of metal about  $\frac{7}{8}$  inches by  $\frac{3}{4}$  inches, or 0.65625 of a square inch. As the cross section of the joint equals 41 square inches of steel, the hole has robbed it of  $\frac{1}{4}$  per cent (.016) of its section. This loss should of course increase the drop just  $\frac{1}{4}$  per cent (.006). Instead of that, it is said to increase the drop from .0107 volts to .0120 volts, which is an increase of  $\frac{12}{100}$  per cent (.1214), which is  $7\frac{1}{2}$  times what it should be. In other words, according to this report, *the rusty rail ends* transmitted about 617 amperes of the current while the contacts on the iron were so poor that only 83 amperes could get through the "cast-weld." It surprises me to find that my tests should give the "cast-weld" joint a far better conductivity than its own advocate. Evidently someone has blundered badly. To settle which of us is guilty, I respectfully suggest that the King direct the Chancellor of his Exchequer to deposit with the Editor of this paper sufficient coin of the realm to cover all expenses, as a guarantee that he is not "articulating through his royal crown." Let the Editor then be requested to select without measurement a "cast-weld" joint that has been in actual daily service with heavy current for two years, or for even one year, in the track of some large road outside of Milwaukee or its suburbs. Let this joint be sent to the electrical testing department of some prominent university and its resistance tested up to the full carrying capacity of the rail. I will then insert a plug of plastic alloy and if with similar tests, this material does not give results similar to those obtained by me at St. Louis, I will pay all expense of tests and humbly crave his royal mercy. But if he proves to be mistaken, then his deposit is to be used to cover all expenses incurred. I cannot close without expressing my admiration for the King's eyesight which can detect in a printed reproduction of a photograph, evidences of a "weld" which do not exist

in the original article itself. So far as has been reliably recorded, no one has succeeded in welding together without a flux, a molten metal and a dissimilar solid metal which is at a different temperature. You may easily inclose one in the other; you may at points burn the surface of the solid and get a degree of adherence, but this does not secure a metallic union and is not a weld.

HAROLD P. BROWN.

### A TROLLEY SWITCHING CAR.

The West Chicago Street Railroad has recently put a dinky motor car at the O'Neil street barns to do the switching for the South Halstead street cable line. The car takes the place of 13 horses and two men and does the work in shorter time and in a very satisfactory manner. It requires but one man to operate the motor. Perhaps the trolley arrangement is the most interesting feature of the car. An ordinary trolley would require another man and be entirely unsuited to the wiring which is without switches. A home-

made contrivance was designed which has solved the problem. At the end of a 2-inch vertical pipe a beam is pivoted. On one end is a 1/2-inch steel wire bent so that it is about 6 feet across and this forms the contact to the trolley wire. On the other end of the beam is a weight which insures a constant pressure of the wire against the line. This makes allowance for the slack in the line, does not break contact when switching from one track to another and makes it possible to use the crude system of overhead wiring now in place. The accompanying illustration represents trolley arrangement.

### SALT WAR IN WASHINGTON, D. C.

The snow storms of last month afforded an opportunity for a legal quarrel between the Eckington & Soldiers' Home and the Metropolitan Railroad Companies of Washington. On January 20 six employees of the former company were arrested for sprinkling salt upon the tracks of the Metropolitan. The case against them was dismissed by Judge Miller, but that did not end the difficulty. The Metropolitan Company has begun suit in the District Supreme Court and prays an injunction against a repetition of the offense. The bill alleges that the company's plant was seriously damaged by reason of the salt water finding its way into the conduits and destroying the insulation, causing short circuits. It is alleged that in three days 51 cars were disabled because of the salt having been used.

The works of the Kepp Gear Wheel & Foundry Company, Allegheny, were destroyed by fire February 7. Loss, \$30,000; insurance, \$7,000.

### PRESIDENT VREELAND ON CONDUIT CONSTRUCTION IN NEW YORK.

President H. H. Vreeland, of the Metropolitan Street Railway Company, says that contracts have been let for the engines and electrical equipment to operate the lines on 6th, 8th and Amsterdam avenues and the 4th street and Madison avenue and the 59th street crosstown lines. The same plans for construction will be used as on the Lenox avenue conduit electric railway. The minor defects of this system have been remedied from time to time until it is now satisfactory in its operations both to the railway company and its patrons. This experimental line has been so successful during the past 18 months that the company feels justified in spending the enormous sums, necessary to transform these lines to the conduit system. The machinery is now building and the work of track construction will be pushed with vigor. In all probability cars will be running on the lines by next fall.

### WAGES REDUCED AT TOLEDO.

On February 1 a general reduction was made in wages and salaries, including every employe of the Toledo Traction Company, from the president down to the water boy. The cut is 10 per cent and will be continued until the business improves. It is hoped that when the summer riding begins the old rate can be restored. Train crews have been receiving 18 cents an hour for a 10 hour day.

### OBITUARY.

Chris. Murtaugh, superintendent of the Rockport (Ill.) Traction Company, died on January 19 of erysipelas.

Charles Parrish, who was for several years past the president of the Hazard Manufacturing Company, Wilkesbarre, Pa., died very suddenly at his home on Christmas day.

Charles Swan, who from 1846 until 1881, was general superintendent of John A. Roebling's Sons' Company's wire rope mill, died at his home in Trenton, N. J. Mr. Swan was born in Breslau, Germany, but came to this country at an early age.

Harvey Hart Woods, who has been secretary of the Second Avenue Railroad Company, New York, for many years, died suddenly of apoplexy. Mr. Woods was interested in politics, being a member of the Progress Republican Club and had been twice chosen as school inspector of the tenth ward.

Col. W. A. Sinclair, whose sudden death at Rochester, N. Y., we chronicled last month, was buried at Galveston, Tex., where he had been so prominently connected for 30 years. The funeral was conducted jointly by the Masonic and G. A. R. societies, and was one of the largest ever held in that city. The floral offerings were many, including pieces from the employes of the Galveston City Railway, who attended in a body and the Texas Street Railway Association, of which he was president.

The White-Crosby Company, of New York, has taken the contract to build 16 miles of electric road in Charleston, S. C., and will let sub-contracts for all material, except rails, but including cars and trucks.

## PERSONAL.

Wm. H. Traner has been appointed receiver of the Lincoln (Ill.) Electric Street Railway Company.

J. A. Ferguson, of Morris, Ill., is the successor of Louis Senseny as manager of the Lincoln (Ill.) Street Railway Company.

Paul B. Secvers, superintendent of the Muscatine (Ia.) Electric Street Railway, has tendered his resignation, to take effect February 1.

J. Frank Pratt has resigned as superintendent of the Southington & Plantsville (Conn.) Tramway Company and is succeeded by R. T. Ives.

John Balch, receiver of the Dubuque (Ia.) Light & Traction Company, has resigned and returned to Boston, his successor probably being H. G. Tarbert.

J. I. Nelson, formerly of Detroit, is the superintendent of the new Milwaukee, Racine & Kenosha Electric Railway which was opened for traffic on January 1.

H. P. Myton, superintendent of the Elkhart, Ind., lines, leaves the operating department to take charge of the construction work on the new line to Goshen.

W. E. Richards, electrical engineer of the Toledo Traction Co., was badly burned in both hands from touching a live wire at the switchboard in the power station.

L. O. Williams, chief engineer and electrician of the Springfield (O.) Railway Company, has been appointed superintendent of the line, vice E. F. Tindolph, resigned.

W. T. Lane, superintendent of the Pontiac & Sylvan Lake Railway Company, Pontiac, Mich., has sent in his resignation to take effect February 15, to accept a position with a Detroit road.

Superintendent McLain, of the Newton & Boston and Commonwealth Avenue Street Railway Companies was on Christmas the recipient of a gold watch and chain from his employees.

Phillips Begley, superintendent of the Nashua Street Railway, has been transferred to the Lowell (Mass.) & Suburban system, vice Leslie Wentworth, who resigns on account of ill health.

Warren C. Griffith, of Philadelphia, was elected president of the Lafayette (Ind.) Street Railway. Mr. Griffith has promised to make repairs and improvements on the system and equipment.

G. H. Campbell, general manager of the Winnipeg Electric Street Railway Company, has resigned that position to devote his entire time to mining interests. The vacancy has not been filled as yet.

Louis A. Wright, general manager of the Carbondale (Pa.) Traction Company, resigned in January and will take a similar position with the Schuylkill Electric Railway Company at Pottsville.

The Lackawanna Valley Company (Pa.) will have the following officers for the ensuing year: President, Lemuel Amerman; vice president, L. A. Waters; secretary and treasurer, Robert C. Adams.

Wm. B. Kilpatrick, private secretary of the general manager of the Staten Island Rapid Transit Company, accepted a similar position at Washington, D. C., under Frank S. Gannon, general manager of the Southern Railway.

C. P. Wilson was on January 1 appointed superintendent of the Sioux City Traction Company. Mr. Wilson's home is in Philadelphia but he comes more recently from Indianapolis where he has been connected with the street railway.

James Young has resigned the presidency of the Baltimore, Middle River & Sparrow's Point Railroad and the office of the company has been removed to the corner of Baltimore and Eden streets. Mr. Young was succeeded by Daniel Crook.

H. F. J. Porter, western representative of the Bethlehem Iron Company, gave a very entertaining and instructive stereopticon lecture on the "Modern Methods of Making Miscellaneous Steel Forgings, Guns and Armor Plate" at the Chicago Academy of Sciences.

William A. Flett, assistant superintendent of the Sioux City Traction Company, who has been connected with that company for a number of years, has resigned to accept a position with I. B. Walker, the former superintendent of the line, but who is now located in Chicago.

John M. Roach will undertake to make a saving of about \$365,000 in the operation of the West Chicago Street Railroad Company this year. This will be about 2.7 per cent of the capital stock. Mr. Roach is a very capable man but this undertaking will likely tax even his capacity.

W. L. Conyngham has been elected president of the Hazard Manufacturing Company, Wilkesbarre, Pa. Mr. Conyngham is very well known in the anthracite coal trade, being the principal partner of Stickney, Conyngham & Co., of New York, Philadelphia, Baltimore and Harrisburg.

J. N. Beckley, director of the Union Street Railroad Company, New Bedford, Mass., resigned, and Thomas B. Tipp was elected to fill the vacancy. Charles F. Shaw, treasurer of the road, severed his connections with it, and the president, Henry H. Crapo will act in both capacities, with A. C. Gardner to assist him in the treasury department.

There have been several changes at the Denver Consolidated Tramway, by which John Curtis, master mechanic, goes to the Gulf Railway Company, and C. F. Musgrove becomes purchasing agent in place of C. C. Keever who resigned. Fred Simmons who has been road master for a long time has also resigned to accept a similar position with the Milwaukee Street Railway Company.

A. H. Ford has been chosen secretary and treasurer of the New Orleans Traction Company in place of Henry Seligman, of New York. Mr. Ford has been connected with this company since its organization and has been a

faithful worker in its upbuilding. Formerly he was auditor of the Louisville Southern Railroad Company and later of the Kentucky & Indiana Bridge Company.

C. A. Denman, general manager of the Toledo & Maumee Valley, was on December 31 appointed general manager of the Toledo, Bowling Green & Fremont Railway Company, to succeed C. T. Geddes. As the two roads are closely connected it was decided to consolidate the management, and Mr. Denman retains his old position. Mr. Denman was for 10 years superintendent of the Consolidated Street Railway Company of Toledo, and accepted his position with the Toledo & Maumee Valley Company in 1896. He started at the foot of the ladder in the old horse car days and by close attention to business worked up to his present position. The REVIEW wishes him continued success.

M. K. Bowen, until January, superintendent of the Chicago City Railway, was at the last meeting of the directors elected general manager of the company. Mr. Bowen was born in Jefferson Barracks, Mo., in 1856. After a technical course at Washington University, St. Louis, he in 1877 entered the service of the United States as assistant engineer on a survey of the Mississippi river. After several years work on topographical surveying for railroads he entered street railway work as engineer and superintendent of construction of the Kansas City Street Railway and later as general superintendent of the road. Mr. Bowen left Kansas City to go to New York as representative of the Short Electric Railway, leaving there a year later to come to Chicago. For several years he has been superintendent of the Chicago City Railway, in which position his executive ability has been demonstrated, and his promotion is a deserved one.

## THE PARIS EXPOSITION OF 1900.

Advance sheets of the consular reports in regard to the Paris Exposition, have been received from the Bureau of Statistics, Department of State, Washington. The report states that work has commenced and will be vigorously prosecuted from this time forward. The details of management and regulation have been worked out. The United States will have a commissioner with absolute power in all questions concerning the distribution of space, erection of buildings and installation of American exhibits. Notice will be given of special tariffs made to exhibitors by railroad, steamboat and transportation companies. No charge will be made for space, water, gas, steam or other motive power in the exposition. All exhibits must be made in the name of the person, firm or company signing the application, and exhibitors are invited to mark the price of their exhibits upon them. Goods should be accompanied by a bulletin, attached to the bill of lading indicating their nature, class, weight and place of origin, and this will exempt them from statistical dues and inspection on the frontier. As much as possible all the products of a single country will be brought into juxtaposition, but where this is not practicable the grouping will follow the nature and utility of the objects rather than the country of production. In the classification, railroad and tramway construction will be under group No. 6, civil engineering and transportation.

The exposition will offer rare opportunities for American manufacturers of street railway supplies, for Europe and

France especially, is now and will be in the immediate future a field of great activity in street railway affairs. Appreciating the value of American experience, the French naturally look to the American builders for the best and most economical forms of railway apparatus.

## OUR FOREIGN EDITION.

The STREET RAILWAY REVIEW enjoys the distinction of having inaugurated the first and only Foreign Edition of a street railway publication, in the world. This was not a few extra copies of some month's home edition with the word "foreign" printed on the front cover, but was made up, printed and bound as a separate and distinct publication. It contains a large amount of matter which would not specially interest American readers, but is adapted to the wants and needs of managing directors abroad. A copy of this FOREIGN EDITION has been sent to every tramway in the world outside of the United States and Canada, and hundreds of copies to officers, directors, engineers, and heavily interested stockholders.

The tramway world abroad naturally looks to this country as the fountain-head of information and experience in electric and cable traction, and is now ready to enter upon that same progressive and wide spread transformation from animal to electric power, which prevailed here a few years ago. The opportunity for American manufacturers of street railway supplies to enter and possess this field is most inviting and promising, and the firms which organize to secure and care for this new business will be richly rewarded. In order to assist in this work, we shall for the first year, at least, print free of cost to our advertisers, all the advertisements which appear in our home edition of the month in which our FOREIGN EDITION comes out. We are making no extra charge for this, and do so as a compliment to our customers.

As the FOREIGN EDITION is the same size and printed with the same care as our monthly, our readers who have ever examined foreign technical and trade journals will readily understand what an impression the FOREIGN REVIEW is sure to make, by comparison with the poorly printed, and as a rule miserably illustrated, foreign journals. We have entered upon this work with a thorough organization, and ample facilities to make it absolutely cover the entire field, and with our advertisers can now truthfully say, "The world is ours."

## NEW MANAGER AT ROCHESTER.

At the last meeting of the directors of the Rochester (N. Y.) Railway Company, T. J. Nicholl was appointed general manager. Mr. Nicholl has had a wide experience on steam roads as well as street railways. During the past few years he has held the position of general manager on two of the railways in Chattanooga, Tenn., and was president of the Chattanooga Terminal Ry. Co. Mr. Nicholl has been division engineer on the Illinois Central and was for four years superintendent of construction on the Chicago & Northwestern.

The North Hudson County Railroad Company, operating trolley lines in Hoboken and North Hudson, is conducting experiments with two new car heaters; one a hot water and the other an electric heater.

### CONSOLIDATION IN NEW JERSEY.

During the month of January the condition of the Consolidated Traction Company of Jersey City, has shown much improvement. The receipts for the month were \$15,000 in excess of those of January 1896, and the operating expenses were reduced \$10,000, making a gain in the net earnings for the month, of \$25,000. In a recent interview D. M. Shauley, one of the directors of the company, stated that the company had just purchased the Passaic & Newark Line, which extends from Bellville to Paterson and connects with the Paterson Street Railway. A traffic agreement has been negotiated with this latter company and as soon as a connection with the Consolidated Traction can be built, the company will have a through line from the Market street station of the Pennsylvania railroad in Newark to the city of Paterson. This line will parallel the Erie Railroad from Newark to Paterson, passing under the latter's tracks at most of the passenger stations.

A syndicate has also been formed to build a road from Westfield to Elizabeth, a distance of five miles, which shall bring the Plainfield Traction Company in direct connection with the Consolidated and the city of Elizabeth. This line will make a valuable feeder for the Consolidated.

### NEW PUBLICATIONS.

We are in receipt of the first number of the National Engineer, a monthly, and the official organ of the National Association of Stationary Engineers.

The Siemens-Halske Electric Company has just issued a big pamphlet containing a partial list of plants installed and a large number of testimonial letters speaking in high terms of the Siemens-Halske machinery.

One of our exchanges which we welcome most gladly is City Government, a New York and Chicago monthly, published by the City Government Publishing Company, of which Clarence E. Stump is president and treasurer. The title is indicative of its contents; it differs from many things municipal in being good.

The Clonbrock Steam Boiler Company, Brooklyn, N. Y., has recently issued a catalog of 128 pages, illustrating the Morrin "Climax" water tube boiler. The book is profusely illustrated with views of the company's works, showing the boiler in process of construction and with views of some large plants where it is used. The last 30 pages contain tables, data, etc., useful to steam users and designers.

The McGuire Manufacturing Company, of Chicago, has just issued an illustrated pamphlet filled with handsome illustrations of various types of trucks both under cars and separate, together with testimonial letters from a large number of street railways which are using the McGuire equipment. A list is also appended of street railways in the United States and elsewhere, which have purchased McGuire trucks.

Electric Tramways and Railways, is the title of a little treatise by H. Scholey, assistant editor of the London Electrical Review. Technical terms are avoided and the subject is treated in a popular style, as the purpose of the book is

that "It may help to dissipate some erroneous notions concerning the overhead wire system and may prove of some service in establishing the great claims of electricity as an economical agent for working tramsways, branch and light railways." It gives a brief history of electrical traction, and then goes on to explain the various systems in use, chiefly those in Europe. The booklet is fully illustrated. Price 2 shillings.

Power Distribution for Electric Railroads, by Dr. Louis Bell; Street Railway Publishing Company, New York, price \$2.50. This is undoubtedly the most complete book ever published on electric railway power distribution, and the ability of Dr. Bell to handle the subject no one will question. It is for the most part a reprint of the series of articles that Dr. Bell recently wrote for the Street Railway Journal. The author recognizes the fact that electric railway power distribution is something about which it is impossible to lay down any fixed rules except as to methods of calculation, and wisely limits himself to outlining possibilities and taking up a few concrete examples.

### THE ATTORNEY OVER DID IT.

The only argument which appeals to a Chicago damage case lawyer is to lose his suit. The appellate court has set aside a judgment obtained in the lower courts, whereby Jessie Krueger was awarded \$50,000 damages against the West Chicago Street Railroad. Jessie was five years old at the time of the accident, which was being struck by a cable car while running across the street, and which resulted in the amputation of one leg.

The award was for the largest amount ever secured in such cases, and the appellate court reverses on account of the inflammatory language plaintiff's attorney used in making his closing argument to the jury. He referred to street car lines as "modern Juggernauts," and said that they operated "machinery of death," and announced that the gripman did not exercise any mercy toward the child when his train struck her.

Justice Waterman wrote the opinion. In closing, he said: "Our experience leads us irresistibly to the conclusion that the very large and most unusual verdict in this case was the result in some measure of the inflammatory and improper address of counsel. So believing, we feel compelled to set aside the judgment rendered."

### HALF RATES TO WASHINGTON VIA B. & O.

#### Inauguration President-Elect McKinley.

Excursion tickets to Washington, D. C., will be sold via B. & O. on March 1, 2 and 3 at rate of \$17.50 for the round trip. The B. & O. is the short line to Washington, and passengers may have the choice of routes either via Pittsburg or via Grafton, or they may go via one route and return via the other, at their option.

Inauguration excursion tickets will be accepted on vestibuled limited trains without extra charge. Dining car service on all through trains. Special trains will be run on March 1, 2 and 3.

Sleeping car reservations may now be made. Further information may be obtained at city ticket office, 193 Clark street, or at depot ticket office, Grand Central Passenger Station, Harrison street and Fifth avenue.

The West End road, Boston, has ordered 75 open cars and 175 trucks of the J. G. Brill Company, Philadelphia.

On February 1, the Ball & Wood Company, removed its New York offices to the Beard building, 120 Liberty street.

The West End Street Railway Company has made a contract with the Westinghouse Electric Company for 450 12 A, 30-horse-power motors.

The Falk Manufacturing Company of Milwaukee, has lately received orders from the Los Angeles Railway Company for welding a large number of joints.

The Newburyport Car Company has received orders from the West End Street Railway Company, Boston, for 35 large open cars, work upon them to begin immediately.

We have received a decidedly unique wall calendar "made in Japan," from Bagnall & Hills, electrical engineers, importers and dealers in all kinds of electrical supplies; Yokahama and Singapore.

Edward P. Sharp, of Buffalo, N. Y., dealer in overhead material, second hand electrical apparatus and electric railway supplies, has removed from the Agency Building to 909 D. S. Morgan Building.

Ford & Bacon, mechanical engineers of New York, Philadelphia and New Orleans, on February 1, admitted George H. Davis to the firm, which will hereafter be known as Ford, Bacon & Davis.

The Hunter Illuminated Car Sign Company of Cincinnati, is meeting with success in interesting street railways in its box signs. Since the St. Louis convention 37 signs have been shipped on trial orders.

W. McLain has been appointed the Pittsburg agent of the Cambria Iron Company and has opened an office in room 318 Park building, where he is ready to negotiate for the sale of all kinds of rails.

A. O. Schoonmaker, 158 William street, New York, importer of India and Amber mica, has issued an 1897 catalog and price list of his large stock of block and cut mica, stamped segments and washers, etc.

We are in receipt of a very handsome calendar from the Peckham Motor Truck & Wheel Co. Each sheet is devoted to one of the Peckham trucks and has two illustrations, one of the truck and one a car mounted on the same.

The Westinghouse Company, from time to time, issues catalogues describing improvements and new forms of apparatus. These catalogues make a useful collection, and for convenience in keeping them, the company kindly provides a cloth cover.

The Westinghouse Company has received orders for five 5,000-h-p. generators from the Cataract Construction Company of Niagara Falls. These are to be of the same type as those already installed and the consideration will be in the neighborhood of \$500,000.

George W. Conover and David E. Goe of Chicago, have combined to act as western agents for a number of electrical manufacturing concerns. The extensive experience and wide acquaintanceship of these gentlemen in the electrical field assure their success in this new enterprise.

Four of the thirty cars recently ordered by the Rapid Transit Railway Company of Syracuse, N. Y., from the Barney & Smith Car Company, Dayton, O., have been put in service. The cars are double enders with seats along the sides and are equipped with double fare registers.

The Central Electric Company, Chicago, furnished a large part of the wire, switches and transformers used in keeping the 25,000 incandescent lamps going in the Coliseum during the Cycle Show recently closed in this city. The promptness and satisfaction with which it furnished all supplies was a source of comment.

Ahearn & Soper, Ottawa, Canada, have received the contract for the complete rolling stock equipment of the Quebec Electric Railway, which it is intended shall be as nearly as possible a duplicate of the Ottawa road. The contract includes the motors, which will be of the Westinghouse make and especially adapted for the severe grades at Quebec.

The Milwaukee, Racine & Kenosha Electric Street Railway Company recently purchased a snow plow from the Taunton Locomotive Manufacturing Company of Taunton, Mass. Two 50-h-p. motors are used to furnish motive power. During the severe storms of January the railway company experienced no difficulty in keeping its tracks clean.

The Wheeler Rail Joint Company has been fortunate in securing the services of Geo. W. McNulty for president. His wide experience in street railway affairs will be of much service to his company. Jay Willard Clark was elected secretary and treasurer. The new officers expect to do a good business this coming year and will soon open a New York office.

The Pennsylvania Steel Company, Steelton, Pa., has been awarded the contract for the steel work of the new Southern Union Station train house to be erected by the Boston Terminal Company. This contract is for 14,000,000 pounds of steel, one of the largest of its kind ever placed. The same company also furnished the steel for the Northern Union Station of the Boston & Maine Railroad and for three sections of the subway.

The largest order ever placed for manufactured tapering yellow pine poles, being for 8,000, ranging in length from 25 to 55 feet, has just been awarded to S. C. Strock of 50 Broadway, New York, by the American Telephone & Telegraph Company, for use on its lines. Mr. Strock is a man well known to the electrical profession on account of his former connection with the Thomson-Houston and General Electric Companies.

A very complete electric power and lighting plant is now being placed in position in the extensive works of the Shoemaker Steel Company, Pittsburg. The power plant consists of one 400-h-p. vertical cross compound engine, direct connected to 225-k-w. generator, and one 175-h-p. vertical compound engine direct connected to 125-k-w. generator. The engines were furnished by the Ball Engine Company, Erie, Pa., and the generators by the Siemens-Halske Electric Company, Chicago.

The Apollo Iron & Steel Company, Vandergrift, Pa., has ordered a direct-connected set for electric lighting. The engine, which is a 150-h-p. vertical compound, built by the Ball Engine Company, Erie, Pa., is direct connected to a 90-k-w. General Electric alternating machine. This company already has an electric light and power plant, consisting of three 400-h-p. tandem compound engines made by the Ball Company, which are direct connected to Westinghouse generators of 225-k-w. each.

The Standard Air-Brake Company, in addition to sales already reported, closed contracts during the first week in February for one lot of twenty outfits for one road, and another lot of fifty outfits for a road near by. The company is building some heavy types of air-brakes for equipping electrified steam roads, and is about to close a contract for furnishing its motor-compressor type to be applied to some extra heavy locomotives to haul passenger trains of four cars, as well as freight.

In view of the criticism which has been occasioned through the failure of the Dornier & Dutton Manufacturing Company of Cleveland, it is but fair to Mr. Dutton to state that he severed his connections with the firm about two years ago, and has since that time been connected with it only as a sales agent and was in no way responsible for the failure. His friends will be glad to learn that he has taken charge of the railway department of the Van Dorn Iron Works in Cleveland, where he will be glad to meet them or hear from them.

The Partridge Carbon Company, Sandusky, O., reports that the prospects are very flattering for a largely increased business during the coming year, and has been increasing the stock carried so that orders may be promptly filled. The company makes three grades of brushes, hard, medium and soft, so that any of the requirements of service can be met. The brushes are truly "self lubricating" as they are treated after they are copper coated, and are recommended to consumers who wish to save commutators, give better service and do away with squeaking.

The Central Electric Company is now the exclusive general western agent for the Billings and Spencer Company, and carries in stock a complete line of all overhead materials, generator and motor patent drop forged commutator segments, also a complete stock of mica and micanite specialties, including commutator rings, segments, cut and uncut mica, both Amber and India. The new Billings & Spencer hangers are a radical departure from other forms and incorporate new and very meritorious features. The Central Electric Company is complimented upon its quick shipments and close attention to the needs of patrons. The line of specialties is unexcelled and a point is made to furnish to the customer whatever may be desired, as it is in a position,

through its agencies, to manufacture all forms of overhead and other materials and it controls many of the best specialties on the market.

The E. P. Allis Company of Milwaukee, is completing two vertical compound beam blowing engines, with steam cylinders 40 and 78 by 60 inches and two air cylinders 76 by 60 inches for the Krainische Industrie Gesellschaft, of Trieste, Austria. These are duplicates of the 12 engines in the Carnegie steel plant at Duquesne, Pa. Negotiations are pending for the machinery of a 1,200-barrel flour mill, to be built at Braila, Roumania. The company has been advised of the completion of a gold and silver concentrating plant for which it built the machinery. A feature of this last plant is that because of the difficulty of transporting it, no piece of material could be made heavier than 150 pounds.

The Cleveland & Chagrin Falls Electric Railway, now building between the above named cities, a distance of about 16 miles, placed an order with the Peckham Motor Truck & Wheel Company, for entire equipment of No. 14 double trucks. The car bodies to be supplied by the Kuhlman Car Company of Cleveland, are 39 feet over all, being vestibuled on the front end only; the two motors, 50-h-p. Walker, will be placed on the rear truck; the cars are to run at a speed of from 35 to 40 miles an hour and to be extremely handsome and comfortable. The Peckham double trucks differ from all other makes of double trucks in that they carry the car bodies as low as the ordinary four wheel street car, which is an important feature in cars which run at high speed through comparatively short curves. The Peckham Motor Truck & Wheel Company, also has an order from the Cleveland Electric Railway, for extra long trucks to be used under 24-foot car bodies, 32 feet over all. This we believe to be the longest closed car ever placed on four wheel truck with 7 ft., 6 in. wheel base.

The manager of a large and well-known road writes the New Process Raw Hide Company of Syracuse, N. Y., the following letter: "Your inquiries in reference to my experience with your raw hide pinions used on electric car motors received. I have used these pinions on three different roads. The mileage obtained from them has been very satisfactory. The greatest point to be observed, however, in the use of your raw hide pinions instead of steel, is the fact that the raw hide pinion does not perceptibly wear the gear. The gears of electric motors represent the greatest cost of repairs on motors of any mechanical part. It is true that the raw hide pinion usually costs about three times as much as the steel pinion. Steel pinions will wear out a gear within eighteen to twenty-four months. When raw hide pinions are used, it will be found that the gear will last for many years. There are other advantages to be taken into consideration by the application of raw hide pinions. These are, that they reduce the noise made by the motor very materially: that they are a factor of safety at times when the motorman, or driver puts his power on too quickly; by their use the gear case is not necessary; a saving will be made on the lubricants which are now used in gear cases. Another advantage is that the absence of grease from the gear cases stops the possibility of any grease dropping on the pavements, which in some towns is a source of great annoyance to the people. Raw hide pinions will be found to work better with new gears. It is not fair to the pinion to place it in service with a partly worn out gear."

The Omaha Street Railway has ordered 7 Dutton trucks of the Van Dorn Iron Works, Cleveland, the contract being taken by W. A. Dutton, manager of the railway department.

The Vilter Manufacturing Company, builders of refrigerating and ice making machinery, corliss engines, etc., Milwaukee, Wis., has recently closed a contract with the Reymann Brewing Company, Wheeling, W. Va., for a 100-ton refrigerating machine; with A. Gettleman Brewing Company, Milwaukee, Wis., for a 75-ton machine; with the Milwaukee Cold Storage Company, for two 40-ton machines; with Ruemmell & Siebert Refrigerating Machine Company, St. Louis, for three 75-ton refrigerating machines; with L. Gerlinger Company, Portland, Ore., for one 25-ton machine; with the Portsmouth Brewing & Ice Company, Portsmouth, O., for one 75-ton refrigerating machine with 15-ton ice tank; with the British American Brewing Company, Windsor, Ont., one 35-ton refrigerating machine; with Born & Company, Brewers, Columbus, O., two 50-ton ammonia condensers; with Fred Miller Brewing Company, Milwaukee, Wis., direct expansion cellar piping; with J. C. Miller Brewing Company, Philadelphia, Pa., direct expansion cellar piping; with Joseph Schlitz Brewing Company, for its Pittsburg branch, direct expansion cellar piping and an ammonia condenser. With each of the above name refrigerating machines an improved "Vilter" corliss engine is included.

The Syracuse (N. Y.) and Oneida Lake Electric Railway will be started as soon as the frost is out of the ground. The franchise for this road was granted about two years ago. At the recent annual meeting of the stockholders the following officers were elected: President, W. B. Kirk; vice-president, T. W. Meachem; secretary, W. S. Wallis; treasurer, J. B. Morgan.

The annual report of the Baltimore Traction Company proves it to be in a very prosperous condition. The income during the past fiscal year amounted to \$1,269,514, an increase of \$90,323 over the previous year. The operating expenses were \$646,127 and the fixed charges, \$445,511, leaving a balance of \$177,875. The board of directors was not altered for the coming year. The board will soon meet for the election of officers, but no change is anticipated.

People, often as soon as they get injudicious railway legislation, begin to find fault with it. Perhaps this is on account of the perverse streak in most men and they look assiduously for something to kick about. A new ordinance in Brooklyn prohibits the opening of the front doors of trolley cars, and now some are dissatisfied with this restriction, for it is thought that there is more danger in getting off the rear end than from the front platform. Such regulations should be left to the companies and the public weal would be better served.

## A QUEER DECISION.

Prior to the building of its road, a suburban belt line, 21 miles long, the Toledo & Maumee Valley Railway Company entered into a contract with the Toledo Traction Company under which the cars of the former company were to be run on the tracks of the latter within the city limits. This contract was fully carried out by both parties.

A few months ago the Toledo & Maumee Valley Company granted to a second suburban company, whose lines connected with its own at Maumee, the right to run cars over the entire loop including the lines of the Toledo Traction Company.

The Toledo Traction Company attempting to prevent this unauthorized use of its tracks, was beaten in the lower court last month but has appealed the case to a higher court.

## STREET RAILWAYS IN MASSACHUSETTS.

The report of the Railroad Commissioners shows that the 83 street railway companies in Massachusetts have 1,368 miles of road at a total average cost of \$46,041 per mile. Of this \$23,396 was spent for the road bed, \$9,804 for equipment and \$12,840 for lands, buildings and other permanent property. The gross assets of the companies were \$62,187,775 and liabilities \$61,117,713. The total income for the past year was \$14,900,941 and the expenditures \$14,423,012. Dividends of \$1,802,846 were paid, an increase of \$196,652. One company paid as high as 10½ per cent.

Sleepy Hollow, N. Y., made famous by the writings of Washington Irving will soon have its echoes awakened by the swift running trolley car. The modern Ichabod Crane can go a courting on electric cars with no fear of headless goblins.

The Halifax Town Council passed resolutions, which were ratified afterwards at a mass meeting of the citizens, to petition Parliament for a bill to empower the corporation to build tramways and operate the same. The mayor gave as his opinion that electricity was the only motive power worthy of consideration.

## AN ENGLISH CONDUIT.

The accompanying drawings show the conduit ducts and methods of jointing used in some underground work at Leyton, England. It is known as the Doulton conduit and is made in two, four or six ducts 2½ inches square. It is supplied in lengths of two feet, and jointed on stoneware cradles with Portland cement, as shown in Figures 1 and 2. While making the joint, plugs of wood were inserted into the ducts to insure their alignment, and to exclude cement from the interior.

Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.

A car barn, 76 by 185 feet, is being built for the Cincinnati & Miami Valley Traction Company at Trenton, O.

The Union Traction Company of Philadelphia is the largest street railway company in the world, being capitalized for \$110,395,910.

Owensboro Electric Railway suffered the loss of car sheds and supply house, together with eight street cars and a number of motors. Loss, \$8,000.

Icy rails caused a Buffalo & Niagara Falls car to jump the track near the Tonawanda Driving Park. It ran into a board fence but suffered little damage.

C. M. Burlingame, the defaulting bookkeeper of the Buffalo & Niagara Falls Electric Railroad, was apprehended and returned to Niagara Falls for trial.

The annual report of the Beaver Valley (Pa.) Traction Company shows a very gratifying condition of the road's finances and good prospects for the future.

By throwing a piece of telegraph wire over the Never-sink trolley wire near Reading, Pa., and grounding it, a thief burned off and stole 200 pounds of copper wire.

It is said that surveys will shortly be made for an electric road between Clinton and Westboro, (Mass.) which is to connect with the proposed line between the latter town and Worcester.

Justice Richardson began the month by assessing the first \$5 fine for violation of the recent order of the health commissioner of Chicago against expectorating in public places.

The new charter for New York city provides for the sale of street railway franchises at auction, with the right reserved for the city to take possession of the road at the end of 25 years.

Two miles of electric road will be built connecting Catskill, N. Y., and Jefferson. W. S. Roberts, I. E. Roberts, W. Conway and Charles S. Williamson have organized the company with a capital of \$30,000.

The Denver Consolidated Tramway Company received during the year 1896, \$724,511, an increase of \$8,472 over the preceding year. The net earnings amounted to \$281,771, which was better by \$7,014 than 1895.

On January 18 a suit was brought in the District Court of Des Moines county, Iowa, by the American Trust Company of New York, to foreclose a mortgage given by the Burlington Electric Railway Company. Ostensibly the suit is brought because the company has defaulted on interest, but the object is to enable capitalists controlling the company to

buy the rest of the stock at a low price and then consolidate with the lighting and power companies of Burlington.

Annie M. Kerrison has sued the Market Street Railway Company, of San Francisco, for \$15,000 damages for alleged personal injuries received through the sudden stopping of a car on which she was a passenger.

The Post Office Department has entered into an agreement with the Consolidated Traction Company of Newark, N. J., to carry mails from the depots to the post office stations. The contract goes into effect February 15.

From January 1 to November 30, 1896, the gross earnings of the Cleveland (Ohio) Electric Railway Company were \$1,499,266, being an increase of \$131,509, and the net earnings were \$510,960, compared with \$480,015 for 1895.

Work is progressing on the Oshkosh Street Railway and it is expected by the management that operations will begin about June 1. A line from Oshkosh to Kaukauna is contemplated by this company, although nothing has as yet been done.

The financial statement of the Metropolitan Street Railway Company of Kansas City makes a very good showing. From January 1 to November 30, 1896, the total receipts were \$1,631,923 and the net earnings \$687,905, an increase of \$42,937 over the same period in 1895.

On the Union Elevated Railroad of Brooklyn, an engine jumped the track while going at full speed and collided with a train going in the opposite direction. The engine and smoking car were pushed off into the street, the engineer was killed and several passengers injured.

The employes of the Camden, Gloucester & Woodbury (N. J.) Railway have formed a relief association and elected officers: President, Benj. E. Poole; secretary, Hugh Brown; financial secretary, William Zinc; treasurer, Edward Foster; directors, Thomas Davidson, Joseph McVey and Joseph Ackroyd.

Charles C. Johnson, secretary of the Raleigh (N. C.) Electric Company, writes that a temporary plant has been installed to supply power to the street railway in place of the one recently destroyed by fire. The power house will be rebuilt and equipped with the latest electrical machinery in the near future.

A serious fire at the car sheds of the Brooklyn & Newtown line was prevented by the presence of mind of the motorman, who, on arriving at the sheds and finding a car on fire, ran in, coupled on to it and hauled it out into the street. The one car was destroyed. Loss, \$1,500, but the barn was saved.

At Mt. Clemens, Mich., there has been considerable trouble between the Rapid Railway and the Lakeside Traction Companies. A city ordinance was passed allowing the Rapid Railway to pass over the tracks of the Traction company, but there was some delay in accepting it. Recently when the Rapid company availed itself of this privilege, the other company chained a car to its track and cut the trolley wires. This almost precipitated a riot, but the mayor interfered. It is expected that the council will straighten out matters.

The Taylor Electric Truck Company, Troy, N. Y., has supplied 25 trucks for use on the Quebec Electric Railway.

The American Electric Heating Company of Boston, has made changes and improvements in its apparatus during the year. A revised price-list has been sent out to the trade.

The Westinghouse Electric & Manufacturing Company has furnished electrical equipment and 12A, 30 H-P motors for 25 cars to be used on the Quebec Electric Railway.

The contract for new track rail for the West End Road, Boston, has been placed with the Johnson Company, and the special work was divided between the Johnson Company, Wharton of Philadelphia and the Pennsylvania Steel Company.

Under an order of court the assignees and receivers of the J. H. McEwen Manufacturing Company, Ridgeway, Pa., will on February 22, sell the plant of the company together with all assets, including patents, shoprights and contracts.

It is stated that F. B. Torrey is fitting up an extensive plant at Bath, Me., for the manufacture of trolley wheels, brass goods, electric car fittings, etc., and it is expected that the works will be opened in March. The plant will be operated by electricity.

The Consolidated Car Fender Company of Providence has sent out a pamphlet bearing testimony of the excellence of the Providence street car fender. Records have been kept of accidents and the figures show that of the number of persons struck by cars equipped with them, 97 per cent escaped.

The Siemens & Halske Electric Company of America, announces that the statements of competitors claiming to absolutely own and control patents covering all underrunning trolleys do not refer to the Siemens trolley or contact bar. This is a well known device that has been often described. And further, that all United States patents covering the main features of the "Buda-Pesth conduit system" are owned and controlled by the Siemens-Halske Company, notwithstanding that other companies claim to install this system.

The F. L. Gaylord Company, of Ansonia, Conn., manufacturer of brass, bronze and composition castings, has added to its manufacture a full line of electric railway supplies. Among the patented articles made by this company are its well known brake handle, its trolley head with detachable springs and swivel ring for trolley rope and the "old reliable" sand box which has been considerably improved. The company makes trolley wheels of a special mixture guaranteed to run 12,000 miles. It is one of the few concerns that make pure copper castings guaranteed solid.

The stockholders of the Standard Underground Cable Company held their annual meeting in Pittsburg, on January 26, and re-elected the old board of directors. The report of the directors showed assets aggregating \$1,112,016 and liabilities exclusive of capital stock of \$106,928; the surplus over and above all liabilities (including capital stock) was \$308,107. The company's plants were reported as in good

condition with very flattering prospects for 1897, as there are contracts aggregating \$250,000 already booked. On January 30, the directors met and re-elected the officers of the company to their respective positions.

Communication comes to us from the Cahall sales department saying that their boilers are the only ones having "flowed" steel headers, etc. Some of their competitors have offered for sale Babcock & Wilcox type of boilers with "flowed" steel manifolds and cross boxes. "Flowed" steel is a special mixture of open hearth steel manufactured under a secret formula which belongs exclusively to the Cahall company. The Penn Steel Casting & Machine Company of Chester, Pa., prepares this steel and wrote the following letter in reply to the question whether any "flowed" steel headers had been furnished to any party other than the Cahall company.

"Referring to your inquiry, we beg to state that we consider the special mixture for 'flowed' steel we are making for you, your property, of which you have the sole right, and that we never have nor never will furnish 'flowed' steel to anyone but yourselves unless authorized by you. Neither will we give to anyone any information as to the formula under which this special mixture is made."

## HOW THE CASUALTY COMPANY WON.

The Electric Mutual Casualty Association, through its attorneys, Taylor, Upton & Smiley, of Niles, Ohio, has just secured a verdict for one of its members in the Common Pleas Court of Trumbull County, Ohio, in the case of Cora Barb vs. Mineral Ridge & Niles Railway Company, and in the case of Aaron Barb vs. same road, dismissed by plaintiff.

On June 30th, 1896, the plaintiff, Aaron Barb and wife were in a covered wagon driving along the tracks of the Mineral Ridge & Niles Street Railway, and when at a point midway between street crossings, they suddenly attempted to cross said tracks without taking proper precaution, consequently their wagon was struck by one of the defendant's cars and demolished and they, themselves, claimed receiving personal injuries to the amount of \$1,500.00 and \$2,500.00 respectively, for which amounts they brought suit. The evidence of negligence on the part of the driver, Barb, was strong, but under the Ohio statutes, such negligence could not be imputed to his wife. However, by the skillful introduction of evidence and cross examination on the part of ex-Congressman Taylor, of the attorneys for the defendant, it was shown that Mrs. Barb usually "wore the pants" and "she would not have allowed her husband to drive across there if she thought there was any danger and he had spoken of crossing the tracks at that point and she had consented to it." The court charged the jury especially as to the significance of the woman's admission and it took but a few minutes for that body to render a verdict for the defendant. Another feature of the trial was the introduction of evidence given by a female detective employed by the association; she had obtained employment in Mrs. Barb's millinery shop and testified that Mrs. Barb, subsequent to the accident, did all kinds of hard work, such as lifting counters, boxes, etc., and boasted that she never was sick. The trial of the wife's case revealed to the husband that a detective engaged by the association, had also been in his employment, to whom he had boasted since the accident occurred of his physical powers and athletic abilities, hence his loss of heart and subsequent dismissal of the case.

**THE WESTERN ELECTRIC KNIFE SWITCH.**

The demand for high grade knife switches has brought upon the market designs of various makers. The most recent are the type "E" and type "Q" manufactured by the Western Electric Company, Chicago. The contacts of these switches are all rolled tempered copper and great care in construction and design has been observed in order that the switches may carry their rated capacity in amperes without heating. In placing and fastening the jaws in position they are not soldered but bolted to the metal plates or lugs as can be seen from the illustrations. By this method the temper of the jaws is in no way injured and they will always grasp

the blade of the switch firmly and the contact will not deteriorate with time. The hinge contact is made in the same way and the bolt which passes through the hinge is provided with a lock nut, preventing any liability of loosening at this point. The blades are of drawn copper, hand finished.

The base is extended for connections on back of board and is secured in place by a lock nut. Swivel connections

are provided which will admit of the circuit wires being brought into the switch from any direction. The switches are all made to gage and any repair part can be obtained and a damaged part replaced in a few moments.

The type "E" is for station and switchboard work, being of the regular jaw pattern. The type "Q" is essentially the same as type "E" with the addition of a quick break spring and is especially approved by the underwriters for an entrance or service switch for motor work, constant potential arc, or incandescent lighting.

Two cuts of quick break switches mounted on slate bases are shown, one for a pressure up to 110 volts the other for a pressure up to 500 volts.

**WHAT BECOMES OF OLD COPPER WIRE.**

Few people outside of a certain line of business know what becomes of copper wire after it has served its purpose and been discarded. There is one firm in Chicago that makes a specialty of buying copper wire and burnt out incandescent lamp bases from electric railways and lighting companies, and handles a million pounds of this scrap annually. This is the Swartz Metal Refining Company, 120-122 West Lake street. The company has men who carefully inspect the old wire, and such as has any life remaining in it is sorted, re-rolled and sold for use again. Old lamp bases are of value only for the platinum they contain. From some of the other scrap the company makes a high grade of anti-friction babbitt metal for high speed dynamos. During the last year when business was dull at home, large quantities of the rejuvenated copper wire were exported.

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. MARCH 15, 1897. NO. 3

A UNIQUE method of discipline, which keeps a man steadily at work instead of granting a sometimes welcome vacation when suspended, has been adopted on a Massachusetts road. Violation of rules not warranting dismissal is punished by being assigned to night car runs. The scheme is not at all a bad one, and we can easily imagine the thoughtful, expectant look on the faces of the owl car crew as they scan the bulletin each night to see if some other unfortunate has slipped up and will let them back on the day run.

WATER power for street railway use is receiving much attention, and from this time on will receive more study than ever. Already Buffalo, Salt Lake City, Niagara Falls, and Portland, Ore., lines, all good sized systems, are using water power in whole or part, and Minneapolis and St. Paul lines will turn on current from water power in a few weeks. Denver is also looking to this kind of power, and others are taking the subject up. The improvement in apparatus during the past two years has made the governing of water quite as uniform as that of steam.

THE FOREIGN EDITION of the STREET RAILWAY REVIEW has elicited scores of complimentary letters from street railway men abroad. The American con-

suls especially commend the enterprise as what was greatly needed to acquaint foreign buyers with our American products, which in street railway supplies and apparatus are without question the best in the world. Our FOREIGN EDITION is the same size as the home edition, though prepared, printed and bound as an entirely distinct publication. The FOREIGN EDITION is issued quarterly, and is sent to every foreign street railway in the world. The next issue will be out May 1.

INTEREST in electric traction in foreign countries is steadily increasing, and each new installation will materially help to decide others to make a similar change. In Germany, particularly, is the work being prosecuted with great vigor. It is estimated that as many miles of electric railway were constructed in Germany alone in 1896 as were in operation with animal power eighteen months previous. The capital invested in electric railways in Germany is now over \$23,000,000. Construction is planned in other countries to a large extent. Our home manufacturers, however, to secure and hold a large share of this trade must be alert and pushing, for already German manufacturers are getting in shape to handle this new work.

THE American Street Railway Association probably never had a better executive committee than the one in office this year. This was made very evident by the thorough and business like methods which characterized its recent meeting at Niagara Falls, at which time arrangements were completed for the convention there next October. There has been a fear expressed by many that the accommodations there so late in the season would not be adequate to the requirements of the association, and that exhibits would suffer for want of proper shelter. The committee insisted on quarters both large enough and warm enough to make the display in comfort and with success. All this the local committee pledged itself to do, and also that the hotels should be warm and equipped with good service. The Niagara people are evidently very much in earnest, and will do their utmost to accommodate and please the visitors in every way. Unless the weather should happen to prove very unseasonable the natural and electrical features of interest will be unusually attractive.

THERE had been some doubt expressed as to the ability of Niagara Falls to take care of so large a guest as the American Street Railway Association. Never before has the meeting been held in any but a big city. Hence President McCulloch was very frank and plain spoken in his address to the local people at the Chamber of Commerce meeting, and the needs of the association even to the matter of small details were set forth. The Niagara people, however, were equal to all demands, and will undoubtedly exert themselves to the utmost to comply with every possible requirement, and promise that the association will be glad it selected that city. The plans, as now arranged for exhibits and meeting hall,

are all that could be asked. The hotels, which are chiefly summer hotels, will be kept open until after the convention, and while not modern, have large rooms, parlors and corridors and name rates to which no objection is made. For those to whom the Falls is an old story, the new power plants will be interesting, while the electric lines along the top of the cliff on the Canadian side, and at the bottom of the gorge on the American side open up new sights no less interesting than the Falls. Altogether the prospect for the '97 meeting is highly gratifying. At no previous meeting have so many details been settled so early in the year.

The phenomenally low price of steel rails has been taken advantage of, not only by steam roads, but by many street railways. Every one appreciates the fact that prices cannot long remain at the figures at which orders have been booked, for as soon as the mills are well loaded on future delivery orders, quick deliveries are going to command a premium. While the price of girder sections has not touched that of the T's, there has been a corresponding reduction, and many roads which were fortunate enough to be in financial condition to place orders have effected the saving of many thousands of dollars. The proposed interurbans, which, of course, lay T sections, have been greatly encouraged by the low prices, and not a few of them were able to place orders at the \$17 price. One such line alone which had its order for this spring delivery placed at \$28 per ton, with proviso of any lower rate which might maintain between date of placing order and delivery of the steel, was able to save \$22,000 on the drop. Another road which did not have the saving clause will have to pay \$28 per ton. In this connection it is encouraging to contemplate the widespread effect of activity in the iron trade. It is estimated that sufficient orders for rail have been placed to keep the mills running steadily for the next eight and some say, twelve months. If this be true, it means the putting in circulation, chiefly through the medium of labor, of anywhere from \$30,000,000 to \$50,000,000. It means activity in coal and coke industries, transportation lines, and scores of smaller industries whose existence depends on the activity in the steel trade. Let us hope that this may prove to be the needed impetus to start that general revival of business which has been dormant so long.

It is against the ethics of the profession for a doctor to pay for an advertisement in the ad columns, but he is free to work the editorial department for as many columns as it is willing to give him. Such a case appears to be that of a Newark physician who boarded a through car and refused to pay more than five cents for a ride within the city limits, when the fare on that car was ten cents. Notwithstanding the fact that in the cross examination he stated he had been sent for in a great hurry, he allowed himself to be ejected from the car rather than hand over the additional five cents. The ejection seems to have been only too readily accepted, for upon

the conductor laying his hand gently on the doctor's shoulder and telling him to leave the car, he lost no time in doing so. Then he rushes into court and lays claims to \$10,000 damages to his tender sensibilities which were so grossly outraged. The fact that five cents, whether justly or unjustly demanded, would have saved this outrage, never seems to have entered into the doctor's diagnosis of the case. Nor the other fact that the company would certainly have refunded the amount in question if it was in the wrong, and had it been demanded by correspondence or in person, does not appear to have been found in the doctor's *materia medica*. What he wanted was not ounces but pounds of corporate flesh. The jury, however, being composed of plain business men, fixed their eagle X-rays on Dr. Mulcahey, and prescribed a return of the doctor's nickle and an additional one cent as damages for the company's malpractice. The expenses to plaintiff, defendant and the county in trying the case amounted to several hundred dollars, and common sense would dictate that such nonsensical suits should not be given a place on the calendar. But then, this is a free country, you know.

THE adaptation of electricity to other than street cars proper, is making steady advance. The first notable exception was upon the elevated road in Liverpool, which was opened for traffic in February 1893. In this country the elevated road at the World's Fair was put in operation the same year, and it was an easy step to apply it to the Metropolitan and Lake street L roads here. Much has been written, and more expected, of the adoption of electricity by steam roads. But it has not been the experienced electricians who have at one bound looked for all the locomotives in the country to dash into the scrap heap. They realize that the change must come first through the suburban departments of steam roads, and that as yet unsolved problems must be worked out in long distance transmission before long stretches of steam lines can be changed to a partial or entire use of current. The work of the switching locomotives in the Baltimore tunnel and elsewhere has been successful, and the electrifying of the Nantasket branch of the N. Y., N. H. & H. was a big advance. At the present time 13 miles of steam suburban road running out of Chicago are being converted to electricity and will go into operation about May 1. It is in this connection the address of President Clark of Boston, before the railroad committee of the Connecticut legislature, appeals with special force and interest. He represents the great consolidation of New England steam roads, and while he has been known for a long time as favorably inclined toward electric power, is the first prominent railroad man to come out as strongly as he has done, in its favor. His experiences as related elsewhere in this issue, as an electrician solving problems of insulation and transmission "according to Clark," instead of by the rule, is decidedly amusing; but the cars are in successful operation as the world knows, and results are what count, not theories. He is not the only one who in the

past two years, being forced by the exigencies of a case, has found it possible to do in practice what was stoutly denied in theory. Mr. Clark utters several statements which are specially noteworthy. He says: "Our locomotives may go into the scrap heap, as the old stage coaches had to go. We must keep up with the times or else we shall be left in the rear." And again: "Gentlemen, you may tell everybody who is engaged in investing his own or any one else's money in lines competitive with steam lines, that they cannot long prosper when the day comes to lay down third rails in this country." We cannot allow this matter to pass without reference to the fact that it was threatened competition by a parallel trolley line, which has decided this railroad company to adopt electricity between Hartford and New Britain. Under the system of steam propulsion it is impossible to give the frequent service that the proposed trolley line would have done, and Mr. Clark publicly recognizes the prediction made by the REVIEW long ago, that on passenger business of the character in question, the steam roads have but one choice. It is to adopt electricity with its frequent service, or go out of the business just as the steam roads between St. Paul and Minneapolis have practically done. And he is the wise steam railroader, who anticipating trolley competition, forstalls it by himself installing the coming universal power. In the above we are commenting of course on passenger service, but while the day may be somewhat remote when the trunk freight lines will operate electrically, there can be little doubt as to the outcome for the transportation of passengers, mail and express.

#### EXECUTIVE COMMITTEE A. S. R. A., MEETING.

The executive committee of the American Street Railway Association met in Niagara Falls on Monday, February 15. There were president Capt. Robert McCulloch; T. C. Penington, secretary; and C. S. Sergeant, Boston; Col. D. B. Dyer, Atlanta; Geo. B. Hippee, Des Moines; H. P. Brantford, Cincinnati and C. F. Holmes, Kansas City. The committee met the local representatives in the Chamber of Commerce, where the requirements of the association were fully stated by President McCulloch. After the arrangement of minor details and securing hotel rates which were satisfactory to both sides, the entire party inspected the site of the proposed convention building. The location chosen was approved and is very desirably situated. It is directly opposite the American entrance to the foot and carriage suspension bridge and faces the state park. Steam railroad tracks are already within 300 feet of the site and will be extended into the building, a condition which exhibitors will highly appreciate. Exhibits in less than car loads can be transferred at the depot and reloaded in a car and switched in, or hauled by teams.

The building which will be erected especially for convention uses by the citizens, will be 120 x 150 ft., and being on a corner and backed by an alley will be nicely lighted by day. It will be amply lighted by night and heated by electricity from one of the water power companies. Plenty of light,

power and heat is promised, for, as President Ely puts it they "have power to burn." The meetings will be held in the second story of the exhibit hall. The building is within five minutes walk of post-office, the Falls and headquarters hotels. The hotel people promise good service and reduced rates.

There is much of interest to visitors in both natural and electrical attractions. The plans for entertainment comprise a trip over the Buffalo & Niagara Falls Electric road; another over the Gorge road, a ride of thrilling interest; a trip over the Lewiston & Youngstown route to Ft. Niagara; one over the Niagara Falls, Park & River Railway, and from Chippewa to Queenstown; the inspection of the power plants of the Niagara Falls Power Company, and the Hydraulic Power & Manufacturing Company. It is also proposed to have a grand ball at the International hotel one evening, in addition to the regular banquet. All

this, with visits to the Rapids, Falls, etc., will combine to fill every moment. It is urged that delegates bring their families, and accommodations for all are guaranteed.

Applications for space may now be made and should be addressed to H. W. Beardsley, secretary Chamber of Commerce, Niagara Falls, N. Y.

After completing its business the executive committee, with several street railway people who were in the city, and officers of the local roads, took a trip down the Gorge road in a special car, and visited the water power stations.

Tuesday morning the party took a special car on the electric line to Buffalo, where they became the guests of H. H. Littell, general manager of the Buffalo Street Railway. They were shown about the city in an elegant special car and royally entertained in Mr. Littell's own hospitable style, dinner being served at the club.

#### PETROLEUM FOR THE TEXAS STREET RAILWAYS.

Woodford Brooks, treasurer of the Glenwood & Polytechnic College Street Railway Company of Fort Worth, Tex., says that the street railways will soon take advantage of the new oil fields in Texas. About three months ago petroleum was discovered at Corsicana and 5 wells bored. Upon investigation the oil was found to be of the finest quality and promises are good for a practically inexhaustible supply. The present cost of oil is 50 cents per barrel of 12 gallons, which makes it more economical for steam purposes than coal. The street railway company, controlling the lines in Fort Worth and Hillsboro, is endeavoring to get the railroads to give favorable rates for the transportation of oil, and arrangements are being made in the power houses for its use.

NEW TRACK CONSTRUCTION AT KANSAS CITY.

The heaviest rail as yet used by street railways is that to be laid in Wyandotte street, Kansas City, Mo., by the Metropolitan Street Railway Company. This line will extend from 2nd street to Southwest boulevard, and serve as a down town connection for the Southwest boulevard line to Rosedale. The new construction comprises 7,600 ft. of

FIG. 1—103-LB. RAIL—HALF SIZE.

double track, in a street where at present no tracks are laid and which for the most part is already well paved with asphalt.

In order not to destroy any more of the pavement than is absolutely necessary the trench construction was adopted in that portion of the street. The contract has been let to the American Railway Construction Company of Chicago, and work will be commenced about April 1.

Fig. 1 shows a section of the rail, one-half size. It is a center bearing girder rail 9 in. high and 60 ft. long, weighing 103 lb., per yard, and is rolled by the Johnson Company.

A cross section through one track is shown in Fig. 2, which illustrates the construction. Oak ties 6 x 8 x 16 in. are laid at intervals of 10 ft. in the trenches 15 in. deep and 20 in. wide, that are dug in the pavement. On these blocks the rails are laid and spiked and the track surfaced. Wrought iron tie-rods are also put in every 10 ft., being placed midway between the blocks. The trenches are then filled up with concrete and the granite tooting blocks set, care being taken to have the spaces between the granite and the rail web properly filled. As only narrow trenches are dug it is impracticable to use temporary ties when surfacing the track, as was done in laying T-rails on concrete beams in Minneapolis.

The concrete is composed of 1 part cement (1/2 Portland and 1/2 Louisville), 2 parts sand and 5 parts of broken stone. After the cement has hardened asphalt is run into the spaces yet remaining between the granite tooting blocks and the old asphalt. The city ordinances require that the company shall maintain the paving between the rails and for 12 in. each side of the outer rails. It will be seen that the 12 in. includes practically the granite headers only.

As the joints are cast-welded it is probable that this construction approaches very closely to the absolutely permanent way of which railway men dream.

ELECTRIC RAILWAYS IN EUROPE.

In a report to the State Department, Thomas Ewing Moore, commercial agent at Weimar, Germany, calls attention to the fact that locomotion by electricity is gaining ground in Europe. After giving the data as to the number, mileage and mode of operation of the street railways of Europe which has already been given in the February REVIEW, the report continues:

"A large number of electric railways which were building during 1895 have been finished in 1896. It is estimated that the new lines of the present year will exceed in number and mileage those constructed in 1895, and it would appear from the activity shown in planning and laying out new routes that next year will show a like increase.

"The capital invested in Germany alone in electric lines is estimated at 100,000,000 marks (\$23,800,000). German industry and German capital are responsible for the advance shown in this new departure in the Empire. It is due in a great measure to the Rhenish-Westphalian iron industries having been for years trained in the production of street railway material, both for the home and foreign market.

FIG. 2—SECTION OF TRACK AT KANSAS CITY.

“German electrical companies and supply manufactories have greatly increased in number and capital during the past few years and are constructing electric lines with steam engines down to the smallest isolator, thus giving an impetus to the boiler and car manufactories.

“Among the larger cities, Berlin is just about to introduce general electric locomotion in its streets. At present it is almost entirely dependent on the old horse tramway and omnibus service. Hamburg and Leipsic have their electric street railways nearly completed.

“The overhead surface system, owing to its being cheaper than the two remaining systems, will continue to be preferred for the lines contemplated or in course of construction.”

**HOME MADE SNOW PLOW FOR THE CALUMET.**

Much of the 75 miles of line of the Calumet Electric Railway Company lies in the sparsely settled districts south

lowered close to the track and any rigid obstruction will not damage the plow. At each end of the plow is a heavy fixed share extending seven feet in front of the car body and about 5 in. above the track. On either side of the car frame, but not shown in the illustration, is a spring suspended wing which can be adjusted to throw the snow as much as 6 feet on either side of the track. In front of the wheels are flanges suspended from a rod on each truck and held in place by springs. These bear on the rails and scrape them clear of snow, sleet and dirt. The brakes are also fastened to the truck and operated by a lever at the side of the controller. If the car should leave the track the chain guide on the truck can be shortened by pulling up the chain and dropping a link on the hook on the car body, a jack put under the car frame and the whole end of the car hoisted back on the track.

Although this snow plow has been built at small expense it is a powerful machine, equal to the most exacting service, and its construction has been such that it can perform its duty with efficiency.

HOME MADE SNOW PLOW—CALUMET ELECTRIC RAILWAY.

of Chicago. In many places the tracks are not protected from drifts by buildings, and this together with the infrequent service on some lines makes a snow storm of serious consequence. The road has been equipped with two sweepers and a snow plow, but the difficulty has been to remove heavy drifts. General Manager Sloan and Electrician Harding put their heads together and decided to build a plow specially suited to their needs. Much of the necessary machinery was on hand and the repair shop had every facility for construction. McGuire axles were used and two four-wheeled trucks were constructed, fitted with 1 W. P. 50-T.-H. motors. These trucks were separated far enough to permit a large adjustable share to go between them. The body of the car is very strongly built and quite large, being 29 feet in length. The car is entirely closed, affording protection to the men operating it.

There are two steel multiple-series controllers. The motors are arranged in two units of two in parallel and can quickly be thrown in multiple so that a burnt out armature does not disable the plow. In the middle of the car is a windlass for raising or lowering the central plow. This plow share is in three sections and on a spring suspension so that it can be

**CITY RECEIPTS FROM RAILWAYS.**

The receipts of the city of Chicago from the street railways during 1896 were as follows:

City Railway.....	\$133,703
West Chicago.....	69,726
North Chicago Street Railroad, North Chicago Electric, North Chicago North Shore, Chicago Electric Transit Company..	71,904
Calumet Electric.....	3,302
Chicago & South Side Rapid Transit Company.....	5,000
Metropolitan Elevated.....	5,750
Chicago & Jefferson Urban.....	1,147
South Chicago Company.....	425
Cicero & Proviso.....	168
Lake Street Elevated.....	6,000
Northwestern Elevated.....	20,000
Total.....	\$317,068

Of this \$69,000 was for car licenses; \$71,000 was paid to the public works department, and \$150,000 to the street lamp fund.

The street railway in Milwaukee paid \$20,485 in taxes last year.

## FLOOD INTERFERES WITH STREET RAILWAYS IN CINCINNATI.

About once in every 5 or 6 years, the Ohio river runs over its banks and goes on a rampage, causing loss and inconvenience to those living along its course. After a long experience with floods, property owners in the districts subject to overflow have erected their buildings above high water mark, putting in substantial foundations, built levees, and made other provision for high water, but all the pranks of the unruly stream can not be anticipated. Heavy rains throughout the watershed of the Ohio caused it to reach the danger point, 45 ft., at Cincinnati. Vast districts on both the Ohio and the Kentucky sides were deluged, making travel in the lower parts of Cincinnati, Newport, Bellevue and Dayton uncertain and dangerous.

The first illustration shows a view on Eastern avenue near the Torrence road. The car in the foreground was abandoned on account of the street being impassable as the water stood from 3 to 6 ft. deep. The Cincinnati, Bellevue & Dayton road can operate only a portion of its line on the

EASTERN AVENUE—CINCINNATI.

Kentucky side of the river. One of our pictures shows a broad expanse of water where is usually high, dry land. The latest mode of transportation is very primitive, consisting of a barge ferry with man power for tractive effort. A cable is anchored on the street car track on either side of the inundated districts and the passengers transferred in the barge. A car may be seen in the distance waiting to take the water bound inhabitants of Dayton to their places of business in Cincinnati and Newport.

Perhaps the most serious damage caused by the flood was the collapse of the 8th street viaduct, in Cincinnati, which is used for the Warsaw avenue, Elberon avenue and Sedansville car lines. A disaster was narrowly averted by the presence of mind of a motorman on the Elberon avenue line. The car, containing 31 passengers, was on the viaduct when the floor began to sink. The motorman turned his controller on to the last notch and as the car sped over the approach the structure went crashing into the Mill creek bottoms. The flood had softened the earth beneath the south retaining wall and it gave way causing the wreck of the viaduct. An idea of the extent of the damage may be had from our illustrations. The car lines are operating on

either side of the structure and the passengers are transferred after crossing on the north side-walk which still remains. It is reported that the Liberty street viaduct over Mill creek is also in danger and is being carefully inspected.

## ADVANTAGE OF ELECTRIC OVER STEAM LOCOMOTIVES IN STARTING.

Perhaps in no other way is the superiority of electric locomotion better shown than in the controlling mechanism for starting and stopping. The controller and reversing handles are very easily and quickly manipulated, when compared with the corresponding appliances on a steam locomotive. The motors respond almost instantly, and give such an even acceleration to the train that there are no great strains in the cars and draw bars. The quick acting air brake which is attached to the electric locomotives permits of higher rates of speed than the steam brake on many steam switch engines. In steam engines there is always a noticeable delay between the time when the throttle valve is opened and the pistons begin to move. This is often the cause of serious delays, for while each stop and start causes only a small loss of time, yet the aggregate amounts to a great deal. Another point worthy of mention is that when idle an electric locomotive absorbs no power, while a steam engine consumes as much coal just keeping steam up as it would to run at a constant speed of six miles an hour.

In switching yards either for making up trains or moving cars in manufacturing districts, the advantages of electric locomotives are so apparent that their use will not be long disregarded. But as E. H. Mullin points out in *Cassier's Magazine*, some alterations are needed in the present designs. The cab should be a circular conning tower, from which the operator could see in all directions, and in this should be placed the handles of the controller, reversing lever and air brake valve. The contact to the trolley wire should be designed to run equally well in either direction without the necessity of its being pulled around by hand. With these improvements electric locomotives should find application in many localities, making a saving in time and cost of handling freight.

## FIVE DOLLARS EXCESSIVE CHANGE.

An interesting change case was decided in Pittsburg recently, action being brought by Thomas Muldowney and wife against the Pittsburg & Birmingham Traction Company, in which \$500 were claimed. On trial it was found that Mrs. Muldowney boarded a car, and on fare being demanded found with the exception of three pennies the smallest money she had was a \$5 bill. This bill was tendered and refused two or three times, and the passenger finally ejected. The case was tried before Judge McClung, who, in the progress of the case, ruled that the tender of a \$5 bill was an unreasonable tender, and that if there was nothing more in the case than the refusal to accept the \$5 note in payment of the fare, which was 5 cents, the conductor would have been justified in ejecting the plaintiff from the car. The judge added that in ejecting the passenger regard must be had for the manner of doing it. While the conductor would have been in the exercise of a legal right, yet he was bound to do it in an orderly and proper manner. The jury concluded there was about \$90 worth of impropriety in the manner aforesaid and awarded the plaintiff that amount.

## ELECTRICITY ON STEAM ROADS

President Clark of the Consolidated as an Electrician—Surprised Himself and Others—  
Success of Experiments to Date—Big Promise for the Future.

Charles P. Clark of Boston, one of the best known and most successful steam railroad men in the country, and president of the big consolidate railroad interests in New England, recently made an address before the railroad committee of Connecticut. The occasion was the fight between a proposed trolley line between Hartford and New Britain which threatened to parallel Mr. Clark's present system of steam locomotives. His utterances are so full of prophecy, based on his experimental electric lines, they are notable as indicative of what other steam roads may expect to come to in the near future. After a few introductory remarks Mr. Clark gets down to what interests us—the application of electricity to his steam road. He said:

About three years ago, east of Boston, there was a cry for the double tracking of a short piece of road, about seven miles in length, upon which the business was extremely variable. On some days the number of passengers carried, being those resident on Nantasket Beach, would not outnumber a thousand or fifteen hundred. Perhaps the next day, a pleasant holiday, the number of passengers would be 25,000. On busy days the handling of the traffic was attended with delay and risk. The use of electricity as a method, not of creating power, but of conducting power, had been very largely discussed, and it seemed proper that an experiment should be made with the advantages of a high, dry, well-graded rail, so that we might learn as to its economy, both under a great volume of business and under a small volume, and it was determined to erect a very substantial trolley line, which up to that time had been the only practicable method of using the fluid. A large line of solid center posts was set up, and the double track was laid at a sufficient distance from these posts to prevent accidents to passengers, who often injure themselves if they have an opportunity. The power house was located at one end of the line.

A trolley wire was strung, the section of which was in the shape of a figure eight, so that a mechanical grip might be had upon it, instead of depending upon the old method. Everything worked as we had hoped it would, and better than those who had been in the business of trolley construction had prophesied. The continual application made to us as managers of the road was to make our rolling stock as light as possible, to assimilate to the practice of the street roads in every respect. All these overtures were resisted, and the equipment put upon that road consisted entirely of open cars, the business being a summer business. The cars themselves weighed between thirty and thirty-two tons. They were fitted with standard Westinghouse brakes and were so fashioned as to comply with the laws in force as to whistles and bells, compressed air being used for the whistles, and large gongs of the requisite weight answering for bells. After the service which had been demanded for the summer had closed we obtained figures which showed us that with business in volume electricity proved a much cheaper source of conveying power generated in a stationary plant than to generate the same force and power at the head of the train. And we found also that notwithstanding the

entire absence of insulation, either on the feeder or trolley wires, saving only the wooden posts upon which they were carried, without an ounce of glass or porcelain, the waste was very much less than had been experienced by any street road with whose figures we had become familiar. At the close of that summer's work, two years ago, it was determined to make further experiments as to the power which can be obtained from these motors and from this power house. As we were engaged in some heavy construction work, which required the use of between fifty and one hundred cars of granite every day, a sufficient number of these were weighed and sent to the power house for the purpose of testing by no spring or no patent contrivance, but by the actual article, the power which was generated and used with the apparatus. We found that we could haul in both directions, lest there might be any slight grade in either more than the other, over one thousand tons of dead weight. And it was determined, first, that electricity with a given volume of business was a cheaper way of applying power generated in a single station than by generating it at the head of a train in a locomotive, and, second, that it was no longer a plaything, but would answer for serious work. That was the lesson of the first summer.

In the fall I directed that the engineers should make an estimate of the cost of extending this trolley, which was entirely satisfactory in every way, toward Boston. The conditions were different. We had to deal with a road already double tracked, and the question of supporting the trolley wires over the center of the tracks was a very different one from the erection of posts alongside of a single track, and the laying of the second track far enough away from the posts to prevent accidents. It was necessary to put either a truss across the two tracks, with a margin of safety from the possible heads of passengers, or in some way to support these trolley wires. There were many bridges which carried the railroad and many bridges that carried the highways over the railroad. There was not room between the tracks for this center line of posts, and to spread the tracks for the purpose of using them involved the reconstruction of the road. The tracks carrying the bridge must be changed and the bridges spread. The tracks carrying the highways over the railroad must have their abutments removed and set farther away from the track. The expense of suspending these trolley wires by a truss or by spanning wires was very much complicated by the grading of a steam road, already constructed, when passing from cut to fill. The expense of either construction forbade any further experiment in that direction.

We then took up the question of a center rail on each track, midway between the running rails, for the purpose of conveying the current and dispensing with the trolley wire entirely. Well, of course, the trouble began. The electricians all told us that the current would be lost, and that we might put as much current as we pleased at one end and at the first five miles it would be dissipated. I asked them if they could suggest any remedy for that, and they handed me

an involved set of figures, such as I have never seen since I left school, which told me how many copper feeder wires must be laid and so on. I asked whether the current passed along the outside, or through the body of a conductor, and of every eleven men, entirely conversant with their business, five said through the inside, five said on the outside, and the eleventh man said he did not know. I took the judgment of the eleventh man, and not knowing myself, determined that we would make this rail in such a section that if this mysterious current for it is mysterious to anybody, street railroad or standard railroad men should take a notion to travel through the body of the rail it should have body large enough to conduct it. And the rail laid was of one hundred pounds weight, having the advantage in making that weight of providing also a very large surface. The electric rail is substantially like a letter "A," the top resembling ordinary surface rails with sloping sides, which gives it an appearance entirely distinguishable from the outside ones. The question came up of insulating the rail to avoid loss of current. The current costs money. We went to work on that and one of the largest electrical companies cast some sections identical to what we proposed to lay down and made some tests, proposing a number of elaborate schemes for insulating this rail. We agreed with them as we agreed with the eleventh man. I said to them that no doubt their scheme would be nicer, but we would try to do it with simple blocks of wood.

We felt our way in that direction and finally laid down five miles of double track with these A-shaped rails bonded therein, and bonded the outside rails in the usual manner, and I give you my word that ever since that day the electrical talent of this country have been trying to invent some excuse for the current keeping on those rails and doing its work and not diffusing itself and wasting. Their tests showing practically no loss of the force amazed them, and they confessed that they could not understand it. But they said trouble would come when we got ice, snow and rain. The kind Providence sent us a cloudburst at that place and all three rails were under water for hours and the cars went on just the same. They said these are the facts and we cannot tell why exactly, but that probably this thing could not be done to any greater distance. A couple of street railroads running up into the interior of the country wanted to get their passengers down to the beach line, and we told them they might lay their tracks on the back side of our station platform. When we put the third rail in operation and began to carry their passengers it developed such a business on those street railroads that their power house broke down. They were in trouble. They came to us and asked us to supply them with current, and the head of the electrical department directed the connection of their entire system at our junction station, made with this same third rail, which had been guaranteed not to be successful without a lot of knitting work. And we ran their whole electric system with better results at our own power house than we did with our own rails alone.

You all know why electricity can be made to propel a car faster than steam. On a locomotive a ton of dead weight comes to a stop twice at every turn of the wheel and reverses its motion; whereas this is a continuous revolving mechanism, and we can run seventy miles an hour, or as fast as it is possible to keep on the rails if the copper wires of the electric motors are so wound.

Having determined that we had the speed; having deter-

mined that electricity is capable of doing serious work, as we did by the granite experiment; having found that it is economical; and having found that its application by a third rail was at about one-fifth of the cost of a trolley line, then another field of duty was opened.

As the custodians of these great railroad properties, if we could serve the public better by four tracks we have invested our money in four tracks. If better served by two tracks where there is only one, we have put down two tracks, and the Consolidated railroad has spent millions and millions of dollars for the purpose of doing business more satisfactorily and at cheaper rates, and everybody seems satisfied with one or two exceptions, both with the method of administration and with the charge for it.

Now, this electric problem is not simply one between New Britain and Hartford, but a living one all through this country. We have more women stockholders in the New Haven road than men. Nearly one-third is held by people who have less than twenty shares each, and if ever an officer or a director of a great corporation was more especially a trustee than a manager, every one of the nineteen men who control the New Haven interests are trustees, and we could not stop here with the development of the electric problem. Because having found that electricity affords the force, and the economy, and that it is practicable to run cars with two-minute headway as well as under two hours with trains, and that accommodation could in many places be afforded, we concluded that the time had arrived when we ought to operate on a larger scale, and we preferred to do it where everybody could see it. We found a place where the roads cross as I cross my hands, and that is Berlin. If it goes on as we have tried it, there is no more question as to what will soon be done on the steam roads than there is of another day. You shall see it before you adjourn. We were held back a few weeks and are so much behind our calculations. We had hoped that cars might be run in this month of February. The experiment is pertinent to Hartford and New Britain and I present it here. The New Haven road has no quarrel with electricity; on the contrary, electricity has harnessed itself in its service and is more highly appreciated by the New Haven road today than by the managers of any other steam railroad in the country. There is no malice about our experiment. Our locomotives may go into the scrap heap, as the old stage coaches had to go. We must keep up with the times or else we shall be left in the rear.

Gentlemen, you may tell everybody who is engaged in investing his own or anybody else's money in lines competitive with steam lines that they cannot long prosper when the day comes to lay down third rails in this country. There is neither malice in this statement nor a desire to injure anybody. The New Haven road is owned alike by rich and by poor in Connecticut and out of it, seven thousand stockholders, who trust Judge Hall, Henry C. Robinson, Mr. Brainard and the rest of us to take care of their affairs. There is no mistake about this use of electricity as far as we can see. If there develops something that we do not know, the exhibition will be made here in the course of a few weeks and you will be able to judge for yourselves. Now, a word about the New England road and about this particular business. If New Britain and Hartford were all that were involved in this question there would have been no building at Berlin. Hartford has 70,000 people. New Britain has say 25,000, but the business between New Britain and Hartford we know is 350,000 people a year.

That is hardly enough to maintain a power plant and all that it involves. It is the first in this part of the state, although it is number three. It is an experiment in the line of the duty and obligation of steam railroads to serve the public better by frequent communication by car service than by train service. The power house is located where the third rail can go to Middletown, to Meriden, run the entire street railroad of Meriden, go up to New Britain, west to Plainville, we know not how far. The transmission of power by the third rail has gone farther than the electricians thought. How far it will answer without commercial loss nobody yet can tell. But the investment is not a large one. A power house costs the same whether put up by a street railroad or a steam railroad. The charges that have been paid by the steam railroad for lighting its different stations, when the lighting is done as an incident from this same power, will pay the interest upon it. Two motor cars, of which there are eight times as many idle all the winter, owned by our road, will give a fifteen-minute service between New Britain and Hartford. If the petitioners wish to go on and construct their road, I want them to understand exactly what they are experimenting with, but the greatest of all questions is whether this house to house business done by lines through the streets or frequent traffic is most desired by the public.

I am president of the New England as of the New Haven road. But I do not appear because we simply do not want these charters granted. The gentlemen should understand what they are to meet. It will go down in the future, if I do not fail in my prediction, that at Hartford in the state of Connecticut was constructed the first practical demonstration of the subordination of electricity to the standard steam road. Instead of having six, eight or ten trains a day, all the New England road could afford to run, we may develop a service and a traffic of ten times that. The business may not want to come by us; it may want to go by the other line, but we shall learn whether it is any use anywhere to proceed farther with these investments and make these constructions, which are infinitely cheaper than building a new railroad, and which, where there is a sufficient volume of business, is undoubtedly practicable and profitable for steam railroads. It is in that spirit that we proceed to lay this third rail. It is with the same interest and with the same views that the managers of these properties have endeavored to serve the public by an expense of millions of dollars in creating additional facilities within the last ten years.

We do not like this parallel scheme, we do not want it, but if it is carried forward it will remain for the public to determine by their use whether it is worth while for steam roads to make further developments. All the machinery from Berlin can be transferred to a location where the road now does a business of four and a half millions instead of three hundred and fifty thousand passengers a year, and all the possibility of loss to the New Haven road will be the transference of these generators to that point.

## EXHIBITION AT MUNICH, 1898.

On the occasion of its fiftieth jubilee, the General Industrial Association of Munich, with the co-operation of the Polytechnic Association of Munich, will hold an exhibition of such machines and auxiliaries as tend to improve industry and the arts. The management of the exhibition, which is under the patronage of the prince-regent of Bavaria, is in the hands of a board of directors of which Max Nagle is the president.

This exhibition is known as the Second Exhibition of Motors and Machine-Tools, the first one having been held in 1888. The exhibit will be divided into five groups as follows:

Group I. Motors, gas, petroleum, benzine, steam and hot-air engines, machinery driven by water and wind power, and electro-motors up to ten horse-power.

Group II. Machine-tools, hand-tools and implements.

Group III. Auxiliary machines, as pumps, ventilators, presses, cranes, clocks, parts of machines, electrical arrangements, safety appliances, apparatus, auxiliary materials.

Group IV. Manufacturing processes in operation, and machinery in motion.

Group V. Special technical literature.

The exhibition will open June 11, 1898 and close October 10. Final applications for space should be made by October 1, 1897, at the latest. The charge for floorspace is 20 marks (\$5) per square meter; for wall space 15 marks per square meter. As a rule machines of more than 10 h. p. will be accepted only in the form of models. The exhibits will be received any time after April 15, 1898.

This exhibition will offer an excellent opportunity to American manufacturers of street railway apparatus and they will no doubt be well represented at it.

Full information in regard to the rules and regulations for exhibitors may be had by addressing the Office of the Exhibition, Munich, or any of the German consuls in the United States.

## SIDE CONTACT TROLLEY.

The daily papers are illustrating a new form of side contact trolley which is promised to do great things. If the original is anything like the pictures, we can readily imagine

that "great things" can be expected of the tower wagon crew.

The inventor is said to be a Denver man, but our correspondent there has been unable to find any trace of any such invention there. By using this form of collector but one trolley wire is required, according to the story. Such an installation would provide one continuous Fourth of July for the small boy.

On February 15 Horace G. Torbert succeeded John Balch as receiver of the Dubuque (Ia.) Light & Traction Company. The final report covered the last fifteen months of the receivership, and shows the receipts since December 1, 1895, to have been \$60,746, which was \$2,246 in excess of the disbursements. All claims against the company have been paid except some special taxes for street improvements.

### MAMMOTH PLANT OF THE MARKET STREET RAILWAY, SAN FRANCISCO.

The illustration shows one of the new engines recently installed in the Bryant street power house of the Market Street Railway Company at San Francisco. This is one of four 1,200-h.p. vertical triple expansion engines built for the company by the Union Iron Works, three of which are now in place. Each engine is direct connected to two 400-k.w. Siemens-Halske generators.

When the company adopted electricity as the motive power for its Mission street line it installed two 600-h.p. and two 300-h.p. vertical compound engines, belted to 200-k.w. generators but soon found them inadequate to supply the demand, as mile after mile of horse car track was rebuilt and converted to electricity. The four engines built by the Union Iron Works bring the capacity of the station up to 6,600 h.p. which is ample for the demands of the near future,

driven by 110-h.p. motors, one being sufficient for the duty and the other held in reserve.

The boilers for supplying steam are of the elephant type arranged in sets of three, and are fitted with the "Howden" system of forced draught. A double line of steam piping has been put in so that a stoppage resulting from a burst pipe cannot take place. The switchboard, of white California marble, 58 ft. long, presents a very handsome appearance and is equipped with all the latest appliances.

We are indebted to H. H. Lynch, superintendent of construction for the illustration.

### NOISELESS ROLLING STOCK.

The REVIEW has several times called attention to the desirability of making cars as noiseless as possible, maintaining that by looking after this matter the comfort of passengers is as surely increased as in any other way, and that money spent in making cars noiseless is just as wisely spent

1,200-HORSE-POWER ENGINE—MARKET STREET RAILWAY, SAN FRANCISCO, CAL.

and leaves something in reserve. The power house, however, was designed for nearly double its present capacity, and will ultimately have 12,000 h.p.

The cylinders of the engine shown are 20, 30 and 44 in. in diameter, all having a stroke of 30 in.; the speed is 150 r. p. m., and the steam pressure 160 lbs. The high pressure cylinder valve is of the piston type with a separate cut-off controlled by a shaft governor; the intermediate and low pressure cylinders have plain slide valves. The bed plate is extra heavy, the condenser forming a part of it, with the tubes at right angles to the line of the crank shaft, and is set on a very heavy concrete foundation bedded in solid rock.

Each engine is fitted with a direct connected vertical air pump. The condensing water is taken from San Francisco bay at a point about a mile from the power house and is pumped through a line of cast iron pipe. The pump house is situated near the inlet and contains two centrifugal pumps

as that employed in making them attractive to the eye. To many persons a rattling car, be it ever so roomy and attractive other ways, can never be a comfortable means of transportation. Modern car building practice uses nearly every possible device to make the car body and windows noiseless. The same can hardly be said of some trucks. Is it reasonable to take great pains to make the car bodies noiseless and let the trucks go on with their rattle? At least one large company has begun to take steps to make its trucks more noiseless, recognizing that while some modern all steel trucks are economical as to repairs, they are not as comfortable for passengers or as economical as they would be were many of the metallic joints cushioned. Our steam road brothers set a very good example in the way of noiseless rolling stock, and it is also fair to presume that because of it they gather in some cash that would otherwise go to electric roads where they are in competition. When buying new equipment give some serious thought to noise prevention.

### UNION TRACTION, PHILADELPHIA, POWER HOUSE BURNED.

On March 3 the power house of the Union Traction Company at Ridge avenue and 13th street Philadelphia was destroyed by fire. Fire was discovered a few minutes after 6 p. m., just after the night force had come on duty, and

POWER HOUSE AFTER THE FIRE.

before it could be located and any attempt made to check it, the employes were all driven from the building by smoke. Aside from some oil stored in the basement, there was but little inflammable material about the building except the floor and the roof, and the fire burned itself out within two hours. Soon after the fire got under headway the roof fell in, breaking the steam mains, and the deafening roar made by the escaping steam is responsible for the only fatalities

that occurred. The horses of one of the fire engines became frightened and ran away, killing two people and injuring from ten to twenty others.

This plant was built in 1893-4 for the central distributing station and was the most important of the company's nine power houses. The building was 200 x 175 ft., the engine and boiler rooms being under separate roofs and divided by a party wall. The equipment comprised 19 boilers, 9 Wetherill engines and 9 Westinghouse dynamos, four of them 1,500-k. w. machines. In addition to the wrecking of the machinery, the cables and feed-wires in the basement and the switchboard were badly damaged. Though the Traction Company carries its own insurance to a considerable extent, this power house was insured for \$275,000, which will probably cover the loss. The cause of the fire is not definitely known as yet, though it is said to have been caused from a chain from the overhead crane falling upon the commutator of one of the large dynamos and short-circuiting it, the sparks igniting oil about the machine.

This station supplied power for about 20 of most heavily traveled lines east of the Schuylkill river, and the accident caused a tie-up that has been unequalled in extent since the strike, but it was temporary only. No sooner was the accident known than all the available men were put at work making the necessary connections for supplying the dead lines with current from the other power houses, and by 10 p. m. all of the cars were able to move. The following morning cars were running on all lines, though on slightly greater headway than usual. President Welsh and his assistants made every effort to save patrons from inconvenience and was eminently successful in rapidly getting the lines into working order.

The work of cleaning up the rubbish was begun as soon as the fire was extinguished. The switches and instruments on the upper part of the switchboard were ruined but the frame work was for the most part uninjured, and the follow

INTERIOR OF ENGINE ROOM—UNION TRACTION COMPANY, PHILADELPHIA.

ing day men were busy installing new instruments mounted on temporary supports so that the station might be used for distributing the power generated at the other stations. The walls are not badly damaged and it will not be necessary to rebuild them in the event that the company restores the station. Whether it will do so has not yet been decided.

Our illustrations show interior and exterior views of the power house as it appeared the morning after the fire.

## TRAMWAYS IN THE UNITED KINGDOM.

A report has been made to the House of Commons giving some interesting information and statistics in regard to tramways and their prospects of future development. At the present time England has 792 miles, Scotland 96, and Ireland 121, making a total of 1,009 miles of tramways in the United Kingdom. Of these lines 116 belong to private companies and 37 to city corporations. There are 4,663 cars operated by 35,621 horses and 568 locomotives. Last year 759,466,047 passengers were carried, making the receipts \$20,760,000, of which \$5,230,000 was net. Electric traction is yet in an embryonic stage. There are but 19 lines operated by electricity, with 110 miles of track. Although few in number these roads represent a great diversity of practice in every detail of equipment. The varied types may be represented by the Liverpool elevated road, the South London underground, the seashore line of the Brighton & Rottingdean Electric Railway, the Dublin-Dalkey line with alternating currents and rotary converters, the storage battery road at Birmingham and, in fact, hardly a line could be noted that has not some peculiar features more or less experimental. The street railway practice is far from crystalization. Although many American methods have been accepted, yet the many municipal restrictions, local prejudices and conditions make these deviations necessary. It could not be questioned, however, that if the Britons would not allow their ultra conservatism to obscure their better judgment, the services of experienced American engineers and the use of superior American street railway equipment would be highly advantageous.

## THE STREET RAILWAY ACCOUNTANTS MEETING.

**Attendance will be Large—Fine Program Prepared—Work to be Laid Out for Coming Months—Will Meet in Cleveland, O., March 23-24.**

The Street Railway Accountants, including auditors, secretaries, treasurers, or by whatever title the accountants of various roads may be called, will gather in the first meeting of the kind ever held, at Cleveland, O., on March 23 and 24. Headquarters will be made at the Hollenden hotel, where suitable and commodious rooms for the sessions have been secured.

While it is contemplated to effect an organization of this department of street railway work, and appoint strong committees to prepare reports and recommendations at the first succeeding meeting, it was not deemed necessary to wait several months before getting down to business. Hence a fine program has been prepared, in which the names of many of the best street railway accountants in the country appear. The subjects are practical and timely and no one who attends can fail of being many times repaid for the

trouble and time spent in going. Among the papers to be read the following appear in

### THE PROGRAM.

- "From Horse to Electric Accounts"..... H. L. Wilson.  
Auditor West End Street Railroad, Boston.
- "Useful and Useless Classifications"..... E. D. Hibbs.  
Auditor Consolidated Traction Company, Jersey City.
- "Suggestions for a Standard System of Accounts; Classification of Operating Expense Accounts, and Form of Report that will Admit of Comparison and Diffuse Information between Companies"..... C. N. Duffy.

Several other subjects have been called for, which will be announced for general discussion.

During the stay of the accountants in Cleveland, they will be tendered a trolley ride by the local street railway men and shown points of interest about the city.

Every road which can possibly do so, should send a delegate to this meeting. It means dollars to the company. No such opportunity to meet and exchange ideas among the heads of this department has ever before been offered, and now the occasion has come the most possible should be made of it.

Delegates are also specially reminded to bring with them sets of blank forms in use, for comparison with others. In this way much benefit can be derived in securing the most perfect forms as yet in use.

Cleveland, March 23-24.

## CLEVELAND & CHAGRIN FALLS LINE PROGRESSES.

The Cleveland & Chagrin Falls Electric Railroad Company is pushing the work on its 14.2 miles of line which it is expected will be in operation by May 1. The track is being laid with 60-pound rail and the overhead work includes the figure 8 trolley wire. Generators and motors will be supplied by the Walker Company, of Cleveland, engines by Russell & Co., cars by the G. C. Kuhlman Company, of Cleveland, and trucks by the Peckham Motor Truck & Wheel Company, of New York. Vincent A. Taylor, who has been the prime mover in the enterprise, is now president of the company, with offices at Cleveland, O. The overhead work will be furnished by the Ohio Brass Company.

## IN THE HALLS OF LEGISLATION.

Not in the history of the oldest street railway man has there ever been at "one consecutive time" so much or so great a variety of legislation pending directly affecting street railway interests as now. The street railway bill fever seems to be epidemic, and while much of it is absolutely iniquitous, and cannot possibly hope to go through, some of the bills are good. Others are only mildly harmful, but with few exceptions the grist has the appearance of a large and healthy sand bag. A glance at some of the bills introduced is interesting:

**COLORADO.**—Vestibule bill pending with petition signed by 2,000 in its favor. As open cars are run throughout the year in Denver, at which the bill is especially aimed, it would seem not to be greatly needed.

**CONNECTICUT.**—To provide vestibules; for street railway tax to be paid the state instead of the cities; for transfers in New Haven; to authorize mayors and city councils to grant extensions of lines; the parallel road bill.

**DELAWARE.**—House passed a bill extending the time in which the Chester & Wilmington road might build, to January, 1898.

**IOWA.**—A vestibule bill covering the time from November 1 to April 1.

**INDIANA.**—To heat cars; 3-cent fare; to terminate charter of Citizens road, Indianapolis, in 1901; to allow companies to take advantage of the Barret law for paving between tracks. The 3-cent fare bill is now a law.

**ILLINOIS.**—Forbidding laying of tracks without valid ordinance; 3-cent fare bill; vestibule bill; to establish a railroad commission; to sell franchise to highest bidder; to extend franchises 40 years on payment of \$2,000 per mile of single track; tax of 3 per cent on earnings; to vestibule.

**KANSAS.**—A vestibule bill.

**MICHIGAN.**—Bill authorizing consolidation; requiring the sounding of gongs at railroad crossings; bill to get consent of railroad commissioners prior to increasing stock or bonds; to give a car service every five minutes in cities over 150,000; to pay employes in cash only; to permit the carrying of freight; to limit franchises to 30 years.

**MISSOURI.**—The Ward bill is for a different method of assessment of street railways, with a view to make a more uniform taxation of street and steam railways in cities over 100,000. The Dunn bill for 3-cent fares in St. Louis and Kansas City was killed. The vestibule bill providing for vestibule protection from November to March inclusive, was passed. Bill introduced allowing street railways to sell power and do a general lighting business under a railway charter. Also one for half-fare for standing passengers.

**NEW HAMPSHIRE.**—Unimportant; being 10 bills to incorporate new roads.

**MASSACHUSETTS.**—Bill to allow roads on which gross earnings do not exceed \$500,000 per annum to combine for accident insurance; a franchise tax of 3 per cent, and in addition a sum equal to the amount paid in excess of 5 per cent dividends; bill for elevated road in Boston; bill to make minimum amount of paid in capital \$5,000 per mile of track instead of \$10,000; also for board of arbitration in Boston.

**MINNESOTA.**—Bill to require the Twin City road to pay 5 per cent interest on deposits required of employes.

**MARYLAND.**—Bill requiring certain roads to issue transfers and to regulate the wages of trainmen.

**NEW JERSEY.**—For the creation of a board of three railroad commissioners to serve for five years at a salary of \$2,500 per year each; to regulate flagmen at steam crossings and to provide other safety appliances at such places; a bill increasing taxation of corporations with a view to prevent stock watering; a bill relating to time schedules and one for vestibules.

**NEW YORK.** Half-fare for standing passengers; to place two motormen on front platform of all cars; to sprinkle tracks twice daily; a penalty of \$500 for violation of local ordinances regarding speed and snow cleaning; to adopt fenders; to adopt vestibules; to permit lines in third-class cities to charge 10 cents fare where 450 feet of elevation are overcome within 1½ miles; to provide transfer stations.

**NEBRASKA.**—Vestibule bill. Several Omaha motormen testified before the committee that they did not consider vestibules necessary.

**PENNSYLVANIA.** Vestibule bill.

**UTAH.**—A bill to compel companies to vestibule, in the absence of which one legislator declared of the men that "the manhood was being ground out of them."

**WISCONSIN.**—To put wires underground (aimed at trolley wires); requiring consent of majority in each mile; 4-cent fares; to tax both capital and property of roads; to tax tracks for improvement or repair of streets occupied; new lines crossing old lines must pay for and keep in repair crossings; to carry free police and firemen in uniform.

**DISTRICT OF COLUMBIA.**—Most of the bills are purely local, relating to desired extensions, removal of dead tracks and the placing of flagmen at steam road crossings.

Few of these bills have yet become laws, and while some of them, particularly the vestibule bills, may pass, there is little likelihood of the rest getting through.

## BICYCLE HOLDERS ON STREET CARS.

As noted in the REVIEW for January the Market Street Railway Company, of San Francisco, has for some time been experimenting with bicycle holders on its cars. The device which we illustrate was adopted on the San Francisco street line on February 7, and its use is rapidly increasing,

FIGURE 1.

and the present indications are that its success will justify the company in equipping several other of its 30 lines with them. On February 28, the number of bicycles carried was 82. The regulations governing bicycle traffic are given in the circular which we reproduce.

The holders adopted carry two bicycles and are shown in Figs. 1 and 2. The two arms from which the machines are

**MARKET ST. RAILWAY CO.**  
**NOTICE.**

Commencing Sunday, February 7th, 1897, the cars of

**The Sacramento Street Line**  
WILL BE EQUIPPED WITH  
**BICYCLE HOLDERS.**

Bicycles that can be safely carried thereon, not exceeding two to any car, will be taken at owner's risk, for a five-cent fare.

Transfers to other lines cannot be given for bicycles.

Tandems, and other bicycles for which the holders are not suitable, cannot be carried.

hung are welded to 1/2-in. rods supported in brackets fastened to the dash at A and B. The arms are swung back against the dash when not in use. At A a square socket in the bracket receives a shoulder on the rod and locks the arm in its closed or its extended position. From

FIGURE 2.

each arm depend three leather lined hooks; two of these are short ones, over which the bicycle wheels are hung, while the third extends down and receives the lower part of one wheel of the bicycle and serves to steady it. As shown in Fig. 2, there is only one of the long hooks to each machine. Application for a patent on the device has been made.

**PROGRESS ON THE POWER HOUSE OF THE CHICAGO CITY RAILWAY.**

The illustrations show the engines and dynamos as installed in the new power house of the Chicago City Railway on 49th street and Oakley avenue. A full description with plans for the machinery appeared in the December issue of the REVIEW.

At present, two units of engines and dynamos are practically finished and work is commenced on the third. Each unit consists of two 36 x 60-in. simple Wheelock engines coupled together and driving two 880-k. w. Walker 500-550-volt generators. When the power house is completed six of these units will be in operation, but it is intended to install but three of them for use in the immediate future.

As shown, the carriage of the tightener for the rope drive runs on a frame work above the engines and the weights hang down the boiler room side of the partition wall. This method of driving the dynamos works in a satisfactory man-

ENGINES—CHICAGO CITY RAILWAY.

ner and in the opinion of the chief engineer, R. J. Hill, is superior to any other for this kind of work.

The load on the old station has become so great that each morning and evening one of the new dynamos is run to supply a part of the feeder system. For this purpose a temporary switch board has been erected. The new switch board is nearing completion and one can now get an idea of its handsome appearance when finished. It is of black enameled slate with nickel plated trimmings and is 104 ft. in length. Each machine is to have a 2,000-ampere Weston wattmeter and with these an accurate record of the working of the station can be kept. Perhaps the most interesting instrument on the board is the large ammeter which indicates the total current of all the dynamos. It was made especially for this station by the Weston company, and is said to be the largest ammeter in the world on a 500-volt circuit. It registers to

GENERATORS CHICAGO CITY RAILWAY.

20,000 amperes, each division recording 200 amperes. The dial is illuminated by two incandescent lamps. The instrument measures 27 in. across and 20 in. in height. The

shunt consists of 14 strips of copper, 4 ft. long and  $\frac{1}{4}$  x 10 in., and the ammeter actually shows the fall of potential in

20,000-AMPERE AMMETER.

this shunt. There is much work yet to be done and it will probably be June 1 before a complete test can be made on the entire station.

### A SUGGESTION FOR THE ACCOUNTANTS ASSOCIATION.

EDITOR STREET RAILWAY REVIEW:—

In looking over the programme for the meeting of the Street Railway Accountants at Cleveland it has seemed to the writer that there is one very important point that has been overlooked—at least it has not been mentioned—and that is the point of "State Reports."

Several states now have Boards of Railway Commissioners who, among other things—require the making out of reports and data on the forms furnished and in the manner prescribed by them, and the prospects are that the number of states that do this will be very materially increased in the near future. The forms used differ greatly in the different states, and, as a rule, are ill adapted to be easily and accurately filled in from a properly kept set of street railway account and record books. This condition is probably due to:

1. The officials who devise the public forms are very often not accountants, or at any rate have not a knowledge of railroad accounting and especially of street railway accounting, its needs, its methods and its aims.

2. These forms are very often intended to be used interchangeably by both steam and street railways; an incompatible combination at present.

3. These forms are generally made up with a view to obtain amounts and statistics for the use of the state, and in consequence everything is sacrificed to that point.

In view of the above facts, would it not have been well for the Accountants to have invited to the Convention—from all the states—the officials having charge of these reports? As this has not been done and as the time is now too short to admit of this mistake being rectified at this convention, would it not be as well for the members to "go slowly" at this meeting in regard to finally determining on any forms or methods which may conflict in any way with the forms and methods as now required by the several states. As a matter of fact these state officials are the final arbiters in the matter; if they prescribe a form or even a method of keep-

ing the books and accounts we are compelled to follow it whether we desire to do so or not. It is policy, therefore, as well as courtesy, for the accountants to call into their councils the above officials, and to endeavor to have the states as well as the companies, use a uniform and co-relative set of forms.

It is only within a year or two that the Railroad Commissioners of this state invited the accountants of the steam and street railways to a sort of convention in order to determine on better forms and methods than were then in use. From this "pow-wow" was evolved a set of compromise forms which are not fully satisfactory from either an investing, an operating or a statistical point of view. We had, however, to change all our books and methods to conform to it—no very acceptable job and one we do not care to repeat unless there is immediate and lasting good to be obtained from it. At that time the street railways were not as important factors as they are now, neither were their forms and methods in anything like a fixed or proper shape. The case is now different, we are beginning to know and feel our value in the community and our rights; we know better our needs and aims in our accounts and departments; we have, by hard experience and conscientious stealing of ideas from our elder brothers the steam railroads, brought our forms and methods into a shape adapted to our needs from an operating point of view; now let us also get them into shape for our directors and probable investors and also for our state and government use.

To do the latter means that we must have the willing and hearty co-operation of the state and government officials who make and prescribe the forms we must use. The only way to do this is to make them "accomplices in the act;" let them be invited—nay urged—to attend the next convention; let them get fully acquainted with our needs, our aims and our present and prospective methods in accounting; get them to agree on a common form or forms of general or special state report, one which will give them the information they desire or may desire and that will still leave us a system of books, accounts and forms that we can use to advantage in our operating and one that we can show to our directors and to possible investors. Let them do this and we will once again (cheerfully instead of tearfully this time) and finally change our books, forms and methods where necessary.

H. S. COOPER,

Supt. Schenectady (N. Y.) Railway Company.

### BRUSSELS EXPOSITION, 1897.

The international exposition to be held at Brussels during the summer of 1897, opening on April 24, was briefly mentioned in the January REVIEW. The seventh section comprises two groups, electricity and traction. Under electricity, group XXIX, are included generators, batteries, accumulators, all forms of meters, systems for the transportation and distribution of power (including poles, insulators, safety appliances and tools), telegraphy, telephony and sundry other applications of electricity. Under traction, group XXX, are machines for locomotion and appliances for cable traction, electric motors, safety appliances, locomotives and self-propelling carriages of all descriptions, and steam and street railway rolling stock.

Further information may be had by addressing Louis Moreau, 725, 218 La Salle street, Chicago.

## A PNEUMATIC SNOW PLOW.

Our illustration shows a decidedly novel snow plow designed by Thomas Elliott, master mechanic of the Atlanta Consolidated Street Railway, which is of interest for the ideas embodied as well as because of those left out. We have illustrated many kinds of snow plows but never before one in which the active agent was air.

The cut, from a photograph, shows the construction. A 5-ft. fan is mounted on a heavy frame over a Brill No. 21 truck, and delivers air through the overhead wooden box to the opposite ends of the plow. The two "shears" are of  $\frac{3}{8}$ -in. steel 36 in. wide and 8 ft. long, and are placed squarely across the track, one at each end. Each shear may be raised

The steel plows serve to scrape the snow from the roadway and it is then blown out of the way by the current of air supplied by the fan. The air pressure required to blow the snow any given distance is very easily regulated by the wind gate which is operated by the small wooden lever shown. The two ends of the plow are duplicates and each blows the snow to the right as the line is double track.

Where the pavement is above the rail the snow remaining on the rails is taken care of by adjustable steel scrapers that fit the rail, and blown to one side by air delivered through the hose shown. It will be noted that neither the snow removed nor that remaining is packed. Back of the rail scrapers and close to the wheels are the sand pipes.

So long as the fan keeps the track and rails clear the

PNEUMATIC SNOW PLOW, ATLANTA, GA.

and lowered by means of a vertical screw at the end of the platform. In addition it is suspended on links so that it will swing backward and upward in case it strikes an obstruction, such as a guard rail or the pavement. The backward movement is resisted by springs which ordinarily hold the sheet to its normal position, and at the same time serve to cushion the blow when an obstacle is struck at high speed.

The fan is a steel disk with the wings securely rivetted in place and is mounted on a shaft 5-in. in diameter. The fan case is built of three thicknesses of matched flooring with a strip of sheet iron around the outside to keep it in shape. The fan is driven by two 30-h. p. Westinghouse motors which may be connected in series or in parallel as required. Two internal gears are shrunk onto the fan shaft and gear with the motor pinions so that no change whatever need be made in the motors, and the latter may be changed in a few minutes.

plow is easily propelled, it being easy to secure tractive effort with clean rails. This saves the time usually lost from slipping and backing up for a new start when a nose plow stalls.

The truck is equipped with two motors and with a powerful lever brake. The brake shoes are of wood and placed between the wheels and high up so as to be well out of the way. With the exception of the four motors, which are taken from open cars not in use, and the lumber, this plow was built out of the abandoned belted equipment of the old power house, and aside from this material and the truck, the plow cost but \$240. It was built at the company's shops.

When passing teams on the road the wind gate may be closed for an instant and the snow permitted to accumulate in front of the plow until the air is turned on again. At full speed the fan requires 50 h. p. and the breeze can give points to a young cyclone.

THE COLUMBIA & MARYLAND RAILWAY.

BY S. W. HUFF, ELECTRICAL AND MECHANICAL ENGINEER.

It has been thought that a sketch of some of the plans considered and problems encountered in the construction of the Columbia & Maryland Railway might be of interest, particularly to those who are contending with problems similar to those presented by this undertaking. This road seems to have been the first of its type to be constructed. The officers of the company, while on an inspection tour of similar roads throughout the country, found nothing that presented the severe conditions characterizing their road. Roads were found upon which high speeds were made, others upon which long runs were made, and still others upon which high speeds were made over light grades and with heavy cars. But no road was found that presented the combination of long runs, high speeds, heavy trains and severe grades which characterizes the Columbia & Maryland. The road extends from the center of the city of Baltimore to the center of the city of Washington, a distance of about 40 miles, and it is intended to make such speed and to carry such a class of coaches as to make the line a formidable competitor of the two existing steam lines operating between these two cities, the service of which steam lines is first-class in every respect.

This high rate of speed with heavy coaches is to be maintained despite grades which, in comparison with those of steam road construction, are very heavy. The ruling grade between the cities is 2 per cent, while the grades in the cities conforming to street grades are much heavier, in one place the grade being as great as 7 per cent, and in another place there is over a mile of 5 and 4.5 per cent grades.

The roadway is of the best type of steam railroad construction. The double tracks are laid with 85-lb. T-rails 60 ft. long, and ballasted with stone. The president of the construction company being a distinguished civil engineer of wide experience, the details of roadway construction have been worked out with great thoroughness, and much of the exactness and care of details characterizing the older profession were infused into other engineering departments of the company. It was decided to provide for a schedule under which an express train would leave each terminal city for the other every 30 minutes, with through local trains leaving each terminal with the same frequency. Both classes of these trains are to make a speed of 60 miles per hour on a level and down grades, and such speed ascending grades as would be possible with motors of proper power and design. Both the express trains and the local trains are to consist of a motor car and one trailer. The express coaches are 45 ft. long, and the train loaded weighs 50 tons, while the local train loaded weighs 30 tons.

No reliable data could be obtained as to the average or maximum power required at the power station, for trains of this description operated under these conditions, and to determine this as accurately as possible considerable detail work was undertaken. Taking the most reliable data obtainable as to the resistance due to wind and track, with this class of track and cars, and from the characteristic curves of standard motors of the proper power, the power was determined that would be required to force trains of each class up to 60 miles per hour on a level and on all down grades, and on up grades to the speed characteristic of the motor. This

power was determined for each grade upon the road with the time required to run the grade—the power and the time being calculated going both up and down the grades and going both ways on a level. Thus, having the power required, and the time for which it would be required, on all the grades on the road, it was only necessary to multiply each amount of power by the time for which it would be required, sum up the result and divide this sum by the summation of time to determine the average power required for the cars while running. Afterward a schedule was laid out upon the profile of the road, and the position of the trains were taken at intervals of 5 minutes during an hour, and the power they required calculated. The average of the power required at each of the twelve positions of

FIG. 1—DIAGRAM OF THREE WIRE SYSTEM.

the trains checked very closely with the result obtained by the method just described. The former being a power average for all positions of the trains, while the latter was a power average for twelve positions taken within an hour, and at 5 minutes intervals. From the data of the power and time required to run up and down the various grades, at the suggestion of the president, tables and afterwards curves were prepared for a guide in establishing the grades of the road. Three sets of curves were prepared. The first to show the relative effects of different grades upon the total power required at the power station. For example what length of 3 per cent grade would be equivalent in drain upon the power station to a 5 per cent grade 1,000 ft. long. The second to show the effect upon schedule time, regardless of power required, of the different grades. For exam-

ple, schedule time alone being considered, what length of 3 per cent grade could be employed in curving around a hill, and the same schedule time result as by going over the hill with 1,000 ft. of 5 per cent grade. The third to show the heating effect upon the motors of different grades. For example, supposing that it had been determined that the motors would stand, without injurious effects from heating, a 5 per cent grade 1,000 ft. long, what length of 3 per cent grade could be run without injurious effects. There being so many variable quantities entering into these values, the tables or curves can be only an approximation, but they are nevertheless interesting and suggestive.

SYSTEMS OF DISTRIBUTION.

The road is so located that coal and water for condensing purposes can be had conveniently about midway of the line, and midway of the halves, or in track parlance, at the center and half-centers. The distance and the power required both being great, it was readily seen that distribution by the standard method, and at standard pressures, was practically out of the question. At that time the alternating current motor was too much of an unknown quantity to admit of an attempt to use it. The rotatory transformer system in operation at Lowell, Mass., was inspected and the cost of installation and operation under this system was worked out. But the choice finally lay between the various forms of direct current distributing, and with a power station located at each

of the two half-centers of the line. The fact that, for traction and power, the motor cars would each require four motors, led naturally to an effort to double up the voltage in distribution over the line, and to divide it out among the motors, they being run in permanent series pairs. It was suggested that the motors thus connected in series pairs be supplied with 1,000 volts in the high speed section, and 500 volts in the slow speed sections, there being 1,000 volts between the trolley wire and track. In addition to other objections to this plan there seemed great probability of one of the motors of a series pair slipping its wheels, while its mate of the series pair stood still, and thus by taking the greater part of the 1,000 volts to itself cause serious trouble.

THE THREE WIRE SYSTEM.

A special form of the Three Wire System was proposed, which possesses features of special interest. It was proposed that the four motors on each car be divided into series pairs, and each pair have its own controller, fuse, trolley and ground connection, the two controllers, however, being under the same cover, and operated by the same handle. Above each track were to be suspended two trolley wires, one being + 500 volts and the other - 500 volts. One pair of motors with its controller, trolley pole, etc., was to operate from the + trolley wire, while the other pair was to operate from the - trolley wire, the current crossing over through the ground connection, and the track rail forming the third wire. The

FIG. 2—GENERAL ARRANGEMENT FOR SINGLE TROLLEY SECTIONS.

accompanying sketch, Fig. 1, indicates this arrangement of circuits as proposed for the high speed section of the line. With this arrangement the equipment would consist of standard motors and controllers working on standard voltage, while the voltage of distribution would be double that of standard practice. There would be a plus and minus generator to each engine, while the plus and the minus switchboards and their feeders would be entirely separate, each being a standard switchboard.

Any derangement at the power house, or on the line, causing the loss of current on one side, would not affect the operation of the motors on the other side. The motor connection of the inoperative side could be switched over onto the operative side, while the trolley pole and lamp circuit could be left connected to the inoperative side, to indicate the return of current. In the slow speed sections it was proposed to pull down one trolley, and breaking the ground connection switch this trolley connection on to the ground, thus throwing the two sides into series relation on 500 volts and reducing the speed. It was proposed to divide the

trolley wire suspended at frequent intervals as shown in Fig. 3, a trolley is secured that is very elastic and without serious dips in the wire. The suspension cable also serves as a feed-in wire, there being no insulation between the trolley wire and the suspension cable.

One drawback to this form of three wire system was the non-use of the efficient track return afforded by the heavy rails and bonds under contract. This did much to detract from its otherwise high efficiency. Another drawback was the liability to unbalance on the slow speed sectioned portions of the line, rendering the system less desirable for the slow speed section of the cities than for high speed service.

It was suggested that the trolley in the slow speed section be all of the same sign, and be connected to the generators of this sign through feeders that upon full load would have a fall of potential of 500 volts. This 500 volts drop through the feeders to be compensated for by a series booster, the booster being driven by a motor receiving its current supply from the generators of opposite sign. By this arrangement the drain upon generators of opposite sign would be about equalized and a reliable voltage maintained upon the line. It was also suggested to divide the trolley into sections of opposite sign as first proposed, and connect the track return or neutral wire to the generators through a series booster located in the power house. The booster thus connected would raise or lower the potential of the track according as the excess of load was on the minus or plus side. By this arrangement the booster would boost only when there was an unbalancing of the line, and then only to the extent of the unbalancing, making this application of the booster very economical.

(To be continued.)

## NEW KIND OF TROUBLE.

A new species of legal trouble of the genus spit has appeared to vex the already distracted claim agent. The crusade against expectorating in cars is being vigorously waged all over the country, and already the results are highly encouraging for the abatement of this old time nuisance. All the surface, elevated and steam suburban cars running within the city limits carry a big sign from the board of health forbidding spitting in cars under penalty of a fine. Recently a passenger on a West Chicago car was arrested and charged with violation of the law. The case failed of convicting evidence, and now the man sues for \$50,000 damages because he didn't spit when the conductor said he did. He should have failed to spit twice and made his case an even \$100,000, while he was about it.

It is understood that the west park commissioners of Chicago have consented to the extension of Division street through Humboldt park on the west side, and it is very probable that the Division street electric line will be extended through it as soon as the street is opened.

FIG. 2 A—DETAIL FOR DOUBLE TROLLEY.

trolley wire in the slow speed sections into plus and minus sections, as is done with the usual three wire system.

The two trolley wires of opposite sign in the high speed section were to be two feet apart and to secure proper insulation between them it was proposed to suspend them from suspension cables attached to the ends of vertical wooden arms, projecting downward from wooden cross arms as shown in Fig. 2 a. Fig. 2 shows the arrangement for the use of a single trolley. These vertical arms being long enough to prevent the trolley pole from striking the cross arm in the event of its leaving the wire, and being of treated timber, there would be interposed between the trolley wires of different sign the insulation due to several feet of treated wood. The suspension cable running in the same direction with the trolley wire and being directly over it with the

FIG. 3—SIDE ELEVATION OF LINE.

### THAT AMPHIBIOUS CAR.

The daily papers have been giving considerable space to the free advertising with text and illustrations of a wonderful car which hails from Boston. Under the front platform is a pair of revolving brushes, each 4 feet long, guaranteed to keep the rail as clean as a parlor floor, while the rear platform brings up with a sprinkler from which oozes a gentle spray to allay the sufferings of the aroused dust. The picturesque condition of a waiting passenger who happened to get within range of those brushes on a rainy day can easily be imagined; and the available space for seats in a tank car carrying sufficient water to be of any account would certainly command a premium. An additional and equally practical innovation would be a compartment for the convenience of an armature winder or two, and an arrangement for grinding the wheels before they are worn flat.

### CLEAN TRACKS AND COAL BILLS.

There is perhaps no place where there is now a better opportunity to work a decided economy in the daily operation of city roads as usually operated, than in the matter of keeping the rails as clean as possible, even if such cleaning costs something. The power required to move a given number of cars from day to day, as the condition of the rail varies, is an interesting study, and reveals many chances for reducing coal bills by cleaning the rails at certain times. It is usually thought that if track brushes and scrapers are used during snow storms and when there is much dust that everything desirable in the way of track cleaning has been accomplished, and it is only in these extreme cases that any attempts are made to clean the rail. That this limited use of track cleaning appliances is a mistake we think will be discovered by any one who takes the trouble to investigate the subject systematically. We have before us a series of very careful tests made on a cross-town line operating in a large city, which show there is a great difference in the power required per car on a perfectly clean rail and one which would ordinarily be called a moderately clean rail. These tests were all made on days when the track was in good condition—that is, there were no snow storms, no very cold days and no days on which the track was covered with stiff mud or much dry dust. The temperature varied between 10 degrees above freezing and 10 degrees below freezing—a very small range—the cars were operating on the same schedule in all the tests and the passenger traffic was uniform. Leaving out variations due to variations in passenger traffic at different hours of the day, and comparing only similar hours of different days, there is still a difference between tests of about 20 per cent that can only be accounted for by variations in the condition of the rail head. The best showing is, of course, made when the rails are wet and clean or dry and clean. A dry clean rail is usually obtained in northern cities in winter by a freeze immediately following the conditions that bring a wet clean rail, and at such a time these tests show the power consumption to be very low. After such a freeze, however, the clean rail does not continue long if the weather continues steadily below the freezing point, for dry frozen mud soon gets pulverized on the rails and the power consumption goes steadily up until there is a thaw. It is safe to assume that the same thing occurs after a rain in summer. The power consumption is low

when first the rails are washed off, but dust soon accumulates and the coal pile pays for it. Stiff mud is, of course, a power consumer.

Now, in view of the fact that nearly all roads have track brush equipments for use against snow or very bad dust, it is certainly a good plan for them to consider whether it is not a paying investment to renew more track brushes and buy less coal; to keep the track brushes on a few cars in operation more of the time rather than furnish power to force cars over the millions of minute obstructions that a dirty track offers? In other words, is it not good policy to pay more attention to cleaning tracks in what is usually considered good weather, and not confine such efforts wholly to the abnormal conditions occurring but a few times a year.

A twenty-car road operating 20 miles of single track and having a coal bill of \$25 a day can certainly afford to keep track brushes operating on two or three cars or more for the sake of \$2 to \$5 a day saving. As the road gets larger, with more cars per mile of track, conditions are approached which make it advisable to run a sweeper over the line once a day in addition to the use of track brushes on the cars.

### DETROIT HOSPITALITY.

A pleasant party of street railway men found themselves in Detroit on February 14, and were met at the Cadillac by a delegation of the local street railway officials. The party embarked in the palace car of the Citizens' line and spent three hours in viewing the city, and bringing up at the Detroit Club. Here a famous dinner was spread in the banquet room and the afternoon delightfully spent. At 6 o'clock an invitation came from Swarts Bros., proprietors of the Cadillac hotel, to come over and visit them, and the meeting adjourned in a body to reassemble in the banquet room of that hotel with the genial landlords as hosts. Another elaborate dinner was spread and enjoyed, after which speeches and the orchestra filled every minute until 11 p. m., at which time the visitors departed for Niagara. The entertainment throughout the day was simply royal and long to be remembered.

In the party were: T. C. Penington, Chicago, secretary; C. F. Holmes, Kansas City; Geo. B. Hippee, Des Moines, members of the executive committee A. S. R. A. Also A. S. Littlefield, Louis Myers, D. B. Dean and H. H. Windsor, of Chicago, and Chas. Castle, New York. Among the Detroit gentlemen were Strathearn Hendrie, A. B. Dupont, J. Grant, Judge Riley, C. N. Goodwin, and Michael Carmichael of the Detroit Journal.

### GASOLINE MOTOR OBJECTIONABLE.

The operation of a gasoline motor car on the tracks of the Brightwood Railway Company, Washington, on 14th and Kenyon streets, has become very obnoxious to the people in that locality. There is no legal provision to prevent the running of the car by the company. At the request of the citizens the commissioners called the attention of the street railway officials to the nuisance and requested them to take the car off the road.

A freight line will be established between Columbus (O.) and Westville by the Columbus Central Street Railway. The company is building a freight car for this service.

# IN THE POWER HOUSE

This department devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

Setting generator brushes on large generators is not by any means as easy a job in practice as it would seem to be in theory. It is well understood by those engaged in erecting generators for the large manufacturing companies, but a few words here for the benefit of those having had little experience with setting brushes on large machines, will not be out of place. Theoretically the way to set the brushes on such machines is to place all brushes exactly the same distance apart, start up the machine and then rock the entire circle of brushes until they are all sparkless. This is beautifully simple but unfortunately the method outlined would give but poor results on the average large direct connected generator. In practice it is necessary to adjust each set of brushes independently at the point which gives the best results. Slight variations in the strength of the different poles of the field magnets or wear in the bearings so as to bring the armature out of center all have their influence on the neutral and sparkless position of the brushes, and the neutral position of each individual set should be determined and the brushes should be set at that point without reference to the others.

\* \* \*

It is nothing uncommon to go into an electric railway power station of small or moderate size and see on a table near the switchboard a blank on which the switchboard attendant is expected to note once every hour, half hour, or fifteen minutes, as the case may be, the amperage and voltage. These figures are averaged at the end of the day and the result is put down as the average station load for the day. From this average, perhaps, the station efficiency for the day is calculated, and perhaps, too, when said efficiency is so calculated the manager or engineer wonders why his boilers, generators and engines do not make a better showing. Or perhaps on the other hand the showing is a remarkably good one—better even than was ever heard of before for that type of machinery. On the other side of the switchboard he may wonder how it is that the cars pull so hard on one day and so easy on another, when the condition of temperature, track and traffic are practically the same. It seems as if a few minutes study of the ammeter and the way the station attendants usually take readings would convince any thinking man that the chance of getting correct average readings by looking at the ammeter but once in fifteen, thirty or sixty minutes would be about equal to a chance in a lottery where forty or fifty tickets were out. The attendant may happen to look at the ammeter at a time when its pointer is somewhere near the average current flowing for the period the reading is supposed to cover, but the chances decidedly against it in a small station with the usual violent fluctuations in output. To take a concrete example, on a road where the actual average is 200 amperes the ammeter will be found on the move the greater part of the time between 50 and 500 amperes. The chance that any one

reading will be an average in this case is about 1 in 90 if the ammeter is calibrated to read to 5 amperes. It may be said in defense of the common practice we are discussing that there is a chance for a low reading at one time to be corrected by a high reading the next time and that the average will come correct at the end of the day. But it will be evident on a little thought that with such chances for error in each individual reading and so few readings in the course of the day there is a very slim chance for the day average coming right. It is not necessary to rely entirely on theory to arrive at these conclusions, for a little testing, by taking ten second readings for a few hours will prove their correctness. Not a few electric railway men have reasoned this matter out for themselves and put little reliance in infrequent switchboard readings, but there are still so many that do place reliance in them that there is room for much more reform. The recording wattmeter is, of course, one way out of the difficulty and a very good way it is too. It is out of the question in any station, be it large or small, to hire two men to take 10 second readings from one end of the day to the other and it would take several clerks full time to average said readings after they were taken, but if a road does not feel as if it could afford a recording wattmeter it would be at least an improvement to take several readings at each time set for taking readings, and make the intervals as short as practicable. For example it would be well to have 15 minute readings and at each reading, instead of taking a single reading take four or five at 10 or 15 second intervals. These could then be averaged by the attendant immediately or at the end of the day, and it is needless to say the day average would be much nearer what it should be than with single readings every half hour.

\* \* \*

The report of the Liverpool Overhead Railway for the half-year ending December 31, 1896, shows an excellent record for the power house. The average power was 4.29 board of trade units or 5.75 electrical horse-power-hours per train mile, a train consisting of three cars. The cost of operation chargeable to the power house was 7.29 cents per train mile or 1.269 cents per horse-power-hour, of which .181 cent was for fuel. When these figures are compared with the reports of power house performance published in the REVIEW from time to time, it is seen that the most remarkable feature is the low percentage of fuel cost to total cost of power. The cost for fuel to the Citizens Traction Company of Pittsburg is .118 cent per electrical horse-power-hour, but the total cost of power is only .335 cent. On a Massachusetts road reported page 139 of the REVIEW for 1896, the total cost is given as 1.201 cents, about the same as on the Liverpool road, but the fuel cost is much higher, being .382 cent, or one-third the total as for the Pittsburg road. The generating plant of the Liverpool

road consists of four horizontal compound-condensing engines with six Lancashire boilers.

### \* \* \* Heating Value of Low Grade Fuels.

In a paper before the Engineer's Club, of St. Louis William H. Bryan gave some interesting data on the heat-

Association of Engineering Societies. Mr. Bryan is a warm advocate of expressing boiler "efficiencies" as the ratio of the heat taken up by the water to the total heat in the coal, and believes that the concordant results obtained with coal calorimeters show them to be reliable instruments for determining the total heat in the coal.

### \* \* \* The Fischer System of Filtration.

The problem of filtration is an important one in many parts of this country where the water supply is drawn from rivers that are very turbid for several months in the year, and in large cities its importance is increased because, as a rule, the river is further fouled by sewage. In a recent report to the state department, Frank H. Mason, consul general at Frankfort, describes the system in use at Worms and numerous other places in Germany. It is the invention of Director Fischer, who has been for many years past the

THE FISCHER FILTER.

water works engineer of the city of Worms, where the water supply is drawn from the Rhine and must be filtered before use.

The fundamental idea on which this system is based is the fact that clean, sharp sand, when mixed with a proper proportion of pulverized glass, forms a porous mass which, by baking at a high temperature, may be hardened in any desired form. In the Fischer filters this mixture of sand and glass is molded into hollow plates or plaques about 40 in. square and 8 in. thick; the sides are 3 inches thick, leaving a 2-in. hollow space in the center of each plate.

These plates are set upright and ranged in tanks built of masonry laid in hydraulic cement. Usually two tiers of plates are set, one above the other, in order to save space. The accompanying drawing shows a front and a sectional view of two pairs of plates thus mounted. The tanks are filled with unfiltered water to a depth of 3 or 4 feet above the plaques, and under this head the water is forced through the porous walls into the interior of the plaques and is drawn off through the pipes as shown. The discharge pipes are rigged with cocks, so that each plate and group of

ing value of low grade fuels. The summary of calorimetric tests made by him is reproduced from the Journal of the

We can scarcely agree with the statements made by "Engineer," in his communication. Of course it costs less to run steam pumps when the exhaust from them can be used for heating the boiler feed, but even then the steam pump leaves much to be desired. An engine which uses from 60 to 200 pounds of water per i. h. p. per hour, can scarcely be called an economical one, and yet that is the "economy" of the small steam pumps and many of the large ones also. The point in regard to the disadvantages of belts is well taken, but is not of the first magnitude, and we feel confident that when the decreased steam consumption is taken into account, the high priced, modern, slow speed motor geared to the pump will be found the cheaper. It is also doubtful whether the supply men will admit the adjective "high-priced" to be well applied. Further we do not think "Engineer" will maintain that a first-class tandem compound single cylinder pump leaves nothing to be desired for economy, if he will take a few indicator diagrams from one. If the superior economy of the crank and fly wheel pump is more imaginary than real, then there are thousands of water works pumps running today that ought never to have been put in.

**STREET RAILWAY NOTES FROM GREAT BRITAIN.**

(From Our Own Correspondent.)

The work of constructing the Leeds Corporation electrical tramways is being rapidly carried forward.

The Newport town authorities are unanimous in favor of adopting an electric tramway scheme for the town of Newport.

The local tramway company at Cardiff is prepared to use electricity on the present horse lines if the Corporation can supply the necessary energy from the lighting station.

The Crewe Town Council has decided not to oppose the application of the British Electric Traction Company to construct a light railway or tramway in the borough of Crewe.

The Sheffield Corporation, after a most exhaustive enquiry into the subject of electric traction, has decided to equip a portion of the town lines for electrical working on the overhead system.

The Waterloo & City Railway which will be the second underground electrical railway in this country, will be completed by March of next year. The line necessitates a double tunnel under the Thames.

The Bury, Rochdale & Oldham Tramway Company is seeking powers to convert its present steam lines to electrical working and the Rochdale Town Council having sent a deputation to inspect the electrical lines at Coventry, Bristol and Walsall, is not likely to oppose the company.

The proposed electric tramways at Hastings, a popular seaside resort on the south coast, is meeting with a good deal of opposition but the fact that the scheme is receiving the support of prominent members of the Town Council is almost sufficient guarantee of the system being eventually adopted.

The Belfast Street Tramways Company which has just paid a dividend of six per cent is anxious to equip the whole of its extensive horse lines for electrical working and though Parliamentary sanction would not be difficult to secure, it is necessary first of all to obtain the permission of the Belfast Corporation. The corporation, however, has declined to sanction the use of electricity except upon terms that are absolutely prohibitory, consequently the question of electric traction as far as Belfast is concerned is shelved for some-time to come.

The Bristol Tramways Company is extending electrical working onto further sections of its lines and recently an extension to Eastville, a point some distance outside the town, was opened to the public. Electrical working on the Bristol lines has proved to be an overwhelming success; the plant at the power house is being quadrupled, the much debated American engine forming the chief part of it, and the fact that the total working costs do not exceed 5½ pence per-car mile will have a very material influence on the spread of electric traction. Extensions are also the order of the day at Coventry, where the recently declared dividend of 8 per cent by the Electric Tramway Company has done much to convince people that electrical working can be made profitable, where steam and horses have proved to be unmitigated failures. A small accumulator line is proposed for the district of Waterloo which is a suburb of Liverpool.

**RAILWAYS HAVE RIGHTS.**

Justice Dickey of the supreme court of New York granted an injunction restraining the commissioners of the Shore road from interfering with the construction of the Coney Island, Fort Hamilton & Brooklyn Railroad. The company had obtained permission from the old town of Utrecht and also consents from abutting property owners and had begun work. In the meantime certain land through which the road was to run was made a park by legislative act, and on this ground the shore road commissioners stopped the work of construction.

The court held, however, that the company had acquired property rights which could only be extinguished by purchase or condemnation proceedings and not by legislative act. It was also held that, under the present law governing railway construction, the failure of a company to build the road within the time agreed upon does not forfeit the franchise, but the city may sue for such forfeiture.

**WAGES REDUCED AT LOS ANGELES.**

The wages of train crews which have been in force several years have now been cut. Gripman are reduced from \$2.50 to \$2.25; conductors, from \$2.25 to \$2. This is for day runs of 10 and 12 hours. The night crews average 8 hours and were receiving \$2 for gripman and \$1.75 for conductors. Night men now receive 20 cents an hour, \$1.60 per night.

There has recently been raised in Allegheny, Pa., a question as to the power of the directors of a railway to change the route as defined in the charter of the company without the consent of the stockholders. The suit was brought to compel one of the stockholders to pay for stock subscribed, his defense being as outlined.

## MAIL SERVICE ON STREET RAILWAYS.

The carrying of the mails is not a source of great financial gain to street railways and the efforts which street railway managers have made to extend this service are due to a desire to accommodate the people in the district served by their lines.

The mail service on street cars is of two kinds; the street railway post-office, and the closed pouch service. The former is a branch of the railway mail service and while yet largely in the experimental stage has made extensive progress in the last year. It suffers like so many other departments of the government service from too small an appropriation. The railways have appreciated the embarrassment of the postal authorities and have met the latter half-way, with the result that street railway post-office system is rapidly extending.

This branch is of course of most importance in large cities, and will be first developed there. As fast as funds permit post-office cars are put in service, replacing, as the case is in Baltimore, the closed pouch service.

Under date of October 26, 1896, the general superintendent of the railway mail service in his report to the second assistant postmaster-general for the fiscal year ending June 30, 1896, says:

"In my last annual report in referring to the railway post office service on electric and cable car lines, I predicted that it would be a success—a valuable and important adjunct of the general mail service and capable of great developments.

"The past year's experience demonstrated that this view was not a mistaken one. The larger experiments made during that period have convinced this office that the best service possible must be a combination of what has long been known as the railway post-office service and the electric and cable railway postoffice service, for by a combination of the two working in perfect harmony and under one direction it is possible to forward the mails deposited in the general office and branch offices of one city to the general offices and branch offices in another city much more expeditiously than is possible in any other way.

"In Boston, Brooklyn, St. Louis and Philadelphia, where a beginning was made with this service previous to June 30, 1895, it has been developed and improved by the establishment of new routes, the adoption of new schedules and the closer joining of the delivery and collection service there-within the contiguous territory.

"This service has been newly established in Washington, D. C., Cincinnati, Chicago, San Francisco and Rochester, N. Y., during the past year.

"The development of this class of service could have proceeded much faster but for lack of sufficient appropriation for car mileage and clerk hire. In the former item the estimates were reduced 25 per cent below what the department considered it prudent to provide.

"A new feature of this service, which is destined to become of great importance wherever possible to adopt it, is the location of special street letter boxes at important street intersections, several squares apart, painted white, to correspond with the color adopted for street railway postal-cars, from which collections are made by the clerks on each trip. It St. Louis the number of such boxes visited during the day amounts to 288, and in Rochester, N. Y., to 120."

The statistics for this service for the fiscal year, ending June 30, 1896, are shown in the following table:

Number of routes.....	21
Miles of routes.....	198.58
Number of cars.....	45
Number of round trips with clerks per day.....	195½
Average number of miles run daily with crews.....	279.45
Annual miles with clerks.....	907,863
Estimated pieces of mail handled daily.....	505,481
Average number of closed pouches handled daily.....	398
Number of crews.....	60
Number of clerks appointed to lines.....	75

For the previous year the statistics showed 12 cars and 17 clerks; the annual mileage for the time in operation was 76,336 and the pieces of mail handled daily but 78,932.

The routes at present in operation on cable or electric railways are given below:

Date of order.	Description.	Length.	Daily average.
		Miles.	Miles.
1893.			
Feb. 3	St. Louis and Florissant, Mo., R. P. O.....	18.10	80.98

### SUMMARY.

Total length.....	Miles.
Total daily average.....	181.16
	2,954.83

Arrangements have been completed which will result in the postal-car service being extended to Baltimore, where the mail is at present carried on the street cars in closed pouches. Two routes with railway postal-cars are contemplated.

Of the various cities where postal-cars have been introduced, Boston has the best arrangement of street railways; the long loop through the suburbs requiring two and one-half hours for the trip, gives more time for distribution and fewer men are required in the car.

In Chicago there are street railway post-offices on four lines; the routes are all short, requiring but 40 minutes for the longest, and hence, rapid work is required of the men. The schedules are so arranged that the cars connect with each other when on the down town loops, and all mail deposited in the cars by carriers or by individuals, that is intended for the territory of a sub-station is transferred to another line, and thus reaches its destination much quicker than formerly, when all the distributing was done in the general office. Also, so far as the completeness of the addresses permits, the mail is sorted for the carriers and a further saving of time effected. This service has resulted in a saving of from 2 to 3 hours in the transmission of letters from

one division of the city to another. On two of the routes, four postal clerks are required for each car, when on the down town portion of the line. It is found that the better service afforded is greatly appreciated by merchants in the outlying districts who are now able to order goods from down town by mail and have them delivered the same day, often after a few hours only.

Within the last month special boxes have been placed at intervals of four blocks on the Cottage Grove avenue route, into which carries dump the collections from the contiguous territory, and collections are made by the railway post-office crews each trip. On this route the mail trains are specials, and as there is about four minutes headway between the preceding and the following regular trains, ample time is afforded for making the collections from boxes. A few of the special boxes have also been placed on the other routes.

So soon as some arrangement is made, which will obviate the blockades which at present occur so frequently on the South Clark street and Wentworth avenue lines by reason of the steam road crossings on 16th street, postal cars will also be placed upon those lines.

The closed pouch service was adopted about 1890, that is, but little later than electric traction on street railways, and has grown very rapidly. This branch of the mail service pays the street railways better than the other, because, while the receipts are small, everything received is clear profit. No special cars and no extra men are required to handle it.

The following data in regard to this service are taken from the last report of the general superintendent of railway mail service. The figures are for those roads and parts of roads over which no railway post-offices run, in operation during the fiscal year 1895-96:

### CLOSED POUCH SERVICE.

Number of companies.....	91
Number of routes.....	126
Mileage of routes.....	726.84
Annual mileage.....	1,986,838
Pouches handled per day.....	1,929

This service is, of course, small when compared with the total mileage on steam roads, but it is one that will become more important with the extension of suburban and the building of new interurban lines.

## AMERICAN GOODS IN SPAIN.

The success which American manufacturers of street railway supplies have had in finding a market in England, France and Germany has led many firms to prosecute inquiries in Spain, with a view of developing that field also. At present there are street railways in but six Spanish cities, Madrid, Barcelona, Seville, Santander, Bilbas and Malaga, and under ordinary circumstances the field could be considered a very promising one.

But there are many obstacles to American imports, and in a report to the state department, Charles L. Adams, United States consul at Carliz, discusses them as follows:

First. There is a high and discriminating tariff imposed on American goods, to which must be added the octroi taxes levied by cities and towns; freight-rates are excessive in Spain; all the carrying trade is by way of Liverpool.

Second. England, France and Germany have reciprocal trade conventions with Spain, placing the United States at a serious disadvantage except with respect to the Cuban trade.

Third. The only direct importations into Spain from this country consist of cotton, petroleum and lumber, all other importations coming through the hands of French or English merchants.

Fourth. The present feeling in Spain is far from friendly to American business interests, because of the active sympathy for the Cuban insurgents which is manifested in the United States.

## A BAD CORNER IN BUFFALO.

The Buffalo Railway Company is endeavoring to make a change in its track layout at a particularly bad crossing. The cut shows the present and the proposed layout. The single track line on Elmwood avenue crosses the double track line on Allen street, and it is necessary for cars going north on Elmwood avenue to wait on the south side of the crossing until the south bound car can turn into Allen street. Tedious delays are caused on both lines and the situation is

aggravated by the jog in Elmwood avenue at this point making a system of signals necessary. The company has purchased a lot 35 by 75 feet on the northeast corner and proposes to widen Elmwood avenue for a distance of 75 feet and put in the track shown by dotted lines. This arrangement would make the angle of crossing better, do away with many of the vexatious delays experienced at present, and altogether greatly improve the service to the public on both lines. Some objection is made to this change by property owners in the vicinity, who would prefer that the street be widened for the entire block at the expense of the street railway company.

The elevated structure for the Union Loop, Chicago, has been completed and everything is in readiness for the electrical equipment. The Metropolitan Elevated has yet to be connected to the Loop, but the iron work for this has been received and will soon be in place. Provision is made for the expansion and contraction of the iron work by slip joints. These are at every third span. No rivets are used in these joints, but the girders just slip into and are held in place by shoes. It is expected that trains will be running on the loop by May 1.

SOME RECENT DEVELOPMENTS IN COPPER MANUFACTURE.

BY HAROLD P. BROWN.

In these days of keen business competition, makers of electrical apparatus and machinery are quick to seize upon each advance in the arts which will reduce the cost of material or increase the daily output of their shops. And the alert engineers in our large electric power houses are always ready to adopt improvements which will effect a saving of power. Both of these classes will, therefore, be glad to learn of a discovery in metal handling which will reduce cost and save time and power. It has been considered impossible to obtain solid castings of copper without mixing with it some other metal.

And it is well known that even one-half of one per cent of alloy is enough to reduce the electrical conductivity of the casting to one quarter that of pure copper. Many processes of mixing or tempering this metal have been invented but their product has not up to this time been able to show the physical properties of rolled or drop-forged copper.

Some months ago in a new type of rail bond I used strips of rolled copper with cast copper terminals. These castings were made for me by a firm which claimed extraordinary things for their product. I, therefore, expected very little from the metal, and in making tests was greatly surprised to find that a piece of this metal with but  $\frac{3}{8}$  of a square inch section, could transmit 1,500 amperes for twenty minutes without excessive heating. A calculation based on this performance indicated a conductivity of at least 90 per cent that of the best rolled copper. As I had never before found cast copper with more than 40 per cent conductivity, I decided to make a thorough and complete series of tests so as to ascertain the facts concerning this metal which is called MB copper. A chemical test, suggested by Mr. Edison showed that these castings had less impurity than was contained in some sheet or rolled metal sold as pure electric copper. To exactly determine the relative conductivity, I ordered a pattern made from which I obtained castings of the best commercial copper and of the MB metal.

These castings were carefully finished so as to present for testing a cylinder 25 in. long and 0.8 in. in diameter; a terminal was left at each end, about  $2\frac{1}{4} \times 2\frac{1}{4} \times 1$  in.

As a basis for comparison I had an exactly similar bar turned up from the best rolled Lake Superior copper. The completed bars were magnificent pieces of metal, without an apparent flaw. The difference in shrinkage of the two castings and a slight variation in the size of the terminals made it impossible to exactly obtain the comparative weight. The terminals of the rolled bar measured  $2 \times 2 \frac{7}{8} \times 1$  in., and its weight was 7 pounds, 6 ounces.

The commercial cast bar was a popular process "tempered" copper with terminals  $2 \frac{1}{8} \times 2 \frac{1}{8} \times 1$  in.; its weight was 6 pounds, 9 ounces.

The MB bar's terminals measured  $2 \times 2 \frac{3}{8} \times 1$  in., and its weight was 7 pounds, 1 ounce. Each of the cast bars gave a clear musical tone when suspended and struck; the MB bar, though the heavier, gave the higher tone. Of course the rolled bar was without resonance. The commercial cast bar had accidentally been turned 0.002 of an inch too small but the other two measured exactly 0.8 of an inch, thus having a section of practically one-half a square inch.

I decided to test the electrical drop in two feet of each bar and its temperature at from 100 to 1,500 amperes, the latter being three times the proper current for that section of copper. In order to prevent any rise of temperature from the contacts at terminals, each terminal was amalgamated by the Edison process and coated with the Edison flexible solder; there was, therefore, no appreciable drop at these contacts. In amalgamating the commercial copper bar by the Edison process, fumes were given off with an odor of zinc, and a black precipitate was formed. This was washed off and the process repeated several times until the surface remained bright. Both of the other bars yielded instantly to the process without fumes or precipitate.

Mr. Edison states that this is a keen test of the purity of copper and so it proved, for analyses subsequently made for

me by Ledoux & Co. showed the commercial casting to have 99.15 per cent of copper; the rolled bar 99.83 per cent and the MB 99.85 per cent.

In spite of the different characteristics of these bars, the variation in composition is less than seven-tenths of one per cent.

From tests of similar samples, the tensile strength of the commercial cast copper was 19,000 pounds to the square inch while the MB was 30,000 pounds, which is practically the same as rolled copper.

The cables used for connection were 500,000 c. m. with triple braided insulation. When heavy currents were used the bare ends of the cables near the bar connections were cooled with wet waste.

The observed temperature of the bars was, therefore, not due to any outside cause. The instruments used were all made by Weston and comprised a shunt ammeter reading to 1,500 amperes; a millivoltmeter reading 0.0002 per degree up to 0.01 volt, another reading 0.002 per degree up to

0.1 volt and a third reading 0.01 per degree up to 1.5 volts. In each case the same voltmeter terminals were used; these were clamped upon amalgamated spots on the bars just 2 1/4 inches apart.

A special dynamo driven by Edison motors was used; its field was excited from the Edison mains; by using a rheostat and a bank of lamps, the amount of current generated could be accurately adjusted.

The first readings were taken at 100 amperes after about one minute's run; the current was then increased 100 amperes and a second reading taken, and so on until 1,500 amperes was reached. This amount of current was continued for ten minutes and increase of the temperature and drop noted. The bars were then disconnected and laid upon a wooden floor and their rates of cooling noted. Since the copper resistance tables are either calculated for a constant temperature or were compiled years ago from data based on impure copper, I decided to use as a base of comparison, the drop of the rolled copper bar at each 100 amperes. Since the performance of the MB copper came so close to this standard, I repeated the tests on each and found the readings accurately recorded.

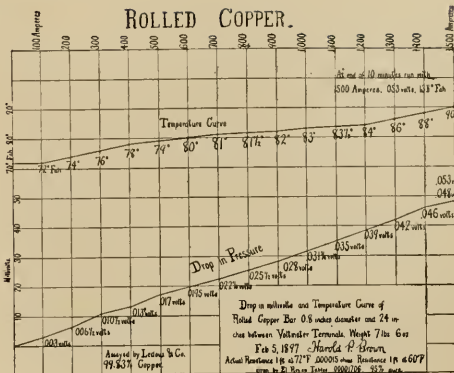

The tabulated results are as follows:

Amp's.	Rolled Copper.		MB Copper.		Commercial "Tempered" Cast Copper.			
	Deg. F.	Mil.V.	Deg. Fah.	Mil. V.	Deg. Fah.	Mil. V.		
100	72	.003	72	.0032	94	72	.010	30
200	74	.0065	72	.007	93	74	.023	30
300	76	.0105	72	.011	95	78	.037	28
400	78	.0134	72	.014	96	79	.046	27
500	79	.017	72	.017	97	80	.060	26.6
600	80	.0195	72	.020	97.5	82	.071	27.4
700	81	.02225	72.5	.023	96.7	86	.086	26.7
800	81.5	.025	73	.027	94.4	92	.096	26.5
900	82	.028	73.25	.0295	95	96	.115	24.3
1,000	83	.03175	73.5	.034	93.4	104	.130	23
1,100	83.5	.035	74	.036	97	110	.145	24
1,200	84	.039	76	.040	97.5	118	.155	25
1,300	86	.042	78	.044	95	126	.165	25.4
1,400	88	.046	80	.048	96	138	.1825	25.2
1,500	90	.048	81	.052	92.3	150	.195	24.6
1,500	138	.053	136	.057	93	354	.220	24

The last set of readings was taken after a ten minutes' run with 1,500 amperes.

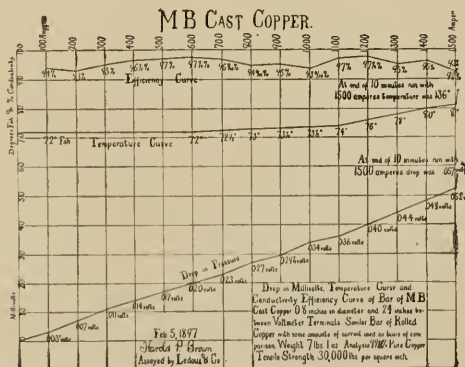

The accompanying curves will show the behavior of the three metals under exactly the same set of conditions. The commercial cast copper averaged less than 28 per cent conductivity, and before the end of the run scorched the wood on which it rested and the cotton covering the thermometer bulb, as it reached 354 degrees Fah. and 0.22 of a volt drop. Before the test the color of this piece was fine and closely resembled that of the other bars; after the test the bar was a mass of red and silver colored spots and had lost nearly all its resonance. At the end of the run it had expanded from increase of temperature 1/8 of an inch in 2 1/4 inches and 0.002 of an inch in diameter.

Allowance should be made for its difference in size. It required two hours and twenty minutes to cool to the temperature of the room. The rolled copper showed a conductivity far greater than called for by the tables ordinarily used. Its actual resistance per foot at 72 degrees Fah. was 0.000015 ohms. In the table published by the London Electrical Review, the resistance of a piece of copper, 95 per cent pure, one foot long, with a section of one-half a square inch, is said to be 0.00001706 at 60 degrees Fah. Without reducing to the same temperature, the latter resistance is

13.7 per cent greater than the resistance observed. The tables based on the Matthiessen Standard Conductivity also show greater resistance; it is therefore wise to use an actual measurement of modern rolled copper as a standard of resistance for cast copper. The rolled copper bar at the end of the ten minutes run with 1,500 amperes, reached 138 degrees Fah. and 0.053 volts. It had then increased 1/8 of an inch in 2 1/4 inches as did the other, but the diameter increased but 0.0005 instead of 0.002 of an inch. It required one hour twenty-three minutes to cool. The performance of the MB copper was a surprise and remains a puzzle. In the test it kept 8 to 10 degrees cooler than the rolled bar up to a load of 1,400 amperes. At the end of the ten minutes run with 1,500 amperes it reached 136 degrees Fah. and 0.056 volts. Its increase in size was the same as that of the rolled bar.

It required one hour and thirty-nine minutes to cool. The varying temperature of the two bars evidently accounts for the up and down movement of the efficiency curve, between 94 per cent and 97 1/2 per cent. If in the test the temperature of the bars should be kept at 72 degrees by allowing time for cooling after each reading, it is my opinion that this curve would be practically a straight line at 95 or 96 per cent. I need not say that this conductivity is marvellous and opens an entirely new field for dynamo and motor construction and for switch board work, where a large saving can be effected by using it in place of rolled or drop-forged copper, both of which will warp or twist when heated,

while the finished cast metal retains its shape. I know of large multipolar dynamos upon which castings of low conductivity have been used for field coil connectors, etc.; on account of the unsuspectedly high resistance of these contacts, the calculations concerning compounding have been upset and the dynamos have been failures. Another surprising quality of these MB castings lies in their elasticity. I have fastened in a vise one end of a casting  $1$  inch wide and  $\frac{3}{8}$  of an inch thick; the other end, 12 inches distant from the point of support, was bent one inch out of its position but sprung back when released. I have driven through a  $\frac{7}{8}$ -inch hole in a hardened steel plate, a plug of MB metal  $\frac{5}{8}$  of an inch in diameter. This required as many hammer blows on the fifth trial as it did the first.

In another experiment I drove into an opening  $1\frac{9}{8}$  inches wide between heavy steel rails, a plug of MB copper cut in two pieces lengthwise, the sum of whose widths was  $1\frac{1}{2}$  inches, thus compressing the metal  $\frac{1}{2}$  of an inch. A current of 1,500 amperes was then passed through the junction whose section was  $\frac{3}{8}$  of a square inch, and a drop of 0.018 volt was indicated from rail to rail through the two copper pieces in series. The rails were then separated  $\frac{1}{2}$  of an inch more, but the drop remained the same, showing that the copper had resumed its previous width. An analysis of another sample of this MB copper gave the following results:

Copper . . . . .	99.870 per cent.	Bismuth . . . . .	None.
Silver . . . . .	.034 per cent.	Lead . . . . .	None.
Iron . . . . .	.011 per cent.	Cobalt . . . . .	Trace.
Arsenic . . . . .	.002 per cent.	Sulphur . . . . .	None.
Zinc . . . . .	.013 per cent.	Oxygen . . . . .	(by difference)
Tin . . . . .	None.		.068 per cent.

This analysis is verified by others made by such experts as Ledoux & Co., Booth, Garrett & Blair, Prof. Frank X. Moerk and others, and shows exactly the same results as the best Lake Superior copper. It is evident that no alloy has been used. And yet the process has increased the electrical conductivity and the tensile strength; has given a certain amount of elasticity and decided resonance; has increased the density and changed the structure of the metal.

On presenting this matter to Mr. Edison he accounted for the evident change in the structure of the metal by the theory that the shape of the crystals has been altered so that their lines are parallel, and that the molecules are thus brought closer together and into more intimate contact with each other.

The fact that MB copper can also be rolled or forged adds new interest to its development. As its tensile strength exceeds that of ordinary copper wire, it is certainly worth while to make wire from it in order to determine its strength and conductivity. If it is possible by this process to make as large an increase in the conductivity of wire as it has made in conductivity of cast copper, it will revolutionize dynamo and motor building, and every electric light and railway company will save money by using it to replace its present line wire. And if the tensile strength of the wire is increased by the process poles can be set farther apart and the wire will be less likely to decrease its diameter during winter. This metal is well worth the attention of all electrical engineers who appreciate the value of high conductivity.

It is understood that Mr. Edison is interested in the development of the process and that the MB copper will be manufactured under his supervision at the celebrated Menlo Park works.

## TROLLEY SUSPENSION WITHOUT POLES.

In Elberfeld and Barmen, Germany, two adjoining manufacturing towns with a combined population of 260,000, the street railways have to contend with great difficulties in the way of steep and narrow streets and sharp curves at awkward points. In two instances the streets are 14 ft., 9 in., and 16 ft. wide, respectively. The steepest grades are 1 in 16 and 1 in 20 and the sharpest curves have a 52-ft. radius. There are two lines, one running through the two towns, of 4 ft. 8½ in. gage, double track, and a cross line in Elberfeld, of 3 ft., 3 in. gage and single track. Where the streets are too narrow for both tracks different routes are taken for the "up" and "down" lines.

The roads are operated on the overhead trolley system. The overhead wires are suspended chiefly from "rosettes"

TROLLEY SUSPENSION FROM ROSETTES.

affixed to the buildings. The distance between rosettes varies from 18 to 20 ft. on curves to 120 ft. on straight track. There is no power to compel property owners to permit the rosettes to be affixed to their buildings, but pressure is brought to bear, and if consent is not obtained poles are used. The illustration, for which we are indebted to the Surveyor of London, shows the method of suspending the trolley wires and also the close quarters at curves. The heavy dotted line indicates the trolley wire and the light dotted lines the guy wires fastened to the rosettes.

## HORSE CAUGHT IN A FENDER.

A peculiar accident occurred recently on the trolley line between Wethersfield and Hartford, Conn. A team of horses being left without a driver for a few moments walked onto the track and were struck by a slowly moving car. One of the horses put his foot through the car fender, and was only released after two hours by filing through one of the iron bars of the fender. When released it was found that the horse had injured his spine in floundering about and it was necessary to kill him. The accident occurred at midnight, it being the last car, and consequently no delay of traffic was caused.

The litigation of the Baltimore & Ohio and the Baltimore & Potomac Railroad Companies involving the right of the Commissioners of the District of Columbia to make the railroads stop their trains at the crossings of street railways, resulted in a decision of the Court of Appeals February 9, in which the power of the Commissioners was upheld.

An electric road is talked of in Glanclan, Germany, so the American consul at Chemnitz reports.

The Cracow (Austria) Tramways Company has completed plans to build five new lines in the city and suburbs.

Ponce, Porto Rico, granted a franchise for an electric railway two years ago, but construction has not yet begun.

There is a valuable concession at Tampico, Vera Cruz, which is held by Louis Goodman, of Neuvo Laredo, Mexico.

The Privy Council of Kingston, Jamaica, invites application for a license to establish rapid transit lines in that city and suburbs.

Perry Barsholow, U. S. Consul at Mayence, Germany, informs us that the street railway of that city is to be changed to electric system.

An extension of 6 miles of double track is being made to the Brussels tramway lines. It is stated that conduit instead of trolley system will be used.

At Freiberg, Germany, a committee has been appointed to study the different systems of street car propulsion. The electric system will probably be adopted.

Claude M. Thomas, United States consul at Marseilles, France, says that the Marseilles Street Railway Company has decided to change its system to electricity.

Consul-General J. B. Richman of St. Gall, Switzerland, informs us that the Gas, Wasser & Electricitatzwerke Company has just built an electric road in that city.

Augsburg, Bavaria, is a city of 60,000; its street railway, the Schuckert Actien Gesellschaft is now operated by horses but electricity will be substituted the present year.

Stephen H. Angell, U. S. Consul at Roubaix, France, writes us that the tramway company at Lille, which is now a horse road will be changed to electric this summer.

Progress is being made on the electric railroad between Buenos Ayres and Floresta, Argentine Republic, and it is expected that the road will be in operation about April 1.

Up to January 1, the number of applications to build light railways presented to the English Light Railway Commissioners was 26, 15 in England, 3 in Wales and 8 in Scotland.

St. Petersburg, capital and largest city in Russia, has only two street railways, operated by horses, using single tracks with turnouts. Cars run from 8 a. m. to 12 p. m., and the service is of a very primitive nature.

Ciseros & Co., owners of the street railway at Barranquilla, Colombia, propose to extend their line to Solidad, a

distance of 6 miles, and very possibly to equip with electricity. The manager of the railway is E. Mejia.

J. C. Monaghan, U. S. Consul, at Chemnitz, Saxony, Germany, writes: "Almost every little town of 20,000 souls and upwards, has or desires to have a street railway, and many of them must soon move in this direction."

The estimates for an electric street railway in Willesden, England, have been completed by the engineers. The road will be 4.5 miles long, costing about \$1,480,000, of which one-third will be for right of way and station buildings.

The Dublin, Wicklow & Wexford Railway Company will apply to Parliament for a permit to extend its lines and equip them with electricity. Provision will be made for freight as well as passenger traffic between Dublin and Bray.

O. H. H. Boyesen, American consul at Gothenburg, Sweden, writes that the Gothenburg Street Railway Company has asked for a concession to start a line of electric cars. The company is known as Goteborgs Sparvags Aktiebolag.

The earnings of the Bristol Tramways & Carriage Company amounted to \$245,225 last year, of which \$61,890 was profit. The Eastville trolley line will be extended to Staple Hill, permission having been granted for this as the new line is outside of the city limits.

The report of the Liverpool Overhead Railway shows a satisfactory condition of its finances. During the past six months 3,919,134 passengers were carried, with total receipts of \$163,910. On a balance of \$60,885 a dividend of 5 per cent was declared on preferred and 3 per cent on ordinary stock.

G. W. W. Gade, consul at Christiania, says that German capitalists are building an electric street railway in Bergen, Norway, and it will be completed this year. The German Electric Company has purchased a controlling interest in the horse car line in Christiania with the view of transforming it into an electric system.

It is reported that the Jungfrau mountain electric railway plans have been completed. The road will be about 7.5 miles long, ascending to within 250 feet of the top of the mountain. An elevator will carry the passengers the rest of the distance. The ascent will be about 6,500 feet, with a grade in places of 25 per cent. It will require 1,100 h. p. to operate the road.

"Up to the present, Bucarest is the only city in Roumania which owns street railways," writes H. G. Boxshall, United States Vice Consul. "Here we have two, one of which was established in the 70's by an English company, whilst the other was established in this decade, about four years ago, by a Belgian company, which then turned the business into a joint stock company. The name of the first is the Bucarest Tramways Company, and that of the second is the Societe Anonyme des Nouveaux Tramways. This latter company has also an electric line. Several other towns in this country are now studying the question of tramways, and are working out projects for this purpose. Those which have so far come under my notice are Galatz, Braila, Jassy, Craiova and Ploesci."

## POWER FOR THE SALT LAKE CITY RAILROAD COMPANY.

The development of the water power in the Big Cottonwood canyon has proven a great boon to the Salt Lake City Railroad Company. It is now using that power to operate its whole street car system. The canyon is located some 13 miles southeast of the city in the Wahsatch mountains. The stream passing through the canyon is fed by eight lakes situated 11,000 feet above sea level, but the natural conditions are such that only a 440-ft. fall is available for power purposes.

About two years ago local capitalists organized the Utah Power Company, of which Francis Armstrong is president, A. W. McCune, vice-president, and J. E. Dooly, secretary and treasurer. Careful surveys were made, plans drawn and an estimate of \$250,000 made on the cost of the work. The sources of revenue were the street car company, lighting the city and furnishing power for manufacturing concerns. The large contracts already on hand demonstrate the financial wisdom of the plan.

Work on the hydraulic part of the enterprise began nearly two years ago. Water was conveyed from the Cottonwood

500. The street car system is operated by direct current, so two rotary converters transform the alternating current of 500 volts to a direct current of the same voltage. The current then passes into the trolley and feeder lines of the Salt Lake City Railroad Company. On the 42 miles of track, 27 motor cars are operated. The power from the Big Cottonwood has only been in use since February 25th, but the system is so simple and complete that no difficulty is anticipated.

Two more dynamos are yet to be installed and another transmission line put up to the city. With this abundant and cheap source of electrical energy the people of Salt Lake City expect greater industrial activity in their prosperous community.

## INTERURBAN EXTENSION IN NEW YORK.

The Auburn & Western Railway Company has been incorporated to build an electric line between Seneca Falls and Auburn, N. Y. This railway will be about 10 miles long and connect the Geneva, Waterloo, Seneca Falls & Cayuga Lake Traction Company with the Auburn City

creek by a wooden flume to a 48-in. steel pipe 1,300 ft. long, which carried it to the power house. This gives a working pressure of about 190 pounds. A Pelton water wheel, about 60 in. in diameter, develops from this head of water about 1,000 h. p. at 350 r. p. m.

The supply of water is such that the minimum flow will give 2,500 h. p. with a possible development of 4,000 h. p. during 9 months in the year. A reservoir was built which holds water sufficient to run the wheels for 24 hours.

The electrical installation was the next problem and this was given to P. H. Knight to solve. Westinghouse apparatus was selected throughout. C. F. Lacombe, western agent of that company at Denver, conducting the negotiations for the sale, and superintending the setting up of the machinery. The dynamo, furnishing power for the street railway company has a capacity of 1,000 h. p. The dynamo was connected direct to the Pelton Water wheel and an alternating current of 1,500 amperes at 500 volts is generated. This is conducted to the transformer house which is close to the power station and the voltage is raised to 15,000 in the two stationary transformers. From here the current passes over the transmission line which is 13 miles in length and consists of 3 No. 2 copper wires. The loss in this line amounts to about 16 per cent. In the power-house in Salt Lake City step-down transformers reduce the voltage to

Railway Company, and make a through line from Geneva, through Waterloo, Seneca Falls and Cayuga to Auburn, a distance of about 20 miles. Application has been made to the state board of railway commissioners for permission to build the line.

It is intended as a passenger road and, through mail and express may be carried, no freight business is contemplated.

The map shows the system as projected. The solid lines indicate the existing electric lines, and the dotted line the proposed extension. The New York Central Railroad, which will be parallel from Geneva to Auburn, will be crossed twice by the proposed line.

The Indianapolis city council has adopted an ordinance providing that the street car company shall heat its cars from December to March inclusive when the temperature is below 20° F.

The election of directors and officers of the Second Avenue Street Railroad Company, New York, was held February 9. William C. Whitney, who recently purchased a controlling interest, was elected to the board. John D. Crimmins was elected president, succeeding George S. Hart, and Thomas F. Ryan was chosen a director to represent new stockholders.

## CAILLETET SINGLE-RAIL RAILWAY.

We are indebted to London Engineering for the following illustrations and description of the very ingenious mono-rail system for light railways, designed by Mr. Cailletet, a French engineer. It is not adapted for mechanical traction, and consequently will not prove a dangerous rival to other light railways, which are most economical when so operated.

FIG. 1.

FIG. 2.

The low cost and wide adaptability, however, make it eminently suited for agricultural districts where the roads are often so bad as to be impassable for loaded wagons, and it has found an extensive and useful application in France and the French colonies; also in Egypt it has received the strong endorsement of the British Engineer officers.

The track may be either permanent or portable, but the latter type has been more extensively used. The rails are of light section, the weight used depending on the nature of the service; up to the present they have weighed 3, 4.7, 6.4 and 8 pounds per foot. For the portable lines the permanent way is usually laid in sections 16.4 feet long, the section of this length together with six bedplates and fishplates,

FIG. 3.—CAILLETET PASSENGER CAR.

weighing 61, 89, 94, 123, 137 or 165 pounds, according to the traffic for which the line will be used.

Figs. 1 and 2 illustrate the rail, bedplate and fishplate, all of which are of steel. The rails are not weakened by drilling, the fish-plates being more or less elastic clamps fitting over the lower flanges of the rail. The bedplates are rectangular, with stiffening flanges on the four sides, being from 8 to 12 inches long and from 1 to 8 inches wide. As

shown in Fig. 2, there are two clamps riveted to the bedplates in such manner that the foot of the rail may be slipped in and then fixed by pulling back so that the clamps lock upon it. For convenience in laying, the rails are in lengths of only 4 to 8 feet. Where the ground is soft it is of course, necessary to properly support the bedplates. The sharpest curves which are used are of 13 feet radius, but this is recognized as too sharp and a 26-foot radius is recommended as the standard minimum. At switches the T-rail is replaced by a channel broad enough to receive the wheel flanges between its own.

The cars for these mono-rail lines are mounted on two grooved wheels, which are of course, placed in the same plane. A very common type is a hand car in which loads up to 700 pounds may be readily transported. For animal traction, cars are in use which have a capacity of 2 tons. The car body is in all cases disposed symmetrically with respect to the line of support and the load is also distributed in the

FIG. 4.—THE CAILLETET MONO-RAIL RAILWAY.

same manner. Fig. 3 shows a passenger car, and Fig. 4 a car for transporting earth, etc. The latter shows the manner of supporting the car body on two light girder frames in which the wheels are mounted. For cars of this size the wheels are from 20 to 30 in. in diameter. The wheels are controlled by brakes as on other railways.

A light frame projects from one side of the car and to this the horses are harnessed. The load being properly placed, practically the only effort exerted by the team is for traction. There is no occasion for turning the cars, as the team may be harnessed to pull in either direction. Other types of cars are in use for handling various classes of material and a quite interesting adaptation is that of an ambulance car, which has been used in Africa.

## OWL CAR WORK AS DISCIPLINE.

The Globe Street Railway Company of Fall River, Mass., has adopted a new method of disciplining its employes, and hereafter men will be put on night duty instead of suspended for violation of rules. This system has many points in its favor. While not so severe upon the man disciplined as is a suspension, the longer hours, unpleasant work and the long walk home when the last car is turned in, all serve to remind him that he has been in fault, and show him the advantage of good conduct. Also the men will not in future feel that the easiest way to get a vacation is not to violate a rule and be laid off for a few days. Suspensions now are for serious offenses only.

## RECONSTRUCTION OF CABLE TRACK IN CINCINNATI.

By Bert L. Baldwin, M. E., Cincinnati.

When the cable roads were first built in Cincinnati, the question of the kind of rail to be used received very careful consideration, and the heaviest rails in use at that time were selected for the purpose; these being the well known 52-lb. Johnson girder rail, for straight track, and an 82-lb. girder rail for curve work. These rails had been put in service on one of the "horse car lines," and after a test of about one year, were found to be so satisfactory in that kind of service, and were so far superior to the old stringer rails, that they were selected for use on the cable construction. The cable yokes, in both straight and curve work, were designed to suit the rails, and for the first two or three years' service the rail answered very well, but it was found that cable road service was very trying upon the rolling stock, the shocks, jars and sudden strains being so severe that cars built upon the same line as "horse cars," were soon racked to pieces, so that it was necessary to have them more heavily famed; again, with the addition of radial couplings, special brakes, sand boxes, bumpers, vestibules, etc., the weight of the cars increased at an alarming rate, so that the rail joints began to let down. To add to the misery, electric cars weighing two and even three times as much as the cable cars, were operated over certain sections of the cable construction, some of these cars weighing as high as 10 tons empty, or nearly a 4-ton load upon each wheel when loaded. This made the joint question rather serious, as it required such a large force of men to keep the track work in proper repair. Almost every type of joint was tried, but there was not sufficient room between the head and base of the rail to obtain the proper

amount of strength. Where the joint was too rigidly supported below, the webs would crush, and if a very solid joint were made to prevent this, the rail would often snap off just beyond the joint; so it was finally decided to make a complete change and substitute the 95-lb. full grooved rail, which was being used upon all new electric roads in Cincinnati. To remove the old rails and lay the new one without interfering with the regular operation of either the cable or electric cars was a point which required careful study before deciding upon a new system. The original design of the cable construction was such that a plan finally decided upon worked without a hitch and for the benefit of those interested, the following description may prove instructive, in event that they may be driven into undertaking a similar reconstruction.

Fig. 1 shows the Walnut Hills and Vine street cable road construction, when in perfect order, with the old 52-lb. rails supported upon wrought iron yoke arms secured to the cast

iron yokes. These yokes were spaced four feet apart and thoroughly imbedded in concrete, so that they formed a very good support for the tracks and slot rails, and although the tracks settled badly out of line, the slot rails have maintained their alignment and grade very nicely throughout the entire system, except in one or two places where a landslide caused the entire street to move and where it was necessary to realign the slot rails, but with the exception of a few hundred feet of track, it has not been necessary to disturb the concrete in tunnel bottom or under the yokes.

Single track was handled in the following manner:

The granite paving was removed to a width of 10 ft., or 5 ft. on each side of the slot rail, and for a length of from 400 to 600 feet, according to the location of the intersecting streets, curves, etc. The concrete foundation below the granite paving, together with all earth, stone or other material was removed for a width of 9 ft., or 4 ft. 6 in. on each side of the slot rail, to a new sub-grade, 21 in. below top of slot rails; this sub-grade was thoroughly rammed solid with hand rammers so as to secure a good foundation; at each yoke a small pocket was made to give access to the bottom bolt in yoke arm (marked C in Fig. 1); following the excavators were other men who removed the bolts C, leaving the yoke arm braces supported and held in position by a lug on the yokes, as shown at D Fig. 2; these men also removed the rivets A, by means of ratchet drills and punches, replacing the same with bolts B, so that the rails would still be supported by the yoke arms; for additional security the rails were blocked up at various points directly from the ground as well as braced from the sides of trench. New sections of lower tunnel siding, made of creosoted yellow pine were fitted in position at F, after which the concrete gang filled in the trench to a level 16 in. below top of slot rail, using a level gage for the purpose, similar to what is

shown in Fig. 2, only with longer "legs." Upon the concrete was spread a bed of stiff cement mortar and short oak ties bedded directly in this mortar, using the "level gage" shown so as to insure their being properly leveled, the mortar being put in place in a heavy layer and the ties rammed until the gage showed it to be at the proper level when tried at both edges. The tops of ties are then still further tested for level by using a steel straight edge 10 or 12 ft. long, slid along the tops of ties and clear under the yoke arms; this located all high or low ties which are corrected for level at once. Two of these ties, size 6 in. x 7 in. x 3 ft. 6 in. were placed between each yoke on each side of slot rail, and at rail joints a 6 in. x 12 in. x 3 ft. 6 in. tie is used, the location of each joint being carefully measured off and marked upon the side of slot rails for this purpose.

All of the foregoing work is done during the day time, while both electric and cable cars are operating over the old rails and, of course, it requires close watching to prevent

tools, blocks, ties and other articles from getting into the tunnel and catching a grip; and it requires a lively gang of men to keep out of the way of the cars, especially at such times of the day as they are passing at the rate of three or four per minute, and still be able to progress with the work.

After the ties are in position for a stretch of say 400 ft., and the cement set sufficiently hard, the new rails are hauled along side of the trench and everything prepared for changing the rails after the last regular cars have passed over the lines, usually about 1 a. m.

Headlights are used for illuminating the work if it is at a point where there are no electric lights.

The rails used are 60 ft. long, and in many cases two or three of these are spliced together before being lifted into position.

After the last regular cars have passed over the line, the track gangs start at work, first removing the yoke arm bolts throughout the entire length of the work, removing the splice plates only where they connect at each end of the work to be changed, then with bars and wooden levers the rails with their splice plates and yoke arms attached, are wrenched from their old position and deposited against the curb stones, care being taken so as not to disturb the new ties. After removing all blocking and rubbish that may have collected upon the ties, the new rails are lifted into position, spliced together and spiked in place, using one hook head spike on outside and two on inside flange of rail base. As it is too dark to sight along the rails and obtain proper alignment, a special track gage is used in laying the first line of rail which gages from the cable slot, as shown in Fig. 3. The opposite rail being aligned by using the usual type of track gage. This, together with the tightening up of all splice bolts puts the road in a condition so that the cars can start again; 600 ft. of single track have been changed in this manner in less than two hours; of course there is other work to be done, holes to be drilled through the webs of rails opposite the yokes, to receive the tie rods, as shown in Fig. 4, and in some cases, spikes have to be drawn so as to straighten out some slight "kink," copied from the slot, while using the slot to gage by, but this work can be performed while the cars are running over the new rails.

Next the two new pieces of upper tunnel siding are fitted in place and the concrete filled in around and leveled with the tops of the ties, the same being well tamped under the rails and in place as well as finished off with thin cement grout, which fills all cracks and voids.

The webs of rails are filled with a stiff cement, as shown at G, after which the granite paving is relaid in the usual manner, on a bed of sand with the joints properly graveled and tarred.

After the paving is in place all old track material and rubbish is then removed and the work of reconstruction may be said to be complete.

In very narrow streets only one side is reconstructed at a time, so as to leave at least one side of the street open for wagon travel, and in double track work the two rails and space between the two sets of slot rails are reconstructed first, and then the outside portions of the work follow, one side at a time. In asphalt paving the work is performed in the same manner as with granite, excepting that the concrete is carried up and over the tops of the ties to a level  $3\frac{1}{2}$  in. below the top of slot rails to allow for the asphalt surface.

It seems rather odd to replace iron yoke arms with oak ties, but where a water proof paving covers these ties and they are bedded almost completely in cement concrete, there is very little danger of the wood decaying. In certain places in Cincinnati ties have been removed after having being bedded in this manner for over eight years, and with the exception of a little white mould, less than  $\frac{1}{8}$  in. deep on the surface, the ties were as sound as could be wished.

In the case of these cable roads, even should the ties rot away the rails have base flanges  $5\frac{1}{2}$  in. wide which rest directly upon the concrete, so that they could not "get away," and they will probably stay where they are until they wear out.

All portions of the forenamed cable line, which have both cable and electric cars operating over the rails, have been reconstructed. This amounts to about 50 per cent of their length, and as the weather permits, the balance of the line will be reconstructed this year.

### EXEUNT HORSES IN PHILADELPHIA.

On January 14 the last horse car in Philadelphia made its last trip, running over the Callohill street line to the new trolley barn at 24th street and Fairmount avenue, where it now awaits its end. Whether that end is to be under the auctioneer's hammer or just a removal to the scrap heap is not yet determined. Business was good up to the last, 35 fares being collected on the final trip. This marks the closing of an interesting epoch in transportation in Philadelphia. The first real horse car in that city was run on Germantown road January 21, 1858, so that horse traction extended over a period just 7 days less than 39 years. Unlike many of the institutions incident to the "good old times," this one has no friends and no one wishes to see the era of the horse car return. While, as stated above, the first horse cars were put in service in 1858, horses were used for drawing cars on the Germantown Railroad for a few months in 1832, before the steam locomotives were put in service, and also for a few trips on the Northern Liberties & Penn Township Railroad in 1834.

### PRIZES AT GRAND RAPIDS.

The Consolidated Street Railway Company of Grand Rapids, Mich., on February 12, awarded the prizes for good conduct during the last six months. Twelve men received awards ranging from \$40 and one week's vacation with full pay to four days' vacation with full pay. At the same time the management thanked the men for the excellent records made, and regretted that all those whose conduct had been good could not also receive an award. During the past year the number of accidents has been greatly reduced.

Buenos Ayres is the largest city in the Western Hemisphere outside of the United States, and the most progressive in the South American republics. Its street car service is operated by animal power but it is quite extensive. There are 10 companies in the city running 191 cars on 231.5 miles of track. The employes number 3,729 and 7,885 horses are used. During the month of December these companies carried 7,137,080 passengers.

On the Construction of a Factory Chimney of the Capacity to Suit a Plant of 2,000 Horse Power, by Robert Kunstman.

In the construction of every factory chimney it is necessary, owing to a concentration of so great a weight on a comparatively small area and on account of its lofty nature as a structure, that a careful examination of the ground by means of proper sounding rods be made; it is of considerable importance to ascertain whether any layers of quicksand intersected with a watercourse may not be concealed in a lower stratum, which would necessitate special consideration and a more careful and elaborate operation in order to secure a good and permanent foundation. It is of no rare occurrence that an apparently solid bed of clay may be of a limited thickness only, overlaying quicksand, or a bed of a different nature of clay that will not sustain the great weight which will have to rest upon it. In hilly country it may occur that layers of clay of different density intersected with a watercourse, begin to slide upon each other, even at a considerable depth below the surface, when great pressure on the surface is brought to bear.

In Fig. I and Fig. II we represent sectional and full elevations of a round brick chimney, 193 feet high from base line to top of cap. The connecting flues from the boilers here reach the chimney at a height of 14 feet from the base line, leaving, for the stack proper, an effective draft height of 179 feet. The inside diameter at the flue inlet is 8 feet while the inside diameter of the discharge opening at the top of cap is 7 feet.

#### FOUNDATION.

The nature of the ground upon which this chimney is erected requires a good and uniform distribution of weight and for this reason the concrete foundation is considerably strengthened by means of completely imbedded steel beams in the lower three layers. A solid concrete bed 18 inches thick and 37 feet square is first placed upon the excavated ground; on this three layers of steel beams 35 feet long, 10 inches deep are laid across each other and everywhere surrounded with concrete; the beams weigh 25 pounds per running foot and are spaced 9 inches from center to center.

The component parts of the concrete must not be too coarse and the latter requires to be thoroughly well rammed between the beams so that the interior shall be homogeneous and free from flaws.

Four concentric circular layers of concrete are then placed on the top of the completed courses of square layers, each circular block raking back along a line of slope making an angle of 60 degrees with the horizon. The whole exterior of foundation is rendered fairly smooth with cement mortar of best Portland cement and left for a week or two to harden and consolidate before the surrounding ground is filled in and the brickwork proceeded with.

We shall now give the quantities of materials used for foundation:

2,053 cubic feet of concrete in the bottom block.  
3,250 cubic feet of concrete round and within steel beams.  
3,445 cubic feet of concrete in the circular blocks.

Total 8,748 cubic feet, at 137 pounds per cubic foot will weigh 535 tons and with 37 tons of steel beams we have a total weight of about 572 tons in the foundation.

#### SHAFT OF CHIMNEY.

The shaft of the chimney is composed of an inner flue reaching within, from base line, 193 feet to the top and an outer surrounding wall, or shell, 178 feet 3 inches long, together with a cap of 14 feet 9 inches terminating the shaft.

Both these flues are erected independent of each other, and only approach within about  $\frac{3}{4}$  of an inch through ribs (as shown in the different sections AB, CD, EF and IK), bonded into the outer walls and projecting inward.

The batter for the outside walls is found thus: The difference in diameter at the base and at the neck of the cap is 17 ft. minus 10 ft. 6 in. or  $6\frac{1}{2}$  ft., and the height from base to neck is 178 ft. Hence the batter is  $\frac{7}{8} \div 178$  or .219 inches to the foot.

For the inside flue it is  $\frac{1}{2} \div 193$  or .031 inches to the foot.

The outside flue is divided in four sections as shown in Fig. I, while the inside flue is divided in three sections, the respective thicknesses are, for the former (taken from the neck of cap downwards)  $1\frac{1}{2}$ , 2,  $2\frac{1}{2}$  and 3 brick, and for the inner flue (from base upwards)  $1\frac{1}{2}$ , 1 and  $\frac{1}{2}$ , width of brick, respectively.

The vacant space left between the two flues is an effective non-conductor of heat to the outside, or against the chilling influence of lower temperature toward the inside.

For the round chimney, which we represent in Figs. I and II, considerable advantages are obtained and a superior and better class of work achieved if the brick are made to specially shaped templates for the different sections; greater strength through better bond and a more economical use of materials, both brick and cement mortar, are gained, with a greater saving of labor in cutting brick.

There will be no necessity of using fire brick for the inside flue as it is not to be expected that the temperature or gases within the chimney will go beyond  $500^{\circ}$  to  $600^{\circ}$  F., which is a temperature not injurious to a good, sound and well burnt brick of ordinary clay. For inside, as well as for outside work, the brick should be laid in cement mortar. The use of lime mortar is objectionable for the inside on account of lime being readily attacked and crumbled away through the constant exposure to sulphurous vapors from the fuel. There is no fear that the cement will be injured at so low a temperature as that prevailing in the chimney.

We show in Fig. VI, diagrams which will illustrate that

the form of the brick, whether it be key form or circle brick, may be so determined that not very many different shapes are necessary. If too many forms were chosen there would probably be confusion in their use. At A we give the two sizes of key form and of circle brick that will be required for the inner flue, while at B the wider circles are shown for the outside walls. From the respective circles it may be inferred that two different shapes of key form and one for circle brick will be sufficient to meet the requirements of obtaining good bonds.

In order to obtain the quantity of brick required for the erection of the chimney, we have to calculate the contents of the flues, together with those of the cap. We treat, for the sake of convenience and of more quickly getting a result, which will suffice for our purpose, the different sections, not as truncated cones, but as so many cylinders, and calculating the sectional area of each division, multiply the same by the height of division, which will give us the cubic contents of the respective flue. For easier calculations we express all dimensions in decimal parts of a foot. For the outer flue, therefore, we have:

Division 1, out. diam., 17'	—12.25'	area 109.1x50.5	= 5,509.5 cu. ft.
Division 2, out. diam., 14'	—11.5'	area 50.1x47.5	= 2,379.7 cu. ft.
Division 3, out. diam., 13'	—10.5'	area 46.1x47.5	= 2,189.7 cu. ft.
Division 4, out. diam., 11.5'	— 9.5'	area 33.0x32.7	= 1,079.1 cu. ft.

Total for outside wall, 11,158 cu. ft.

In Fig. 5, we show the cap in enlarged scale, and how the same is constructed with projections and recesses. It should not be unnecessarily heavy, but of such proportions as are appropriate to its character, namely, such as to give the chimney a finish pleasing to the eye, and worthy of its destination. A cast-iron ring plate is put on the top and secured with anchor bolts, as shown in plan. For obtaining the cubic contents of this part of the chimney, we will treat the cap as a truncated cone, deciding upon an outline that will embrace projections and allow for recesses, deducting from this solid cone the inner cylinder, we shall get the desired approximate result.

Let a, c, d, b, in Fig. 5, indicate the area of solid contents of the truncated cone, we have:

Diameter at top,	= 17 ft. 9 in.;	(17.75 ft.) <sup>2</sup>	= 315.0
Diameter at bottom,	= 10 ft. 7 in.;	(10.50 ft.) <sup>2</sup>	= 111.0
10.58x17.75			= 187.7
			614.6

614.6 x 0.785 x 13.25..... = 2,128.8

3

Inner cylinder ..... = 699.7

Total cubic contents of cap..... = 1,429.1      1,429.1 cubic feet.

For the contents of inner flues we have:

1 division 38.00 square feet x 64.3....	= 2,443.4
2 " 25.52 " " x 64.3....	= 1,640.9
3 " 14.50 " " x 64.3....	= 932.3

Total cubic contents..... = 5,016.6 cubic feet.

For outer flue, cap and inner flue... = 17,603.7 " "

We now have to add the contents of ribs, with an average projection of 8 inches and 12 inches wide and for these we can allow..... 500 cubic feet.

Total for shaft..... 18,103.7 " "

From the foregoing result we can at once obtain the quantity of brick required to erect the chimney. In a cubic foot of brickwork with a 1/8 inch joint and using a brick 8 x 3 5/8 x 2 1/4 inches there are 21 1/2 brick, so that we shall require 389,229.5 for the whole chimney. Both kinds, the key form and circle brick can be brought to a size that will

contain in volume an equivalent of the size of brick on which our calculation for the quantity is based, but as we have previously stated, the specially shaped brick is preferable, as waste of material is obviated and labor for cutting is saved and a stronger and superior class of work obtained. It will also be found that in building the chimney entirely from the inside without the use of outside scaffold, greater accuracy of the work is secured, as the plumb rules or straight edges when specially regulated for the batter of the walls are easier handled with better results on the face of the walls.

Provision is made at the base of the chimney by means of a small man hole to enter the chimney and free it from accumulating ashes and soot; iron spikes are also fixed into the inner face of the flue, at convenient distances to reach the top if it may be found necessary when the chimney is completed.

Having obtained the cubic contents and quantity of brick, we have no difficulty in arriving at the total weight of the chimney and the pressure which the structure exerts on the concrete foundation and, with the latter, upon the ground.

Let one cubic foot of brick work set in cement mortar weigh 126 pounds; we have a total weight of shaft and inside flues of 1,016 tons. To sum up the foregoing remarks on the constructive details and quantities, we will append a table of dimensions, etc., as follows:

Working capacity of chimney.....	2,000 H-P
Depth of foundation.....	12 ft.
Height of chimney inclusive of foundation.....	205 "
Height of chimney from base line to top of cap.....	193 "
Height of cap from neck of shaft to top.....	14 ft. 9 in.
Effective height from inlet of boiler-flues.....	178 ft. 3 in.
Batter per foot on side walls 2 1/8 inches outside, and 1 1/8 inside.	
External diameter of chimney at base line.....	17 ft.
Internal diameter of flue at base line.....	8 "
External diameter at neck under cap.....	10 ft. 6 in.
Interior diameter at extreme top.....	7 ft.
Thickness of outer wall under the cap, 1 1/2 brick.....	12 in.
" " " " at section C D, 2 ".....	16 "
" " " " " E F, 2 1/2 ".....	20 1/2 "
" " " " " G H, 3 ".....	24 1/2 "

Size of inlet flue from boilers 9 feet by 4 feet 6 inches, with an area of 32 square feet.

Area of outlet on top of chimney.....	38.5 square feet
Total weight of chimney, including foundation.....	1,588.5 tons
Total weight of brickwork, from base line upwards.....	1,016.5 tons
Load on concrete foundation 2.9 tons, or nearly 3 tons per square foot.	

The load on the ground and distributed over an area of 1,370 square feet is therefore 0.86 tons per square foot.

It should not be difficult to arrive at the cost of this chimney at any locality if, according to local conditions, prices of materials and labor are estimated from the quantities we have given.

#### AN IRON CHIMNEY OF SIMILAR DIMENSIONS.

We also give in Figure III and IV, for comparison, an iron chimney of nearly equal dimensions as regards height and inner dimensions, namely, total height 194 feet from base to top of cap, with an interior diameter of 8 feet at the inlet of boiler flues and 6 feet, 6 inches at the top. In view of these dimensions the outer flue, which is constructed of steel plates, reaches to the foundation and is bolted down to an iron bed plate, with which the foundation is covered, by strong anchor bolts.

This chimney is lined inside with brick from base line to top of cap. The foundation is constructed in a similar man-

ner to that of the previously described round chimney; here are also two layers of steel beams imbedded in the concrete, and a square block of 30 feet is formed; on this concentric circular blocks of concrete are placed until the base line is reached. The long anchor bolts are imbedded in the concrete while it is rammed in, extending down three-quarters of the depth of concrete; the bolts are spaced 18 to 20 inches from center to center in a circular line, that is, corresponding with the cast iron top plate.

Provision is here made for bringing the inlet flue from the boiler plant through the foundation underneath the foundation plate into the inner flue, as shown in the section.

The inner flue is divided into three sections, of the lengths shown, with three thicknesses, or  $1\frac{1}{2}$  brick from base upwards, two thicknesses, or 1 brick for the second division, and 1 thickness, or  $\frac{1}{2}$  brick for the upper section; the inner face of the flue is carried up flush and true to the batter as in the previous case, ribs are formed where room will permit for it, and the space between steel flue and brickwork is filled up with fine dry ashes.

The outer flue, as shown in sectional plan, is made of steel plates of the following thicknesses,  $\frac{1}{8}$  inch for the first,  $\frac{1}{2}$  inch for the second and  $\frac{3}{8}$  inch for the third division, a cap is formed of steel plates as indicated in Figure III and Figure IV. The erection of an iron chimney of the foregoing dimensions requires, no doubt, a safe scaffold and good tackle, with the skill and experience of good boiler makers to insure a satisfactory result.

The chimney as represented here may not exceed in weight 55 to 60 tons, while the inside brick flue, containing about 5,000 cubic feet, would increase this weight by about 225 tons, giving a total of only 285 tons, being somewhat more than one-third of the weight of the round brick chimney of similar dimensions.

### SOME VIEWS IN LYONS.

Lyons, the second city in France, has a population of 450,000 and is located at the junction of two navigable rivers, the Rhone and the Saone, by which it is divided into three parts. The Rhone here follows a nearly straight course from northeast to southwest, while the Saone approaching from the north, is turned by the surrounding

flow nearly parallel to the junction. The old town is on the narrow tongue and now also includes the quarter of La Croix-Rousse lying on the bluffs to the north, just above

REPAIR CAR—OULLINS LINE.

the bend in the Saone. To the east on the left bank of the Rhone are the divisions of La Guillotiere and Les Botteaux occupying the slopes of the hills which are crowned by

SNOW-PLOW—OULLINS LINE.

fortifications. On the right bank of the Saone the bluffs are much sharper and the quarters of Fourviere and Vaise are on plateaus overlooking the rest of the city.

When compared with other European cities, Lyons has an extensive system of tramways, there being ten lines of street railways which connect the several parts of the town and the numerous suburbs surrounding it. The most progressive of these lines are operated by electricity, as described in the REVIEW for February, and all of them will probably be so transformed in the near future. The first line equipped with electricity runs from the Place de la Charite, near the center of the old town, along the right bank of the Rhone, through the Perrach quarter (so called from the name of a citizen who in the latter part of the last century enlarged the town by moving the junction of the rivers farther south) to Oullins, a town of 9,000 inhabitants, 3 miles below the junction. One of our illustrations shows a construction car used for overhead work on this line, and another a snow "plow." The snow question is not a serious one for the railways of Lyons, and no special cars are

PLACE CARNOT—LYONS.

bluffs and makes a broad curve to the left and then to the right, forming a sharp shoulder in the tongue of land between the two rivers. Below this shoulder the two rivers

needed for cleaning the tracks. Snow falls but seldom and is never so deep as to block traffic. For clearing the tracks however, the triangular plow shown is drawn behind a car in regular service.

The Place Carnot, a handsome square in the central

"FICELLE" TO CROIX-ROUSSE.

part of the city ornamented with a statue of the Republic, is the terminus of several of the tramway lines. Our illustration shows the old style double-decked horse cars.

In addition to the horse and electric lines in Lyons there are four cable lines, called "Ficelles," which are employed for reaching the plateaus to the north and west of the city. These are double track lines on the "balanced" system. The two cars, one ascending and one descending, are attached to the ends of a steel cable which passes about a drum at the head of the incline, to which the motive power

"FICELLE" TO ST. JUST.

is applied. The cable is supported on pulleys placed at short intervals along the center of each track. The Ficelle to the Croix-Rousse ascends 100 feet in less than half a mile, making trips at intervals of five minutes and very considerably shortens the time required for reaching this quarter of the town.

The Ficelle to St. Just affords ready access to the railroad station, Gare de St. Just, which is a few minutes walk from the cathedral of Notre Dame de Fourviere.

In the report of the Scranton Traction Company for the six months ending December 31, 1896, the gross earnings were given as \$191,625, an increase of \$23,095 over the previous six months, while the operating expenses amounted to \$102,390 and the fixed charges of \$67,476 left a surplus of \$21,758.

EXHIBITION IN NEW SOUTH WALES.

On June 26 an important exhibition will be opened at Sydney, New South Wales. The exhibition is solely for the advancement of engineering science and will embrace all the branches of engineering. No charge is to be made for space but the executive committee reserves the right to limit the space of each exhibitor.

Group VI comprises railway, tramway and vehicular appliances and embraces rails, switches, signalling apparatus, locomotives, goods wagons, carriages, tram cars, brakes, bicycles, tricycles and auto-cars.

Group IX covers electricity and is an important one, embracing generators, conductors, testing and measuring apparatus, telegraph, telephone and electric lighting apparatus, transmission, distribution and utilization of power, etc.

The exhibition will remain open throughout July and August and it is expected that it will be an even greater success than those held in 1883 and 1886. The executive committee has appointed Edward Noyes, of Sydney, as its representative in Europe and America. All communications on the part of intending exhibitors may be addressed to him care of the Standard Air-Brake Company, 100 Broadway, New York, and they will receive prompt attention.

A MODEL RECORD.

The Calumet Electric Street Railway, Chicago, of which H. M. Sloan is the progressive manager, has made up a statement of operating expense, from May 1 to December 31, 1896, and the result appears in the following table:

Expense item.	Average operating expense per car-mile.
General .....	.00502
Taxes, insurance and legal .....	.00559
Power .....	.01061
Transportation .....	.04246
Line .....	.00152
Track .....	.00075

Generators and appliances .....	.00017
Trucks .....	.00070
Bodies .....	.00052
Buildings .....	.00013
Steam plant .....	.00020
Tools and machinery .....	.00004
Sundries .....	.00020
Total .....	.07003

STREET RAILWAYS FOR CHEYENNE.

The old horse car system of the Cheyenne Street Railway Company has been abandoned for the past four years. The city now has a population of 20,000 and is able to support a good system of street railways. Recently a franchise for 99 years was granted to the Cheyenne Electric Railroad Company, incorporated by M. S. Weller, A. N. Butler, J. N. Freeman, of Denver, Col., and C. T. Metz and M. McGill, of Cheyenne. Three lines will radiate from the Union Pacific station, making the length of track about 9 miles. The organization of this new company has aroused the old one to life and action. It now proposes to relay its old tracks and introduce electric traction. Between the two companies the prospects for street car service are very good.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Riding on the Front Platform of a Street Car.*

It is not negligence per se to ride on the front platform of a street car, even though there are seats inside; the question of negligence is one of fact for the jury taking into view all the circumstances of the case.

The Court, by Patterson, J., in its opinion said, this action was brought to recover damages for personal injuries sustained by the plaintiff while a passenger upon a car belonging to the defendant, a street railway company, which injuries, it is alleged in the complaint, were caused by the negligence of the defendant's servant, the driver of the car. The plaintiff, at the time the accident occurred was riding on the front platform of the car, which circumstance induced the trial judge to dismiss the complaint, on the ground that the evidence showed that the plaintiff failed to place himself in as safe a position in the car as he was able to obtain. That was attributed to the plaintiff as negligence on his part to defeat his right to a recovery. From the judgment entered upon the dismissal of the complaint and from an order denying a motion for a new trial the plaintiff appeals.

It appears that the plaintiff entered the car on the rear platform and was smoking, and, according to his story, he was told by the conductor that if he wished to smoke he must go to the front platform. There were not many passengers in the car and he could have found a seat in it. Acting upon the assumed invitation of the conductor, he went to the front platform. The car was going along West street, and when it reached the curve at West Eleventh street, the condition of the pavement between the tracks was such that the horse drawing the car was compelled to stop. There appears to have been quite a network of tracks at or near this point. According to the plaintiff's version, the driver gave the horse a blow with a whip, the horse made a plunge and the car went off the track. The next thing the plaintiff knew was that he was picked up by two laborers and carried across the tracks to a woodshed in the neighborhood. He was seriously injured by falling or being thrown from the car. The plaintiffs' account of the occurrence with respect to the act of the driver, and the cause of his falling off the car is contradicted by the defendant's witnesses. The plaintiff further testified that the street and the tracks generally were in very bad condition; repairs were being made to the pavement on the street, but those repairs had not been completed at the place at which the car went off the track. It was apparently a perilous place, in consequence of the condition of the street. The plaintiff says that, noticing that fact, he had grasped the handrail, but had released his grasp upon being called on by the conductor to pay his fare.

The motion for a non-suit was made upon two grounds: First, that negligence on the part of the defendant's servant, the driver, was not shown, and secondly alleged contributory negligence of the plaintiff. There was evidence (coming from the plaintiff himself) to show the negligence of the driver. Counsel for the plaintiff insists that negligence is to be imputed to the defendant, from the mere fact that the car left the track, upon the authority of *Edgerton* against *N. Y. & H. R. Co.* (39 N. Y. 237), and subsequent cases to the same effect. But the rule applied in that case refers altogether to steam railways and to cases where not only the vehicles, but the tracks, are within the entire control of

the defendant. It would be grossly unjust to extend that rule to street railway companies, which have no exclusive control over the track or roadway, but whose tracks are daily used by thousands of other vehicles, and are placed in public streets under the control of the city authorities, and in which work is constantly being done on or under the roadways and tracks. But there was in the testimony of the plaintiff, if it is to be believed, very positive evidence of negligence on the part of the driver, and it is only upon the theory that the statement is true that the question of negligence could properly have been left to the jury.

The condition of the street and of the track according to that testimony was such as called for more than ordinary care on the part of the driver. The difficulty of making progress was so great, according to the plaintiff's account, that the horse stopped and it was (if the plaintiff's story be true) the sudden blow with the whip that started the horse, whose plunging forward cause the car to leave the track. There was, therefore, some evidence of negligent conduct on the part of the defendant's servant inducing the accident.

The learned judge held that it was contributory negligence on the part of the plaintiff to ride on the front platform, that not being the safest place for him. We assume that the learned judge meant the safest place under all the circumstances of the case. It is not negligence per se for a passenger to ride on the front platform of a street railway car. *Spooner v. B. C. R. R.*, 54 N. Y. 230; *Sheridan v. B. C. N. R. R.*, 36 N. Y. 39; *Clark v. 8th Ave. R. R.*, 36 N. Y. 135; *Nolan v. B. C. & N. R. R.*, 87 N. Y. 63; *Graham v. Man. R'y*, 149 N. Y. 336. It is suggested that in the cases in which the rule referred to has been applied, it appeared that the passenger on the platform was riding on a crowded car and could not find a seat in the interior; but that is not so, and the rule is not confined to such conditions only.

In *Nolan v. B. C. & N. R. R. Co.*, supra, the facts closely resembled those in the case before us. There, the plaintiff got upon a car of the defendant in which there were many vacant seats inside; he went to and was smoking upon the front platform, the conductor took his fare, the driver struck one of the horses with his whip, the horse plunged, gave the car a jolt which threw the plaintiff off and the plaintiff was run over and injured; and it was held that contributory negligence as a matter of law could not be imputed to the plaintiff from the fact of his riding upon the front platform, but that that question was one for the jury. In the opinion in that case the authorities are collated and criticised and it is stated that the rule is settled (independently of a statute not applicable to this case); that even with relation to cars on steam railways, it is not negligence per se for a passenger to stand on the front platform while the car is moving, and it is said that the question is one of fact for the jury, taking into view all the circumstances of the case.

(Supreme Court of New York, *Hastings vs. Central Crosstown Railroad Company*. 29 Chicago Legal News 26.)

*Change of Motive Power, — Acquiescence. — Paramount Right of Street Railway Company to use of Street.*

Where the consent of a borough is necessary to empower a street railway company to change its motive power, the acquiescence of the borough in the change for five years will

be presumed to give such consent, and will estop the claim of an individual, in an action against the company for personal injuries, that the maintenance of the new system of active power is negligence per se.

Although the right of an electric street railway, even to that part of the street occupied by its rails, is only in common with that of other travelers, yet it has the paramount right to the use of the street for a reasonable time, and to place there usual and ordinary appliances for the repair of its wires.

Supreme Court of Pennsylvania. *Potter vs. Scranton Traction Co.* 4 *American & English Railroad cases.* (N. S.) 307.

### THE METROPOLITAN STREET RAILWAY ASSOCIATION.

The benevolent association recently organized among the employes of the Metropolitan Street Railway Company, of

of death his representatives receive \$150. These dues secure medical services for members without further expense to them.

In keeping accounts, each month is made to stand by itself and any surplus is invested for the benefit of the association. A wise and responsible financial management is secured by the constitution, which provides that the general manager and the treasurer of the Metropolitan Company shall be ex-officio president and treasurer, respectively, of the association. In accordance with this provision, H. M. Littell is president, and H. S. Beattie treasurer, and to their efforts the present flattering condition of the association is due.

### A STREET RAILWAY IN HAYTI.

Through the courtesy of Alexander Battiste, United States deputy consul at Port au Prince, Hayti, we are enabled to present illustrations of the street railway in that

STREET RAILWAY IN PORT AU PRINCE, HAYTI.

New York, started business on February 1, with 1,120 members and its success is assured. In addition to the benevolent and insurance features, the Metropolitan Street Railway Association, as it is called, offers social advantages which, as the present membership indicates, are keenly appreciated by all classes of the company's employes.

The company has very generously provided a large club room at 50th street and 7th avenue, and furnished it with chairs, tables, bookcases and piano. This room will be supplied with about forty weekly and monthly papers, and also with models of tracks, curves, grips, signal boxes, trolley plows, motors, etc., so that the men can always find amusement and instruction here when off duty. Concerts, lectures and smokers will be given frequently as special entertainments.

Membership in the association is purely voluntary, but is limited to employes of the company, and ceases when this connection is severed. The dues are 50 cents per month with an initiation fee of one dollar. When disabled, a member is entitled to one dollar per day sick benefit, and in case

city. The line when completed will comprise 18 miles of track, there being 6 miles already built. The original intention was to procure the equipment in France, but on the death of H. Laforesterie, to whom the franchise was originally granted, and the reorganization of the company under its present title of the *Societe des Tramways de Port au Prince*, it was decided to have the rolling stock built in America.

The track is narrow gage and laid with 35-lb. T-rails rolled in Pittsburgh. As shown in the illustration, steam is the motive power, but a change to electricity is already a mooted question. The cars were furnished by the Jackson & Sharp Company, Wilmington, Del., and are of the ordinary open type used in this country, but shorter and smaller in every way for the proper adaptation to the narrow gage. The engines are small tram engines, built by H. K. Porter & Co. of Pittsburgh.

The capital for the enterprise was furnished by German and Haytian capitalists, and the management is under the direction of F. Hermann & Co., a German firm. The chief

engineer, H. Tomasset, and the manager, Charles Thomas-set, are Frenchmen, with extensive experience in street railway work.

The second illustration shows the principal street of the capital on the occasion of the celebration of the national independence. The present progressive spirit in Hayti is in marked contrast to that of a few years ago, when it could be truthfully said: "There is not a railroad nor a common road worthy of the name in the country; no public improvements and no public weal. Her motto might well be, 'millions for dissension and not one centime for improvement.'" The investment of capital in such enterprises as this means that there is more confidence in the stability of the government, and the "black republic" is to be congratulated.

### LITERALLY SNOWED UNDER.

General Manager Sergeant, of the West End road, Boston, relates an amusing incident which occurred on his road during the last big snow storm. In order to get quick

of arrest the old man sadly drove off with his load of snow, the boys from Italy tossing a few farewell shovels which filled the front of the box up to the driver's knees. When last seen, the old man was headed down Washington street with a load of snow as big as a small house, looking for a place to unload.

### TROLLEY CAMPAIGN IN NEW HAMPSHIRE.

The friends of the trolley in New Hampshire have formed a permanent organization for the purpose of conducting a "campaign of education" during the next two years and electing a legislature that will grant charters to electric railway companies in all parts of the state where a demand for them exists. The organization was effected at a meeting held in Concord on February 10, which was attended by about 35 prominent men from New Hampshire and Massachusetts. It is not intended that the association shall exert its influence in behalf of the roads which have charters now pending, but is to look to the legislature of 1899.

SCENE IN PORT AU PRINCE, HAYTI.

action every available team in the city was hired, some among the lot being very antiquated. At the same time hundreds of shovelers were employed, including one large gang of Italians who could not speak a word of English.

It chanced an honest old farmer with a big lumber wagon wandered into the down town district, and unfortunately for him stopped a moment in the midst of these Italians. In an instant several big shovels full of snow were in the air and descended into his wagon. The old man heard the noise and looking around called out to them to stop. This was accepted as encouragement to work faster, and the snow came in more rapidly than before. Then the driver began to wax wrath, and the more he waved his arms the faster the boys let it come. His language, quite un-Bostonian was taken as an admonition to "shake-em-up," and that wagon was filled with a ton of snow in less time than it takes to tell the story. About this time an officer came along, and seeing the wagon loaded and blocking the street, ordered it to move on. Explanations were in vain, and under penalty

### POSSIBLE FIELD FOR INTERURBAN LINE

Our attention is called to what promises some day to be a profitable interurban enterprise in Colorado. The distance from Denver to Cheyenne is 107 miles, with good towns along the line. Greeley has 4,500 people; Brighton, 1,200; Ft. Lupton, 1,000; Evans, 2,000, and Athol 3,500. There are numerous smaller places and a rich farming district. Good freight business can be secured, as the local rates on the Union Pacific are very high, with no competition. Several good water powers are available for power.

Rapid progress is being made on the Elm avenue line, Philadelphia, which skirts West Fairmount and East parks. The grading had been done for the road bed and the loops finished, six miles of steel cable is being used for fence work along the way. The 60 cars, now stored in the barns, will soon be carrying passengers.

**ORGANIZATION OF THE CHICAGO CITY RAILWAY.**

At the annual meeting of the Chicago City Railway some slight changes were made in the scheme of administration; the office of general manager, hitherto filled by the president, was annexed to that of superintendent. The diagram which we publish shows in a graphical manner the organization, the lines indicating the channels through which the reports of officers and heads of departments reach the president. The following extracts from an order taking effect February 15, will explain further the duties which devolve upon the different officers and heads of departments, whose duties are not made clear by the title of the office:

The general officers of the company, vice-president, secretary, treasurer, general manager and superintendent, general counsel, and auditor, report to the president direct. The vice-president in the absence of the president receives the reports otherwise going direct to the latter. The claim department and the right of way department are under the supervision of the general counsel. The auditor keeps all accounts, checks bills, makes out vouchers and attends to rents, collections and statistics.

The general manager and superintendent has charge of all questions of operation, discipline of train service employes, and purchasing department.

The chief engineer reports direct to the manager, sending daily written report of amount of pay roll for each power station and for floating gangs, as compared with last year.

The storekeeper buys articles needed when ordered on requisitions approved by manager, and submits reports on

station); also all heat, light and insurance questions; makes daily report as to number of men employed and pay roll as compared with last year. The inspector of heat, light, signals and insurance reports to the electrical engineer upon the economics of these subjects and also upon cleanliness, fire service, fire drill of employes, and keeps signals, etc., in order.

The superintendent of time tables attends to the fitting of cars and trains to the demands of traffic, and has charge of and gives orders to all officers of the operating department as to the movement of trains and time tables. In this connection an effort is made to have the system pliable so that trains may be arranged to suit conditions on short notice. The superintendent of time tables also has charge of transfer tickets and points of transfer.

The receivers report to the manager and also send in daily duplicate reports to the treasurer.

The chief inspector has charge of special agents, of examination of applicants for train service, and of examination of men turned in. Uniforms, trainmen's lists, trip sheets, registers, pay rolls, lost articles, complaints, and miscellaneous office duties not otherwise assigned are also included in the inspector's department.

The chief supervisor has charge of all outside work in connection with train service; hires and discharges, subject to the approval of the general manager, all watchmen, switchmen and signalmen. He has immediate charge of barn foremen and two regular assistant supervisors, and will employ others when needed. The supervisor, his assistants and barn foremen will, at their discretion, suspend employes in the transportation department, to report to general manager for discipline, and will send in written report of such action on the same day. The supervisors are also the custodians and inspectors of buildings, waiting rooms, cars and repairs of the same (except the general office building).

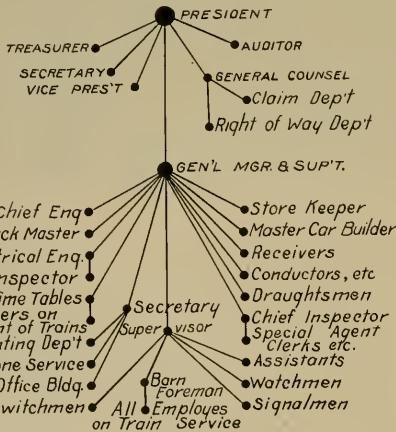

The barn foremen, subject to the directions of the supervisor and the superintendent of time tables, have charge of barns, cars, property and men and train service each in his own division.

The general manager's secretary has charge of the printing department, employes' passes, telephone service and the general office building.

The general orders conclude as follows:

"Reports from all chiefs of departments to the manager will be made daily, and will be made out by them personally, as their personal familiarity with their expenditures is important.

"Officers and foremen will not employ relatives of any employe already on the road; will not board or room men under them; solicit business or subscriptions, or in any other way make use of their positions for personal profit to the possible detriment of the company's interests. No two members of the same family will in future be employed in the operating department."

receipts and expenditures of material and stock in store room.

The master car builder has charge of shop employes, fixes standards, and employs shop men. He makes daily report to manager as to number of men, cars turned out, and amount of wages as compared with last year.

The track master makes similar report in regard to his department.

The electrical engineer has charge of construction and operation of all 500-volt circuits (except inside of power

**OPEN CARS IN WINTER.**

Many of our readers will be surprised to learn that open cars are kept in operation a good portion of the winter, each year, in Denver. The past season has been unusually favorable with much mild weather, and opens have been the rule and closed cars the exception. One day about the middle of February there were only 22 closed cars in operation on all the lines, the balance being summer cars.

### SHOPS OF THE CINCINNATI STREET RAILWAY COMPANY.

The new shops of the Cincinnati Street Railway Company are located at what was the once famous "Chester Park Race Track". Chester Park comprised about 26 acres of almost level land lying northwest of Cincinnati, just outside of the corporation line. When the company acquired possession of the park a portion was set aside as a pleasure resort and the company has built a club house, amphitheatre, bicycle track, cinder sprinting track, etc., so that it remains a popular resort, and retains the old name. The eastern portion of the grounds is occupied by the shop.

The company had a large number of small shops, acquired through consolidation with other systems, but wished to concentrate the work at one point. Accordingly after a careful

The buildings lie on either side of Mitchell avenue and are separated by cross streets giving good light and fire protection as well. The Spring Grove avenue fronts of the paint shop and car house are shown in one of the illustrations. Being the ones most seen by the public they have castellated towers at the corners and imposing arched doorways at the car tracks.

Beginning at the south end the first of the buildings on west side of Mitchell avenue is the paint shop, a building 205 ft. wide and 325 ft. long on the longest side. The building has 12 tracks. The floor is of cement except where the rail heads show themselves. On the south side are the oil room where the paints are mixed and a room for the heating apparatus. The office building joins the paint shop on the southwest corner.

North of the paint shop is a large building 378 x 205 ft.

FIGURE 1—SHOPS OF THE CINCINNATI STREET RAILWAY COMPANY.

examination of several car works the present plant was built. It has a capacity for overhauling and repairing 500 or 600 cars in the four months that open cars are in service and of course an equal number of closed cars are cared for during the winter months. In addition the company will build its own cars. Work was begun at the shops on February 15.

Work on the plans was begun in the fall of 1895, and as the Chester Park athletic grounds were to be opened in May, 1896, the generating station was the first to be completed. The generating station is located at the north end of the plant on the tracks of the Cincinnati, Hamilton & Dayton Railroad, so that coal is delivered to the boiler room in cars. The building is of brick with stone trimmings and is the only brick building on the grounds.

The boiler plant comprises five 72-in. x 18-ft. tubular boilers, equipped with Murphy furnaces. The engines are of the Hamilton-coriiss type by the Hooven, Owens & Rentschler Company, Hamilton, O. They are belted to a line shaft which drives three 62-D generators supplying current at 500 volts, used for motor purposes, and three Card 75-k-w machines for the incandescent lamp circuits. It is of interest to know that the engines, boilers and generators in this plant formed part of the first electric railway equipment used by the company in its original Brighton plant.

The other buildings are all built of broken ashler lime stone, quarry face, with Indiana stone water tables, sills and copings. The roofs are supported on trusses and all the buildings are provided with ventilating windows or skylights which serve to light them no matter how the floors may be crowded with cars.

which contains the erecting shop 175 ft. long, the cabinet shop and the mill shop. In these shops the line shafts are driven by a 62-D generator working as a stationary motor.

The company transferred the wood working tools from the old Pendleton shop to Chester Park, but has also made extensive additions of new machinery, which was furnished by the J. A. Fay & Egan Company. Some of these new machines are shown in the illustrations. Fig. 3 is the No. 3½" surface planer. It takes material up to 26 inches in width and 10 inches in thickness, is provided with divided feeding-in roll and pressure bars, permitting the planing of two pieces of different thickness at the same time, and altogether is well adapted to the needs of a car shop. The tenoning machine, Fig. 4, is a recently designed tool for medium work and is adapted for door work as well as for tenoning

FIGURE 2—INTERIOR OF CAR HOUSE.

framing timbers. The self-feeding ripping saw is shown in Fig. 5. This tool will take all classes of work, from the most delicate to the heaviest. It is largely used for reducing rough lumber to the proper width for framing timbers. For reducing material for panels and other thin work the band resawing machine, Fig. 6, is well adapted. It will receive material up to 30 inches wide and 12 inches thick, and will saw through the center of stock 10 inches thick and resplit from the side of an 8-inch timber. The tool has a variable feed, ranging up to 100 feet per minute, and is provided with outside bearings for the wheels, and with a sensitive weight device for regulating the tension of the saw blade, which latter is so essential to a band resaw. The vertical boring machine, Fig. 7, is provided with three spindles that have lateral motion, across the table, instantly

drums, so that in case of accident the latter may be easily repaired.

The wood working department is excellent in its general appointments and reflects credit on the company and on the tool makers.

The dry kiln is just west of the generating station and is reached by a side track from the C., H. & D., so that lumber may be unloaded directly into it.

On the east side of Mitchell avenue are the car house and warehouse, the armature shop, the machine shop and the blacksmith shop. This last is 90 x 107 ft. and is equipped with 12 heavy cast iron forges by the Buffalo Forge Company, arranged with the draft and exhaust pipes underground. In this shop is also a 1,250-pound steam hammer. The punch, shears and drill press are operated by a 20 H-P

WOOD WORKING MACHINERY AT CINCINNATI STREET RAILWAY SHOPS.

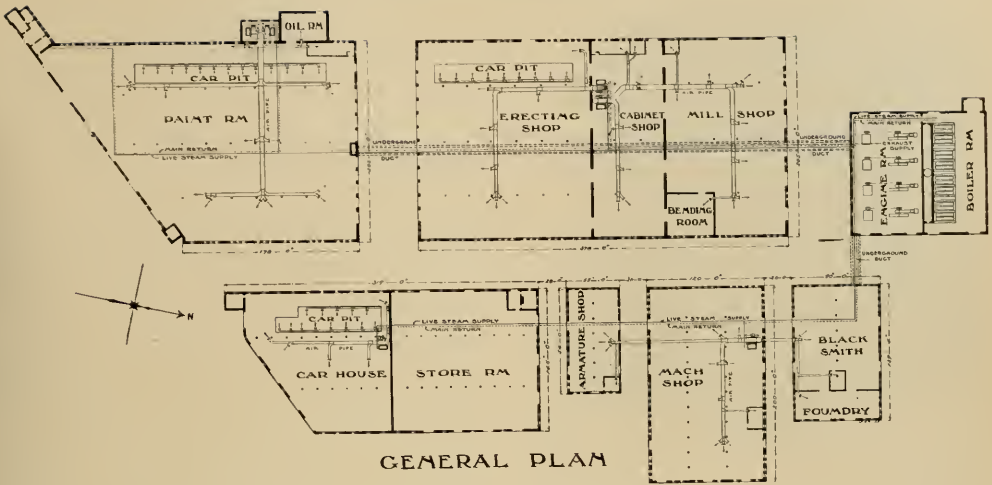

controlled by levers and with vertical adjustment by means of hand levers for controlling the depth of boring. The table has power driven rolls and heavy material is easily handled. Fig. 8 shows the double circular saw used for pattern shop purposes where there is a rapid change from one class of work to another. The many adjustments of this tool make it admirable for the purpose. Perhaps the most important tool in the wood shop is the triple drum sander, Fig. 9, used for polishing. This is a heavily built and very efficient machine. The finest veneers may be sanded without cutting through them. The feeding rolls, pressure bars, plates in the table and the drums themselves all admit of the finest adjustment from both ends independently, and the machine is provided with oscillating devices on the drums for automatically varying the position of the rolls for various thicknesses of stock, and the whole of the upper works may be instantly raised above the line of the

electric motor which also drives the blowers for the forge blast and exhaust.

The machine shop is 120 x 200 ft. and well lighted. The machines, which are for the most part by the Niles Tool Works, Hamilton, O., are located in the south division of the room, the other portions being reserved for erecting motors, trucks, etc. A 5-ton hand power crane is used for handling heavy work. The shop is driven by a D-62 generator working as a motor.

The armature shop is 55 x 109 ft. and has a steam heated bake oven for drying out armatures and field spools. The work is easily handled and moved about by means of chain blocks suspended from trolleys running on a system of I-beams suspended from the roof. The shop is equipped with various binding and winding machines, and presses for forcing armature pinions on and off.

The supply warehouse is 145 x 152 ft. with overhead wir-

ing for three tracks, so that an "express" car can be run into the building for loading and unloading. In one corner of this room is the timekeeper's office. The warehouse is connected with the erecting shops by an iron foot bridge over Mitchell avenue so that the men do not need to pass the gates to get from one department to another.

The car house which joins the warehouse has a capacity for 40 cars and is used for the temporary storage of cars sent to the shops for repairs or of cars bunched at the park to meet unusual conditions. All of the buildings are connected by a very complete system of tracks so that material can be readily transferred.

One of the features of these shops is the heating and ventilating apparatus installed by the American Blower Company of Detroit. In the plant are a total of 5,386,000 cubic feet of space and this is heated by means of six separate steam coils which altogether contain 45,000 lineal feet of 1-inch pipe. Six fans are used for forcing the air over the steam coils, where it is heated, and thence through galvanized iron pipes into the various buildings. These fans deliver 301,000 cubic feet of air per minute. The heating system is subdivided into five plants: No. 1 being used for the paint shop, No. 2 for the erecting shop, No. 3 for cabinet and mill shops and bending room, No. 4 for the armature, machine and blacksmith shops, and No. 5 for the car house. The heaters are of the A. B. C. sectional base pattern having the supply and drip headers on the same side. The fans discharge vertically at the top and the air piping throughout the plant is carried up to the roof trusses. The engine for each fan is direct connected to it but supported on a separate foundation. The location of the different heating plants and layout of the piping is shown in the general plan.

Plant No. 1 which heats the paint shop is the largest and heats about 1,200,000 cu. ft. of space. It comprises two heaters with 8,000 feet of pipe in each. The fans are 160-inches in diameter and are driven by 12 x 10-in. engines. Plant No. 2 heats about the same space as No. 1 but comprises only one 8,600-ft. heater coil, one 160-in. fan and one 12 x 10-in. engine. No. 3 heats the same extent of space and contains one 9,500-ft. coil, one 180-in. fan and one 12 x

10-in. engine. No. 4 heats 970,000 cu. ft. and has one 7,600-ft. coil, one 160-in. fan and one 8 x 10-in. engine. No. 5 heats 440,000 cu. ft. and has one 3,200-ft. coil, one 120-in. fan and a 6 x 6-in. double engine.

The coils of plants 1 to 4, inclusive, are made up of six sections; No. 5 of three sections, each containing four rows of pipes. The first two sections of heaters in plants 1, 2 and 3 are set aside for the exhaust steam from the blower engines; plants 4 and 5 have only one section for the exhaust.

A 10-in. exhaust main is led from the engines in the power house and supplies heating plants 2 and 3, a 7-in. branch being used for each. An 8-in. high pressure main is taken from the steam heater in the boiler house leads to plants 1, 2 and 3 through a 7-in. branch and to 4 and 5 by a 5-in. branch. By this arrangement a live steam supply is provided for all the coils in the event that exhaust steam should not be available. The steam and return mains for plants 1, 2 and 3 are carried underground as far as the paint shop and thence along the ceiling of the shop. For plants 4 and 5 the steam main is everywhere overhead. The water of condensation is discharged into tanks at each heater and carried to the boiler room through a single main where it is returned to the boilers.

In the buildings containing car pits (the paint shop and

IMPROVED A. B. C. HEATING COIL.

the car house) hot air pipes are carried down from the overhead duct and run along the sides of the car pits. These pipes have outlets about 10 feet apart provided with adjustable nozzles so that the current of hot air may be turned in any direction desired. The object in thus supplying heat to the car pits is to render it easy to thaw out cars that are frozen up and to dry out "grounded" cars in wet weather.

By this system the questions of proper heating and ventilation are solved in a satisfactory manner. In summer no steam is admitted to the heating coils and the plant is a ventilating one only. The fans supply a complete change of air for the paint shop every 15 minutes and for the other buildings every 20 minutes, but they are of sufficient capacity to increase one-third the air delivered.

When the Cincinnati Street Railway determined upon the general arrangement of the plant, the work was intrusted to the company's mechanical engineer, Bert. L. Baldwin, who prepared a complete set of detail drawings for each building. The contracts were let separately for each building, and as each class of work had its set of detail drawings and specifications the bidding was very close. This together with the "hard times" secured good buildings at low cost. The engineering department superintended the inspection and erection.

### NEW COMPANY IN CHARLESTON.

On February 12 the directors of the City Railway of Charleston, S. C., held their last meeting and closed up the affairs of the company preparatory to turning the property over to the Charleston Street Railway Company, which took charge on the next day. The last important business of the old board was to dispose of a surplus of about \$20,000. The stockholders received a dividend of \$7 per share in addition to the purchase money from the new company.

At Palermo, Italy, electric railways have been talked of, but as yet nothing has been done. The only line in the city is operated with horses and owned by the "Societa Sicula Tramways-Omnibus."

### SNOW PLOW AT MAUCH CHUNK.

The snow plow shown in our illustration was constructed last summer by J. A. Bonnell, the general superintendent and electrician of the Carbon County Electric Railway of Mauch Chunk, Pa. The body is short and mounted on a single four-wheel truck of 6-ft. wheel base, equipped, with two 30-h.-p. Westinghouse motors. The platform is surrounded by a bulwark about 3 feet high, so that the view of the operator is always unobstructed, and yet he is in a great measure protected from the wind. The trolley base is supported on a 3-in. gas pipe in the center and braced by rods running from the four corners of the car. Under the canopy below the trolley base are 5 incandescent lamps for use in night work.

At each end of the car is a steel shear, which may be raised or lowered by means of the ratchet lever seen in front. Following the shear is a set of small steel scrapers which remove any ice or snow that may have remained on the rails.

During the winter this plow has been used when occasion offered, and has given perfect satisfaction. The Carbon County road is short, only  $4\frac{1}{2}$  miles in length, but is nearly all grades and curves. There are 26 curves on the line and there is no piece of level track longer than 25 feet.

Mr. Bonnell began his street railway career in Philadelphia in 1859. In 1864 he was on the Atlantic avenue line

SNOW PLOW AT MAUCH CHUNK, PA.

in Brooklyn, and the next year became assistant superintendent of the Dry Dock & East Broadway line in New York city. In 1888 he entered the employ of the National Improvement Company of New York, and constructed a line in Norfolk and Portsmouth, Va., and in 1889 reconstructed the railway at Allentown, Pa., for the same company. Mr. Bonnell remained at Allentown until he accepted his present position with the Carbon County road in 1893.

The report of the Wheeling (W. Va.) Street Railway Company shows the financial condition of the road to have been so much improved during the past year that a 5 per cent dividend will be declared, payable quarterly. The completion of the Benwood and Moundsville line has added greatly to the traffic of the road.

Chas. P. Steinmetz, of the General Electric Company, has gone to Milan, Italy.

Albert Vickers has been made general manager of the Buffalo, North Main Street & Tonawanda Electric Railroad.

F. S. Stewart has been appointed superintendent of the Pontiac & Sylvan Lake Electric Railway Company, Pontiac, Mich.

It has been reported that ex-Secretary of War Lamont was offered the presidency of the Metropolitan Traction Company, New York.

Charles S. Howell, claim agent of the Consolidated Traction Company of Pittsburg, has been chosen superintendent of the West Penn Hospital.

E. W. Ashe has been placed in charge of the Lakeside Railway lines, Mahanoy City, Pa., recently leased by the Schuylkill Traction Company.

John M. Ward, the famous ex-short stop of the New York base ball team, has been engaged by the Nassau Electric Railroad to take charge of the claim department.

Frank De Ronde, of the Standard Paint Company, New York, participated in the inaugural parade at Washington, being captain of the 2d regiment of the National Guards of New Jersey.

On the evening of March 10, H. F. J. Porter, the western representative of the Bethlehem Iron Company, delivered a very interesting address to the students of Lewis Institute on "Steel Forgings."

Edwin R. Gilbert, who has been connected with the Hartford Street Railway Company, recently was appointed general manager of the Holmesburg, Tacony & Frankford Electric Railway, Philadelphia.

Mark H. Hubbell, general manager of the Schuylkill Electric Railway Company, Pottsville, Pa., has resigned. In the two years he has been in charge the system has been greatly improved and extended.

S. B. Stillwell, who has been associated with the Westinghouse Company in its work at Niagara Falls, has severed this connection and accepted the position of electrical director for the Cataract Construction Company.

B. F. Jones has resigned his position as superintendent of the South Chicago City Railway Company, and will engage in the manufacture of electrical specialties with J. M. Atkinson & Co., who are now making Mr. Jones' horse-shoe rail bond.

D. A. Brooks, superintendent of the Weymouth & Braintree Street Railway, Weymouth, Mass., has resigned his position to accept a similar one with a new company organized to build from East Weymouth, through Randolph and

Stoughton to Canton. Mr. Brooks left the Weymouth Company February 1.

Julian S. Yale has resigned his position as general sales agent of the Illinois Steel Company, and with Townsend V. Church has opened offices in the Rookery, Chicago, in the interests of a general iron and steel business. A. M. Crane, who has been Mr. Yale's assistant, now takes his place with the Illinois Steel Company.

John Balch, who has been for the last two years the receiver of the Dubuque (Ia.) Light & Traction Company, was on February 16 married to Miss Katherine Torbert of Dubuque. Mr. and Mrs. Balch left at once for New York and on the 20th sailed for Italy. Upon his return from abroad Mr. Balch will make his home in Boston.

F. H. Fowler, representing the Bemis Car Box Company, Springfield, Mass., spent several days in Chicago during his western trip this month. Mr. Fowler's long experience in engineering and steam railroad work, and three years as master mechanic of the Springfield road, peculiarly fit him for the excellent work he is doing with the Bemis trucks and street railway specialties.

T. M. Burt on March 1, severed his connection with the Berlin & Waterloo (Ont.) Street Railway, a road with which he has been identified ever since it was built. Mr. Burt went to Berlin from New York in 1888 and purchased the charter of the railway company; the road was built the following spring, and continued in successful operation as a horse line until 1895, when the motive power was changed to electricity. Until January 1896, Mr. Burt held the position of president and treasurer; at that time the line was sold to Berlin capitalists, but Mr. Burt remained as general manager. He is also president of the Preston & Berlin Street Railway and director in other companies. T. E. McLellan is the new manager of the Berlin & Waterloo Company.

C. F. Uebelacher has entered the employ of the Peckham Motor Truck & Wheel Company. He is a valuable acquisition to the company, for his practical experience has made him conversant with steel railway usages. He took charge of the works at Kingston, N. Y., on March 1 in the capacity of superintendent. Mr. Uebelacher is thoroughly familiar with both shop and railway practice, having been for two years with the Short Electric Company of Cleveland, O., as chief engineer. During the past four years he has filled the position of master mechanic of the Consolidated Traction Company of Jersey City, N. J., where he has had supervision of from 150 to 250 men in the various departments of car building, repairing and operating. We wish Mr. Uebelacher success in his new position.

The committee on railroads of the New Hampshire legislature has heard applications for four charters for electric railways in Nashua, Manchester and Concord. The representatives of the street railways in these cities testified that as soon as there was a demand for such roads that they would build them under their existing charters. It seemed that the proposed lines were for speculative purposes only, so an adverse report was given by the committee.

## J. A. RUTHERFORD.

J. A. Rutherford, who has for the last ten years been with the Westinghouse Electric & Manufacturing Company, has tendered his resignation, to take effect February 20, and accepted a position with the Johnson Company, Johnstown, Pa., as salesman in the street railway department. Mr. Rutherford is an ex-Canadian, having been born in Hamilton, Ontario. He commenced his business career with the steam railroads, but left that service to start with the Edison

J. A. RUTHERFORD.

Company, at Hamilton, when that company was organized in 1883 to manufacture under Edison patents for Canada.

In 1886 he was transferred to the main office of the company in New York, but left there that year to accept flattering overtures to return to his first love, steam railroad-ing. Having tasted of electricity, the old work did not prove congenial, and Mr. Rutherford in 1888 accepted a position in the office of the general superintendent of the

Westinghouse Electric & Manufacturing Company.

When this company commenced the manufacture of street railway apparatus he was the first to be transferred and was made assistant to H. McL. Harding, the manager. Under Mr. Harding's tuition he began his experience as salesman, and since 1892 has acted altogether in that capacity.

Mr. Rutherford has made a host of friends who will be glad to know that he will remain in the street railway world.

## LAUGH AND GROW FAT.

I was extremely pleased at Mr. H. P. Brown's article in the REVIEW of February, entitled, "Every Inch a King." He does me honor to take the time and attention he must have taken with his article.

It is true I do not know Mr. Brown, personally, and I am sorry I do not, for I would then have been more careful in my language and not brought him to the pitch of anger that seems to have possessed him.

Calling names is no argument, nor a support of one, and your mathematics, Mr. Brown, is far less convincing.

"Figures are queer things for kings to fumble with."

The definition of "fumble" in the sense as used is "to seek awkwardly."

Now, the only figures I made were from an experiment by Mr. Ran, as compared to one made by Mr. Brown, and he assumes they were both made fairly, of which assumption I grant the truth.

I did not even intimate that "cast scrap iron assumes the tensile strength of rolled steel," nor that "the expansion co-efficient of steel rail shrinks modestly to zero," and the cool reader will quickly see that I "assumed" nothing.

All of this is an exhibition of anger and should not enter into an argument of mathematics. Mr. Brown says, "Certainly some one has blundered badly." Let the reader, coolly, with paper and pencil, see who:

I accept Mr. Brown's basis of figuring; that is, the rail

is 90 pounds to the yard, the hole  $\frac{7}{8}$  in. by  $\frac{3}{4}$  in., and that the cast-weld joint has 8 times the sectional area of the rail, but with  $\frac{1}{2}$  the conductivity of the rail and that the voltmeter terminals were placed in both cases alike.

Mr. Brown says, "The actual section of the joint at junction is 81 square inches, 9 of which are steel and 72 iron. The latter is equal to 36 square inches of steel and the joint to 41 of steel." Evidently some one did blunder; 9 and 36 are 45, not 41 Mr. Brown.

This, however, is a small affair and as every one is liable to make errors, I will admit it is an error. Of course this throws the whole of his mathematical calculation out, as the 41 was his basis. If, however, he had used the 45, his deduction would be still greater in his favor, providing his method of figuring was at all proper.

He says, "There are, therefore, two paths for the testing current, connected in parallel with each other; one directly through the rail ends, and the other from the sides and bottom of the rails through the metal of the joint."

The figure quoted by his majesty (me) now give us common mortals (him) a means of getting the resistance of each of these two paths.

"Now, this hole has taken from the contact area of the rail ends a piece of metal about  $\frac{7}{8}$  inches by  $\frac{3}{4}$  inches, or 0.65625 of a square inch. The hole would affect only the path through the rail ends."

Now, if there are two separate and distinct parallel paths

and Mr. Brown disturbs one, he should leave the other alone, as he says they are two distinct paths, and if he takes 0.65625 of a square inch from the rail ends, he has added to their resistance just as much as that amount relates in percentage to the whole area of the rail ends. He assumes that with the rail ends intact, the drop is .0107 volts and with the hole, the drop is .012 volts, a difference of .0013 volts. This latter figure, then, represents the resistance of the hole in this separate and distinct path.

Now, much to my surprise, he declares that paths 1 and 2 are one path and that the hole in path 1 is 1.6 (1.46) per cent of the two separate and distinct paths and then reasons on in this illogical way.

To illustrate the peculiar system of mathematics, as presented by Mr. Brown, I will ask the reader to draw an imaginary line around the joint, of sufficient diameter to make the sectional area of the joint and rail forty-five square feet instead of forty-five square inches.

We now have the area of the hole the same .65625 of a square inch, the drop is .0013 of a volt, just the same, as the paths are separate and distinct, but how different the relations - we find that .65625 instead of being 1.6 (1.46) per cent is reduced to .0001 of one per cent and is represented by the .0013 of a volt just the same.

Now, what a wonderful transformation: The rail ends, if insulated, would increase the drop .01857 volts, if the joint was 45 square inches; but, if it was 45 square feet, it would increase the drop 13. volts and as this represents the carrying capacity of the rails, you can go on ad infinitum increasing the joint, only at the junction of the rail ends, until the rails carry a current far greater than the ammeter shows, issuing from the station.

Mr. Brown evidently forgot that path 2 is based upon contact area and not sectional area at the rail ends. I trust that all of Mr. Brown's figures are not as faulty as these are.

Regarding the challenge, I will say I have no authority to accept a challenge for the Falk Manufacturing Company, but I have no doubt but that it would gladly accept one, if it is offered on fair terms, and would suggest that as Mr. Brown has seen fit to criticise its joint with no aim in view other than to advertise the plastic-alloy plug, if he does challenge them, he should also agree that if the joint has at least the carrying capacity of the rail, he will publish a testimonial over his signature that the Falk cast-welded joint is not only mechanically but also electrically perfect, and by so doing restore himself to his former professional standing.

Again, Mr. Brown, evidently in the absence of good reason, calls attention to the title cast-welded as a misnomer, in this he may be right, but I do not believe it is of interest sufficient to take space to explain to him why the name is better than cast-fluxed or cast-amalgamated.

In concluding this controversy, I desire to thank Mr. Brown for his kindness in offering an opportunity of resenting a very unjust and unprofessional attack on the Falk Cast-Welded Joint.

HENRY R. KING.

## COLUMBUS STREET CARS RESUME OPERATION.

In the February issue of the REVIEW mention was made of the fact that the street railway of Columbus, Ind., had ceased operation on account of the advance in insurance rates.

Electric traction was inaugurated on the horse car line in the spring of 1893, but the traffic was light. Electric lights were furnished to parties wishing a day-time service, which could not be obtained from the local lighting company. Current for both the lights and street cars was taken from the same generator, but the lamps were supplied with current from a separate circuit. This arrangement gave satisfaction and not an accident of any kind occurred during the four years it has been installed. Some two years ago the board of underwriters required the payment of an additional 1 per cent premium where the electric lighting service was in use. The case was argued before the Indiana State Board, the Local Board Commission No. 1, at Cincinnati, and the Underwriter's Electrical Bureau at Chicago, and the ruling was set aside. After several vacillating decisions the underwriters decided to enforce the rule on January 6th. The essential objection on which the rule was based was that the light and power line was grounded through the generator. As this was the more profitable part of the plant

the street car service was abandoned. However, Mr. Crump succeeded in securing a sufficient number of light subscribers to justify the purchase of a low potential dynamo. This was installed, removing the ground for objection by the underwriters, and after two weeks of idleness the street car service was continued.

## A NEW CROSSING SIGNAL.

Homer A. Parrish, of Jackson, Mich., a few months ago received a patent on a crossing signal, applicable to steam or trolley roads. It has been in operation on the street car system in Jackson for two years and has given entire satisfaction. For railroad work perhaps the greatest objection is that it is an "open circuit" alarm and does not indicate when it is out of order, yet this is not a serious objection here for the lighting of the lamps will assure the trainmen of its being in good repair. The accompanying diagram shows the arrangement of the connections. At a safe distance from the crossing, say 500 feet, a box is supported by the span wire above the trolley. When the trolley wheel strikes the trip A, it presses the springs B and C together, thus forming a circuit from the feed wire through the 5 incandescent lamps G, the bell H, and to the ground. These magnesium bronze springs, B C, immediately separate, but not before the bell has sounded and the electro-magnet D, lifted the trigger F, which drops the tongue E on a set screw,

connected to the ground. The five lights G, are now burning in a box of red glass which is located at some convenient place on the crossing.

When the car passes the crossing the trolley wheel strikes the trip A, which presses the springs B and C together, forming a circuit for an instant through the electro-magnet L. This actuates the arm M, which presses the tongue E into its former position and breaks the circuit through the lamps. Thus the gong is rung when the car is some distance from the crossing and the incandescent lamps remain lighted until the car is past the danger point. Very little power is absorbed by the signal, the incandescent lamps only taking about 2.5 amperes for a few seconds. Such a current necessitates but small wires in all the connections. If need be, ordinary iron wire can be used. The parts are so designed that there is little wear and the cost of repairs is very small. This device would assure greater safety at the points of intersection of trolley lines with each other or with steam roads as well as at street crossings.

### Alabama.

MOBILE, ALA.—A franchise for the use of Water street was granted the Mobile Street Railway Company.

MOBILE, ALA.—The Mobile Light & Railway Company has commenced work on altering and extending the system. Car sheds, 75x200 feet will soon be erected at Monroe Park. Mr. Wilson of this company says that these improvements will be in readiness for the spring traffic.

### California.

LOS ANGELES, CAL.—Wealthy men are said to be considering a proposition to construct an electric railway from Los Angeles to Redlands, to be operated with power derived from the Santa Ana and San Gabriel rivers.

SAN BERNARDINO, CAL.—C. R. Lloyd of the San Bernardino Electric Company proposes to build a street railway with a loop line to Harlem Springs. Mr. Lloyd asks a bonus of \$5,000 and the franchise held by the company now operating the car line.

LOS ANGELES, CAL.—The Los Angeles & Pasadena Railway Company is now building a large bridge over the river and this, with the new line proposed, will obviate the necessity of running its cars over the tracks of the Los Angeles Railway Company. For the new line 40 car loads of 60-pound rails have been received and these will be welded.

SAN FRANCISCO, CAL.—The Santa Rosa & Sonoma County Railroad Company, of which Col. Geo. Stone, of the Union League Club, is president, is receiving bids on 21,000 tons of rails and 75,000 cross ties. The \$700,000 worth of bonds have been contracted for by New York York parties and will be advanced about February 25. The gage of the road is to be 3 feet 6 inches; electric freight cars will be used as well as passenger.

SAN BERNARDINO, CAL.—The Southern California Power Company has been formed to develop the power of the Santa Ana River for transmission to Los Angeles, 75 miles distant, for railway and lighting purposes. Capital stock, \$1,000,000, and principal stockholders Henry Fisher, of Pittsburg, Pa., and H. S. Sinclair, manager of the Redlands Electric Light & Power Company. The company will make its headquarters at Redlands, Cal.

### Chicago.

CHICAGO.—G. Herbert Condit, receiver of the Englewood & Chicago Electric Street Railroad, has petitioned the federal court for permission to issue \$313,000 of receiver's certificates to pay off liens and complete the road.

CHICAGO.—The reorganization committee of the Englewood & Chicago Electric Street Railway suggests an immediate sale of the road. Judge Showalter orders that all claims against the road be filed with Henry W. Bishop, master-in-chancery.

CHICAGO.—The \$60,000 of receiver's certificates, issued for the Englewood & Chicago Electric Railway, have been purchased by the Hanover National Bank. The certificates bear 7 per cent interest and were purchased by the bank at par, less 2 per cent commission.

### Connecticut.

HARTFORD, CONN.—The railroad committee has reported favorably on the bill granting a charter to the Central Railway & Electric Company of New Britain for an extension to Hartford.

DANBURY, CONN.—Senator Woodruff, of Sherman, has introduced in the Legislature a bill to incorporate a company to build a trolley line from Danbury north to Sherman, to furnish transportation for farm produce.

BRIDGEPORT, CONN.—Henry Setzer, Jr., a member of the board of directors of the Traction Company informed the Board of Appointment that the company would begin and complete as soon as possible the double track on Park avenue, south of State street.

SUFFIELD, CONN.—Jesse Starr of New York, is the chief promoter of the Southwestern Electric Railroad Company, which will connect Springfield, Mass., with this city. Others interested are Arthur Sikes and A. R. Pierce of this place, Frank Grange of East Granby, and Frank C. Root of West Suffield.

### Delaware.

WILMINGTON, DEL.—It is reported that J. Edward Addicks, W. B. Rockefeller and George Gould of New York, will be the incorporators of the Peninsular Electric Railway Company, which will connect every town in Delaware by trolley. Capital, \$1,000,000.

DOVER, DEL.—Notice was given of a bill to incorporate the Chester, Claymont & Wilmington Electric Railway Company with a capital stock of \$50,000. Those interested are I. N. Carswell, Dr. Jacob Derickson, I. S. Elliott, E. T. Cooper, F. A. Hanby and Clifford Perkins.

### District of Columbia.

WASHINGTON, D. C.—A. E. Randle, president of the Capital Railway, has applied for a permit to erect trolley poles through Anacostia.

WASHINGTON, D. C.—R. L. B. Clark, of East Washington, has secured the sanction of the commissioners to a bill before Congress, giving the East Washington Heights Traction Railway a right of way in the district. Col. Archibald H. Bliss, James G. Berret, Hamilton Disston, George S. Bantwell and others are interested.

WASHINGTON, D. C.—The Washington, Westminster & Gettysburg Railroad Company has been incorporated to build through Montgomery, Howard, Frederick and Carroll counties, with a lateral branch from Sandy Spring or Laytonsville to Frederick. The capital stock is \$100,000, and the incorporators are William B. Thomas, James A. C. Bond, T. Reifsnider, T. Herbert Shriver, John A. Shoob, Stilson Hutchins, George Colton Smith, James B. Colegrove, H. A. Cacey, E. M. Hoffer, John R. Cunningham, David Cowan, H. Stewart Roberts, John L. Reifsnider, Milton Schaeffer and Edward T. Lawyer.

### Florida.

ORLANDO, FLA.—J. M. Cheney of Orlando, Fla., on March 1 purchased the Orlando Street Railway at sheriff's sale. The property, which was sold for taxes, has been neglected for two years, and will require extensive repairs.

### Illinois.

OTTAWA, ILL.—The Ottawa Electric Railway Company has purchased 18 acres to be improved as a pleasure resort.

DIXON, ILL.—There is talk of an electric line from this town to Rockford, traversing the Rock river valley. Jason C. Ayers is one of the promoters.

WAUKEGAN, ILL.—The county board of supervisors in a special session granted a 20 year franchise to the Bluff City Street Railway. This makes the right of way secure as far south as the Cook County line. Chas. E. Loss, Pullman Building, Chicago, is president of the company.

### Indiana.

MADISON, IND.—Charles R. Johnson has been appointed receiver of the Madison Light & Railway Company by the federal court on application of John Dona, of Chicago.

MARION, IND.—Supt. W. C. McWhinney of the Marion City Railway Company, has gone to New York City to place orders for machinery for the new power house and material for the Fairmount extension.

## Maine.

EASTPORT, ME.—The Eastport Street Railway Company will be incorporated.

BANGOR, ME.—Right of way for a line through Newburg, Dixmont, Monroe and Searsport is wanted by the Hampden & Winterport Railway & Light Company.

KITTERY, ME.—Stockholders of the Portsmouth & York Beach Electric Railroad Company met March 1 at Kittery and voted to increase the capital stock from \$50,000 to \$200,000.

WATERVILLE, ME.—A. O. Lombard has purchased the interests of I. C. Libby in the Waterville & Fairfield Electric Railroad, Light & Power Company, and has been made general manager. A new power station with steam plant will be commenced in the spring.

BANGOR, ME.—All the property of the Pen Argyl, Bangor & Water Gap Electric Railroad, was sold at auction to John C. Merrill, of Easton. Mr. Merrill bought the property at a judicial sale recently, but this was a foreclosure sale to divest a mortgage of \$500,000 and give him a complete title. The road will likely be built this summer.

## Massachusetts.

NEWTON, MASS.—Watertown has granted a franchise to the Newton Street Railway Company.

WESTFIELD, MASS.—The Woronoco Street Railway Company has accepted its franchise for a line to Springfield.

TAUNTON, MASS.—The Taunton & Brockton Street Railway Company has filed a petition for a franchise in Taunton.

BROCKTON, MASS.—Right to extend its tracks on certain streets has been granted the Brockton Street Railway Company.

NEW BEDFORD, MASS.—The Union Street Railway Company has been authorized to issue \$100,000 additional capital stock.

BROCKTON, MASS.—I. N. Nutler and J. S. Allen, of East Bridgewater, are interested in a proposed electric road to Brockton.

BOSTON, MASS.—A petition has been filed to incorporate the Bay State Elevated Railroad with a capital of \$10,000,000. Wm. B. Mack and F. W. Longstreet are named as incorporators.

NEEDHAM, MASS.—A franchise has been granted the Newton & Boston Street Railway for a road from the Newton boundary to the Newton Upper Falls, the line to be built in the spring.

BOSTON, MASS.—John Graham is at the head of a company recently organized to build an electric railway from Forest Hills to Neponset, in connection with the Quincy & Boston Street Railway. The capital stock is \$100,000.

ANDOVER, MASS.—The selectmen have granted a franchise to the Lawrence & Reading Street Railway Company for tracks in Mam street from Andover to North Reading. A portion of the work must be completed by September.

WESTFIELD, MASS.—The Woronoco Street Railway Company has placed an order for 6 miles of rails for the contemplated extensions. The stockholders have voted to petition the railroad commissioners for the privilege of increasing the capital stock from \$50,000 to \$100,000.

BRIDGEWATER, MASS.—The selectmen have granted the franchise asked by the Bridgewater, Whitman & Rockland Street Railway Company for a line in Broad street. The proposed line is part of a system which is to provide a direct route from Taunton to Nantasket.

AMESBURY, MASS.—The Haverhill & Amesbury Street Railroad Company has petitioned the Salisbury selectmen for permission to erect poles and equip a road from the Square to the New Hampshire line. If this is granted it is expected that the road will be built at once, so as to be ready for the summer's traffic.

ROCKLAND, MASS.—The Bridgewater, Whitman & Rockland Street Railway Company has applied for a franchise to extend to miles of trolley road. Charles H. Wilson of Boston is treasurer, and the directors are, Geo. J. Morse of Hyde Park; Fred C. Hinds of Newton; Chas. L. Stevens of Rockland; Chas. H. Wilson of Boston; J. T. King of Abington; Chas. F. Allen of Whitman, and Richard W. Nutter of East Bridgewater. Capital stock is \$25,000.

## Michigan.

CARO, MICH.—F. S. Wheat has been granted a 30-year franchise for a street railway at Caro.

PONTIAC, MICH.—The Plank Road Company has finally given a right of way from Birmingham to this city for the construction of the electric railway.

GRAND RAPIDS, MICH.—The pavilion of the Consolidated Street Railway at Reed's Lake was burned February 22, causing heavy loss. Well insured.

PONTIAC, MICH.—The Oakland Electric Railroad will be extended to this place and the management intends to apply to the Plank Road Company for a right of way between here and Birmingham.

NEW BALTIMORE, MICH.—John B. Dyar filed a certified check for \$2,000 with the treasurer. This is the last check necessary by terms of the franchises for the road between Detroit and Port Huron.

ERIE, MICH.—Mr. Riopelle, of the firm of Johnson, Jacobson & Riopelle, Detroit, offered the township a bonus of \$3,000 for a right of way to build an electric road. It was referred to the township board which will report next week.

SAGINAW, MICH.—John E. Nolan, of this city, who is interested in the Flint & Fenton Transportation Company, says that the company will be ready to begin operations about April 1. The cost of the line, which will be 21 miles long, is to be \$250,000.

SAGINAW, MICH.—The court has denied the application of bondholders for a receiver for the Consolidated Street Railway on the ground that by the terms of the mortgage six months must elapse between default and the appointment of a receiver.

MT. CLEMENS, MICH.—James G. Tucker, receiver of the French road, was granted a franchise for an electric line between the city limits and Chesterfield township. A bond of \$3,000 must be filed in 20 days, guaranteeing the road to be built by November 1.

BENTON HARBOR, MICH.—The Benton Harbor Electric Railway & Transit Company has let contracts for a tunnel 2,300 feet long, under the residence portion of the city. The disused Courtright factory will be converted into car house and power station.

DETROIT, MICH.—John B. Dyar was given a franchise, March 2, for a line on Crocker avenue, Front and East streets, Mt. Clemens. At the same time James G. Tucker, receiver of the French line, was given a franchise on North Gratiot avenue. Each gave \$2,000 bonds to carry out the contract.

BAY CITY, MICH.—There seems to be every prospect of two electric roads being built this summer. The one to Port Huron is backed by Charles Montague, of Caro, and he is considering a plan to dam the Cass river for power. The other road will connect this city and Unionville, F. S. Wands and L. L. Culver being the chief promoters.

MONROE, MICH.—Messrs. Jacobson & Johnson, of Detroit, have asked the council for a franchise through this town, promising to build the line next month. Right of way has been secured from Trenton to LaSalle. Those interested in the Detroit & Toledo line are W. C. Sterling, Strathearn Hendrie, Truman Newberry, Geo. Hendrie, G. F. Smith, Cameron Currie, Frank T. Lodge and James S. Carleton.

## Missouri.

KANSAS CITY, MO.—The Metropolitan Street Railway Company has finished its big electric power station at Riverview.

ST. LOUIS, MO.—The Shaw Avenue Electric Railway Company has been incorporated to construct a line. Capital stock, \$40,000; incorporators, J. D. Peckington, Chris Von der Ahe and Charles E. Wehner.

ST. CHARLES, MO.—The St. Charles & St. Louis Bridge Company will endeavor to secure the operation of an electric line to St. Louis. Contracts for a bridge over the Missouri river have been let, contingent only on the construction of the electric railway.

ST. LOUIS, MO.—Charles Green on March 6 was appointed receiver of the People's Railway Company, which defaulted its interest on bonds January 1.

ST. LOUIS, MO.—Application has been made for the appointment of a receiver for the Fourth Street & Arsenal Railroad, which failed to meet the semi-annual interest on its bonds March 1.

ST. LOUIS, MO.—James D. Houseman, of the Highlands Scenic Railroad Company, made application to the county court at Clayton, for a franchise to build an electric road connecting the De Hodiamont and the St. Louis & Kirkwood electric lines.

KANSAS CITY, MO.—Frank Dixon, who bought the old Union cable road at special master's sale for \$1,250, says that the line will not be torn up, but will be put in condition for running with the expectation of using electricity as power.

## New Hampshire.

CONCORD, N. H.—The 6 bills introduced in the Legislature, to incorporate 6 companies to construct a chain of electric railways from Massachusetts to Canada, have been killed.

KEENE, N. H.—Surveys of the Keene Electric Railway have been made between Keene, Swanzey and Marlboro. E. F. Lane, of Keene, is president; and Samuel Wadsworth, of Keene, chief engineer.

## New Jersey.

TRENTON, N. J.—Chancellor McGill has ordered the South Jersey Traction Company's lines to be sold at master's sale.

PLAINFIELD, N. J.—The Brunswick Traction Company and the New York & Philadelphia Traction Company are rival applicants for a franchise in Piscataway township.

NEWARK, N. J.—The petition of Union Traction Company has been granted to lay a double track on Elm street from the New York & Greenwood Lake Railroad north to the township line.

EAST ORANGE, N. J.—The Consolidated Traction Company was granted permission by the township committee to build a line on Central avenue. David Young is president of the company.

JERSEY CITY, N. J.—The Consolidated Traction Company contemplates a general extension of its lines. An important line is mapped out between the Jersey Central Railroad Ferry in Jersey City and the Oranges.

CAMDEN, N. J.—Articles of incorporation were filed by the North Jersey Traction Company, its object being to build a trolley line in Amboy; capital stock, \$100,000. Theodore T. Hansen, Geo. D. Armstrong and Richard H. Turner of Atlantic City, are the incorporators.

ROCKAWAY, N. J.—The Rockaway Electric Railway Company has been incorporated to build a double track street railway in Rockaway. Capital stock, \$250,000; incorporators, Remington Vernam, of Averte, L. I.; Joseph McClean, George F. Keller, Cornelius Connolly, Theo. Bernard, James Crowley, Henry C. Davidson, and Fred. Gibbs, of Brooklyn, and Michael Crowley, of New York.

## New York.

BUFFALO, N. Y.—George P. Smith is negotiating a sale of the Tonawanda & Wheatfield Electric Railway.

BUFFALO, N. Y.—The Crosstown Street Railway Company has filed plans for its car house, which is to cost \$15,000.

ELMIRA, N. Y.—The Elmira & Horseheads Railway Company are considering the adoption of electric heaters in all the street cars.

WATERTOWN, N. Y.—The Watertown & Brownsville Street Railway will be sold under foreclosure of four mortgages aggregating \$160,000.

YONKERS, N. Y.—An extension of the Yonkers trolley line down New Main street and South Broadway to the New York city line is to be built very soon.

PENN YAN, N. Y.—The recently incorporated Penn Yan, Keuka Park & Branchport Electric Railroad Company has applied to the village trustees for right of way.

WHITE PLAINS, N. Y.—The White Plains & Elmsford Electric Railway Company has been granted a franchise to construct a line down Lexington avenue and Post road.

CORTLAND, N. Y.—The Cortland & Homer Traction Company proposes to equip its plant with new machinery, provide new lamps and rearrange its entire circuit to do the city lighting.

NEW YORK, N. Y.—The Third Avenue Railroad Company and the Metropolitan Street Railway Company have discontinued their fight against the granting of additional franchises to one another.

NEW YORK, N. Y.—It is said that the Metropolitan Street Railway Company has closed contracts with the General Electric Company to supply insulators, generators, motors and all electrical equipment for the new conduit systems.

BUFFALO, N. Y.—The Niagara Falls & Lewiston Electric Railway has been mortgaged for \$1,000,000 to the Knickerbocker Trust Company of New York. This sum will be used in paying indebtedness and making improvements.

SYRACUSE, N. Y.—President Palmer, of the Suburban Railroad Company said that the cars would likely be running on the road by June. McCartney, McElroy & Co., of New York, are preparing the plans. No contracts have been made as yet.

BUFFALO, N. Y.—President Herbert P. Bissell, of the Traction Company, has practically closed a deal with Bankers Tallman & Co., of New York, securing money to build the 66 miles of road projected by the company. Charles W. Ricker, electrical engineer, has the specifications ready. Estimated cost of extensions is \$1,980,000.

SYRACUSE, N. Y.—The Syracuse Rapid Transit Company has spent large sums for relaying the tracks, equipping the road with new cars and building a power house. About \$25,000 more will be spent on the power house machinery and \$60,000 on the new car barns which will include a modern machine shop with all conveniences for handling the motors.

BUFFALO, N. Y.—The Buffalo, Gardenville & Ebenezer Electric Railway Company has been given a franchise by the highway commissioner of West Seneca to put down tracks on Clinton street, Aurora Plank road and on the Union road. These extensions are to be from 5 to 6 miles in length and will be built this spring. Chas. F. Schoepflin is president and Wm. P. Smith, secretary.

PENN YAN, N. Y.—The Penn Yan, Keuka Park & Branchport Railway Company has been incorporated to build the long talked of electric railway between Penn Yan and Branchport. Capital stock, \$100,000; incorporators, William S. Reed of Leominster, Mass.; W. H. Tylee, O. W. Rugg and A. White of Worcester, Mass.; C. L. B. Tylee, Frank Viele and George Tylee of Corning; H. S. Sill of Bluff Point, and John H. Lawer of Penn Yan.

**COXSACKIE, N. Y.**—The Greene County Traction Company has been incorporated to operate a street surface electric railroad five miles long, from the village of Coxsackie to a point three miles beyond the village line. Capital, \$50,000; directors, Edward J. Duggan, Albany; Henry E. Stern, William E. Drisland, E. J. B. Murray, Michael F. Cantwell, and Edward J. McCaffrey, of Albany; Matthew J. Duggan, of Greenbush; William G. Raines, of New York City, and George C. Spencer, of Chicago.

**CATSKILL, N. Y.**—Application to incorporate the Catskill Electric Railway Company has been made by Charles S. Williamson, M. D., 25 Third Place, Brooklyn, N. Y.; William S. Robert, 200 Halsey street, Brooklyn, N. Y.; Daniel W. Sharpe, Catskill, N. Y.; Louis F. Robert, 200 Halsey street, Brooklyn, N. Y.; Michael W. Conway, 187 Monroe street, Brooklyn, N. Y.; William C. Courtney, 406 Vanderbilt avenue, Brooklyn, N. Y.; William C. Wood, 229 Quincey street, Brooklyn, N. Y.; Howard A. Mock, 106 Monroe street, Brooklyn, N. Y.; Schuyler W. Mattison, 67 Lincoln avenue, Newark, N. J. Two miles of road will be built; capital stock, \$30,000.

## Ohio.

**XENIA, O.**—Jno. P. Martin has asked the council for a franchise to build a street railway.

**WARREN, O.**—The Trumbull Electric Road of Warren expects to extend its line to Leavittsburg.

**WARREN, O.**—Daniel Moynahan has sold for \$90,000 his electric railway to the Mineral Ridge & Niles Street Railway Company.

**LIMA, O.**—The Lima Street Railway has applied to the council for a franchise to extend its lines to Hover's Park and the Solar Refinery.

**DAYTON, O.**—Surveyors are in the field for the new electric road from Dayton to Wilmington via. Beavertown, Bellbrook, Spring Valley and New Burlington.

**YOUNGSTOWN, O.**—The Youngstown Park & Falls Street Railway Company has been granted right to extend its line over Warren avenue and South Market street.

**TOLEDO, O.**—A franchise will soon be asked for 12 miles of electric street railway. C. T. Geddes, formerly superintendent of the Bowling Green road, is attending to the affairs of the new company,

**AKRON, O.**—It is stated by Geo. C. Mozer, one of those interested in the Canton-Akron Electric Railroad Company that the line would be built this year. Wm. A. Lynch, of Canton, and president of the Canton-Massillon Electric Railroad Company, is backing the new road.

**CINCINNATI, O.**—Right of way has been given the Dayton Traction Company through Bond Hill for 23 years. The company agrees to have the road in operation by the close of the year. Senator Foraker, Andrew Hickenlooper and Senator Chas. Fleischmann are interested in the company.

**MANSFIELD, O.**—W. E. Haycox writes that the franchises for the construction of the electric railway from Bucyrus to Galion have all been secured, except in Galion, where the ordinance has passed its second reading. Mr. Haycox expects to be ready to start the construction by April 1.

**DAYTON, O.**—The Dayton & Western Traction Company was incorporated at Columbus with a capital stock of \$400,000. The line will be from this city through New Lebanon, West Alexandria and Eaton to Richmond, Ind. County Commissioner John B. Hunter, Dr. J. E. Lowes, Col. R. M. Nevin, C. L. Kurtz of Columbus, Oscar Sheppard and J. E. Feight are the incorporators.

## Pennsylvania.

**CHARLEROI, PA.**—The Charleroi, Bellevernon & Fayette City Street Railway Company has been incorporated. Capital stock, \$20,000; president, William M. Bell, Pittsburg.

**PHILADELPHIA, PA.**—The Philadelphia & Merion Railway Company has been incorporated to build an electric railway. Capital stock, \$25,000; president, William G. Huey, 1815 Vine street.

**HARRISBURG, PA.**—A charter was granted to the Doylestown & Easton Electric Railway Company, to construct a line between the two cities. Capital stock, \$100,000. Harry J. Shoemaker is president.

**PHILADELPHIA, PA.**—John H. Fow is president of the Gray's Ferry & Woodland Avenue Connecting Street Railway Company, which has just been incorporated, with \$6,000 capital stock, to build one mile of road.

**BRADFORD, PA.**—H. L. Pierce, of Leominster, Mass., is president of the Olean, Rock City & Bradford Railroad Company, which was recently incorporated to build 10 miles of road from Bradford to the New York state line. Capital stock, \$100,000.

**HOMESTEAD, PA.**—The Homestead & Highland Street Railway Company is preparing to complete its connections for a through line to the heart of Pittsburg. To obtain funds the company has just given a mortgage for \$400,000 to the Union Trust Company.

**DOYLESTOWN, PA.**—The Doylestown & Easton Street Railway Company is getting right of way for 16 miles of road. No contracts for construction will be made for some time. Harry J. Shoemaker, president; M. H. Stout, secretary; and S. A. Hellyer, treasurer.

**TITUSVILLE, PA.**—Mayor Benedict has signed the ordinance granting the Titusville Electric Traction Company the right to construct and operate a street railway in Titusville. One year's time is allowed in which to complete the road in the city, after which it is proposed to extend to Pleasantville and Hydettown.

**BADEN, PA.**—The Baden Electric Street Railway Company has been incorporated to build a line from Allegheny to Baden, where it will connect with the Economy Electric Railway Company, controlled by the same interests. Capital stock, \$50,000; incorporators, Richard R. Quay, of Sewickley; John C. Oliver, Allegheny City; Edward G. Applegate, Braddock; Henry D. Atwood, Leet township, and James F. Burke, Pittsburg.

## Texas.

**CORSICANA, TEX.**—W. B. Brooks, of the Glenwood & Polytechnic College Street Railway, is looking over the ground with a view to constructing an electric railway in Corsicana.

**AUSTIN, TEX.**—Ira H. Evans, of Austin, has been appointed receiver of the Austin Rapid Transit Company at the instance of the International Trust Company of Boston, which holds \$343,000 of first mortgage bonds.

## Wisconsin.

**EAU CLAIRE, WIS.**—H. N. Bates and Arthur Appleyard, both of Boston, were inspecting the street car system here with the view of purchasing it. If the deal is consummated the system will be reconstructed throughout.

**WAUKESHA, WIS.**—S. I. Henderson and others have incorporated the North Greenfield & Waukesha Electric Railway Company. Summer pleasure travel will be catered to. The company has right of way and capital, and a traffic arrangement will be made with the Milwaukee Street Railway.

## Wyoming.

**CHEYENNE, WY.**—A franchise for 99 years has been granted the Cheyenne Electric Railroad Company. Three Denver parties are interested: M. S. Weller, A. N. Butler and J. M. Freeman also C. T. Metz and W. McGill, of this city. The proposed line is to be about nine miles long. The Cheyenne Street Railway Company also contemplates putting in an electric system.

## Canada

**ALGOMA, ONT.**—T. M. Kirkwood and others have petitioned for the incorporation of the Mineral & Timber Electric Railway Company to operate a railway from a point between Chelmsford and Sturgeon Falls north to Wahnapitae Lake, and south to a point between Killarney and French River.

**HALIFAX, N. S.**—The Halifax & Bedford Electric Railway Company has been incorporated. Capital stock, \$300,000; incorporators, William E. Crowe, Henry J. Crowe and A. E. Sulis.

## W. H. HANSELL.

William Henry Hansell, president of the Hansell Spring Company, was born in Philadelphia. At the age of 15, having been graduated from the Friends School in Philadelphia, he entered the University of Pennsylvania, where he remained for three years, working in the drafting room of the Baldwin Locomotive Works during the vacations. Leaving college, where he had pursued an engineering

W. H. HANSELL.

course, Mr. Hansell went with the Charles Scott Spring Company, where he remained four years, first as mechanical engineer, then as superintendent and finally as manager of the street railway department. In February, 1895, he left the Scott Company and purchased an interest in the old Keller & Cook Spring Company of New York. Within one month he bought the entire business and changed the name from the Keller & Hansell Company to the Hansell Spring Company. The business quickly responded to the energy and ability of Mr. Hansell, and outgrew the New York shops. The works were removed to Newark, N. J., and in August, 1896, increased to twice the size of the old plant. Within two months the capacity was again doubled by building a new two-story building

60 x 110 ft. On February 1, 1897, a further addition was made, and the present quarters are as shown in the illustration. The company manufactures all types of springs, but makes a specialty of elliptic and spiral springs for steam and street railway rolling stock. In his long experience Mr. Hansell has made many friends in the trade who wish him a continuance of prosperity.

## A CHAPTER OF ACCIDENTS.

Several bad accidents have occurred during the past month. A motorman on the Geneva, Waterloo & Seneca Falls road, mistook the conductor's signal, and on crossing the New York Central tracks, was struck by a passenger train. The car was wrecked and four passengers injured, none fatally.

On the South Milwaukee line a car jumped the track on

down grade and turned over two or three times. The 18 passengers were more or less injured but none fatally.

In this city a Calumet car was run down by an Eastern Illinois passenger train and the motorman and two passengers killed and four others badly injured. The car was reduced to kindling wood.

One of the oilers on the Brooklyn avenue cable road, Kansas City, remained in the conduit while a car was passing and in some manner was caught by the grip and dragged nearly 100 feet. He died shortly after being taken out.

A West Side electric car took a good start toward going into the Chicago river. The draw had been partially opened

by the bridge tender for the purpose of more conveniently cleaning and oiling the machinery, and when this fact was discovered by the motorman of the approaching car, the slippery rails prevented his stopping. A horse and wagon that had been waiting for the bridge to be swung back into place were struck by the car and pushed into the river. Both drivers, the conductor and four passengers had ample time to escape. The car slid over the approach but the front end rested on the abutment, where it remained poised at an angle of 45° all day. The assistance of a floating derrick was necessary to dislodge the car.

## AN IOWA INTERURBAN LINE.

The Mason City & Clear Lake Traction Company is now building a line between these points in Iowa that is typical of the new class of electric railways, which in addition to the ordinary passenger traffic, handle express, baggage and mail and receive and distribute standard steam railway freight cars to various side tracks along the line. The cars ordered for this company consist of one combination passenger and baggage car with 32-ft. body and 42 ft. over all, two of the same style 22-ft. body and 29 ft. 6 in. over all, five 42-ft. open trail cars, one 40-ft. closed trail car, one 30-ft. milk car and two 16-ft. closed passenger cars. The motor cars are equipped with four 50-h. p. Walker motors and all of them mounted on Peckham trucks. A switching locomotive for handling the steam railroad cars is also ordered; it is to be a specially constructed car mounted on a Peckham extra heavy 7-B truck. The entire electrical equipment is to be supplied by the Walker Company, the steam plant by the E. P. Allis Company, and the rail bonds, of the horse shoe type, by the J. M. Atkinson Company.

**THE SADDLER SIGNAL SYSTEM.**

In a previous issue we have mentioned the signaling system invented by I. N. Saddler, and manufactured by the Saddler Switch & Signal Company, 309 Monroe street, Toledo, O. This month we present a description of the system with cuts illustrating its main features.

This system is entirely automatic and leaves but little to be desired in a simple, effective and economical method of electrical signaling.

The illustrations show the signal box in place upon a bracket, though it may be placed upon a span wire when desirable. The box, Fig. 1, is of iron with a short projecting arm, which is struck by a pin erected upon the top of the car, and is thus driven to one side in the direction in which the car is advancing. This action throws into permanent electrical connection the trolley wire and the projecting arm of the next box which is located at the farther end

FIGURE 1.

of the block or running section. After the car has passed, the arm of the signal box returns to its vertical position.

The photophone box, Fig. 2, is placed upon the car, either overhead, or upon the sash in front of the motorman, and the binding posts are connected, one with the pin on the top of the car and the other with the gearing beneath the car, thus grounding that side of the box.

If now the car has passed the box as shown in Fig. 3, and has driven the arm to one side, the arm will return to its vertical position but the connection between the trolley wire at the box and the projecting arm at the next box will remain. If a car attempt to leave the switch ahead, its contact pin will strike the arm on the box, allowing current to flow through the photophone box, ringing the bell in the box and causing the lamp to burn.

FIGURE 2.

After the car has run through the block to its end its pin will evidently strike the arm there in the opposite direction from that in which the connection was made at the last box. This action will cut the circuit at the box last left, at the

entrance of the block, and thus throw the second arm out of circuit. Thus the car throws on the connection at one end, and throws off the same connection at the other end of the block; no attention is required on the part of anyone, nor is

FIGURE 3.

the circuit grounded, nor the lamp burning except at the instant of giving the signal.

If a car having left the switch, and thus set the contact box in communication with the arm at the next switch ahead, should be compelled to back into the switch again for any purpose, the contact will be broken, thus allowing the car ahead to leave its switch and come on.

The advantages of the system are that it is automatic, simple, economical and not easily tampered with. No lamps or semaphores are required, as the signal is given on the car; the apparatus is simple and easily installed, the connecting wires being all numbered; not having ground connections, there is no danger from lightning; the signal wires need not be of good conducting material, but may be of common iron; the current consumption is trifling, as the contact is but for a moment; there are no parts under the car or on the track; the system works whether the trolley is in contact with the wire or not.

Boxes are provided at points between switches, so that in the event of a car breaking down, the car in the next block may be released and come to the aid of the former; or a device is provided by means of which the signal ahead can be thrown off at any point between switches.

**PROJECTED ROADS IN CONTINENTAL EUROPE.**

Among the many cities of Europe which have granted concessions for or contemplate the construction of electric railways are the following: Olmutz, Austria; Bekes, Hungary; Cologne, Germany; Vienna, Austria, for the Vienna Tramway Company; Prague, Bohemia, for the city council; Teplitz-Schonau, Bohemia, for the city council; Pressburg, Hungary, for Ganz & Co., of Budapest, and Temesvar, Hungary, for the Temesvar Street Railway Company. The following lines now operated with horses will be equipped with electric motors: Gyor, Hungary, for Jakob Lathesz & Co., of Budapest; Czernowitz, Austria, Hungary, for the city council; Aussig, Bohemia, for the city council; Herne to Recklinghausen, Prussia, for the Herne-Recklinghausen Street Railway Company, and Linz, Austria, for the Landerbank, of Vienna.

In the case of the seven men accused of shooting Motorman Breen during the street car strike at Milwaukee last spring, the jury disagreed after being out 65 hours. It is reported that 11 were in favor of conviction.

**Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.**

At Galveston a short strike was occasioned by cutting the men on extra list from 14 to 13 cents an hour. The men won.

A Rhode Island road has two damage suits pending, one alleged to have been caused by ringing the gong, the other because the gong was not sounded.

Additional tracks have been laid on the Brooklyn bridge and two new cables are in place. A sufficient number of new cars have been placed on the line to take care of the heavy traffic.

The report of the Syracuse (N. Y.) Rapid Transit Company showed a deficiency for the last quarter of \$2,537. The Syracuse & East Side road also reported a deficit for the quarter of \$2,895.

The Columbus (O.) Street Railway Company last month made its fifth semi-annual distribution of cash prizes to conductors and motormen for best reports of accidents. Two \$10 and six \$5 prizes were awarded.

On February 8 a car on the line between New York Mills and Utica, N. Y., left the track near the bridge at Yorkville and rolled down the embankment. The car was wrecked but none of the passengers were injured.

The old officers of the Milwaukee Electric Railway & Light Company, were re-elected as follows: President, William Nelson Cromwell; vice-president, Henry C. Payne; treasurer, Edward Edes; secretary, C. A. Spofford.

The war between the big iron companies which has brought the price of T-rails to \$17 a ton, has not materially affected the market price of girder rails. This difference has amounted to about \$4 per ton during the past two months.

The first electric locomotive built south of the Ohio river is a seven-ton machine now building at the Hood Machine Shops, Birmingham, Ala. It is to be used for mine work near Birmingham and will be operated on the overhead trolley system.

The city council of Cedar Falls, Ia., has refused to grant a franchise to the Waterloo & Cedar Falls Rapid Transit Company on the ground that it would kill the business interests of the town by furnishing cheap and rapid transit to Waterloo.

The Greensburg, Jeanette & Pittsburg Electric Railway Company is experiencing difficulty in getting a solid road-bed near Penn station. The ribs in a coal mine near there have been drawn and the ground is settling. The tracks have already been relaid four times.

The Amalgamated Association of Street Railway Employees, proposes to invest \$6,000 in discarded cassettes, which it can buy for \$200 apiece. The pleasures of a car-

ette ride as compared to street car travel makes the price of cassettes seem 200 per cent too high.

At Knoxville, Tenn., a dispute occurred between the Citizens' railway and the city over some track repairs and a small riot ensued. The police got the fire department to help them, and the 200 negroes in the railway's camp were routed when the hose was turned on.

A literal illustration of the scriptural text about the man who climbed up some other way, being a thief and a robber, was discovered in New York when the police arrested a man who for three months has climbed the elevated railroad posts, and thus got around the turnstile.

An accumulation of illuminating gas between the roof of the Boston subway, now building, and the temporary roadway, became ignited, and a disastrous explosion resulted. Three cars of the West End Street Railway Company were completely wrecked and the passengers injured.

Seemingly without provocation an electric car on the Pittsburgh (Pa.), Neville Island & Coraopolis road jumped the tracks at the approach of the Ohio river bridge and plunged into the river. Fortunately there were no passengers on the car, and the motorman saved himself by jumping.

At Rome, N. Y., one of Robert Hardie's new compressed air cars drew 10 loaded freight cars weighing 300 tons on a New York Central switch track. It is reported to have made 8 miles an hour with the load. This is the locomotive which will be tested on the Manhattan elevated in a few days.

The Midland Electric Railroad Company has received a bridal car from the St. Louis Car Works which is to be used by wedding parties wishing to take trips across Staten Island. It has a dining apartment, comfortable sofas and all modern conveniences to make the trip very pleasant and desirable.

J. A. L. Waddell read a paper in New York before the American Society of Civil Engineers on elevated road structures which he considered weak in design. This brought forth a statement from Thomas C. Clarke that in 20 years the Second avenue road had only cost \$300 a mile per year for repairs, which would not warrant Mr. Waddell's conclusion.

It is probable the General Electric Street Railway Company of Chicago, will apply for additional franchises to extend its lines to Pullman and Kensington, which with the previous grants will give it control of 40 miles of streets. Contracts for the iron work have been closed and a part of the material completed. Work will begin on the conduit as soon as the frost is out or the ground.

Lots of funny incidents are resulting from the "no spit" signs, which are now epidemic. A Des Moines conductor has adopted a sure cure method against spitters. When the offense occurs he doesn't say a word, but gravely goes in and industriously sweeps one spot on the floor in front of the guilty party. When he gets tired of this he gets out a cloth and polishes the "spit sign" and about that time the passengers are enjoying the discomfort of the man who is not apt to do it again.

The Manhattan Elevated Railway celebrated McKinley's inauguration by paying all its employes, from the section hands to the president, in gold.

Copious rains in many parts of the country have caused considerable inconvenience to street railways. At Springfield, O., Buck creek ran over its banks, flooding the street railway power house, thus cutting off the power and rendering the system inoperative for some time.

W. Walmsley has been appointed superintendent of the South Chicago City Railway. Mr. Walmsley has been connected with street railways for some years, but heretofore has had little to do with the operating department, devoting his attention rather to the general business and claim departments.

The Detroit street railways have instituted a new rule, requiring the conductors to make full returns at the end of every trip instead of waiting until through their day's work. The registers are to be used differently. On the register on which, heretofore only cash fares and six-for-a-quarter tickets were rung up, the cash fares and all paid tickets will be registered, while on the old three-cent fare register all transfers and passes will be rung up.

The following directors were elected at the annual meeting of the Westport (Conn.) & Saugatuck Street Railway Company: Wm. E. Nash, A. S. Hoyt, Wm. G. Staples, Loyd Nash, Samuel Purdy and Wm. E. Osborn. At a subsequent meeting, A. S. Hoyt was chosen president; Loyd Nash, vice-president; Samuel A. Purdy, secretary; Wm. E. Nash, treasurer, and Wm. S. Staples and Wm. E. Osborn, auditors.

A rather unusual suit is reported from Dubuque, Ia. About two years ago a street car ran into the buggy of the late Dr. Staples. Motorman Cook now brings suit against the executors of the Staples estate, alleging that at the time of the accident he rang the bell and the accident was due to the carelessness and neglect of the doctor's driver. In the collision the motorman was struck by the shaft of the buggy and permanently injured, consequently a suit for \$10,000 damages is brought.

C. D. Wyman, general manager of the New Orleans Traction Company, has issued a very interesting little folder, of which the first edition of 20,000 was exhausted in a few days. It contains a map of the company's lines and a short description of the scores of historical and other points of interest in that quaint city, with directions for reaching it by street car route. Special inducements are also offered to visitors for the chartering of special cars to take in all the points of interest in the city.

Boston capitalists contemplate building 22 miles of electric railway at Kingston, Jamaica. Among those interested are Mr. Burnham, the wholesale coal dealer, and Mr. Preston, president of the Boston Fruit Company. President Charles A. Richardson, of the Worcester Construction Company, accompanied by W. B. Ferguson, the Boston capitalist, and J. W. Wolfe, attorney of the Boston Fruit Company, is now in Kingston to estimate the cost of building and equipping the line with a view to its construction next winter.

## WEATHER-PROOF RAILWAY SOCKETS.

The R. B. Benjamin Manufacturing Company, of Chicago, has lately introduced a line of incandescent lamp sockets of simple and strong design. The accompanying illustration gives a general idea of the construction of the socket. The porcelain base is cast in one solid piece and is of ample size to insure good insulation on a 500 volt circuit. The two brass terminals are of large size and well separated. A two-part shell, of brass or aluminum finish, with threaded

connection holds the parts together. The socket is designed for durability and all its dimensions are sufficient to insure it against breakage and to prevent arcing. One figure represents the standard weather-proof fixture socket which may be used separate or grouped in clusters suitable for lighting the interior of a car. Canopies are also furnished which make excellent reflectors and are suitable for outdoor work. The Union Elevated Loop, the Chicago City Railway and the North Chicago Railroad have adopted this style of socket in most of their lighting systems.

## SOLID FORGED CLIMBER.

The illustration shows a new climber manufactured by the Oshkosh Logging Tool Company of Oshkosh, Wis., which has proved to be popular wherever introduced. It is forged, including the spur and the loops for straps, entirely from

one piece of crucible steel, and in consequence is to be relied upon at all times. Strength is combined with lightness, and as the spur is not riveted or welded on it does not become loose or break off when subjected to hard knocks, as is so frequently the case with climbers. A patent has been applied for on the device.

## BATES ELECTRIC FANS.

One of the most common uses of electric power in a small way is for driving ventilating fans, and all our readers who are renting power will be interested in the fans manufactured by D. L. Bates & Bro., Dayton, O. They are designed for currents of different voltage from 110 to 500, and may be run with two or more in series. Among the attractive designs are those with revolving lamps and also the "electrolier" column fans. They are finished in nickel, oxidized copper or polished brass as desired.

## MURRAY IRON WORKS.

Although Iowa is largely an agricultural state it possesses many factories and one of the best known of these is the Murray Iron Works of Burlington. The plant was established in 1870 and has steadily grown in size, especially since the hard times set in. The company foresaw that only the fittest could survive and took advantage of the low prices prevailing to equip the works with modern machinery, with the result of outstripping many competitors who had adopted the waiting policy.

The plant comprises foundry, machine shop and boiler works, admirably located on the C., B. & Q. The output has heretofore been throttling stationary engines, mining engines, ice and refrigerating machinery, boilers, heaters, etc. The company's experience in the engine business taught that the Corliss would soon displace other types, as more attention was given to economy in the power house, and especially in electrical plants since the increased use of low speed generators has robbed the high speed engine of its only claim of vantage. To save the time, labor and expense of developing a new Corliss engine, it decided to buy a good one outright, and accordingly purchased the business of a firm in Sioux City which was manufacturing engines under many disadvantages owing to the remoteness of the works from its sources of material and fuel. These

CORLISS ENGINE—MURRAY IRON WORKS.

disadvantages do not exist in Burlington, situated as it is in the midst of coal mines and on the Mississippi river, with low freight rates from iron furnaces and steel mills of the south and east.

This engine, known as the Sioux City Corliss, has earned an enviable reputation for its regulation and economy as well as for its excellent design. The Murray Iron Works Company secured the drawings, patterns, good will and even the experience of the old builders, for with the engine they secured the best of the men who had been building it. A new shop was built at Burlington, adjoining the old one, and has been in operation for six months, turning out many Corliss engines, both simple and compound.

Having facilities for building both engines and boilers, and supplying complete power plants, the Murray Iron Works Company will make a specialty of street railway plants. Numerous inquiries are reported and a good trade is confidently expected.

The tax of one per cent of its gross earnings paid to Marinette, Wis., by the street railway company for 1896 amounted to \$216.

## A TRAIN OF CEDAR POLES.

The opening for traffic of the extension of the Detroit & Mackinaw Railroad between Bay City and Alpena, Mich., was a boon to the cedar pole industry, as it gives easy access to the large cedar swamps along the route. For several years past W. C. Sterling & Son have bought nearly all the poles cut in this region and taken them to market by

A TRAIN OF CEDAR POLES.

driving them down the rivers and then rafting them to Monroe, an expensive and dangerous method. Since the opening of the railroad, the firm has established piling and sorting yards at various stations on the line, where poles can be delivered and loaded for shipment direct to the consumer by rail. Our illustration shows the first train over the new line. It consisted of 33 cars of cedar poles, the largest shipment ever made, consigned through to Monroe. Fifty cars had been provided and were all loaded, but the locomotive was able to haul only 38 of them.

CALIFORNIA LEGISLATURE DEFEATS  
LOW FARES.

Not in many years has anything called out as great interest generally and given occasion for as brilliant forensic battle in the California legislature as the iniquitous bill to reduce street car fares in San Francisco to 2½ cents during morning and evening hours. The period included in the cut rate represents the hours in which probably 80 per cent of the business of the road is done, and is, therefore, practically "the whole thing." On his own responsibility, without a single demand from any other citizen, one of the senators, who ought to have been in better business, introduced the bill, and at one time it appeared in a fair way to go through under a system of committee manipulation. When the case was once understood, however, there was a mighty protest. It came from the 5,000 street railway employes in San Francisco, who did not need anybody to tell them what the bill meant for them. They took matters energetically into their own hands; prepared a monster petition, and with a big delegation of their men went up to the halls of legislation. And they didn't stop out on the front steps, either. They gave each senator individually to understand what would happen to him if he let the bill go through, and the result was an overwhelming defeat for the bill and success for the boys.

## THE BRYANT COLD METAL SAWING MACHINE.

The illustration represents a metal saw which will likely prove a valuable addition to the repair shops of street railways. It is the result of exhaustive study and planning by the engineers of the Q. & C. Company, Chicago, and has just been introduced to the trade. The machine shown is equipped with a motor and has a circular base. For street railway companies, any old motor in stock will serve for power, thus saving the price of a new one. This machine requires 3 h. p. to operate it; total weight, 7,000 lbs.; capacity, solids 24 x 10 in. at all angles; horizontal travel of saw, 28 in.; diameter of saw blades, 25 in. It contains several improvements, among which are increased feeding speeds, prolonged life of saw blades, lateral adjustment of saw blades. The feeding mechanism has been much improved and change can be made from slow to fast, or vice versa, without stopping the machine. The saw carriage is provided

An incident of the affair was the arrest of three young men, who to make a test case rode on the cars and refused to deposit their fares, demanding that a conductor collect them.

Judge Thompson, of the police court, heard the case and fined the young men \$5 each. In giving his decision he said:

"The naked question is this: Admitting that the street car people are wrong in refusing to put conductors on their cars, have these people the right to force them to do so by riding on their cars and refusing to pay to anyone but a conductor? Clearly, if we do not like their way of doing business we have a perfect right to refuse to ride on their cars, but to say that we have a right to ride and refuse to pay fare when properly demanded until they put conductors on their cars, is to assert a right in any class of citizens who may feel aggrieved by the conduct of another set, to substitute their private will in the place of the law, and to enforce that will by acts in violation of the laws of the land; in

THE BRYANT COLD METAL SAW.

with quick return by means of rack and pinion. All bearings are adjustable to compensate for wear and the machine throughout is made of best material, the saw arbor of Jessop's steel; worm wheel of phosphor bronze, engaging with steel worm. It is adapted for sawing out frogs, layouts switches, turnouts and any other iron work to be used in track construction. The South Chicago City Railway, the Metropolitan Street Railway Company of Kansas City, the Citizens Street Railway Company of St. Louis, the Milwaukee Electric Street Railway and several other roads are using similar machines to great advantage.

## CONDUCTORS FOR LOUISVILLE.

The Louisville Railway, the largest street railway in the country operating without conductors, will put them on some of its lines. The labor unions which wanted to see the company employ more men, started a crusade of "no conductor, no fare" by refusing to deposit fares in the cash box. The matter has been settled by President Speed promising to put conductors on the three lines of heaviest travel by October 1. The transfer privileges are also increased, and cars will be heated next winter.

other words, it is mob law. It means the usurpation by a part of the community, of that sovereign authority, which only resides in the whole body, and which can have no force or effect except when legally enacted into law. It is a principle, which if carried out, would wreck the whole fabric of our government."

There is a statute providing for a fine of from \$5 to \$10 for refusal to pay fare on demand, and the motorman had made a call for fares to be put in the box.

## "SHE FELL OFF THE CAR."

A female passenger sues the Des Moines street railway for \$10,000 for alleged damages caused by slipping on a rear step where ice had accumulated. She thinks if there had been a conductor somewhere around the car she need not have sued the company. It is not even claimed the car was moving. General Manager Hippee says that on the few light travel lines where conductors have been dropped the accident record is no greater than before, and by dispensing with conductors on such lines he is enabled to give a much more frequent service than the receipts would otherwise warrant.

A. G. Hathaway, Cleveland, reports an increasing number of inquiries in his line, and improved prospects for business.

The order for 20 closed cars and trucks for the Milwaukee Street Railway was given the Barney & Smith Company, Dayton, O.

The New Castle Car Manufacturing Company has received a contract to build 15 summer cars for the New Castle Traction Company, New Castle, Del.

The Northern Supply Company, of Chicago, reports numerous inquiries for cedar poles with promise of many orders the coming spring and summer.

The Brussels Tapestry Company, of New York, has sold its brussellette to the Metropolitan Traction Company for curtains for the 150 new cars building for that company.

The McGuire Manufacturing Company, Chicago, has been given the contract for the trucks for 15 summer cars now building for the New Castle, Pa., Traction Company.

Russell & Herbert, the well known theatrical agents of Chicago, have closed contracts with seven western street railway managers for park attractions during the coming season.

The Standard Air Brake Company, New York, in a booklet of sixteen pages illustrates its latest apparatus, and also the cars used on several of the lines that use the "Standard."

The Springfield Street Railway Company of Springfield, Mass., has contracted with the Wason Car Company for 6 modern snow plows to be equipped with Westinghouse 100-h. p. motors.

A contract has been closed by the Saddler Electric Switch & Signal Company, Toledo, O., with the Toledo, Bowling Green & Fremont Railway to install the Saddler signal system on its lines.

L. K. Hirsch, of 549 Rookery, Chicago, dealer in old and new railway material and relaying rails, reports that since the recent fall in the price of steel rails business has been improving in his line.

The E. P. Allis Company is extending its operations into foreign fields. Recently three 1,000-h-p. engines were sent to South Africa to be used in generating power for electric pumps in the mines.

A. Groetzinger & Sons, of Allegheny, Pa., report that business is keeping up exceedingly well. Dermaglutine pinions are always in demand and they have recently received a number of large orders for them.

M. A. Coolidge of Fitchburg, Mass., has been awarded the contract to build 4 miles of road for the Amherst &

Sunderland, Mass., Electric Railway Company. Work is to begin very soon and be completed in June.

The St. Louis Iron & Machine Works have issued a third edition of their catalog of the standard St. Louis corliss engine, which comprises descriptions, with illustrations, of the important details as well as of the engines in general.

W. W. Wilcox & Co., of Chicago, will remove on May 1 to 201 Lake street, a few doors west of their present location. The new factory will contain more space and be better equipped to handle their growing business in railway badges, ticket punches, etc.

Naugle, Holcomb & Co. have recently placed an order with J. H. McGill, representing the Ohio Brass Company, for about 3,000 type "D" hangers, equipped with Dirigo insulated bolts, and a like number of Walker ears. They are for the Chicago Suburban.

The Ohio Brass Company, Mansfield, O., manufacturer of the Walker trolley ear advises us that specialty is rapidly growing in favor and meeting with largely increased sales. The company confidently expects its sales of Walker trolley ears to aggregate 25,000 this season.

The Meaker Manufacturing Company has just shipped the Union Traction Company of Philadelphia, Pa., 865 additional equipments. This will make 2,800 car equipments for this register. This is the largest system and the largest register equipment in the world.

The Standard Air-Brake Company has secured the services of Herbert B. Taylor, late with the Consolidated Traction Company, as chief assistant in the electrical department to F. Uberlacher. Mr. Taylor entered the service of the Standard Air Brake Company on March 1st.

The Ball Engine Company, Erie, Pa., has recently built a 60-h. p. engine direct connected to a General Electric dynamo, for the Church Home & Infirmary of Baltimore, and a 350-h. p. horizontal cross-compound engine for the Wilmington Gas Light Company of Wilmington, Del.

W. H. P. Fisher so long and favorably known as one of the pioneers on the traveling force of the Hoppes Manufacturing Company, Springfield, O., has been placed in charge of the eastern office of the company which was recently opened at Room No. 604 Girard Building, Philadelphia.

Hooven, Owens & Rentschler, of Hamilton, Ohio, have been awarded the contract to furnish four 300-horse-power engines for the Cincinnati & Miami Valley Traction Company. The Barney & Smith Company, of Dayton has received the contract to build fifteen 45-foot cars for the same company.

The Lombard Hydraulic Brake Company, of Boston, has just issued a new catalogue with illustrated descriptions of the mechanism of its new street car brakes. It is claimed that at an instant's notice, the braking effect, from the slightest contact with the shoes to a full stoppage of the wheels can be produced, and this pressure remains absolutely constant until the motorman moves the handle.

The American Electrical Works, Providence, R. I., in remembrance of February 22d, sent to their friends a handsome steel plate portrait of Washington, and on an accompanying card presented a diagram of the cherry tree incident and called attention to the fact that they are the largest makers of the best bare and insulated electric wires and cables.

The Taunton Locomotive Manufacturing Company, Taunton, Mass., has furnished a number of street railways with snow plows and these have met with great success this winter. The Milwaukee, Racine & Kenosha Street Railway Company, the Portland & Cape Elizabeth road and the railway at New Bedford have all testified to the efficiency of these plows.

The Berlin Iron Bridge Company, East Berlin, Conn. has been awarded the contract for the new power house to be erected at Berlin by the New York, New Haven & Hartford Railroad. The building is to be 110 x 200 ft., divided into two rooms of nearly equal size, one for the boilers and one for the engines and dynamos. The entire frame work will be of steel, with the side columns enclosed by brick walls.

The G. C. Kuhlman Company, Cleveland, O., intends to make a specialty of suburban cars. The company is now delivering eight cars for the Cleveland & Chagrin Falls Electric Railway. They are 41 ft. long over all with reversible cross seats seating 44 passengers. The general lines are those of a steam coach, but with a large front vestibule for the motorman. The doors are double with a 42-in. opening.

The Conover-Goe Company, recently organized, is composed of men who have been actively engaged in electrical work for 15 years. The company will be factory agent in the west for several eastern firms, among them are C. S. Knowles and the Paragon Arc Lamp Company, of Boston, and the Gibbs Electric Manufacturing Company, of Hartford. This company also represents the Dicke Tool Company, of Chicago.

W. P. Van Dorn, of the Fitzgerald & Van Dorn Company, Chicago, advises us of the receipt of several large orders for its automatic couplers. The heavy double truck cars that are now used on so many interurban roads require automatic couplers, and to meet this demand a special coupler, No. 7, has been put on the market. The Van Dorn ball joint attachment for securing the body of the coupler to the car has also met with success.

The American Engine Company has just secured the order for the entire engine equipment of the new station of the Scranton (Pa.) Illuminating, Heat & Power Company, to be built on the site of the old station recently destroyed by fire. The equipment will consist of six American-Ball engines, five of which will be compound and one simple. Direct connected generators will be used on 4 of these engines, and the station will be modern in all its appointments.

The Forest City Electric Works, Cleveland, has just issued an extremely neat and interesting little pamphlet, describing and illustrating its roll drop and drop forged commutator bars. Several pages are devoted to testimonials with fac-simile autographs of well known street railway

managers, and a long list of roads in all parts of the country which are using the Forest City products. The protected rail bond and improved Cleveland bond welder are also explained.

The Abendroth & Root Manufacturing Company, 28 Cliff street, New York City, has through its St. Louis office secured an order from the Alexian Brothers for two Root improved water tube boilers, 150-horse-power each, to be installed in the new hospital in Chicago. The company has also secured in the face of a close competition the Schwarzhild & Sulzberger order for water tube boilers for the packing plant in Kansas City. This order calls for 1,000-horse-power.

While the fire engines were yet playing on the ruins of the power house of the Union Traction Company, Philadelphia, which burned March 3, the chief electrician of the company ordered 165 I-T-E circuit breakers of the Cutler Electrical & Manufacturing Company of that city for immediate delivery. Standard switchboard types were ordered so that the greater portion could be filled out of stock, and inside of 24 hours 116 circuit breakers had been delivered to the Traction Company.

Warren, Webster & Co., of Camden, N. J., report that they have been pressed with work for several months past and that the prospects continue good. The Webster system of steam heating, which is owned and operated by this firm, has been specified for the new post-office at Washington and a number of other large structures now building in various parts of the country. The firm also has several contracts for heating street car barns and its success in this line has elicited numerous inquiries.

The Standard Paint Company, 81 & 83 John street, New York, finds that the demand for its P. & B. compounds, preservative paints, armature varnish and insulating tape is constantly increasing, particularly among street railway men, as the consumers find that it is expensive to experiment with other than standard goods. The company makes a specialty of tape in all widths, which is free from rubber and will not carbonize. A new material, introduced last year is "ruberoid" motor cloth, a very elastic waterproof material.

After a shut down of only 10 days the Dornier & Dutton Manufacturing Company, of Cleveland, opened its works and gradually put on additional men, until now the works are running full time. The company is now finishing up an order for 10 trucks and two smaller orders. Large orders for gears and pinions have been received. H. A. Dornier has been relieved from the financial end of the business and made general manager, and is now enabled to devote his time to the mechanical and sales departments.

The Garton-Daniels Electric Company of Keokuk, Ia., has issued a small pamphlet to the trade which discusses the Garton lightning arrester as an investment, and shows that it is a good one. The company is looking forward to large sales in 1897, as the business for December and January was twice, and for February three times, as large as the corresponding month a year ago. The company has recently received orders from Mexico, Japan, France and England. Nine of the railways using the Garton arrester aggregate 520 miles in length.

On February 22 the property of the J. H. McEwen Manufacturing Company, at Ridgway, Pa., was sold to the Ridgway Dynamo & Engine Company. The new company comprises some of the strongest and most prominent business men in western Pennsylvania, and sufficient capital will be back of the business to enable every advantage to be taken of discounts. At present the company is engaged in perfecting the new organization and getting into shape for actively pushing the business. Mr. McEwen no longer has any connection with the company.

The Lombard Water Wheel Governor Company of Boston, has closed a contract with the St. Anthony Falls Water Power Company, of Minneapolis, to furnish the seven governors to be used in the new plant now building. These seven governors are to regulate four water wheels each, or 28 water wheels in all, aggregating 10,000 h. p. The style of governor to be employed in this plant is designated by the manufacturers as type "C." During the past year the Lombard governors have been used to regulate over 40,000 h. p. of water wheels in the United States.

Regardless of the great business depression of the last year, W. C. Sterling & Son, Monroe, Mich., dealers in cedar telegraph, telephone and electric light and railway poles, report a constantly increasing trade, and now have large orders for poles for future shipment. The firm has recently been compelled to seek more territory in the pole producing region, and has established new sorting yards at Omer, Turner, Rose City, Lupton and Maitby, Mich. The increase in trade is due the merits of the goods furnished, and the reputation for fair dealing which this firm has.

Brownlee & Co., wholesale lumber dealers of Detroit Mich., have long made a specialty of poles for electric railway work. The firm has been in business for 27 years and was the first to put on the market the octagonal pine poles which proved so popular. Recently they have begun manufacturing a pole built up of three pieces and like an I-beam in section, thus making it both light and strong. When desired the poles are creosoted under pressure, which process gives them an estimated life of thirty to fifty years.

S. C. Munoz, for some years special sales agent for the Heine Boiler Company and for the past year general sales agent for the Edgemoor boiler, and E. C. Darley, late of the Rankin & Fritsch Engine Company, St. Louis, and previously with J. P. Witherow the celebrated builder of steel works, have formed a partnership. The firm of Munoz & Darley has taken offices at 553-555 the Rookery, Chicago, and will act as general western representative of the Cahall vertical and Cahall-Babcock & Wilcox boilers, manufactured by the Aultman & Taylor Machinery Co., Mansfield, O.

The New York Steam Company, of New York City, has laid a new trunk line of underground steam mains from the East river to connect with pipes previously in use at 58th street and Fifth avenue. This line is composed of 16-in. and 20-in. pipe and is about one mile in length, believed to be the longest line of large steam pipe ever constructed. From the steam station to the extremity of this line of mains is more than one and one-half miles of continuous pipe. Altogether the company is successfully supplying steam by the Holly system for both power and heating through more than eight miles of underground pipe.

The International Register Company of Chicago, has removed from 197 South Canal street to 133, 135, 137 and 139 South Clinton street, where it has much better facilities for handling its increasing business. The company reports a much larger business for the winter months than a year ago, and that prospects for the spring are better than for several years. Many railway managers are now considering a change of register equipment who would not give a moment's thought to the matter under the unfavorable political conditions of last year. Others are beginning to realize that old and worn out registers are expensive affairs, and cost in loss of fares due to breakages, or incorrect registration, in a year, many times the price of a new equipment of the modern durable and accurate machines.

In the autumn of 1896 the Davenport Consolidated Gas, Electric Light & Steam Heating Company constructed nearly two miles of steam mains in the streets of Davenport, Ia., the largest being 10 in. and the smallest 5 in. in diameter, at a cost of \$30,000. This is what is termed an exhaust plant, the design being to heat mainly with the large amount of exhaust steam which the company had previously being allowing to escape into the atmosphere. The revenues from heating this season will amount to \$8,000 and this sum will be more than doubled in another year when time is given to secure additional customers adjacent to the line of mains. The company is well pleased with its experience so far; everything in the heating plant is working smoothly, and the people are delighted with the service. The underground work was done by the American District Steam Company, of Lockport, N. Y.

Among the recent sales of the Buckeye Engine Company, Salem, O., are two 11 x 18 in. engines for the Pennsylvania Railroad Company for lighting station and yards at Cincinnati; two 17½ and 30½ x 33 in. tandem compounds for the Marion City Railway Company, Marion, Ind.; two 17½ x 27, East Hamilton Light & Power Company, Hamilton, O.; one 14½ x 24, R. R. Donnelley & Sons Company, Chicago; one 9 and 13½ x 16, W. D. Wood Company, McKeesport, Pa.; one 13 x 16, Canby, Ach & Canby, Dayton, O.; two 17½ and 30½ x 33 and one 18 and 32½ x 33 tandem compounds, Carnegie Steel Company; one 15½ x 24, L. D. Rohrer, Cumberland, Md.; one 15 and 28½ x 16 vertical compound, Fall River Electric Lighting Company; one 13 and 22½ x 18 tandem compound, Water Works, St. Mary's, O.; one 14¼ and 25 x 18 tandem compound, Otis Steel Company, Cleveland.

Although J. A. Hanna, western manager for the Peckham Motor Truck & Wheel Company, has been in a critical condition for some time past through the bursting of a blood vessel in the brain, his energetic assistant, William Gray, has not missed anything in view for the Peckham Company, having secured the entire equipment for high speed double trucks for the Detroit River & St. Clair Railway, the entire equipment of double and single trucks for freight and passenger cars, also a switching locomotive for distributing standard steam railroad freight cars for the Mason City & Clear Lake Traction Company, Mason City, Iowa, and an order for single trucks from the Waterloo & Cedar Falls Rapid Transit Company. Suburban managers seem quick to appreciate the merits of Peckham's double trucks, the orders for which are almost equal to those for the famous single trucks, which are known the world over.

**THE SOLUTION OF AN IMPORTANT STREET RAILWAY PROBLEM.**

To the street railway man the interurban or long distance suburban service is especially attractive, not only on account of large profits, but because of its greater freedom from competitors. This special form of street railway work presents a most difficult problem to the engineer. He finds

NO. 27 BRILL TRUCK.

himself obliged within city limits and in paved streets to use a tram rail with paving close to his rail head. The head must be shallow so that traffic may not be too much inconvenienced, while the curves from the necessity of passing street corners must be very sharp. These conditions force him to use a wheel with a very narrow tread to avoid touching the paving and a shallow flange in order not to cut the tram of the rail at the bottom.

For economy of construction, stability of roadbed and

TRANSVERSE STABILITY COMPARED WITH M. C. B. TRUCK.

speed the track outside of city limits is laid with T-rails. For safety of operation on the T-rail wheels should have wide treads and deep flanges.

Under these diverse requirements the engineer has no alternative. He must use the narrow treads and shallow flanges and outside the paved streets either reduce his speed or trust to luck to keep his cars on the rails. Common experience is that the cars run just a little too fast and there is now and then a little "slip-up" in the matter of luck.

Late in the year 1895 an unexpected solution of this problem was reached, by which the narrow treads and shallow flanges are able to make any desired speed on T-rails without any danger of derailment. In September of that year the J. G. Brill Company put a number of trucks in operation upon the Buffalo & Niagara Falls Railway. This is a typical city and suburban line with a long haul in the coun-

SPRING LINK.

try. The terminals are both inside cities and there are so many miles of track along paved streets. The country portion of the line is laid with T-rails. Two competing steam roads, each running frequent trains, make high speeds necessary at any cost.

A pair of trucks of peculiar design were included in the order. These were of the type known as "No. 27." The object in the design was to obtain certain conveniences of operation and construction. Several experts in such matters were consulted in regard to their probable advantages, but none of them hinted at any superiority in riding qualities or in the matter of safety. Before New Years day, however, every railroad man in the city had heard of the performances of "No. 30" the car mounted on these trucks. A stranger a month later found the city conductors well posted as to the car and her trips and in one

instance was met by the volunteered information that "she was not riding very well on account of a flat wheel."

The first point that was noticed was the ease with which the car took the curves. The short curves in the city and the long curves in the country were passed with an ease and smoothness, at any speed, which was before unheard of. The next thing which caused surprise was the fact that the truck never left the rails at any time nor for any cause, and it may be added that from that day to this there never has been a case reported in which one of these trucks has been derailed.

The new truck solved the problem. It could run over T-rails at the highest speeds while using a  $\frac{3}{4}$ -in. flange and a  $2\frac{1}{4}$ -in. tread. At the same time it took the short city curves more smoothly than any standard trucks on steam roads pass around curves of 2,000 feet radius.

The features which have made this surprising record possible may be stated in a general way thus: There has been in the equalization of the load between the wheels a great improvement made over that employed in the Master Car Builders' standard truck. The load being placed at the center of the equalizer with the springs at its outer ends they are entirely freed from leverage and the load more perfectly distributed than in the standard M. C. B. truck. Journal springs are also introduced in addition to those ordinarily employed, adding fifty per cent to the spring carrying power. The swing links are made elastic by putting the equalizing springs into them. The latter feature makes it impossible to bring a blow upon the flanges of the wheels no matter how irregular the horizontal alignment of the track may be. Curves in the same way are robbed of their power to bring a jerk upon the truck. The links lengthen as the truck moves to one side and cushion what would have been a shock and the body follows with a motion so gentle and so regular as to be almost imperceptible.

It is difficult to write of the performance of the new truck and compare it with those of the ordinary standard patterns on steam roads without making statements which appear incredible to those who have not had an opportunity to try them.

The engraving shows some of the leading features of the truck, including the spring links and the equalizer, which it must be remembered forms a part of the spring plank and swing motion.

As a sort of confirmation of the case it may be added that the Buffalo & Niagara Falls road have just ordered 21 sets of these trucks, 19 of which are to replace pivotal trucks of the ordinary pattern, and several roads using these trucks have displaced other trucks for them.

### PROPOSED WATER POWER FOR DENVER.

James E. Rhodes, of Denver, interested in the Denver Power & Irrigation Company, is promoting an enterprise to furnish electric power. The plan is to build a huge reservoir on the south fork of the Platte river, at the mouth of a big canyon where the natural conditions are said to be perfect.

Nature has there formed a natural basin and all that remains for man to do to create an immense reservoir is to close the narrow gateway, where the great towering walls pinch almost together. By doing this a great lake four miles long will be formed. The dam will be built of solid masonry and will be over seventy feet in height.

From the reservoir a pipe line six or eight feet in diameter will conduct the water to Stevens' gulch, two miles below Deansburg in Platte canon, a distance of six miles from the dam. In this manner a fall of over 200 feet is secured.

After using the water for power it will be sold to irrigators. It is promised to furnish power delivered in Denver for 65 per cent of what it now costs to produce it with fuel. The Denver tramway would be a large user in event of the scheme being carried out.

In Brockton, Mass., there is rather a peculiar provision in the street railway franchise which reads as follows: "Whenever there shall occur a fall of snow of depth sufficient to allow the use of conveyances on runners on said streets, no snow plow shall be used on said tracks, nor shall said company cause or allow snow to be removed therefrom, nor use or allow to be used any salt or other substance or substances for the purpose of melting snow on said tracks, unless written permission be obtained of the board of aldermen or its committee on highways." Perhaps it was intended to have the cars put on runners, but it does not work in that primitive way. When the snow begins to fall, before a "sufficient depth" has accumulated, the snow plows are set to work.

The Peckham Motor Truck & Wheel Company reports orders aggregating 400 trucks, having received recently large orders from the following roads: Metropolitan Street Railway Company, New York City; Brisbane Tramway Company, Brisbane, Australia; Leominster & Clinton Street Railway Company, Leominster, Mass.; Olean, Rock City & Bradford Street Railway Company, Olean, N. Y.; Worcester Construction Company, Worcester, Mass.; Mystic Valley Street Railway Company, Mystic Valley, Mass.; Wakefield & Stoneham Street Railway Company, Wakefield, Mass.; North Woburn Street Railway Company, North Woburn, Mass.; Cleveland & Chagrin Falls Electric Railway Company, Cleveland, O.; Cleveland Electric Railway Company, Cleveland, O.; Tama Electric Railroad Company, Tama, Ia., and others. The works are now running on full time, and present indications point to a continuance of the same for the entire year.

### NEW PUBLICATIONS.

Catalog N issued by the Hilles & Jones Company, Wilmington, Del., is a pamphlet of 44 pages, on each of which is an illustration of one of the new or special tools built by this company for working iron and steel plates, bars and structural shapes.

No. 1, Vol. II of the Journal of the Western Society of Engineers, contains Edward Barrington's paper on "Street Railway Construction," read before the society November 18, 1896. The author discusses the subject in detail and the paper constitutes an epitome of what is the latest practice in street railway construction and equipment.

Whitaker & Co., of London, will shortly publish a Technical Railway Vocabulary, compiled by Lucien Serrailier. The book will contain over 5,000 French, English and American technical terms used in railway management, construction and working, and is destined for the use of engineers, railway men, contractors, patent agents and inventors.

"Caball" is the title of the new catalog just issued by the Cahall Sales Department, of Pittsburg. The introduction discusses the evolution of steam generators and the elements of perfection and is followed by an elaborate description of the Cahall boilers and the data of numerous tests. It is profusely illustrated, half of its 98 pages being full page illustrations.

We have received No. 10 of Vol. 1 of the Bulletin of the University of Wisconsin, on "Topographical Surveys, their Methods and Value," by J. L. Van Ornum, C. E. Like the other numbers of the bulletin which have appeared in the last two years, this is a report of a lecture delivered before the students of the university by an expert in the field treated, and constitutes a valuable addition to technical literature.

We are in receipt of "Electric Street Railways," a book of 331 pages issued by the Allgemeinen Elektrizitäts-Gesellschaft (General Electric Company) of Berlin, which contains much valuable information on this subject. After some remarks on electric railways in general and overhead trolley lines in particular and a note on the opposition to trolley lines by telegraph and telephone companies which use low potential current, the book is devoted to descriptions of the street railways in 24 cities in Germany where the overhead trolleys are used, on the system of this company. In each case full data as to line, grades, power house and equipment are given; there are many illustrations, showing track layouts, profiles of lines and interior views and plans of power houses.

### 100-MILE ELECTRIC INTERURBAN.

H. McFarland, of the Century Engineering Company, Cleveland, advises us his company has closed the contract and begun construction work on the Benton Harbor Electric Railway & Transit Company. The present plan is to make the road 100 miles long, running through a thickly populated fruit country and passing 27 lakes. Track to be standard gage, 15 miles 80-lb. and balance 70-lb. T-rail. Cars to be operated on steam road practice.

ing in the power house must be made on the 11.5 per cent, of which a little over half is for the coal bill. The maximum saving is only about 2.6 per cent of the whole operating expense, between inefficient and the most economical engines. While Mr. Davis states that he is in favor of concentration of power, compounding and condensing, yet in many cases the money spent upon other items, which are a larger percentage of the total operating expenses, would result in greater savings.

To corroborate his statements he compares the itemized expense of two roads.

	No. 1.	No. 2.
Length of track in miles.....	7.54	6.36
Average number of cars used.....	9	4
Indicated h. p. of engines.....	425	300
Indicated h. p. per car.....	47	75
Car-miles run.....	317,656	92,400
Operating expense, per car-mile cents.....	9.77	13.68
Cost of power plant.....	29,750	39,000
Cost of equipment.....	58,500	16,800
Cost of track and line.....	148,480	53,894

It will be noticed that the power plant of each road cost about the same, but the equipment of No. 1 is heavier and more powerful; also the track and line is much better and more substantially built. The expense per car-mile is largely in favor of the first line. Good rails and road bed, a high grade car equipment, with high speed service and a consequent less cost per car-mile for labor will be instrumental to keeping down the operating expenses and should receive no less attention than the power house.

### REPAIRS ON THE SOUTH CHICAGO CITY, RAILWAY.

The South Chicago City Railway has been very successful in keeping its rolling stock in first class order. A thorough system of inspection every night brings to light any defect in the cars or motors. The "stitch in time" saves any extensive repairs which would come from neglect. There are 42 cars in operation, and 6 men in the repair shop attend to all of these. All through the winter, when snow and frozen mud on the track are such a source of danger no armatures have been burned out and the armature winder

has been devoting his time to other work. Good care is also taken of the trucks and Mr. Powell, who has charge of the repair work, states that there has not been a flat wheel running on the road for over a year.

The arrangement for testing the fields and armatures is very simple and inexpensive, the connections being as shown in sketch. In the armature room, a discarded circuit breaker

was resurrected from the scrap pile and mounted on the wall. In series with this is a 150-ampere meter and a water resistance. This consists of a barrel beneath the floor with a pipe from the water main and an overflow. Two copper plates, 10 x 14 in. are fastened on the end of a rod extending above the floor. The resistance can be varied by raising or lowering this into the water. A wire leads from one plate into the armature room and to the car pits. If an armature is to be tested it is mounted in bearings on two trestles, and one terminal of this series connected to one brush, and the other brush is grounded. Any defective coil is quickly detected and replaced by one already in stock. When a field is to be tested it is placed in series with the apparatus and the fall of potential is taken across the terminals. Should the readings differ from the usual observations the indication would be that the insulation has been broken down and the necessary repairs are made.

### RICH BUY CHEAP TICKETS—POOR DON'T.

Several months ago we gave the experience of a street railway president who thought to educate people up to riding on a certain line by selling an 8-for-a-quarter ticket. The line connected a business and outlying manufacturing district, and was largely patronized by employes of the factories. For a considerable portion of its length the route was through a fashionable residence district occupied by the well to do. When the educating prices had been in force two months without any alarming increase in business a thorough count was made by the ticket sellers of the class to whom the cheap tickets were sold, when it was discovered fully 90 per cent were being bought by the bankers, merchants and professional men in the swell neighborhoods. The working people scarcely touched them. This practical experience is in direct opposition to the theoretical claims set up by alleged reformers who do their street railroading in their heads. The following from the Detroit News is along the same identical line as claimed by street railway men everywhere:

The talk about the relative benefits enjoyed by the city from the Detroit railway franchise as compared with those granted to the older companies has led Manager du Pont of the Citizens' company to do a little figuring and he admitted that the results were surprising to himself.

"The much-boasted 3-cent fare," he said, "is shown on investigation to include only from 10 to 12 per cent of all the fares collected. From 88 to 90 per cent of the street car patrons are still paying at the 6-for-a-quarter rate.

"Another surprising thing demonstrated by my inquiry," continued Mr. du Pont, "is that by far the greater portion of our so-called workingmen's tickets are collected on the Woodward avenue line. The real workingmen, who live on Michigan and Gratiot avenues, pay their nickel oftener than do the well-to-do people adjacent to Woodward avenue. The reason is, apparently, that the average workingman has very little capital to invest in street car tickets and prefers to pay for single rides."

The Union Traction Company, Philadelphia, is preparing a handsome book illustrating its route along the Old York road and the special features of Willow Grove park. For the coming season at the park Damrosch's Symphony Orchestra has been engaged.

### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. APRIL 15, 1897. NO. 4

THE article on "Reduction in Street Car Fares" in the February REVIEW has attracted widespread attention, not only from street railway officials, but the daily press as well. The article, in whole or in part, has been republished in the leading dailies in all parts of the country, from San Francisco to Boston. The street railway interests are indebted to those papers which did publish the article for having given even this much space in contradiction of the columns of matter which have been misleading and unjust. We ran an extra large edition of the issue in question, but it has been entirely exhausted. We have, however, a few hundred copies of the article in sheet form, and our friends are welcome to these as long as the supply lasts.

NO ONE seems to ever think of any possibility of going back temporarily to horses when once electricity sets the cars in motion, and it is a high tribute to the exactness with which the science of electric installation is made that when steam is turned on it comes to stay. A little city down in Connecticut, however, met with an accident in its power station, and for some reason several weeks were allowed to elapse before the current was turned on again. In the meantime the few cars were dragged about by horses. Once this was considered a first-class means of conveyance, but the way the dear

people stormed and ridiculed the honest old horses was a caution, and yet these same people, with thousands of others, not so many years ago did all they could to retain horses in front of their cars and keep electricity out.

WE print elsewhere in this issue extracts from a paper prepared by P. F. Sullivan, general manager of the Lowell & Suburban railway. It is entitled a "Comparison of Street Railway Conditions and Methods in Europe and the United States." It is the result of a most careful and thorough personal investigation by Mr. Sullivan, who has just returned from Europe. The writer has long been a close student of municipal conditions and affairs, and combines with it a most practical knowledge of American street railways growing out of actual experience as a successful, and progressive manager. His report is the most important treatise on the subject ever presented, and explains for the first time many things which American managers could not understand. He punctures the bubbles which theoretical writers have brought over and which have been floating in the minds of the American public. He emphatically proves the vastly superior accommodations of our roads, and shows the so-called penny fares to be higher rates than are paid by American riders. We call special attention to the section on "Rate of Wages." This shows that in the case of one American road alone, the West End, of Boston, *if it should pay the same wages as are paid in Glasgow, the company could afford to pay \$2,000,000 per annum for its franchises and still maintain its dividends.* The West End road, last year, paid in wages (and exclusive of wages paid contractors for track renewals) twice as much as the entire earnings of the Glasgow lines; and yet the population of Glasgow exceeds that of Boston and its suburbs by 58,000 persons. Mr. Sullivan, being a practical railway man, is able to go to the root of these matters as the average student could not and has not done, and in his investigations and report has rendered a lasting service to the entire railway interests. The article will be found intensely interesting and of great value.

THE meeting in Cleveland, on March 23 and 24, of street railway accountants, was in every respect a grand success, and resulted in the permanent organization of the Street Railway Accountants' Association of America. Not only was the meeting a most harmonious one, but we have rarely ever seen a deliberative body which was so thoroughly in earnest, or which conducted itself in so systematic and business-like a manner. Not a minute was allowed to be wasted. When a paper was read it was thoroughly discussed, but in not one instance did the debate wander from the question strictly before the house. The fact that a most excellent constitution and by-laws were adopted in just one hour and a half, where similar bodies often spend one or more days in accomplishing the same result, is but a single instance of their business methods. Nor let any one suppose the matter

was not thoroughly considered, for it was scrutinized in every detail. The exhibit of blanks and forms was a most excellent, interesting and instructive feature, covering several large tables, and representing the accounting systems of over 30 roads. These forms were carefully studied and discussed, and not a delegate present but carried home, not only sample forms, but suggestions for improvements in his own. The plainly evident spirit was earnest work. Before and after the sessions, the delegates were in constant conference, and even "talked shop" during meal time, arrangements having been made for a separate dining room. It was a matter of general comment and surprise that so much could be accomplished in so short a time, and also that the quality of the work surpassed the expectations of all. The roads not represented at the meeting are losers thereby.

\* \* \*

One of the chief opportunities of the association centers in the work of standardization. This has been put in motion by the appointment of a strong committee, which will report at the October meeting. This committee has a lot of hard work ahead, and must not be expected to have the question all worked out in the next seven months. It will doubtless be a work extending over two or three years at least, but will become easier all the time. For the first time the machinery is now in motion to undertake this task, and deserves the strongest support and encouragement from every street railway in the land. Every possible assistance has been freely afforded the operating departments in the way of outside experts in solving their hard problems, and no one questions for a moment either the advisability or economy of having done so. But the accounting department has been left to shift for itself, and each one has had to be his own expert.

\* \* \*

Economy is the watchword from now on, but general economies are fast reaching their limit; that is, those larger and apparent savings which can be readily discerned. But the lines are being so closely drawn on street railways that savings must now be made in all the smaller details which formerly were not considered of much account. But the rub is going to be to ferret out and determine what and where the further possible economies are, and it will be found that the operators will have to look to the accountants to furnish the data which will enable these discoveries to be made. In order to do this one road will have to exchange figures with other friendly roads; but the present system of diverse accounting gives but little opportunity for this exchange, even where mutually desired. It is to secure such a standardizing of accounts as will enable a valuable and intelligent comparison to be made that the accountants have organized. As the proceedings will show, this does not mean a radical change in every company's system of bookkeeping, or the throwing away of hundreds of dollars worth of unused ledgers and other books, but a gradual coming together along certain lines

as agreed, with a probable eventual system which will be generally adopted, because generally conceded to be the best. No one man, and no one company can possibly hope to work this all out alone; it can only come as a result of careful study, conference and interchange of ideas and methods.

\* \* \*

The managers and operating departments have really much more to gain from this self imposed task which the accountants have taken up, than the accountants themselves. It is evident that so far as the accountants are concerned that they can go on indefinitely with their present systems, and unquestionably save themselves much hard work in studying out a better one; but the fact that they realize as no one else can, the necessity and value in dollars, of a better system, is highly creditable to these hard but comparatively unknown workers. The steam roads have been through the same experience and evolution years ago, and street railways have now reached a point where they will surely have to do the same.

\* \* \*

The STREET RAILWAY REVIEW takes modest but genuine pride in the success of the accountants' meeting. All the preliminary work of securing a general expression as to the advisability of the organization, the correspondence necessary to selecting the place and time, and in fact all the arrangements up to the moment of electing the temporary officers was done by this paper. We are glad at the success, but had it been a failure we would have reported it so just as strongly as the facts have warranted us in commending it.

#### THE HUMPHREY BILLS.

The two bills now before the Illinois legislature and popularly known as the Humphrey bills, are sadly misrepresented by the daily press and held up to obloquy as the iniquitous conceptions of iniquitous men, principally street railway men, designed for the purpose of oppressing the people. They should properly be regarded as measures to protect good citizens and the street railway corporations, from being sandbagged by boodle aldermen.

One bill provides for a "Board of Street and Elevated Railroad Commissioners" composed of three men holding for terms of 15 years, with power to regulate the time of running cars; to prescribe the headway; to prescribe the cars used; to regulate the manner of heating cars; to establish rate of fare, provided that a rate once fixed shall not be changed for twenty years; to determine whether new lines for which franchises may be asked are necessary, and whether the law on the subject has been complied with, the granting of a franchise being obligatory upon the city council or county commissioners, when recommended by the state board; to authorize a change of motive power; to prescribe a maximum speed; to regulate signals; to regulate the manner of crossing the tracks of another company.

The other bill confers upon street railways the right to condemn property, compensation being ascertained and made in the manner provided by law for the exercise of eminent domain; consent of council or commissioners of high-

ways in counties, and full compliance with law is made a condition precedent to the laying of tracks; the railways may not be obstructed or their operation interfered with, by reason of street improvements; franchises are to be granted for 50 years and the franchises of existing roads are extended for 50 years from date; three per cent of the gross earnings of the companies is to be paid to the city in which they operate; a company may not use the tracks of other companies without the consent of the latter; consolidation of parallel or competing lines is prohibited.

Objection is made to these bills on the ground that the city would thereby be deprived of its right to control its street railways. This is one of the best reasons that the bills should become laws; any measure that will deprive the city council of its power to levy blackmail will weaken the influence of the corrupt politician and bring nearer the day of pure municipal politics. State control is better than municipal in that the legislature meets biennially instead of weekly.

As to what the Humphrey bill proposes: The exercise of the right of eminent domain by street railways is nothing to which exception should be taken. It is by this means that steam railroads, telegraph and telephone companies and other quasi-public corporations secure their rights of way and in the great cities of today the street railway is as important as is the steam road. Compensation for property condemned is amply guaranteed, as is the consent of municipal or county authorities to the building of the road, and the railroad commission would be a check upon granting franchises for speculative purposes only, and also upon the refusing of those really necessary and desired by those interested. The prohibition upon municipal authorities against obstructing or interfering with the operation of the railways by reason of street improvements merely closes an avenue through which the city fathers would be tempted to levy tribute.

The 50-year extension clause is bitterly attacked upon the ground that the term is too long, and that three per cent of the gross earnings is too little compensation.

The position taken by too many of our people is that of inviting capital to embrace an opportunity to invest with the proviso: "If you lose money, it is your own look out; if you make money, we shall take it away from you." Even if a corporation "has no body to be kicked and no soul to be damned," its stockholders have and should be protected against the irresponsible parties whom our people see fit to choose to make our laws and ordinances. The three per cent of the gross receipts, in addition to general taxes and licenses at present imposed, is an additional burden imposed upon the street railways, but it would be partly compensated for if it would secure exemption from burdens now imposed by the peoples' representatives in their private capacity from which the people receive no benefit.

The conditions that obtain in Illinois are no different from those existing elsewhere, but as this is about the only legislature which has not indulged in the sport of railway baiting, the amount of vituperation heaped upon these bills by the political "leaders" and particularly by candidates is very great. It is not proposed to rob the railways, hence the bills are bad.

It can easily be understood why the majority of the Chicago council are opposed to them—they cut off an important source of revenue, but it is remarkable that Mr. Harlan, the candidate for mayor of Chicago heading the "reform"

ticket, and a man who poses as honest in his purposes, should for the sake of gaining votes, deliberately mislead the public and falsify the fact, as he did a few days since in the following speech:

"Do you know that the dogs of Chicago—the common yellow curs that run about our alleys and shrink from carriage and street car wheels—are a greater source of revenue to the city of Chicago than are the miles and miles of street railways that fill our thoroughfares? Did any one ever tell you that the licenses issued to owners of dogs bring more money into the city treasury than all the fees that are paid by the cable and trolley lines? They don't wear out the pavements, they don't endanger human life, they make no money out of the people, and yet they do more to support the city government than the street car magnates, who pretend to the ownership of our streets."

The Chicago city controller gives the city receipts in 1896 from the dog tax as \$34,842, and the city receipts from street railways, exclusive of taxes, as \$317,068 (page 141 March REVIEW).

If Mr. Harlan will make such statements as this, what chance has the street railway with the other "reformers" who are trying to break into the city council!

---

### THE SUBURBAN RAILROAD COMPANY, CHICAGO.

---

Although electric traction on suburban steam roads has been much discussed since its success on the Nastasket Beach road, the suburban lines of the Chicago & Northern Pacific Railroad were the next to be equipped electrically. The Suburban Railroad Company was incorporated May 8, 1895, to build and operate lines connecting the suburban towns to the west and southwest of Chicago with the terminus of the Metropolitan and of the Lake Street Elevated Railroads.

The capital stock authorized is \$1,250,000. The property is mortgaged to the Chicago Trust & Title Company as trustee to secure the payment of bonds, of which the issue is limited to \$3,000,000, to be issued as the construction progresses. The present officers of the company are: Charles H. Crossette, president; David B. Lyman, treasurer; Homer K. Galpin, secretary.

The company leased for a term of 50 years the Chicago, Harlem & Batavia and the Southwestern divisions of the Chicago & Northern Pacific Railroad, the two divisions comprising 9 miles of double track and 5.75 miles of single track; the lessee has the privilege of making the entire line double track. A more recent lease is that of 1.7 miles of single track of the Wisconsin Central, from its connection with the Northern Pacific at Viaduct Junction through River Forest to the Desplaines river. The rental for these lines is based upon the number of passengers carried, but the minimum rental is that due for 2,000,000 passengers annually. For the other portions of the line not over private right of way, the franchises are for periods of from 20 to 40 years.

The population of the towns lying west of West 48th street and served by the Suburban Railroad is about 175,000, and the estimated minimum traffic of 5,500 passengers per day appears to be a very reasonable one. The company proposes to run special funeral trains to the three large cemeteries, Concordia, Waldheim and Forest Home, which are reached by its lines; a conservative estimate of the traffic to these cemeteries is 1,000,000 passengers per year. The territory along the Desplaines river is very popular for picnics

LINES OF THE SUBURBAN RAILROAD COMPANY.

and the long suburban route and the loops will prove attractive for trolley parties.

It is intended to run trains consisting of motor car and one trailer at an average speed of 15 to 20 miles per hour on a 10-minute headway during the busy hours, and a 20-minute headway the remainder of the day.

The construction of the road was undertaken by the Suburban Construction Company of New Jersey, which contracted with Naugle, Holcomb & Co., of Chicago. This firm contracted to construct the track, overhead work, power

FIG. 2. TRACK IN PAVED STREETS.

house, furnish machinery, rolling stock, equip the road, and operate the same for two years from the date of completion; and took charge of the work December 3, 1896. Since that date Naugle, Holcomb & Co. have operated the leased lines of the Chicago & Northern Pacific by steam, using the main line from 40th street to the Grand Central Depot, under a temporary lease.

The engineer who has had charge of the design of the new work, as well as of the operation of leased lines is George Weston, manager of the construction department for Naugle, Holcomb & Co.

The map shows the system of the Suburban Railroad Company, the leased lines shown with dash and two dots and the companies' lines full, and also the Metropolitan Elevated over which the down-town district is reached. The company by making its entrance over this line is enabled to make use of the elevated Union Loop as its terminal. An approach to the Metropolitan at its terminus in 48th street is now building; it is contemplated to build a second one at the intersection of the main line at 40th street. These approaches are 820 ft. long with a grade of 2 1/2 per cent.

Aside from the leased lines there are 17 miles of double track. The new track is laid with 7-in., 70-lb. T-head rails in 60-ft. lengths; cedar ties spaced 2 ft. on straight track, oak ties on curves; Servis tie-plates; tie-rods spaced 7 ft., 6 in. Fig. 2 shows the track construction in streets paved with cedar blocks. Fig. 3 illustrates the arrangement of the guard rail on curves in paved streets; the space between the running rail and the guard rail is filled with concrete up to the tops of the cast iron distance blocks. About 40 per cent of the construction outside of the leased lines is over a private right of way making possible the use of the spiral curves shown in Fig. 4.

Current is supplied by overhead trolley wires, No. 00. Washburn & Moen furnished the wire and the Ohio Brass Company the insulators, trolley ears, etc. The present equipment consists of 14 motor and 10 trail cars. The motor cars are 42 ft., 6 in. over all with closed vestibules at the ends; 24 double seats of the Hale & Kilburn "walk-over" spring edged pattern, rattan covered; Gold hot water heaters. Push buttons are provided at each seat for signaling the motormen to stop. The trail cars are of the same dimensions but not vestibuled. The motor equipment consists of two 50-h. p. Walker motors. The controllers are of the series parallel type. The cars are mounted on two McGuire No. 26 trucks of 5 ft., 6 in. wheel base and 23 ft. between centers. The motors drive the forward and the rear axles of each car. Two trolleys are provided on each car, the rear one only taking the current; but as the third rail is used on the elevated portion of the route, the motor cars will also be equipped with shoes for taking the current in this manner. The cars are equipped with both hand and air brakes; the latter are furnished by the Christensen

FIG. 3.—GUARD RAIL ON CURVES IN PAVED STREETS.

Engineering Company of Milwaukee, part axle-driven and part motor-driven compressors. The estimated weight of a motor car loaded is 38 to 40,000 lbs.; a trail car 30 to 34,000 lbs.

The power house and car barn are located at Harlem avenue and 22nd street. The layout of the buildings and tracks is shown in Fig. 5. Land being cheap the company could afford to arrange the car house and entrance tracks in this manner and gain the important advantage of removing the special work from the street and also that of permitting a car to be run into the car house for inspection or slight repairs, and out again to continue trip without loss of time by switching, etc.

The present power equipment comprises three 250-h. p. Stirling boilers, delivering steam to the engines at 125 lbs.,

FIG. 4.—LAYOUT OF CURVES.

two tandem compound condensing engines, 17½ and 33 x 48 in. and 12 and 22 x 48 in. running 100 r. p. m. and direct connected to Walker generators of 400 and 250 k. w. capacity respectively. Deane jet condensers and pumps are used; Mesner stokers.

In the present building space is provided for engines and boilers for two more 100-k. w. units.

In the design of the boiler room there are several departures from the usual practice. The breeching is steel, lined with fire brick. The connection from each battery of boilers to the 16-in. steam header consists of a 12-in. wrought iron pipes bent in a semicircle of 7 ft., 6 in. radius. The openings admitting the furnace gases to the breeching are staggered, ensuring a better distribution of the currents toward the stack.

The stack is 115 ft. high above grade; the first 22 ft. of brick and the remainder of steel, 3¼-in. plates for 20 ft.; 1½-in. for 48 ft., 6 in.; ¼-in., for 56 ft., 7 in.; with the cap of ½-in. The height effective for draft is 113 ft., 6 in. The foundation extends 12 ft. below grade, the bottom course of concrete being 26 ft. square.

Near the stack is the house tank 12 ft. in diameter and 12 ft. high. Water is lifted to this tank from an 8-in. well 185 ft. deep by a Pohle air pump driven by a 10-h. p. electric motor.

FIG. 5.—POWER HOUSE, CAR HOUSE AND SHOPS.

North of the power-house is a reservoir 100 x 200 ft., 7½ ft. deep with cooling tables for cooling the condensing water. The bottom is in blue clay and water tight. The sides have a slope of 1 on 1½ and are of concrete. To take the weight of these walls a concrete base was built. The bottom of the tank has been covered with crushed stone. The cooling tables are three in number 30 ft. wide and 184 ft. long, with a fall of 8 in. in 184 ft. These tables, one above the other and inclined in opposite directions, are of 2-in. matched flooring, laid on 2 x 10-in. joists spiked to 4 x 4-in. posts. There are three rows of these vertical posts 15 ft. apart; the posts in each row are 4 ft. between centres; at the bottom they are mortised into mud sills 8 x 12 in. extending along the bottom of the reservoir.

The system is divided into five portions; the first consisting of 5 miles of double track on the Chicago, Harlem & Batavia, is fed by two lines of 500,000 and 350,000 c. m. respectively; the second, comprising the remainder of the C. H. & B. and the Wisconsin Central line, by one of 350,000 and one of 216,000 c. m.; the Harrison street division has one feeder of 350,000 c. m.; and the remaining two divisions the Lagrange and the 22nd street, Robinson avenue and South-western (C. & N. P.), are each fed by two lines of 350,000 and 500,000 c. m. respectively.

The fact that the Wisconsin Central and the Suburban will operate trains over the same track, the one by steam and the other by electricity, has made necessary unusual precautions in the overhead construction. The Wisconsin Central specified that the trolley wire should be at least 22 ft. above the rails, and that the poles should be set at least 7 ft. from the outside of the rails. The poles are spaced 110 ft. apart. Along this branch, 1.7 miles, each pole has a cross-arm running in the direction of the track, to which two  $\frac{5}{16}$ -in. span wires are secured, being about 18 in. apart. The two wires are provided close together, so that if the trolley leaves its wire and strikes one of them, breaking it, it will in all probability be deflected downward by the reaction and pass under the second span without striking. Also at each pole a third span wire of  $\frac{1}{4}$ -in. steel is placed above the other two; these span wires support a  $\frac{1}{4}$ -in. steel wire parallel to and 21 in. above the trolley wire. Midway between poles the trolley wire is suspended from the longitudinal steel span wire by insulated hangers. Thus, if both the lower span wires should be broken the trolley wire would still be suspended at 110-ft. intervals. It is thought that this construction will protect brakemen on the steam trains from contact with live wires.

### THIRD AVENUE RAILROAD ABSORBS A STAGE LINE.

The Fifth Avenue Transportation Company has turned over to the Third Avenue Railroad the control of the stages which run from 88th street down 5th avenue to Washington square and thence down Broadway to Bleecker street. This service will be greatly improved by increasing the speed and making the coaches more pleasing in appearance. Transfers will be given between the horse car, cable lines and stage coaches.

Plans of a light railway from Kittybrewster to Oldmill have been filed by the Great North of Scotland Railway Company, which also is promoting the Skene & Echt Light Railway. The line will be 3 miles in length.

### MORE CAST WELDING IN CHICAGO.

During the coming season the Chicago City Railway will cast-weld the joints on about 25 miles of track; work was begun March 22, being done at night in order not to interfere with the regular traffic. In order to secure data as to cost of operating poor track, the company's dynamometer car, which was illustrated in the REVIEW for January, is run over the track before and after welding the joints. A representative of the REVIEW gladly accepted an invitation to accompany the trackmaster, Mr. Heidelberg and Mr. Price on the car's first trip out. Leaving 39th and Wallace streets at 1:30 a. m., a run was made on Wallace street to 29th and then east to South Canal, with the recording apparatus in gear, and then back over the other track. For hauling the dynagraph a motor car fitted with resistance coils for cutting down the current was used. The speed was about 6 miles per hour, which proved to be plenty fast enough for the comfort of the observers who were on the dynamometer car, which it may be remembered is unprovided with springs. The track on Wallace street was laid with 4½-in., 63-lb. rails about 9 years ago and was in good condition when electric cars began to operate over it in 1895; now the joints are in such bad shape that cars can not be run at more than 10 or 12 miles per hour for fear of derailment. The few blocks in 29th street is new track laid with 7-in., 83-lb. girder rails and as yet is in good condition, there being but few low joints. With the track on Wallace street there was no question as to whether the joints needed welding and the run was made merely to find out how expensive it is to operate over it, in its present condition.

### SINS IN CAR WIRING.

The REVIEW has several times called attention to a common carelessness in car wiring, a carelessness which, taking the United States over, results in numerous car fires in a year. But bad car wiring is more excusable in a street railway repair shop where some of the men may not know what is the most advanced practice, than it is in a car building shop where only the best work is supposed to be turned out. The car wiring that some car builders send out is a disgrace to the builder and a menace to property. A 500-volt grounded circuit is entitled to considerable respect but it is put in by some car builders in a way that insurance inspectors would not pass for a 50-volt circuit. This is a detail in car building that may well be looked after in car contract specifications and scrutinized carefully before accepting cars from the car builders.

### HANNIBAL STREET RAILWAY SOLD.

An eastern syndicate, represented by D. Thomson, of Ithaca, N. Y., has purchased the property of the Hannibal (Mo.) Street Railway Company. Many improvements and some extensions are contemplated, a new power house is to be built and a 300-h. p. engine with dynamo and boilers will be purchased. New lines to Riverside and Mt. Olivet cemeteries and to Oakwood are suggested. Indian Mound park will be made attractive for outing parties by constructing a dancing pavillion and refreshment booths. Mr. Thomson, the new manager has held a similar position with the Ithaca Railway & Electric Light Company. He is a brother of Elihu Thomson and a competent electrician.

## STREET RAILWAY ACCOUNTANTS' ASSOCIATION OF AMERICA.

## Successful Gathering and Organization of the Accountants — Valuable Papers Read — Active Discussion — Imperative Need of Work in Standardizing.

A meeting of street railway accountants was held in Cleveland on March 23 and 24, and resulted in the permanent organization of the Street Railway Accountants' Association of America. All the preliminary work leading up to the date of assembling was done by the STREET RAILWAY REVIEW, and the results are equally gratifying to this publication, and to those present.

The meeting was well attended, particularly so for an organization meeting, and represented widely separated territory. Delegates were present from Minneapolis, Omaha, Toronto, Montreal, Boston, Baltimore, Washington, Augusta, Ga., Cincinnati, St. Louis and Chicago, and many cities within the range of the above.

As this was the first gathering ever had of members of the accounting departments, scarcely any one present had ever met more than one or two of the others, but no time was lost in becoming acquainted, and no convention was ever more pleasant and harmonious in all its details than was this. The whole proceedings were conducted with that systematic and business-like thoroughness which characterizes the daily official life of the delegates, and the amount of work accomplished in the brief space of two days was at once astonishing and highly creditable. Every one took hold with an earnestness and determination which showed unmistakably he was there for business, and the convention had not been in session 15 minutes when it was plainly evident that the Accountants' Association would be a great success. The meeting was fortunate in its selection of temporary officers, though there was no disposition to wander from the subject under discussion. When a question came up it was strictly adhered to until it was thoroughly discussed and then it was laid aside. The enthusiasm of all present, their willingness to take part and in short to do cheerfully whatever was to be done, was specially noticeable and reflects great credit on the new organization, which is now equipped for work. The value and amount of that work is now realized and appreciated as never before, after having had this opportunity to exchange ideas the Accountants' Association is beyond any question destined to prove of inestimable value to street railways, and to the American Street Railway Association. It has a work to do which the American has never yet been able to do, and which each year with its own growing labors will be less and less able to accomplish. But the new work is now plainly seen to be in no respect less valuable and necessary from now on, than has been the splendid record of the older society. The operating department is constantly increasing its demands upon the accounting department for data, present and past, and to evolve the most perfect yet economical methods of accomplishing this, is one of the things the new association finds to do.

## Tuesday Morning.

The rain was busily falling outside when the accountants assembled in the banquet room of the Hollenden, but failed to dampen the ardor of the delegates assembled. Introductions occupied an hour, and shortly after the arrival of the eastern trains the meeting was called to order at 11

o'clock, by H. H. Windsor, of the STREET RAILWAY REVIEW, who spoke as follows:

Gentlemen, the pleasant duty seems to have devolved upon me to call to order the first national gathering ever held of street railway accountants, and in doing so I congratulate you on the presence of so many earnest workers in this particular branch of street railway work. In this connection a few words as to the events which have culminated in this meeting may not be without interest. On November 23, last, just four months ago today, Mr. Brockway, auditor of the Toledo, Bowling Green & Fremont Railway Company, wrote me expressing the wish that a national gathering of the auditors of interurban roads might be brought about. He modestly insisted that his name should not be mentioned, so we will omit that.

On studying the matter, however, it was found so few roads comparatively are exclusively interurban, and even these in most cases use the tracks of urban companies to get into the city, making the relations of both very intimate for the accounting, even more than for the operating department; and in view of the fact that the need has long been felt for an effort toward standardizing accounts, it was decided that the accounting departments of all street railways should be invited to meet. Further correspondence resulted in a majority expressing a choice for the city of Cleveland as a central meeting point, and the latter part of March as the time. During the evolution of things an impression was erroneously conceived by some that the proposed organization might in some way prove antagonistic, or at least competitive with the American Street Railway Association. This was doubtless caused by this meeting for organization being called in March when the American Association always meets in October.

Right here let it be said, the idea of something in the way of a separate or individual association for the accountants was occasioned in this way. In the American Association almost all the time is occupied by the operating departments, leaving practically no time available for the accounting departments. The work of the American has grown larger each year and will continue to do so, making it more and more difficult to assign sufficient time to suitably take care of the accountants' interests. Again, the work of the operating and accounting department while intimate at many points, is in the main radically different, just as banking and manufacturing are related, but distinct. What most interests the operating men, and for which they attend conventions, is of little help to the accountant, and conversely, what would be meat to the accountants would be crumbs to the operators.

Hence the necessity and desirability of at least a separate meeting room and a distinctively accounting program. The very urgent need of getting the work started so that committees can be appointed at this meeting, and have the intervening months between now and October in which to work, was deemed sufficient to warrant a gathering now. \* \* \*

The first business before the house is the election of temporary chairman, and nominations are now in order.

Mr. Duffy: I nominate Morris W. Hall, of Camden, for the position of Chairman.

Mr. Hall: I thank you very much for your kindness; but I prefer that some more aged person be put in this position.

Mr. Windsor: We will put the age on for you if you come up here.

The question was then put on the nomination, and Mr. Hall was unanimously chosen Temporary Chairman.

Mr. Windsor: Mr. Hall, please come forward and take the chair. Gentlemen, Mr. Hall, of Camden.

Chairman Hall: Gentlemen, I thank you very much for this honor which you have conferred upon me. It is entirely unexpected. This is the first time I have ever had the pleas-

ure of meeting with my associates in the street railway work. It has been the privilege of the higher officers of our company to attend the conventions of the Street Railway Association. I have not been to them, with one exception, the Buffalo meeting, held in 1890.

I felt when I received the notice concerning this proposed organization, that it was a good thing for us to come together and exchange ideas and opinions in regard to the affairs of our companies which come under our supervision; and I hope that this meeting will prove to be what we all expect it to be. (Applause.)

M. W. HALL.

The next business in order will be the election of a Secretary pro tem.

Mr. Smith: I nominate W. B. Brockway, of Toledo. He was the first gentleman to suggest the formation of this association, and it is proper he should keep it up to date.

The question was then put on the nomination, and Mr. Brockway was unanimously chosen Temporary Secretary.

The Chairman: It will be in order, I presume, to have a speech from Mr. Brockway.

The Secretary: I made my speech as I was coming down the aisle. I said objections didn't go. I don't think a speech is necessary, and it is suggested that these slips be passed around for the names and addresses of all the gentlemen present, so that we will have a complete list of those in attendance.

The slips were then handed around and the record of those present made.

The Chairman: We will now listen to the reading of the names of

#### Those in Attendance.

Morris W. Hall, Secretary Camden & Suburban Railway Co. Camden, N. J.

M. C. Lytle, Wadsworth, Ohio.

W. W. Herrick, Adjuster Cleveland Electric Railway Company, Cleveland, O.

Frank R. Greene, Secretary Chicago City Railway Company.

A. F. Walker, Allentown & Lehigh Valley Traction Company, Allentown, Pa.

William P. Ham, Secretary Nassau Electric Railroad Company, Brooklyn, N. Y.

D. A. Keister, Auditor for the Marion City Railway Company, Marion, Ind.

W. B. Brockway, Auditor Toledo, Bowling Green & Fremont Railway, Toledo, O.

F. S. Borton, Secretary Akron, Bedford & Cleveland Railroad Company; Painesville & Eastern Railroad Company, Cleveland, O.

F. E. Smith, Auditor Lynn & Boston Railroad, Lynn, Mass.

Charles L. Wight, Auditor Toledo Traction Company, Toledo, O.

J. F. Calderwood, Auditor Twin City Rapid Transit Company, Minneapolis Street Railway Company, Minneapolis, Minn. The St. Paul City Railway Company, St. Paul, Minn.

E. S. Doud, Secretary Lehigh Traction Company, Hazleton, Penn. H. C. McJilton, Secretary Baltimore Traction Company, Baltimore, Md.

W. R. Avery, Auditor Cincinnati Street Railway Company, Cincinnati, O.

P. V. Burington, The Columbus Street Railway Company, Columbus, O.

W. G. Ross, Comptroller Montreal Street Railway Company, Montreal.

J. M. Smith, Comptroller Toronto Railway Company, Toronto, Ontario.

A. L. Linn, Jr, Book-keeper, Cleveland Electric Railway Company, Cleveland, O.

A. T. Walter, Secretary and Treasurer Allentown & Lehigh Valley Traction Company, Allentown, Pa.

Dana Stevens, Accountant Belt Railway Company, Eckington & Soldiers' Home Railway Company, Maryland & Washington Railway Company, Washington, D. C.

C. R. Keavis, Secretary and Auditor Augusta Railway & Electric Company, Augusta, Ga.

E. D. Hibbs, Auditor Consolidated Traction Company, Jersey City, N. J.

John Erhardt, Assistant Secretary Cleveland City Railway Company, Cleveland, O.

F. T. Pomeroy, General Manager and Treasurer Cleveland, Berea & Elyria Railway, Cleveland, O.

H. J. Davies, Assistant Secretary and Treasurer Cleveland Electric Railway Company, Cleveland, O.

W. G. McDole, Auditor Cleveland Electric Railway, Cleveland, O.

E. R. L. Tighe, Accountant Brooklyn Rapid Transit Company, Brooklyn, N. Y.

Walter N. Barnaby, Chief Accountant Brooklyn Heights Railway Company, Brooklyn, N. Y.

H. L. Wilson, Auditor West End Street Railway Company, Boston, Mass.

W. S. Dimmock, General Superintendent Omaha & Council Bluffs Railway & Bridge Company, Council Bluffs, Iowa.

C. N. Duffy, Secretary & Treasurer Citizens Railway Company, St. Louis, Mo.

Robert V. McCullough, Cashier Southern Electric Railway Company, St. Louis, Mo.

Henry H. Windsor, Street Railway Review, Chicago.

Edward E. Higgins, Street Railway Journal, New York city.

T. E. Crossman, Official Stenographer, Brooklyn, N. Y.

The Chairman: We shall now have the pleasure of listening to the first paper on the programme, by Mr. Wilson.

Mr. Wilson: When I was requested to write a paper on this subject, I consented without giving it much thought. Upon being able to take up the matter a few days ago, I found it was apt to be an introduction to everything that was to follow, and my payer will about cover that, and nothing more, I think.

#### From Horse Car to Electric Accounts.

BY H. L. WILSON, AUDITOR WEST END STREET RAILWAY, BOSTON

The first horse railways for the transportation of passengers of which there seems to be any record, were used in England early in the present century. These, however, were not operated on the street, but over private ways similar to the present steam railroads.

The system of transporting passengers by street cars may be said to be an American invention, as the first successful horse railway for this service was established in New York city in 1852.

We can, therefore, safely assume that the first accounts ever kept in our business were started at that time.

From the time the first horse railway started to the present the accounting methods have, no doubt, steadily advanced, but have probably progressed more during the last eight or ten years, or since the new method of electric motive power has been in use, than during the previous thirty-five. The accounting methods in nearly all lines with which I am familiar have improved lately, but perhaps in no business as rapidly as in this, and it is a great pleasure to say that the importance of this department is now generally appreciated. Some people think that neglect in this branch is as fatal to the success of a company as neglect in the operating division, as it should be a complete and perfect check on the skill and economy shown by every department. The people interested in it are not only the managers, directors, stockholders and railroad commissioners, but also bankers, investors and creditors, and I am sorry to say sometimes lawyers, judges and receivers.

At the present time there is no branch of accounting that does not come within the scope of street railways. It is necessary, or at least desirable, to have some knowledge, not only of what might be termed

commercial bookkeeping, but also of manufacturing, banking and insurance, as they all enter in a greater or lesser degree in railway accounts.

In the earlier days of the horse railways the stockholder's only interest seemed to be the answer to the question, "Is or is not the usual dividend to be paid?" and the management did not seem to care to know much more.

This is not true in all instances, but was in a majority of cases. I regret to say that even at this time there are some companies of considerable magnitude which keep what books they have in such a slack way that it would be impossible for any one to tell what their condition is by an examination of what they call their accounts.

As an instance, I have been told within three weeks of a company of considerable size in one of our largest cities which has paid on bills, rendered in different forms, three times for the equipment, and yet does not know it. It is easy to judge what might be done with that road under proper management of the accounting department.

The property accounts of the horse railways were generally few in number, and in most instances were only divided into Real Estate, Construction, and Equipment. At the present time the directors or officers of most roads who represent millions of invested capital in property of this kind where before it was only tens or hundreds of thousands, wish to know: What car houses, equipment of same, power stations, steam and electrical equipment of same, track, poles, overhead trolley lines, overhead feeder lines, feeder conduits, feeder cables for same, cars, trucks, motors, snow plows and other vehicles, machinery, tools, etc., cost, and in some instances want even greater detail than the above, or, in other words, what the different kinds or methods of construction cost in certain streets or districts, and what the different makes of equipment cost. To one who has not had the experience it may seem very much a task to keep all this information, but it is often very surprising to find how much can be accomplished with system when it is thoroughly understood. It is, of course, necessary to have more or less help from the men who are actively engaged upon the work. As a general rule they do not appreciate the importance of the accounting department, but will, in most instances, do all in their power when a system is laid out for them to follow, if it is not too complicated, and as these men are not hired for their ability to consider these matters any more than we are to build or equip the road, care should be used to make them as little trouble as possible.

While the accountant may not be employed for his knowledge about the practical mechanical construction, or operation of the railway, he will find that in many ways it is very desirable to obtain as much information on these subjects as possible. If he is able to discuss understandingly with the managers and heads of departments about the construction, equipment and operation, it will be found very much easier to keep records and accounts that will be valuable to all the parties interested in the management of the company.

At times it often appears as though the amount of detail which some companies have is more than would ever be required, but no one can tell when they may be asked to give some particular item of information and when the time does come the person requesting it is almost sure to be in a hurry and is usually very much surprised if it cannot be finished at once.

The managing director of a consolidated road in one of the large cities was in our office one afternoon when the president sent word that he wanted to know the number of feet and kind of track built on each street since the road was consolidated, and when word was sent back that the statement would be ready the following morning, he seemed very much surprised. He wanted to know if similar questions could be answered as promptly, and when told that they probably could, made the remark, "It must be a happy board of managers that can ask such questions and receive answers so promptly." It was only about a year afterward that the company which this gentleman represented was forced to go into the hands of a receiver. Possibly if its accounts had been kept in a different manner, its condition might have been brought so forcibly before it at some earlier date that this could have been avoided. If not there might have been some records that would have been of much value to the parties who reorganized the company.

In this connection it seems to me to be a very important part of the accountant's duty to make all the entries on the books so very plain and explicit that if referred to years afterward or by another person there can be no question about the meaning.

In the days of horse railways there were some companies, generally

owned by one or two men, who cared to keep few or no accounts. They knew how much money it cost to start their business and after that the only thing they thought of was how much they could get out of it. In one large city in the west that I know of, there was a road of this kind, where, so I have been informed, the man who practically owned it would walk into the office while the conductors' returns were being counted and help himself to whatever cash he desired. Whether he wanted it for the business of the company or for private use was never known. It is unnecessary to state that the books in this office were never balanced, and yet the owner grew rich and sold the road for about two million dollars. The condition of the equipment can readily be imagined when the riding public used to claim that the cars were devoted to them during the day and used to stable the mules in at night. The best managed roads kept comparatively few accounts, those in charge being generally satisfied if they knew what it cost to repair track, to repair cars, to repair buildings, to feed horses, to repair harness and general equipment, and to pay for operating labor. You might almost say this is as much as they know now, but the detail in any large, well managed company is kept in such a manner that these accounts are so sub-divided that very much more is available and constantly required.

John Locke, the eminent English philosopher once wrote. "The skill of keeping accounts is a business of reason more than of arithmetic." I think when a system is to be started that "reason" should enter very largely into it.

First. What is it we want to know?

Second. What is the shortest and best way of obtaining this information?

When the electric roads started, the first question was a very hard one to answer, and I think most companies found before long that they had more or less complete records of what they did not care particularly to know, and not enough of what they should have liked to have found out.

When anything new is introduced the projectors always claim a great deal and the electric companies which wished to introduce this system on the street railways were certainly no exception to this rule. The important thing to find out was whether or not all their claims could be substantiated, and this was where the accountant's duties began. As the company with which I am connected was the first to take hold of this new system of propulsion on a large scale, our experience may be as interesting as any.

The first line was built and the cars equipped by the electric company and it guaranteed to keep the equipment in order for a specified sum per car-mile.

Very shortly after, it wanted to pass this business over to the company, and it was agreed to take it. Naturally the managers and directors were anxious to see if they could do this work as cheaply as was claimed, that they might have some basis on which to work when they considered the advisability of adopting this method on other lines. The next time any new equipment was added it was of an improved pattern and the question came up, How much cheaper can this be maintained than has been the former? Improvements came along so very fast in the early days that this was considerable of an undertaking, but the information obtained proved so valuable that it is practically continued to the present time with constantly improving methods, which makes the same information available with very much less work.

When the electric road was in its infancy it was frequently almost an impossibility to get many of the small parts necessary to maintain the equipment, as most of the manufacturing companies were bending all their energies to get out complete new equipments. In many instances when parts were obtained the price seemed to be out of all reason. This drove some of the larger companies to the necessity of establishing what might almost be termed manufacturing plants, and this of course added new features to street railway accounting.

The more important companies as a general rule now divide their operating expenses into a large number of accounts, but how many they might have at this time if horse power had been continued is mere conjecture.

General expenses which can be, and in most instances are, separated into such accounts as salaries of officers and clerks, general expenses of offices, stationery and printing, legal expenses, inspector's services and expenses, insurance, rents, etc., would apply equally well to either.

The material and labor used in the maintenance of buildings was generally included in one account in the old days, but in many

instances is now subdivided into such accounts as repairs of car-houses, repairs of shops, repairs of power station buildings, repairs of miscellaneous buildings, and sometimes a separate account is provided for such items as maintenance of miscellaneous fences, sewers, etc.

The maintenance of track is now one of the most important accounts with which electric railways have to deal, and is capable of considerable analysis with good results. The total cost of this work on the West End Street Railway for the last fiscal year was over \$938,000, and this was separated into such accounts as superintendence, engineering and general expenses; labor, repairing track; labor, paving track; labor of teamsters; labor of watchmen, etc.; timber and ties; rails and fastenings; frogs, switches and guard rails; paving blocks; sand, gravel and cement; maintenance of track department carts and vehicles; maintenance of track tools and equipment; use of horses and miscellaneous expenses.

A small road would not care for all this information, but when the expenditures amount to almost a million dollars in any one department it is well to know for what it has been expended.

Experts when called upon in the early days decided that the wear and tear upon the tracks by electric cars was about 45 per cent greater than by horse cars, but the accounts show that this was underestimated, as the cost of the material and labor that goes to make up a mile of track in a large city at the present time would build several miles of old construction, and the life of the latter would be much longer if operated in the old way.

Maintenance of rolling stock was in most instances in the old days one account, but at the present time is generally so separated that those operating the company know what it costs to maintain the car bodies, the car trucks, the car fenders, the snow plows, and carriages, wagons and vehicles, and in some instances these are so divided that the cost of the summer or open car equipment, and the winter, or closed car equipment, is kept separate.

The principal difference in the operating expenses of the old companies and the new, comes in the subdivision of what goes to make up the cost of motive power. In the days of animal power, there was at most, provender and bedding, shoeing, veterinary, harness repairs, horse renewals and stable labor. Today there is labor in power stations, fuel, oil, water and miscellaneous supplies for power stations, maintenance of steam equipment of power stations, maintenance of electric equipment of power stations, maintenance of underground conduits, maintenance of underground cables, maintenance of overhead feeder lines, maintenance of poles, maintenance of overhead trolley lines, maintenance of track wiring or bonds, maintenance of motor armatures and fields, maintenance of motor gearing, miscellaneous maintenance of motors, maintenance of controllers or rheostats, and maintenance of trolleys.

The cost of power furnished from the stations is also capable of considerable analysis and quite often with very good results. Where there is more than one station, the cost per mile, or per car-hour, or both, or total cost per kilowatt-hour is information which it is often desirable to know. Some want to know the amount of water that is evaporated per pound of coal consumed, or cost of coal per kilowatt-hour, or answers to some similar questions.

This not only gives a basis for comparison between the different power stations on the company's own road, but if another corporation is willing to give its cost of operation there is an opportunity to compare the plants and the results often give some valuable knowledge as to what kind of boilers, engines or generators it is for the advantage of the road to purchase for some contemplated addition or new station.

Many of the horse railway companies kept a separate account of the cost per day or per meal of feeding horses in the different stables in order to compare the efficiency of the men in charge. The condition of the animals was, of course, a very good check, as if neglected in any way it would at once be apparent.

If the maintenance of motor accounts are kept separately by car houses and the total cost computed per car-mile run, it gives an extremely good comparison of what the different foremen in the car houses are capable of doing with the mechanical equipment in their care, as if a man is extravagant it is immediately detected and as they know that their expenditures are being closely followed they are extremely careful of both their material and labor, yet realize their work cannot be neglected as a delay on the street is now much more serious than it used to be.

This information is not only valuable for the purpose mentioned

above, but also as a basis of deciding when it is cheaper to buy new equipment than to continue operating the old, and the accounts are the only way that this knowledge can be obtained.

To some of those engaged in the business in the past, the present methods seem altogether foolish, as I found one day when a gentleman who was formerly the chief accountant of the largest horse railway in this country called upon me, after devoting about twenty minutes to looking over the methods used in the office, he informed me that it was all very pretty but that it was all nonsense.

The revenue accounts have received considerable consideration lately and this, to my mind, is a very important department of the accounts.

Not only is it important from the standpoint of the company, but equally so from that of the conductor, who has a large personal interest in knowing that he is to be protected as well as the corporation. No one is infallible, and if the collector of fares thinks a mistake had been made in the office he should be encouraged rather than blamed if he wishes to look the matter up. If he should call and the error is found to be a mistake of the clerical force it gives him a very bad impression and in the long run probably acts to the disadvantage of the company, as his experience will be thoroughly talked over by the men in the lobby of his car house and perhaps travel over the entire division.

On the other hand, if the seeker after information meets with a rebuff he is very sure that he has been cheated and is liable to try to get square with the company. The force in the office working in this department should, therefore, use every care possible to avoid mistakes and be sure and treat the conductor with proper courtesy if he wishes to investigate any shortage with which he may have been charged.

It is only within comparatively recent years that a registering device for fares has been in use on street railways. When this was first introduced in Boston, many conductors resigned, claiming that it was implying that they were dishonest, but at the present time any honest man ought to feel that this is only a mechanical device to help him keep his accounts.

The total miscellaneous earnings of many companies are divided among the different lines, but on some where the routes number away up in the hundreds and in many instance run over tracks used by several other lines, this is found impracticable. The best way that I know of to keep well informed about what the different lines are doing is to make a report once or twice a month of the passenger earnings per-car mile on each route operated. If this is done anyone interested can see at a glance whether the number of trips should be increased or diminished or allowed to remain as they are, and if the patrons claim that they are not having the facilities that their patronage warrants, this record will at once prove or disprove their claim. If it is figured only by trips it hardly give a fair comparison on a large road where the lengths of the rides vary.

Some of the largest companies have several divisions, any one of which is as large as a majority of the roads now operated, and have a separate superintendent in charge of each. Where this is the case if the transportation expenses are divided and the cost figured per car-mile run, the manager has an opportunity of knowing what his subordinates are doing. Of course when comparisons of this kind are made it is necessary to take into consideration the territory operated by the different divisions, as one might be largely in the crowded streets of the city, while the large part of the mileage of another might be made over suburban lines where the speed would make a considerable difference both in the earnings and expenses.

In many places the opinion prevails that an electric road is a veritable gold mine and that the management can afford to do almost anything in the way of extension of lines, and improvement of facilities as well as pay large sums for taxes of different kinds, and perhaps maintain the streets through which the cars are operated. One of the most important things that the accounts are frequently called upon to prove is that the company is doing all that ought to be expected of it considering the amount invested, the operating expenses, and the patronage given by the riding public.

Mr. Avery: I move that the report be received and placed in the record of the meeting, and the thanks of the meeting be tendered to the reader. Carried.

The Chairman: The next on our program is a paper on "Useful and Useless Classifications" by E. D. Hibbs,

auditor of the Consolidated Traction Company, Jersey City. I have just learned that the gentlemen is not present.

Mr. Hibbs (entering the room): Mr. Hibbs has just arrived. Gentlemen, I must claim your indulgence in this matter. I am sorry I have not prepared a paper. I did not until yesterday noon expect to be here. I have been busy with our annual meeting which occurred yesterday, and if you will accept my excuse this time, it will not occur again, I assure you.

The appointment of committees was then taken up, the number of members, on motion of Mr. Tighe, being placed at five. Committees were as follows:

#### Committee on Organization.

FRED. E. SMITH, Lynn, Mass.  
C. N. DUFFY, St. Louis, Mo.  
H. H. WINDSOR, Chicago, Ill.  
J. F. CALDERWOOD, St. Paul, Minn.  
WILLIAM F. HAM, Brooklyn, N. Y.

#### Committee on Nominations.

P. V. BURINGTON, Columbus, O.  
E. D. HIBBS, Jersey City, N. J.  
FRANK R. GREENE, Chicago, Ill.  
F. T. POMEROY, Cleveland, O.  
E. R. L. TIGHE, Brooklyn, N. Y.

The Chairman: We will now listen to Mr. Duffy's paper.

#### Suggestions for a Standard System of Accounts, Classification of Operating Expense Accounts, and Form of Report that Will Admit of Comparison and Diffuse Information between Companies.

C. N. DUFFY, SECRETARY & TREASURER CITIZENS STREET RAILWAY, ST. LOUIS.

When notified that I was expected to prepare and read a paper at the organization of the Street Railway Accountants, I signified my willingness to do so on the above named subject, with the understanding that the paper would be in the form of suggestions, with a view of opening the way to a thorough discussion. Fully appreciating the magnitude and importance of the subject and the task I have assumed in offering to present suggestions I ask your kind indulgence in the consideration of them.

Beyond any question of a doubt, I think it will be admitted by all the gentlemen present, as well as the operating officials at home, that a "Standard System of Accounts, Classification of Operating Expense Accounts, and Forms of Report that will admit of comparison and diffuse information between companies," is not only desirable, but a consummation most devoutly to be wished for. The operating officials meet annually to talk on all questions pertaining to the operations of their roads, read, listen to and discuss papers, exchange opinions and experiences, but have no means of knowing if they profit by the information received and imparted, by a comparison of results as would be possible with the adoption of a standard system. To demonstrate the truth of this statement, I will say that recently the general manager of one company in sending the annual report of his company to another general manager, took occasion to say that there was very little statistical information of interest or practical value in the report; that he would be glad to exchange information of this character with his correspondent, and hoped to see some form of report adopted by the members of the American Street Railway Association, that would provide for an exchange of such information.

It would be entirely practical to adopt a standard system, notwithstanding the objections we may all have to making changes. This need not prove a stumbling block, as a standard system could be conformed to without changing the methods and system now in use on any one road, provided, however, that the accounting officer would arrange his figures to conform with such standard as may be agreed upon, supplementing his present system with what would be found necessary to take care of such changed conditions as he may have to meet. For example, if any particular road objects to abandoning or changing its present system because the officers, directors and stock-

holders are familiar with it and can more readily comprehend and understand the figures, because they would not be willing to throw away the ruled account books, form of report, etc., now in use, or because they are obliged to keep their books and accounts as prescribed by a state board of railroad commissioners, as I understand is the case in some states; or for any other reason, it would be perfectly feasible and practical for the accounting officer to follow the classification of operating expense accounts as adopted, arrange his figures to conform with the same on blanks prepared for that purpose, leave his present methods and system unchanged and conform with a standard system, as well. Unquestionably it would be far better for all to follow completely from beginning to end any standard system that would be adopted, but it must be remembered that it may not be possible on some roads to do this.

With regard to the question of methods and systems now in use. One of the first things that suggests itself is the method of charging in operating expense accounts, purchases of material and supplies. On some roads it is the custom to charge such purchases when the goods are received, on others when the bills are paid, on others when the goods are used. Undoubtedly the last named is the only method that is absolutely correct, but it is not possible to use this method unless the road has a storekeeping system, which, of course, is the proper and best system. Small roads cannot afford the expense of a storekeeping system, as it is useless to have a storeroom without a complete system of bookkeeping and checking. The argument that unless goods are charged only when used, that the exact cost of operating for any one month cannot be determined is true, but is not of such great importance. The result of the year is what we all look to, and not of any one month. Besides, in order to get at even an approximation of the exact cost of operation for one month, it is necessary to estimate and prorate the month's proportion of the yearly expense of water license, taxes, insurance, interest and extra weekly pay rolls on roads that pay their employes weekly. Then, too, there is the damage account. With the liberality so characteristic of the juries of the present day a road may be called upon to pay and charge up in one month a sum equal to the average amount of any year. This is a condition that every road is ever confronted with, and one that cannot be controlled. On some roads the month's proportion of the estimated amount that will be charged up to damages in the year is prorated and carried like insurance, taxes, etc. Take the items of coal for heating cars and salt for track. On the majority of roads it is customary to buy these articles in large quantities in the fall of the year, pay the bills then, charge them on the office books to the accounts they properly belong to, and not put them on the storeroom books. On some roads, where purchases of material and supplies are charged when the bills are paid, the bills being paid regularly each month, purchases are made to conform with what a month's requirements are. I know of one system with a total expense account of \$765,000 in the year 1896, where the purchases of material and supplies of every kind charged in operating expenses were only 12 per cent of the total expenses; of that amount 40 per cent was for power house coal. Whatever may be the practice in vogue on any road as to the charging of supply bills, it will not affect the adoption and use of a standard system, but uniformity of methods is desirable, if not absolutely necessary, to accomplish the results to be attained.

The one object that should be uppermost in the mind of the accounting officer of a street railway, is to keep his operating expense accounts in such a way that the management of the road will profit by the information. In order to have a classification of operating expense accounts that will admit of this, there is great danger of having too much subdivision and itemization. This necessitates not only a mass of figures, but a corresponding amount of detail work that sometimes proves unwieldy. Another source of trouble is the difficulty of putting into practical operation any system or standard that may be adopted. I refer to the dependent position occupied by the accountant with reference to the necessary information and discrimination that must be relied upon from subordinates and heads of departments as to the basis of charges. This is especially true of

C. N. DUFFY.

pay roll charges. Printed classification books and special ruled and printed time books do not remove the difficulty. It is one thing to have a theoretically perfect system, another to have it properly carried out. Whilst this is true, it is highly essential for the accountant to have a system that will show in a comprehensive and practical way just how the money of the company is being spent, comparatively with the preceding year, with such details of statistics that he can answer any question put to him.

Above all the accountant should be something more than a mere book-keeping machine. He should be thoroughly posted on the affairs of the company and have a general knowledge of the operation of the road in all departments. Without these qualifications his sphere of usefulness and the value of his services will necessarily be limited.

One of the problems that is perplexing and troublesome to solve in actual practice, is the separation of maintenance charges from operation or transportation charges. On this question there is a difference of opinion as to what properly constitutes a charge to either one, separately. Some hold that certain expenses of the electrical plant, the car, motors and electrical car equipments, track and roadway are operation or transportation charges and not maintenance charges.

Others contend that such expenses are maintenance charges, for example, carbon brushes for the dynamos, repairs and renewals of fare registers, trolley cord, motor brushes, etc., are classed operation or transportation expenses by some, because these expenses are incurred or rendered necessary by the operation of the cars. Others argue that every expense of this kind is a maintenance expense, because it was incurred and rendered necessary in order to maintain the dynamos, fare registers, cars, motors, etc., in perfect condition, or in the same condition as prevailed when the operation of the road commenced, notwithstanding that the wear and tear was incidental to, and the result of operation of the cars. With regard to track and roadway the same difference of opinion and practice exists. The expense of cleaning and sanding the track and removing snow and ice is considered by some a maintenance expense, by others an operation or transportation expense. It appears to me that the expenses of the electrical plant, the cars, motors and electrical car equipments previously referred to are properly maintenance charges; the expense of cleaning and sanding the track, removing snow and ice, operation or transportation charges. This question of distinction between maintenance and operation or transportation charges is one that could be discussed to such length that our patience would be exhausted and our minds brought to a state of hopeless confusion. This distinction and the application of it applies not only to those items previously spoken of, but to many others. For example, shop machinery, tools and appliances, water, sand, and salt cars, snow plows, sweepers and scrapers, wagons and vehicles. It is the universal practice I believe, to charge to "Maintenance of Buildings," all expenses incurred in connection with the repairing of buildings. Some accountants keep a separation of power-houses, repair shops, car houses, stables, offices, etc., others do not. If it is thought proper to transfer the cost of maintaining any particular building or buildings to the account chargeable for its use in order to ascertain the total expense of that account, as for instance, power-houses to cost of producing power, car houses to the cost of operating the cars, etc., the separation should be made. Again we are confronted with the problem of making the proper distinction, as there will of necessity be charges to both maintenance and operation or transportation, in "Maintenance of Buildings" account. In the operation of the road, this question of distinction between charges is not one of great moment, although it is desirable that the lines should be closely drawn, that the separation will be clearly defined and as distinctly made as possible. Regardless of the separation of maintenance from operation or transportation, the practical general manager would probably be more interested in knowing, and the accountant should be able to tell him, the cost of power per kilowatt-hour, per mile, per passenger; the cost of repairs and renewals of the steam and electrical plant, with such itemization as would be considered important; the cost of fuel, water, lubrication, supplies and tools; the cost of lighting the power-house building and such other information concerning the operation of the power plant, as he may desire, the cost of each car, and car equipment per car-mile and per passenger separately, making a separation of car bodies, trucks, fixtures, and trimmings; the cost of wheels, brake shoes, painting, glass, seats, curtains, registers, etc.; the cost of oiling, lighting, cleaning and heating a car; the cost of lubricating the motors, the cost in detail of the different parts of the motors and car equipments; the cost of

the track per single mile, the track and the roadway, the line, the expense of watering, sanding, salting and cleaning separately; making a separation of the ties, rails, fastenings, joints, special work, paving, crushed stone and ballast, etc., with such other details and statistics as may be found valuable or important.

On the question of statistical information concerning the operating expenses of a road per car, per car-mile, per passenger, per mile of single track operated, conditions must be taken into consideration and complete data pertaining to them fully and explicitly set forth. It is important to know the kind of cars in use, whether single or double truck and how many of each, the number of open and the number of closed cars, the size of the car bodies, whether or not trail cars are operated, the type and capacity of motors, the number of car-miles made over each mile of single track operated, showing the motor and trailer miles separately, the passengers carried per car-mile, giving the adults and children, fare and transfer passengers, separately. The car-mile unit appears to be the only basis to figure on, but for the purpose of comparing results, it is sometimes misleading and unsatisfactory by reason of the conditions previously referred to.

Sometime ago a road operating double truck closed motor cars and single truck closed motor cars with closed and open trail cars, for its own information and education, gathered data and statistics to determine which was the best kind of car to operate, from every standpoint. In making up the figures it was found that the only way in which a comparison could be made with any degree of correctness or satisfaction, was to figure on the seating capacity available with each style of car operated. It must not be inferred from this that the basis of figuring operating expenses should be per passenger carried per car-mile, and not per car-mile run, as roads enjoying a heavy traffic would have a great advantage over those having a light traffic and there could be such a thing as running car-miles without carrying passengers.

With reference to construction and equipment accounts, too much care cannot be exercised in making charges. Frequently the management of roads charges to construction and equipment, expenses that properly belong in operation. This is all wrong and should not be done under any circumstances. This practice is apt to prevail on roads that do not make a favorable showing. Any expenditure that is not not absolutely and actually an increase, betterment or addition to the property of the company should be classed and charged as an operating expense. It is desirable to keep such subdivisions and itemization of construction and equipment accounts as will enable the accountant to have full and complete data, showing the cost in detail of each account, and of the items that compose each account. An indexed "Cost Book" will be found a convenient reference, having the cost of the principal items indexed under the proper headings. It is important that the accountant should be in a position to give any information that may be called for, concerning construction and equipment accounts, as he should be able to answer any question that may be asked him concerning operating expense accounts. Whilst on the subject of construction and equipment, it will not be out of place even at the risk of appearing to overstep the boundaries and duties of his position, or of assuming the responsibilities that properly belong to those higher in authority than himself, for the accounting officer to draw attention to the necessity of charging off annually a certain amount for depreciation, wear and tear, etc., of the property of his company, and of the creation of a sinking fund or surplus account, that will really be what it means, having the amounts credited to it invested in some safe interest earning investment, so that when the time comes, as it surely will come, sooner perhaps than is anticipated, when it will be necessary to renew the power plant, cars and motors, track, buildings, etc., that the money will be on hand available for that purpose. Then the company will not be obliged to increase its bonded indebtedness even if it is fortunate enough to be able to dispose of the bonds, open up a "bills payable account," in either event adding to its annual interest charge, or be forced to suspend dividends for a long period of time, in order to raise money to make the necessary improvements.

The argument that the maintenance of the property prevents any depreciation of wear and tear, and therefore there is no necessity of charging off an amount annually to such an account will not hold good in actual practice, as has been very forcibly demonstrated in the last ten years, in the change from animal to cable, and electric power, and still more so on those roads that first changed their power from animal to cable and then to electricity.

Before preparing this paper it was my intention to correspond with the accounting officers of every street railway company of the world, receive the benefit of their experience, learn their methods and system, find out their troubles, secure a set of the blanks and forms in use on their roads, and then present to you in a condensed form the result of the correspondence with such comments and suggestions as I would be able to make. Upon reflection I realized that 30 days would not be sufficient time to carry out my plan, so I was obliged to abandon the idea and had no alternative but to offer such suggestions as came from my own experience. In compliance with the request in Mr. Windsor's circular letter, I have brought with me a set of blanks and forms in use on the roads I am connected with, our classification of operating expense accounts, list of construction and equipment accounts, form of annual report, etc., representing the methods and system in use on our roads which I will be pleased to submit and explain to any one who may desire to go into the matter. Our system differs in many respects from those in use on the majority of roads; whilst I believe it possesses some advantages, I am fully aware of its disadvantages. In common with other of my fellow accountants and co-workers in the street railway office, I have troubles of my own which I am confident will be dispelled by the aid and co-operation of the Street Railway Accountants' Association and the adoption of a standard system.

On motion of Mr. Reavis a vote of thanks was given Mr. Duffy, and the paper ordered on the records.

Mr. Hibbs: I rise to ask if there has been any preparation made for the exhibition of the different forms which have been brought here so that they can be examined.

The Chairman: I do not think anything definite has been done in that direction. There is quite a collection of the forms here.

Mr. Hibbs: It is an important item, and should be cared for properly.

The Chairman: Will you have a committee appointed to take this matter in charge and arrange the exhibit?

Mr. Smith, Toronto: I desire to see the suggestion of Mr. Hibbs carried out. A committee should be appointed to put the forms in such shape that we will have an opportunity to see them in some place where we shall be quiet and undisturbed. A good many of the gentlemen have brought forms and we ought to have an opportunity to examine them all.

The Chairman: I will appoint E. D. Hibbs, Walter M. Barnaby and William R. Avery a committee to take charge of the blanks and arrange them for the inspection of the gentlemen in attendance.

Mr. Davies: I regard the subject of the last paper read as the most important that can come before this meeting. I do not desire to cut off any discussion that the gentlemen here may desire to engage in. It might be discussed at every session of this convention and no definite result be attained. I want to make a motion that a committee of five—perhaps three would be better—be appointed at this meeting to take this subject into consideration and report at a later meeting, perhaps in October, a recommendation as to a standard system of a street railway accounts. The subject is so important and diverse that no committee which could be appointed by this convention could devise a system which would be satisfactory to all or a majority to be presented at this meeting. Such a committee could correspond with the street railway fraternity, obtain blanks, study them, and possibly, I think probably, make some recommendations towards a standard system which would be adopted at a later meeting.

Mr. Avery: While appreciating the necessity for such a motion, it strikes me, and perhaps will strike a good many others here, that we are not a body of men like those who

attend the meetings of the American Street Railway Association, who are acquainted with each other and who know the different capabilities of the members. We are practically unacquainted. I know personally but one or two of the gentlemen present, and I suggest that the appointment of such a committee would be better made near the close of this session, when we get acquainted with each other, and perhaps learn the strength of some few men over that of the many. I would suggest the postponement of the consideration of this matter until tomorrow.

Mr. Davies: The suggestion is a good one, Mr. Chairman, and I will withdraw the motion for the present. I supposed the subject was being dismissed, and I did not want this matter to be overlooked.

Mr. Wight: I wish to inquire if any gentleman present is connected with a company which runs an electric lighting plant in connection with its street railway.

Mr. Reavis: Our company in Augusta, Ga., operates an electric lighting plant in conjunction with the street railway system.

Mr. Pomeroy: Mr. Chairman, some time tomorrow, after the business of the convention is completed, we desire to tender you arolley ride. There are lots of trolley rides out of Cleveland; the woods are full of them; they run from one mile to 35 miles. I would like to ask this question: Whether you desire a long ride, to go into the suburbs, or simply to ride around the city? This information might help us to decide upon some route. We are prepared to have you ride over them all, but Mr. Windsor suggested that the local people should come together and agree on some particular route. It may help us to know if you want a suburban ride, for instance, to Elyria, Painesville, Akron or Berea, or simply to ride around the city. We would be glad to have you give us some idea of what you desire, so that we can arrange for it.

The Chairman: Perhaps it would be well to have the members talk the matter over between themselves, and then we can find out what is desired, and you can get the information in that way and make the necessary arrangements. It must not be forgotten that we have a very limited time in which to consider a large amount of business, and we must subordinate amusement to business. We shall, of course, be delighted to avail ourselves of any ride that may be tendered to us provided it will not infringe too deeply upon the time at our command.

On motion adjourned until 2 o'clock.

#### Tuesday Afternoon's Session.

Chairman Hall called the meeting to order at 2:15.

The Chairman: The first item on the program this afternoon is the paper on "Earnings, Handling and Accounting," by John Hourigan, auditor Albany Railway Company. The gentleman is unexpectedly detained, and the secretary will read a letter from him.

The next was the reading of the paper:

#### Transfers.

BY FRANK K. GREENE, SECRETARY THE CHICAGO CITY RAILWAY COMPANY.

The subject of transfers is always an important one to street railway men, and should be given a great deal of thought and study on the part of street railway accountants as well as the general managers. While it is an important factor in the earning power of a road, it also presents problems that the auditor should become

familiar with, for, on close inspection, many loopholes for leakage may appear which, if not closed up, may prove costly to a company.

While I will not attempt in these lines to cover the subject in its entirety, I will touch briefly upon certain points of bad practice that have come within the range of my observation and experience. What is true of one road cannot always be applied to others, as circumstances alter cases; yet, there are general rules applicable to all. I will state in a general way how transfers are handled on the lines of the Chicago City Railway Company, and will refer to different changes and improvements that time and experience have taught us to make, and we are still making them, and shall keep on changing.

The company with which I am connected has its own printing office located in the general building, and in this manner we reduce to a minimum the chance of dishonest employes of the printing shop carrying on an illegal traffic in transfer tickets, which is more likely to occur where the tickets are printed at a public printing office.

We print about 100,000,000 tickets each year, or about one for each passenger carried, some passengers requiring two tickets on a single continuous trip, while others receive none. We, of course, print a considerable number more than we expect to use, and these are returned to the general office and destroyed. As the month, year and day are printed upon the face of the transfer, we usually print them from two to three months in advance. They are then assorted and put in packages and sent out to the several depots only one day before they are used. The conductor receives a package of new transfers each morning as he goes to work. All transfers unused by the conductor are turned in to the receiver at the depot when his day's work is done, together with those he has collected as fares.

After the cancelled ones have been duly examined and checked with his trip sheet, they are all thrown into a large bag and sent to the general office, where they are destroyed by being dumped into the furnace. The Chicago City Railway Company operates about 30 different lines, and originally printed about 50 different forms of transfers, while today we issue only 12 different forms. While formerly the conductor punched out the hour and the street after ascertaining from the passenger to which line he desired to be transferred, today he is able to punch his tickets before starting upon the trip, giving to all transfer passengers at the time fare is paid a like ticket.

This is an important improvement, as it gives the conductor more time to attend to the collection of fares and other duties. Thus you will see that the transfer ticket used today must be simple in form and less complicated in all details, yet covering all essential points claimed for the one formerly used.

It is important that it should contain these features, not only for the benefit of the conductor issuing it, but when the conductor takes up a ticket in payment of a fare he should be able to read it at a glance and thus lose no unnecessary time in working his train, and be able to collect all the fares.

In the good old days of horse cars the conductor had plenty of time to collect fares and issue transfers, but since the advent of rapid transit the conductor must necessarily hurry through his train for fear that some of his patrons will reach their destination before he has had time to present his bill. Thus you see a perfect transfer ticket must be one that can be "quickly issued," and "quickly collected." We of course use the different colors to represent different lines, which materially assists the receiving conductor in quickly reading the transfer correctly. As passengers on some of our lines are entitled to receive a transfer only on the payment of a cash fare, it is necessary to issue the transfer at the time fare is paid. On other lines where we issue a transfer on a transfer it was the custom formerly to collect the fares first and issue the transfer later. This, I think, is bad practice, as the passenger can easily impose upon the conductor in this way, and we have adopted a rule that all transfers be issued at the time fare is paid.

Next month we will make still further changes in the form of our tickets, by adopting the coupon style, which will permit us to issue transfers only upon payment of cash fares on all lines at time fare is paid. The time limit, one hour, has remained the same on our tickets, and we find that it is satisfactory for our system, but a shorter limit might answer for a smaller road where the conductor has more time to devote to this part of the work. As most of our patrons require one change of cars to reach their destination, the loss is very small in consequence of the passenger giving away his ticket. As we do not, as a rule, issue transfer except upon the payment of a cash fare, you can readily see that it would be a rare case where two people can make a complete journey upon a single fare. Formerly it

was the custom to ring up transfers the same as cash fares, but we soon found that this was bad practice, as the conductor could easily obtain unused transfers from conductors from intersecting lines, punch them accordingly and turn them in as part of his collection to balance the register account. Now our conductors only ring up cash fares or tickets that have been sold for cash. This I think is a very important item when considering the subject of transfers, and should be given thorough investigation by all roads that are in the habit of registering transfers. It is the custom of some roads that are in the habit of registering transfers, to have a separate register for transfers, and yet I doubt very much if this is any improvement over the old plan, as the passenger seldom notices anything beyond the usual tingle of the bell and does not look to see whether the bell is located over the door of the car, or up the conductor's sleeve.

We have found also that it is excellent practice to make the transfer read "good only at transfer point," and not allow the passenger to go shopping and then take transfer car at a point several blocks perhaps from the intersection of the two lines used by him in his journey. Thus the value of the transfer as a commercial commodity is reduced and the traffic in them becomes less when confined to a given point in a given time.

I doubt the advisability of using any form of ticket that does not have the date printed or stamped upon it, and yet I have not given this phase of the question sufficient thought to determine if other forms are not advantageous in some cases, when considering the question of economy as against fraudulent uses and abuses of the transfer ticket. Our custom is to "railroad" them, if I may use this phrase, as from the time they leave the strong room in the general office till they have become useless and have been duly consigned to the fire furnace, their brief existence of active life is measured by two nights and a day. It is an excellent plan to indicate "half-fare" transfers by punch in order that they may not be used in the latter half of the trip by an adult, as we have found cases in our system where persons living near a transfer point would send two of their children a few moments before making a journey who, paying a nickel, would each receive a transfer, which would be used by older members of the family in the second and longer half of the journey. However, these are rare cases, and would not apply to roads having a single fare for all ages. It is well, as is the custom with most roads to identify each transfer issued by the several conductors in order to trace irregularities by special punch or stamping the number of the conductor upon the face of the ticket before issuing.

The transfer ticket is an important tool in the hands of the general manager in educating the people to ride, which to a certain extent, is a habit on the part of the patron, and it is the auditor's duty to see that he does not overstep the boundary of liberality, and he should assist the general manager in throwing safeguards around the system in order to prevent frauds, etc., and to do this he should become as familiar with the subject in all its details as the general manager. It is for this reason that I have touched upon points that would seem to be foreign to the duty of an accountant; in fact, the auditor should be thoroughly informed upon all matters connected with the street railway business in order to satisfactorily discharge the duties imposed upon him.

As stated before, it is impossible to lay down any set of rules that would be applicable to all roads, and all I can say is that the accountant should become perfectly familiar with the conditions that exist on his road, and it is his duty to see that no loop holes are left open in the system adopted, for frauds, etc. With the general manager on one side pulling in the direction of liberality to patrons and trying to please a never satisfied public, as a positive pole, and the auditor on the other side pulling in the direction of conservatism and a properly guarded system, being the negative pole, there should be generated a system perfect in details which will result in a current of nickles that will flow into the treasury of the company with less ohms of resistance than when transfers were unknown, while the return current through the pockets of the employes will be in like proportion to the mysterious fluid that now makes its daily trips over the wire and rail like the beautiful stream down "Peaceful Valley," upon whose banks the street-car patron and the street-car magnate dwell in peace and harmony, and both are happy and contented.

The writer received a vote of thanks and the paper was ordered on the records.

Mr. Ham: There are two or three questions I desire to ask. Do you have the date printed on your ticket?

Mr. Greene: Yes, sir.

Mr. Hibbs: Did you ever check up with reference to the collection?

Mr. Ham: I have some of our tickets here, and I will hand them around. A certain man is running on a certain line. We have three punch marks on each transfer (which is the weak point). We punch from the line, say, 5th avenue, to the line, say 7th avenue, and the time.

Mr. Hibbs: Do they know when you are going to check these up?

Mr. Ham: No sir. Nobody knows this before hand. For instance, I may go into the office on Thursday, and say, "Take hold and sort Wednesday's tickets." We have about one hundred different designs of punches; it is impracticable to get more than one hundred plain designs.

Mr. Calderwood: Do the conductors keep the pad of transfers while they are off on a swing?

Mr. Ham: Yes, sir.

Mr. Tighe: You only issue transfers for cash fares?

Mr. Ham: That was originally our system, but we have modified it to the extent that a second transfer can be issued to reach some point that cannot be reached by one transfer. The conductor who originally issues the transfer punches the ticket from his line to two other lines. For instance, if a passenger is riding on a 15th street car, and wants to get to a point reached by Bergen street car, and it is necessary in some special case to take a 7th avenue car to do it, the conductor will punch the transfer ticket from 15th street to 7th avenue, to Bergen street. The conductor receiving the ticket on 7th avenue will issue another transfer to Bergen street.

Mr. Tighe: We are unfortunate enough to issue them for either transfer ticket or cash; only about 90,000 a day.

Mr. Ham: The weakness of adopting the plan of having one color of ticket for one day only is that we cannot have different colors for different lines. That is the point I want to get at—is it more valuable to have the different colors for the different days, or the different colors for the different lines?

Mr. Avery: We have thirty-six lines. When you have a large number of lines you do not want different colors.

Mr. Ham: Having different colors for different lines involve printing a great many more tickets. I am not able to get our transfers down to a very fine percentage of waste. One road represented here loses 15 to 20 per cent only. The best we can do is to get it down to 35 per cent.

Mr. Greene: Reference was made to the possibility of a conductor giving away transfers at a transfer point. A conductor who gives them away is not going to stamp his number on them, if they are going to be taken into a store and lie around, in view of the public, or handed out to any one who calls for them. He knows if he gives them away, and they have his number on, that he will likely be detected. Therefore, occasionally, we take all the transfers and look them over, and if we find there are some without the conductor's stamp, we know there is something crooked and investigate it at once.

Mr. Ham: Any outside party could easily get a little stamp like that.

Mr. Greene: That would be easily detected.

Mr. Avery: They forged the dates on us.

Mr. Wilson: Are your transfers registered as a fare by the conductor?

Mr. Ham: We have two registers in every car, different style of registers; one is the Stirling and the other is the Meaker. The system of ringing up is entirely different. As the conductor collects the cash fare he is obliged to ring it up immediately; but he cannot ring up the transfers that way. He has to go up to the front of the car after he passes a transfer point and ring up all the transfers collected at that point. Of course, a conductor might have a transfer ticket in his hand and when he received a cash fare he might pretend that he had collected a transfer; at the same time he has got to get the transfers from somebody else. He cannot turn in his own transfers. As the girls in the office count the transfers they look to see that none of the tickets turned in are the tickets of that particular man. If the tickets are swapped this frequent checking shows what tickets are punched incorrectly, and any which are punched incorrectly the conductor must make good in cash.

Mr. Tighe: You punch the line from?

Mr. Ham: From, to, and the time. The conductor receives the ticket only at the intersection of those two lines and at no other place.

Mr. Duffy: How many lines are there, Mr. Ham?

Mr. Ham: This transfer shows about twenty-two. The printer of the ticket says he has all the detail on the ticket that he wants.

Mr. Duffy: Suppose each one of the twenty-two lines had its individual transfer tickets, to be good on connecting lines?

Mr. Ham: That would increase the number of tickets which would not be used each day.

Mr. Duffy: As to the waste you speak of, they are not dated, and there is no waste at all.

Mr. Ham: You will have to date them.

Mr. Duffy: You have a ticket where the month and the day of the month is punched out.

Mr. Ham: That is what we want to get away from. We think it is more serviceable to have that ticket good only on the particular day, and run no risk whatever of the ticket being used again, than to consider the matter from any other standpoint. We think it is the most important thing in the matter of transfers.

Mr. Duffy: I think the percentage of the tickets misused that way would be small.

Mr. Calderwood: Why not have a ticket for every line, and let the conductor punch out the dates in advance?

Mr. Ham: Where a conductor takes on fifty transferred passengers, you cannot expect him to examine the tickets carefully; we try to make them; they are supposed to do it, but it is beyond reason to expect them to do so. If anyone gives the conductor a transfer a month old, he will not know the difference. If he knows that it is Tuesday, March 23, and it must be a white ticket, and a blue one is handed to him, he knows it is not the right ticket.

Mr. Wilson: We have had a transfer turned in a year late.

Mr. Ham: On our road March 23 another year would be another color.

Mr. Wilson: How many places do these lines end up with; how many car houses or things of that kind.

Mr. Ham: That would be difficult for me to say just now. I do not recall how many we have, but there are as many as there are lines. It is a more recent feature to have the name of the terminals on the ticket instead of the lines; and I think that would be an advantage.

Mr. Wilson: We have one division on an island which is entirely by itself, where all the cars at the end of the route center at the ferry. That is the only line or division where the conductor issues the transfers—everywhere else they are issued by transfer agents on the street. At that point we have a girl, and the transfers are turned in on every trip. They are numbered consecutively, and have the conductors' numbers printed on them; and in that way there is no question about which conductor issues them and the order in which they are given out. They are registered on the same register as cash fares, but as the conductor turns them in on his half trip, as soon as he arrives at the ferry, there is no question about his exchanging with other conductors, because the cars do not intersect, in such a manner as to make this possible.

Mr. Ham: We have one other device which I have not mentioned and that is at the end of each half trip the conductor has to put all of his tickets that he has received on the half trip into an envelope and deposit it in a box in the end of the car. With us we change conductors on the cars frequently. One car may be run by ten or twelve conductors during the day. By reason of these changes, there is much less opportunity for the conductor doing anything wrong in connection with the transfers, because he has to put them in the box in the car, and he may not be on that car again.

Mr. Avery: Do the conductors settle every trip?

Mr. Ham: Turn in their cash? No, only once a day; but the transfers are put in this box every half trip and collected at night by the starters at the depot.

Mr. Smith, Lynn: Suppose he forgets to put them in?

Mr. Ham: We have accompanying every car a pad of blanks, which blank is a complete statement of the cash and transfer register. Each conductor marks on this blank the state of the register at the time he takes the car and leaves it. He does that as well as putting it on his day card. This pad is with the car all day long; so that if there is any discrepancy either in the transfers or cash fares, we can locate immediately which conductor is at fault. I would like to ask if any one here has adopted the use of a separate transfer for the forenoon and the afternoon?

Mr. Wilson: We have an 8-cent check, good for two rides, which is different for the forenoon from what it is in the afternoon.

obtain bill without further delay, impressing upon the creditor in question the importance of always sending bills promptly. This should prevent future annoyance from that party.

When invoice covering an order is received, and proper time has elapsed for receipt of goods, if no manifest or receipt has reached accounting department, inquiry can be made. Before closing the month's business any incomplete transactions can be looked into and proper explanations reached.

DANA STEVENS.

All materials and supplies that are not properly chargeable direct to operating expenses, or other similar accounts, but are held for gradual consumption, are to be charged to stock, the storeroom clerk reporting daily to the head of the department all issues and the number of account chargeable (as shown by classification of expenses, etc.); the head of department will approve the report if correct and send same to accounting department where the reports will be compiled into a monthly distribution and credited stock account.

Each storeroom will furnish monthly a statement of amount of goods received, amount issued, and balance of stock on hand, which must agree with amount shown for that account on accounting department's sheet.

Pay rolls to be checked against previous rolls and current copies of pay roll authorities and distribution of expenses compiled for the monthly entry.

The accounting department should keep a list of regular monthly entries, such as pro rata of interest, insurance, taxes and all debits or credits that regularly occur each month. This list checked off monthly, as entries are made, is, perhaps, unnecessary, but is a safeguard.

Expenses and earnings accounts should have balances brought down monthly, but not to be closed into income account except annually.

The practicability of the foregoing ideas depends largely upon the volume of business to be handled, and also the efficiency of the clerical force in other departments, and the time that can be devoted by them to this branch of the service. In many instances it might be more feasible for the store department to voucher its own bills and pay rolls, simply turning them over to accounting department to check. Be that as it may, the same line could possibly be followed by store department, and in conjunction with the accounting department, result satisfactorily.

The Chairman: Gentlemen, you have heard the paper; what action will you take upon it?

Mr. Greene: I move that the paper be received and filed and entered in the minutes.

Mr. Calderwood: Does the gentleman run all his material, and and labor in connection with the material, through the store house?

Mr. Stevens: Yes, sir.

Mr. Calderwood: What difference does it make whether the bills come in or not, so far as closing the books is concerned?

Mr. Stevens: The store room may receive an invoice of one hundred dollars, and include materials in the stock, and yet failed to forward invoice to accounting department for voucher and entry.

Mr. Calderwood: That will not affect the closing of the books, so far as the operation is concerned.

Mr. Stevens: No; but it will show so much more stock than you have on your books. If through the negligence of the store keeper I do not receive it, my balance sheet will not show it, and the company's liabilities as shown by general ledger will be just to that extent incorrect.

Mr. Calderwood: Do you keep one material account?

Mr. Stevens: I have three different places. It is carried in the general books under one account for each store room.

Mr. Calderwood: Do you run separate power-house material accounts?

Mr. Stevens: They keep the sub-accounts. I keep one general account.

Mr. Brockway: Why would it not be a good idea for the person in charge of the store-room to insist on having the invoice come with the goods, or within a day or so, to properly check it up for the accounting department. In that way, you get your bill almost immediately, while the matter is fresh in your mind.

Mr. Stevens: You will always find that there are some who will not comply promptly, and there are other departments slack in sending in reports and accounts.

Mr. Avery: Adopt a system of receiving no goods unless on an order, recognized for the purchase of any material unless issued by the purchasing agent, or approved by the auditor, because of its being a contract; and that made in triplicate; one to you, one to the purchasing agent and one to the store keeper.

Mr. Stevens: That would be a pretty good plan. The trouble with me has been we have been carrying deficiencies all the time, and when we make up a statement of liabilities, we have to be sure it is complete and correct.

Mr. McJilton: I will explain our method of treating the supply account. At the beginning of each month requisitions are made on our supply department by the heads of the different departments for supplies required during the current month. The store-keeper honors the requisitions and delivers the material to the different stations as called for by the requisition, charging the different departments with the material delivered, and sending bill to them for their approval. If it should happen that he has not all the material in stock, the purchasing agent (who is also the storekeeper), after receiving quotations, issues the company's general order on firms from whom we make our purchases, which are mailed as early as practicable.

The goods, after being shipped, are received in our supply department, where record of same is entered in our receipt book. Upon receipt of bills by the auditor, they are entered in a small book and charged to the supply department, to which they are referred for approval, setting forth the date, name of firm, and amount. This is done in order to keep an accurate record of all invoices from the time they enter our office. When they have been checked up and found to be correct by the storekeeper, they are returned promptly to the auditor, who credits those returned by setting opposite the date sent out, the date returned.

At the end of each month before the books are closed, the account kept with the supply department (in book, as I have explained) is gone over to see what bills are still out, and those that cannot be approved for various reasons, are noted.

The order book (stubs of which are to be audited by the auditor when bills are approved) is then checked up, and all orders not audited are accounted for by bills held in the supply department for various reasons, or the same never having been received by the auditor. In the latter case, postal cards are mailed to the various firms, requesting that they forward their bills by return mail.

Failure to receive bills, however, does not interfere with the closing of our accounts, other than our liabilities are not as much as they would be had we received them—as the department receiving the goods has been charged by the supply department.

Upon closing our books for the year 1896, although we issued over two thousand orders during that year, we had failed to receive only forty-two bills. This is a very small percentage, and is all brought about by carefully checking up at the end of each month—not only the supply department but the order book as well.

#### The Relation of Accountants to Managers and Employees.

BY P. V. BURLINGTON, SECRETARY AND AUDITOR COLUMBUS (OHIO) STREET RAILWAY.

It is probably a recognized fact that the day has passed when the accounting of a modern equipped street railway can be successfully done by a clerk or stenographer to the superintendent.

The application of electricity brings with it a multitude of details that in old horse-car times were not thought of. These details practically constitute a new factor in accounting, not altogether unlike those of steam railways, and the process of working them out in the past few years to a satisfactory basis, has not as yet been entirely successful.

There has been little or no reciprocity or exchange of forms and ideas between street railways, emanating from the men who directly have to deal with the problems of proper classification of receipts and disbursements. As I understand it, the object of those assem-

bled here today is largely aimed to a closer union and acquaintance, from which may evolve a system of simple and comprehensive accounts, which shall recommend itself to both owners and managers, and bring with it a larger share of respect from employers, and naturally a wider range of independence for accountants.

A study of this subject has led me to formulate the views here presented as to the relation of accountants to managers and employes; believing that the proper relations being first established, the way to a successful method of accounting will be comparatively easy.

Managers as a class have well fixed ideas as to what the investors in street railways desire, but too often these ideas are far more local in the application than otherwise, and when data and figures are furnished as to operation, investors are often unable to make satisfactory comparison with the figures of similar corporations, in which they may have like interest, so that the value of one kind of securities placed beside another of like character cannot well be determined. One manager furnishes a statement of operations with an abnormally low operating per cent, while his construction and equipment accounts are apparently exorbitant; another reports little or no construction and equipment and an abnormally high operating per cent. These statements placed together in the hands of the investor naturally lead him to distrust them both; the first on account of the possibility of trying to shoulder upon construction and equipment, (to be lost sight of for the time being in property cost), what should have been in a great measure placed in maintenance; and the second on account of a possible scheme to wreck the value of the property and its net earning capacity by loading maintenance with all kinds of expenditures, and by this means discourage security holders to the brink of unloading their holdings at a sacrifice resulting to the benefit of promoters of the scheme.

Investors as a class are men able to closely scrutinize the conditions under which securities obtain their value, and are usually distrustful until well satisfied that proper figures have been given, and I only mention the two foregoing possible cases that I may more clearly bring out the great necessity of securing reports that shall come nearer to honest and judicious comparison.

Managers of the general affairs of a street railway are not always in the position to estimate from day to day how and in what account channels, expenditures are finding their way. The accountant lacking discretion, knowledge or backbone, whichever it may be, to put a check upon this and that distribution of expenditures, finds at the close of the month or year that his figures as to cost of operating are vastly out of joint, and his comparisons with previous months or years grossly out of proportion.

It is at this point I would have the accountant first school himself as to what to do and how to do it, and then systematically assert his independence. It is no credit to the accountant to go hit and miss in order to accord with the notions of this and that one. Neither is it a duty or a kindness to the manager not to set wrong matters right, and place things where they belong.

When I speak of independence, do not understand me to mean either arrogance or obstinacy, but rather a well-bred and well-schooled instance, if you please—just that kind of independence that gives character; and where is the sensible manager who will not respect this?

The Street Railway Accountant has superseded the book-keeper and is coming to a place in the official family. To maintain this promotion and command respect, he must of necessity be active and expert; not altogether unlike his brothers of the steam railways, among which some of the finest accountants in the world have been schooled. We may not for a time succeed in wholly gaining the relative rank they occupy, but we, as they, have intricate problems to master, and why should we not eventually succeed in our way as truly as they in their way?

I have spoken of the difficulties of owners and investors in comparing reports. I believe it within the province of the body of men here assembled to map out a system by which at least the greater defects may be remedied. It is true that local conditions of railways may differ in a way to effect comparison, yet cannot these varying conditions too be systematized so as to become adjuncts rather than factors? Succeeding in this we place ourselves at once in line with the needs of owners and investors, and at once through this channel bring ourselves into direct relation with managers who have the interests of these people at stake.

I bespeak for what may be accomplished at this convention a careful consideration by managers, and I believe they will in time more

fully appreciate the desirability of leaving the duties and problems of an accountant to the accountant himself, and to that end hold him responsible. The manager of any street railway of considerable size, should not attempt to be everything, and thus fail of doing anything well. The maintenance of the property and attention to the needs of patrons are the first elements to be by him considered, and if these are well worked out, the figures of the intelligent accountant will as surely and proportionately follow as evidence of vigorous and healthy management.

In securing the relations here outlined between managers and accountants, we shall be far more successful if we give due attention to the proper relations which should exist between accountants and employes.

When the writer first entered street railway service, some six years ago, it was with some misgiving as to whether the new era of electric power would bring with it a higher order of service than obtained in the horse car days. The then existing order of inferior intelligence and character of employes was too apparent everywhere, entailing lack of courtesy to the public, and far too often exhibiting acts of uncalled for brutality. Both arrogance and coarseness of superintendents and foremen, and rude and familiar intercourse of employes, was much too prevalent. Proper names were lost sight of in nicknames, such as Slim Jim, Fatty, Limpy, English John, Irish Ted, Dutch and a host of others of similar grotesqueness. It is gratifying to be able to say that the higher order of intelligence required from the highest official to the lowest employe to operate street railways by electricity, is rapidly and steadily relegating these unwholesome features from the service. With greater intelligence, naturally comes higher standards of character, greater respect for discipline and proper courtesy to the public.

In all this the accountant has a part to play. His position requires a steady and unremitting watchfulness of the manner in which reports of any character are made, noting the weakness of one and the thoroughness of another, promptly investigating the one and commending the other; each to be done with courtesy and without familiarity. If you find an employe in error in his reports, do not require correction without explanation, but rather call him to your office, go over the work with him and establish his confidence in your claim. You cannot spend a few minutes to the interest of the company more effectually than in this. Matters of this kind should never be submitted by accountants to employes on cars or before the public. When riding on a car be seated as a passenger, and insist that the clerk do the same, and that they enter into no familiar talk with employes. The familiarity of a clerk may often lead to telling important matters of the company not intended for general gossip; to the discussion of methods of checking reports and of detection of dishonest returns; of fancied favoritism shown one to the detriment of another, and a score of other things calculated to create uneasiness and distrust. If you have methods peculiarly your own by which to ferret out dishonest work, they should not be known outside the office. When results have resolved themselves into proof, they should be promptly submitted to the manager for his action. If an employe has a grievance which does not concern you, he should not be argued with, but rather referred at once to the proper officer.

The office should be understood as the only place where business is transacted, except such affairs as may be delegated to inspectors or other officers as a part of their duties, and as this place should have the business air of an express counting room or bank, in which transactions are made quickly and with business courtesy. Nothing will more surely establish confidence with employes than an observance of these, and nothing more surely be an incentive for them to perform their duties in a like manner. By adopting these higher business principles, the accountant not only paves the way of respect for himself, but contributes largely to the enforcement of correct rules of discipline desired by the management.

There are at times many exasperating errors committed by employes, which require great patience in treatment, but when you have a case of this kind, always remember that not all the virtues can be expected to exist in the average man. Patience and moderation will find the remedy. If you find upon investigation that the supposed error comes back to you as the fault of the office, be quick to both acknowledge and correct it. Give every man his just due, and he will be more likely to accord you like treatment.

In conclusion let me say that if the brief outline here given as to the relations of accountants to managers and employes shall serve to quicken a nobler and more efficient sense of what may be accom-

plished in the realm of street railway accounting, the object of this paper will have been accomplished, and I believe that we may safely anticipate the hearty approval of our superior officers.

Mr. Avery: I move a vote of thanks and the placing of the paper on the records. Carried.

Mr. Smith, Lynn: I would like to ask the gentlemen whether it is the custom in most roads to give the conductor the benefit of a reasonable doubt; whether you simply hold him down to the law every time, or when there is a reasonable doubt whether you give him the benefit. Our general manager thinks I am too soft, but I am inclined to be lenient with the fellows who only get twenty cents an hour. If there is a reasonable doubt, I think the company can better afford to lose a few cents than the conductor.

Mr. Calderwood: Give him the benefit of the doubt, or he will take it out of the road the next day.

Mr. Ham: The benefit of the doubt in what sort of cases?

Mr. Smith: Sometimes there will be a question in regard to the register; the proper record is not taken when they go out, or the register might be taken into a barn to be repaired and some of the mechanics neglect to make a record and rings up four or five fares to get the register in shape again. If we think the man is honest, and the foreman says it may have been done, we give the man the benefit of the doubt.

Mr. Wilson: I think it is no more than fair, in many instances, to give the man the benefit of the doubt. Liberality shown that way is of benefit to the company. Most of us probably have a complete record from our inspectors in the office, and I know personally that we have had a few instances where the registering clock has been claimed to have jumped a hundred fares; once in a year, or once in six months—something of that kind. The clock has been taken out and sent to the machine shop and tested and perhaps rung up a hundred thousand times, and nothing can be found wrong. However, if upon investigation we find the man has been with us a number of years, and that his record is good, we have given him the benefit of the doubt, with the distinct understanding and his being so informed, that it was only his good record which warranted us in doing so. We give him to understand that if he had a poor record this would not be done. I think such cases should receive careful consideration and the man's record looked up. This last week we had a ten dollar bill turned in, or what appeared to be a ten dollar bill, which had been changed from a two dollar bill. It was taken to the President, and shown to him with the remark: "Mr. Little, here is a ten dollar bill apparently, on the face of it, but it is really a two dollar bill which has been altered." He looked at it and said: "We cannot hire men for two dollars and a quarter a day, and expect them to be experts in detecting so good an imitation as this; let the company stand it." I think it is very beneficial to give the conductors the benefit of the doubt in a good many cases, provided you know your men. We have found it so, and the men appreciated it.

Mr. Hibbs: I think Mr. Wilson's remarks are true, provided always that his men are working for the interests of the company. We have labored under the disadvantage at times of having the men work for their own benefit and not the company. There are cases where the register has been claimed to have jumped a hundred fares. Has it jumped a hundred in registering, or taking the register?

Mr. Wilson: Registering.

Mr. Ham: We started in to give everybody the benefit of the doubt, and last summer it was surprising how many times the register jumped; and finally we decided that we would have to stop the registers jumping, and they did not jump so much afterwards. There is no doubt that they do jump once in a while.

Mr. Wilson: Within the last two years there have been two instances where we gave the men the benefit of the doubt.

Mr. Ham: We had them reported more frequently.

Mr. Hibbs: Without any corroboration?

Mr. Wilson: Only in looking over his daily reports and that sort of thing.

Mr. Duffy: As to the errors in the working of the registers and the ringing up of registers in the shop, we can all back that up by our experience. I know that the registers jump. I have known conductors to report when the records worked to their advantage a hundred fares. The whole question, perhaps, can be summed up in this way: Under all circumstances and conditions give your men the benefit of the doubt, particularly if you know your men; and if you exercise the proper discretion and judgment which you expect the conductors

to exercise under your rule book it will be to the advantage of the men and the company both.

Mr. Avery: It is a question in my mind whether it is the province of the auditor to decide such matters. I report such matters to the superintendent, and he holds the division foreman responsible, and he decides whether to give the conductor the benefit of the doubt or not.

Mr. Dimmock: Our auditor finds that the registers do jump, as the gentleman from Boston states; and these cases are always referred to the management. We keep the minutest record of every man in a record book, and if the man in question has had a good record—we record the number of times that he reports the registers jumping, and I believe as a rule the probability of their jumping is a hundred fares—we are inclined to overlook the first case or two. If the report comes in the second or third time it is investigated very closely, and special agents are put upon the man to see whether his other work checks out correctly, and if we find his record is not good he is dismissed from the service of the company; otherwise we give the man the benefit of the doubt.

Mr. Wilson: If there is any question the man is checked every trip during the day by a different inspector; no two of the latter being acquainted. They meet the chief inspector perhaps on the corner of one street one day, and a mile farther away the next day, and make their report to him; and if any inspector has any feeling against a particular conductor it will not work, because if he reports a man we put our other inspectors on and ride him every trip, and a book which the chief inspector keeps shows a complete history of the man from the time he entered our employ. This goes into the greatest detail, having such items as when the conductor was reprimanded for failing to call streets, etc., and all the minor errors which he has committed. We, perhaps, have a better record than some other roads from which to look up the character of our men.

Mr. Burrington: In relation to the matter of a register jumping, it is a fact that it does occur occasionally. We had a case in Columbus about a year ago, where a register jumped when it was impossible for the car to have carried the additional one hundred passengers. The corresponding runs probably had ten, fifteen or twenty passengers. There was nothing unusual going on in the vicinity of the line, and the inspectors could find nothing at all to account for the hundred passengers. We were satisfied that the register jumped, but to make sure we had it taken off and sent to the factory with instructions to determine whether the register jumped, and report the result. We did not want to trust it to our own machinist; we wanted to get the decision of the makers. They reported back that the register had unquestionably jumped on account of a defect in the works. The man, of course, made his claim promptly when he noticed it, and we held the claim in abeyance until we heard from the register people. We called him in and told him the machine was at fault, and he would be given allowance for the hundred fares. We have since had one or two cases in which we were almost as surely satisfied, taking all the facts into consideration. If you investigate the number of passengers calculated to be carried in a given half hour or hour, and compare reports, that is the best way you can satisfy yourself about the jumping of the register. It would be an unusual occasion for a conductor to have one hundred passengers above his regular run with ordinary travel.

If the conductor reports it at once—we would not think of making any allowance if he delayed doing so—there is no question that you can trace the matter out and satisfy yourselves without difficulty. It takes patience and work, but you had better do it. In that way you establish the confidence of the men. In minor things, even in the matter of a single ticket, go to the bottom of it and establish your position above all question. I find this has a great deal to do with the character of discipline which it is possible to maintain. If a man sees you are fair with him he will be fair with you. I believe the matter of dishonesty is a good deal overestimated. There is some of it, of course, but it can be easily traced in the majority of instances. We ought to get away from that idea, and hold our men honest until they are proven dishonest. Our business is to see whether they are dishonest or not by their returns.

#### A Simple System of Interurban Accounting.

BY W. B. BROCKWAY, AUDITOR TOLEDO, BOWLING GREEN & FREMONT RAILWAY COMPANY.

I confessed to Mr. Windsor when I was asked to read this paper to you that my interest in this convention had somewhat selfishly cen-

places on the line, from which record the time of himself and the motorman are figured. On his last report for the day he shows the hours and minutes in service claimed, and the closing numbers of his tickets.

When a conductor is relieved before completing the round trip he and the conductor relieving him make two separate reports, but use the same trip number. In other words, in having a trip instead of a daily report, we do not enlarge the conductor's labor, but lessen it. We have less work in the office and I think we obtain as satisfactory results.

In accounting return tickets we use the whole round-trip fare when the ticket is sold, giving that day credit for the whole value of the ticket instead of letting the day of sale have half and the day of return have half. When the returns come in, the report of the day shows how many were lifted and of course they are counted in the number of passengers carried.

The earnings book is almost an exact counterpart of the conductor's report, having columns provided for nearly all things shown on the report with the exception that all tickets sold by the conductor outside of half-fares, express and local city-fares are shown in one total number and their total value. Where two conductors have the same

round trip, one starting and the other completing it, the two reports are combined and shown as one on the record. As the round trips are numbered so also is there a space provided on the record so that it will show what any particular round trip was worth. At each change in time I affix a new time card to the page for the day of effect to show the changes in any particular run for comparison at any time. Each day's page is complete in itself, but the total receipts to date and the total passengers to date are carried forward from day to day. At the end of the month each day's several totals are carried forward to a page where the whole month is shown, and as already referred to, postings are made directly into the general ledger from this book.

As the tickets have no actual value when issued from the office, the conductor receipts for one hundred tickets at a time. A record is made of these issues and the conductor charged. Each day the tickets returned with their value punched are assorted numerically and checked in on a sheet having 100 numbers, as soon as the 100 tickets are shown as having all been returned, a simple check mark on the ticket register cancels the charge against the conductor. Should any ticket not be returned the conductor is required to pay the highest value of the ticket. The tickets are then assorted by stations from and to stations, and filed away in a case for the purpose, having a pigeon hole for each station from and to. By the way, when I wanted this case made, the price quoted was entirely too high and I would not order it, but obtained 49 cigar boxes with square ends, knocked out one end, tacked the covers down, piled them in the shape I wanted and fastened them together with light boards. It looks much better than I thought it would, fills all needs required of it, and best of all cost 18 cents instead of \$23. The tickets thus filed are counted each week to lighten the labor and at the end of the month a traffic statement is made, showing the number of tickets sold from one station to another. The tickets are then enclosed in rubber bands for ready reference, shelved for one month and then burned. It is customary, perhaps, to keep the tickets for a longer period, but we have had but a single instance to refer to the shelved tickets and that developed within two weeks after being filed.

As far as it applies to our needs. This classification is the result of the labors of a committee of the Association of American Railway Accounting Officers, an association similar to this. Their methods of charging items in operation is very clear and is the result of long experience, and I would suggest that their plan be examined before finally adopting one of our own. All payments made during or for any month in operation are distributed upon the vouchers and the several columns of the voucher record are charged directly from that record into the General Ledger. Car, line, and track foremen furnish a daily statement to the office of the amount, kind, and value of labor and material used; whether for repairs or for construction. The total material used from the storeroom is compiled in the office and charged from the Journal.

We pay but once a month, but the time allowed is kept daily. A record of the power house meter readings is also kept daily at a given time. This, on the office record, shows the reading of the ammeter, the number of watts used for the 24 hours, the total cost per day, the number of cars run, and the average cost per car per day. We buy our power, so that when the bill does not agree with our record we want to know why.

And now, in closing, just a word about the payment of vouchers. Since the road commenced construction up to the present time we have not paid out one cent by check, so called. All vouchers when ready for payment are stamped as good for payment at such and such a bank, when properly dated and signed; and we have no trouble, it is needless to say, about receiving the vouchers back, properly signed, and that quickly. Papers pertaining to the voucher are never attached, but bear the same number, and when the voucher is returned through the bank they are filed inside of it.

We close our books, of course, at the end of the month, but the voucher record is held open for several, usually 10 days, to permit the entrance of all bills for that month, so that when the balance sheet is finally taken off on the 15th, it shows the actual earnings and expenses for the month in question.

Thus, in brief, I have outlined the general points of our system of accounting interurban traffic. I believe it is simple, and it has proven itself effective; but, as I said in the beginning, circumstances are different and so must systems of accounting differ and still be similar.

I understand, of course, that we have not the only system of accounting, and I presume I shall understand it more fully after the discussion which may follow me, but preceding that discussion I feel as though we are at least not encumbered with a number of unnecessary ways of reaching the desired results.

I have also tried to keep in mind that simplicity of accounts means not only that my successor (for none of us always stay in the same place all our lives) may the more readily pick out my methods of work, but that it requires less time to work a simple system to the results, less clerical help in manipulating, and thus is more economical in the matter of office expenses, etc., as shown on the balance sheet.

As to the operating expenses and the distribution of them I have again gone to the steam railroads for assistance. I have taken the Official Classification of the Interstate Commerce Commission so

Mr. Wilson: I move that the report be accepted and placed on file, with thanks. Carried.

Mr. McJilton: When you receive the cash for tickets sold, is that credited up immediately to earnings?

Mr. Brockway: Yes, sir.

Mr. McJilton: What do you do with tickets not presented?

Mr. Brockway: We have the duplex style of ticket and they must be presented.

Mr. McJilton: Suppose a man does not continue his passage?

Mr. Brockway: If he gets off, he loses it, of course.

Mr. McJilton: You do not have a number of stations on your line where you have a different rate of fare? It is five cents between two stations, and you do not permit a passenger to leave the car, and continue his passage later on?

Mr. Brockway: No, sir: the fares are so arranged that if a passenger wishes to make a stop-over at any point, by buying two tickets, one from the place of starting to the place of stop-over, and afterwards from the place of stop-over to his final destination, the fare is the same. Our tickets being of the duplex style they must be bought on the car.

Mr. McJilton: That is the only kind?

Mr. Brockway: Yes, sir, except commutation. We credit the day of sale with the value of the whole commutation ticket sold, and we keep a record, of course, of the numbers of the commutation tickets, and they are checked in as they come in, but not as earnings accruing to that day for carrying the passenger.

Mr. McJilton: The tickets are good until used?

Mr. Brockway: Yes, sir.

Mr. McJilton: You credit up in one month the earnings which, in many cases, you do not really earn until the next month?

Mr. Brockway: It has been part of our experience that they are used just as fast as they can be; in other words, people do not put a dollar or five dollars into a ticket unless they intend to soon use it up.

Mr. McJilton: We carry our ticket account as a liability, and we find that we have a balance always outstanding in the neighborhood of two thousand dollars, which we have to redeem by carrying the passenger. We do not credit up the earnings until the ticket is received.

Mr. Brockway: As fast as the tickets come in you credit your earnings, I understand. We figure this way, that if our tickets are credited to the day of sale, irrespective of when they are returned, and in consideration of the almost immediate use of the commutation tickets, and that we sell just about the same number of commutation tickets every day, we find that we can do that and save ourselves much labor.

Mr. McJilton: One of the reasons that we carry it as we do is that our conductors have an exact manifest of every fare they receive and, of course, our earnings have got to tally with the manifests of the conductors; and for this reason it is necessary to treat the account in the manner we do.

Mr. Brockway: I tried to do away with a general ledger account, and that is the method we have adopted.

Mr. Pomeroy: In regard to the round trip tickets picked up after they are sold, do you check them back with the conductors' stubs?

Mr. Brockway: We do that about once in two or three weeks.

Mr. Pomeroy: You require the conductors to put their money in an envelope and turn in every round trip or single trip?

Mr. Brockway: Every round trip. The nature of the line is not such that they could do it at the end of the trip, but we have adopted an arbitrary place as the end of the line.

Mr. Pomeroy: I go further and require where they can that they shall deposit on each trip. They make the eastern trip, and when they leave the west to go east our office is part way on the line, and they are required to deposit their east bound report on the first trip west, and vice versa.

Mr. Ham: You said in the paper that you did not pass anything through the journal, but posted directly from the original books. In your opinion that is sufficient to save enough time to make up for the disadvantage of not having everything in one book?

Mr. Brockway: I told you why—because the ledger record shows the page of reference, and by getting back to the original book you have the whole transaction there, and there is very little chance for error such as you would have by putting it through the journal first and then into the ledger.

Mr. Higgins: Do you make your voucher book a distributing book?

Mr. Brockway: Yes, sir.

Mr. Ham: I have gone on the principle that it is desirable to have one book which would contain a summary of everything, and consequently I have journalized everything.

Mr. Pomeroy: You charge five cents for a part of a division?

Mr. Brockway: We have, of course, the regular rates between stations. If a passenger goes five hundred feet beyond a station he must pay to the next station.

Mr. McJilton: I should like very much to get some information as to the handling of ticket accounts where you exchange passengers with an entirely foreign company, and both companies sell a continuous ride good over one another's lines. I refer particularly to suburban traffic.

Mr. Brockway: We do not do it.

Mr. McJilton: Is there any one here representing a company that has such an arrangement? We have an agreement with a company whereby we both sell round trip tickets good between the city of Baltimore and Emory Grove—the round trip being 35 miles—and our company carrying the passengers 14 miles of the entire distance. We transfer our passengers to the foreign company at the terminus of our line. Commutation books are also sold, but are only good during the month purchased. If there is any one present representing a company having such an arrangement, I should like very much to have the method of accounting, sale of tickets, etc., explained.

At this point, on behalf of Mr. Ehrhardt of the Cleveland City Railway Company, and Mr. Davies of the Cleveland Electric Railway Company, complimentary tickets good on these lines were distributed to the delegates.

The Chairman: I believe street railway men are never known to decline anything, and we accept the tickets.

Mr. McJilton: I move that a vote of thanks be returned for the courtesy. Carried.

#### Depreciation.

BY H. C. M'JILTON, AUDITOR BALTIMORE TRACTION COMPANY.

Having been selected by your committee to prepare a paper upon "Depreciation," I have consented somewhat reluctantly to give a treatise on a subject of so great importance to either corporate or private enterprises; embracing as it does features so difficult to handle I would much rather it had been left to one who may have had more greater experience than myself.

I will first take up what the definition of the word "Depreciation" is. As laid down by Webster's Unabridged Dictionary, it is as follows: 1st. The act of lessening or seeking to lessen price, value or reputation. 2nd. The falling of value; reduction of worth. Burke. 3rd. The state of being depreciated.

The second definition seems to most clearly define the subject to be treated, and with that view my next step will be to divide the subject under two heads, as follows:

First. What should not be charged to depreciation, and

Second. What should be charged to depreciation.

For convenience I will give, first some of the most important items which should not be charged under the heads of the different subdivision of accounts.

#### TRANSPORTATION EXPENSES.

Renewal of fare registers, punches, etc.

#### MOTIVE POWER.

Repairs or renewals of dynamos and their parts, the labor in removing and replacing; renewals or repairs of the switchboard equipment and labor making such repair or renewal.

Renewal of armatures, commutators, bearings and boxes, fields gears, pinions, trolleys, lightning arresters, rheostats, switches, etc. the cost of labor replacing same and making connections with those damaged or destroyed.

Renewals or repairs to steam plant in power houses including boilers, engines, pumps, shafting, belts, piping, steam fitting, station fixtures, etc., nor the cost of labor necessary in making such renewals or repairs.

Repair or renewals of tools, machinery, shafting, boilers, engines, etc., in shops of the company, including labor, etc.

#### MAINTENANCE OF WAY.

Renewal of conduits (cable or electric), rails, cross-ties, paving, trolley poles, feed and span wires, and appliances for suspension and insulation of same; track bonding, drains under tracks, flooring bridges, frogs and switches, joint fastenings, tools, implements, wages of laborers engaged in this work; repairs to power stations, car houses, car shops, repair shops, blacksmith and machine shops; coal chutes and bins; pits in car houses and shops; cranes in power houses; buildings, wharves, etc.

#### MAINTENANCE OF CARS.

New cars taking the place of old to make the number good; repairs, including labor to keep cars up to standard; renewals of trucks, axles, wheels, brakes, headlights, brake shoes, axle boxes, springs, sand boxes, etc.

None of the above items should be charged to "Depreciation," for the reason that the first cost has either been charged to construction or plant account, or carried as an asset in other accounts and to which nothing should be added except for the first and original cost of the property, and therefore if not chargeable to either of the above accounts, repairs of every description and character must necessarily be chargeable to operating expenses—less amounts received from sale of removed or defective parts—in order not to wrongfully increase the assets of the company.

Further, inasmuch as the operating of the road receives all benefits of the cost of the first installation, operating expenses should stand the cost of repairs, including labor and all renewals. This is essential, notwithstanding they all add materially to the present or future

value of the property; but in order to get at the correct cost of the operation of the road as a whole, or per car-mile, you do not arrive at a proper basis for calculation until the second or third year of operation, and it is not fair to compare a newly equipped road with one which has been in operation a number of years.

#### WHAT SHOULD BE CHARGED TO DEPRECIATION.

It is, no doubt, a well understood fact that it matters not how much is spent and charged to operating expenses in order to keep the plant of a street railway company or manufacturing corporation in A No. 1 condition, it is never after once put in operation considered as good as new, for the reason that more improved machinery, etc., can be purchased later on to replace same, often at a reduced cost.

This is most important in the case of loss by fire when you are making up your schedule, preparing for settlement of your loss with the insurance companies (as those having gone through the experience of fires know), there is always a certain amount deducted by insurance companies on account of depreciation, whether apparent or not. And the same state of affairs applies to the sale of any particular piece of machinery, etc., which has been discarded.

Therefore, conceding the above to be true, that is, by charging the cost of repairs and renewals to operating expenses, your property is virtually in as good a condition physically at the end of each year as it was in the beginning, at the same time agreeing that there is a depreciation, it is wise and appropriate for corporations to set aside at the end of each year such an amount as is warranted after a thorough and impartial inspection of the property.

I further believe that it is thoroughly understood that circumstances alter cases, but by carefully following out the above method, it is the opinion of the writer that you will not go wrong, but will be protecting the assets of your company, and I know of no better way of doing this than by charging to operating expenses all renewals and repairs, as I have indicated in the first part of this paper, and by the accumulation of a fund as an offset against such depreciation as cannot be covered by charges to operating expenses.

Mr. Greene: I move that the paper be received and spread upon the minutes, with thanks. Carried.

Mr. Hibbs: How do you ascertain depreciation?

Mr. McJilton: The depreciation can be arrived at by a committee appointed from the board of directors in conjunction with the heads of the different departments.

Mr. Hibbs: How would you treat a car purchased to replace one which has seen service?

Mr. McJilton: When a car has seen all its service, and is done for and is replaced by a new one to make good the number, the cost of the new car should not be charged to depreciation, but should be charged direct to operating expenses; operating expenses receiving credit for whatever may be derived from the sale of the material, etc., from the old car.

Mr. Hibbs: Have you had any difficulty with insurance adjusters on account of depreciation?

Mr. McJilton: I have, and I have been unable to find any one that has not, in adjusting a loss.

Mr. Brockway: My experience in steam railroad accounting has been that they have no depreciation account there, but as Mr. McJilton says, when a new car is purchased or built to replace an old one, it is repaired; but when one railroad company destroys another railroad company's car, depreciation is figured at 6 per cent per year. In the interchange of freight cars, when one is wrecked belonging to another company, the bill is rendered with 6 per cent depreciation; otherwise, there is no depreciation.

Mr. Ham: There is an inconsistency in calling it a depreciation account, because you are not charging all items into it; if it has the effect of a sinking fund, it is a bad term. When the car is depreciated, you do not charge it to depreciation.

Mr. McJilton: What would you do when there is a large fire?

Mr. Ham: That would come in under insurance.

Mr. McJilton: What would you do with the amount knocked off by the insurance company for depreciation? You cannot charge that into operating expenses. The difference between the actual worth of the car to you, and what the insurance company allows you should go to depreciation.

Mr. Wilson: When you replace a thing, is it your opinion it should be charged to operating expenses?

Mr. McJilton: I beg your pardon; I do not want you to think that

everything replaced should be charged to operating expenses, because you may replace something that has not actually seen service; but my idea is, that after you have gotten all the service possible out of a thing, upon replacing it the cost is properly chargeable to operating expenses.

Mr. Barnaby: That would give one little item placed against depreciation fund to reduce it, but if you happen to have the cars insured, you would practically have no need of using the fund.

Mr. McJilton: The insurance companies in our State will not insure for over 80 per cent and you, therefore, should have some provisions made for the depreciation which is claimed by them.

Mr. Duffy: I should like to hear from Mr. Higgins on this subject.

The Chairman: Will Mr. Higgins kindly give his views.

Mr. Higgins: In trying to get at the net earning power of certain properties, I had occasion to go into the question of depreciation a good deal, because it was a new thing—that is, this electric railway business was new; and it is difficult to apply to it the same plan of procedure which obtains in steam railroad practice. As some one has said, it is not customary in steam railroads to have such a reserve fund; but it is because they have been in operation longer and have found by experience how much per annum can be charged up to maintain the property perpetually. With the electric railway, the system is too new to do this; but in order to get at something which might approximate correctness—that is to say a method of procedure which would be at least better than mere guess work—this plan was hit upon; that is to say, to have in each particular case under consideration the engineer of the road called in, as Mr. McJilton says, the different department heads, and for them to determine the probable average life of the different sections of the plant; which will be, we will say, 15 years; electric station plant, which will be we will say, 25 years; the life of the cars exclusive of trucks, which will be, we will say to years, or including trucks and motors, 10 years; the life of the track, we almost dare to hope with the modern construction, 10 years. If we have the initial investment of the different sections of the plant, and estimate what it is probable we may be able to replace those for at the end of their respective lives, and allow something for scrap value, we will get a sum of money which at the end of the life of the track, we will say, that it will take eighty per cent of the initial cost to replace the track at the end of that time, or when the track has to be replaced. Meanwhile, all the ordinary current repairs are going on from year to year, and there must be an estimate of the average repairs, or at the end of the time the track is worthless and must be thrown away. Some money must be provided to do that, and it is easy, mathematically, to figure a sum, which put at interest from the beginning of operation in the first year, will at an agreed rate of interest, say, four per cent, amount at the end of the 10 years time to the sum fixed upon to replace the track.

That annual sum figured for every section of the plant, in its different estimated life, will be, it seems to me, a true depreciation, always supposing the time is correct, and the sums are large enough to cover these renewals so that the accumulating sums for the reserve fund, or depreciation fund, if you call it so, passed every year to the fund, will just balance the increased depreciation year by year, and the sum of the value of the plant, the operating value of the plant, not the selling value (for the instant you put a car into service the selling value depreciated) but the operating value of the plant as it decreases is balanced by the depreciation fund, so that the two together make up the original investment, and there you have your assets constantly kept up to their original value by the operation of this reserve fund. Charges to this reserve fund should be charged to operating expenses, to some definite department, such as reserve fund, not general expenses, or to the depreciation fund, or something like that.

That scheme of finding the true earning power of street railway property, and incidentally the depreciation of the plant, has passed muster with some of the brightest lawyers in New York. They have adopted it as a plan for action and are at the present time engaged upon a more definite plan for accomplishing that in their books.

Mr. Brockway: Is not that guess-work, to a certain extent?

Mr. Higgins: It is, but it is guess-work based upon a principle, which is less guess-work than simply saying 5 or 10 per cent is depreciation. It presupposes a definite life, which from the past experience of engineers and judgment of probabilities can be arrived at with a sufficient approximation to correctness to serve the purpose.

Mr. Dimmock: We have a bridge on our road between Omaha and Council Bluffs where attention has been given to certain parts of its depreciation which may be of interest while we are discussing the

matter. While the bridge is made mostly of steel, time would cause a depreciation in its value provided it was not properly protected by paint. I refer to that part of the bridge composed of iron and steel. The floor of the bridge is made entirely of wood. The life of certain parts of the wood might be estimated to be 10 years, while the life of the paving blocks might be 5 years, according to the wear and tear from vehicles, etc. Therefore at the end of every 5 or 10 years the owners of said bridge would be called upon for an amount of money sufficient to renew these parts as well as to repaint the bridge, say, every three or four years. In our case we opened a paving and painting fund (which may be called a depreciation fund) and charge off each month of the year a proper proportion of said sum, which of course we would be compelled to estimate, from the fact the cost of repaving and repainting the bridge this year might be entirely different on account of a change in the markets 10 years hence, therefore when a monthly statement is presented to the directors showing how much it cost to operate the road, we include in said expense the proportion per month of this depreciation account, crediting the paving and repainting fund each month and debiting cash as said amount is laid aside for paving and repainting when the proper time comes.

While these repairs will not take place for 5 or 10 years, when that time arrives, the directors will not have a surprise in store for them on the grounds that they knew nothing of such an expense from the fact that we have laid it before them each month as time progressed.

Of course, if labor and material had advanced after the 5 or 10 years had elapsed, the fund would not be sufficient to cover the repairs to the extent of the difference of our estimate and the market value. On the other hand, if labor and material had depreciated the fund would exceed the repairs and could be transferred to some other account and put to some other use. Again, if the travel over said pavement increased its depreciation, said repairs would have to be made sooner or later than the estimated time, which would cause another discrepancy in the account. However, is it not better to have the matter always before us (although on account of being estimated it may not be exactly correct) than it would be to have nothing at all to remind us that sooner or later we would be called upon to renew these parts of the bridge, and when said time arrives be unprepared for it, and surprised also at the cost. While such an account has its advantages, it has its disadvantages, and it is an account which I think will bear discussion. You might also apply this to all parts of a road or its equipment, but in doing so it would be almost impossible to open an account for each department or part of the road, as the accounts would become too numerous; therefore, if a depreciation account is kept at all, which is a question according to argument here today, every department should be gone over thoroughly, and an estimate made of the depreciation of each particular item and one depreciation account opened to cover all.

Mr. McJilton: Acknowledging that you do put the pavement in proper or first-class condition, when you get the pavement down do you consider the bridge as good as the day you built it?

Mr. Dimmock: The pavement is.

Mr. McJilton: I mean the bridge in its entirety.

Mr. Dimmock: No.

Mr. McJilton: For that reason you have got to set aside a certain proportion for the depreciation you cannot see.

The meeting was then adjourned until 10 o'clock Wednesday morning.

### Wednesday Morning Session.

Chairman Hall called the meeting to order at 10 a. m. and called for the report of the committee on organization. Mr. Smith, of Lynn, chairman of the committee, presented its report, which after careful consideration was adopted article by article, as follows:

### Constitution and By-Laws of the Street Railway Accountants' Association of America.

#### Constitution.

##### NAME.

1. The name of the Association shall be "The Street Railway Accountants' Association of America," and its office shall be at the place where the Secretary resides.

##### OBJECT.

11. The object of this Association shall be to bring together those engaged in the accounting department of Street Railway Companies, for the interchange of ideas, to promote the adoption of a uniform system of accounts, and to improve the work of the accounting department.

## MEMBERS.

III. The members of this Association shall consist of American Street Railway Companies, or lessees, or individual owners of street railways; and each member shall be entitled to one vote by a delegation presenting proper credentials.

## AMENDMENT.

IV. This Constitution may be amended by a two-third vote of the members present at a regular meeting, after 30 days' notice thereof has been given to each member in writing by the Secretary.

## By-Laws.

## APPLICATIONS.

I. Every applicant for membership shall signify the same, in writing, to the Secretary, enclosing the requisite fee, and shall sign the Constitution and By-Laws.

## OFFICERS AND EXECUTIVE COMMITTEE.

II. The officers shall consist of a President, three Vice-Presidents, a Secretary and Treasurer, and four others, who shall constitute the Executive Committee. The Executive Committee shall have entire charge and management of the affairs of the Association. The Officers and Executive Committee shall be elected by ballot, at each regular meeting of the Association, and shall hold office until their successors shall be elected. The duties of Secretary and Treasurer shall be performed by the same person.

## DUTIES OF OFFICERS.

III. The Officers of the Association shall assume their duties immediately after the close of the meeting at which they are elected; they shall hold meetings at the call of the President, or, in his absence, at the call of the Vice-Presidents, in their order, and make arrangements for carrying out the objects of the Association.

## PRESIDENT.

IV. The President, if present, or, in his absence, one of the Vice-Presidents, in their order, if present, shall preside at all meetings of the Association and of the Executive Committee.

## TREASURER.

V. The duties of the Treasurer shall be to receive and safely keep all money of the Association; to keep correct accounts of the same, and pay all bills approved by the President, and he shall make an annual report to be submitted to the Association.

## SECRETARY.

VI. The duties of the Secretary shall be to take minutes of all proceedings of the Association and of the Executive Committee and enter them in proper books for the purpose. He shall conduct the correspondence of the Association, read minutes and notices of all meetings, and also papers and communications, if the authors wish it, and perform whatever duties may be required in the Constitution and By-Laws appertaining to his department.

## MEETINGS.

VII. The regular meeting of the Association shall be held at the same time and in the same place as the meeting of the American Street Railway Association. Special meetings may be held upon the order of the Executive Committee. Notice of every meeting shall be given by the Secretary, in a circular addressed to each member, at least 30 days before the time of meeting. Ten members shall constitute a quorum of any meeting.

## ORDER OF BUSINESS. (1.)

1. The reading of the minutes of the last meeting.
2. The address of the President.
3. The report of the Executive Committee on the management of the Association during the previous year.
4. The report of the Treasurer.
5. Reports of Special Committees.
6. The election of officers.
7. The reading and discussion of papers, of which notice has been given to the secretary at least 30 days prior to the meeting.
8. General business.

## ORDER OF BUSINESS (2.)

IX. At other general meetings of the Association the order of business shall be the same, except as to the 3rd, 4th and 5th clauses.

## NOTICES.

X. The Secretary shall send notices to all members of the Association at least 30 days before each meeting, mentioning the papers to be read and any special business to be brought before the meeting.

## EXECUTIVE COMMITTEE.

XI. The Executive Committee shall meet one hour before the opening of each annual meeting of the Association; and on other occasions when the President shall deem it necessary, upon such reasonable notice, specifying the business to be attended to, as the committee shall, by vote, determine. A vote of the Executive Committee may be taken by mail when deemed advisable.

## VOTING.

XII. All votes, except as herein otherwise provided, shall be viva voce, and in case of a tie the presiding officer may vote.

## READING OF PAPERS

XIII. All papers read at the meetings of the Association must relate to matters connected with the objects of the Association, and must have the authority and approval of the Executive Committee before being read. Persons to whom subjects are assigned must signify their intention in writing to prepare the paper, and to forward the paper to the Secretary at least 30 days previous to the date of meeting.

## PAPERS, BLANKS AND FORMS.

XIV. All papers, blanks and forms submitted to the meeting of the Association shall remain the property of the owner, subject, however, to be retained by the Executive Committee for examination and use.

## FEES.

XV. Members shall pay annual dues of ten dollars, payable in advance. The Executive Committee shall have no power to expend, for any purpose whatever, an amount exceeding that received as hereinbefore provided for. It shall be the duty of the members to make such returns to the Secretary as shall be required by the Executive Committee.

## ARREARS.

XVI. No member whose annual payments shall be in arrears shall be entitled to vote.

## WITHDRAWAL.

XVII. Any member may retire from membership by giving written notice to that effect to the Secretary, and the payment of all annual dues to that date; but shall remain a member and liable to the payment of annual dues until such payments are made, except as hereinbefore provided.

## EXPULSION.

XVIII. A member may be expelled from the Association by ballot of two-thirds of the members voting at any regular meeting of the Association, upon the written recommendation of the Executive Committee.

## RULES OF ORDER.

XIX. All rules not provided for in these By-Laws shall be those found in Roberts' Rules of Order.

## AMENDMENT.

XX. Notice of all propositions for adding to or altering any of these By-Laws shall be given to the members of the Association at least 30 days before the meeting at which they are to be acted upon.

## COPIES OF CONSTITUTION AND BY-LAWS.

XXI. Each member of the Association shall be furnished by the Secretary with a copy of the Constitution and By-Laws of the Association, and also a list of members.

Mr. Calderwood: I move the adoption of the Constitution and By-Laws as a whole, as amended. Carried.

The Chairman: The next business is the report of the Nominating Committee.

Mr. Greene: Mr. Chairman and gentlemen—Mr. Burington was named as the Chairman of the Committee, but afterwards turned the matter over to me. It has been difficult for your Committee to get a ticket which will please all, or which will be even satisfactory to ourselves, when there was so much good timber to choose from, but we present the following:—

President, Henry L. Wilson, Boston, Mass.

First Vice-President, C. N. Duffy, St. Louis, Mo.

Second Vice-President, J. F. Calderwood, St. Paul, Minn.

Third Vice-President, C. B. Reavis, Augusta, Ga.

Secretary and Treasurer, W. B. Brockway, Toledo, O.

The Executive Committee, the foregoing and Dana Stevens, Washington, D. C.; W. S. Dimmock, Council Bluffs, Ia.; W. G. Ross, Montreal, Can.; E. R. L. Tighe, Brooklyn, N. Y.

The Chairman: You have heard the report of your nominating committee. What will you do with it?

Mr. Avery: I move that the report of the committee be received Carried.

On motion Mr. Keister cast one ballot for the ticket and the chair declared the gentlemen named as duly elected.

The Chairman: Mr. Davies made a suggestion yesterday morning that a committee be appointed to take charge of the matter of standardizing our accounts. The matter was postponed until today. I regret that he is not here to take the matter up again.

Mr. Hibbs: I move that a committee of three be appointed to correspond with the different roads represented, and receive blanks and other information, showing the different sub-heads that they have in use at present, and that the committee tabulate the matter for action at the next meeting. Carried.

The Chairman: There is yet one paper to be read by J. P. E. Clark, of Binghamton, who is unexpectedly detained at home. The secretary will read his regrets as telegraphed and the paper.

## Naming and Standardizing Apparatus.

BY J. P. E. CLARK, GENERAL MANAGER BINGHAMTON RAILROAD COMPANY, BINGHAMTON, N. Y.

Upon glancing over the list of papers to be read at this convention I am inclined to think the subject assigned me, a mis-allotment, as I find myself the only general manager upon the list, surrounded by a number of the most efficient and widely known Street Railway Auditors and Office Men of the country, whose practical experience

enables them to treat much more intelligently the various timely subjects of interest, than a man who looks on from the outside and whose principal duty as far as the office is concerned is to find fault and create as much work for the department as possible; however, an interchange of ideas between our respective departments at this time may not be amiss.

With the advent of rapid transit upon street surface railways and the almost universal adoption of electricity as a motive power, came an entire and complete revolution in the manner and mode of operation of the street railways of this country. The relegation of the horse and mule to the pasture and bone yard and the substitution of the electric motor opened up an entirely new and uncultivated field to practical street railway men, who, for the time being, were in an almost dazed condition, owing to the radical changes demanded, and the then largely experimental condition of the new theory; however, with the never failing resources and undaunted energy and courage with which the average up-to-date street

railway man is necessarily endowed, one by one the various obstacles have been overcome, and today, notwithstanding the extreme youth of the modern street railway system, it has developed into a strong, robust child, with promise of a useful maturity.

While the development of the street railway systems of this country for the past few years has been rapid, it has at the same time been thorough, and from the chaotic and experimental stages have almost universally emerged thoroughly systematized and well managed plants, organized to best subservise the interests of the people and to produce the best financial results for their owners. This condition is due, in a large measure, to the advantages afforded in various ways for an interchange of ideas pertaining to the practical management and operation of street railways.

The most approved methods of construction, cost of maintenance and the efficiency and life of electrical equipment, appliances and trucks, the cost of larger and more commodious car bodies, the care and inspection of equipment, the best means of stimulating traffic, how to select employes, and many other practical operating questions of vital importance have been satisfactorily demonstrated by practical results, and thoroughly discussed at the various State and American Street Railway Association Conventions, and commented upon at length by the various Street Railway journals. The time devoted, even by the busiest of street railroad officials, in attending those conventions and the careful perusal of the various articles upon practical subjects written by practical men, has proved time well expended, much benefit being derived by the free exchange of ideas and the comparison of results obtained by different methods adopted.

Until I received notification from the Editor of the Street Railway Review of the proposed convention of Street Railway Accountants, it had not occurred to me how completely the Auditor, Accountant and Office had been ignored at conventions, in the preparation of papers read thereat, the general discussion ensuing and even through the columns of the various journals published throughout the country devoted to Street Railways and their interests.

Active and thorough research for data, useful in compiling this paper, revealed to me forcibly that the Auditor, Accountant, and the best method of office work and record has been "lost in the shuffle," as, in looking over carefully the files of street railway journals and reports of several State and National Conventions, I found absolutely nothing relative to the subject, except in a brief and general way.

When the important relation of the office to the practical managing department of the street railway is considered it is surprising that the state of affairs just mentioned exists. That this condition is radically wrong, none will gainsay. I am pleased that the Street Railway Review has taken the initiative in what I consider a move in the right direction, which should prove of incalculable benefit, not only to the auditing department, but to every person directly interested in the management and operation of street railways.

This conference of Street Railway Accountants, called for the purpose of considering different forms, methods and plans used by the various roads represented in compiling accounts, records, etc., and to arrange, if possible, a standard, which can be adapted to meet the requirements of both the larger and smaller roads, thereby affording a correct basis of comparison and the diffusion of general valuable information, will have accomplished valuable results, if the purpose of the convention is fully carried out and a standardized form of accounts generally adopted.

In order to successfully accomplish the desired end it becomes necessary, as far as practicable, for the operating department to standardize and name equipment, apparatus, and parts of every description, also materials of all kinds used in construction, in order that the various articles purchased as new outfit or used in repairs and maintenance will be charged under the proper heads. In view of the fact that a store-keeper's catalog, recently published by an enterprising street railway manager, for the general use of street railways, contains two hundred and twenty-five different headings, with numerous items under each, in many instances upward of one hundred, a person is overwhelmed at the outset by the vast number of articles used in the operation and maintenance of a street railway system, and the first general impression gained, is that the naming and standardizing of the apparatus and equipment is a hopeless task; but a more detailed investigation of the catalog reveals that a majority of the articles mentioned therein are of minor importance and could be easily disposed of by a more general classification, so that, from the standpoint of the number of articles used a standard could be arranged without great difficulty. There is, however, in my mind, a greater obstacle to overcome in standardizing and naming apparatus than the one I have just commented upon, and that is the fact that no two electric railways are equipped alike; the style and pattern of car bodies, trucks, type of motors, station apparatus, the miscellaneous equipment and the character of work and material used in track and overhead construction varying according to the requirements of the respective roads, thereby precluding the possibility of as complete a standardizing of equipment and apparatus as might be desired or has been attained by steam railroads.

I am also frank to confess that I do not consider it altogether essential to street surface railways that an absolute standard should be adopted. I do, however, firmly believe that there should be a formula arranged that would enable the accountant to enter charges under their proper headings and that there should be an understanding and agreement between the practical managing department of the various street railways as to what constituted motor parts, trucks, car bodies, generators, engines, boilers, station appliances, and all other classified equipment, and I submit that there should be detailed accounts and necessary forms for same, showing exactly the expense of maintenance and repairs, not only of the different classifications; for instance,—"maintenance of trucks" should show the cost of repairs to brakes, renewal of wheels, general repairs to truck frame; likewise, "repairs to electrical equipment," "repairs car bodies," etc., should be classified in detail showing the cost of repairs and maintenance of each classification. I consider that a standard form giving the various sub-classifications and what should constitute same, could be easily arranged, which would prove of incalculable benefit; and in preparing same, name and standardize as far as practicable the apparatus, equipment and parts used.

If you will permit me to digress (which I have assumed the liberty of doing throughout this paper, as the subject allotted me did not afford the opportunity to state all I desired to say), I think the most important suggestion in accomplishing the desired standard, and arriving at a fair and equitable basis of comparison, is that there should be a plain straightforward distinction made between cost of maintenance, repairs, renewals and betterments, and a standard form agreed upon so that when operating expenses of various roads are compared, the official, director, stockholder or bondholder making the comparison would at least have the satisfaction of knowing that the figures shown demonstrated the expense of operation based upon similar charges and computed according to the standard adopted by the most competent street railway auditors of the country.

The same suggestion applies to construction, as at the present time there are as many systems of division of accounts in this department as there are street railways, and it is generally understood, not only by street railway men, but by investors, that the manner in which repairs, renewals, and new construction are divided and charged has an important bearing on the account "operating expenses." There-

J. P. E. CLARK.

fore, if a proper and equitable standard and division can be arranged and universally adopted, whereby the charges in this department belonging to "operating expenses" are properly assigned it will redound to the benefit of the general street railway interests of the country, and when understood by investors that a standard form of charges has been adopted and is prevalent it will beget confidence, thereby directly affecting and strengthening street railway securities.

As I have observed above, the standardizing and naming of material used in the construction department, as far as practicable, is as necessary to the accountant as in the operating department, and in my opinion can be more easily accomplished. While a perfect standardizing and naming of apparatus, equipment and material used in the operation of street railways may not be possible, a classification sufficiently explicit and complete can be arranged and the parts and material pertaining to the respective classification properly assigned, whereby the accountant will be enabled to enter charges under proper heads, and when statements are submitted to the operating department the latter may have the pleasure and satisfaction of knowing that the account "repairs to steam plant," does not include any charges properly belonging to "removal of snow and ice."

An important factor in enabling the auditors or accountants to make proper classification is to familiarize themselves as far as possible with the practical operating department of their respective roads, become acquainted with the appliances and apparatus in use and the parts necessary to the repairs and maintenance of same. The operating department should in turn afford the office daily classified reports of repairs made and material used for same and give necessary details and information, thereby enabling the accountants to perform their work intelligently and with confidence.

The necessity of a standardized form of accounting is plainly apparent; obvious reasons demand it, but as a basis of satisfactory comparison and information to the individual road, it is particularly essential and of paramount benefit, and I believe the association of the Street Railway Accountants will be an invaluable adjunct to one of the largest and most enterprising business interests this great nation possesses. I prophesy a useful and busy future for the organization, and think the annual interchange of ideas and practical results and hours of social pleasure passed at forthcoming conventions will enable all present to render their respective interests renewed and improved service.

Mr. Burlington: I move that the paper be accepted and entered on the minutes, with the thanks of the meeting. Carried.

Mr. Reavis: I move a vote of thanks be tendered to the local members of the Association for their courtesy, and also to Messrs. Windsor and Higgins of the street railway press.

Unanimously carried.

Mr. McJilton: There is one point I do not think we are up to date on, and that is in the matter of notifying conductors properly about their shorts. I would consider it a particular favor if the members who are here would send me a copy of the blank which they use for that purpose. I do not like to rob the table over there and I would like to get blanks on the subject.

Mr. Barnaby: Our people are anxious to get a good storekeeper's method of reporting. We find sometimes that several thousand feet of track will be missing, and it takes a great deal of labor to trace it.

The Chairman: I have the pleasure of introducing to you, not a stranger, but one who is known to us all, our new president, Henry L. Wilson, of Boston.

President Wilson: Gentlemen, I accept this position rather reluctantly; but as it is only for a short time, as our next meeting occurs in a few months, I will try to fill the position in the meantime. This election puts me in mind of a story of an occasion where a small infant died, and the wake which followed was attended by very many people. The master of ceremonies got up and said he wished to apologize, he was very sorry he was obliged to present so small a corpse to so good an audience. (Laughter.) I feel in the position the corpse must have felt, and I think the committee which nominated me owes the rest of you an apology for having nominated so small a man for this position. I know we are in a hurry, and I will not go into any elaborate remarks. (Applause.)

I think there is one committee which failed to report, the committee on blanks, but perhaps it was discharged by its own acts when it fulfilled its duties. There is one other thing which comes up before us, and that is the committee which is to be appointed on the standard-

izing of accounts. I have had that delegated to me. I would appoint C. N. Duffy, St. Louis; William F. Ham, Brooklyn, and J. F. Calderwood, Minneapolis. The Chair is now open for further business. Is there any?

Mr. Burton: I move a vote of thanks be extended to our retiring chairman and our secretary, who succeeds himself.

The motion was put and carried.

Mr. Hall: I want to thank you for the courtesy which you have shown me in electing me as your temporary chairman, and also for the vote of thanks which you have just passed. I do not want to weary you with a long speech, because I am not a speech maker; but I want to express to you what I have heard from everyone to whom I have spoken since we have been here, and that is, that this meeting has been a success. It seems to me we have accomplished the object which brought us together. Some of the members in speaking this morning have mentioned about our getting through with the business and attending to it properly. I do not think that is anything more than should be expected from such a body of men as we are, occupying the positions which we do in our companies. That has been our education; that is what we are employed for, to attend to the business in a systematic manner, and in such a way that we may show the results of what we do, and we have done that here in our meeting. Personally I came here to learn, and I feel that I have been individually amply repaid by coming, and that I can go back to the company which I represent and make myself of more value to them in dollars and cents than I was before coming here. It may have been a narrow, contracted and selfish view which I took in regard to having the meeting in October, but I reached that conclusion simply because I cannot be with you, and this I regret now, and shall regret it until the time of the meeting is changed, which I believe is only a question of time. (Applause.)

The President: What further business is there?

The secretary called for the payment of dues, which was promptly responded to, and at 1 o'clock the meeting adjourned.

At 2 o'clock the delegates were taken in charge by a committee of Cleveland street railway officials, including: J. B. Hanna, F. T. Pomeroy, A. E. Aiken, W. G. McDowell, John Erhardt, F. S. Burton, W. W. Herrick and A. L. Lynn, Jr. The trip was made in a handsome interurban Brill car of the Painesville line, and went over some 40 miles of the Cleveland Electric and the Painesville, Cleveland & Eastern lines. An enjoyable lunch was served on board by the Cleveland roads, and the trip was a most delightful and interesting one. The return was made in time to catch the early evening trains, and it was with genuine regret the hosts and visitors parted. An inspection was also made of the offices of the Cleveland Electric, which are unusually well arranged, and which suggested several improvements to some of the visitors for their own office work.

#### Convention Notes.

Several of the accountants took advantage of the trip to visit several cities going and returning, to study other system of accounts and office methods.

The convention was under obligations to J. B. Rutherford, of the Steel Motor Company, who has headquarters in Cleveland, for appreciated courtesies.

H. A. Dörner, manager of the Dörner & Dutton Manufacturing Company, distributed neat souvenir gears.

The proceedings were reported by T. E. Crossman, who has reported the meetings of the American Association for so many years.

It was generally conceded that the accountant who can always figure out a dividend is a valuable man.

The Hollenden hotel management took splendid care of the convention. The large banquet room was tendered for the meetings and set with small tables around which the delegates sat and upon which they could spread their papers and take notes.

The display of blanks and forms as arranged by the committee was a most interesting feature and was constantly surrounded by delegates examining and studying the exhibit. At future meetings a

F. E. SMITH.

J. F. CALDERWOOD.

E. R. L. TIGHE.

C. B. REAVIS.

large room will be required for the classified display and the committee in charge promises a collection in October, which alone will be worth a trip to examine.

During the trolley ride several of the famous Cleveland viaducts were crossed, and afforded F. E. Smith, who has made quite a study of viaducts, an opportunity to entertain and enlighten his comrades on the subject.

C. B. Reavis, auditor of the Augusta, Ga., lines, wore a fine new knight templar watch charm, which with a highly complimentary letter from Colonel Dyer, was presented him by the employes of the company just as he was leaving to attend the Cleveland meeting.

The illness of H. J. Davies, of the Cleveland Electric, which prevented him from attending any but the first session, was greatly regretted. Mr. Davies is an acknowledged authority on accounts, whose assistance would have been most gratifying.

The discussion of what date is best for subsequent meetings was extended and earnest, and the matter will probably come up for action and possibly change at the October meeting. The advantages of meeting at the same time as the American are an opportunity to

even one session of the Cleveland meeting could fail to mark the earnest, business-like, hard-working character of the convention; and only those who were present can realize the amount of work accomplished in the two days.

## LOCOMOTIVES AT STREET RAILWAY CROSSINGS IN WASHINGTON.

The Commissioners of the District of Columbia have revoked their order, requiring all trains to stop at street railway crossings and have substituted the following regulation: "No locomotive or train with or without a locomotive attached shall pass over any street railroad crossing where the cars of a street railroad are propelled by cable or electric power, except in obedience to signal given by the gateman employed by the corporation owning the tracks over which such locomotive or train is to pass and such signal shall not be given until the crossing gates are closed in such manner as to effectually prevent access to said tracks from the highway."

## THE FIRST ELECTRIC LINE IN MEXICO.

Up to the present time, mules have held full sway as a motive power for street car lines in all the cities of Mexico. One insurmountable difficulty in nearly every locality is that mechanical power is so expensive as to be prohibitory. The coal for steaming purposes is brought from England and the meager railroad facilities make its cost very high. It is predicted by engineers, who are cognizant of the conditions in Mexico, that the future of electric street railways is not very promising unless coal is discovered in considerable quantities. However, there are some water powers which might be used with great profit. It would almost take the breath out of an American street railway engineer to learn that a mule car line, 15 miles long, conducts visitors and the people of Guadalajara to see the beautiful falls of Juanacatlan, the "Niagara of Mexico." There is a water power of some importance near the city of Jalapa and it is now used to generate power for electric lights. This same station is to be used to operate an electric line from Jalapa to Cordoba, 25 miles distant.

The contract for the line and equipment has been given to C. E. Loss & Co., railway engineers, 621 Pullman building, Chicago. Six cars are to be run on the line, freight as well as passenger service being rendered.

An electric road is proposed between Balza and Ubeda, Spain.

W. S. DIMMICK.

FRANK R. GREEN

meet the large number of operating men and managers, study the exhibits and secure the same reduced rate of fare. It would also permit such operating men as have much to do with the accounting department, as is the case with many small roads, to attend at least a part of the Accountants' sessions, while in attendance on the American Association meetings. On the other hand it is very hard for many roads to spare all the men at one time that ought to be in attendance at both meetings. There will also be many questions which the Accountants' Association will want to refer to the American for advice and opinion, and this can better be done if the two meetings had an interval of some months, so as to permit a proper consideration and study of the questions. The unanimous sentiment also was that the new association would have to put in long hours of work and did not want to be thought desirous of seeking the pleasure trips which are prominent features of the other. No one who sat through

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

At 11:45 p. m. on March 24, a fly-wheel burst at the Edgar Thomson steel works, Braddock, Pa. The wheel was 24 ft. in diameter, weighed 60 tons, and was in two segments; the engine cylinder was 54 in. in diameter and 60 in. stroke. It was set to run at 67 r. p. m. being controlled by a Porter-Allen governor. The engine was used for driving rolls; when the accident occurred a rail had just left the rolls causing the engine load to drop from 2,000 h. p. to friction load, and the belt to the governor breaking, the engine ran away. Before the engineer could shut off steam the wheel had burst. It is said that one segment struck a double 12-in. I-beam 20 ft. long and cut it in two without bending it more than 1 in. The engineer was fatally injured by a piece of the wheel which fell upon him.

\* \* \*

Cheap coal, most frequently slack or culm, requires for its combustion specially constructed furnaces and grates, and even with the so-called smokeless furnaces, so many types of which are on the market, it is an extremely difficult matter to avoid producing smoke. Culm has been successfully burned for several years at Scranton, Pa., and the Delaware, Lackawanna & Western Railroad burns the finer sizes of coal, rice, buckwheat, etc., on most of its locomotives. With a view to utilizing dust that is too fine to burn on any grate, and perhaps more particularly to avoid the production of smoke much attention has been given to various types of dust burners. The finer the coal the more difficult it is to secure a proper supply of air, and in burning dust it is essential that the coal be thoroughly mixed with or suspended in the air as it is introduced into the furnace, so that air may reach each particle and complete combustion ensue. In one form of burner, known as the Lindenstrasse Market apparatus the chimney draft carries the dust into furnace. In this apparatus the only entrance for air is through a pipe, at the intake of which is placed a wind wheel, given motion by the draft. The motion of this wheel operates to shake a screen placed in the lower part of the dust reservoir, and thus a supply of dust is constantly shaken down into the air current and carried into the furnace. In other types the dust is fed to the burner by means of an Archimedes' screw or other positive motion, and then blown into the furnace by a current of air under pressure or by a jet of steam which, by its inspirator action, draws air for combustion with it. The form of chamber or nozzle where the coal and air meet is such that the two are thoroughly mixed, and the stream spread it as it enters the furnace. Experiments at Scranton some years ago showed that culm would give from 70 to 90 per cent of the heating effect of the screened coal. Recent experiments by Herr Schneider, chief engineer of the Steam Users' Association of Berlin, gave the heat utilized in making steam as from 66 to 77 per cent of the theoretical heating value of the fuel; the type of boiler was not mentioned in the report giving these figures. With our

ordinary low grade fuels this means an evaporation of from 7 to 9 lbs. of water from and at 212°.

\* \* \*

EDITOR STREET RAILWAY REVIEW: In making comparisons between the crank and flywheel pump I never thought of the large pumps used in waterworks, and since you refer to them you must acknowledge that nearly all waterworks pumps of a size to be compared with feed pumps are decidedly not of the crank and flywheel type. As reported in your paper the city of Chicago has just closed a very large contract for pumps. Are they of the crank and flywheel type? One reason for the popularity of this type of pump in England is because they are usually plunger pumps, which are much better for feeding boilers than piston pumps, and thus the type got some credit that really belonged to the water end only.

I have already made the test you recommend, except that weighing the steam used is much better than figuring the consumption from the cards, and the result is that a first class compound single steam jacketed pump will do a horsepower on a good deal less than 60 pounds steam. How much less the electric driven pump will do it on I don't know, but not enough to make the steam pump the least desirable under the circumstances.

In marine work where it has been customary to drive all the pumps from the main engines, the practice is being abolished and they are using the very apparatus that you want retired from the power plants. Even on the rivers the cumbrous old doctor is giving way to the better pump for feeding boilers, and simplicity is too much of an item in power plants to permit the universal application of electric driven pumps.

ENGINEER.

\* \* \*

## The Chevalet Feed Water Heater.

The illustrations for which we are indebted to the Electrical Engineer, London, show the general arrangement of plant and a sectional view of the Chevalet feed water heater. Exhaust steam enters at B, the baffle plate E, acting as a separator to remove any oil, and passes, as shown by the arrows, up through a series of six rings or trays. Cold water enters at the top of the heater and runs by gravity from each tray to the one below. In each tray are six or more inlets for steam and three water overflow tubes.

By boiling the water, the carbonic acid is driven off and the carbonate of lime precipitated; the sulphate of lime if present is eliminated by a solution of carbonate of soda introduced at the same time as the crude feed water. The supply of soda solution is proportioned to the water drawn from the heater by the feed pump, the soda pump being actuated by one of the moving parts of the feed pump. About one-fifth of the exhaust steam is required for the heater.

This heater has been in use at the electric lighting station at Brompton for about a year and has resulted in keeping the boilers free from scale. The heaters must be cleaned

every six or eight weeks; but although the amount of incrustation is great, the scale is soft and easily removed. This is thought to be because the heat transferred to the water is not transmitted through the plates on which the scale accumulates.

\* \* \*

### Economy of Condensing.

There is no question as to the advantages of condensing over non-condensing engines when the power house is located where water for condensing may be had for the taking. Recently, however, a number of railway power plants have been built remote from such sources of water, and in these cases it is merely a question of whether the saving in cost of operation and interest charges on the plant will justify the additional investment necessary to secure water, or other means of condensation. The bulk, cost and difficulty of maintenance preclude, for large plants, all those air condensers in which the steam is condensed in pipes or closed tanks presenting a large surface to the atmosphere. Where other conditions than economy require that the steam shall not escape to the atmosphere these air condensers are often used to advantage on a small scale as on the steam tram cars in France.

For condensing in large plants two plans are in use for cooling the condensing water so that it may be used over and over again. The simpler is to discharge the water onto broad tables, slightly inclined, over which it flows to a shallow basin. This method, however, requires a relatively large area, which is a decided disadvantage where the price of land is high. The second is by means of a cooling tower, which being vertical, takes up but little ground area, but is much more expensive to install. The Worthington tower consists of a cylindrical steel shell open at the top and filled with layers of cylindrical tubular tiling. The water is pumped to the top and flows over the tile while a current of air is at the same time forced upward by means of a fan or blowing engine.

The Barnard cooling tower made by the Wheeler Condenser & Engineering Company, consists of a rectangular casing in which are suspended the requisite number of mats woven of steel wire and galvanized, over which the water flows. The casing is preferably of steel plate but may be of wood or brick. At the top of the tower the water is distributed so that each mat receives its due portion. A fan is provided to force a current of air upward through the tower. The cost of this tower, including fan, fan engine, surface condenser and circulating pump, may be taken as

\$6 per horse-power (f. o. b.) for an engine with an economy of 15 lbs. of water, and the power for fan and pump as from 3 to 5 per cent of the i. h. p. of the engine.

In Chicago, H. M. Sloan, general manager of the Calumet Electric Street Railway, was the first to use the cooling troughs. He excavated a pond 80 x 200 ft. and 6½ ft. deep, and built three troughs 15 x 85 ft., giving a cooling surface of over 24,000 sq. ft. The soil is stiff blue clay and practically water tight, making the cooler very cheap to construct, the total cost being \$1,200, to which is added the value of the land, \$2,500, making in all \$3,700. This same method for cooling condensing water is to be used by the Chicago Suburban Railway.

The scheme adopted by the West Side Metropolitan Elevated was more heroic, and consisted in building two tunnels, 5 ft. in diameter, from the Chicago river to its power plant a mile distant.

The following table taken from that of Dr. Charles E. Emory by Mr. McElroy, shows where we may expect a saving by condensing. A comparison of the reported performance of power houses with the economy given in the table will show the figures in the latter to be in close accord with modern practice.

	Indicated horse-power for 500 h. p. net.	Steam pressure by gage.	Water per i. h. p. per hour.	Commercial h. p. per horse-power.	Cost of engines erected and con- densed per net horse-power.	Cost of buildings and stacks per net h. p. of en- gines.	Total per net h. p. of engines.
Simple high speed.....	542	100-120	33	596	\$17.50	\$26.22	\$58.00
Simple low speed.....	556	100-120	29	537	25.00	23.03	62.85
Comp. high speed.....	542	100-120	26	470	21.00	20.68	54.81

Triple l. s. condensing.....	556	160-170	15	278	45.00	13.90	67.25

Taking up now the case of the Calumet. The maximum net power of the station may be taken as 2,000 h. p. in summer and half that in winter. Assuming the average load for 24 hours to be one-fifth of the maximum, we have as the output 300 x 24 x 365 or 2,628,000 horse-power-hours per year. We see that the condensing engine will give a water rate at least 6 lbs. less than the non-condensing engine of the same class. Assuming coal at \$1 per ton of 2,000 lbs. and that this coal will evaporate 6 lbs. of water per lb., this means .05 cent per horse-power-hour, or \$1,314 per year. Aside from this return of 35 per cent on the cost of the cooling troughs a saving of the cost of feed water is also effected as the feed pumps draw from the cooling tank.

The Metropolitan Elevated power house has four units, two of 2,000 and two of 1,000 h. p. with an average output at the switchboard of 2,000 h. p. for 24 hours per day. With the former assumptions as to cost of coal and boiler performance there is a saving of 24 tons of coal per day by the use of condensing engines, which amounts to \$8,760 per annum. The reduced first cost taken at \$3 per horse power, the saving being effected in the boilers and buildings, is \$18,000.

If the reduction in the coal bill be capitalized at 8 per cent we have \$109,500, and that with the saving in the cost of the plant gives \$127,500 as the maximum which could be profitably invested in the tunnels for supplying condensing water, which is somewhat in excess of their cost. From these figures it appears that even with the present

capacity of station and the cheapest coal the tunnels show a small margin of profit, which will be increased as the output of the station is increased.

The simple non-condensing engine is not without friends and the new power house of the Chicago City Railway, which will eventually have a capacity of nearly 12,000 h. p. at the switchboard is equipped with engines of this type and with return tubular boilers.

In a future issue we hope to be able to present the records of these plants which will enable interesting comparisons to be made as regards the economy of condensing.

\* \* \*

### Power House Record.

Through the courtesy of G. B. Coleman, secretary and general manager of the Metropolitan Railroad of Washington, we have received itemized statements of the cost of power generated at the 9th street station of that company during the six months ending February 28, 1897.

#### OUTPUT, COAL CONSUMPTION AND COST.

Month.	Coal, lbs.	Kilowatt-hours.	Coal per kilowatt-hour, lbs.	Total power expense.	Cost per kilowatt-hour.
September.....	880,800	234,455	3.757	\$ 1,908.53	\$.00814

This station is equipped with three 250-h. p. water tube boilers; Goubert exhaust heaters; three slow speed compound condensing Green engines, 17½ and 32 by 48 in., direct connected to 300-k. w. General Electric generators; steam feed pumps and steam pumps for lifting water from an artesian well which furnishes the supply. The fuel is Georges Creek Cumberland run of mine coal costing \$2.79 per long ton. The boiler pressure carried is 120 lbs. The station is operated about 20½ hours per day.

In the REVIEW for November, 1895, page 716, a statement of the performance of this station was given. At that time the daily output was 3,444 electrical horse-power-hours; the total cost per electrical horse-power-hour (including repairs, but not including interest) \$.00916, and the interest charges on cost of plant \$18 per day. The rate of interest is not stated but an estimate on the cost of the plant leads us to think that it was 5 per cent. In July, 1896, a portion of

the F street division began to be supplied with power from this station and the present output is between 10,000 and 14,000 horse-power-hours per day.

From the data furnished by Mr. Coleman, the cost per electrical horse-power-hour has been computed. As no additions have been made to boiler or engine equipment the interest charges are the same as before, \$18 per day. For January this makes the interest charge per h. p.-hour .13472 cent or the total cost of power .62602 cent. The excessive water cost in September is due to a break in the piping making it necessary to use water from the city mains.

### CYLINDER WITH SMALL CLEARANCE.

A steam cylinder of novel design, adopted by Bollinckx & Co., of Brussels, is shown in "The Engineer," from which we reproduce the cut. As shown, the cylinder is in three pieces and is steam jacketed, the jackets serving as the steam chest. Steam is admitted to the barrel jacket at the top and passes to the heads, thus making the jacket of the barrel act as a separator. The admission valves are of the

corliss type but being placed across the end of the cylinder the clearance space is very much reduced. The exhaust valves are of the piston type and move in the direction of the axis of the cylinder; when closed the piston is flush with the head of the cylinder. The clearance by this design is reduced to less than 1 per cent, and the surface which is alternately heated and cooled is a minimum, with consequent smaller loss from cylinder condensation. The valves and valve chests are of hard cast iron and the wear is said to be very slight.

## ELECTRIC SNOW PLOW AND LOCOMOTIVE.

Unlike most snow plows the one built this last winter by the Akron, Bedford & Cleveland Railroad does not rest inactive during the summer months, but, with the snow scrapers removed, serves as a locomotive, and is used for hauling excursion trains from various steam roads to Silver Lake, a summer resort located on the A., B. & C. Our illustration shows this plow, which was built at the company's shops and is known as No. 100.

The plow is 43 ft. long over all, the main body being 35 ft. long, 7 ft. 5 in. wide and 8 ft. high from bottom of main sills to roof. The weight is 44,000 lbs.

The construction throughout is very heavy, oak being used for all the framing. The two center sills are 7 x 9 in., 35 ft. long, and the two side sills are 7 x 9 in., 29 ft. long; all the cross timbers are 7 x 9 in. except the two which are directly above the bolsters at each end of the car, these being 14 x 9

three windows in each end and two in each side of the car. On each side in the middle is a sliding door 5 ft. wide and 7 ft. high with two windows. The entire outside of the car and the roof inside are painted white; the walls inside are dark red.

The snow scrapers consist of a large blade on each end of car and set at an angle of 45 degrees. These scrapers are 3 ft. wide, 3 in. thick and 11 ft. long, built of oak throughout, bolted together by large bolts and slabs of  $\frac{1}{2}$  x 6-in. steel. On the inside and at the same angle is a 4-in. shaft with tumblers; these are connected to the scraper with  $\frac{3}{4}$ -in. chains. Additional safety chains are provided which take most of the weight of the blade. Three  $\frac{3}{4}$ -in. chains run from the extreme ends of main sills to the bottom edge of the scraper to withstand any end or side thrust when the plow is working a heavy snow bank. A 4-in. toggle shaft 6 ft. long, with one end fastened to the main side sill of the car and the other to the scraper blade, also adds stiffness to the scraper. On the rear side of the blades are fastened steel brushes

ELECTRIC LOCOMOTIVE AND SNOW PLOW—AKRON, BEDFORD & CLEVELAND.

in. All the cross timbers are mortised into the main sills, the mortises being white leaded, and the frame tied together by six heavy bolts. To stiffen the main timbers two truss rods are placed under the outside sills, passing over the ends of the bolsters and fastened to the extreme ends of the side sills, with turn buckles in the middle.

The bolster proper is built up of two pieces of steel  $\frac{5}{8}$  x 6 in. by 7 ft., with oak between them and on the sides, and bolted together. The bolsters are bolted to the cross-timbers by eight  $\frac{3}{4}$  x 16-in. bolts, making solid bolsters 14 in. wide by 15 in. deep. The framing above the floor is all of oak timbers 6 x 7 in. mortised together. Eight mortised braces on each side stiffen the car against end thrusts. On each side a truss runs from the ends of the side timber up over the door posts. The side frames are tied together by six vertical bolts. The inside of the car is ceiled, hiding the framing and truss rods.

The floor is laid with 2-in. matched Norway pine. The roof is of  $\frac{5}{8}$ -in. white pine matched ceiling, laid on rafters spaced 16 in. apart, and is covered with heavy canvass, the latter being given three coats of heavy paint. There are

which clean the rail when the blades are down. In order to raise and lower the blade of the scraper, either a lever or compressed air may be used. As the plow is equipped with automatic air a jam cylinder is used for this purpose, the piston of which is connected to a chain which connects to a tumbler on the shaft. Air being admitted to the cylinder the piston at once rises, carrying with it the scraper. Letting the air out of cylinder lowers the scraper.

The plow is mounted on two heavy trucks of 5 ft. 6 in. wheel base; the axles are 4 in. in diameter and the wheels 33 in. with double plates and 1 in. flanges.

The electrical equipment comprises four No. 38 50-h. p. Westinghouse motors, one on each axle, two rheostat controllers, one at each end of the car, and two 500-ampere circuit breakers. The wiring in the car is of ample capacity for the heaviest current that the motors can stand. The rheostat was built in the company's shops. It is constructed of wire such as is used for heater coils, over 17,000 ft. of wire being used; it measures 4 ft. x 5 ft. x 14 in. Two trolleys are used, and are so arranged that it is unnecessary to turn the poles when the direction of the car is reversed.

The plow is equipped with automatic air throughout. An independent air compressor is located inside the car. Westinghouse engineer's valve, brake cylinder and triple valve are used, and the air reservoirs are of the standard size, to fit the car for its summer service where it replaces a steam locomotive.

At each end and within easy reach of the motorman are two sand boxes of about two bushels capacity each. The mechanism for these boxes was designed in the home shops and they have been found to be a decided success.

Recent trial trips have shown that the car can easily make 30 miles per hour.

Those interested in working out general design and details of construction were William Christy, general manager; F. J. J. Sloat, superintendent; L. M. Sheldon, electrician, and Z. Mostellor, master carpenter.

### ELECTRICITY FOR THE "ALLEY L," CHICAGO.

The South Side Elevated Railroad of Chicago is to be equipped for electrical traction at an estimated cost of \$1,500,000, and it is probable that the work will be completed by October 1. The city council has granted the company permission to connect with the Union Loop, building an elevated structure through Harrison street to Wabash avenue.

Sargent & Lundy, consulting engineers, have completed the preliminary plans which were accepted by the directors of the company on March 27. The power house is to be at the northeast corner of State and 40th streets, with a frontage of 191 ft. on State and 93 ft. on 40th street; the first installation will be of 5,000 h. p. capacity; four units consisting of cross-compound condensing corliss engines and direct connected generators; eight water tube boilers of 500 nominal h. p. each; Green economisers; approved coal handling machinery and mechanical stokers. The stack is to be of steel, 200 ft. above the grates and 13 ft. in diameter. The company owns a lot with 50 ft. frontage, just north of the power house location, so that the plant may readily be increased when it becomes necessary.

The initial voltage is to be 650, with a drop of 25 volts on the line. The line is to be divided into 18 sections, each supplied by a separate feeder; at stations, which so far as possible will be at the ends of sections, the rail from which the motors take current at starting will be connected to both sections, so that advantage may be taken of both feeders at starting. A third rail, similar in design to that on the Lake Street "L" and the Union Loop will be used, with perhaps a different type of insulator. At the yards the tracks will have the third rail so that switching may be done by motor cars.

The present plan is to operate trains of one motor car equipped with two motors of about 135 h. p. each, hauling two trailers, and making an average speed of 14 miles per hour. Extensions of the line are contemplated but nothing definite has as yet been decided.

The Piedmont & Mountain View Electric Railway is to have cast-welded joints,

### ST. LOUIS CORLISS ENGINE.

The illustration shows a view of the "heavy duty" corliss engine which has been designed by the St. Louis Iron & Machine Works to supply the demand in recent years for an engine which combines great strength, constant regulation under wide range of load, economy of operation, and ability to operate continuously under great overload. This combination makes the engine especially suited for electric railway power houses and for service in rolling mills and other places where the conditions are very severe.

The main frame is of box form, stiffened by heavy ribs, and designed to resist all stresses due to the weight on the main bearing and to the working of the engine. The guide frame is circular in section, and has a pillar or foot extending the length of the guides and resting on the foundation. The cylinder is made with heavy walls and flanges, and in this type is designed for a working pressure of 150 lbs. On the gear side the cylinder feet are extended to receive the self-contained dust-proof dash pots. The valve gear is of the standard hook type and operated by double eccentrics and wrist plates. This movement gives a cut-off variable between zero and three-quarters stroke, with a constant exhaust opening and compression. The valves are made single or double ported according to the type and speed of

"HEAVY DUTY" ST. LOUIS CORLISS.

the engine. All rods and pins are forged of crucible steel the crosshead and crank of 60,000-lb. open hearth steel and the crank shaft of selected wrought iron. The governor is of the centrifugal ball type, provided with a weighted lever for changing speed, dash pot to prevent chattering, and an automatic safety stop which closes down the engine in case of accident to the governor.

The St. Louis Iron & Machine Works have had an experience of 40 years in the manufacture of engines and machinery, and have every facility in the shape of modern works and abundant capital to enable them to undertake works of magnitude and guarantee satisfaction.

The Consolidated Traction Company of Newark, N. J., has a rather interesting case pending. It has brought action in the Court of Chancery to restrain the Howard Savings Bank from paying \$1,400 which a former conductor, accused of dishonesty, has deposited there. No action has yet been taken.

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*The Doctrine of Comparative Negligence no Longer the Law.*

The law of contributory negligence forbids the recovery by one who by his own fault brings any injury upon himself, and it is no longer a question of comparison as to who was most at fault.

Justice Shepherd in giving the opinion of the Court says:

In a suit for personal injuries received by the appellee, he recovered a verdict against the appellant for \$3,800, which was remitted down to \$2,000, and judgment for that amount was entered upon the verdict. The circumstances of the accident under which the suit arose were, briefly, that the appellee was driving his team south on Stony Island avenue, between 76th and 75th streets, on which avenue the appellant operates a double track line of electric cars. About the time he reached 75th street he turned his team and attempted to cross the tracks, but before he got over, the rear of the wagon was struck by an electric car going north and he was thrown out and sustained the injuries complained of.

Appellee seems to have driven both slowly, and at nearly a right angle with the track. But whether under the circumstances rendering such a course wise and prudent, he should have attempted to cross in front of an electric car which was coming toward him at so short a distance away, as in this case, and which he saw before he started to cross the tracks, the very important and close question whether he was not guilty of contributory negligence to such a degree to bar him from any recovery.

It is wrong to say that the question of his contributory negligence in bringing the accident upon himself was the controlling question of fact in the case. We need not at this time say that the want of evidence upon that subject was so clearly opposed to the verdict as to justify our reversal of the judgment on that ground, although it is made our duty under the law to consider the evidence, and to set aside verdicts that are not so supported by it: *C. & E. R. R. Co. v. Meech*, 163 Ill. 305; *C. & N. W. Co. v. Holdom*, 66 Ill. App 201. But there was, at least, so much evidence tending to show contributory negligence by the appellee, as to require a critical examination of the instructions that were given considering that question.

The 7th instruction asked by the appellant, was as follows:

7. "If the jury shall find from the evidence that both the motorman and the plaintiff supposed that the plaintiff would get across the track without being struck by the car, and that in so doing they both erred in their judgment in respect to the matter, and that the accident was due to such error in judgment on their part, then the plaintiff can not recover, and the verdict must be for the defendant." Instead of giving it as asked the court modified it by inserting after the words "in respect to the matter" the words, "and both exercise ordinary care and caution up to the time of the collision."

The theory upon which the instruction was drawn was that both the motorman and the appellee were chargeable with the exercise of ordinary care and judgment in the situation in which they were placed, and that if in such regard they both erred, and the accident resulted in consequence of such joint error, no recovery could be had. If both were

equally negligent there could be no recovery, is well settled law.

The instruction was warranted, under the evidence that tended to show that the appellee erred in judgment in supposing that he had time to cross the tracks, and that the motorman likewise erred in judgment in not beginning sooner than he did to try to stop his train, and should have been given as requested.

The modification of the instruction was equivalent to telling the jury that appellee could recover, unless both himself and the motorman were in the exercise of ordinary care. In other words, if the motorman was exercising ordinary care and the appellee was not, then appellee could recover, which was much the same as saying that the degree of care on the part of the appellee was immaterial, however careful the motorman may have been.

Such is not the law. The law of contributory negligence forbids the recovery by one who, by his own fault brings any injury upon himself, and it is no longer a question of comparison as to who was most at fault. The appellant had a right to have the instruction squarely presented to the jury, the law, that if the accident were due to the joint negligence of the motorman and the appellee, no recovery could be had, disconnected with other and inconsistent elements embodied in the modifying words inserted by the court.

For the fault in modifying the instruction, and upon the question of whether the appellee was guilty of a degree of negligence which should bar his recovery, we think there should be another trial.

(Appellate Court of Illinois, South Chicago City Railway Co. v. Adamson, 29 Chicago Legal News 240.)

[NOTE. In the case of Calumet Electric Street Railway Co. v. Nolan, 29 Chicago Legal News 240 the same court said of the doctrine of comparative negligence. The old doctrine of comparative negligence formulated by Judge Breeze in *Galena and Chicago Union Railroad v. Jacobs*, 20 Ill. 478, and running its course through several volumes of Illinois report, after being often nibbled at, has been formally repudiated in *Lake Shore & Michigan Southern Railway v. Hessions*, 150 Illinois 546." E.D.]

*Crowded Condition of Car—Duty of Conductor to Stop—Reasonable Time Should be Allowed to Alight.*

This was an action by Frances Waniata, as administratrix of the estate of William Waniata, deceased, to recover damages for the death of her intestate, caused by the alleged negligence of the West Chicago St. R. R. Co. Appellant was bound to afford the deceased a reasonable opportunity to alight with safety.

The crowded condition of the car was no excuse for lack of attention to the request of the deceased that the car stop for him to get off. The conductor was bound to pay heed to the manifest movements and desire of the deceased that the car stop for him to get off, and appellant was negligent in not holding the car until the deceased had a reasonable opportunity to get off at a place and in a manner that he would not be injured by a passing team drawing another car.

The judgment for \$3,000, in the opinion of the court, not being excessive is affirmed.

(Appellate Court of Illinois, West Chicago Street Railway Company v. Waniata, 29 Chicago Legal News 198.)

## THE COLUMBIA & MARYLAND RAILWAY.

By S. W. Huff, Electrical and Mechanical Engineer.

(Continued from Page 154.)

### THE BOOSTER SYSTEM.

The choice of a system of distribution for the Columbia & Maryland Railway lay between the Three Wire System, and the Booster System. The Booster System, as proposed and finally adopted, differs in several respects from that now used in Railway Service. The use of the series booster to compensate for a heavy drop during periods of excessive load in feeders supplying isolated sections is familiar to railway engineers. But in this system it is not proposed to boost an isolated section, but the ends of the main line, which ends are not insulated from that portion of the line fed direct from the generators. It is proposed that the point on the line where the booster-fed and direct generator-fed portions of the trolley unite shall not be fixed by section insulators, but be allowed to move backward and forward over the line with the shifting of the load.

It will be seen that careful adjustment in the boosters and feeders is necessary to prevent the boosters from raising the potential of the line fed through them higher than that portion of the line fed by the generators, and thus force the division point above referred to into the power station and the boosters boost upon a short circuit. To avoid serious results from this cause it is proposed to so design the boosters, so that their characteristic will be as near a straight line as possible and the voltage supplied the trolley through them under normal conditions be kept under the voltage supplied to the trolley direct from the generators. It is probable however that a certain amount of current will flow back through the short circuit whenever there is a sudden falling off of the current through the boosters, the magnetism of the boosters keeping up the voltage for a moment after the current and its resulting drop of potential has disappeared. It is hoped however that the loss from this cause will not be appreciable. With this system it is proposed to use boosters placed upon the same shaft with motors that derive their power from the standard generators that supply that portion of the line within economical reach of the power stations. The generators and motor-boosters are controlled from the same switchboard and provision is made for feeding the various portions of the line either through one or more boosters, or from the generators direct.

### OVERHEAD CONSTRUCTION.

The necessity for high speed and a reliable schedule made the overhead construction a very serious problem. In view of the unsatisfactory experience of several roads attempting high speed, it was thought advisable to look for something different from the standard overhead construction. A suspension cable carried directly over the trolley wire similar to that described and shown in Figs. 2 and 3 under the Three Wire System was considered. There is however serious doubt whether the trolley wheel could be relied upon to stay on the ordinary copper trolley for long runs at 60 miles per hour and under adverse conditions of weather. It would seem that something more reliable is needed for high speed service.

The use of a slotted tube with an internal sliding shoe was considered. The tube it was proposed to suspend from a

suspension cable running directly over it by means of adjustable clamps. The section of the tube with the attaching clamp is shown in Fig. 4. The clamps are formed of half round iron, and the ends threaded into sections of pipe cut to the desired length. The ends of the pipes are threaded internally with right and left hand threads, and afford a cheap means for suspending the tube from the suspension cable and one which is capable of ready adjustment.

It seems practical with this system to attach the conductor to the side of the car, and hence it is unnecessary to suspend the line conductor out over the centre of the track. This permits of a much stronger construction, as the suspension cable can be attached directly to insulating blocks bolted to the sides of the centre poles. The method of attaching the suspension cable and tube to the insulating blocks, and the blocks to the poles is shown in Fig. 5. It was found that this tubing made from hard steel and shaped as shown in Fig. 4, could be gotten in 40-ft. lengths. By placing the poles 80 ft. apart only two tube lengths are required per pole section. It is however entirely practical to place the poles 120 ft. apart. At the tube joints between poles it was proposed to make a permanent and rigid joint as shown in Fig. 6 by the use of a coupling of the same form as the tubing but larger and cut into lengths 12 in. long. At the poles the tube ends are attached by means of a casting Fig. 9, which allows a limited movement of the tube so as to provide for expansion and contraction. On slight curves the tubes are cut longer than for the straight line, the length varying with the degree of curvature. The ends butting at the poles the centre swings out to make the curve. Sliding in the tube are as many shoes or current collectors as may be necessary, usually two. The shoes as shown in Fig. 8 are shuttle shaped and connected to each other and to the car by a spring connector through which passes the cable carrying the current. Some experiments were conducted to determine whether the heat due to the friction of the shoe moving at high speed would give trouble. A fly wheel was selected, the periphery of which was travelling 70 miles per hour, and upon this periphery was first allowed to rest lightly, and then pressed, a piece of metal similar to the shoe. The heating was found to be inconsiderable. With this construction, which consisted, with the exception of the centre poles and suspension blocks, of steel, it was thought that by allowing the same factor of safety used in suspension bridges the resulting structure would be as durable as these bridges and thus be more reliable than the standard overhead structure in which a copper trolley wire of uncertain strength figures so prominently. As it is practical with this construction to dispense with the bracket arms and the usual insulating material, the cost of construction is considerably less than with the standard construction of equal conductivity.

Owing to the experimental nature of this structure, and the little value of the old material in the event of its failure, it was decided to equip the two ends of the lines (the portions to be operated first) with some form of copper trolley, while a test of this tube structure was being made over a four or five mile section.

The form of copper trolley wire construction adopted for the ends of the line consists of a centre pole construction in which iron bracket arms are formed by passing pipes through wooden poles and bracing them to the poles. Attached rigidly to these pipe bracket arms and projecting downward are suspensions similar to that shown in Fig. 2, except that these arms are made of pipe and are shorter. At the lower

## TEXAS STREET RAILWAY ASSOCIATION.

The Texas Street Railway Association convened in Austin, Texas, March 17th, and ended its two days' session at 11 p. m., Wednesday, the 18th. The meeting was called to order by Carl F. Drake, vice-president. The companies represented were the Laredo Electric & Railway Company, the Austin Dam & Suburban Railway Company, the Austin Rapid Transit Railway Company, the Elm Street Line of Dallas, the Dallas Rapid Transit Company, the Fort Worth City Railway Company, the Houston City Electric Street Railway Company, the San Antonio Street Railway Company, and the San Antonio Edison Company. After the minutes were read Mr. Drake spoke as follows:

## ADDRESS OF THE PRESIDENT.

"Gentlemen:—It gives me much pleasure to welcome you to Austin in attendance on the fourth annual convention of the Texas Street Railway Association, and while I thoroughly appreciate the honor conferred upon me in permitting me to preside over so representative a body, at the same time it is with a feeling of regret that I am called to the chair.

"Our association has met with a very great misfortune during the past year in the death of its president, and there is probably no man interested in street car work in Texas who will be able to represent us as was Colonel Sinclair. In his death the association and the street car interests of Texas suffered an irreparable loss. The citizens of Galveston, which was his home, have testified in the many eulogies which have been published from time to time as to his sterling worth and their appreciation of him as a citizen. The Texas street railway men, and the citizens of Galveston and the state of Texas lost, in his death, an earnest worker and a faithful citizen, full of energy and progressiveness.

"Street railway men are called upon from time to time to become acquainted with municipal officers, and I want today to introduce to you what we consider a model mayor, one who embodies all the progressive elements of a nineteenth century man, coupled with the discretion necessary to make a perfect head for a municipal government. Gentlemen, I have the honor of introducing to you Mayor Hancock of Austin."

Mayor Hancock, of Austin, made a neat, short welcoming address, and the convention proceeded to business, appointing of committees were as follows:

On Resolutions—C. B. Hendricks, Ft. Worth; H. C. Chase, Houston, and J. D. Chiles, Austin.

Constitution and By-Laws—H. C. Chase, C. F. Yeager, Laredo, and C. L. Wakefield, Dallas.

Topics for Next Meeting—George D. Hartson, Dallas; R. S. Wakefield, and D. D. Willis, San Antonio.

Membership—A. H. Hayward, Houston; D. D. Willis and B. M. Hammond, San Antonio; Henry Carrett, Dallas, and J. K. Urie, Galveston.

Legislation—F. E. Scovill, Austin; I. H. Evans, Austin; W. H. Weiss, San Antonio; Julius Runge, Galveston; C. L. Wakefield, Dallas.

The last three named committees were, by motion, made permanent.

Invitation was extended by the Austin Club to all the delegates, and by the Austin Dam & Suburban and the Austin Rapid Transit companies to inspect their lines. The

meeting adjourned until 2:30. At that time there was first introduced the following resolution:

Resolved, That we oppose the passage by the Texas legislature of House Bill No. 416, entitled "An Act to Amend Article 651, Chapter 3, Title XXI of the Revised Statutes," etc.

Because the proposed legislation is not responsive to any public demand, and is for the benefit of a particular class and affords no advantages to the general public.

It leaves a dual responsibility, uncertain in its enforcement, for the maintenance of the street railway tracks on the streets of the city. There is no more important feature of modern city government than the right and power on the part of the municipality to regulate street railway properties in this respect, and in a manner resulting in the best maintenance of the roadway in a city. The shifting of blame from one corporation to another would be fruitful of litigation, damaging to the general public, and to a great extent prevent the proper and speedy regulation of the corporation by municipal authorities.

It will defeat the effort of street railway companies to adopt regular schedule and time cards for the running of cars, and will result in great confusion, to the damage and inconvenience of the traveling public.

Resolved, further, That this resolution be at once printed and a copy be mailed by the secretary to each member of the Texas legislature.

This was referred to the committee on resolutions, which recommended its passage.

The Committee on Resolutions made its report on the death of Colonel Sinclair, and the following resolution was adopted:

Resolved, That in the death of our honored and esteemed President we have lost a valued guide and counselor, a worthy citizen, a true and tried friend and co-worker, who was so intimately associated with us that we experience a sense of personal loss in his sudden taking off in the very fruition of his career.

Resolved, That we extend to his bereaved family our sincere condolence and sympathy in this their time of mourning.

Resolved, That a copy hereof be transmitted to the family and also a memorial page be suitably inscribed upon our records.

The Convention then went into the discussion of

## UNIFORM RATE OF WAGES AND NUMBER OF HOURS WORKED.

It was developed that in the main 12½ cents per hour was paid. Several roads had the three men to two car swing system. A few had long hour days, with third or fifth day off; in the latter case, the wages were from \$40.00 to \$55.00 per month. There seemed to be no uniformity as to the number of men worked in barn or repair shops.

Discussion was had on the "Life of Pinions and Gears."

## LEGISLATION, STATE AND MUNICIPAL.

This was opened by a few impromptu remarks by C. L. Wakefield, in the course of which he said that the Association should be careful that its vigorous action and remarks on legislation should not be such as to suggest the idea to the general public that there was more in the matter than there really is. That many legislators introduced anti-corporation bills because they did not feel that personal sense of responsibility, or fear of doing a personal wrong, as they would were the parties individuals instead of corporations. He said further, that we should try to live as closely to public men as we can, frankly stating our position, and frankly admitting that there may be wrongs done by corporations which ought to be stopped, and that our efforts will be directed that way. Make no statements to legislators that you cannot prove beyond a reasonable doubt.

Mr. Willis spoke upon the bill about which a resolution had been previously introduced, in which he said that he understood that the nature of the bill was to provide that a

street railway in any city in the state could have the use of the track of another street railway by getting permission from the City Council, and paying a portion of the expenses of construction and maintenance of that portion of the track over which it runs, the length of track the use of which the bill contemplated legalizing being 2,500 feet, or nearly half a mile.

In the next day's proceedings the bill itself was presented by Col. H. E. Barnard of San Antonio, from which it appeared that it sought to legalize the use of 2,500 feet of another railway company's track, but compensation was to be fixed by arbitration, and this compensation was not limited by the bill to the payment of its proportion of the expense of construction and maintenance, and this could only be used in order to connect terminal points. No reconsideration of the action of the Convention, however, was had. Messrs. Drake, Hendricks and Evans, followed with remarks on the bill.

Mr. Yaeger asked if there was a law enabling municipalities to pass ordinances fixing a penalty for interfering with wires, cutting them, stealing power, etc. So far as the members could tell, there was no such a bill. Mr. Hendricks moved that the Committee on Legislation prepare a bill covering the point in controversy, and report to the Convention during its present session.

Mr. Drake suggested the advisability of each road sending to the secretary copies of the franchises under which it operates; a motion covering this was carried, and further that any road wishing a copy of these franchises should apply to the secretary, and pay the necessary expense.

The pass question, among city officials, was then taken up, and very generally discussed. Most of the roads, it was found, were very liberal in this regard; some, however, were more fortunate. The question of passes to newspapers was taken up also under this discussion. With only three exceptions, it appeared that the newspapers gave full value for all passes they received, in the way of advertising entertainments, etc.; and it also generally had the effect of making them get both sides of a story in case of an accident. It was found that in every case policemen and firemen are passed on their badges; the means of passing were discussed, and, with two exceptions, a coupon ticket was used; and this, in two cases, bore on each side the stamped name of the holder.

Adjourned until Thursday, March 18, at 10 A. M.

At that time the first question taken up was the resolution on the joint track bill, known as the O'Connor bill, previously set out.

The Committee on Topics for the Next Meeting, reported as follows: 1st, Power Construction; 2nd, Overhead Construction; 3rd, Construction and Maintenance of Car Bodies; 4th, Brakes; 5th, Discipline of Employees; 6th, Rail Joints; 7th, Methods of Increasing Traffic. On recommendation of the committee the list was left open, and afterwards the committee was made permanent for further suggestions.

The Committee on By-Laws recommended an increase in dues to \$10.00 per annum, which was passed.

(The three papers read at this session of the Association and abstracts of the discussion follow the report of the proceedings.)

The following nominations were made:

Carl F. Drake, president for the years 1897-1898; A. H. Hayward, vice-president; C. L. Wakefield, secretary.

Both Ft. Worth and San Antonio were put in nomination for the next place of meeting, San Antonio winning by one vote.

The meeting adjourned until 1:30, at which time the proposed trip up the lake above the Austin dam was taken. The Austin dam is a magnificent piece of stone work, and stands about 65 feet high. There was about three feet of water running over it, making a beautiful cascade. The lake above the dam extends up the river 27 miles. The water power is considerable and the city, which owns the dam, has an electric light and power plant and water works all operated from this water power. The cost of the dam was one and a half million dollars, and although it has been in operation but a short time, has already gone far toward paying interest and sinking fund. Ex-Mayor McDonald, the father of the dam, was with the party. A trip was made eight miles up the lake and proved a genuine surprise to most of the party. At Fish Pond House a stop was made; here are large private grounds belonging to the Austin Fish Club. The dam is reached from the city by a fine system of street railways, operating cars by power furnished by the city from the water power.

The Convention was called to order for the night session at 8 p. m., when Col. Barnard was heard on the joint track legislation.

#### HOW TO MAKE STREET RAILWAY EMPLOYEES HONEST.

Mr. Wakefield suggested that to get them honest was better than to attempt to make them honest. Mr. Drake suggested that a wrong hypothesis was held by the majority of the street railway and steam railway managers, by starting out with the idea that all men are dishonest. He believed that the majority of men (provided they are below the rank of manager or superintendent) are honest.

Mr. Hartson keeps a record of each trip, using it as a check on the motorman, showing the aggregate at the end of the month to stimulate each man, and checking also the men who collect the fares.

Mr. Hendricks agreed with Mr. Wakefield that honest men should be got in the first place, and fired as soon as they fall from grace.

After a general discussion the subject of

#### THE REPAIR SHOP

was taken up, which was largely technical in its nature.

One member advised the use of all copper and brass in having new bearings made. Raw hide pinions were found in some cases to have lasted from five to eight months, and in some cases were found to be entirely unsatisfactory.

Mr. Hendricks, of Ft. Worth, said that after his brass bearings have worn down he fills them with rabbit, and finds them very satisfactory.

Mr. Scovill explained a scheme that he had seen at the National Convention at St. Louis, of fitting the axle with a pipe clamped to the motor, making a long bearing, and an arrangement for filling the pipe with oil; it was represented to him there that the amount of oil used was less than in the old way, and the bearings lasted a great deal longer.

R. S. Wakefield's experience with magnolia metal bearings had not been satisfactory.

Trolley wheels were found to last from three to six months.

Car wheels in some cases cost 50 cents to press on, 50 cents to press off, and one dollar a wheel to have the wheel bored. In other cases \$1.30 for boring, and in some cases 75 cents

each way for pressing. There seemed to be no uniformity in the length of the life of the wheels. It was suggested that the life of a wheel was frequently shortened by the use of a brake shoe that is too hard, and by the carelessness of the motormen in skidding the wheel.

Double as against single trucks were here brought up, and Mr. Chiles entered into considerable discussion, holding that the double truck was far superior in every way; some contended that for short cars they would not do. Mr. Chiles, however, contended that in the one case you have the whole weight distributed in eight parts, while with the single truck you have it distributed in four parts, making the weight on the truck much less, and more evenly distributed, in the case of double trucks.

Mr. Hendricks asked that special discussion be had at the next meeting on the weight of rails.

This completed the discussion on topics.

The Association went into the election of two directors, who with the president, vice-president and secretary are the five officers provided for under the by-laws.

Thanks were extended to the Austin street railway men for their entertainment, to the Driskill Hotel for the use of its parlors, to the Austin Club for its courteous manner of receiving the members and giving them the prize fight returns.

Mr. Drake then brought up the question of allowing supply men to join the association as associate members. On motion, the constitution was so amended, fixing the fee at \$1.00 initiation and annual dues of \$5.00.

Mr. Drake thanked the members of the Association in behalf of the citizens of Austin, etc., and said that what little courtesies had been extended them had come straight from the heart, assuring the members that they would always be welcome, and expressed the hope that they would visit Austin frequently.

The meeting officially adjourned, to meet again in San Antonio on the third Wednesday in March, 1898, unless sooner called together by the president.

The badges furnished the members on the 17th of March, the date of the meeting, were bright green, printed as follows:

"Fourth Annual Convention of the Texas Street Railway Association, March 17th, 1897, Austin, Texas."

#### Accidents; Their Liability and How to Prevent.

BY R. S. WAKEFIELD, SUPERINTENDENT, SAN ANTONIO EDISON COMPANY.

This subject is one that at every national and every state convention is imposed upon some manager or superintendent, who tells us all about the liability, and on this part of the subject we are all thoroughly posted. But how to prevent accidents is one of the things on which the street railway man is not nearly so well informed as the lawyer on the plaintiff's side, and whose advice is too often taken by the "twelve good men and true."

We are all satisfied as to their liability, not only in the street railway business, but, as ancient history tells us, in the best of families, so that part of the subject we will pass, and suggest a few ways to prevent some accidents, at least.

I have found by sad experience that Texas is inhabited largely by a race of people whose ideas as to the correct thing in driving are quite crude, and you will often see them sitting in their conveyances with lines hanging loose, engaged in some deep reverie, from which they will likely be awakened by the sound of an approaching street car. Our hero then pulls up his lines, and in many cases pulls too strongly on the wrong one, and the result is a broken wheel, sprung axle, and many other ailments to a buggy, which is never over a

year old, and which always costs \$195. Now, the way to have prevented that accident would apparently be to have given instructions to the motorman that when approaching a rig he should slow up and allow the driver to have right of way. I have found that many motormen seemingly think that because they ring the gong they have done their duty, and if the property of someone gets injured, it is the fault of no one but the driver of the vehicle.

The motorman should be given to understand that everybody is not always looking for a car, and for that reason he should have his car under perfect control before attempting to pass anyone.

In the majority of the accident reports I have seen, where a wagon or buggy was damaged, I have noticed that the vehicle was on the right side of the street, going in the same direction as the car, and; as the motorman usually puts it, "I rang the gong and thought he would drive straight on, and just as I got to him he swung onto the track and the car struck the wheel." It takes a great deal of reasoning with a motorman before he will learn that he is not the only one who has a right to the streets, but a few minor accidents for which he has to pay, will diminish their number.

As to the damage to persons: These are very often caused by the lack of proper diligence on the part of the injured person, and I don't believe a preventive will be discovered which will restrain some people from being careless, and I think that so long as people ride on street cars, street railway companies are liable to have such accidents; but there are, in my estimation a few rules that may be made which might reduce them, and the reduction of one accident in a thousand is good.

Very few motormen exercise the proper amount of care when running a car past little children playing in the streets. A company can very well make a rule that motormen shall run very slowly when passing children who are on the street, whether they be on the sidewalk or on the roadway. When children are playing, they are apt to suddenly take a notion to run across the track, and it takes an incredibly short space of time for a child to get to the center of the average street, and I have known some excellent motormen to have accidents of that kind, whereas a rule as before mentioned would have avoided trouble.

Too many motormen rely on the gong to warn people of their approach. The gong is a good thing, and cannot be used too much at the proper time, but all people cannot hear. There are a great many people who use the streets who are deaf, and motormen should be cautioned on this line.

Too much cautioning is impossible, and a superintendent should be blessed with a perfect vocal organism, so that he can indulge in continued cautioning.

I think it is advisable to require a deposit of employes, and believe it reduces the accident list. I also believe that a penalty should be attached to every accident, either in the form of a "lay-off" or cash fine.

In discussion, C. L. Wakefield said: An ordinary wagon or buggy in this country makes more noise than a street car, and therefore the man that is in the buggy cannot hear the car, and it is not safe for the motorman to attempt to pass until he knows he has the attention of the driver. He advised, in towns that were not too large to make it impossible, a close acquaintance with all possible jurors, so that, although they might not be friendly, some of the prejudice might be obviated.

Mr. Willis, of San Antonio, said that he made it a rule to get on the ground as soon as possible, and interview personally outside witnesses immediately, and get both sides of the case; and if the accident is serious, get a photographer and have a picture taken as nearly as possible giving the place where the accident occurred and the position of wagons, cars, etc. Have measurements made by the civil engineer, and get ready for a law suit. If there seems to be a possibility of a settlement, settle at once, with the cash in hand and displayed to the plaintiff. If there seems to be no possibility of a settlement, pay no attention to it. In small cases, we advise settlement, as the chances for a corporation in a justice court are very small.

Mr. Hendricks advised fighting every case that the company was not to blame, as the reputation for so doing would deter a great many from bringing suit.

Mr. Chase: I consider no accident, when a car is going in the same direction as the vehicle, excusable. A motorman ought never to form the opinion that a wagon is not going to cross the track in front of him. I advise settlement for small damages at once.

Mr. Hartson, of Dallas, cited a case where suit was brought, when, he believed, no accident had occurred. Such a case had come up also in Dallas on another road, in which considerable damages were obtained.

Mr. Scovill, of Austin, instanced a case in St. Paul where in a collision there were 74 passengers on the car and 122 suits were brought against the company.

---

### Amusements.

BY J. K. URIE, SUPT. GALVESTON CITY RAILROAD COMPANY.

In an unguarded moment I accepted the request of your secretary to prepare a paper on the subject of amusements as a source of revenue to street railway companies.

What follows will be a reflection of my own views, gathered from personal experience, rather than an attempt to discuss the subject from the standpoint of one qualified to properly present the matter. If the reading of this paper will result in the free and frank discussion of the subject, and an interchange of views between the members of the Association, I shall feel that the short time devoted to the matter by me will have been more or less repaid.

The word amusement is a very comprehensive one, and it will be necessary for me to confine my remarks to the usual class of attractions furnished, or to a greater or less extent, supported by street railway companies.

Attractions of any character (provided, of course, they are reasonably meritorious), undoubtedly increase the gross receipts of the local street railway; they cannot be obtained without compensation, however, and as the average street railway manager or superintendent does not employ attractions for the amusement of himself or friends, the all important question to him is the difference between the cost of the attraction, including cost of extra cars, etc., and the increase in fares as the result of the attraction.

As a general proposition, I think it cannot be denied that the amusement feature is an important one in the larger sized towns and cities. The larger the city, the more important the matter becomes on account of the natural demand for relaxation on the part of the inhabitants of the more thickly populated portions of the city.

The selection of the location of a pleasure resort is the most essential feature. It should naturally be the most attractive available spot in your city, and its naturally attractive features should be added to as much as possible; it should be just a little too far from the center of population to encourage pedestrianism, and at the same time not too far to make a trip on a more or less overcrowded car an unpleasant journey. My experience is that ten people will go out to see a free show to one that will attend where admission fee is charged, even though the charge be a merely nominal one.

Band concerts and vaudeville attractions of the better class have always taken well in Galveston, and I believe in most cities of the state.

There is another class of attractions which might be termed local, such as base ball games, foot ball games, bicycle tracks, etc., which deserve encouragement on the part of the local street railroad companies. Very few of the last class became self-sustaining, and without proper encouragement they would, to a certain extent, cease to exist.

A body of water in the shape of either a lake, natural or artificial, or a running stream is one of the best possible features of any pleasure resort. People who spend eight, ten or twelve hours a day in the busy parts of a city are naturally inclined to seek something akin to nature.

Pleasure resorts are the essential features of the summer season, and the patrons of them should be provided with as many comforts and luxuries as the street railway company can reasonably be expected to provide in anticipation of a remunerative return.

The question of entertainments is one which, like almost any other feature of the street railway business, must be handled with due regard for local conditions. In the larger cities in the state, Sunday invariably proves to be the banner day of the week, and attractions on that day are demanded by a large proportion of the population who find very little time for rest and recreation on week days. In some of the small towns and cities it might be found advisable, if not compulsory, to omit Sunday attractions.

Wherever your resort will be located you will invariably find that a certain proportion of visitors to it will accept your hospitality without contributing anything in return. In other words, they walk. In case

your resort is enclosed, or can be enclosed without too much expense, I think each person entering the ground should be required to produce a street car ticket, such ticket to entitle the party to free admission to the grounds. This could be readily accomplished by having a man stationed at the main entrance to sell car tickets at five cents each. Those who come on the cars would be nothing out, being simply compelled to purchase their return tickets in advance, and the walking brigade would have to buy their tickets whether they wanted to use them or not.

The street railway manager who attempts to make a success of attractions by building a cheap theater on a bare prairie several miles from the heart of the city, is doomed to disappointment. His profit may be represented in the shape of experience, but it will appear on the wrong side of the profit and loss account.

A resort which is worth establishing and maintaining should be so attractive in itself as to draw to it without the aid of additional attractions a greater or less number of people daily. The constant dropping of the nickel helps to wear away the interest on our bonds and other indebtedness.

In discussion Mr. Hendricks said that he had success with balloon ascensions, one in particular. The same success had attended the roads represented by C. L. Wakefield and H. C. Chase in this regard.

The value of popular price theater shows was discussed, and it was found that they did not pay the street railways.

Base ball was conceded to be a good thing, but rather expensive, in that the base ball people generally demanded considerable assistance.

It was suggested by Mr. Drake that each member of the association furnish the secretary with a list of the attractions he found good, the terms on which they are secured, and the measure of his success. A motion covering this was carried.

---

### How to Obviate Public Prejudice Against Corporations.

BY GEORGE B. HENDRICKS, SUPERINTENDENT FT. WORTH STREET RAILWAY COMPANY.

I regret exceedingly that the subject which you have seen fit to allot to me is one of such vast and vital importance to every enterprise of our national and social existence, and I feel totally unable to cope with its magnitude. The thought inspired by this momentous question that is disturbing every element of our government, leads me into a labyrinth of confusion from which I fear shall never extricate myself with any degree of credit.

How can prejudice be overcome? Prejudice, like rumor, rides on slanderous tongues, filling the ears of men with false reports; prejudice is unthinking, unreasoning, intangible and insidious in its nature. How the finite mind can apprehend or grapple with the illusive monster is a problem of which the solving is doubtful.

Notwithstanding all this, there is a cure for this growing evil, at least a check that can prevent its further growth; if the public has no cause for this feeling of hatred, if it only springs from a diseased mind, it will die of pure nature, but if it is well founded by actual deeds of aggression from the corporations that persist in turning a deaf ear to the complaints of the people, then let the public apply the remedy it holds in its own hands.

In the first place the tendency of human nature is to abuse power. Corporations, with their boundless opportunities from centralized wealth, are somewhat to blame for the great prejudice that now exists in the minds of the people. The dominant feeling in the minds of the public is that corporations are nothing more or less than trusts, or combines formed for the purpose of defeating, so to speak, individual competition, and thus necessarily absorbing all of a nation's most fruitful resources, conserving them to further selfish gains. There is no prejudice against corporations, pure and simple. The public know that the corporation, individually, is of boundless benefit. A benefactor to the country, for it brings wealth and prosperity in its train, makes the desert bloom, and converts the wilderness into thriving towns and fertile farms. Trusts and corporations have, in the minds of the people, been thrown together, and trusts are inimicable to the best interests of the masses, and to good government, because they are in total disregard of the people's rights and in defiance of the law. The public sits in judgment only upon avarice and greed, and the people demand that corporations be made amenable to ordinary law, and held to a strict accountability or deeds done by them. If corporations wish to take the initiative in allaying

the bitterness that is manifested by the people, they should return to first principles and live up to the spirit of their first dealings, that is the individual should act toward his fellow men as he would have others to do unto him. Let corporations from their vantage ground of wealth and power, teach the public, by their glowing example, that liberty does not mean license, and that by the law and under the law it is intended that all men should enjoy just and equal legislation. Capital and labor are so vital to each other's very existence, and yet sometimes we might as well ask the lion and the lamb to live together in peace on the same plains.

I do not wish to convey the idea that I hold the corporations responsible for all the wrong doings, but I do believe, in the majority of instances, they have been initiative in a natural result arising from moneyed power that had grown too rapidly.

I think we too often forget that we are a part of this great public that forms our nation, that as our influence may be felt or our lives lived, so are others around us. We forget that we, also, have wrongs and injuries at times, of which we wish to talk to some sympathetic friend, and the best educator which the heads of corporations can use for the working people is kindness and patience. We should never allow an opportunity to pass us to speak a kind word, give a pleasant smile, or do a kind act to the most humble citizen of our community; be not selfish; think of those around us, who, possibly, have much less cause than we with which to be happy; and be ever so humble, a coal heaver or a track greaser, a kind word or a pleasant good morning is never lost upon him, and he learns to look upon the members of the corporation as his friends, and not as men who use him simply as a machine to do their work. If your employes realize that you are kind and considerate and patient, do you not know that your influence among them is much greater than that of a man who is seeking to get all he can from those under him, and then drop them? He should realize that through our employes the public form its opinion of the men employing them.

I have tried to treat this subject in an impersonal manner, for I certainly have no selfish aims in view, am not a demagogue, nor an applicant for political favors. It is only the honest opinion of one man who has tried, through a life of hand to hand fight with adverse fate, to look things squarely in the face and judge the world charitably. I have learned that while all men are not honest, yet they are not all desperately wicked. If the people themselves live in rigid observance of the laws there would be nothing of which to complain. They cry out against unjust legislation, and yet, year after year, they persist in sending irresponsible men to represent them, to fill responsible positions, and to make their laws, which are detrimental to the country's good. The people are responsible for the abuses they endure. That honesty is the best policy is not a meaningless platitude, but a wholesome proverb to be applied to the daily conduct of life.

### HOME MADE TRUCK.

We illustrate herewith a truck designed by Thomas Elliott, master mechanic of the Atlanta Consolidated Street Railway Company, which embodies some new features. In appearance it is plain and stiff, and the effect of stiffness is

HOME MADE TRUCK—ATLANTA, GA.

increased because of the springs being all concealed. As shown in the cut the springs are a sort of series parallel arrangement. The centre spring carries the empty car, and at the same time is in series with the other two, giving greater travel and flexibility than a single spring. The com-

pression of the center spring is limited by the yoke and can not be injured by excessive loading. This arrangement was adopted because most trucks ride easier when the springs

CAR AND TRUCK—ATLANTA, GA.

are well loaded. The spring boxes shown in the center are for extra springs to suit heavier cars. Four helical springs 5 in. long are placed over each journal box.

The journal boxes are very large, holding a gallon of oil, and are provided with ring oilers. The dust guard has a double ring and keeps the box free from dust without the use of wick or felt. The box is threaded and the lid screws in, butting against the journal brass, which fits down over the end of the axle. The axle ends are plain and not liable to be injured in the wheel press.

The pedestals are solidly braced, and the truck itself well braced diagonally. Across the center is a 12-in. 1-beam. The car body rests on the four corners of the truck.

The brake rigging is peculiar. The brakes are inside

BRAKE LEVER AND BEAMS.

hung and applied by spreading the brake beams apart by the partial revolution of a center shaft shown in the plan. The brake beams turn upon knife edges. Adjustments are made by sliding taper wedges along the faces of the beams. The brake hangers are rectangular links, four to each half of the rigging, so that it may swing free without sliding of rods.

The fenders will swing either way or in case the car leaves the track will raise up. Ordinarily, stiff springs hold the fenders in place with sufficient pressure to remove obstructions on the track, but flexible enough to give way to solid obstacles.

TRAMWAY AND OMNIBUS DIVIDENDS IN ENGLAND.

The following table from the London Economist shows the dividends of the principal tramway and omnibus companies of the United Kingdom for the last five years.

Company.	1895.	1895.	1894.	1893.	1892.
	%	%	%	%	%
Belfast .....	6½	6½	6½	7	7½
Birmingham and Aston .....	14	13	13	13	12½
Dublin United .....	5	5	5	4½	4½
Edinburgh and District .....	6½	5½	5½	5	5
Edinburgh Street .....	2½	4	6½	5	5
Glasgow .....	7½	nil	4½	5	5
Imperial .....	2½	1½	1½	1	nil
Liverpool .....	5	5	5	5	5

Provincial .....	2½	1½	1	1	1
South London .....	4	2½	1½	1	nil
Sunderland .....	4	4½	4½	4½	4½
Wolverhampton .....	5½	4	3½	3½	3½

The year has been a very good one and in most cases the reports showed an increase in gross revenues, while the low prices for forage enabled the working expenditure to be kept down. The London omnibus companies did particularly well; two reasons are given, there is no permanent way to keep up and no provisions to make against the purchase of their undertakings by the local authorities. The North Metropolitan Tramways Company was compelled to reduce its dividend for the last half-year of 1896 from 4 to 2½ per cent, although its gross earnings were \$75,000 in excess of those for the last-half-year in 1895, for this latter cause. The reduction in the case of the North Staffordshire Company was due to the cost of maintaining the permanent way and equipment.

STRIKE LEADERS EXPOSED.

Hiram Lutz and William H. Copeland, two self-constituted leaders in new organizations, which it was attempted to form among the employes of the Union Traction Company of Philadelphia were exposed by the company on March 22. Lutz is the labor agitator, who, two years ago, organized the strike among street railway employes in Philadelphia. Lutz and Copeland having made propositions to "sell out" to the company, they were invited separately to interviews with the assistant general manager. A committee of the company's conductors and motormen was placed in an adjoining room and one of them describes the interview with Lutz as follows:

"Lutz came into Mr. Shanley's room alone. We heard him tell Mr. Shanley that if the company would give him \$15 a week he would be loyal to the company and expose all the workings of the organization. These were the terms he stated in his written agreement. He said he was in a position to do the company good service, and that the thing could be worked on the dead quiet. We couldn't stand it any longer and we rushed in on him."

Copeland was more avaricious and wanted \$25 per week for a year or \$1,000 cash.

SHUNT MOTORS FOR HIGH GRADE SERVICE.

In early electric railway lays it was considered an open question by some as to the relative desirability of shunt and series wound motors for street car service. This contest, as all know, resulted in the survival and almost complete victory of the series wound motor. Nor is it likely that the shunt motor will ever come into extensive use for ordinary street railway service in connection with a 500-volt trolley system. It is being used on a street road at Barmen, Germany, but the conditions there are exceptional. There are some heavy grades on that road which the cars ascend and descend by means of a rack. By using shunt motors the cars are made to generate current which is fed back into the line when the cars are going down grade, thus accomplishing the double object of a safety brake and recovering part of the energy that would otherwise be wasted. However, not many street railways are so situated that much energy can be recovered by the use of shunt motors, and what little power would be thus saved would be more than compensated for by the objections to shunt motors. Shunt field coils for a railway motor must necessarily consist of a large number of turns of fine wire, which fact not only brings up the first cost, but makes insulation difficult. Controller combinations and connections would also be rather complicated with shunt motors, and the inductive kick when the shunt circuit is broken causes break-downs in insulation that can only be prevented by a still further complication in the way of a non-inductive resistance in parallel with the field coils.

However, on elevated roads and on those which are closely related to steam roads, the conditions are somewhat more favorable to the shunt motor, and the advantages to be gained are more marked. As indicated before, the chief advantage a shunt motor offers in railway work is the possibility of turning it into a generator which can return power to the line at times when the car speed is to be retarded, thereby saving the energy that would otherwise be expended in wearing out brake shoes. On a street car where the speed is not high it is manifest to any electrical engineer that it is not possible in making an ordinary stop to return much energy to the line. Suppose a pair of shunt motors be wound to run a car 18 miles an hour maximum speed on a level when in multiple. By connecting them in series when making a stop it would be possible to use them as dynamos to brake the car and feed back into the line until the car speed fell to something less than one-half the maximum. When this point is reached it is impossible for the motors to generate a voltage in excess of the line voltage, and consequently they will begin to act as motors again instead of generators. It is apparent from this that very little energy would in practice be recovered by using shunt motors as brakes in ordinary city street railway service. The maximum speed is high, the stops are at fairly regular intervals and there are few places that call for slow running, so that quite an amount of energy could be recovered with every stop made. The motors would also be operating under cleaner conditions and the shunt coils would not be so hard to insulate. Series motors have practically the field to themselves now, but the development of higher speed and heavier suburban service may bring back to the shunt motor some of the consideration it formerly received.

avenue line at 146th street. Recently the company has purchased a piece of land at 96th street on North river, upon which a station of 20,000 horse-power ultimate capacity will be built. Another station of the same capacity is projected in the southern part of the city, but its exact location has not yet been determined.

FIGURE 4—STANDARD RAIL.

The accompanying map indicates how extensive this new system is to be, and it is likely only a step in changing all the lines of the Metropolitan Company to electric conduit.

The heavy dark line represents the extent of the Lenox avenue line and the dotted lines the proposed extensions. As the lines stretch from one end of the island to the other they go far toward giving New York a system of rapid transit.

### CINCINNATI SUBURBAN SERVICE.

D. G. Edwards, president of the Cincinnati, Hamilton & Dayton Traction Company, which has been incorporated by several officers of the Cincinnati, Hamilton & Dayton Railway Company, to operate rapid transit lines in connection with the latter company, writes as follows:

"We have not decided to equip our suburban lines with electricity; on the contrary, we are opposed to the overhead trolley as being cumbersome, to some extent dangerous and not the highest type of service for interurban work, in its present condition.

"We do not propose to make any radical changes on our suburban lines until conditions are more settled and we know positively that such a change would be an improvement.

"With the exception of the Illinois Central Railroad in Chicago our suburban business between Cincinnati and Hamilton is probably better cared for in the matter of train service, accommodations and low rates than in any other section of the country. Our commuters have the benefit of a train service of 52 trains a day in the space of about 14 hours; the rates are as low as any interurban rates I have heard of; the accommodations, consisting of standard passenger coaches well warmed and ventilated, comfortable riding, on the highest type of railroad in the country, will not allow any electric service being compared with them.

"We are trying to find some method of handling this travel cheaper than we are doing at present if this can be done without destroying the character of the service, and, for that purpose intend to equip one or two branch lines with some motive power that will enable us to run a more frequent service during the hours of the day, when travel is very light, than we can afford to do with regular passenger trains. If the result of the experiment on our branch lines is satisfactory, the service will be extended.

"We are investigating electricity, compressed air and steam motors. So far as our investigations have gone, we do not consider that either electricity or air compares at all

favorably with steam. The question presented to us is to find out what character of service we can adopt that will enable us to run at high speed through the country and not be objectionable in traversing the streets of the town."

### THE HEILMANN LOCOMOTIVE AGAIN.

The original Heilmann locomotive was described in the REVIEW for April, 1894. As a result of the trials of the "Fusee," as she was named, the Western Railway of France ordered two electric locomotives on the same general design, and one of them has been completed. The new locomotive is more than twice as powerful as the old one, developing 1,300 h. p. It is designed to haul 300 tons at a sustained speed of 60 miles per hour. The total weight is about 265,000 lbs., equally distributed on 16 wheels. The length over all is 59 feet. The boiler is of the usual locomotive type, but with a larger fire box than is common in French practice. The two engines are vertical with three cylinders each, the cranks being 120 degrees apart, but connected to the same crank shaft. The balance is made as nearly perfect as possible. The generators are direct connected to the engines, but are excited by a dynamo driven from a smaller independent engine. It is claimed for this machine that the admitted loss of 12 per cent caused by transforming mechanical into electrical energy is more than compensated by the advantages due the uniform tractive effort secured and the absence of hammer blows on the rails. If the use of this engine proves economical electric traction certainly has a clear field in France.

### STREET RAILWAYS IN JAPAN.

The Japanese have been so occupied by the great wave of industrial progress which has rolled over the empire during the past few years that not much attention has been given to street railways. This condition will not be lasting, for many of the cities of Japan are very populous and the smaller towns are so close together that electric traction will certainly prove the best and cheapest means of transportation. The government has been educating engineers in the United States and Europe and the electrical profession has not been neglected. These young men are now returning to their native land and as a result electric lighting and other applications of electricity are making great advancement. In many places water powers are situated near the cities and some of these are being developed and electricity used as a means of transmission.

In Kioto the street railway system is electric and in the capital, Tokio, there is agitation to convert the present extensive system into trolley lines. A horse car line is in operation between the cities of Kodzu and Yumoto. Perhaps the most notable motive power is that between Atami and Odawara where the cars pass from the former to the latter place by force of gravity and are returned by "man power."

The Union Street Railway of New York, prohibits the ringing of gongs on its cars except in cases of absolute necessity.

At the suit of holders of third mortgage bonds Charles Green, president of the Peoples Railway Company, St. Louis, was appointed receiver for the company.

## METROPOLITAN OF WASHINGTON IN WINTER.

During the winter, street railway men have watched with interest the working of underground electric conduit roads. The Metropolitan of Washington has been put to severe tests. On January 27 occurred the most severe snow storm of the winter, five inches of snow falling in eight hours. When it became evident that a snow storm was at hand, the sweepers were ordered out and kept going the entire night. Not a car was stopped and no hitch of any kind occurred. The full schedule was operated, demonstrating that snow is not an impediment to the operation of this road.

The carrying capacity of the road was thoroughly tested in March, when thousands of visitors were drawn to Washington to witness the inaugural ceremonies. G. B. Coleman, general manager, in speaking of the car service this week says:

"The greatest test came on March 3, 4 and 5, when we carried about 300,000 people. On the 4th, owing to the program of that day we could only operate the cars until 11 a. m. and again after 6 p. m. From that time until midnight every car was loaded to its utmost capacity. In fact, people were hanging from all parts of it. In addition to the regular number of cars we put on everything we had and within the space of about five hours carried 96,000 people, and this without a mishap of any nature; not a circuit breaker or a fuse blew out. This we consider the greatest test the road ever had. From the inception of its operation to the present time the road has demonstrated to us that this is the greatest system on the face of the earth."

## CARS RUN AT LOW VOLTAGE.

The Oakland Railway Company, of Detroit, was temporarily embarrassed recently by the burning out of both dynamos in the power house. Very soon after the accident arrangements were made with the Detroit Citizens Street Railway Company to have power supplied over its trolley lines to the Oakland trolley. As shown in the diagram the two roads have a common terminus at Palmer Park which is the farthest point on each road from their respective power-houses. When the dynamos at the Oakland power house were disabled the trolley wires of the two lines were joined at Palmer Park. This transmission of power was under the most unfavorable circumstances, as the source of supply was at one extremity of the road, about 21 miles in length, and this was aggravated by a hill of 5 per cent grade a quarter mile long at the outer terminus. The voltage dropped as low as 250, which causes considerable heating of the motors and dim lights in the cars at night. The feeder system is roughly represented by the sketch. The Detroit company has a 1,000,000 circular mil feeder extending 21,200 ft. from its power house and the rest of the line is

fed from a conductor of 500,000 circular mils, connections to the trolley wire being made at suitable points. The Oakland line has but one feeder and that of 500,000 circular mils. Thus it may be seen how inadequate were the provisions for a long distance transmission, but still the system is so flexible that the cars could be run even at half the normal voltage. For three days the cars were operated on a one hour schedule and little difficulty was experienced in making the 12½ mile trip in one hour. When everything else is sacrificed to service it shows that there are few accidents which will confound a resourceful railway electrician and his apparatus.

## CHEAP POWER FOR THE LEAVENWORTH ELECTRIC RAILWAY.

The Leavenworth (Kan.) Electric Railway has operated 18 cars on 15 miles of track by power supplied from the company's dynamos which have been in the station of the Leavenworth Light & Heating Company. The state penitentiary is located at Lansing, a suburb of Leavenworth, and the convicts are partially occupied mining coal for the state. L. M. Erb, manager of the street railway, recognized that this might prove a source of cheap power and entered into negotiations with the directors of the Kansas penitentiary. As a result a contract for fuel has been closed which goes into effect June 1 and continues for six years. The street car company is to extend a line to Lansing and remove its four boilers, four dynamos and large engine within the penitentiary walls. This will save all expense of hauling and switching the coal and the power house labor will be attended to by the convicts.

## A CORRECTION.

Thomas C. Pole, president of the company operating the gasoline motor in Washington, hands us the following correction:

I noticed an article on page 157 of the March issue of the STREET RAILWAY REVIEW, under the head or title of "Gasoline Motor Objectionable." I wish to state that I am the president of the company operating the gasoline motor and that you are misinformed. The fact is that the car was run on that branch of Henyon street several times and no complaint was made of the running; but the Brightwood Railway Company had not any room in its car house and the car was compelled to stand at the said corner or on the street (Henyon). On account of the motor standing there the citizens there complained of its standing and therefore asked the commissioners to have it removed. I appeared before the commissioners myself and was requested to either run it or take it out of the way. The said motor ran upon the Anacostia track for about three months and no complaint was entered against it.

LINES OF THE OAKLAND AND DETROIT CITIZENS' RAILWAY.

## NEW BRIDGE OVER NIAGARA GORGE.

A new steel arch bridge is being sprung across the Niagara gorge just under the existing railway suspension bridge, which it is intended to replace, and this without the slightest interruption to traffic on the railroad or the highway which it supports. The erection of a bridge of such proportions over the gorge is, of itself, a task of no small magnitude, but to build such a structure in the place of a bridge that is in use, is an undertaking that requires engineering ability. The engineer in charge is L. L. Buck, who had the supervision of the rebuilding of the railway suspension bridge with steel in 1880, and who also took charge of the work of replacing the stone towers of the structure with towers of steel in 1886. The changes were made, as is the present one, without interfering with travel on the bridge at any time.

The illustration shows the progress made in building the arch up to date, and how it is being fitted in the place of the suspension bridge. A portion of the false work is seen at the left of the picture.

The new bridge was made necessary by the business of the Grand Trunk Railway, which required a second track.

NEW BRIDGE AT NIAGARA.

It compares favorably with any bridges of its class. It will have a span of about 550 ft. between the end piers, and a trussed span will connect it with the cliff on each side of the river. The main span is formed by an arch with horizontal upper chords. At the skewbacks it will be hinged. Each truss has a batter of 1 horizontal to 10 vertical. The width between the axes of the top chord is 30 ft., while between the axes of the rib at the crown the width will be 56 ft. 7 $\frac{3}{4}$  in. Above the centers of the skewbacks the axes of the upper chords will be 134 ft., and the axes of the ribs at the crown 114 ft. above the skewbacks. On the American side the bed plates of the arch rest on abutments built on Clinton limestone half way between the water's edge and the top of the high bank. On the Canadian side the abutments rest on a concrete foundation built about half way up the slope.

This new arch will have two decks. On the upper one will be laid the railroad tracks, while the lower will have ample room for a carriage way, sidewalks and trolley tracks. It is probable that the first trolley car to pass from the United States into the Dominion of Canada on its own

wheels will cross this bridge, for one incentive to the construction of the arch is to afford trolley connection between the two sides of the river in what will probably be a belt line service around a portion of the gorge.

The Pennsylvania Steel Company has the contract for building the arch, and has made rapid headway considering the season of the year, and the dangerous point of work. It is expected that the arch will be sprung early in April, but the bridge will not be completed until the latter part of June or the first of July.

The total weight of steel work is estimated at 3,000 tons. The bridge is expected to carry on each track two 160,000-lb. locomotives with train of 3,500 lbs. per ft., and on the lower deck a live load of 3,000 lbs., making in all a live load of 10,000 lbs. per foot.

The suspension bridge will be carefully taken down and rebuilt at another point on the gorge, perhaps Lewiston. It will be used until the new bridge affords crossing facilities. At present the suspension bridge rests on the lower floor beams of the new arch, and the upper floor beams will be left out until the suspended structure of the present bridge is raised clear of the new one.

## WATER IN VESTIBULE WALLS.

A weak point in vestibules, or one that will some day be a weak point if neglected, is the leakage of water down behind the wainscoting when the front window is lowered. This point is one which has not received attention but will force attention on itself as vestibules on electric cars get older. Probably the majority of vestibules in use today have a solid wainscoting, between which and the outer panel the windows are lowered. This arrangement would be all right if the windows were lowered only in fine weather but unfortunately they almost invariably have to be lowered when there is a storm. In such case the motorman does not usually let the window entirely down but only opens it enough so he can see out over the top. The rain or snow strikes what glass is exposed and follows it down between the outer and inner vestibule walls. When once in there, unless some special provision is made, the only way for water to get out is to slowly leak out and consequently the platform where the vestibule walls come down is kept constantly wet and in time will rot. The effect of this continued dampness on the controller wiring is also bad. The remedy is of course to make an outlet somewhere for the water that gets in the vestibule wall. The presence of water in that place will not usually be noticed except by accident even by employes that are handling cars daily hence it is so commonly neglected.

## ELECTRIC TRACTION FOR RHEIMS.

Rheims is a city of over 100,000 inhabitants and has about 10 miles of horse car lines. The Campagnie des Tramways de Rheims is very desirous of introducing electric traction, and has made propositions to that effect to the city council. There is considerable opposition to the trolley, and the council has not yet given its consent. Several other systems of mechanical traction have been proposed, but the general manager states that the company will stick to electricity. It is proposed to put 40 cars in operation and install 1,200 h. p. of engines, boilers and dynamos.

## COMBINED POWER PLANT FOR ELECTRIC LIGHTING AND STREET RAILWAY SERVICE.

This has not been a potent question in American practice as different companies usually control the electric lighting and the electric railways. In England and many places on the Continent this subject has been freely discussed and the circumstances there warrant its consideration. Electric light stations have long been established, either by private companies or by the city corporations. The question of electric traction is just presenting itself and the engineers are careful figuring on the cheapest as well as the best plans for its inauguration. They have large and well equipped power plants, to furnish electric light, with day loads which are almost negligible. Recognizing that the heavy service for street railway purposes are at times when the light load is a minimum they are trying to devise alterations in the machinery which will make it suitable for both systems.

In London Lightning John H. Rider and Wilfred L. Spence discuss this subject at some length. As far as possible the same machinery must be used, so a summary is made of the current installation. The systems can be classified under three headings, viz.:—1. Continuous current stations, generating at between 400 and 550 volts. 2. Con-

tinuous currents under 400 and over 550 volts. 3. Alternating currents of any pressure but generally 2,000 volts. In the first case either the 3 or 5 wire systems are in use for lighting. The voltage is such that the machines can be used directly for street railway service, but the objection to this is that one side of the lighting system would be permanently connected to earth by the rail return. The railway service must not be supplied direct from a machine which is feeding the lighting system, but it may be supplied indirectly through the medium of a motor-generator, used simply for the purpose of keeping the traction and lighting mains separate. If permission could be obtained either from the municipal authorities or from the underwriters for an earth connection, the best plan would be to ground the middle conductor, as is the case in Manchester.

For the second class of stations, voltages under 400 or over 550 are unsuited for street railway work. Machines of 220 and 250 volts might be connected in series, as is done at Gera, but the switch board complications make this plan undesirable. The alternative is to use motor-generators in conjunction with accumulators and the current may be taken from the station bus bars if desired.

The alternating current station offers the most flexible solution. The voltage is usually high, as much as 2,000 volts and must be transformed down and be converted to a continuous current of 500 volts, as no suitable alternate cur-

rent motors are designed for street railway service. There are two ways in which this change may be accomplished: (1) by means of static transformers in conjunction with rotatory converters, and (2) by means of alternate current motor-generators.

In the first method, the arrangement of connections may be as shown in the diagram where the voltage is transformed from 2,000 volts down to 390. The rotary converter gives a continuous current of 550 volts. The speed at which the machine runs will depend on the frequency of the alternating current and the number of magnet poles. It will run in synchronism with the generator, and must be brought to speed before switching in. The ratio between the mean alternating pressure at one side and the continuous pressure at the other will be  $1 : \sqrt{2}$ , and the current value just the reverse. This ratio is not absolutely constant for a considerable range of voltage on the direct current side is caused by varying the field strength so as to control the phase relation. With a weak field the alternating current will lag and the direct electric motive force will diminish, while an over-excited field will cause a leading current and an increase in the voltage. Phase displacement may be objectionable in a steam-driven plant, on account of the reduced plant efficiency or power factor it entails. A good plan would be to partially separate the two windings on the armature, so that an independent field control may be obtained over one of them, and in this way very considerable variations in the ratio can be effected without any corresponding loss in the plant efficiency. The same machine can then feed the trolley wire direct or, with the same primary e. m. f., charge storage batteries at 30 per cent greater voltage.

One great advantage of a rotary-converter is that it need only be large enough for the maximum alternating current and for the highest continuous current voltage, thus saving the double wound armature and double machine of the motor-generator type. It is stated that the larger machines are liable to spark at the continuous current commutator, owing to the armature current, and the consequent field distortion, varying as the armature is acting first as a motor, then as a dynamo. In spite of the opinions of some of the learned European electricians, large machines of this type are in successful operation, as at Niagara and Salt Lake City. Also at Geneva 100-k. w., 220-volt machines are giving perfect satisfaction with an entire absence of sparking. Should these methods be applied, the all day efficiency of a plant will be greatly increased, much to the benefit of its earning capacity. There are many places where these plans are feasible and careful thought can be given to them with much profit. Such considerations have been taken into account in designing the great water power plants at Niagara, Sacramento, Portland and elsewhere.

### A NEW BENEFIT ASSOCIATION.

The employes of the Middletown and the Portland street railways have formed a benefit association, adopted a constitution and elected the following officers: Superintendent, E. A. Goss, president, and Charles H. Chapman, secretary and treasurer. The by-laws of the association are really a part of the rules of the street railway companies as all employes are required to belong to it and pay 25 cents a week dues. After being in the employ of the companies one month, a man is entitled to draw a daily sick benefit of 50 cents.

## COMPARISON OF STREET RAILWAY CONDITIONS AND METHODS IN EUROPE AND IN THE UNITED STATES.

BY P. F. SULLIVAN.

Statements have been seen and heard from time to time of the marvelous results obtained by street railways in Europe, of the low rates of fare which prevail there, and of the very favorable conditions, for the municipalities, upon which franchises were granted. I never doubted the statements. Some of them appeared strange, to say the least, in the light of experience; yet the only conclusion I arrived at was that if the conditions and accommodations are the same in Europe as in America with respect to street railway transportation, then we have much to learn from that side of the water.

Without intending to reflect upon the enterprise and ability of the people of Europe, I must state that my experience taught me that the men engaged in street railway transportation in this country were an industrious, energetic, enterprising set of men. I knew that no men engaged in any enterprise on this or on the other side of the water devoted so many hours of thought and labor to their duties, and notwithstanding that no enterprise on earth showed such marvelous progress in the last ten years as street railway improvements in this country, I knew of no investment that has up to the present time given so little return. I had also met several street railway gentlemen from Europe who had come to this country to study street railway methods here, and they appeared about as fallible as others; and they invariably left loud in their praises of the wonderful results achieved in American street railways. It seemed, then, that the only way in which one could learn what to American street railway people was a secret was to go to Europe, and look into the methods. With that purpose in view, I visited several cities in the United Kingdom, in France, and in Germany; but inasmuch as the principles and methods are practically the same in all the large European cities with the exception of Paris, I will select only two typical cities—Glasgow and Berlin—the former owning and operating its own street railway, the latter granting a franchise to one or more stock companies for a period of years. I stated that Paris is an exception with reference to principles and methods; therefore a word relative to that city may not be out of place here.

I shall use the same terms as are used in the United States, and the value of foreign money will be stated in United States values.

Paris.

The street cars and omnibus lines of Paris are operated by a stock company as they are in this country, the franchise being granted for a limited term of years. The rate of street car fare is usually a fixed sum, 6 cents for first-class and 3 cents for second-class fares; the second-class passengers are compelled to ride on the roof seats regardless of the weather. First-class passengers are entitled to "correspondence" or transfers. Second-class passengers can obtain transfers by paying 1 cent in addition to the previous 3 cents. All transfers can be used only at regular stations, in the same manner as if the holders of transfers had not previously ridden on a car. The carrying capacity of all cars is limited to the seating capacity and four additional who may stand on the rear platform. Passengers are compelled to take cars at regular stations or stopping places, situated apart in distances varying from one-quarter to one-half mile. A person who intends to take a car goes into the station and signifies his intention, whereupon the attendant gives him a check numbered. When the car arrives the conductor announces the number of vacant seats, and a number of persons holding the lowest numbers given by the attendant and equal to the number of vacant seats is allowed on the car. Payment is made after boarding the car. Persons have frequently to wait from ten to twenty minutes before they can get a vacancy. It strikes me that this is a European "improvement" that would not work very satisfactorily in this country.

Glasgow.

Glasgow has the second largest population in the United Kingdom, there being practically 840,000 persons in the territory of

14,661 acres through which its horse car system runs. It is one of the best governed cities in the world, and in respect to the management of its various departments suggests a good subject for all reformers who can see no chance for improvement in anything but street car franchises.

## STREET CARS.

The street cars of Glasgow are practically the same style as those of all other cities of Europe, viz., double-deck close cars, usually fourteen-foot car body and seating eighteen persons inside and twenty-two persons on the outside or roof seats. There are no open cars. Passengers are not allowed to stand in the cars, so that in wet or other stormy or cold weather they are compelled to ride on the roof seats. A car, therefore, will seat nearly twice as many as an ordinary size close car in the United States. This, coupled with the fact that there are no open cars, means that in this country it would require four times as many cars to accommodate the same number of persons as would be accommodated in Glasgow.

## RATES OF FARE AND COLLECTIONS.

The principles and methods of street car fares in Glasgow are the same in general as those employed throughout Europe with the exception of Paris; viz., a distance rate upon the same principles as railroad fares are made in this country. The rate in the United Kingdom is limited by an Act of Parliament to a maximum of 2 cents a mile. In subdividing routes, however, the companies do not adhere strictly to the mile basis; the limit may exceed it, but one will find that to go two miles, or upward to about five, will cost from 4 to 6 cents. In all cities in the United Kingdom other than Glasgow 2 cents is the minimum fare. In the latter city, however, a subdivision of this fare is made so that the minimum is 1 cent for approximately one-half mile. The fares are 1, 2, 3, 4, 5 and 6 cents. It is not possible to get such long rides in Glasgow as are obtained regularly in any city in this State, and the longest ride in that city costs 6 cents, whereas a ride of a similar distance would cost only 5 cents in any city of the United States.

Conductors are provided with distinct colored tickets consecutively numbered and usually representing one or more distinct rates of fare on each route. A passenger signifies to the conductor what his destination is, and, after paying a proper amount, receives a ticket or receipt which shows the amount paid and the limit of ride. When approaching a fare limit or station each car is usually boarded by an inspector who examines each ticket, and if he should find a passenger without a ticket or with one beyond the fare limit the passenger must pay again or get off. It does not matter if the passenger in ignorance threw his ticket upon the floor with many others which he may see there; the inspector performs his duty, and properly, too. This method of fare collection and regulation is an absolute protection to the company, and is regulated by a by-law. Under the general street railway law of 1870 each railway company is authorized and empowered to adopt by-laws for its own protection, and these by-laws have the same force as an Act of Parliament. Under the by-laws in question each passenger is compelled to receive and exhibit the ticket or receipt given by the conductor, under a penalty of about ten dollars. It would be interesting if such a by-law should be adopted in any part of this state, and if it were, to see whether it could be legally enforced.

## STREET RAILWAY SYSTEM.

The street railway system of Glasgow consists of seventy-three miles of well constructed track in thirty-seven miles of streets and operated for the fiscal year ending May 31, 1896, by an average of two hundred and seventy-seven horse cars. The tracks were constructed and were always owned by the municipality. The original line was built in 1871—when the city had a population of 478,000, and operation began in August, 1872; and from that time until May 31, 1864, the road was leased to and operated by a stock company. Upon failure to agree to terms for a renewal or extension of the lease the municipality assumed control, and began operations July 1,

1894. The basis upon which the original lease was made was practically the same as that upon which the municipality does business with the street railway department now, viz., annual payment or sinking fund of sufficient amount to liquidate the capital invested; payment of the interest upon the capital invested; and annual payment to meet the expense of renewals and a rate of \$750 per mile of track. After the original investment the municipal authorities found that "public convenience and necessity" required that extensions should be made, but the lessee could not see its way clearly to do so under the original contract. Accordingly amended contracts were made by which the municipality invested \$717,475.00, for which no provision was made with respect to sinking fund for liquidation. The mileage payments made by the lessee were a varying and increasing amount, depending upon the amount of operation, and was therefore greatest in 1894. The amounts paid to the "Common Good" or general municipal treasury for three years were as follows:

By the lessee for 1894.....	\$28,300 00
By the Street Railway Dept. for 1895..	41,300 00
By the Street Railway Dept. for 1896...	45,000 00

In other words the municipal treasury received \$16,700 more in 1896 from its own operation than it received in 1894 from the lessees, but there was this difference that in 1894 the municipality had only \$717,475.00 invested; in 1896 \$2,582,780.00 with the added responsibility. It must be added, however, that the street railway department paid the interest on the loan at a rate less than 2%.

The department is well managed by John Young, Esq., and an able corp of assistants, and the method of accounts is conducted upon the most substantial basis. The equipment and appointments are good, and its operations are "up-to-date" and the service is excellent so far as it goes, but it does not go far enough, a fact which its present management appreciates, and it gives only about one-fourth the accommodations for the same population as are given in American cities. To this I will refer later at length.

The street railway results in Glasgow are frequently referred to in this country in language which makes practical men wonder, but which in Glasgow is attributed to American humor. For instance, it has been said that municipal control reduced the rates of fare one-half, and that sufficient profit was made to remove the necessity of further taxation, and that the sinking fund from the operation of the street railway would in a few years liquidate the entire municipal indebtedness. The facts do not seem to bear out the assertions, and the assertions are ridiculed by those who manage the Glasgow street railway.

The facts are that under the new management a rearrangement of routes was made, and such change made necessary new station limits, and in addition the fare of 2 cents was reduced to a minimum fare of 1 cent. This change did not mean that one could ride as far for 1 cent as he could previously for 2 cents. It simply made shorter fare limits. With reference to profits and taxation. The city of Glasgow has an average of 10,000 employes, to whom, together with other expenses, it disburses annually \$10,000,000, or six times as much as the gross receipts from the street railways; and the net returns to the municipal treasury from the street railways are only \$45,000.00. When it is remembered that the debt for water, gas and electric lighting, markets, and street railways is \$39,852,175, which expires on an average in 1934, it does seem as if the municipal millennium is a few years off even in Glasgow.

#### Berlin.

Berlin may be cited as a representative continental city with respect to surface transportation. It has a population of 1,800,000 in an area of 17,500 acres. Its street system is practically owned or operated or both by one company, and its franchise from the municipality is granted for a term of years. The present franchise expires in 1911. At the present time negotiations are pending between the municipality and the operating company. The former desires extensions and a modern system of motive power. The latter has decided to make no changes unless an extension of the franchise is granted. This was the experience of Glasgow. The municipality sees the necessity for extensions and accommodations, and the operating company cannot afford to make the changes under the old contract.

This company operates one hundred and eighty miles of tracks in ninety-five miles of streets, and owns all of the tracks which have

been built and extended from time to time since 1865. All of the above tracks are not built and operated under the same general franchise. In general it may be stated that the company pays rates from 4 to 8 per cent. on its gross receipts. Notwithstanding these payments, the company paid and has paid 12 per cent. dividends on its capital stock. This will not surprise any street railway man when he considers that there are only one hundred and eighty miles of track for 1,800,000 people.

#### CARS AND FARES.

Cars are pretty much the same as those in the United Kingdom, and the company operates on an average one thousand and fifty. It has one thousand and eighty-seven cars, three hundred and forty-eight one-horse and seven hundred and thirty-nine two horse cars. The two-horse cars are usually about sixteen-foot body and most of them have double deck seats. Fares are graded and collected in the same manner as those in the United Kingdom. In Berlin, however, the minimum fare is 2½ cents. The fares are 2½ cents, 3¼ and 5 cents. On one route within the city limits two 5-cent fares are necessary. These rates are higher than those of any city in the United Kingdom.

#### Comparison Between American and European Methods.

From the above, therefore, I will endeavor to show:

First, that the rates of fare in Europe are actually higher and not lower than the rates of fare in the United States, and when the earning capacity of the people is considered, that they are relatively higher still.

Secondly, that the principle of charging a distance rate works injuriously against the laboring and artisan classes, the very classes that street cars are chiefly intended for; that it has resulted in such crowding, such density of population as to cause the municipalities the greatest concern; upon which they spend as much, if not more, to regulate than is received from street railway franchises; and that such a condition, with respect to density of population, is not known in the United States because of superior street railway facilities.

Thirdly, that under the conditions which obtain in Europe with respect to high rates of fare, low rates of wages and prices, density of population, low mileage and therefore low capital invested, and owing to the protection which capital receives, street railway investments are more desirable and are better than street railway investments in the United States.

#### RATES OF FARE.

The prevailing general opinion in the United States is that street car fares in Europe are 2 cents regardless of distance, and that because of this fact, together with the fact that some of the companies in the larger cities make money, the 5-cent fare generally prevailing in this country should be reduced. I have shown above what the rates are and such rates prove that it costs more than 2 cents for a general ride. In November I paid 6 cents for a ride in Glasgow, and in December 10 cents for a ride in Berlin, a longer ride than either of which I could regularly obtain for 5 cents in any city of Massachusetts; and in neither city, in fact in no city in Europe, with the exception of Paris, are transfers issued.

When we look at a car of the West End Street Railway Company and see all seats occupied and a few persons standing, we are led to think that such a condition of things represents a large income. We do not stop to consider how long some of the passengers rode in that particular car, nor do we further consider that in the morning most cars are comparatively empty going in one direction and in the evening comparatively empty going in the other direction; and that there are many trips the receipts of which do not pay the actual wages of the conductor and motorman. What is true of the West End Company is true of every other company in the State. The West End Company averaged for the fiscal year ending Sept. 30, 1896, to carry fewer than seven persons per car mile. How, then, can we account for thirty or forty persons that we see so frequently upon one of that company's cars? It means that if you divide thirty or forty by seven, they averaged to ride four and two-sevenths or five and five-sevenths miles, and when we know that many ride a longer distance than that for 5 cents we can account for some who ride shorter distances. If those passengers paid 5 cents for limited distances of about one mile or so, the West End Company would then average to carry instead of seven persons per mile at least

thirty persons per mile. You will then account for the fact that Glasgow cars averaged to carry over eleven persons per mile in its last fiscal year as against seven by the West End cars. From investigations and comparisons made in the last two or three years I find that the rate of fare in this State averages between 1 and 1 1/4 cents a mile.

The above 5-cent rate of fare is paid principally by laborers and mechanics who average between \$1.50 and \$2.50 a day, as against a rate of wages for the same classes averaging between 75 cents and \$1.25 a day in Europe; and assuming that the American pays twice the average rate, or 2 1/2 cents a mile, he pays from one-sixtieth to one-hundredth part of his wages, while the European pays from one thirty-seventh to one sixty-second part of his wages. In other words, a European gives twice as much labor as an American for a car ride. And when it is remembered that every American city and town which changed from animal to mechanical traction extended its lines and in many instances nearly doubled the length of ride without increasing the rate of fare, the additional advantage is apparent.

This point is so well covered editorially by the Street Railway Journal in its issue of July, 1896, that I have taken the liberty to quote it in full, adding Glasgow and Berlin as follows:

### CHEAPNESS OF MUNICIPAL TRANSPORTATION IN AMERICA.

"In view of the occasional agitation of the question of reducing fares on our street railway systems we have sought information as to the longest rides given for a 5-cent fare in American cities above 50,000 inhabitants, and as to the regulation of transfers within those cities. The results of our inquiries are found in some detail on another page, while here we wish to call attention to a little table containing some figures upon the street railway systems of cities above 100,000 inhabitants, which are significant and interesting to an unusual degree.

CITY.	Approximate Population, 1890.	Track Mileage.	Longest ride for 5 cent cash fare, miles.	Transpor-tation rate per mile.
New York, N. Y. . . . .	1,851,060	458	12.5	.0040
Chicago, Ill. . . . .	1,100,000	760	15	.0033
Philadelphia, Pa. . . . .	1,047,000	462	11.75	.0043
Brooklyn, N. Y. . . . .	839,000	393	18	.0028
Boston, Mass. . . . .	678,000	275	9.9	.0051
St. Louis Mo. . . . .	452,000	335	15	.0033
Jersey City-Newark, N. J. . . . .	388,000	175	8.25	.0060
San Francisco, Cal. . . . .	299,000	269	12	.0041
Minneapolis-St. Paul, Minn. . . . .	298,000	222	12.94	.0039
Cincinnati, O. . . . .	297,000	263	13.44	.0037
Cleveland, O. . . . .	261,000	269	10	.0050
Buffalo, N. Y. . . . .	256,000	143	13.75	.0036
Lynn, Mass. . . . .	250,000	153	6	.0083
New Orleans, La. . . . .	242,000	169	7	.0071
Washington, D. C. . . . .	230,000	138	9.5	.0053
Detroit, Mich. . . . .	206,000	202	10	.0050
Milwaukee, Wis. . . . .	204,000	159	9	.0056
Kansas City, Mo. . . . .	171,000	142	11.2	.0045
Louisville, Ky. . . . .	161,000	150	9	.0056
Rochester, N. Y. . . . .	124,000	93	9	.0056
Denver, Col. . . . .	107,000	212	11.5	.0043
Indianapolis, Ind. . . . .	105,000	107	11	.0046
Glasgow, fare 6 c. . . . .	840,000	73	5.37	.0117
Berlin, fare 10 c. . . . .	1,800,000	180	7	.0143

"In the first place, the size of the systems as shown in the third column commands attention. The city of Chicago, for example, contains as much track as would reach from New York to Cincinnati, while the length of line would reach from New York to Rochester—a very respectable size for even a steam railroad system. Large mileage in street railway system necessarily means a widely ramified network of lines, and indicates a far greater convenience to the public than would be the case with a smaller system in the same city. It also means, or may easily mean in many cases, that the street railway corporations of a city, taken as a whole, may be operating more mileage than would really yield them the greatest percentage of profit upon the investment. Corporations are not always philanthropic, but they are, when prosperous, almost always more generous and more far sighted in their treatment of the public and in their plans for the future than is the case when they are ground down to

the lowest possible margin of profit or compelled to fear too much the effect of possible contingencies.

"In the fourth column will be found the longest rides which can be taken for a 5-cent fare on the different city systems by a passenger desiring to get from one point to another by the shortest possible route. On several of these systems the transfers are so arranged that a passenger can ride indefinitely, if he so desires, but the longest legitimate rides, so to speak, are those given in the table. The figures in column five will, we imagine, strike our foreign friends with amazement as showing how wonderfully cheap is municipal transportation in America. A penny (2 cents) for the first mile, and a half a penny per mile thereafter is the usual English charge for horse car transportation on the generally short routes of their principal cities. Here in our larger cities a passenger may ride at one-quarter penny per mile or less, and ride at much greater speed and in comparative luxury and ease. It is not too much to say that American street railways afford the cheapest transportation in the world—and yet it is sought in some cities to bring down rates even lower.

"We have recently commented at some length upon the tremendous advantages which have accrued to the American public from the policy of liberal street railway franchises which has usually been adopted by our municipalities, in comparison with the restrictive policy common abroad, and nothing further need be said upon this point here except that a reversal of this American policy would be in the highest degree unwise, and its effects would never be tolerated by the American public. Foreign cities are beautiful and most attractive as places of residence and enjoyment for the rich, but the living conditions for the poor—alas, the poor must live as they may.

"The longest ride possible in our cities of 50,000 inhabitants and above varies from about eight miles in the smaller cities to from twelve to eighteen miles in the larger, this variation being, of course, due to local conditions. In all but a few cases these longest rides can be had at a single 5-cent fare, there being but three or four cities in which double fares or special higher rate transfer checks are issued. In fact, we have been much surprised to see how universal is now the custom of issuing free transfers to all parts of the company's system. Only nine cities out of thirty-eight from whom we have heard refuse this, and in several of these latter there are genuine reasons for such refusal. For example, a passenger can ride in any part of St. Paul or in any part of Minneapolis for a 5-cent fare. The same company, however, controls a line from St. Paul to Minneapolis, and for a 10-cent fare will carry a passenger from any point in St. Paul to any point in Minneapolis, so that he may ride for twenty-four miles for 10 cents. Before the advent of electricity the steam railroad running between St. Paul and Minneapolis carried passengers between its own stations in the said cities for 30 cents each way, and ran trains not oftener than once in thirty minutes, instead of once in seven minutes as by the electric lines at present.

"In Philadelphia the consolidation of three great systems has made it exceedingly difficult to arrange transfers properly without a strong probability of their abuse, and while free transfers are given upon many lines, an 8-cent fare is charged on some of the longest routes—from fifteen to eighteen miles. In Boston the conditions are somewhat the same, the West End Company having a number of long lines extending far into the suburbs, but even there reductions are constantly being made in the direction of a general 5-cent basis.

"Altogether it does not seem just or reasonable to demand further concessions from the street railway companies in most of our cities. The public is being served by them as no other public in the world is served, and is getting more for its money than would ever have been thought possible until the advent of electricity. Enormous investments have been made, and are still being made, with a view to better service of the public. Dividends are being withheld from the stockholders in a large number of cases, and turned back into the property. A few men have undoubtedly made larger profits from the manipulation of franchises and in the building up of the street railway systems, but the great body of security holders is surely not receiving unusual or extortionate profits."

And again, bearing upon this point, we have the following from Mr. Alex. McCallum, of Glasgow, in the Herald, of that city:

"Recently I received a commission from the Glasgow Herald, which occupies a foremost place among the great daily provincial newspapers in Britain, to pay a visit to the United States and make a series of inquiries on the spot as to the position now reached in the application of mechanical power to the propulsion of street cars.

In Glasgow, as some readers may be aware, the street railways are not only owned, but are operated, by the municipality for the benefit of the citizens and consequently the general interest in methods of traction is much more keen than can be expected in cases where the lines are worked by companies. It is nearly two and a half years since the lease under which the old tramway company operated expired, and since then the Town Council has had the whole business entirely in its own hands. It has been fairly successful so far, and has given a much improved service, but both it and the Glasgow public are very desirous to have some better method of traction than the present horse system which on all hands is found to be insufficient. Delegations from the council have in recent years made many excursions for the purposes of inquiry, the last of which was to the United States, and at present it seems as if their long investigations and deliberations would soon reach a point and result in action. These things being so, I was asked to get whatever information was available in America, particularly in regard to electric traction, and as its mechanical success is already thoroughly established attention was largely turned to its financial aspect.

"Evidently one of the greatest, if not the greatest, benefits that electric traction has conferred on the public is the removal of the working classes from crowded areas to healthy suburban homes. Thus electric traction is one of the greatest social and sanitary reformers that America possesses. Without the system of uniform fares, however, the thing would be impossible. Of this admirable system it seems scarcely possible to speak too highly from a reformer's point of view. No doubt it is a hardship that a man cannot ride a hundred yards without having to pay 5 cents, but the compensating advantages are immeasurable by comparison. In Great Britain, where almost as much has to be thought of a penny by the poorer classes as in America they think of a nickel, I am afraid we are very far from the uniform five, no matter what sort of traction we adopt. The tendency in fact is quite the other way, as witness the adoption of half-penny (or 1 cent) fares for a half-mile ride in Glasgow and London. A uniform fare of a penny would probably mean ruin to many British tramway companies. Three half-pence might suit at a pinch in some cases, but it is a very awkward sum, necessitating the payment of two coins of different values, the penny and the half-penny, or else three separate half-pennies, so that there would be endless waste of time, and continual worry for the conductors in finding small change. Two pence might suit, but in relation to wages and prices it is rather a higher figure than the American 5-cent fare, and would probably lead to a ruinous diminution in the amount of short distance riding.

"While it is the case that in Britain we shall not be allowed to drive electric cars at as high a speed as is common in the United States, I think this will to a great extent be counterbalanced by the lower rate of wages paid to employes as compared with the scale in America."

#### Density of Population.

##### GLASGOW.

In "Municipal Government in Great Britain" we find the following statistics relative to Glasgow:

"The density of London according to the census of 1881 was 51 to the acre, while that of Glasgow was 84, which was increased to 92 by the census of 1891, the annexed suburbs not being included. The average density of sixteen of the twenty-four sanitary districts, moreover, is above 200, and the average density of five districts is 300. Localities are not few where single acres contain a thousand or more people. The tenement house is almost universal. The best as well as the worst of the laboring class, and a large majority of the middle class live in the 'flats' of stone buildings three or four stories high. In some cases two or three hundred people use a common staircase and much greater numbers may be found using common passage-ways, or 'closets,' as they are called in Scotland. For no other English speaking city, so far as I am aware, are the statistics for house room and inhabitancy so complete as for Glasgow. To quote Dr. Russell, the distinguished medical officer for the city, '25 (24.7) per cent. (of the inhabitants of Glasgow) live in houses of one apartment; 45 (44.7) per cent. in houses of two apartments; 16 per cent. in houses of three apartments; 6 per cent. (6.1) in houses of four apartments; and only 8 per cent. in houses of five apartments or upward.' This simply means that 126,000 of the people of Glasgow lived in single-room housekeeping quarters in tenement

buildings and 228,000 in two room quarters, at the time of the census of 1881. In Scotland the word 'tenement' is usually applied to the entire building, and the word 'house' to the one or more rooms arranged for the occupancy of a family; thus the ordinary 'tenement' contains many houses. The census of 1891 shows a cheering improvement. Dr. Russell informs us that whereas in 1871 the Glasgow people living in houses of one room amounted to 30.4 per cent. of the whole proportion had fallen to 24.7 per cent. in 1881 and to 18 per cent. in 1891. The proportion of the two room dwellers, on the other hand, had greatly increased. Thus in 1891 there were only 100,000 people living in one room houses, while nearly 264,000 were in two room houses, this class of dwellers constituting 47.5 per cent. of all the people within the city limits at the time of the census. A population thus housed might well give employment to an army of sanitary inspectors. 'Small as these abodes are, great numbers of them take lodgers in addition to the regular family,' Dr. Russell, the medical officer remarked. 'Nor must I permit you, in noting down the tame average of fully three inmates in each of these one apartment houses, to remain ignorant of the fact that there are thousands of these houses which contain five, six, and seven inmates, and hundreds which are inhabited by from eight, even to thirteen.'

The effect of such living upon the public health is considered of such importance that the apartments are "ticketed" to show how many persons may lawfully live in each, and fines are imposed for violations.

It may be noted here that the percentage of one-room dwellers decreased in the periods between 1871 and 1881, and between 1881 and 1891. It may be interesting to note in that connection that Glasgow had no street railway accommodations in 1871, when its population was 478,000; that from 1871 to 1881 it built and operated forty miles of tracks and between 1881 and 1891 seventeen miles additional. It is, therefore, a fair inference that transportation facilities had something to do with the above healthful change.

The effect of street railway accommodations upon density of population may be further shown by the impartial testimony of Messrs. Young and Clark, present general manager and engineer respectively of the Glasgow street railways. In September and October, 1896, they visited the United States and Canada as a committee from the government of Glasgow to investigate American street railways. They visited as follows: New York, Brooklyn, Jersey City, Staten Island, Philadelphia, Baltimore, Washington, Pittsburg, Cincinnati, Chicago, Detroit, Cleveland, Buffalo, Niagara, Toronto, Montreal, and Boston. In a very able report presented by these gentlemen December 9, 1896, they spoke as follows (page 30):

"We never were prouder of Glasgow than when we heard of the high place assigned to her as a municipality by the Americans. But we have not served twenty years in the Health Department, and been acquainted with 'life in one room,' without knowing Glasgow's blemishes—and they are common to all of our older cities. One great city improvement scheme has been carried out in our city, and another is now being favorably considered. In Glasgow as it was five years ago there was a population of 565,714 on an area of 6,111 acres, giving ninety-two persons to the acre, or 58,880 to the square mile. In the present Greater Glasgow, apart from the adjoining but still separate burghs, we have a population of 705,000 on an area of 12,311 acres, giving 57 persons to the acre, or 36,480 to the square mile. When the four separate burghs now served by our tramway system are included, we have a population of 841,000 persons on an area of 14,661 acres, which also gives fifty-seven to the acre, or 36,480 to the square mile. No American city, with the exception of New York, is half so densely populated. No one wishes our citizens to continue so closely packed together as they now are. How are they to spread out? In our humble opinion and judging from what we have been privileged to see in America, the most powerful instrument which lies to the hands of the municipality for effecting this purpose is the best and cheapest possible tramway service radiating from the center of the city outward in every direction.

"Such a system must be safe, rapid as far as consistent with safety, elastic as to speed, clean, comfortable, and attractive, flexible enough to apply to all routes and meet all contingencies of street traffic, and, of course, as cheap as possible, and it would be all the better if each route had its suburban attractions in the shape of a park for music, and the usual facilities for amusement and recreation generally. As surely as you give cheap and rapid transit, which will enable all sorts and conditions of people living at a distance to travel com-

fortably to and from their work in the city, so surely will houses to accommodate them be built on cheaper ground—meaning cheaper rents—and with healthier surroundings.”

BERLIN.

In volumes 17 and 20 of Berlin statistics of 1893, by Herr R. Bodkh, Chief Statistician of the city of Berlin, we find statistics which are very ably described in "Municipal Government in Continental Europe," as follows:

"All thorough students of the problem of life in modern cities are now agreed that the housing of the people is the question that requires, from this time forth, the deepest consideration and the boldest and most serious treatment. It is a subject that has many phases. It was the unapproached excellence of their statistical work that enabled the Germans to grasp the social importance and pressing nature of this problem. Circumstances that I have recounted were and are causing their cities to grow very rapidly. The temptation was strong upon property owners to make their tenement hives hold the largest possible swarms. Rear-buildings were hastily run up to fill court-room spaces that ought to have been spared for necessary air and light. The German cities were beginning to repeat in aggravated form the mistakes of the great British industrial towns a half century or more ago, which left the housing question unregulated by the authorities, with the consequence of frightful overcrowding and horrible slums in which some form or other of epidemic was prevailing almost constantly, in which infant mortality was shockingly great, and in which vice and crime were nurtured as in an irresistibly favorable soil and environment.

"In 1885 it was found that 73,000 persons in Berlin were living in the condition of families occupying a single room in tenement houses; 382,000 were living in houses (I mean by 'house' the distinct apartments of a household) of two rooms; 432,000 occupied houses of three rooms; and 398,000 were quartered in the luxury of houses having at least four rooms. It was found that although the one-room dwellers were only one-sixth as numerous as the three-room dwellers, their rate of mortality was about twenty-three times as high and the actual number of deaths among them was four times as great. Compared with the dwellers in houses of more than four rooms, the mortality of the one-room dwellers was at a thirty times greater rate. In a total population at that time of 1,315,000 the 73,000 people who lived in one-room tenement quarters suffered nearly half the entire number of deaths. Their death-rate per thousand for the year was 163.5, or about one-sixth their entire number; while the two-room dwellers sustained a death-rate of only 22.5, the three-room dwellers escaped with the marvelously low rate of 7.5, and the well-to-do people who had four or more rooms for their household suffered by death only at the rate of 5.4 per thousand of population.

"I am of the impression that the relation of mortality in cities to the character of the housing of the people was never before shown with such frightful distinctness as in these Berlin statistics which were compiled and published in 1888. We are wont to regard an annual city death-rate of about 20 per thousand of the entire population as normal and satisfactorily small. We have not, however, become accustomed to the minute analysis of such a rate which might show up of rates for different classes varying from 3 to 4 per thousand to 200 per thousand. Half the mortality of the Berlin one-room dwellers occurred in households where five or more persons occupied the one enclosed space.

"It would require many pages to give anything like an adequate idea of the wide range of the Berlin inquiry of 1885. To have discovered that in one great ward of the city the death-rate among children of all classes and conditions under one year of age was five times as great as the death-rate for infants in another great ward was to reveal a fact of thrilling—even of alarming—significance. It was important to have learned that in one locality the deaths of young infants constitute half the total deaths, while in another locality only one-fourth of the death-rate is due to infant mortality. It was worth while to have ascertained the precise effects of residence in basements and in garrets.

"Berlin's population as yet is almost wholly housed in tenement or apartment buildings. The number of households or distinct housekeeping establishments was in 1890 about 367,000, and these were included in some 21,600 buildings. The average was about seventeen families under each roof, comprising about seventy-five persons. Including the Emperor and his nobles and all the rich families of Berlin, there were only about 2,200 households of 10

367,000 that had rooms on more than one floor; and of the 2,200 nearly 1,400 were connected with business rooms. That is to say, the 1,400 families had a living-room or two 'back of the shop' and some more space upstairs. Fewer than six hundred families had private houses totally separate from business uses for their own individual occupancy. Not one family in six hundred in Berlin lives in what Americans call a 'house,' as distinguished from a 'flat' or an apartment in a tenement building. The average size of Berlin's tenement buildings has been increasing materially. The buildings that shelter less than about forty people were not in 1890 so numerous by one-tenth as in 1880. Those occupied by from fifty to one hundred people had increased about 40 per cent. in number, while those that house from one hundred to three hundred people had increased from 50 per cent. to 300 per cent., the increase being more rapid according to size. About half the inhabitants of the city now live in buildings containing not fewer than one hundred people. Such a system has its advantages and its disadvantages. It makes the distribution of water and gas easier and renders perfect sewer connections more feasible. Everything depends upon the question whether or not the building is a proper one of its kind. In 1885 about 120,000 Berliners lived in cellar or basement rooms. The actual number of such subterranean dwellers was about the same in 1890, but the relative number had decreased somewhat. It is the policy of the authorities to discourage or forbid, as rapidly as possible, the occupancy of unwholesome basements."

COMPARISONS BETWEEN AMERICAN AND EUROPEAN CITIES.

That the foregoing instances of deplorable density of population are not isolated may be seen by glancing in columns on next page at the figures given for Manchester and Birmingham, representative British cities, Paris and Lyons, representative French cities, and Berlin and Hamburg, representative German cities. It will be seen that the cities of Europe and the cities of the United States form two distinct classes with respect to density of population:

CITIES.	Population.	Acres	Population per acre
New York . . . . .	1,851,060	37,059	49.95
Chicago . . . . .	1,700,000	116,480	14.6
Philadelphia . . . . .	1,047,000	82,560	12.68
Brooklyn . . . . .	1,053,398	44,800	23.29
St. Louis . . . . .	644,000	40,000	16.1
Baltimore . . . . .	613,965	26,880	22.8
Boston and suburbs accommodated by West End Street Railway Co. . . . .	782,859	65,102	12
Cleveland . . . . .	368,895	20,480	18.01
Buffalo . . . . .	360,000	26,880	13.4
Detroit . . . . .	280,000	17,280	16.2
Glasgow . . . . .	840,000	14,661	57.3
Manchester . . . . .	520,000	12,911	40.2
Birmingham . . . . .	500,000	12,365	40.4
Paris . . . . .	2,500,000	19,200	130.2
Lyons . . . . .	416,000	10,800	38.2
Berlin . . . . .	1,800,000	17,500	102.8
Hamburg . . . . .	600,000	14,200	31.2

The foregoing list of cities and the figures given in connection with them prove a lesson in themselves. New York City is an exception to American cities, regarding density of population; yet a study of it will explain it more clearly. New York within its municipal boundary can grow in only one direction, viz., north, and the greatest growth of New York, in what may be called Greater New York, is toward Brooklyn, Long Island, and New Jersey. New York proper, then, may be compared to old Glasgow, in which exists at present a population of 595,714 in 6,111 acres, or 92 persons

an acre. The figures prove beyond question that the conditions are not the same with respect to population in European cities as in American cities. In European cities there is a dense population crowded into very small space; no suburbs as there are in this country, and consequently a smaller track mileage, therefore less capital invested, and greater population per mile than exists here. Under such conditions is it any wonder that street railway companies in Europe are profitable investments?

### EFFECT UPON RENTS.

The matter of cheaper rents referred to above bears important relation to surface transportation. This is best illustrated in the city of Berlin. Owing to the graded fare and the low rate of wages, suburban residence is beyond the means of the masses. They are therefore compelled to reside near to their places of employment. This leads to demand for apartments or tenements in the central portion of the city. The effect is that rents are abnormally high. How this item compares with American tenement property may be learned when we know that an average working man would pay all of his earnings for two rooms on the first floor front of a tenement building, and would pay the income of 125 days' labor for two rooms of the third floor of a court in the rear of the same building, while an average working man in any of the suburbs of Boston would have a five or six room tenement or cottage with modern conveniences, and light and air, for which he would pay the earnings of from 85 to 95 days' labor. Assuming, then, that the American wage earner rides to and from his labor every working day, and that the European wage earner does not ride at all, it is clear that the former is still better off even viewed from a pecuniary standpoint only.

### Comparison of Accommodations.

Having shown that the conditions affecting street railways are not the same on both sides of the water we come to the next point—comparison of accommodations. They are as follows:

CITIES.	Population.	Miles track.	Population per Mile Track.
New York . . . . .	1,851,060	458	4.042
Chicago . . . . .	1,700,000	595	2.857
Philadelphia . . . . .	1,047,000	462	2.266
Brooklyn . . . . .	1,053,393	393	2.680
St. Louis . . . . .	644,000	335	1.922
Baltimore . . . . .	613,965	225	2.728
Boston and suburbs . . . . .	782,839	290	2.700
Cleveland . . . . .	368,895	269	1.371
Buffalo . . . . .	360,000	143	2.517
Detroit . . . . .	280,000	202	1.386
Paris . . . . .	2,500,000	184	13.587
Berlin . . . . .	1,800,000	180	10,000
Glasgow . . . . .	840,000	73	11,507
Liverpool . . . . .	600,000	60	10,000
Manchester . . . . .	520,000	50	10,400

In the foregoing figures the elevated railroads of New York, Brooklyn, and Chicago are not included, therefore these cities should properly be not included; and should they be omitted we find that seven representative American cities have an average population of 2,127 persons, while the five representative European cities have an average population of 11,099 persons per mile of track. In other words the people of American cities are accommodated on an average in excess of five times better than are the people of European cities. When we take into account, therefore, the pro rata rate of fare and the limited track mileage, is it any wonder that the people of European cities are crowded into buildings in a condition of grave menace to the public health, and is it any wonder that in American cities there are so many individual houses with an abundance of light, room and air?

But it may be urged that the American cities have too many miles of track, that the European cities have about enough, that they are satisfied with the accommodations, and that the people of the latter are satisfied with their conditions of living and do not need suburban houses. If one would say that the American cities have too many miles of track for the investors it would be right, for the greater amount of track and therefore of capital invested the less return can be obtained from the investment; but that the American public does not think that there are too many miles of track, too many accommodations, may be evidenced by the fact that the public is always petitioning for more tracks and more cars; and the people have never accused street railway companies of providing too many cars. In European cities, on the other hand, the public authorities deplore their transportation facilities and are trying to improve them. It was shown in the case of Glasgow, when the municipal authorities gave easier terms and conditions to the lessees so that additional accommodations might be obtained in particular localities. It is also true of Berlin. As bearing upon this point, the following may be of interest:

"At a meeting of the Liverpool City Council on June 3, Mr. Rutherford moved: 'That it be an instruction to the Health Committee—or in the alternative that a special committee be appointed—to inquire into the present means of inter-communication and locomotion, such as railway, omnibus, tramway, etc., between various portions of the city, with special reference to (1) the absence of the means of locomotion on certain routes and from certain districts in the city; (2) the inadequacy of the present means of locomotion in point of speed and accommodation on certain routes and from certain districts; (3) whether any other, and if so, what systems of locomotion could be advantageously made use of in Liverpool, and to report thereon to the council as early as possible, together with any scheme or schemes of improvement which they may consider desirable.' He brought forward this motion in no spirit of hostility to the Tramway Company. Inter-communication was a working-man's question. Cross-city traffic in Liverpool was entirely neglected. Some parts of Toxteth Park and Everton were without direct communication with the city. There were routes in Liverpool which occupied forty minutes, a similar distance in London being covered in twenty-five minutes. The rates in Liverpool were charged in proportion to time, and not in proportion to distance. With the exception of the Overhead Railway, no improvement has been made in Liverpool in inter-communication during the last seventeen years, while other municipalities had adopted electric, oil, gas, or cable cars. There were some streets in Everton in which a cable tram service could be adopted without infringement of any agreement in existence. He trusted that in the interest of the city generally, and of the working class in particular, the council would accept the motion.

"Mr. Lloyd seconded.

"After further discussion the motion was agreed to."

### ADDITIONAL CITIES OF THE UNITED KINGDOM.

The following list of cities shows that the lack of accommodations in the few larger cities is general throughout the country:

CITIES.	Population.	Miles track.	Population per Mile Track.
Bradford . . . . .	216,400	21	10,304.8
Bristol . . . . .	221,600	18	12,311.1
Cardiff District . . . . .	129,000	2.33	55,364.8
Leicester . . . . .	174,700	9	19,411.1
Newcastle and Gosworth . . . . .	186,300	13	14,330.8
Nottingham . . . . .	213,900	10.25	20,868.3
Sheffield . . . . .	324,300	9	36,033.3
Sunderland . . . . .	131,000	5	26,200
Aberdeen . . . . .	109,800	10.25	10,712.2
Dundee . . . . .	153,000	7.25	21,103.4
Edinburgh . . . . .	256,400	13.5	19,000
Belfast . . . . .	256,000	20.	14,800

The above list shows an average of 21,703 persons per mile of track against an average of 2,558 in all the cities of Massachusetts except Boston and cities accommodated by the West End Street Railway Company. In fact, the exception in the United States is the rule in Europe, viz., that there are few cities under 50,000 population which have no street railway facilities, and very few suburban towns which are not connected by tracks with a city or with other towns, while in Europe very few of such cities or towns have any street railway accommodations.

If anything further were needed to show the difference in accommodations on both continents, it may be noted that the United Kingdom in 1895, with a population of 40,000,000, had 982 miles of street railway tracks and in round numbers \$70,000,000 invested; while the State of Massachusetts alone had 2,500,000 population, 1,368 miles of railway tracks, and in round numbers \$60,000,000 invested.

#### Municipal Ownership.

A few words regarding municipal ownership and operation of street railways may not be out of place here. The impression intended to be conveyed by its advocates is that there is a universal demand for such a change in Europe, but the facts do not warrant any such conclusion. It is true that ways and means are discussed at present with a view of adopting policies at the expiration of present contracts. All the street railways in the United Kingdom were constructed and are operated under the general act of 1870, and as all contracts were made for periods not less than twenty years, they have expired or are about to expire within a few years. Glasgow has acquired its own plant and London is attempting to purchase the rights and property of a few small companies. In London, however, the acquisition is not for the purpose of operating the railways, but in order that contracts may be made which will remove the objections to the present unsatisfactory service.

Huddersfield and Leeds are referred to as cities which own and successfully operate their own plants. Huddersfield is a city of nearly 100,000 population and twenty miles of track, an average of 5,000 persons per mile greater than the average of any city in the United States. The city acquired the street railway property in 1891 and up to 1896 it has just about paid the interest at less than 3 per cent. on the investment since the acquisition. In one year a tax of 2 1-12 per cent. was added to the general tax to help pay the deficiency of the street railway department. Leeds has a population of 368,000 and acquired the ownership of the tracks of the street railway company in 1894. It is too early yet to look for results, but we shall hope that the municipality will succeed better than the late stockholders, who lost \$392,095 out of an investment of \$800,000.

Birmingham, one of the most progressive and best governed cities in the world, with a population of nearly 500,000, does not take kindly to municipal ownership and control. At a meeting of the city council of that city, held July 7, 1896, after a very full discussion upon the report of the Public Works Committee, it was voted to extend the present lease for a period of twenty-one years to a syndicate represented by gentlemen, one from Toronto and one from Montreal. The following quotation comes nearest to expressing the business sentiment of England: "That the opinion of competent judges is that the lines, etc., should rest in the local authority, but the working be left to private enterprise, and that this would be a just settlement of the question."

I stated previously that the conditions with respect to density of population were such as to cause the municipalities to spend more than they received from street railway franchises. This is illustrated in the case of Glasgow. In that city it has been decided that the public safety and health could best be protected by having all common entrances to dwellings and stairways cleaned and lighted by the municipal authorities. These items alone cost the city in the last fiscal year \$130,064.

#### Street Railways as an Investment in Both Countries.

Street railways in Europe in their relation to public accommodation are about in the same condition as they were in the United States twenty years ago; therefore, there is need of improvement. To bring about improvement, however, will require a revolution in rates of fare, for in order to get people to and from the suburbs cheaply, the fare must be brought within their income, but

that cannot very well be done owing to the conditions which prevail. There is, as shown above, a very large population to be accommodated, and that fact insures good business; for it is safe to apply to European cities the same general principles as are applied to American cities, viz., that large cities are better than small ones, owing to a larger population.

#### CAPITAL INVESTED.

Owing to prices of material, rate of wages, and local conditions, it will require less capital to perform the same work in Europe than in the United States. For instance, Glasgow street railways have invested \$3.48 for each person in its population; Berlin, \$5.25; Boston, \$33.72. In the one item of cars alone to accommodate about the same population, Glasgow has \$249,740, and Boston \$5,510,544.66 invested. The interest on the capital invested in street cars of the West End Company alone, at 6 per cent. per annum, would be \$330,632.68, an amount greater than the whole capital invested in street cars in the city of Glasgow. But it may be asserted that the West End Company is over-capitalized. That is hardly so, for among the twenty-four largest and leading street railway companies of the United States the West End Company has the lowest capital invested per mile of track, while it is second in amount of track.

#### RATES OF WAGES.

The rates of wages are so low in Europe (although the rate of wages paid by the street railway companies is higher than the general rate prevailing elsewhere) that the cost of operation is reduced to a minimum. The scale of wages in Glasgow, adopted in September, 1896, is higher than that in Berlin. Hostlers receive from \$0.83 to \$0.87 a day; laborers, \$0.95 to \$1; conductors and drivers, from \$0.85 to \$1.12; all per day of 10 hours' duty performed. The total receipts of the Glasgow Street Railway from all sources for the last fiscal year were \$1,671,801; of Berlin, \$3,890,201.50; while the amount of wages paid by the West End Company was \$3,812,230 without taking into account wages paid to contractors for track renewal, etc., an amount nearly equal to the total Berlin receipts and more than twice the total Glasgow receipts. If the West End Company, therefore, paid the same rate of wages as is paid in Europe, it could afford to pay \$2,000,000 per annum for its franchises and still maintain its dividends.

#### PROTECTION TO CAPITAL.

The street railways of the United Kingdom are constructed and operated under the General Parliamentary Act of 1870. That act in practically its present form has been the basis upon which all contracts and franchises were made and granted. Those who invested their capital, therefore, knew with reasonable certainty what the conditions would be with respect to legislation during the existence of the contracts. Inasmuch as petitioners are compelled to pay all parliamentary expenses, which usually reach the sum of about \$20,000, there are very few changes in local affairs. The same situation with respect to changes exists in Germany. The financial departments of municipal governments are skilled in all matters relating to finances, so that when the government and those seeking a franchise meet, both parties are fully informed, and the result is usually satisfactory to both parties. After contracts are signed, there is no disturbance. How different in the States! Capital is invited to embark in an enterprise, the public is enthusiastic in its applause, and in a very few years the same public is clamorous against the particular investment which it fostered and encouraged.

#### TAXES, ETC.

Street railways in Europe pay no taxes upon the capital invested in tracks. In Massachusetts, in addition to paying the local tax, they pay a tax into the State Treasury upon the net capital invested, and said net capital is represented by all items of investment. Glasgow paid in the last fiscal year for all taxes \$23,072, and the West End Company \$338,996.

#### Summary.

It therefore follows that the conditions and accommodations are not the same in Europe as in the United States, and that the people of the United States could better afford to subsidize the street railways to maintain the present conditions at any price, and that the European cities have a grave problem on hand to obtain the same conditions as obtain in American cities.

### LATEST ADVANCES IN ELECTRICAL CONTACTS.

The illustrations show a new form of rail bond called the E. C. A. (elastic copper amalgam) and made by Thomas A. Edison and Harold P. Brown, of the recently discovered elastic copper. This form is designed for rebonding girder rails without disturbing the pavement and is the only bond which permits of this being done. A large electro-magnet whose pole pieces fit the head of the rail, is used to hold the drill to its work and to support a hardened steel templet with a pair of intersecting holes. These holes are bored in the tram at the end of each rail so that one is in each and so that they bottom  $\frac{1}{8}$  of an inch on the upper edge of the angle plate, as shown in Fig. 1. The terminals are cylinders with one side flattened, made of the Edison elastic copper, welded to flexible copper conducting strips which are bent into the shape of a U. The surfaces are covered with the Edison flexible solder which serves to make a perfect electrical contact and to prevent rusting. After the holes in the rails are amalgamated, the U-shaped portion of the bond is passed through the slot connecting the holes, and the termi-

FIGURE 1.

FIGURE 2.

FIGURE 3.

nals driven home, their flattened sides coming together with  $\frac{1}{8}$  in. compression. This establishes two paths for the current; one through the U, which is heavy enough for the maximum current, and the other directly across the terminals.

The elasticity of the copper maintains the latter contact even when the rails have slackened apart  $\frac{1}{8}$  in. The terminals are driven below the surface of the rail and the steel is burred over to retain them in place. The edge of the angle plate also shares in carrying the current. Fig. 2 shows the bond ready for service and Fig. 3 is a section of rail and angle plate showing position of bond. Tests of the leading rail bonds were made in February by a Franklin Institute committee, and the E. C. A. bond was found to carry 1,500 amperes with but 0.018 volt loss, the temperature of the bond being practically the same as the rail. The rails were then slackened  $\frac{1}{8}$  in. without increasing the drop, proving the elasticity of the copper. With the angle plates entirely removed, and the rails separated  $\frac{1}{2}$  in. and the same current passed through the U, the drop was still less than one-half that of the best of the ordinary copper bonds and its temperature below 110 degrees, while the copper bonds of same section were from 200 to 496 degrees with same current. For new construction, when the shape of rail or angle plate will not permit the use of the standard plastic rail bond, other forms of the E. C. A. are found very advantageous.

It is stated that most of the new work in New York city will be done in this way. Many roads with an old stock of copper bonds on hand are following the suggestion of George W. Knox, of the Chicago City Railway, and applying the Edison amalgamation and flexible solder to the bond terminals, thus cutting the resistance down to one third and preventing corrosion. But the E. C. A. is the only bond which can be applied to girder rail on paved streets without disturbing the pavements and it has already met with great favor.

### AIR MOTORS IN WASHINGTON.

The Hoadley-Knight compressed air motor has been given a preliminary trial on the Eckington & Soldiers' Home Railroad. There are 34 "bottle" air reservoirs, under the seats of the car, charged to a pressure of 2,000 pounds and of sufficient capacity to run the car for 15 miles. The car is 33 feet long, weighs 21,000 pounds and is lighted by the Pintsch gas system. In the test, the car started and stopped without jarring or jolting and ran at a good rate of speed. It is said that 15 motors for this road have been ordered and will be delivered inside of 90 days.

### COST OF STREET PAVING OPPRESSIVE.

The officials of Sioux City seem to have a mania for paving the streets upon which the lines of the Traction Company run. Wherever there is a double track the company is compelled to pay one-third the cost of improvement. As long as the paving was being done in the business portion of the city or where public traffic required it, the company offered no objection. But when it was proposed to put down costly pavements on streets where its use was not justified, the company protested and said that one of its tracks would be removed rather than pay for paving one-third of the street with asphalt. As most of the property owners are opposed to excessive taxation, the company will probably carry its point.

The Municipal Council of Paris granted leave for the construction of five new tramway lines on condition that 20,000,000 francs would be contributed to the exposition fund. One of these lines was being constructed across the Champs Elysees, when the Minister of Public Works ordered the work to cease. There seems to be a clash between government and municipal authorities with justice on the side of the city officials. These electric roads would much facilitate traffic during the exposition of 1900.

## INSULATORS FOR HIGH POTENTIAL.

The development of water power and the transmission of electricity to distant points for distribution has made very high voltages necessary and consequently there has been a recent demand for line material of the highest class. Line

FIG. 1.—HIGH POTENTIAL INSULATORS.

insulators, exposed to the deleterious effects of rain and sleet, have presented quite a problem for successful solution. The two cuts represent high voltage insulators manufactured by F. M. Locke, Victor, N. Y. The picture to the left in Fig. 1, is the triple petticoat "Niagara" type used in the transmission lines from the Falls. This is made of china as are also the other two styles, "No. 6" and "Pony" which are represented in the same cut. Fig. 2 shows the two part insulator, one being of porcelain and the other of the same material with a glass center and the two fused

FIG. 2.—TWO PART INSULATOR.

together. Being thus made, the parts are quite thin and can be thoroughly vitrified. A test of 120,000 volts has been made upon these insulators without affecting them in the least. It is mounted on a high carbon steel pin with a cap of locust wood. These insulators are made of high grade material throughout and are mechanically and electrically well suited to stand the arduous service expected of them.

## HUNT AIR BRAKE NOTES.

I. E. Storey, president and general manager of the Storey Motor & Tool Company, Philadelphia, becomes consulting electrical and mechanical engineer of the Hunt Air Brake Company. Mr. Storey has had 20 years' experience in mechanical engineering, has been engaged in electric

engineering since '85, and is the inventor of the Storey motor used with the Hunt brake. He will make a valuable addition to the company.

During March, orders were received for 10 double truck brake equipments for the Olean & Bradford Mountain road, to go on Peckham trucks, the cars seating 90 passengers; a second order from the Loraine (O.) road. Brakes were installed on 12 cars of the Mt. Clemens fast line and trial equipments sent to Washington, Boston, Cleveland and Wilkes Barre. Good work is reported from the trial equipment on the Second Avenue line, Pittsburg, working on heavy grades. A new feature is the storage cylinder for trail cars, by which, if a trailer breaks away the air is instantly applied stopping the car automatically.

The combined motor compressor is now handling five and more trail cars in train and is interchangeable with the Westinghouse system and thus steam cars when desired to be taken off a steam road to go over the electric line can be coupled up and air used on all the cars.

## WORK OF COMPRESSED AIR.

Two compressed air motors of the American Air Power Company have been operating in New York city several months, and from this service valuable data is now obtainable. The two air cars took the place of two cable cars on the 125th street line, the round trip being 4.11 miles. Each car makes 19 round trips, or 79.09 miles daily except Sunday. Each car runs from 12.50 to 16.67 miles on a single charge of air. On the line are two grades, one of 1.96 and one of 7.7 per cent. Fires were kept under the boilers the entire 24 hours, although the compressors were worked only 7 hours daily, while of course the engine room help necessary would have been no greater for a much larger car service. Under these unfavorable conditions, however, the following records are given out over the signature of E. E. Pettee, engineer of the American Air Power Company:

Actual average cost per car-mile for entire period—seven months—125.16 miles per day.

Coal .....	\$.0563
Water .....	.0103
Oil and waste .....	.0013
Power plant labor.....	.1261
Conductor and motorman.....	.0608
Repairs, car equipment.....	.0038
	\$.2586

Average present cost per car-mile, with one car service performed—78.09 miles per day.

Coal .....	\$.0675
Water .....	.0113
Oil and waste.....	.0017
Power plant labor.....	.0833
Conductor and motorman.....	.0608
Repairs, car equipment.....	.0038
	\$.2284

Average present cost per car-mile, with two car service—156.18 miles per day:

Coal .....	\$.0433
Water.....	.0103
Oil and waste.....	.0013
Power plant labor.....	.0833
Conductor and motorman.....	.0608
Repairs.....	.0028
	\$.2018

The mechanical features of the motors are practically identical with those of a steam locomotive, minus the fire box and boilers. Air brakes of course are used.

## EXPLOSION AT ELMIRA, N. Y.

A boiler in the power plant of the West Side Railroad Company, Elmira, N. Y., exploded on the morning of March 29, wrecking the station and badly damaging the car house adjoining. The plant consisted of three tubular

INTERIOR OF STATION.

boilers 60 in. x 16 ft. with 72 4-in. tubes; they had been in use four years, and were regularly inspected by the Hartford Insurance Company. The boiler which exploded parted near the middle transverse seam; the rear end was blown through the wall into the engine room; the front portion with the tubes was carried through the opposite wall, pass-

AFTER THE EXPLOSION.

ing completely through the car house, wrecking two cars, and landing 180 ft. from the boiler room. The fireman was found dead and the engineer very badly injured. No fire broke out in the ruins and the engines and dynamos though covered with debris were probably not badly damaged. No cause is assigned for the accident; both the men about the plant were known to be competent and careful.

Swansea, Wales, has voted in favor of the electric railway and lighting project.

## WHITE TRANSFER TABLE.

The illustration shows a 12-ton flush transfer table made by the White Manufacturing Company, 556 West 34th street, New York, designed for electric roads. The one shown is operated by an electric motor, current being taken by a trolley from the overhead lines; but hand mechanism may be used if desired. These tables are made in sizes desired up to 20 tons capacity, and are designed for cable as well as electric roads. The material is of special grade and rolled to suit the table; the gearing is cut from solid blanks,

THE WHITE TRANSFER TABLE.

machine fitted and interchangeable; roller bearings reduce the friction to a minimum. Among the roads using the White transfer tables are the Broadway and the Lexington avenue cable roads, the Metropolitan and the Union Railroad Companies of New York; the Brooklyn City, the Brooklyn Heights, the New York & Queens County and the Coney Island & Brooklyn roads of Brooklyn; the Steinway of Long Island; Consolidated Traction, Newark, N. J.; Scranton Traction, Scranton, Pa.; Lynn & Boston Railroad Boston; Newburgh Electric Railroad, Newburgh, N. Y.

## BUILDING STREET RAILWAYS IN AUSTRALIA.

Although most parts of Australia are very sparsely settled, yet some of the cities are quite populous and have all the modern municipal improvements and conveniences. Melbourne is as large as Boston, Sydney contains more inhabitants than Detroit, and Brisbane and Adelaide are cities of considerable importance. Street railways have been introduced for many years in Melbourne and Sydney, and recently an electric system has been put in operation in Brisbane.

J. J. Walklate has been connected with this installation as resident engineer and has been quite successful in his efforts. Before returning to the United States and thence to London, he has visited Rockhampton in Central Queensland, and has suggested that the city would be a good field for street railway work. Mr. Walklate has drawn up plans for three lines, which will be about six and a half miles long, and the estimated cost \$200,000. English capital supplemented by local backing will likely make the project a certainty.

### California.

**SAN PEDRO, CAL.**—The city council has decided to grant John T. Gaffey his desired street car franchise.

**SAN DIEGO, CAL.**—The San Diego Electric Railway Company will build an addition to its power house at an expense of \$2,000.

**SAN FRANCISCO, CAL.**—The Market Street Railway has just started the work of reconstructing the tracks on Market street from Jones west to the junction of Valencia and Haight street.

**LOS ANGELES, CAL.**—The application of A. S. Short and others for an electric railway franchise has been referred to the city attorney with instructions to prepare a notice of its sale by auction.

**SAN JOSE, CAL.**—An effort is being made by some of the principal owners of the San Jose & Santa Clara Railroad Company and some of the creditors of the First Street Railroad Company, each having \$500,000 stock, to bring about a consolidation and operate under one management and from one power house. Those most active in this move are J. H. Henry, president, and J. P. Burke, vice-president of the San Jose & Santa Clara Railroad Company.

### Chicago.

**CHICAGO.**—A bond for \$20,000 given by the Chicago Electric Transit Company to guarantee the construction of 2 miles of road has been accepted by the county commissioners.

**CHICAGO.**—An ordinance giving the Calumet Electric Railway right of way in Erie avenue has been passed. Another ordinance giving right to extend in 3 streets has been introduced in council.

**CHICAGO.**—Sargent & Lundy are preparing specifications for the 40 to 50 motor cars to be built for the Alley L. The power plant is to consist of compound condensing engines direct connected to generators.

**CHICAGO.**—Commissioner of Public Works Downey issued a permit to the Chicago Transit Company to put down a trolley line on Irving Park boulevard between the Chicago river and Milwaukee avenue. The line will be operation by May 1.

**CHICAGO.**—The Chicago City Railway has been given another year's time in which to extend its lines in Sixty-third, Fifty-first, Thirty-eighth and Forty-seventh streets and Archer, Western and Kedzie avenues, because of the interference of track elevation and sewer building.

**CHICAGO.**—The North Shore Interurban Railway Company has been incorporated to build 17 miles of electric road between Waukegan and Highland Park, as another link in the Chicago-Milwaukee interurban system. The capital stock is \$340,000, and the incorporators are William J. Louderback, Arthur D. Wheeler and William P. Sidley.

**CHICAGO.**—Aside from a slight difference in the question of fares, the Cicero town board has practically agreed to permit the Suburban Electric Railroad to extend its lines in two branches; one will run through Clyde, Berwin and Hawthorn to Riverside and La Grange; and the other will run through Austin, Ridgeland and Oak Park to Maywood.

### Connecticut.

**NEW LONDON, CONN.**—The charter of the New London Street Railway Company has been amended to permit it to furnish electric light.

**BRISTOL, CONN.**—Pierce & Norton have arranged for the construction of a cable road from the lake shore to the top of Comjounce Mountain.

**WINSTED, CONN.**—Judge A. H. Fenn has granted the petition for a trolley line from Winsted to Torrington, paralleling a portion of the Naugatuck division of the New York, New Haven & Hartford Railroad.

**SOUTH MANCHESTER, CONN.**—A 500-h.-p. direct connected unit will be erected in the station of the Hartford, Manchester & Rockville Tramway Company to provide power for the extension this spring to Rockville. The boiler capacity also will be doubled.

**ROCKVILLE, CONN.**—The charter granted the East Windsor, Broad Brook & Rockville Street Railway Company has been approved by the governor. The construction of the road is said to be assured. Among the incorporators are H. L. James, Frank Grant and C. E. Harwood, all of Rockville.

**NEW BRITAIN, CONN.**—Work has commenced on the trolley line which will connect this place with Hartford, and as the consolidated electric companies have purchased the supplies, rails, poles and wire necessary, rapid progress is expected. The New England Railroad has also commenced preparing its tracks for a third rail and the power house is under way, five boilers having already arrived.

**BRIDGEPORT, CONN.**—The construction of an electric railway between Westport and South Norwalk and between Westport and Southport is favored by the people. The Norwalk Tramway Company and the Westport & Saugatuck Street Railway Company are rival applicants for the franchise between Westport and Norwalk; while the Bridgeport Traction Company and the Westport & Saugatuck Company are competing for the franchise between Westport and Southport.

**MILFORD, CONN.**—Directors of the recently organized Milford Street Railway Company met in New Haven at the office of Attorney S. Harrison Wagner, to arrange for the early construction of the line. A large amount of the necessary land for the layout has been already purchased and the company has obtained option on the balance. Contracts for the construction and equipment have been drawn and will be awarded as soon as a few matters which are now pending are disposed of. It is expected now that the work of construction will be commenced by May 1 next, and that it will be completed in time for the summer traffic. Connection will be made with the Winchester Avenue Electric Road at Woodmont and the Bridgeport Traction Company at Washington Bridge. Ex-Sheriff Charles A. Tomlinson has been elected president; Dumond P. Merwin, vice-president, and Frederick Tibbals, secretary and treasurer.

### Delaware.

**WILMINGTON, DEL.**—The Wilmington & West Chester Electric Railway Company has been incorporated to construct a freight and passenger line to West Chester, Pa. The capital stock is \$200,000, with privilege of increasing to \$500,000, and the incorporators are Joseph A. Bond, Harry Emmons, Thomas Mitchell, Philip R. Clark, Charles M. Townsend, F. Harvey Day and J. Jackson Peirce.

### District of Columbia.

**WASHINGTON, D. C.**—The Eckington Railroad Company's equipment for compressed air traction has been made ready for trial.

**WASHINGTON, D. C.**—Condemnation proceedings have been begun by the Washington & Great Falls Electric Railroad Company to obtain right of way.

### Florida.

**JACKSONVILLE, FLA.**—The Jacksonville Street Railway Company is installing a 200-h.-p. dynamo for commercial lighting.

### Georgia.

**ATHENS, GA.**—Track repairs will be made by the Athens Street Railway Company.

ROME, GA.—Manager J. B. Marvin of the Rome Street Railway Company, says the line to Moberly Springs will be completed by May 1. A pleasure resort will be established at the Springs.

### Illinois.

PEORIA, ILL.—The Central Railway Company will extend its Knoxville line to Glen Oak park along Nebraska street, and will relay its tracks on West Jefferson street. Work will begin about May 1.

EAST ST. LOUIS, ILL.—The St. Louis & Belleville Rapid Transit Company has been granted its franchise, over the mayor's veto. The line will connect with another to be constructed between Belleville and East St. Louis.

AURORA, ILL.—The project to build an electric railway up the Fox River, noticed some time ago in the DAILY BULLETIN, has now been incorporated as the Aurora, Yorkville & Morris Railway Company. Capital stock, \$10,000; incorporators, Vine A. Watkins, H. P. Harde and Fayette D. Winslow.

HARVARD, Ill.—H. S. Williams of Harvard, Ill., Herbert T. Windsor and George K. Wheeler of Chicago, are applying for a franchise for an electric railway to run from this city to Lake Geneva, Wis., distance thirteen miles. The territory is densely settled with big possibilities for summer travel to the lake. A large amount of freight is created along the proposed route.

### Indiana.

INDIANAPOLIS, IND.—George W. Armentrout, an employe, has brought suit for the appointment of a receiver for the Indianapolis & Broad Ripple Rapid Transit Company, alleging that \$1,623 is due employes for wages.

MARION, IND.—"Noah Clodfelter has filed a \$5,000 bond at Marion as surety that he will put in the electric road from Marion to Anderson, and do the roads of Grant county no damage. Clodfelter does this every spring, and like the budding leaves he can't help it."—Elwood Call Leader.

### Iowa.

WATERLOO, IA.—The Cedar River Park Board has voted to give right of way and \$500 bonus to the Waterloo & Cedar Falls Rapid Transit Company.

CEDAR FALLS, IA.—C. W. McElyea, of Ames, has petitioned the Cedar Falls council for right to construct a street railway to be operated by storage batteries, compressed air or gasoline motors.

### Kentucky.

LOUISVILLE, KY.—The Louisville Railway Company is putting up poles and wire on Oak street for electric cars.

LOUISVILLE, KY.—The Metropolitan Railway Company has been incorporated to construct 150 miles of electric lines on the following streets: Main, Story, Frankfort, Market, Jefferson, Green, Walnut, Chestnut, Broadway, York, Breckinridge, Kentucky, St. Catherine, Oak, Ormsby, Weisinger, High, A, B, C, First to Thirty-ninth, inclusive, Brook, Floyd, Preston, Jackson, Hancock, Clay, Shelby, Campbell, Wenzel, Underhill, Barrett and Morton. The capital stock is \$1,000,000, and the incorporators are George H. Harries, Washington, D. C., 5 shares; Robert M. Kilgore, 5 shares; P. Gault Miller, 5 shares; J. W. Woolfolk, New York City, 5 shares; Hugh R. Garden, 5 shares; John H. Dewitt, 5 shares; James F. Grinstead, 5 shares; Thomas F. Hargis, 5 shares.

### Maine.

PORTLAND, ME.—The Portland & Cape Elizabeth Electric Railroad Company is making preparations to extend its tracks from Willard to Delano Park.

LIVERMORE FALLS, ME.—Business men of Jay and Livermore Falls have formed the Electric Railroad, Water Works & Power

Plant Company to build 2½ miles of electric road from Jay bridge to Livermore Falls. Eastman & Clifford, of Lewiston, have been invited to go into the deal.

NORWAY, ME.—The Oxford Central Electric Railroad Company held a meeting March 11 and voted to build from Norway to Rice's Junction, thence a branch to South Waterford and another branch to East Stoneham; distance, 21 miles. It will be the first long-distance freight electric line in Maine. The work of construction will begin as soon as the frost leaves the ground, and the estimated cost is \$200,000. Towns and individuals along the line have raised \$40,000. Fred C. Wilson, of Boston, furnishes the balance. The officers are: President, Fred C. Wilson, Boston; vice-president, L. H. Burnham, Albany; treasurer, S. S. Stearns, Norway; clerk, Freeland Howe, Norway; chief engineer, L. B. Wilson, Boston; directors, Fred C. Wilson, Boston; L. H. Burnham, Albany; B. G. McIntire, Waterford; A. S. Haggood, Waterford; Jonathan Bartlett, Stoneham; Freeland Howe, Norway; E. W. Eastman, Auburn.

### Maryland.

BALTIMORE, MD.—The new barn of the City & Suburban Railway will soon be completed. It will be 450 x 140 feet, with one short and 12 long tracks.

BALTIMORE, MD.—For the second time has the council granted the Edmondson Avenue, Catonsville & Ellicott City Electric Railway Company an additional year in which to complete the construction of its road in Baltimore.

BALTIMORE, MD.—The reorganization of the Columbia & Maryland Railway is progressing, all bond and stockholders having deposited their holdings. All the claims of the Baltimore & Catonsville Construction Company are being settled on the basis of 75 per cent cash and 25 per cent stock of the railroad.

BALTIMORE, MD.—Judge Dennis has dismissed the bill filed by L. Robert Coates against the Baltimore, Middle River & Sparrows Point Railway Company for a receiver. Coates was granted an order for an accounting against John T. Smith and Henry Y. Brady, co-defendants. Smith & Brady build the road while Coates financed it.

### Massachusetts.

WESTFIELD, MASS.—Contracts for the construction of the Woronoco Street Railway will be awarded about May 1.

WORCESTER, MASS.—Receiver Phineas W. Sprague has been authorized to sell the Blackstone Valley Street Railway.

WORCESTER, MASS.—The contract to supply ties for the Worcester & Marlboro Electric Railway has been awarded to Allen & Knowlton.

BOSTON, MASS.—Extensions of its car service to East Lexington, Lexington, Lincoln and Waltham are said to be contemplated by the West End Railway Company.

FALL RIVER, MASS.—The Globe Street Railway Company has leased the Fall River Street Railway for 99 years, guaranteeing 6 per cent dividends on the \$50,000 capital stock.

BROOKFIELD, MASS.—The Warren, Brookfield & Spencer Electric Railroad Company has ordered a 450-h.-p. engine of the Slater Engine Company, and will put in a new boiler and generator.

HOLYOKE, MASS.—The directors of the Holyoke Street Railway Company have voted unanimously to extend their lines over High, Hampden, Washington, Lincoln and Cabot streets. A franchise will be asked.

MANSFIELD, MASS.—The Mansfield & Easton Street Railway Company will be incorporated with \$100,000 capital stock by William S. Reed, Leominster; Joseph A. Prescott, Foxboro; C. W. Shippe, Milford, and Frank E. Lowe, Greenfield.

**SUFFIELD, MASS.**—The Springfield & Southwestern Electric Railway Company is to be granted a charter, with all rights and privileges, without opposition, with the condition that it be forfeited to the Suffield & East Granby Company, June 1, 1898, provided that the said Springfield & Southwestern Company does not have at that time an electric railway fully equipped and operated from the state line to West Suffield, through Crooked Lane to Suffield Center. The town is unanimous for an electric road, and this compromise seems to provide for the speedy building of one.

### Michigan.

**DETROIT, MICH.**—J. N. Bick, of Toledo, will have charge of construction for the Jacobson syndicate's proposed electric road from Monroe, Mich., to Toledo, O.

**BENTON HARBOR, MICH.**—Seeley McCord will use horses at first on the proposed street car line to Eastman Springs via Morton Hill. Electricity will be installed later.

**MANISTEE, MICH.**—The Manistee, Flier City & East Lake Railway Company contemplates laying out a park and extending its lines. Modern pleasure resort features will be included.

**SAGINAW, MICH.**—The council has declared the Consolidated Street Railway franchise forfeited and instructed its attorney to take steps toward preventing operation until the track is rebuilt.

**MONROE, MICH.**—The council has annulled the franchise granted the Monroe & Dundee Electric Railway Company for not complying with the terms of the contract requiring 1 mile of track material to be on right of way previous to March 15. The company forfeits \$500 deposit. Jacobson & Johnson were given the forfeited privileges.

**BENTON HARBOR, MICH.**—Four power stations will be established at Benton Harbor, Dowagiac, Decatur and Paw Paw, by the Benton Harbor Electric Railway & Transit Company. The company on May 1, will place a line of steamers on the run between Chicago and St. Joseph, and also operate a car ferry to Milwaukee. J. M. Hamilton, of Chicago, is president; W. H. Hollis, of Puget Sound, Wash., secretary, and H. D. Deam, of Benton Harbor, general manager.

### Minnesota.

**STILLWATER, MINN.**—Flint & Scott, the new owners of the Stillwater Street Railway, are preparing to tear up and remove the entire plant.

### Missouri.

**ST. LOUIS, MO.**—Bondholders of the People's and the Fourth Street & Arsenal Railway have prepared a plan for the consolidation of the two properties.

**HANNIBAL, MO.**—The Hannibal Street Railway was purchased March 15 by an eastern syndicate represented by D. Thompson of Ithaca, N. Y. The property will be improved and extended.

**ST. LOUIS, MO.**—William J. Leinp, Charles F. Orthwein and others, have purchased the large interests of Louisville parties in the Southern Electric Railway. About 6,000 shares of preferred and 2,000 shares of common stock changed hands at \$82.50 for the former and \$40 for the latter. Mr. Orthwein will probably be elected president in place of Claude Kilpatrick.

**ST. LOUIS, MO.**—The East St. Louis Electric Street Railroad, better known as the Scullin line, and which recently changed hands, has elected the following new board of directors: Julius S. Walsh, E. P. Bryan, C. K. Walsh, H. D. Sexton, F. C. Daab, James Hanna and C. T. Jones. Julius S. Walsh was elected president of the reorganized company in place of John Scullin; E. P. Bryan succeeds H. D. Sexton as vice-president; C. K. Walsh was elected secretary, and F. C. Daab was chosen treasurer.

### Montana.

**BUTTE, MONT.** The Massachusetts Loan & Trust Company brought suit against the Butte Consolidated Street Railway Company to foreclose a \$500,000 mortgage by reason of default of interest on January 1.

### New Hampshire.

**CONCORD, N. H.**—The Rockingham Electric Railroad, with a capital stock of \$150,000, has been incorporated, and will build a line between Exeter and Hampton.

### New Jersey.

**BELMAR, N. J.**—The Atlantic Coast Electric Railway Company has been granted a franchise through F street. The line must be in operation by July 1.

**BEVERLY, N. J.**—The Beverly Construction Company has been incorporated to build a trolley line in Burlington County. Capital stock, \$100,000, with \$1,000 paid in.

**BRIDGETON, N. J.**—At the Master's sale of the property and franchises of the South Jersey Traction Company, F. L. Lewis, trustee for the bondholders, was the successful bidder. The price was \$90,000.

**BRIDGETON, N. J.**—The South Jersey Traction Company's lines, which recently were purchased by bondholders, will be relaid and extended through Port Norris, Fairton, Cedarville, Newport and Durding Creek.

**NEWARK, N. J.**—The Compressed Air Power Company has been incorporated to manufacture air motors. Capital stock, \$50,000; incorporators, Hayward A. Harvey of Orange; Hobart Tuttle of Paterson, and Lawrence S. Mott of Newark.

**BELLEVILLE, N. J.**—The Belleville township committee has given the Consolidated Traction Company the right to operate a trolley line on Washington avenue, the cars to run from the Pennsylvania railroad station in Newark to the Franklin township line.

### New York.

**CORNING, N. Y.**—An electric railway franchise has been granted the Corning Construction Company, of which F. C. Frenyear is president.

**NEW YORK, N. Y.**—The 146th street power house of the Lenox avenue conduit railway is to be enlarged by the Metropolitan Street Railway Company.

**CATSKILL, N. Y.**—The railroad commission has granted the Catskill Electric Railway Company a certificate to construct its line from Catskill Landing to Jefferson Heights.

**CANAJOHARIE, N. Y.**—W. J. Arkell is one of the leading men interested in the proposed electric railway from Sharon Springs to Canajoharie. Right of way has been obtained and work is soon to begin.

**BUFFALO, N. Y.**—The Buffalo Railway Company, it is said, will assume control of the Buffalo, Bellevue & Lancaster Railway. The line is to be relocated and double-tracked to reduce the distance from 8 to 6 miles.

**BUFFALO, N. Y.** The Buffalo Traction Company has obtained the consent of abutting owners to the construction of 15 miles of road. It is proposed to construct 30 miles of road this year. Niagara Falls power will be used.

**PORT JERVIS, N. Y.**—M. B. Waller, president of the Electric Street Railway, is looking for a suitable location for the car house of the proposed electric line. Work must begin by June 1, '97, or else the company must pay the forfeit of \$2,000.

**PENN YAN, N. Y.**—The Penn Yan, Keuka Park & Branchport electric railroad has deposited a bond of \$2,000 to insure for failure to leave the streets of the village on which the company expects to operate its line in as good condition as when occupied.

**BUFFALO, N. Y.**—Permission has been given the Buffalo Railway to lay and operate trolley tracks in Clinton street, Jefferson street, Parkside avenue, Tonawanda street, Amherst street and the Military road for a period of 40 years, after which time the city may buy the lines.

HUDSON, N. Y.—The Hudson Electric Railway was sold March 6 by auction. A. V. S. Cochrane bought the road for \$55,000 on behalf of William H. Traver and Smith Thompson, who represented two banks of Hudson. A company of local capitalists may be organized to operate the line.

SEA CLIFF, N. Y.—A trolley line, connecting the village with the depot, will be built by the North Side Construction Company. Among those interested are James Norton, of Glen Cove, John Graham, William Schoelles and George Muller, of Sea Cliff, and C. E. Silkworth, of New York.

OLEAN, N. Y.—Those interested in the Olean, Bradford & Rock City Railway Company will organize the Rock City Park Improvement Company to establish a pleasure resort on the line. H. L. Pierce, of Leominster, Mass., who is the prime mover in the enterprise, says the road will be in operation by June 1.

PALMYRA, N. Y.—A party of gentlemen interested in the proposed electric road from Palmyra to Marion recently went over the ground. Among them were V. R. Nash of Providence, R. I., who represents Syracuse capitalists; C. E. Prun of Syracuse; A. J. Grant and Le Grand Brown of Rochester and G. R. Stetson of Palmyra.

GLOVERSVILLE, N. Y.—The new Mountain Lake Electric Railroad Company has elected Charles King, president; James G. Haggart, vice-president; Myron Hiltz, secretary; A. J. Zimmer, treasurer, and Elman Hiltz, superintendent; directors, Charles King, George Kendrick, Richard Ansell, James G. Haggart, S. L. Foster, A. J. Zimmer, Elman Hiltz, R. J. Williams, William A. McDonald and Myron Hiltz.

NEW YORK, N. Y.—The New York & North Shore Railway Company, of Long Island, has been incorporated with a capital of \$1,000,000, to operate a street surface road in the county of Queens. The directors are: Rudolph T. McCabe, W. R. Heath, Garret H. Perkins, E. L. Bushe and W. A. Pease, of New York City; E. J. Matthews, of Philadelphia; James B. Radel, East Orange, N. J., and C. D. Simpson, of Scranton, Pa.

SAVONA, N. Y.—J. D. Nares of Corning, represents New York capitalists who contemplate constructing an electric railroad from Savona to Lake Keuka to be operated by a company known as the Lake Keuka & Savona Railroad Company, capital stock, \$200,000. Mr. Nares and C. A. Cockroft of the Chenango Engineering Company, Binghamton, have been making measurements of bridges, culverts, for the line, which for the greater distance, will follow the old Sodus Bay road.

GREENBUSH, N. Y.—The Greenbush & Nassau Electric Railway Company has been incorporated to operate a street surface road from Greenbush to Brainard station in the town of Nassau, Rensselaer county, seventeen miles distant. The capital is \$180,000 and the directors are: William D. Barnes of Brainard Station; S. C. Curran of East Greenbush; Fred Carr, B. R. Lansing and W. H. Nichols of Greenbush; C. J. Field of Brooklyn; T. D. James, Gardner Morey, G. W. Whitbeck and J. T. Morey of Nassau; C. J. Smith of Bath-on-the-Hudson; J. L. R. Davis, L. N. S. Miller and J. V. B. Garrison of East Schodack, and T. W. Cantwell of Albany.

NEW YORK, N. Y.—Valter A. Pease, a director of the newly incorporated New York & North Shore Railway Company, says that the company proposes building a trolley line from Newton to points in Jamaica, and also other lines connecting the towns of Jamaica, North Hempstead, Middle Village, Flushing, Whitestone, Willets Point and Manhasset. "While this is virtually an independent company, the roads to be built will really be a part of the Brooklyn, Queens County & Suburban Road, as the same men are interested in both companies. Work will probably be commenced on the new lines this summer, and we hope to have them in running order by next winter."

BUFFALO, N. Y.—The Buffalo, Hamburg & Aurora Railway Company has been incorporated with its principal office in Hamburg, Erie County, to construct a street surface electric road 18 miles in length from the Buffalo city line along the Abbot road and the Hadlem and Big Tree roads, and in the towns of West Seneca, East Hamburg, Hamburg and Aurora, to the villages of Hamburg and Orchard

Park, and to East Aurora. Capital stock, \$200,000; directors, William W. Wheatley, of Brooklyn; John A. Donaldson, Arthur W. Hickman, Lester J. Chase, Ernest Wende, Willis G. Gregory, U. L. Upson, Frank W. Everett, George R. Vaughn, Loren F. Boise and William J. Wright, of Buffalo.

### North Carolina.

ASHEVILLE, N. C.—The Asheville Electric Street Railway Company has been incorporated to build a car line.

CHARLOTTE, N. C.—An extension to Dilworth will be constructed by the Charlotte Electric Railway Company.

### Ohio.

LIMA, O.—The ordinance granting the Lima Railway an extension has been passed by the council.

CINCINNATI, O.—Work on the extensions of 5 car lines has been begun by the Cincinnati Consolidated Street Railway.

COLUMBUS, O.—Vice-president Stewart, of the Columbus Street Railway, petitions for a change of route on the Livingston avenue line.

CANTON, O.—The survey of the Canton-Akron Electric Railroad is progressing. W. A. Lynch says its completion this summer is certain.

AKRON, O.—Creditors of the Akron Street Railway, on March 29, petitioned for the appointment of a receiver. An assessment of stockholders is wanted.

TIFFIN, O.—Samuel B. Sneath, owner of the uncompleted Tiffin & Fostoria Electric Railway, has decided to take up 2 miles of track and relay on the Fostoria line.

CLEVELAND, O.—Henry W. Avery, of Painesville, will superintend the construction of the electric road between Painesville and Fairport, which is soon to be begun.

CINCINNATI, O.—Superintendent H. P. Bradford, of the Main Street Railroad, has petitioned for a 25 years' franchise, offering to pay the city 5 per cent of the gross earnings.

EAST LIVERPOOL, O.—The judicial sale of the East Liverpool & Wellsville Street Railway will take place May 6. The claim of the Cleveland Trust Company is \$280,000.

CLEVELAND, O.—The route of the proposed electric railroad from Cleveland to Orwell will pass through New Lyme, Dodgeville, Andover, Espyville, Conneaut Lake and Meadville.

COLUMBUS, O.—The Columbus Central Railway has absorbed the Worthington line running from North Columbus. An extension of 18 miles from Worthington to Delaware is considered.

NEWARK, O.—James F. Lingafelter, receiver of the Newark Consolidated Electric Railway states that new trucks will be placed under the car bodies, the cars painted, and the roadbed graded.

UPPER SANDUSKY, O.—John V. Beery, of Fremont, is interested in the proposed electric railway from Upper Sandusky to Port Clinton, Catawba Island and Lakeside, by way of Fremont and Tiffin.

CINCINNATI, O.—The Cincinnati Street Railway Company has been granted a franchise for a single track extension to Cheviot, giving a bond of \$10,000 to guarantee the performance of the contract.

DAYTON, O.—It is said the county commissioners have denied the franchise asked by the Dayton, Johnsville & Eaton Electric Street Railroad Company, and will give the right to the Dayton & Western Company.

CINCINNATI, O.—W. A. Davidson, attorney, of Cincinnati, says he represents Pittsburg capitalists who will build an electric railway from Cleves to Anderson's Ferry. William L. Kayser represents citizens who want the car line between Home City and Delhi.

ELYRIA, O.—The Elyria & Oberlin Electric Railway Company was incorporated April 1 to carry freight, passengers, mail and express between the two cities. Capital stock, \$100,000; incorporators, A. E. Akins, F. I. Pomeroy, S. C. Smith, A. G. Hutchinson and M. J. Mandelbaum.

DAYTON, O.—The Dayton & Western Traction Company has purchased a two-thirds interest in the Dayton & Western Turnpike Company, thus obtaining control of a portion of the right of way for the proposed electric railway. This move, it is believed, kills the Dayton, Johnsville & Eaton Company.

TROY, O.—Promoters of the Troy, Tippecanoe & Dayton Electric Railroad met citizens in Tadmor recently to interest them in the project. Among those present were Judge Theodore Sullivan, president of the company; John T. Knapp, J. W. Cruikshank, Frank T. Workman, Dr. W. S. Thompson and George S. Long, attorney for the road.

COLUMBUS, O.—Although Mr. Shipherd's option on the Clintonville & Worthington Street Railway has expired the road will be preserved for the Columbus Central by T. A. Simons and Receiver Worthington, who now have possession. A road is planned up Summit street to Clintonville, as well as a theater at Minerva Park, with a toboggan slide and other pleasure resort features.

## Oregon.

SALEM, ORE.—Archie Mason, in behalf of the Salem Consolidated Street Railway Company, purchased the Salem Motor Railway. An extension reaching to Highland is being discussed.

## Pennsylvania.

PITTSBURG, PA.—The franchise for a line on the Hilltop has been granted to the Pittsburg & Mt. Washington Traction Company.

PHILADELPHIA, PA.—The Union Traction Company has applied for a right to extend its trolley line down Broad street from Porter to League Island.

COLUMBIA, PA.—The Columbia & Ironville Electric Railway project seems to have fallen through since the death of H. H. Heise. The ties are being removed from Eighth street.

POTTSTOWN, PA.—Work has been begun by the Pottstown & West Chester Electric Railway Company on a new bridge which will form part of its new line from Pottstown to West Chester.

ALTOONA, PA.—Local capitalists have projected a trolley line to run to Elmwood Park, 5 miles distant. A franchise will be asked by a company which is being organized with \$75,000 capital.

ALLEGHENY, PA.—The North Side Traction Company has been granted certain franchises by the council, in consideration of a promise to pay 2 per cent of the gross receipts into the city treasury.

NEW CASTLE, PA.—The New Castle Traction Company has purchased 70 acres 2½ miles from the city, for \$16,000, to be beautified as a pleasure resort on the line, which will be extended to the grounds.

WILKES-BARRE, PA.—As soon as the weather permits the Wyoming Traction Company will begin double tracking its Nanticoke line. The double track will save 10 minutes between Wilkes-Barre and Nanticoke.

WEST NEWTON, PA.—Surveys have been made and part of the right way obtained for the West Newton Northern Street Railroad. Seventeen miles of road are to be built. W. W. Patterson, of Homestead, is president.

PITTSBURG, PA.—The Homestead & Highland Street Railway Company has begun the extension of its line up the Monongahela River to Harden. Superintendent J. C. McFarren says cars will be running from Bradlock to Pittsburg by July 4.

MCDONALD, PA.—P. Hoey and other business men of McDonald, are considering the formation of a company to build an electric railway from Carnegie to Canonsburg via McDonald, Walker's Mills Hays station, Greigs, Oakdale, Noblestown, Sturgeon and Laurel Hill.

TAMAQUA, PA.—A franchise has been granted by the council to the Tamaqua & Lansford Street Railway Company. The company must use a "T." rail and give a bond of \$5,000. When finished the road will connect Tamaqua and Summit Hill with all towns in the Panther Creek Valley.

SOUTH BETHLEHEM, PA.—The South Bethlehem & Hellertown Street Railway Company will be incorporated to build to Hellertown and operate in connection with the Bethlehem Traction Company. Pascoe & Crilly will do the construction. The incorporators are Hon. John H. Pascoe, Hugh E. Crilly, W. O. Pass, Joseph R. Wieand and P. F. Cannon.

POTTSTOWN, PA.—The Ringing Rocks Electric Railway Company, of Pottstown, has just been granted right of way by the town council of Boyertown. The local company intends to extend its line from Ringing Rocks Park to New Hanover, and thence to Boyertown, and if arrangements can be completed the extension will probably be made this spring.

BRISTOL, PA.—Although permanently enjoined from occupying the Bristol turnpike, the Philadelphia & Bristol Electric Railway Company will complete its line, leaving a gap of 800 feet, over which passengers will have to walk. As the trolley fare will be only 15 cents, against 55 cents over the steam railroad, it is expected travelers will not object to the walk.

SHAMOKIN, PA.—The Shamokin-Mt. Carmel Electric Railway Company will extend its lines down the mountain from Centralia to Ashland during the summer. This extension will be two miles in length, and will connect with the line of the Schuylkill Traction Company at Ashland, thus completing a continuous trolley line from Shamokin to Shenandoah, Mahanoy City and East Mahanoy Junction, a distance of nearly thirty miles.

MONONGAHELA, PA.—The Monongahela Valley Traction Company has been incorporated to build 18 miles of electric railway connecting various towns in Washington County. The road will extend from Monongahela to Phillipsburg and West Brownsville. Capital stock, \$200,000; president, John D. Rively, Pittsburgh; directors, F. W. Wentz, Charleroi; James D. Irons, Wilkingsburg; W. W. Staub, Avalon; F. F. Wentz, Pittsburgh.

TAMAQUA, PA.—President Riley, of the Lehigh Coal & Navigation Company, is authority for the statement that in a few days the Tamaqua & Lansford Street Railway Company will begin the construction of the electric railway which will connect Tamaqua with Mauch Chunk by way of the Switchback Railway at Summit Hill. The power house will be located at Lansford. The work is to be pushed forward toward completion by August 1.

PHILADELPHIA, PA.—Directors of the East Penn Traction Company met at their office, 1345 Arch street, and elected additional officers as follows: T. Howard Atkinson, of Buckingham, vice-president, and John C. McNaughton, treasurer. A. S. Cadwallader, of Yardley, is president. The capital stock was increased to \$1,000,000 and an issue of \$1,000,000 bonds approved. It is now said construction will begin at an early date.

NEWTOWN, PA.—Permission has been granted the East Penn Traction Company to build and operate its line along Washington avenue, and ordinances have been introduced in Morrisville and Yardley, the two other boroughs between Trenton and Newtown. An effort will also be made to get right of way between Newtown and Doylestown. The distance by the proposed trolley would be 2½ miles, a saving of 50 miles of travel between Trenton and Doylestown.

MEADVILLE, PA.—The project to build an electric road 51 miles in length between Erie and Meadville appears to be making progress. The road will pass through Cambridgeboro, Edinboro, Saegerstown, Venango and California, in addition to a number of smaller towns and hamlets. Cambridgeboro, Edinboro and California are expected to contribute the largest number of passengers to the road. In the latter places are State normal schools, while Cambridgeboro is a summer resort of considerable note. A hotel, which will cost \$500,000, is now in course of construction in that place. One of the power houses will be located at Meadville and the other at a point between that city and Erie, which has not yet been definitely decided upon.

## ELECTRICITY ON THE ILLINOIS CENTRAL.

When provisions were being made by the Illinois Central for the heavy traffic incident to the World's Fair, J. F. Wallace, chief engineer, prepared careful and itemized estimates for the substitution of electric for steam traction. While the estimates indicated a considerable saving in operating expenses for electricity, yet the directors felt the experiments at that time gave no satisfactory evidence of the reliability of such motive power for that kind of service and the matter was dropped.

Since then electric traction has been given a thorough trial on the elevated roads, the Nantasket Beach road and a number of interurbans and its success demonstrated. Its application does not present so many problems now, and last fall a committee was appointed to again study the question for the Illinois Central and report to the directors. The recommendation was that the tracks used for suburban service from Randolph street to Jackson Park should be equipped for electric traction. On March 25 the directors gave their approval to the suggestions embodied in the report and authorized the president to take steps to carry out the plan. As yet the details are being worked out and no bids have been let or construction work commenced.

## INDIANA LEGISLATURE PASSES 3-CENT FARE BILL.

Applies Only to One City However—Injunction Asked by Indianapolis Road.

The fight which has been waged by certain parties against the Citizens' road of Indianapolis, has been carried into the state legislature, where a most unusual and remarkable bill has become a law. It provides for a 3-cent fare in "any city having a population of 100,000 or more, according to the census of 1890," and this, of course, limits the law now and for many years to come to one city—Indianapolis. The bill gives every evidence of malice and persecution as will be clearly evident from a perusal of its strange provisions. It puts a premium on dishonesty. Under the law, any conductor who refuses to accept a 3-cent fare, or give a transfer on a 3-cent fare, brings a fine on himself, also on the company, and forfeits the franchise of the company. Any corrupt employe could, under the provisions of this law, absolutely wreck the company, leaving it without a franchise. The employes could be hired to do this by people who wanted to annoy the company. \$100 of the fine goes to the person who was refused the fare or transfer. Employes could stand in with such parties, and get a portion of the penalty.

The bill is so evidently a persecution, and legislation against one individual interest that it does not seem possible the courts can sustain it.

An injunction has been asked restraining the city from enforcing the law until the case can reach a decision in the courts.

Following is the text of the bill:

"Be it enacted by the General Assembly of the State of Indiana, that Section 9 of an act entitled, 'An act to provide for the incorporation of street railway companies,' approved June 4, 1861, the same being Section 4,151 of the Revised Statutes of 1881, being the same, is hereby amended so as to read as follows: 'Section 9. The directors of such company shall have power to make by-laws for the management and disposition of stock, property and business affairs of such company, not inconsistent with the laws of this state, and prescribing the duties of officers, artificers and servants that may be employed, and for the appointment of all officers for the carrying on of all business within the objects and purposes of such company, and for regulating the running time, fare, etc., of said road or roads. Provided, however, that in cities in this state having a population of 100,000 or more, according to the census of 1890, the cash fare shall not exceed 3 cents for any one trip or passage upon the street railroad or roads of the same, and every passenger upon such road or roads shall, upon his or her request or demand, without any further cash fare or charge, be transferred from the line upon which he may take passage to and upon any other line or lines in such city owned, controlled or operated by such company to which he paid his cash fare, and such company, its officers, servants, agents or employes shall, upon the request or demand of any passenger give transfer ticket or pass to such passenger, entitling him to passage upon the line or lines to which he desires to be transferred, so that he may have one continuous trip or passage over and upon any two of its lines, without additional cash fare or charge to the point nearest his destination.

"Be it further provided, however, that such directors may provide reasonable regulations for the transfer of such passengers as to the place where such transfers shall be made, and when such transfer tickets shall expire, but every passenger desiring to be so transferred shall be given a reasonable opportunity to do so and to be carried upon the line to which he desires to be transferred. And should any street railroad company in any city charge, receive or collect more than 3 cents cash fare, or refuse or neglect to transfer passengers as herein provided, then said company shall forfeit and pay to the person from whom it receives, charges or collects the said cash fare in excess of 3 cents, or whom such company refuses to transfer as herein provided, the sum of \$100, to be recovered in a civil action in any

court of competent jurisdiction, and the city in which such railroad company is doing business, running and operating its line or lines of road or roads may, upon the failure of such street railroad company to comply with any of the provisions of this act, declare the rights, terms, contracts and franchises of such company to the use and occupancy of the streets, alleys and highways of such city for street railroad purposes forfeited and at an end, and may proceed to oust such company from the use and occupancy of such streets, alleys and highways and may contract and let to any other street railroad company the use and occupancy of such streets, alleys and highways for street railroad purposes, the same to be granted and let in accordance with the provisions of this act and the laws governing cities having a population of 100,000 or more, according to the census of 1890.

"That it shall be unlawful for any company organized under the provisions of this act, and owning, controlling, running or operating any street railroad, or system of street railroads, in any city having a population of 100,000 or more, according to the census of 1890, or any officer, agent, servant or employe of such company, to demand, charge, receive or collect from any passenger upon its road, or system of roads, a cash fare of more than 3 cents for any one trip or passage upon the same, and for any violation of the provisions of this section, such company, officer, agent or employe shall, upon conviction thereof, be fined in any sum not less than \$50 and not more than \$500.

"That it shall be unlawful for any company organized under the provisions of this act, and owning, controlling, running or operating any street railroad system or street railroads in any city having a population of 100,000 or more, according to the census of 1890, or any officer, agent, servant or employe of such company, to refuse or neglect to transfer any passenger upon the same from any of its line or lines upon which he may have become a passenger to any other of the lines of such company owned, controlled, run or operated by it in such city, and to which he may have requested or demanded to be transferred; or neglect or refuse to give to any passenger upon demand or request a transfer ticket or pass, entitling such passenger to be transferred or carried upon any other of its lines in such city to the point of his destination thereon, or who shall neglect or refuse to receive and carry any passenger after he shall have received a transfer ticket or pass entitling him to be transferred and carried by and upon some line or lines other than that upon which he originally took passage, shall, upon conviction thereof, be fined in any sum not less than \$50 and not more than \$500.

"Whereas, an emergency exists for the immediate taking effect of this act, the same shall be in force from and after its passage."

The application for restraining order set for April 12 hearing did not come up, and will be heard April 14 before Judge Showalter, of Chicago.

## TWIN CITIES GOOD YEAR.

The Twin City Rapid Transit Company, Minneapolis-St. Paul, is out with its annual report for the fiscal year and shows gross receipts of \$2,059,217, an increase of 3½ per cent. The debt was reduced a quarter of a million and \$300,000 spent in improvements, chiefly relaying track and cast-welding. The passengers carried numbered 41,232,149; car mileage was 11,015,938. Wages were maintained and an increase in the net earnings is shown. A lease for water power, for 40 years was closed. All repairs and improvements are being made of as permanent a nature as possible with a view to future economies in maintenance. New tracks are all laid in concrete, no wood being used in the construction.

Three axles on the new motor cars on the Brooklyn Bridge have broken during the past month. The stresses in these axles are especially severe, due to torsion when starting and stopping. Steel axles of larger dimensions will be substituted for those now in use. Fortunately the accidents have not been attended by any loss of life or serious property damage.

## STOPPING ANOTHER LEAK IN ELECTRIC RAILWAY OPERATION.

BY J. R. CRAVATH.

It is hardly necessary to tell any experienced electric railway man that under the present methods of operating there is a considerable waste in power and repairs, due to the carelessness of motormen. This fact has been fully recognized ever since the first electric roads were started. There are two things directly responsible for this waste, human nature and a certain characteristic of the electric motor. Even when skillfully handled the electric motor is not an efficient machine when starting; but when in careless hands the waste in starting is something enormous, and but a relatively small per cent of the power used gives any useful results in the way of accelerating a car, the balance serving only to heat motors and resistances and wear out the equipment. On the other hand, it is not human nature to be careful and economical of anything that costs the user nothing and of which no record is kept. The motorman has a full and free supply of power. He has been thoroughly taught how he should handle his controller, but it is less trouble to be careless than to be careful, and it is natural to want to crowd the power on with scarcely a pause at each notch, or leave the power on until the brakes are partly set. There are evidently only two directions in which to hope for relief from this evil. There must either be changes in the motors and controllers or in the men that handle them. Series-parallel control has greatly lessened the necessary waste in starting cars, and the education and more careful selection of motormen has in a measure reduced the waste due to carelessness in starting and other bad habits, but that there is still room for much improvement no one familiar with the way cars are handled on all large roads will deny. The well known tests made by Hermann Hering at Baltimore, published in 1895, showed that even and above the average motorman used 20 per cent more power than was necessary to get his car over the road on time, which result has doubtless been confirmed by many railway electricians in private tests.

It has long seemed evident to the writer, in common with many other electric railway men with whom he has talked, that the only way to strike at the root of the evil and get permanent results in the way of proper handling of the equipment at all times, would be to keep a continuous record of the performance of each man. This is simply in a line with the recently adopted practice of our best steam roads, of keeping a ton-mile fuel record for every engine crew on the road and comparing the records of all those in similar service. The Chicago Great Western Railway has by this plan reduced its fuel bill 26 per cent from what it was under the old plan, where no check was kept on the performance of an engine crew.

It is manifest, however, that before any comparative record of all motormen can be kept there must be an instrument to keep it with. The ideal thing for the purpose would in theory evidently be a recording watt-meter of the portable type, but financial reasons prohibit the adoption of such an instrument for every motorman, to say nothing of its doubtful ability to stand hard knocks.

The requirements of an instrument for such a purpose are many and severe. It should first of all be reliable, so as to do justice to all the motormen concerned. It must be low

in first cost, simple to operate, easy to repair, and not liable to get out of order or break. It must be detachable from the car after the plan of a stationary fare register, so that each motorman can turn his instrument in to the clerk or receiver at the end of his run, thereby saving the labor and time that would be necessary to read the instrument on the car between shifts where a car is run by two crews each day. It should be able to stand hard usage without interfering with its accuracy, and for that reason should preferably be free from delicate adjustments, magnets and the like.

RECORDER AND RECORDER CASE.

The writer having been engaged in the development of an instrument to fill these requirements, and having thoroughly tested it in actual practice, it will no doubt be of interest to electric railway men to learn of the commercial results attained. The instrument in its present form consists of two parts. The recorder proper, Fig. 1, is given to every motorman before he starts out on his run, is put in position on the car by him, and at the end of the run turned in by him at the office. This recorder fits into a recorder case, Fig. 2, which is a fixture on the car and contains the car circuit terminals. The act of pushing the recorder into its case closes the car circuit through the recorder, and unless the recorder is in its place the car circuit is open and the motorman can not run his car. The recording device consists of two very simple elements—a horizontal German silver wire held between the terminals A B and of such cross section as to be heated by the current operating the car which flows through it and a thin strip of alloy of low melting point. This strip of alloy is supported in vertical guides above the wire and held against the wire by a weight clamped to its lower end, as shown in the illustration. When the temperature of the wire has reached a certain point due to the passage of current through it, the wire begins to melt

its way through the alloy strip and the strip and weight descend. The amount of strip melted through in a day is used as a record of the motorman's efficiency. In practice the hot wire is made of such a size that a good man under ordinary conditions will melt through but little of a strip—the strips being 17 inches long—while some of the more careless men will go through the full length. The proper size of wire is determined by actual experiment with a careful motorman in regular service, and of course will need to be varied with the weight of the car and local conditions. While this instrument is not a recording ammeter (because it does not record current below a certain amount) that fact in no way detracts from its value for the special use in which it is employed. The superintendent wants chiefly to know which motormen are in the habit of running with the least starting current, for it is the excessive starting current that wrecks the equipment, wastes power, makes necessary the running of a large amount of generating machinery in proportion to the average load, and a needlessly heavy

strip, a hot wire and two terminals, which terminals are provided with switch lugs on the back which fit into switch jaws in the iron recorder case on the car, to complete the circuit when the recorder is pushed into position. It contains also an automatic short circuiting device as a precaution to prevent injury to the instrument or stoppage of the car should the hot wire melt under an abnormal current. This however seldom occurs. Mr. motorman having received his recorder may drop it on the floor while on the way to his car without likelihood of serious injury to anything it contains. It is but the work of a few seconds for him to shove the recorder into the case, close the case door and be off. At the end of his run he turns it in at the office and the clerk unlocks and reads it at his leisure. If more than a small fraction of the strip is melted through a new one is put in and the old one thrown into the scrap pile to be sent back for remelting and rerolling. The cost of these strips is thus made nominal. The refilled recorder is then put in the pile ready to go out. A record of "miles run" and "inches melted" is kept for each man, and the clerical work is so slight that it can in most cases be done in spare moments by men already employed. While a man may have bad luck as to delays and heavy loads one day, such things will not happen to the same man all the time, and as a matter of fact it is found that there is a striking persistency in the way in which some men pile up a record until they are given a hint to reform.

In order to thoroughly test the practical working of this recorder and to determine what could actually be accomplished in the way of commercial economy by its use, arrangements were made with Superintendent W. F. Brennan of the Chicago General Railway to equip all the cars of that road. It was realized by the writer at the outset that the saving possible by the use of this device on this road was far less than on many others because it operates a comparatively small number of cars and the men are thus brought more directly under the eye of the superintendent than on large systems. Furthermore, Mr. Brennan has always been specially careful in teaching his motormen economy and care, and the men now running on the road are the "survival of the fittest" from several years of operation and a reduction in car service, and every one familiar with the road knows that its motormen are an unusually painstaking lot of employes. In fact, as REVIEW readers will remember, Mr. Brennan once, during a shortage in power, gave his motormen a course in running cars with a No. 25 copper wire for a fuse, from which they nearly all successfully graduated without being suspended during the course. It was almost a question in the writer's mind whether recorders were needed on a road so managed, but as Mr. Brennan seemed to think there was still room for improvement by the use of recorders a thorough test was prepared for by taking a series of readings at the powerhouse switchboard. A summary of this first series of tests is shown in one of the accompanying tables. These tests were all made between the hours of 8 a. m. and 6:15 p. m. and were made under conditions of track favorable to a low power consumption. Frequent light snow storms during the nights made necessary running the sweeper early in the morning on several of the days and the track was thus kept clear of dirt clean and wet. The averages shown are from 10 second readings of station ammeter and voltmeter, each test lasting about one hour. Nine tests were taken during hours of heavy, and eight during hours of medium traffic,

Cravath recorder on Chicago General Railway.

investment in feeders. A feature of this excessive current recorder that makes it specially valuable for its particular purpose is that it records according to the square of the current flowing through it, provided, of course, the current is of sufficient volume to cause it to record at all. The careless motorman thus has his record magnified in a way that may not be very satisfactory to him, but leaves no doubt in the superintendent's mind as to where improvement or "reprovement" is needed.

With hot wires all of the same diameter and material, with terminals of the same size and distance apart and with an alloy of uniform mixture and thickness it is evident that there is little chance for difference in the performance of one recorder as compared with another, and we have here a fair means of comparing men in the same class of service and a comparison is after all the main thing of practical value.

As to practical operation this recorder is ideally simple. When the motorman is called for his run he is given a locked recorder containing a fresh strip of alloy. As is seen by the illustrations, it is a strong wood box 35 inches long by 2 $\frac{3}{4}$  by 2 $\frac{1}{4}$  inches. It contains simply a weight, an alloy

This company operates two types of cars, one on double tracks with two G. E. 1200 motors and weighing 23,200 pounds complete; the other with same motor equipment but shorter and on single trucks weighing 18,600 pounds complete. A Sperry motor car is also operated at times, its weight being 16,000 pounds. Six cars are operated on the company's main line on Twenty-second street, doing a cross-town business and scheduled for 8½ miles round trip in one hour including numerous stops for railroad crossings. One transfer car is also run on the Homan avenue branch. Owing to variation in the proportion of long and short cars operating, all results are figured in power required per ton of dead weight operating, it having been determined that the power required to operate the road was proportional to the total weight of the cars without regard to whether that weight was in the shape of long or short cars.

After taking the first series of tests the six cars on the main line were equipped with recorders, one on the branch line remaining unequipped. The moral effect of having a recorder on each car of course caused all men to use more care from the first day the recorders were put in service, but it was found that still there was a marked difference between the weekly records of the various men. After about two weeks of operation with recorders a comparative record was posted showing the relative standing of each motorman as to amount of strip melted per trip. The more efficient men were thus given an incentive to try to stay at the top of the list, and those making a less favorable showing naturally felt the importance of getting nearer the top, which latter fact was made evident by the recorder readings after the record was posted.

The second series of tests (shown herewith) was made after the recorders had been in service some time. Unfortunately the rail surface was not in as good condition during the second as during the first series, owing to the fact that a great quantity of pasty mud had dried on the rails about the time the second series was begun and no rain came to wash it away during the test, but still the showing is favorable enough to leave no doubt as to the beneficial effects of the recorders. The conditions (aside from track surface as before mentioned) were as nearly alike in the two tests as was possible. The same time schedule was maintained and the same proportions of heavy and medium load tests were taken in both series.

The tests show that it took nine per cent more power to operate the road without recorders than it does now with them. Not only is the average power cut down, but the maximum power is, as might be expected decidedly reduced. If such a saving can be shown by equipping with recorders, six-sevenths of a small road where the men are already noted for careful handling of motor equipments, the readers of this article can perhaps imagine what the effect would be on the majority of roads having fifty motormen and over where close supervision is impossible.

Considered from the standpoint of the power plant alone, the employment of recorders means a fuel saving due to a reduction of the average load, but in many cases it means much more. The reduction of the maximum power needed to handle a given number of tons of rolling stock makes it possible to either run more cars with a given capacity of generating machinery or to reduce the capacity of the generating machinery that must be kept running to handle a given number of cars. In the former case the saving will not only be in fuel but in investment and it immediately

becomes a question for the engineer to consider whether it is not cheaper to buy recorders to put on the cars and keep down the power consumption rather than invest so much money in feeder and power plant capacity. In this connection it may be said that some snow storm and bad track tests made at the Chicago General plant after the recorders were in service showed the maximum and average demand for power at those times to be only about equal to the average of the entire first series of tests. The use of a smaller engine has also been made possible there during light load hours.

However, the saving in power and the investments connected therewith are by no means the only items to be considered. Electrical and mechanical repairs are nearly as important. An accurate test as to saving in repairs by the use of recorders is difficult to make, but no electric railway man needs to be told that most of the electrical and many of the mechanical repairs on motors are necessitated by the misuse of the controller, which misuse the presence of the recorder puts a stop to.

Another evil that the recorder effectually checks is that of running recklessly, at a much faster rate than called for by the schedule in order to get a long lay over at the end of the route. Men are also more careful not to get behind time for useless reasons as they know their recorder record may suffer in making it up.

In conclusion the writer wishes to acknowledge the courtesies shown him by Mr. Brennan of the Chicago General Railway and his staff in making this first practical test of an excessive current recorder for motormen, thorough and complete and especially to express appreciation of the careful attention given by Mr. Caywood, chief engineer, to making the power plant tests. Mr. Brennan has always been one of those managers who realized keenly the importance of some recording device of this nature. To him much credit is due for being the means of bringing out information that can not but benefit the entire industry.

James R. Cravath is already well and widely known as a deep student of electric railway problems, and a popular and successful writer on these subjects.

J. R. CRAVATH.

Mr. Cravath for over four years past has most acceptably served as electrical editor of the STREET RAILWAY REVIEW, which department he has conducted with marked ability. It is with genuine regret to the REVIEW that Mr. Cravath severs his connection with us in order to devote his entire time to his recorder, although he will continue to contribute to its columns from time to time. The exceptional opportunities he has had to study street railway problems has specially fitted him to undertake his new work, and we wish and predict for him the same success in his new work which has attended him as a technical journalist. The members of the Chicago Electrical Association have also recognized his strong work in that organization, and he is now serving a second term as its secretary. He will be at home to old and new friends at 825 Monadnock building, Chicago.

## FIRST SERIES OF TESTS, CHICAGO GENERAL RAILWAY (BEFORE EQUIPPING WITH RECORDERS).

Date.	Hour of day.	Condition of Track and Weather.	Temperature.	Average h. p. per ton.	Average amperes per ton.	Maximum amperes per ton.
Feb. 5,	*8:30 to 9:50 a. m.,	slight snow changing, to rain.....	32° to 35°	1.013	2.741	5.874
" 6,	9:45 to 11:10 a. m.,	rails covered with water; fair weather.	36°	1.830	2.651	4.666
" 7,	*4:15 to 5:15 p. m.,	rails damp and fairly clean; fair.....	36°	1.774	2.526	5.874
" 8,	10:15 to 11:15 a. m.,	little mud fresh frozen on rail; fair.....	26°	1.515	2.168	4.569
" 8,	4:00 to 5:00 p. m.,	little mud fresh frozen on rail; fair.....	26°	1.655	2.364	5.874
" 9,	9:30 to 10:30 a. m.,	frozen dirt pulverized on rail; fair.....	26°	1.675	2.386	5.703
" 9,	4:15 to 5:15 p. m.,	frozen dirt pulverized on rail; fair.....	26°	1.740	2.509	5.703
" 9,	*5:30 to 6:10 p. m.,	frozen dirt pulverized on rail; fair.....	26°	1.774	2.517	5.703
" 10,	4:15 to 5:15 p. m.,	rail wet with light melting snow; fair..	33°	1.802	2.593	5.720
" 10,	*5:23 to 6:08 p. m.,	rail wet with light melting snow; fair..	33°	1.881	2.683	5.383
" 12,	*4:45 to 5:45 p. m.,	rail wet with light melting snow; fair..	35°	1.859	2.673	6.011
" 13,	9:30 to 10:30 p. m.,	rail wet with light melting snow; fair..	35°	1.674	2.394	6.364
" 13,	*4:50 to 5:50 p. m.,	streets muddy; fair.....	36°	1.884	2.677	9.011
" 14,	*4:20 to 5:20 p. m.,	rail wet; fair.....	36°	1.500	2.282	5.644
" 15,	*4:55 to 5:55 p. m.,	streets flooded with melting snow; fair.	38°	1.765	2.524	6.011
" 16,	4:05 to 4:55 p. m.,	rail muddy; fair.....	40°	1.701	2.437	5.657
" 16,	*5:00 to 5:50 p. m.,	rail muddy; fair.....	40°	1.786	2.550	5.304
Average.....				1.754	2.510	

\*Made during heavy load hours; morning and evening and Sunday afternoon traffic.

## SECOND SERIES OF TESTS, CHICAGO GENERAL RAILWAY (AFTER EQUIPPING WITH RECORDERS).

Date	Hour of Day.	Condition of Track and Weather.	Temperature.	Average h. p. per ton.	Average amperes per ton.	Maximum amperes per ton.
April 2,	2:56 to 3:56 p. m.,	rail very dirty with dried mud; fair....	46°	1.548	2.187	4.316
" 3,	*8:00 to 9:00 a. m.,	rail very dirty with dried mud; fair....	48°	1.564	2.193	4.316
" 3,	11:00 to 12:10 p. m.,	rail very dirty with dried mud; fair....	48°	1.454	2.081	4.316
" 3,	*4:40 to 5:40 p. m.,	rail very dusty; fair.....	50°	1.625	2.359	5.312
" 4,	*3:40 to 4:40 p. m.,	rail very dusty; fair.....	50°	1.689	2.400	4.832
" 5,	2:07 to 3:07 p. m.,	rail very dusty; fair.....	42°	1.541	2.210	5.479
" 5,	*4:40 to 5:40 p. m.,	rail very dusty; fair.....	42°	1.608	2.284	4.794
" 6,	*4:40 to 5:40 p. m.,	rail dirty with dried mud; fair.....	36°	1.677	2.303	4.316
" 7,	*8:00 to 9:00 a. m.,	rail dirty and slightly damp; fog.....	38°	1.728	2.430	4.794
" 7,	10:35 to 11:35 a. m.,	rail very dusty; fair.....	43°	1.636	2.317	5.136
" 7,	3:47 to 4:47 p. m.,	rail very dusty; fair.....	45°	1.743	2.493	4.931
" 8,	*7:52 to 8:54 a. m.,	rail very dusty; fair.....	40°	1.598	2.269	3.983
" 8,	9:50 to 10:50 a. m.,	rail very dusty; fair.....	42°	1.577	2.248	5.312
" 8,	2:57 to 3:57 p. m.,	rail very dusty; fair.....	45°	1.557	2.231	4.666
" 8,	*4:52 to 5:52 p. m.,	rail very dusty; fair.....	43°	1.702	2.424	4.666
" 9,	*7:56 to 8:56 a. m.,	rail very dusty; fair.....	36°	1.554	2.189	4.510
" 9,	10:00 to 11:00 a. m.,	rail very dusty; fair.....	48°	1.538	2.187	4.510
Average.....				1.608	2.288	

\*Made during heavy load hours; morning and evening and Sunday afternoon traffic.

## STREET RAILWAYS TO PAY LICENSE IN WISCONSIN.

A bill for the payment of licenses by street railways and electric light and power companies, has been debated and is almost certain of passage by the Wisconsin legislature.

Street railways having gross cash receipts in excess of \$800,000 per annum constitute the first class, those having receipts less than this amount the second class. The bill provides that on the first Monday in December each company shall pay to the treasurer of the city, village or municipality in which the road is located a percentage of its gross cash receipts as follows: Railways of the first class, three per cent on the first \$800,000 and four per cent on receipts in excess of \$800,000. Railways of the second class, one and one-half per cent on the first \$250,000 and two and one-half per cent on receipts in excess of \$250,000. Six per cent of these license fees goes to the state and three per cent to the county. If the road is interurban the tax is divided in proportion to the mileage in the two or more cities except where the railway extends from a city to neighboring towns and villages, then the city is to receive three portions of such tax per mile to one portion in the neighboring towns

and villages. Where there is more than one taxing district in the municipality the fees from the railways are proportioned among them according to the number of feet of track laid in each such district. These fees are in lieu of all taxes and fees and all property, franchises and real estate used in the operation of the company's business shall be exempt from all other taxation.

## GOOD RECORD IN BIRMINGHAM.

Last year over 5,000,000 passengers were carried and 200,000 tons of freight hauled by the Birmingham (Ala.) Railway & Electric Company. Under the capable management of J. B. McClary, the roads, which were consolidated in 1890, have been united into one complete system and many improvements and extensions in the service made. The company now owns 55 miles of track, 45 motor cars, 15 locomotives, 38 passenger coaches and 6 freight cars. It is expected that the Ensley and Bessemer steam lines will be converted into an electric system by fall.

The Jenney Electric Motor Works at Indianapolis, Ind., were burned on the morning of March 12.

Isaac Bearinger, president of the Interurban Electric Railway Company, Saginaw, Mich., was married April 1, to Miss Adelia McCormick.

W. B. Bucklin, of Little Falls, N. Y., has taken up his duties as assistant superintendent of the Zanesville (O.) Street Railway and Electric Company.

Joseph Leiter, son of L. Z. Leiter, has been elected a director in the Chicago City Railway to fill the vacancy caused by the resignation of his father.

Another change has been made in the management of the Lincoln (Ill.) Electric Street Railway Company, Elmer Simonton succeeding J. A. Ferguson as superintendent.

D. J. Duncan of Carbondale, Pa., has taken up his duties as superintendent of the Schuylkill Electric Railway Company, and L. J. Wright has been appointed general manager of the same road.

On March 13, the Hood Machine Company of Birmingham entertained at its shops in honor of the first electric locomotive built in Alabama. The locomotive was built under the direction of G. F. Perin, E. E.

After several conferences with President McKinley, Henry C. Payne has decided not to accept an appointment in the diplomatic service, and has returned to Milwaukee to attend to his street railway and other business interests.

Robert Hardie, inventor of the Hardie compressed air system now being tried in New York, was a REVIEW caller. He is delighted with the demonstration thus far and is confident compressed air will yet prove to be the railway motive power.

W. F. Rudolph, superintendent of the Oakland (Cal.) Consolidated Street Railway Company met with a very painful and serious accident, being crushed between two cars, sustaining internal injuries and a lacerated leg. Fortunately the accident will not prove fatal.

E. W. Goss, superintendent of the Middletown and the Portland (Conn.) Street Railway Companies has recently been appointed superintendent of the Middletown & Portland Bridge Company. His new position does not interfere with his duties in street railway affairs.

A new field of usefulness is open to the trolley car. Recently one of the employes of the Columbus (O.) Street Railroad Company moved into a house in Olentangy park, owned by the company and his goods were transferred on a sand car and one of the construction cars.

As a token of their appreciation the employes of the Rochester Railway Company presented C. A. Williams, the retiring secretary, with a handsome solitaire diamond ring. He has been in the service of the company for seven years, but has been compelled to give up his work on account of ill health.

The Baltimore papers announce again the certainty of the oft-reported consolidation of the Baltimore Traction, the City Passenger and the City & Suburban lines. The interests, however, are difficult to adjust to the satisfaction of all, and the effort will probably fail, as preceding attempts have failed.

Frank C. Homsher, who has been assistant superintendent of the Harrisburg (Pa.) Traction Company for six years, has retired from the services of the company. C. L. Brinser, of the operating department, and J. H. Tinker of the office force have also been relieved, to curtail expenses, and the positions abolished.

R. T. McCabe, president of the New York & Queens County Railway Company will be succeeded by Mr. Sheldordine of Philadelphia. J. R. Beelan, who has been general manager of the Peoples' Traction Company of Philadelphia, will take the place of George Chambers as manager. The system has recently changed hands.

F. S. Jones, who for several years past has so acceptably managed the Chicago office of the Stillwell-Bierce & Smith Vaile Co., has had his good work recognized in a promotion of which his many friends will be glad to learn. He has gone to Dayton, and will hereafter be found in the home office as treasurer and manager of the company.

C. S. Van Wagoner, president of the Van Wagoner & Williams Hardware Company, Cleveland, and Frank X. Cicott, manager of the railway department of the Ansonia Brass & Copper Company, were callers on the REVIEW when in Chicago a few days ago. Mr. Van Wagoner, by reason of a new department in his works will now be interested in street railways, and will be found a progressive and accomplished gentleman.

## WHERE WILL YOU SPEND THE SUMMER?

It is not too early to begin to think of the best place to spend your summer vacation. Do not leave this matter until the last moment, make up your mind in a hurry and then—regret for the next six months that you did not take more time in making your decision. And while you are thinking of this matter it will pay you to investigate some of the many hundred beautiful resorts situated along the line of the New York Central & Hudson River Railroad. You cannot get a better list to choose from. If you want a gay social time, and can afford it, take the New York Central to Saratoga, Lake George, Lake Champlain, or the Thousand Islands. If you want a quiet, rustic time, you can find it in one of the many small villages scattered through the Adirondacks, the Catskills, or the Berkshire Hills. The New York Central lines will take you into the heart of these famous regions. If you want to spend your vacation in sight seeing, take this same railroad to Boston, Buffalo, Niagara Falls, Montreal, Toronto, Chicago, St. Louis or Cincinnati. In addition to simply taking you to these different places, the New York Central will take you in the best possible manner. It has the fastest and most perfect through train service in the world, with new and elegant sleeping, drawing room and dining cars made by the Wagner Palace Car Company. It has justly been said of this road that, "For the excellence of its tracks, the speed of its trains, the safety and comfort of its patrons, the loveliness and variety of its scenery, the trade and importance of its cities, and the uniformly correct character of its service, the New York Central & Hudson River Railroad is probably not surpassed by any similar institution on either side of the Atlantic."

For further information about any place along this road apply to George H. Daniels, General Passenger Agent, Grand Central Station, New York City.

**Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.**

Contracts will soon be let for a large power house costing \$500,000 to be built by the Consolidated Traction Company of Pittsburgh.

The Birmingham (Ala.) Railway & Electric Company has recently provided balloon ascensions as park attractions with great success.

The electric road between Westerly and Watch Hill, Conn., has been re-opened with R. H. Fillmore, Jr., acting as superintendent.

Geo. M. Perrin was sent to the house of correction for 90 days for stealing several fare registers from the Citizens' Street Railway Company, Detroit.

R. W. Clay, a director and one of the principal stockholders of the Citizens' Street Railroad Company, Indianapolis, died at his home in Philadelphia.

The last quarterly dividend of the Manhattan Consolidated Railroad was 1, instead of 1½ per cent, as heretofore. For the past three months the earnings were \$430,000.

The New Castle (N. J.) Traction Company has placed an order for \$3,000 worth of machine tools. These are to be used in the shops at the car barn where all the repairs will be made.

The officers and employes of the Citizens Street Railroad Company of Indianapolis presented A. L. Mason, president of the company, with a gold headed cane as evidence of their good will.

Regular day cars operated by the Consolidated Traction Company of Pittsburgh make 182 miles per day. During the last year, however, the car mileage has been irregular because of repairs on the system.

The Sheboygan Light, Power and Railway Company, of Sheboygan, Wis., is actively engaged in building extensions to its lines; a loop line through residence districts, an extension to Krezville and a line to the Wildwood and the Lutheran cemeteries, over which funeral trains will be run.

The tenth annual banquet given by the New Haven Street Railway Company to its employes was a most pleasurable occasion. As a token of good feeling to the officers, the men presented President Corey with a handsome tobacco box and fine Morris chairs to Superintendent Mather and to M. J. Donlon.

The Wilmington & New Castle Electric Railway celebrated its opening by carrying the members of the general assembly, the mayor and council of New Castle and many prominent citizens on the first trip. After these distinguished gentlemen had completed the circuit the cars began to run on schedule time.

A Council Bluffs street car was the scene of a unique marriage recently. A young man and woman were taking

a trolley ride and at a prearranged place a clergyman boarded the car, the license was produced, the nuptial knot tied, with the conductor and motorman as witnesses, the fee paid, and the wedding journey taken, all in one trip.

A conductor was recently discharged by the Consolidated Traction Company of Jersey City and prosecuted for embezzlement. Expecting only a fine he practically pleaded guilty, but Judge Hudspeth considered it no less a crime to steal from a railway company than from an individual, and sentenced the erring conductor to six months in the penitentiary.

Ex-President Harrison appeared before the supreme court at Washington in behalf of the Citizens' Railway Company of Indianapolis in the suit brought against it by the City Railway Company. The Citizens' company contends for the perpetuity of its franchise, and claims that the state could not delegate its franchise granting power to the Indianapolis city council.

A report extensively circulated by the daily press to the effect that the Reading & Southwestern Street Railway Company of Reading, Pa., had issued an order requiring car employes to be clean shaven is denied in toto by the company. This report has caused the officers considerable annoyance. The only request made of the men is that they make a tidy appearance.

Application was made by the Central Trust Company, of New York, for the appointment of a receiver for the Brooklyn Elevated Railroad Company, to foreclose a first and second mortgage. Judge Van Wyck, of the Supreme Court, Brooklyn, named Frederick Uhlmann for the position. A plan for reorganization has been formulated and \$16,000,000 first mortgage gold bonds will be issued.

The Piedmont & Mountain View Railway of Oakland, Cal., has abolished horse traction on all its lines. The main line, 6½ miles, is operated by cable, but is equipped with overhead trolley wires, and electric cars are run on Sundays and holidays. The crosstown and branch lines, 8 miles, are electric. No change has been made in the officers of the company with the exception of the appointment of W. Tiffany as superintendent.

The Oxford Lake Line of Anniston, Ala., recently lost in a damage suit, \$500 being awarded the plaintiff. This is a rather unique case, as the plaintiff did not allege that the street railway company was running its cars too fast and thereby violating a city ordinance. The facts, as admitted, were that the car had passed a long wagonette or carryall, and then the team attached to the latter turned and chased the car, finally passing it and coming to a halt on the track in front. The trainmen and passengers testified that the wagon struck the car in passing; the people in the wagon, that the latter had stopped and that the motorman deliberately ran his car into it. Apparently the company lost the case, because there was, it being the 14th of July, a canvas advertising banner 2½ ft. square fastened on the front dash board, which the court did not consider necessary to the conduct of the company's business. There was but little evidence that the horses were frightened by this. The case has been appealed. The company has had but one other accident in six years.

## VAN WAGONER & WILLIAMS HARDWARE COMPANY.

The Van Wagoner & Williams Hardware Company, of Cleveland and New York, has been favorably known for over 25 years to the general hardware trade of the United States and Canada, and in England and Germany, but until recently not as a manufacturer of electrical supplies. Entering upon the manufacture of drop-forged commutator segments for street railway motors and generators brings it into the electrical field.

C. S. VAN WAGONER.

This company, with a capital of \$750,000, has a large and thoroughly modern manufacturing plant at Cleveland, O., and is up-to-date in equipment and methods. The plant is new and embodies some remarkable features for economical manufacturing. It is situated most advantageously for the purchasing and handling of raw material, and for the delivery of goods to all important points. For many years the character of its product has been most favorably known; its goods have a high reputation. The company has long followed the principle of making a thoroughly good article and giving it a fine finish.

In taking up the manufacture of drop-forged commutator

the company, who, with Wm. H. Williams, founded the business in 1871. The mechanical and manufacturing part of the business have been particularly under Mr. Van Wagoner's care, together with all matters of general importance. Mr. Williams, until his death in 1895, had charge of the sales and financial matters. Mr. Williams was well known and valued in the hardware trade, and occupied a high position politically and socially in Brooklyn, N. Y.

DROP-FORGE BUILDING.

The Van Wagoner & Williams Hardware Company, in taking up this new article of manufacture, desires to become as popular, and as favorably known in the electrical trade, as it is in the hardware trade. The merit of this concern is a

PLANT OF VAN WAGONER & WILLIAMS HARDWARE COMPANY, CLEVELAND, O.

segments of pure lake copper, the large experience of this company in drop-forging generally has come into service. Recognizing that an unusual degree of accuracy is required in this article, and a high degree of conductivity, it has experimented in the preparation of the copper and in the methods of drop-forging, so that a bar of great excellence has been produced. It has made arrangements with one of the very largest concerns of the country to furnish special copper rods from which the bars are made. Skillful die-sinkers and hammermen are employed under the direction of an expert forgemaster of recognized ability. The result is that the commutator segments produced are superior in every way, especially in accuracy, conductivity and durability.

The illustrations accompanying this article show a general view of the plant, the exterior view of the drop-forge department, and a portrait of C. S. Van Wagoner, the president of

guarantee of a prominent standing among the users of the new line of goods.

A new catalog has just been issued by the Cincinnati Manufacturing Company which illustrates and describes the various types of ticket and conductor's punches made by this company. The design is neat and compact, so as to easily fit the hand, and there are no sharp corners to catch or tear the conductor's clothes. The improved unbreakable and interchangeable springs insure good service and long life. The movement and form of the plunger are such as to prevent wearing out the dies by abrasion. This punch is handsomely polished and nickel plated. A list of 207 die designs figures, letters and forms, single and double, are shown, which at all times are in stock. Special dies are also made to order.

### A NEW FLUX FOR CAST-WELDING.

I wish to thank Mr. King for his kind and courteous method of calling to my notice a misprint over my signature in the February Review.

He does not, however, properly locate the error, which consisted in printing 36 instead of 32, since the ratio between the conductivity of steel and cast iron observed in a sample joint was found, after letter was written, to be 2.25 to 1 instead of 2 to 1. I did not go far enough back in my corrections, but the calculations and conclusions are based on 32, and are, therefore, in no way vitiated by this substitution, which I ought to have detected, since I read the proof myself. The laugh at my expense has its compensations, nevertheless, since it has been the means of putting into my hands a flux discovered by Mr. Edison which, when properly used, will effect an almost perfect mechanical and electrical union between solid steel and molten iron poured around it. Another flux gives the same result when used between wrought and molten copper. I shall be glad to send a sample of either to any responsible firm having facilities for accurately testing the result. But I cannot permit the genial Mr. King to perform the "cuttlefish act," and escape from the point of this controversy in a meaningless cloud of his own ink.

He claims to believe in the "perfect conductivity" of a joint around steel rail ends without a flux. To justify his faith, he quotes three measurements on a single unused joint, but gives neither details nor means of verifying the same. Since these three measurements do not agree with each other, nor with results obtained from hundreds of measurements made on similar joints in service, I ventured to show up some of their inconsistencies. At the same time I suggested a perfectly fair method of settling the controversy by arbitration.

Mr. King's faith is strong enough to justify a liberal flow of ink, but it evidently goes no further. To give him a chance to prove his sincerity, I again suggest that he deposit with the editor of this paper sufficient to cover all expenses. The editor is then requested to select without measurement a "cast-weld" joint that has been in actual service with heavy current for two years in the track of some large road outside of Milwaukee or its suburbs.

Let this joint be sent to the electrical testing department of some prominent university and its resistance tested up to the full carrying capacity of the rail. I will then insert a plug of plastic alloy, and if, with similar tests, this material does not give results similar to those obtained by me at St. Louis, I will then pay all expenses of tests. But if he proves to be mistaken in his claims then his deposit is to be used to cover expenses incurred.

HAROLD P. BROWN.

### MUSICAL ATTRACTION FOR PLEASURE RESORTS.

Managers who are operating pleasure resorts in connection with their roads—and there are scores of them now—are constantly on the alert for good attractions. Experience has already shown that nothing is more universally popular than good band music, which catches everybody, old and young. Even where local bands can be contracted for at low rates for such service, the expense grows into the hundreds very quickly, and a resort must draw big crowds to

warrant such outlay more frequently than one or two days in the week. What comes the nearest to the full brass band, and which can be operated at no expense whatever, is the new band piano, the orchestron, manufactured by August Pollmann, 70 Franklin street, New York. The instruments are operated either by hand or  $\frac{1}{2}$ -h.p. motor, and is supplied with any choice out of hundreds of pieces of popular and operatic music. New cylinders are made as fast as new music is brought out, enabling the "band" to be always up to date. The instruments are well made, do not easily get out of order, and do not have to stop for liquid refreshments on hot days. They are already doing good work in a large number of resorts, and giving decided satisfaction.

### CAR HOISTING JACK.

The cut shows diagrammatically the car hoisting jack designed by C. B. Easty, superintendent of the shop of the Cleveland City Railway. The four screws are provided with nuts in the form of 30 in. sprocket wheels. A fifth sprocket wheel 20 in. in diameter is geared to a small motor as indicated, and drives the four jacks in unison through the chain shown. A capstan head is provided on the shaft so that the jacks may be turned by hand-bars. The screws are

supported in suitable sleeves, provided with splines to prevent rotation. Ball bearings are placed between sprocket wheels and the upper faces of the screw sleeves so that the friction is no greater than with an ordinary jack. All the mechanism is below the level of the floor, only the screws projecting through, and is for the most part at the sides of the car pit. This jack lifts the car body evenly and quickly and saves both time and labor, with only a small expenditure of power.

### H. W. JOHNS COMPANY'S NEW OFFICE.

On May 1 the H. W. Johns Manufacturing Company will leave its present quarters, occupied for 25 years past, and move into the ground floor offices of the new Woodbridge building, 100 Williams street, New York, where elegant quarters have been arranged. Ten years ago, on a small scale, the company began its sale of vulcanite for electrical purposes. This well-known insulating material with its exceptional heat-proof and mechanical properties, is now generally used in almost every kind of electrical apparatus, over 1,000,000 pieces of vulcanite having been sold to manufacturers of dynamos, motors, street car controllers, arc lamps, etc. In addition to this enormous number of pieces used strictly for electrical purposes, the company has sold tons of the "steam" vulcanite, used as packing in steam, gas, water, compressed air and other apparatus. The sale

of the moulded mica trolley line insulating materials has also greatly increased. The first overhead lines constructed in the United States were insulated with moulded mica; several hundred roads are now on the list.

The "H. W. J." electric car heaters have met with good sales the past winter and is a very promising feature of the business. The company extends a cordial invitation to its friends to visit it in the new quarters.

### A GOOD TROLLEY WIRE HANGER.

The accompanying cut represents a trolley wire hanger, designated as type D by the Ohio Brass Company of Mansfield, O. These hangers are made in all forms required for the different styles of suspensions, and ample allowance has been made in their design, so that they will support with safety the heaviest trolley wires in use. The body is of

malleable iron, and machined to fit the standard size of types D and D-W bolts. A special feature is that the hanger cap and insulated bolts are supplied with hexagonal nuts of the same diameter, and the wrench supplied is of proper size to fit easily over the nuts. Around the lower edge of the hanger cap is a series of lugs which may be riveted over and hold it securely in position. The company reports that this style of hanger is very popular, 9,000 having been ordered in the last two months.

### A DUPLEX RAIL BOND.

Realizing that a bond, of great cross-section, of minimum length, one that provides the advantages of double bonding

SIDE AND END VIEWS OF RAIL WITH BOND.

and can be protected by the fish plates was required, the New York Electrical Works designed, and now make a bond fulfilling these conditions. The illustrations represent the manner in which the bond is attached to the rails. The bond is made from drop forged or the new process pure cast copper, with the body of it corrugated to provide for any expansion or contraction in the rails. At either end of the bond are tubes or eyelets, as shown in the section. A hole of the same diameter is drilled in the end of each rail and the terminals inserted from both sides of the joint. A rivet is then driven through and upset as shown, thus expanding the tubular ends into the closest possible contact with the rails, and securing the bonds firmly against displacement. This operation is quite simple, and can be accomplished in a few minutes with a riveting outfit. In this way double conductivity is secured, good electrical contact assured, the fish plates protect the bond from mechanical injury and the joint is water and moisture proof.

### WALDRAN AUTOMATIC BRAKE HANDLE.

On March 20 the St. Louis & Kirkwood Street Railway made a public test of the Waldran automatic brake handle. After a trial of two months, all of the cars on this road were equipped with the new handles. As shown by the illustration the device is extremely simple, consisting of a ratchet on the upper end of the brake staff and a reliable trip. The dog is kept engaged by gravity only, no springs

being used; when it is desired to release the brake the motorman raises the handle slightly, thus releasing the dog, but need not at any time quit his hold on the brake handle. By this means both motorman and passengers who are on the front platform are protected from injury by the handle, when the brakes are released. Its few parts and positive action will commend it to street railways.

J. D. Waldran, the inventor entertained quite a large party in the special car "Rambler" when the demonstration above mentioned was given.

The Metropolitan Railroad Company, of Washington, has rewarded the faithfulness of its employes in a substantial manner. On inauguration day each man found a slip in his envelope stating that the company appreciated the energy, politeness and efficiency of the force and desired to thank each man for his efforts. One day's extra pay was in each envelope. President Harris is very popular with his men on account of his manifest interest in their welfare.

The Consolidated Car Heating Company has removed its Chicago office from room 208 to room 514 Western Union building.

C. F. Parker & Co., of New York, have received the contract to build the electric railway up Mt. Tom at Holyoke, Mass.

The Taunton Locomotive Manufacturing Company, Taunton, Mass., has recently put on the market a line of solid brass thermometer cups.

J. G. Brill & Co., of Philadelphia, have been awarded the contract by the Louisville City Railway Company to build fifty cars for August delivery.

The Garton-Daniels Electric Company, Keokuk, Ia., maker of the Garton lightning arrester reports that its business is booming and exceeds all expectations.

Partridge Carbon Company, Sandusky, Ohio, reports that business is good and improving. It has been a little behind on orders but is now in a position to fill at once.

The Pennsylvania Iron Works has been awarded the contract to build the engine for the great power station of the Consolidated Traction Company, of Pittsburg, Pa.

The White-Crosby Company, Baltimore, has been awarded the contract to convert the Blue line of the Baltimore City Passenger Railway from cable to electric.

The Schenectady Railway Company of Schenectady, N. Y., will purchase a good, large, second-hand merry-go-round. Proposals should be addressed to H. S. Cooper, superintendent.

The Chauncey Tapestry Company has purchased the manufacturing plant, merchandise, etc., of the Brussels Tapestry Company, Chauncey, N. Y., and will continue the operation of the works.

The Wells & French Company, car builder of Chicago, has established Frederick Saxelby as its eastern representative with offices in the American Surety Building, 100 Broadway, New York.

Richard Peters, Jr., has been appointed sales agent and C. L. Mahoney assistant sales agent for the Philadelphia office of the Pennsylvania Steel Company, with headquarters in the Girard building, Philadelphia.

A. D. Chandler has been appointed general western agent of the Cutter Electric & Manufacturing Company, of Philadelphia, with offices at 1114 Marquette building. Mr. Chandler expects to considerably increase the sales of the well known I. T. E. circuit breakers in the western territory.

The Jackson & Sharp Company, Wilmington, Del., has built and has now ready for painting, lettering and trimming, some standard 10-bench open cars which can be finished to suit on short notice for quick delivery.

The Sanitary Car Grip Company has been incorporated at Portland, Me., to manufacture straps for street cars. The capital stock is \$50,000, and the incorporators are Frederick B. Wentworth and Edwin W. Brown, of Boston.

The H. W. Johns Manufacturing Company, Chicago, has sent us recent catalogs describing its electrical materials, moulded mica insulators, sockets, etc., vulcabeston controller parts, electrotherms and "H. W. J." electric heaters.

The entire plant of the Laconia Car Company has been sold to Frank Jones, of Portsmouth and Edward H. Gilman, of Exeter, representing a new company with a capital of \$200,000 which will probably be increased to \$500,000.

Among the orders now going through the shops of the John Stephenson Company are 150 open cable cars for the Broadway line, New York; cars for Salt Lake City and nice orders for Ecuador and Mexico. The works are quite busy.

The J. W. Atkinson Company has been incorporated at Chicago to manufacture electric street railway and railroad supplies. The capital stock is \$20,000, and the incorporators are John M. Atkinson, Theodore H. Pletsch and George E. C. Johnson.

Fred C. Ley, of Springfield, Mass., who built the Bristol & Plainville Tramway, has been given the contract to build that part of the New Britain & Hartford line extending from the present terminus to Newington. The work is to be finished by May 15.

Col. N. H. Heft, chief electrician of the New York, New Haven & Hartford Railroad, has just purchased of the Washburn & Moen Manufacturing Company a large number of its "crown" rail bonds to be used on the new electrical equipment at Berlin, Conn.

The various improvements on tin rollers for car use that have been added by the Stewart Hartshorn Company have produced the natural effect of inducing more car lines, both steam and electric, to equip their cars with shades instead of the old fashioned wooden slat blinds.

The Brooklyn & New York Railway Supply Company, Elizabeth, N. J. reports its trade improving, and the register and bronze trimming departments quite busy. Cars are going through the shops for Plainfield, N. J., Brooklyn, Norwalk, Conn., with others to follow.

Russel & Co., Massillon, O., have recently been awarded several large contracts for their four-valve, medium speed, corliss engines, which are intended for street railway duty. Among the roads purchasing are the Pittsburg, Allegheny & Manchester, the New Paltz & Wallkin Valley, of Ulster county, N. Y.; the Detroit & River St. Clair, the Indianapolis, Greenwood & Franklin, and the Cleveland & Chagrin Falls. Future prospects are reported as very promising, particularly in the street railway line.

The Washburn & Moen Manufacturing Company has received the order from the N. Y., N. H. & H. R. R. Company for the rail bonds to be used in the new electric line from Hartford to Berlin. These are the stranded "crown" bonds of 300,000 circular mils and two to each joint.

The E. T. Burrows Company, Portland, Me., maker of the waterproof curtain material "oakette" has just issued a small pamphlet illustrating its screen factories, which are the "largest in the world." The company's large catalog, with samples, prices and testimonials, will be sent on request.

The J. G. Brill Company has just received an order for 10 new cars from the Niagara Falls & Lewiston Railroad. They are to be summer cars and supplied with every appliance for the safety and convenience of tourists. Automatic electric brakes of new design are being fitted to the cars.

The Dornier & Dutton Manufacturing Company, Cleveland, O., has recently sent to the trade a new catalog of its electrical railway appliances. Trucks for motor and trail cars, wheels, axles, sweepers, gears and pinions, heaters, roller bearings and various special machines for railway repair shops are illustrated.

In describing the equipment of the power house of the Union Traction Company, Philadelphia, which was destroyed by fire on March 3, we stated that Wetherill engines were used. There were also in the plant several 600-h. p. Westinghouse compound engines, two of which are shown in the view of the interior.

The Chase Construction Company, of Detroit, has been awarded the contract by the Lorain & Cleveland Railway Company, to put in the electrical work on the line now in course of construction between Cleveland and Lorain, O. E. P. Mann, formerly superintendent of construction for the Detroit Railway, will supervise the work.

The Paul O. Stensland Building, of Chicago, has increased its electric plant by the addition of a direct connected engine and dynamo, the engine being furnished by the Ball Engine Company, Erie, Pa., and the dynamo by the Jenney Electric Company, Indianapolis. This is the third direct connected outfit, furnished by the same companies, in this building.

The R. D. Nuttall Company reports a gratifying increase in orders, and for the past month has been compelled to work overtime to meet them. During all the months of depression the works ran full time, which, with the present report, would seem to indicate that goods of its manufacture, as well as the methods of doing business, meet with the approval of the street railway trade.

The Standard Air-Brake Company of New York reports an excellent business for March, and in addition to deliveries at home, secured several good orders from abroad, including one by cable for air-brakes for the Colonies. This company will make an extensive exhibit at the Brussels Exposition, which opens this month; the shipment made per the "Friesland" contained full working outfits for motor and trail cars, and will no doubt prove of great interest to street railway men in Europe. General Manager Wessels expects to attend the exposition in June.

The Edward P. Allis Company, of Milwaukee, Wis., has purchased the business formerly carried on by the Hercules Ice Machine Company and the Reliance Engineering Company of Aurora, Ill., and is prepared to supply repair parts on all ice and refrigerating plants erected by these companies, as well as to design new machines for refrigerating plants of from 1 to 500 tons capacity.

C. E. Loss & Co. of Chicago, have received the contract to build a street railway in Jalapa, Mexico. The road will connect the towns of Coatepec and Huatusco, near the port of Vera Cruz. A waterfall will generate power for the line, which will carry freight as well as passengers. The backers of the enterprise are J. B. Haggin of New York, and Gen. E. C. Frisbie of the City of Mexico.

The Sterling Supply & Manufacturing Company of New York has removed to the Lexington building, a fine new structure at 145 to 155 East 25th street, between Third and Fourth avenues. Here it occupies the entire third floor, the business having grown so fast that a division has become necessary of the special departments, of sand boxes, registers, brakes, fenders, and miscellaneous supplies for street railways.

The Cutter Electrical and Manufacturing Company has a printed check, with a small coupon receipt attached at one end, which saves correspondence and is very convenient. The check is made out to the creditor and signed by the president and treasurer of the Cutter company and on the detachable slip the amount paid is stated and to what account together with these words: "We send herewith our check in settlement of account as below. If found correct, the proper indorsement of the check is the only receipt required, The C. E. & Mfg. Co."

Graphite paints have received a very scientific recommendation from Professor Spennrath, Director of the Technical School at Aix-la-Chapelle. Experiments were conducted with various pigments and oils, covering a period of several years, and the results indicated that well made paints of graphite and linseed oil are the most enduring for iron work and surfaces exposed to the weather. The Joseph Dixon Crucible Company maintains that this report corroborates the claims that the silica graphite paints are superior to all others for this class of work.

The Sterling Supply & Manufacturing Company, New York, is now nicely established in its new plant, Nos. 141 to 155 East 25th street, and has a thoroughly representative establishment for the manufacture of general street railway supplies. President J. H. Carson reports business since the first of the year as very good indeed, having received a large amount of work from the Metropolitan Street Railway Company, the Nassau system of Brooklyn, the Richmond Traction Company and two or three systems in Canada. In addition to that there is considerable inquiry as well as some business from Europe. In general, the outlook is very satisfactory.

S. C. Strock, 50 Broadway, New York City, has received some large orders for poles, both for street railway and telegraph purposes. Recently, he secured the largest contract for manufactured yellow pine poles ever given. The American Telephone & Telegraph Company needed 8,000

taper poles from 25 to 55 ft. in length and this order was placed with Mr. Strock. The poles are to be of long leaf yellow pine, square cut and tapering from a large butt to one-half size at the top and creosoted throughout. Mr. Strock is well known in the electrical field, having been with the Thomson-Houston and General Electric Companies before going into the pole business.

The Ajax Metal Company, Philadelphia, is placing on the market its new patent interchangeable trolley harp, for which special claims are made as to simplicity, durability and cheapness; the new harps being sold for about 50 per cent less than the old style. They are made entirely of steel and malleable iron, and from practical experience by a trolley road in Baltimore, the average life is estimated at three years, without any cost for repairs. The company also has on the market its celebrated Ajax trolley wheels made of Ajax metal and which give exceptionally long life. A specialty is made of babbit metals for electric roads, attention being called to the uniformity of mixture and low price.

The Standard Air Brake Company of New York, through General Manager Wessels, has recently closed contracts with the Mason City & Clear Lake road, Iowa, for two special air-brake equipments for freight motor cars and seven trailers; also with the Norfolk & Ocean View road, Virginia, for equipment for freight and passenger car; also with the Richmond Railway & Electric Company, Richmond, Va., for supplying air brakes for its new cars. For the two first-named installations the "Standard" motor compressor type with automatic current controller will be used, and in the last-named the geared type compressor will be used, similar to those in service on the Akron, Bedford & Cleveland, and Washington, Alexandria & Mt. Vernon roads.

Greater attention is constantly being given to long distance transmissions and the results of high voltage on the equipment is watched with interest. The General Electric Company was gratified to receive the following letter from John J. Seymour, president of the San Joaquin, California, Electric Company: "It affords me great pleasure to write you regarding the successful operation of the Fresno long distance transmission plant installed for our company. The entire plant as furnished has been in actual, practical operation for a period of several months. The 35 miles transmission has given us no trouble whatever. Our load at present consists of 145 arc lights, 5,000 incandescent lights and 410 h. p. in motors, the latter including 180 h. p. for the Sperry Flour Mill and 75 h. p. for the city pumping plant. All of the machinery doing this work has worked with perfect success from the start."

The McGuire Manufacturing Company of this city is running all its departments full time and has on hand a very flattering number of orders for trucks and ratchet handles, and we understand has been awarded the contract for 200 trucks for the new Benton Harbor Electric Railway & Transit Company. It has finished delivery of 50 No. 26 pivotal motor trucks to McNaugle, Holcomb & Co., of this city, and is working on the following orders: Buffalo & Williamsville (N. Y.) Railway Company, People's Railway Company, Dayton, O.; Chicago City Railway Company, Frederick (Md.) & Middletown Railway Company, New Castle (Pa.) Electric Street Railway Company, Second

Avenue Railway Company, Pittsburg; Waterloo & Cedar Falls (Ia.) Rapid Transit Company. The company's foreign trade is steadily increasing and the outlook for business abroad this year is very encouraging.

The Weston Engine Company, Painted Post, N. Y., during the first week in April closed the following contracts: Masonic Temple Association of Detroit, for two 10x12 and one 6x8 Imperial engines, direct connected to Triumph generators; McCoy's Hotel, Chicago, 14x14, direct connected to Western Electric; Soldiers' and Sailors' Home, Xenia, O., one 12x12 and one 10x10, direct connected to Western Electric generator; Jacob Reed's Sons, Philadelphia, 14x14 and 10x10, direct connected to General Electric generators; Julian Scholl & Co., one 14x14, belted. Manager Hollister writes: "Business is improving with us every day, and we are securing all the work we can possibly handle with our present plant. We are running our plant from midnight Sunday night until midnight Saturday night, and working nearly 100 men in our machine department alone. We now contemplate the erection of another large building, probably 50x150 or 200 ft. to take care of our daily increasing business."

## RELIABLE SWITCHBOARD INSTRUMENTS.

The Keystone Electrical Instrument Company of Philadelphia has made some important alterations in the design of its switchboard instruments. This is the result of years of experience and careful study of the electrical principles and mechanical construction of voltmeters and ammeters.

FIG. 1.

The purpose was to get an instrument that would indicate correctly both direct currents and the virtual potential and amperage of alternating currents. Fig. 1 represents the "K" type of voltmeter, with and without illuminated dial.

Fig. 2 shows a galvanometer ground detector, which is very valuable in indicating the extent and on which side of the line the ground is located. These instruments are all carefully calibrated, and the scales are so divided that readings can be quickly and readily taken. The bearings are jeweled. There is no effect from change of temperature or external magnetization.

FIG. 2.

The instrument is dead heat, and there is no heating within itself. The moving parts are inclosed in a dust proof, handsomely finished case.

## PRUSSIAN ELECTRIC STREET RAILWAY.

We show a cut of the type of motor car which will be used on the Oberschlesische Dampfstrassenbahn system in Prussia, a steam road which is soon to be equipped electrically. The Standard Air Brake Company, through its continental agent, the Bergische Stahl Industrie, secured the contract for equipping 30 motor cars and 50 trail cars with its brakes, this type being specified because of the satisfactory results obtained in Leipsig, where one road has some 300 of these equipments.

These 80 cars will make a very handsome appearance, and in addition to carrying first-class passengers it will be noticed that there are compartments for second and third class passengers as well.

The Oberschlesische is a narrow gage road, 30 in., and as

## WATER POWER AND HIGH VOLTAGE IN SOUTHERN CALIFORNIA.

A new enterprise has been started which promises much for the street railways in Los Angeles and cities in that vicinity. The Southern California Power Company has been incorporated with a capital stock of \$1,000,000 to develop the water power of the Santa Ana river. The water is to be taken from the junction of Bear creek with the river and carried in a stone ditch and pipe line along the hills to the head of the Bear valley canal where it will be delivered to the turbines at a head of 1,100 ft. It is estimated that 10,000 h. p. will be developed and this is to be transmitted 75 miles to Los Angeles at a voltage of 30,000. San Bernardino, Pomona, Ontario and Pasadena will also be supplied. Henry Fisher of Pittsburg and H. H. Sinclair, president of the Redlands

MOTOR CAR—OBERSCHLESISCHE STEAM STREET RAILWAY.

there is no room on the axles for the axle-driven compressors, gearless motor-driven compressors are used. The motor compressor furnished is 16 x 24 x 18 in.; its location is shown in the cut. The hand brake staff is retained. Each car is equipped with four motors, one to each axle, of a specially narrow design. The weight of a train loaded is about 50 tons. The steepest grade is about 5 per cent, and the average speed contemplated about 16 miles per hour.

General Manager Wessels, of the Standard Air-Brake Company, is pushing a vigorous campaign, not only at home but abroad, and doing a vast amount of good work in making the value of air brakes understood and appreciated.

W. T. Van Brunt, general manager of the St. Joseph (Mo.) Railway, Light, Heat & Power Company, states that the cars on his lines make a daily average of 126 miles.

The Columbia & Western Railway Company is considering the feasibility of using electricity on the lines in British Columbia. Water rights have been secured in the vicinity of the road which can be used for water power in generating electrical energy.

Electric Light & Power Company are the leading spirits in the undertaking. The surveys have been completed and the specifications asking for bids on work and material are now ready. It is proposed to deliver power to Los Angeles by January 1, 1898. As this voltage is to be the highest in practical operation, its use will be watched with much interest.

## ALLEGHENY TAXES GROSS RECEIPTS.

An ordinance was passed by the Allegheny council requiring all corporations to pay into the city treasury a certain per cent of the gross income and for street railways this was fixed at four per cent. This was protested by the railway companies as being exorbitant. After considerable negotiation, Dawson Callery, president of the Federal Street & Pleasant Valley Passenger Railway Company, and Geo. B. Hill, president of the Pittsburg, Allegheny & Manchester Traction Company made a compromise with a committee from the council. The agreement is that the companies will pay two per cent of the gross receipts, amounting to about \$35,000 annually and promptly meet the payments for street paving for which suits are now pending.

# Removal Notice.

We beg to announce that we have removed from the Betz Building, to 10 So. Tenth Street, Philadelphia, where we have established a large and commodious warehouse. We now have in stock a full line of material manufactured by the well-known Companies we represent, together with a Full and Complete Stock of Electric Railway Material and Supplies for immediate shipment. Our facilities for handling our rapidly increasing business are now strictly first-class.

MAYER & ENGLUND,  
10 South Tenth St. Philadelphia, Pa.

WRITE FOR LATEST PRICES. IMMEDIATE SHIPMENT FROM STOCK.

## Directory of Street Railway Associations.

### American Street Railway Association.

President, R. McCULLOCH, St. Louis, Mo.; First Vice-President, C. S. SEROANT, Boston, Mass.; Second Vice-President, D. B. DYER, Augusta, Ga.; Third Vice-President, C. F. HOLMES, Kansas City, Mo.; Secretary and Treasurer, T. C. PENNINGTON, Chicago, Ill. Executive Committee: H. M. LITTLE, New York; H. P. BRADFORD, Cincinnati, O.; C. H. SMITH, Troy, N. Y.; H. SCULLIN, St. Louis, Mo.; G. B. HIPPER, Des Moines, Ia.

Next meeting, Niagara, N. Y., third Tuesday in October, 1897.

### New York State Street Railway Association.

President, G. TEACY ROGERS, Binghamton; First Vice-President, W. CASYL ELY, Niagara Falls; Second Vice-President, JOHN N. BECKLEY, Rochester; Secretary and Treasurer, H. A. ROBINSON, New York. Executive Committee: H. H. VRESELAND, New York City; JOHN W. McNAMARA, Albany; H. M. WATSON, Buffalo, C. L. ROSSITER, Brooklyn.

Next meeting, Niagara Falls, first Tuesday, September, 1897.

### Ohio State Tramway Association.

President, A. A. ANDERSON, Youngstown; Vice-President, T. R. CATLIN, Canton. Secretary and Treasurer, J. B. HANNA, Cleveland; Chairman Executive Committee, W. F. KELLY, Columbus.

Next meeting, Columbus, June 15, 1897.

### Pennsylvania State Street Railway Association.

President, JOHN LLOYD, Altoona; First Vice-President, ALBERT JOHNSON, Allentown; Second Vice-President, ROBT. E. WRIGHT, Allentown; Secretary, S. P. LEIGHT, Lebanon; Treasurer, W. H. JANUS, York. Executive Committee, JOHN LLOYD, B. F. MYERS, S. P. LEIGHT, JOHN A. HIGG and E. C. FELTON.

Next meeting, Allentown, first Wednesday in September, 1897.

### Michigan Street Railway Association.

President, W. L. JENES, Port Huron; Vice-President, W. WORTH BEAN, St. Joseph; Secretary and Treasurer, B. S. HANBETT, Jr., Grand Rapids; Executive Committee, OFFICERS OF THE ASSOCIATION and CHAR. M. SWIFT, Detroit, and E. E. DOWNS, Kalamazoo.

### Massachusetts Street Railway Association.

President, PRENTISS CUMMINGS, Boston; First Vice-President, P. F. SULLIVAN, Lowell; Second Vice-President, JOHN R. GRABAM, Quincy; Secretary, CHAR. S. CLARE, Boston; Treasurer, W. F. POPE, Boston. Executive Committee: E. P. SHAW, Newburyport; E. C. FOSTER, Lynn; CHAR. B. PRATT, Worcester; G. H. CAMPBELL, Lawrence, and S. M. THOMAS, Taunton. Auditing Committee, J. N. AKARMAN, Worcester; C. S. SEROANT, Boston, and ROBERT S. GOFF, Fall River.

Meetings are held every month.

### Connecticut Street Railway Association.

President, H. HOLTON WOOD, Derby; Vice-President, HENRY S. PARMELEE, New Haven; Secretary, E. E. BRADF, New Britain; Treasurer, E. S. GOODRICH, New Britain. Executive Committee, A. L. YOUNG, Waterbury; E. I. RAEL KILBY and A. W. DODGE.

### Texas Street Railway Association.

President, CARL F. DRAKE, Abstin; Secretary and Treasurer, C. L. WAREFIELD, Dallas. Executive Committee: The OFFICERS and GEO. B. HENDRICKS, Fort Worth, and A. H. HAYWARD, Houston.

Next meeting, Austin, third Wednesday in March, 1897.

### The Maine Street Railway Association.

President, W. R. WOOD, Portland; Secretary and Treasurer, E. A. NEWMAN, Portland. Executive Committee, W. B. WOOD, Portland; H. TWITCHELL, Bath; A. F. GERRARD, Waterville; J. HYNES, Augusta; G. E. MACOMBER, Hockland; E. H. BANKS, Biddeford; E. K. DAY, —; F. N. LAUGHTON, Bangor; F. W. DANA, Lewiston.

Next meeting, February, 1897.

### The California Street Railway Association.

President, CHAR. F. CROCKER, San Francisco; Vice-President, S. B. McLENNAN, San Francisco; Secretary and Treasurer, J. E. MORRIS, Oakland. Executive Committee, E. P. VININO, San Francisco; F. W. WOOD, Los Angeles; L. WREKLER, Alameda.

Next meeting, third Tuesday in April, 1897.

# 20th CENTURY FEEDER WIRE.

WE MANUFACTURE THE BEST GRADE OF WEATHERPROOF WIRES, RUBBER WIRES, LEAD ENCASED CABLES AND ALL OTHER KINDS OF INSULATED WIRES.

NEW YORK STORE, 136 LIBERTY ST.  
D. G. SCOTT, MANAGER  
CHICAGO STORE, 19 S. CANAL ST.  
TESCHEN-MACOMBER-WHYTE CO., AGTS.

FACTORY: SAYLESVILLE, R. I.

invention is bound to fill a niche in mechanics and the most conservative manufacturer, capitalist or expert should see the model. Address

D. J. SINCLAIR, Caledonia, Livingstone Co., N. Y., U. S. A.

## DRAUGHT PERFECT.

New because radically unlike any other. Great because the same drawhead allows a flexible, rigid, direct-slack, long-link and short-link coupling, and will couple automatically with all of them, it can therefore be used in nearly all kinds of lifting, holding and drawing, and specially adapted to the use of Trolley Cars, Traction Engines and Field Artillery. A full size working model with attachments will be on exhibition the third Wednesday of each month at No. 303 Ellicott Square, Buffalo, N. Y. American, Canadian, British, French and Belgian patents on royalty or outright. This

Patentee and sole owner of these patents.

## A RAILWAY MOTOR FOR HEAVY SERVICE.

The accompanying cut represents a G. E. 51 railway motor which has been specially designed for high speed suburban and elevated railway work. It has a capacity of 80 h. p., rated according to the standard basis of a rise of 75° C. above the temperature of the surrounding air after a run

G. E. 51 RAILWAY MOTOR.

of one hour at rated load. A considerable range of speed can be attained by different gear reduction combinations. For high speed work a reduction from 1 to 1.74 can be used and two motors of this type will drive a train of 25 or 30 tons at speeds up to 45 or 50 miles an hour. For snow plows, freight locomotives and slow speed work this style of motor can be satisfactorily used with larger gear reductions. In general appearance the motor resembles the G. E. 1,000. The field frame consists of two steel castings parted, horizontally but extended back to envelop the car axle, and when closed makes the motor dust and water proof. A large opening is provided, allowing easy access to the motor for the adjustment of the brushes and the inspection of the interior. A hand hold is provided in the bottom of the frame for the removal of any refuse that may accumulate there. The axle bearings are of ample dimensions and lubricated from wool waste packed in the oil reservoir. The armature bearings are adjustable, set screws at the bottom being used to raise or lower the armature. The armature, commutator and brush holders are of the standard G. E. type.

## AUTOMATIC CIRCUIT BREAKERS.

It is now recognized that fuse wire does not furnish adequate protection against short circuits, overloads or lightning, and automatic magnetic circuit breakers are a necessity in any well designed station. The illustrations show the latest, improved circuit breakers, closed and open, made by the Automatic Circuit Breaker Company of Newaygo, Mich.

This instrument can be regulated over a considerable range of current and is guaranteed to operate within one per cent of the set capacity. When the current exceeds the pre-arranged amount a magnetic armature strikes a sharp blow,

releasing a catch. This permits a spring in the dash pot to act and by a hammer-like blow the break frame is struck and the circuit broken. The action is instantaneous and saves the machines and instruments from any serious effects of an excessive current in the circuit.

The Railway Material & Tool Exhibit Company has a new office in the Great Northern Building, Chicago, where those interested either in steam or electric railway appliances are always welcome. Material and equipments are on exhibition and catalogs are issued at intervals giving an account of the machinery and appliances. The rooms are in a convenient location, and visitors will find the manager ready at all time to show and explain the exhibits.

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supply or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that supply. We make no charge for publishing such notices in our DAILY BULLETIN.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 7. MAY, 1897 NO. 5

CONNECTICUT has passed a law which compels suit, to be brought against street and steam railways, or notice of suit to be brought later, to be served on the company within four months of the date of accident or death. This is a good law, and while working no hardship on any legitimate claimant, will go a long ways toward reducing the number of fake-injury suits which are the bane of transportation companies. A company obviously stands very little show to secure witnesses who might have been on a car one or two years previous, for of course in the fake cases the conductor has put in no report. It often occurs that the conductor who was in charge of a car on a certain trip two years ago has left the company, and no one knows where he has gone. Four months will be quite bad enough in these fraud cases, but a great improvement on the several years as still in force in many states.

SECRETARY PENINGTON, of the American Street Railway Association, has already issued the official notice of the October meeting at Niagara Falls. Assignments have been made for the eight papers which will be presented, and are in the hands of very strong committees. The subjects are all good, and include such 20th century questions as municipal ownership, gas engines in power

houses, and long distance transmission. In this connection we cannot refrain from reminding our readers that companies may join the association at any time during the year, and that the membership ought to be double what it is. The arrangements for exhibits promise to be good, although at this writing the local committee at Niagara which has the space in hand, has issued no plat of ground floor, or made assignments of space to applications, some of which have been on file now nearly seven months. The size and arrangement of the building were determined on long since, and if the committee at Niagara appreciated the anxiety of exhibitors to know at the earliest date possible, the shape and location of their space, it certainly would give this matter the attention it deserves.

ON another page will be found a notice that the Cincinnati Street Railway will in the future refrain from insuring its property against fire. This was brought about by the short sighted action of the insurance companies in raising the rates, and also by the insertion of arbitrary and unjust conditions in the policies. In all probability the example of the Cincinnati company in effectively resisting these demands will be followed by the street railways in other cities where the same or similar conditions exist. Unfortunately this course is only permissible with those companies which are large enough to carry their own risks, but for the most part it is only in the large cities that these important differences between the underwriters and the insurers arise. Not long since, however, the REVIEW published an account of a small road which had been obliged to cease operations because of the arbitrary rulings of the local underwriters.

THE X-rays promise to be of great and unequalled service in a certain class of damage claims. We refer to fraud claims, fake accidents and the like, of which in many cases the claim department is certain, but heretofore found it a very difficult matter to prove. Such a case was recently worked on the City & Suburban, of Baltimore, but the company's adjuster cleverly exposed the swindle by causing the claimant to sit for an X-rays photograph of his alleged broken arm. The startling result caused a drop in estimated damages from \$2,000 to \$25 on the part of the attorney for the plaintiff, while the injured (?) party hastily left town to avoid arrest, taking his arm with him. The suggestion of possibilities to claim departments in employing this method to determine the actual facts in such cases is highly promising of good results, and will gladly be accepted by companies. An account of this interesting case is given in detail in this issue.

Too many companies, like individuals, begin at the wrong end when planning to reduce insurance charges by the employment of precautionary measures. Some go ahead and erect a building with little or no regard as to the arrangement and location of oil rooms, heating apparatus, etc. After the building is up they consider

the installation of sprinklers, extinguishers and similar devices. In many cases the advantage gained by such means, and for which allowance is made by insurance companies, does not begin to equal what would have been allowed on different and no more expensive construction without the extra expense of fire apparatus. We have in mind a case to which our attention was called a few days ago of a manufacturing plant. The owner spent several months and some hundreds of dollars dictating the layout of his new works before turning his plans over to the architects. But he so carefully studied the matter, and finally arranged his danger points in such a way, and by erecting mill construction, he secures a rate of about \$500 per annum on \$250,000, where ordinarily, and in his old works the rate was \$2,500 per annum. The amount of money saved in a long term of years is readily seen to be quite important. While our power house construction, as now practiced, is practically fire proof, and does not admit of marked improvements, there is abundant opportunity for study in car house building, and in the erection of new depots managers will do well to give this subject the most careful and thorough investigation.

THE collision of a trolley and steam train at Tampa, Florida, in which one passenger was killed, and two others seriously injured, should be a lesson to the managers of roads operating without conductors. The car was left running at a slow speed while the motorman went to the rear to collect fares. An altercation occurred over change, and while two passengers and the motorman fought it out, the car reached a steam road crossing just as a train approached, and a terrible accident resulted. Strangely enough the man killed, and the one most seriously hurt were the ones who had the motorman down on the floor. It is practical to operate some lines with only one man in charge, but cars should never be allowed to move while that man is away from his controller.

THE most serious accident of the month and the worst in some time, occurred at Portland, Oregon. A car with thirty-four passengers was descending a grade when the brake failed to work. When some distance from the accident the motorman jumped. The conductor did his best to stop the car which was now running wild but failed, and at the foot of the grade at the entrance to a sharp curve the car jumped the track, and passing on went through a bridge into a slough, resulting in the death of three and severe injury of nearly all the other passengers. The cowardly action of the motorman cannot be too deeply censured, for no man should accept a position where the lives of others are entrusted to his keeping, who is not willing to stand by his post to the last. His behavior at the critical moment of danger is in marked contrast to others who in similar positions have remained on the front platform to the last, several even at the loss of their lives, thus proving themselves as true heroes as ever fell in battle.

WE direct the special attention of intending exhibitors at the next convention of the American Street Railway Association to that portion of the secretary's announcement which refers to the appointment of a representative to superintend installation. It was through the efforts of the REVIEW exclusively that the opinions of a large number of leading exhibitors found expression in the article published last December. The executive committee has most courteously recognized those requests, and promised to recognize, subject to the committee, whoever the exhibitors may unite upon. Now let the exhibitors make their plans for a superintendent of exhibits, bureau of information, or whatever he may be termed. Of course, the principal work of installation will, as heretofore, be conducted by the exhibitors themselves, but it will be a great help and a big saving of expense for such an officer to get on the ground early, secure sufficient and competent teaming and carpenter forces, etc., and at prices which are right. The functions of such an official were fully explained in the December article referred to above. We hope to see the matter taken up at once.

#### THE HUMPHREY BILL.

The now celebrated Humphrey bill will probably be called up for its second reading in the Illinois legislature about the time this reaches our readers. No bill in years has aroused so much hostile expression in Chicago as this, and much of the work of the opposition would put to shame that of ward heelers of the most unblushing type. In the name of "reform," business men are standing shoulder to shoulder with boodle aldermen of the worst class, and using every effort to assist these parasites to gain their desired ends. The daily press has been the willing tool of these same politicians, and has fairly exhausted itself in printing columns of lies. Two illustrations will suffice; the dailies came out simultaneously with the startling discovery that the bill as framed called for a payment of percentages on "gross earnings" which they thereupon proceeded to prove was what would be left after paying all operating expenses, interest, dividends, taxes, insurance, and anything else the company might incline to do, and that the percentage would be figured on what was left; admittedly not very much. We need not comment on this. Another scheme was a great furore over an alleged case of attempted bribery, to a man said to resemble a senator and who was occupying his seat while the senator was absent on committee work. The canard was a fake of the thinnest kind, but was given columns and deceived many people. Some aldermen went so far as to print slanderous posters calling certain legislators thieves, and posted these on bill boards in the district from which the member assailed was elected. One man is already defending a libel suit for \$50,000 as a result. If one-half the anarchy now preached from public platforms and pulpits in this city by people who ought to know better, had been talked by workmen, the public would have asked for police interference and had the meetings stopped. When a prominent politician on the recent "reform" ticket addresses a meeting and urges his hearers to use a rope and the first handy lamp post because men with good reputations and understanding the bill have seen fit to favor it, little remains

to be said as to the position occupied by the frantic and misguided opposition. The bill is a good one and ought to pass, even if the value of a seat in the Chicago city council is greatly depreciated in consequence.

Ex-Governor Altgeld has frequently been accused of strong anarchistic tendencies, but even he, from a public platform in this city, at one of the "reform" meetings, gave expression to the following strong language:—

I tried to get all the light I could two years ago; tried to see if there was something I could suggest that could solve some of these great problems. The corporations, on the one hand, said: "Why are we literally eaten up at home. We have to defend ourselves every week in the year against almost every man that holds office. We want to look somewhere else for protection. We do not wish to be bled 365 1/4 days in the year. We would like at least to have rest on Sunday." And they are right. They are right.

These great interests, these great corporations, are entitled to protection on the one hand. I had almost reached a point two years ago where I would have winked at monopoly, provided I could have felt that there is a strong, powerful agency of the law standing between the public on the one hand and monopoly on the other.

The railroad people claim we have no adequate law for organizing elevated railroads; that we have no adequate protection to offer to street railway companies against the constant intermeddling of the local city council. They say it affects the value of their security; that they cannot tell from one month to another where the next attack is coming from, and they claim that they should have reasonable protection.

Let us try to follow the line of justice. Let us hear in mind that these great interests have rights. Let us also recognize the fact that they have been seriously and frequently abused, that they have been bled at almost every pore, and not for the benefit of the public either

## CAR WHEELS FOR BALLAST.

Mention has been made in the REVIEW of the dinkey motor cars or locomotives that are used on the North and West Chicago Street Railroads for hauling trailers on electric lines which branch off from cable lines. They are simply short motor car trucks, equipped with two G. E. Soo motors, and surmounted with a motorman's cab. The past winter these dinkeys have had their traction increased by the weight of six old car wheels, making in all about a ton of weight added. These wheels are put in diagonally opposite corners of the cab. As the motorman expressed it, "It makes her stick."

## TROLLEY IN CALCUTTA.

J. W. Maples, managing agent of the Calcutta Tramways Company, Limited, advises us that it is contemplating a change to electricity from the steam and horse power now in use. The general plans have been decided upon, but the details have not all been worked out as yet. The track to be changed covers 20 miles of streets, all double track except one section. The overhead trolley system will be used, the generating plant to be operated by steam. The cars at present running are 150 two-horse cars, seating 40 passengers, and 36 one-horse cars, seating 25 passengers.

The present law of Iowa prohibits street railways from having a bonded debt of more than \$16,000 per mile of track. President Polk, of the Des Moines City Railway, appealed to the senate corporation committee to make such alterations in the law that the street railway companies may bond their roads for \$25,000 a mile on paved streets and \$15,000 a mile on unpaved streets.

## COST PER CAR-MILE

vs.

## COST PER PASSENGER.

### A Symposium.

That there is abundant work for the Accountants' Association is evidenced by the diversity of opinions as shown in the following symposium. The replies are in answer to the inquiry, "Which affords the better comparison, the cost per car-mile, or the cost per passenger?" As will be apparent from reading the opinions offered, the widely varying local conditions have very much to do with determining the verdict, whether or not any given figures in either case are high or low for that road, even though in comparison with other roads a wide difference is shown.

### P. V. Burington, Secretary and Auditor, Columbus, (O.) Street Railway.

The question of computing cost of operating street railways on the basis of cost per car-mile, or cost per passenger, is in many respects a perplexing one. Allow me to present the following argument, in the hope that it may be of service in discussing this matter:

We will start out by assuming that mileage and operating expenses are the two more stationary items of account, while the number of passengers carried varies according to conditions of weather, trade or special attractions, and under these conditions may either increase or diminish to a marked degree, at the same time no more or no less cars were run or mileage made, and practically no additional expense or reduction of expense incurred. If more than the usual number of passengers were carried, we have an increased earning per car-mile; if a less than usual number, then a corresponding decrease per car-mile. In one sense this is a matter of profit and loss while the matter of expense is largely fixed by car schedules, and general operation maintained, whether few or many passengers are carried.

If we compute the cost of carrying by the passenger, instead of the car-mile, we do so with varying conditions of travel as a basis and obtain a result corresponding with these conditions; in other words, if a large number of passengers are carried, we show small cost per passenger, and if a small number, a large cost. As an instance; the month of December in a preceding year may have been a month of storms of sleet and snow and severe cold, by which business was seriously obstructed and persons used the cars only as necessity required, yet not so severe as to prevent about the usual schedule mileage. In this case we would have the usual mileage over which to distribute the increased operating expense, if any, amounting we will say to only a fraction of a cent per car-mile; whereas, by the passenger method we would have the probable increased operating expense to distribute over a decreased number of passengers, and, instead of showing only a fraction increase as in

P. V. BURINGTON.

the case of the car-mile, the difference would be many fractions.

Now, assuming that the same month of the year following to be on an open one, with large regular and holiday travel, and with no special increase in operating expense, what possible value could be placed on the passenger comparison thus obtained? Let me give assumed months and figures to illustrate:

PER CAR-MILE.		
	December 1896.	December 1895.
Miles run.....	371,400	371,400
Earnings.....	\$63,000	\$49,500
Earnings per car-mile.....	.170	.133
Operating expenses.....	\$33,000	\$35,200
Operating expenses per car-mile.....	.088	.095
Net.....	.082	.038
Decreased expense 7.4 per cent per car-mile.		
PER PASSENGER.		
	December 1896.	December 1895.
Passengers carried.....	1,400,000	1,100,000
Earnings.....	\$63,000	\$49,500
Earnings per passenger.....	.045	.045
Operating expenses.....	\$33,000	\$35,200
Operating expenses per passenger.....	.024	.032
Net.....	.021	.013
Decreased expense 25.0 per cent per passenger.		

The per cents in these two cases tell the story. In the one case the earning per passenger does not vary, the cost only being affected; while in the other case both earning and cost per car-mile are changed, relatively, as earnings and expenses are high or low.

When it is considered that the investor is constantly watching the more important question of expenses as a matter that can be more or less adjusted to meet times of varying earnings, and that he as well as we know that the number of passengers carried cannot be adjusted to our pleasure, is it not better for us and fairer to him that our comparative showings be based on the method less seriously affected by fluctuations? The number of people carried we cannot materially change, but the true operating expense we can keep from dancing about like water on a hot griddle.

#### J. M. Smith, Comptroller, the Toronto Railway Company.

In reply to your question I will say that in my opinion the best expression for comparison would be "cost of operating per mile run," for while "cost per passenger carried" would enable a comparison being made between companies (everything else being equal), it would not answer where a company is making comparisons by routes, which I think every company should do, especially so far as earnings are concerned, that they may always be in a position to tell whether or not there are more cars running on any route that the earnings of such route would warrant.

To illustrate what I mean take two routes, No. 1 route has 15 cars, while No. 2 route has 16, both earning \$500 per day, the average per passenger being the same in both cases, but owing to the difference in the mileage No. 1 route earns 25 cents per mile run, while No. 2 earns only 18 cents. This shows at once that No. 1 could stand another car better than No. 2. The same rule applies to the maintenance of tracks, pavements, overhead wires, poles, etc. No. 1 route being shorter than No. 2, will of course cost less to keep up, while if figured by the passengers carried, the routes would

appear to cost the same to maintain. I think, therefore, as it is necessary to make certain comparisons on the mileage basis, that the best term to use is "cost of operating expenses per mile run."

#### F. R. Greene, Secretary, Chicago City Railway.

Replying to your question I will say that I am of the opinion that the "cost per car-mile run" is the best expression for comparison.

One road might carry twice as many passengers as another, both having nearly the same mileage, yet the latter road might not be able to reduce its mileage, owing to certain conditions, and the comparison in this case on the basis of "cost per passenger carried" would be unfair. However, it is difficult to make a fair comparison between a small road and one doing a large business on either of the above expressions, as allowances must be made in either case for different conditions, such as long hauls vs. short hauls; heavy traffic vs. light traffic, etc.

I think the better plan would be to compare the "cost per car-mile run," together with the "receipts per car-mile."

#### F. S. Barton, Secretary, Akron, Bedford & Cleveland Railroad.

In reply to yours as to expression concerning the advisability of computing cost on car-mile run, or passenger carried, I would advise you that our people are interested in a good many lines, and they are persistent searchers after valuable statistics, and in every instance the records are kept, figuring cost on car-mile run.

Many arguments in favor of this course could be produced, but there are none more convincing than that while, on two successive days, the actual expense of operating a line may be exactly the same per car-mile, yet the weather may so affect the travel that it will cost two or three times as much per passenger. Take Saturdays and Sundays, for instance, on our suburban lines, the numbers of passengers carried are very greatly in excess of the other days in the week, and yet the expense of operation is practically the same. In other words, a cost figured on the passenger basis would be extremely variable and affected by a number of outside influences, such as weather, temperature, holidays, special parties, etc.

#### H. M. Sloan, General Manager, Calumet Electric Railway, Chicago.

You ask my opinion as to what gives the best results for comparison: "Cost per car-mile," or "Cost per passenger carried."

I will state that I believe entirely in figuring results per car-mile run. I think this way certainly gives fairer results for comparison than any other. Figuring the cost per passenger enters too largely into the question of receipts. It is true it would fairly tell whether or not the road was making money, but it would not give the results of operating so clearly as the cost per car-mile. It is a well understood fact with all railway managers that the larger roads doing a heavy business do not operate so cheaply as the smaller roads. I think this is taken into consideration when making comparisons. Take as an example any one of the large roads of Chicago. Their cost of carrying a passenger would be ridiculously low as compared to a small road, which would show a ridiculously high figure, and from neither one could you tell whether either road was operated cheaply or not.

In conclusion, I will say, that in figuring the cost per passenger there enter into the subject two separate and distinct elements which are impossible to separate except by reference to other figures, while in figuring cost per car-mile there is but one element that enters into the construction of the result.

**Both Figures Are Necessary. (Name withheld by request)**

My opinion is that both "operating cost per mile run," and "cost per passenger carried," are required in order to make an intelligent comparison between companies; and that in addition the capital per mile or per passenger carried, or both, are also required; and as to whether you should use either solely would depend upon what you wanted to prove.

To illustrate: One company may average to carry 10 persons per car-mile run and another, 7 persons per car-mile run, both operating under precisely the same expenses, yet in the case of the latter company, the cost per passenger carried would be 43 per cent more than in the case of the former company.

In the case of the former company it may be required to pay a percentage of its gross receipts to the municipality and the municipality of the latter company may say that it, too, should and could pay because its operating expenses per mile run were exactly the same as in the case of the former company.

Or the positions of the companies may be reversed, the latter company paying a percentage of its receipts to the municipality, yet it would not follow that the former could do the same. The latter company may have unpaved tracks, and may not have been called to construct bridges and bear other onerous burdens and as a result could earn as great or greater percentage on the capital invested, notwithstanding that the cost per passenger was more.

I should use all of the above elements in making comparison, and should go further with reference to rates of wages, rates of speed, cost of fuel, winter expenses, etc.

**J. C. Hutchins, Vice-President Detroit Citizens Street Railway.**

I would say, that the "operating cost per passenger carried" affords a better and fairer comparison than the "operating cost per mile run." The "operating cost per mile run," may mean nothing, for the reason that such cost may at any time be reduced by useless mileage; while the cost per revenue passenger carried, surely indicates the real cost of operating.

**Wm. R. Avery, Auditor, Cincinnati Street Railway.**

No two companies operate under the same conditions. The different divisions of the same company differ in results. The bad goes with the good. The management, familiar with these variations, may need mileage figures which only an expert can safely use. Made use of by experts in the employ of the company, they are useful in determining value of cars, motors, wheels, power plants, generators, etc., for private information of manager or engineer. To the stockholder, general public, or even officers of other companies, they are confusing and misleading.

Many "expert accountants" have used mileage comparisons as the devil fish slings ink—to obscure and cover actual conditions.

Steam railroads have a fare per passenger per mile; street railways have a fixed fare—say five cents—for any distance, be it one mile or 15 miles. What the investor or officer wants to know is, "What have you done with this nickel and how much of it have you saved to pay dividends?"

Determine also what a car-day shall be in your calculations. We say 18 hours. Have statements show earnings and expenses per car-day (or car-hour), also per cash passenger, and let them know how many transfers you had to carry, increasing cost of carrying passengers, or other information, explaining increase or decrease, leaving out all misleading and confusing mileage calculations. The interested parties will then understand your figures and quickly determine whether their investment is properly and profitably managed.

The Cincinnati Street Railway Company is owned by its stockholders, having practically extinguished its bonded debt. It must make a certain net earning per passenger to pay its dividends. As before stated they want to know what became of the nickel; the quarterly dividend checks sent our stockholders represent the net earnings.

Our officers approve my statement that the income being per passenger paying fare, the cost of carrying should be given on the same basis.

**E. D. Hibbs, Auditor, Consolidated Traction Company, New Jersey.**

You ask my views on the question which is the better basis for comparison, the operating cost per mile runs or, "the operating cost per passenger carried." I beg to say that my opinion is probably a biased one, from the fact that I have used the "per car-mile" basis for a large proportion of the comparisons furnished from my office, and in ninety-nine cases out of a hundred, special requests for information will specify the "per car-mile" as a basis. The majority of electric roads in operation to-day are in a measure regulated by provisions in their franchises which compel them to give a more or less short headway, and these limitations are made regardless of the number of passengers to be handled. These provisions compel the running of a certain number of car-miles between certain hours and as it is compulsory upon the company to perform the service, the question naturally arises, "How can the requirements be met most economically?" The pay roll expense is virtually the same whether you haul two passengers or whether you haul 20, the only difference being in the time consumed in stopping and starting, to load or unload the smaller or larger number of passengers. Assuming two different lines of cars running on the same headway, say 10 minutes, under the same conditions so far as equipment and platform expenses are concerned, covering a distance of six miles for the round trip, one of these lines handling 20 passengers, the other 60 passengers, the cost of operating these two lines would be to all purposes the same, say 72 cents, the cost of operating per car-mile would be the same for each line, about twelve cents; the cost of operating per passenger carried, however, would be vastly different, in one case 3.6 cents, in the other 1.2 cents.

The different ways of handling transferred passengers by the different lines also makes a "per passenger carried" basis a very unsatisfactory one. In some cases the transferred passengers are registered; in others they are not registered and only original passengers from whom cash fares or tickets are received are registered, and as the register is the source from which the number of passengers car-

ried is arrived at, two lines actually carrying the same number of passengers would show a very widely different result.

One other phase of this subject presents itself to me. One line equipped with 25-ft. cars, capable of seating 36 passengers is compared with a line equipped with 18-ft. cars with a seating capacity of 22. The "per passenger carried" cost of operating the smaller cars would be very much greater than the cost of operating the larger cars, while as a matter of fact the cost of operating per car-mile run is very nearly the same; the cost of maintaining the car and track and the power consumed would be slightly more in the case of the larger as compared with the smaller equipment.

These are some of the reasons why I am inclined to favor the "per car-mile" basis.

(Continued next month.)

## RIGHTS OF STREET RAILWAYS IN WISCONSIN.

For some time past a dispute has been pending between the Chicago & Northwestern Railroad and the Milwaukee, Racine & Kenosha Electric Railway in regard to the latter crossing the tracks of the former in South Milwaukee, and the matter finally reached the Supreme Court. The decision handed down by Cassody, C. J., discusses the question of whether the construction of an electric line in a street constitutes a new burden on the abutting property, and it is held that while a mere street railway for the transportation of passengers only does not necessarily impose a new burden, a railway carrying freight does, and must make compensation to or obtain the consents of abutting owners. The mere difference in motive power is not sufficient to relieve the street road from the obligations imposed upon a steam road under similar circumstances.

In part the court says:

"A mere street railway for carrying passengers only as the statute prescribed under which the Harbart case was decided would greatly relieve the streets of a city or village from travel and hence would to that extent facilitate travel on foot or by carriage. Such street railways, under the decision in that case do not necessarily constitute an additional servitude or burden for which abutting property owners are entitled to compensation. The same would to some extent be true as to the suburbs of the cities and villages. But the principle has no application to the country towns between Kenosha and Milwaukee. The several amendments to the revised statutes purposely omitted the word 'only' and added 'freight,' and also added the words 'other power' as well as horse power. In other words, the manifest purpose of the amendments was to authorize the construction and operation of commercial railways upon such streets and highways without consent of or compensation to abutting owners.

"The charter of the defendant company contemplates the construction and operation of such commercial railways between Milwaukee and Kenosha, which, of course, on the same theory, might be extended to Chicago. That such commercial railway upon public streets and highways, engaged in the carriage and transportation of merchandise, personal baggage, mail and express matter, as well as passengers, would tend to obstruct and interfere with the ordinary uses of a street or highway would seem to be quite

manifest. Such use of streets and highways constitute, in our judgment, an additional servitude or burden on the lands of abutting owners, for which they are entitled to compensation."

This will not affect the Milwaukee, Racine & Kenosha line as it has the consents of all the abutting owners except the Chicago & Northwestern and the dispute with this company has been settled amicably and a subway will be built at South Milwaukee at a cost of \$25,000. Probably the most far-reaching effect of the decision will be that of the holding that a street railway may do a freight and express business upon obtaining the consents of the abutting owners.

This, together with the act of the Wisconsin legislature, approved April 2, puts the two classes of roads on the same footing. The act is as follows:

Section 1. Any street railroad corporation, or any electric railroad corporation may, by purchase, grant or condemnation, acquire such real estate and other property as may be necessary for the construction, maintenance and operation of its railroad and of the stations, depot grounds and other accommodation reasonably necessary to accomplish the objects of its incorporation; to hold and use the same. Nothing in this act shall be construed as conferring on such street or electric railway company the right to lay or construct its track or tracks over or across the track or tracks of any steam railway company other than such as may now exist at law.

Section 2. All the provisions of the revised statutes and of the act or acts amendatory thereof relative to acquiring land by right of eminent domain by railroads, shall apply to all street railroad companies and electric railroad companies incorporated under the laws of this state; provided, that the provisions of this act shall not apply to any streets, alleys, viaducts, parks or boulevards in any incorporated city in this state.

Section 3. This act shall be in force from and after its passage and publication.

## GET READY FOR THE OCTOBER CONVENTION.

Secretary T. C. Penington, Chicago, of the American Street Railway Association, has started in early and has already issued official circulars outlining the plans for the October meeting at Niagara Falls. He has also sent out to supply men printed application blanks for space and as will be noted in the circular, the association proposes to give the exhibitors all possible assistance.

The opinions of exhibitors published exclusively in the REVIEW for December, 1896, are recognized by the association and for the first time a chance is offered the exhibitors to help themselves. The executive committee will allow the exhibitors to select some one to represent them, and if so chosen he will be so recognized by the association. This is exactly what has been asked for and now the executive committee has kindly granted the request, exhibitors should lose no time in accepting. Just how the selection is to be made is the question.

### CIRCULAR TO EXHIBITORS.

The American Street Railway Association will hold its Sixteenth Annual Convention at Niagara Falls on Tuesday, October 19th, 1897, continuing in session four days.

The exhibits and displays of the supplymen are so important a part of our conventions that the Executive Committee, in making arrangements for the meeting, has been as mindful of our wide-awake allies, and as zealous in providing for their convenience and accommodation as for any other feature of the gathering.

We have held an Executive Session at Niagara Falls and give you in this circular the substance of the arrangements we have made in your interests.

A commodious exhibit hall, 120 x 151 feet, is now being erected in the centre of the city and very near all the hotels. The steam railroad tracks are now within two hundred feet of the building, and we secured an agreement to have these tracks extended directly to the building, thus saving to the exhibitors all charges for cartage. A side-track will be laid in front of the hall for cars, sweepers, etc.

The Convention will be held on the second floor of the Exhibit Hall, all stairways leading up from the inside, thus insuring the attention of all delegates and visitors to the exhibits; the entire hall is to be lighted and heated during the entire presence of the exhibits. Written agreements have been secured that all the hotels will be kept open and that their rates will not exceed the following:

Hotel.	Rooms.	Rates per day.
International Hotel.....	350 to 450 people.....	\$3.50 to \$4.50
Cataract House.....	350 to 450 ".....	3.50 to 4.50
Imperial.....	110 rooms.....	2.50 to 4.00
Tower Hotel.....	35 ".....	2.00 to 3.00
Columbia.....	50 ".....	2.00 to 2.50
Niagara Falls House.....	25 ".....	2.00
Salt's New Hotel.....	30 ".....	2.00
Temperance House.....	50 ".....	1.50 to 2.00
Atlantique.....	22 ".....	2.00
Kallenbod.....	30 ".....	3.00
Prospect House.....	40 ".....	3.00 to 4.50

The income from sale of space will go to the American Street Railway Association. The Executive Committee of the Association has fixed the price at ten cents per square foot, and ruled that no space of less than one hundred square feet will be assigned, but applicants may have as many multiples of this quantity as they may wish, all in one body. Payment for space should be made to Mr. T. C. Penington, Secretary and treasurer of the American Street Railway Association, 2020 State street, Chicago, Illinois, on or before October 1st, 1897. Application for space should be made to Mr. H. W. Beardsley, Chairman Committee on Exhibits, Niagara Falls, New York. We hope to have you with us with an extensive display.

Space must be applied for by September 1st. Assignments will be made as promptly as possible after that date and exhibitors notified of their location. Exhibits of like character will be grouped together, and space will be assigned in the order of application.

It is earnestly requested that all exhibits shall be in place and all work finished by Monday evening, October 18th, which is the evening prior to the opening of the Convention. Possession of the hall can be had on Monday, October 11th, thus giving ample time for preparation. Watchmen will be in charge of the premises so that exhibits will be safe.

If the supply-men so desire, and will designate one of their own number who will be willing to go to Niagara Falls at some short time previous to the meeting, and whose necessary expenses they will defray, the Executive Committee will invest him with the requisite authority to supervise the reception and placing of displays. He can arrange with local carpenters, lumbermen, etc., to the effect that there may be no unfair charges for services or material that may be necessary in arranging exhibits.

The Executive Committee found the Niagara Falls and Buffalo brethren so enthusiastic as to the coming meeting, and so hospitable and seductive in their greetings that success is assured, the location being central and accessible, and the natural attractions wonderful beyond description, and the inquiries and information already received being so encouraging, an unusually large attendance seems guaranteed.

The annual dinner will be held at the International Hotel, Thursday, October 21st, at eight o'clock p. m. Tickets will be sold at the actual cost to the Association.

The railroads will sell tickets on the certificate plan. Be sure and leave your certificate with the clerk the first day of the Convention; it will be signed, vised and ready for you on Thursday, October 21st, 1897.

Please make your arrangements and applications as above noted as promptly as possible.

With kindly greetings and wishes for the health and prosperity of all, and with confidence in meeting you in October,

We are yours to command,

T. C. PENINGTON, SECRETARY-TREASURER. ROBERT McCULLOCH, PRESIDENT.

The business sessions of the association will all be held in the convention hall, located in the second story of the exhibit building. Papers on the following subjects will be read:

- "Municipal Ownership of Street Railways."
- "Modern Electric Railways; their Construction, Operation and Disadvantages."
- "Application of Electricity to Railroads now Operated by Steam Power."
- "The Best Method of Settling Damage Cases, and the Prevention of Accidents by the Use of Fenders and Otherwise."
- "Producer Gas for Use in Street Railway Power Houses and Gas Engines."
- "Storage Batteries for Street Railways."
- "Discipline of Employees."
- "Long Distance Transmission and the Use of Multiphase Current for Ordinary Street Railways."

The meeting will last from October 19 to 22 inclusive.

### LONDON TUNNEL RAILWAYS.

A committee of the House of Commons has been considering plans for some system of tunnel railways to relieve the congested traffic in a number of the principal streets of London. Of the schemes suggested one has met with approval and that is to build a double tunnel from Piccadilly Circus to Brompton road. The line is to be 3,476 yds. long, and its construction is to be similar to that of the Central London line. Each tunnel will be 11 ft. 3 in. in diameter, and from 55 ft. to 75 ft. beneath the surface. The estimated cost is \$3,750,000. The power house will be located at Chelsea Creek, about 1½ miles from the line. This location was selected by Prof. A. B. W. Kennedy on account of an abundant supply of water for condensation and easy access to coal. The capacity of the power house will be about 1,200 h. p. Concentric cables will conduct the current to the tunnels at a voltage of 1,200 which will be reduced to 600 for the trolley lines.

### REPORT OF THE GENERAL ELECTRIC.

The fifth annual report of the General Electric Company, dated April 27, shows the gross receipts for the year to have been \$12,820,000; expenses \$11,207,000; after the deduction of fixed charges, depreciation, etc., the reduction of the deficit of previous years was \$960,000. A considerable shrinkage of orders received occurred in the latter part of the year, but the result of this was made apparent in the decreased amount of work in progress rather than in a material falling off in shipments. The volume of business secured during the first three months of the present year is slightly in excess of that for the same period of last year.

### CINCINNATI STREET RAILWAY CARRIES NO INSURANCE.

The Cincinnati Street Railway Company has decided by resolution of its board of directors not to renew the insurance now carried when the present policies expire, and in the future to "carry its own insurance," as the popular phrase puts it. For the purpose of protecting itself a sinking fund has been provided, which is known as the Insurance and Security Guarantee Fund, and placed in the care of a trustee for proper investment, through which all fire losses will be cared for.

## STILLWATER STIRRED UP.

Several years ago when hopeful railway builders imagined a street railway could be built anywhere, an electric line was put in at Stillwater, Minn. The people never appreciated the enterprise and the city council made its corporate life a burden in many ways. It shortly went into a receiver's hands and later was shut down. Finally the court ordered a sale, but the price bid was afterwards declared too low. A second sale took place and the road was bought by another party who bid less than the first. This deal also was declared off and recently a third sale was held and the property knocked down for \$4,700 to Flint & Scott—the

## LONG DISTANCE TRANSMISSION AT BAKERSFIELD, CAL.

The plant which the Power Development Company, of San Francisco, has recently completed for utilizing the power of Kern river, the third stream in California, is in point of size, in all probability, except for Niagara, without a peer in the perfection of its transmission and equipment. The generating plant is located at the mouth of the Kern river cañon, on the edge of the Sierra Nevada mountains, 16 miles to the northeast of Bakersfield, Cal., by wagon road, and 14 miles in a straight line. Here the river after its course of nearly 100 miles through rugged cañons from

THE FLUME GRADE AT WATER LEVEL.

INTERIOR OF FLUME.  
PIPE LINE CONSTRUCTION.

lowest sale of all. At this time deep snow was upon the face of the earth. When the snow melted and the pig came out of his poke, the buyers concluded their best way to success was to pull up the iron and sell it for scrap. This they proceeded to do, but the city secured an injunction; and there they are. This would be an excellent place for municipal ownership and a 3-cent fare.

The friends of W. W. Bean, president of the lines at St. Joseph, Mich., who some time since was forced to defend his property by force of arms will understand the following from a neighboring Michigan paper, which says: "It is said that because W. W. Bean, president of the street railway company does not like Gov. Pingree, he wanted the Pingree Rifles of St. Joseph, to change their name. One of them suggested that they call themselves 'Bean Shooters.'"

Mt. Whitney, breaks into a number of cataracts and rapids before finally settling down to a peaceful flow through the valley. There is an abundance of water flowing at all times to insure 7,000 h. p. at the power house, and the water needed is diverted from the river at a point nearly two miles up the cañon, by merely tapping it, no dam or reservoir being needed.

From the point where the river is tapped, the water is carried along the north side of the canon for a distance of 8,575 ft. in a wooden flume, to secure a bed for which it was necessary to blast out a roadway in the solid rock for the entire distance. The flume is built of redwood, 8 ft. wide, and 6 ft. deep, with a grade of 5.28 ft. per mile, making the capacity 14,400 cu. ft. of water per minute. The flume is laid out on tangents and curves, sharp turns being avoided, and is covered the entire distance. A tramway is laid on

the cover. At one point there is a break in the cañon side and the flume is carried on a bridge of 87 ft. span, the arches of which are built up of 16, 1 x 6 in. planks sprung into place. One of the illustrations shows the false work for this bridge and another the bridge as completed.

THE FLUME AT GIBRALTER AND THE PALISADES.

flume progressed a track was laid along the bottom and the material delivered at the far end by pony power.

At the terminus of the flume it is 102 ft. above the power house and the water is conducted to the latter through a steel

THE GENERATING STATION.

Lumber for the flume was all hauled by team a distance of 16 miles to the south side of the stream, a bridge thrown across, and a tramway 325 ft. long, with a grade of 30 per cent, constructed up the steep hill to the point where the flume was to end. A steam saw-mill was then set up at the foot of the tramway and after the timber was cut to size it was loaded onto cars and hauled up the grade. As the

pipe 66 in. in diameter and 540 ft. long. The pressure at the lower end is about 80 lbs. per sq. in.

In the generating station are four water wheels of the Girard type direct connected (two wheels to each) to two 450-k. w. 28-pole General Electric alternating generators operating at 257 r. p. m., making 7,200 alternations per minute. The current is generated at 550 volts, stepped up by

# Street Railway Review

transformers to 11,000 volts, and transmitted to the sub-station in Bakersfield with a line loss of 7.5 per cent. The town distributing systems carry current at 2,680 volts, and the systems for distributing current in the agricultural districts, where it is used for pumping purposes, at 10,000 volts.

The wheels are regulated and water hammer in the pipe prevented by special governing devices designed by the Girard Water Wheel Company of San Francisco, which give excellent results.

In the panoramic view of the station the flume, main waste gate, forebay, pipe line, power house, employes' quarters and superintendent's residence are shown. The safety gate is located about midway along the flume and is shown in another view.

The current is conveyed from the generating station to the sub-station in Bakersfield over six No. 4, B. & S., copper wires. We show two views of this sub-station, which also contains the offices. As will be seen from the interior of the transformer and switchboard room, the high potential board is inclosed in a glass case.

All the material and work entering into this plant have been first class in every respect. Dr. Cary T. Hutchison of New York designed and had charge of the electrical work and machinery, while the mechanical and hydraulic engineering has been handled by Messrs. Cobb and Hesselmeyer of San Francisco. W. R. Macmurdo, of Bakersfield, was the civil engineer in charge of construction and Walter James of the same place, consulting engineer. The direction of the work from its inception has been in complete charge of C. N. Beal, secretary and treasurer of the Power Development Company. The other officers of the company are Charles Webb Howard, president, and W. F. Goad, vice-president.

We are indebted to Mr. Beal for the photographs from which our illustrations were made, and which show the engineering problems encountered. Records thus far taken give evidence of results which are in no way second to those at Niagara, except quantity.

The illustrations grouped on the opposite page give a good idea of the picturesque scenery in Kern cañon, and also of the difficulties of construction. In the view looking up the river is seen a reminder of a former enterprise of

considerable magnitude which did not prove successful; the grade on the right of the picture was constructed by an irrigation company and then abandoned. One of many places where danger was wont to lurk is shown in No. 6

SUB-STATION IN BAKERSFIELD—INTERIOR OF TRANSFORMER AND SWITCH BOARD ROOM.

the eight men are carrying dynamite up the pathless mountain side, 50 lbs. to the man, where a mis-step of one meant instant and terrible death to them all.

The cylinder head of one of the engines at the Muskegon Street Railway Company's power plant blew out but no serious results followed. The load was transferred to the other engines and operations did not cease while repairs were being made.

FALSE WORK FOR ARCHES.

## THE INDIANAPOLIS 3-CENT FARE LAW.

Exciting Scenes Mark the Attempt to Enforce the Law—Company Refuses to Accept 3-Cents—Passengers Are Ejected—Company's Officers Arrested—Judge Showalter Grants Injunction in Favor of the Company—City Takes Case to State Supreme Court—President Mason Resigns.

Incidents in the history making of the now celebrated 3-cent fare case at Indianapolis have crowded fast one after another since our previous issue. In April we printed the full text of the legislative bill, which provided that in cities of more than 100,000 inhabitants by the census of 1890, the street car fare should not exceed 3 cents, including transfer. The bill was also specially vindictive since it was so worded as to make it easily possible for a dishonest employe to work a forfeiture of company's franchise. We branded the bill as unconstitutional because it was distinctly worded so as to apply only to Indianapolis, and Judge Showalter of the United States Circuit Court, has since so ruled. A short review of the exciting events pending his decision is interesting.

The bill became a law when signed by Governor Mount, on the evening of April 14, and was published by proclamation early on the morning of April 15. The company, meanwhile, through its bondholders, the Central Trust Company of New York, had filed its petition for an injunction in the United States Court, which, however, did not make its ruling for two weeks. Interested parties started out early on the 15th to test the law, and boarded the cars tendering 3 cents, and refusing to pay more. Many were ejected, some were carried free rather than accept three cents; some paid 5 cents rather than have trouble, and in a few hours the condition was chaotic. The excitement increased all day, frequent blockades occurring through conductors refusing to start their cars until full fare was paid. On the morning of the 16th the situation was at fever heat, and before noon the police were obliged to take a hand. A special session of the grand jury was convened and indictments promptly returned against the resident officers of the company and several conductors. Arrests were made at once, but bail in the amount of \$200 each, promptly given and accepted. That afternoon a truce was effected between the mayor and President Mason, and for two days following either 3 or 5 cents was accepted as fare, the conductors so far as possible securing the names of those who refused to pay full fare, and notice given that the company would reserve the right to prosecute such person under the statute which prescribes a \$50 fine for refusing to pay fare on street cars.

On April 19th, the United States Supreme Court handed down a decision in the case that had been before it for some time, in favor of the company and against the city, confirming the company's right to the streets until 1901.

On April 23rd, Judge Showalter, of the United States Circuit Court, ruled on the petition for injunction, holding that the law was unconstitutional because special legislation, and issued the order restraining the city and state officers from enforcing the law, and the company from obeying it. One of the most interesting features of the controversy is the manner in which the case was brought before the Indiana Supreme Court without putting all parties concerned in contempt of the Federal Court. The company

proceeded under the statute which imposes a fine of \$50 for refusing to pay street car fare, and a party so refusing to pay was fined in the police court, appealed to the Circuit Court of Marion county, and upon that court sustaining the fine and ruling in accordance with Judge Showalter's decision, a further appeal was taken to the Supreme Court of Indiana, where a hearing is expected on May 19.

The annual report of president Mason, of the Citizens Company, at its annual meeting, May 5, 1897, reviews the situation fully, and is such an interesting document we publish in full

### PRESIDENT MASON'S REPORT.

As the writer is about to retire from the presidency and board of directors of the Citizens' Street Railroad Company, a brief outline of the events of the past four years in the affairs of the company is herewith submitted:

On March 15, 1893, there was a change in the ownership of the stock of this company, and on that day a new board of directors was chosen, consisting of H. Sellers McKee and M. A. Verner, of Pittsburgh; R. W. Clay, of Philadelphia, and W. L. Elder, Henry Jameson, W. J. Holliday and A. L. Mason, of Indianapolis. The board organized by electing the writer as president.

At that time the company had but four of its lines operated by electricity; the remainder, and by far the larger part of the property, was operated by mule power, the company having more than one thousand mules. No electric car had at that time ever been seen on the south side of the city, nor on the west side, embracing two-thirds of the population. Crown Hill cemetery, the Fair Ground and Irvington were reached by electric cars, but the Insane Hospital and Stock Yards, Haughville and Brightwood, Garfield Park and West Indianapolis, were all reached only with small mule cars, containing fare boxes, having no conductors and traveling slowly over inferior track.

The new board electric entered at once upon the work of giving Indianapolis first-class electric street railroad service. A new power station was built on the banks of White river, supplied with powerful condensing engines; single track roads were rebuilt in large part into first-class, double track lines. Important extensions were made on Prospect, Shelby, Union, South Meridian, East and West Washington, and Blake streets, and Columbia and Clifford avenues. Within two and one-half years the entire system was electrified and supplied with modern vestibule motor cars. The old and unsatisfactory electrical car equipment, previously owned by the company, was abandoned and replaced with new and powerful motors, and the service throughout the city brought to a point of efficiency which, while not claimed to be perfect, nevertheless compares favorably with the street railway facilities of any city the size of Indianapolis.

Another important change was made in the transfer system. Previously passengers had been permitted to transfer between many of the lines without charge by passing into a small transfer car located in the middle of Washington street. The transfer car was abolished and instead there was adopted a free transfer ticket, which permitted transfers between all lines at every junction point in the city without extra charge. As this increased the transfer points from one to nearly thirty, there was, of course, a corresponding increase in the number of free transfers. Besides this, the transfer privilege was enlarged so as to include even the suburban lines, with the exception only of the Fair Ground, and Fairview Park line on Sundays.

It is not too much to say that during this period of construction an enormous work was developed upon the management of the company. The laying out of every new line, the planning of every piece of special work, the designing of cars, location of power station, construction of feeder lines, strengthening bridges, in short, the whole work of reconstruction received the constant and unremitting attention in all its details, not only of the writer, but largely of the executive committee from the board of directors. At the same time economy of operation has by no means been lost sight of. Mr. McKee, chairman of the executive committee, for years received a copy of the pay-roll each week and personally checked off the names and suggested constantly most important economies. The writer failed not to consider the most minute details of the expense account. Even within the last year, during the most successful superintendency of Miller Elliott, there have been introduced many improve-

ments and economies. Such matters as substituting pressed steel for bronze pinions, cut steel gears in the place of malleable and cast iron gears, malleable gear casings instead of cast iron, hammered iron axles in the place of steel, the best system and materials for car painting and varnishing, the best and cheapest engine oils and motor greases, economy in boiler repairs, the improvement of track joints and a thousand similar things have been carefully studied by skillful employes and passed upon, after thorough investigation, by the president.

Under Mr. Elliott's superintendency of the last year there has been a continued improvement in the character and efficiency and loyalty of the men in the company's employ. The accident list, which is so serious a question with all electric roads, has undergone an enormous reduction, owing partly to increased care on the part of the people, but largely to the improvement, skill and discipline of the car service men. It is not too much to say that the working organization of the company at present is the most compact, efficient and economical one in its history. Mr. Milholland, secretary and treasurer, has charge of the office, having been in the employ of the company for many years, and reached his present position by well deserved promotions. Besides the superintendent, of whom mention has been made, I take pleasure in mentioning W. T. Lewis, assistant superintendent, who has been in the employ of the company for twenty years, Mr. McCreary, who has been in the electrical department from its beginning and now, as electrician, has charge of the two power stations, the overhead lines, repair shops and rolling stock of the company. The roadmaster, C. S. Butts, was first employed about four years ago, and has shown himself to be a skillful surveyor as well as roadmaster. In mentioning these faithful servants of the company, there is, however, no disposition to exclude from honorable mention the office employes and barn foremen, the road officers and others on whose successful efforts the efficient service rendered by the company so largely depends.

#### FRANCHISE MATTERS.

While the company has thus gone steadily forward in the improvement of its property, its organization, its service to the public and its economies, it has, nevertheless passed through most trying ordeals in its relations to the municipal government of the city of Indianapolis.

Previous to March 15, 1863, there had been much public criticism of the company on account of its inferior service and failure to give the entire city rapid transit. There were, no doubt, other sources of criticism, but of these the chief one was the fact that the company did not pave between its tracks. At the time the original ordinance was passed in 1864, under which the company operates, it required the company to pave between its tracks, but a few years later an ordinance was passed, prepared by the city attorney and not opposed by a single paper in the city, relieving the company from the burden of paving, and substituting only the requirement that the company keep the space between its tracks in repair. As Indianapolis has, in the last few years, been passing through a period of extensive street improvements, including the use of asphalt, brick and block pavements, the question of the company paving between its tracks assumed much greater importance than at the time the amending ordinance had been passed in the year 1878.

Feeling the dissatisfaction of the public and desiring to discharge their whole duty to the city of Indianapolis, the new board of directors, on March 16, 1893, made it their first task to appear before the board of public works and state that the company was willing to enter into any fair, reasonable and just arrangement by which it should comply with the demands of the city of Indianapolis and at the same time have proper security for the necessary investment. To this proffer, the board of public works, under advice of the city attorney, answered that they would have no negotiations with the company whatever as to terms of settlement of existing controversies. On the contrary, the board declared that the company's rights in the streets would expire in the following January, after which it would be treated as a trespasser. The board of public works then proceeded, a few days later, to advertise and sell a so-called franchise to the highest bidder, commencing immediately and running for a period of 30 years. This alleged franchise was purchased by the City Railway company, a new organization, consisting of a number of influential local capitalists. The new company immediately laid claim to all the streets and parts of streets occupied by the Citizens' Company. An injunction suit was thereupon brought by the Citizens' Company

against the City Company in the Federal Court, to enjoin the defendant from interfering with the occupying company and to quiet the title of the latter to the use of the streets. This suit resulted in a victory for the Citizens' Company in November, 1894. There was a difference of opinion between the two judges as to the time of the expiration of the rights of the Citizens' Company. The original city ordinance, under which the company operates, ran until January, 1894. A so-called extension ordinance was passed in 1880, making the time of expiration 100 years. Both judges agreed that the extension ordinance assumed to be invalid. Both judges agreed that the extension ordinance was valid, and that the City Railway Company should be enjoined. But Judge Woods, presiding, held that the city had no power, by ordinance, to fix a time limit for the use of the streets for street railway purposes, and that the Citizens' Company, being a corporation in perpetuity, had a continuing right to use the streets, subject only to the reserved power of the legislature to alter, amend or repeal the charter of the company itself. The City Railway Company appealed this case immediately to the Supreme Court of the United States.

Pending this appeal, the Citizens' Company renewed its efforts to obtain a settlement with the city of Indianapolis, being ready at all times to make just and reasonable arrangements with the city. These efforts, however, were met from the beginning with the statement on the part of the city government, that the new company now had acquired, by the so-called franchise of 1893, certain contract rights with the city, or claimed to have acquired them, and therefore the city was morally, if not legally, bound to refuse to make any negotiations or settlement with the Citizens' Company, unless the City Railway Company should consent to surrender its rights. By this ingenious opposition on the part of the city government, the Citizens' Street Railroad Company was put in a false position before the people, most of whom supposed that the company was stubbornly refusing to pave between its tracks or to make any other proper return for the privileges it was enjoying. In the summer of 1895 a negotiation was undertaken for the settlement, which was to include not only the city government but also the City Railway Company, it being intended to procure that company to surrender its so-called rights. The writer was not a member of the committee which conducted the negotiation and did not personally participate in the matter. However, at one time there was, as I believe, good reason for believing that this settlement would go through, notwithstanding the extraordinary concessions which were required by the City Railway Company in order to induce it to surrender its supposed rights. So far as the city was concerned, its special counsel, the late Hon. John M. Butler, in a long letter to the mayor, outlined substantially the terms of settlement which he advised the city to make with the Citizens' Street Railway Company. The directors of this company were then and continued to be entirely willing to settle on the basis proposed by the city's own attorney, Mr. Butler. Meanwhile, an injunction suit was brought by a citizen of Indianapolis to enjoin the proposed settlement, and the city government began to raise its demands from day to day, until, in the course of two or three months, the plan of settlement advised by its attorney, Mr. Butler, was declared to be utterly impossible and not to be thought of. The terms of settlement proposed by the city were impossible and impracticable for this company, taking into view the enormous sacrifice necessary to secure the retirement of the City Railway Company from the field. In the fall of 1895, it became apparent that the proposed settlement was a failure, and in October the mayor and council went out of office and a new administration came into office.

So far as the Citizens' Street Railroad Company was concerned, the change in administration did not improve the chances of a settlement. The demand of the City Railway Company, as the price for its retirement from the field, was larger than it had previously been, and the new mayor was equally as firm as his predecessor in the position that the city of Indianapolis would consider no settlement unless the City Railway Company were gotten out of the way. Our board of directors found it impossible to comply with the double requirements thus imposed by the city government of Indianapolis and by the City Railway Company.

In this situation the Legislature of 1897 met, and there was immediately introduced Senate Bill No. 61, which provided that the rights of street railway companies in the streets of cities should absolutely terminate at the time fixed for the same in any ordinance under which such companies were operated, and that the occupying company should remove its tracks from the streets unless it elected to sell the same to its successor at an appraised value. This appraisal was

to be made by a board of three members, one to be appointed by the company which was quitting business, one by the new company, both subject to the mayor's confirmation, and one by the mayor. The new company was not required, however to buy the property, even after the appraisement had been made. After a hearing before the committee, this bill was amended by the consent of its author so as to place the appointment of appraisers in the hands of the Circuit Court, and the law was limited to cities now having 100,000 population. A severe contest ensued in the Senate over this bill. It was pointed out that this bill at once extinguished the rights of the Citizens' Company in 1901 and confirmed the rights of the City Company for the next thirty years, and placed the property of the occupying company actually at the mercy of the new company, because the latter was still not compelled to buy the plant, even at the appraised value. Senator Hogate introduced an amendment which was designed not to lengthen the life of the Citizens' Company, but to avoid confirming the rights of the City Railway Company. It provided that when the rights of the occupying company expired, the city should open the field to free competition and sell the street rights for thirty years to the best bidder. If the occupying company was not successful, the successful bidder was strictly bound to buy the property at an appraisement to be fixed by the Circuit Court, and pay for the same in cash. The Hogate amendment was bitterly fought by the friends of the original bill, but the amendment was adopted, and the bill passed the Legislature without further opposition. It was supposed that this would end the legislative attack on the company. However, the moment the Hogate amendment had passed the Senate, a bill was introduced prescribing street railway fares in Indianapolis at three cents for each cash fare, and requiring free transfers between all lines.

This extraordinary measure, which had never been suggested until the passage of the Hogate amendment, was, if valid, a substantial confiscation of the Citizens' Street Railroad plant. The law went into effect about the middle of April of the present year. In the meantime, the Central Trust Company of New York, trustee of the consolidated mortgage bonds of this company, brought an injunction suit in the Federal Court against the city of Indianapolis, the prosecuting attorney and the Citizens' Street Railroad Company to enjoin the enforcement of this law and compliance with it by the company. The case was argued at great length in behalf of the Central Trust Company, by Gen. Benjamin Harrison, Ferdinand Winter and W. H. H. Miller, before Judge Showalter of the United States Circuit Court of Appeals. Judge Showalter promptly delivered a careful opinion declaring the three-cent fare law to be unconstitutional and void for the reason that it was local and special legislation. Since that decision was rendered, a case has been taken to the Supreme Court of the State of Indiana, which is now set for argument in that court May 19. It is hoped by the city government that the State Supreme Court may render a different opinion from that of the United States Circuit Court, or, at least, this is supposed to be the object of this new proceeding.

In the meantime, while Judge Showalter had the three-cent fare law under consideration, the Supreme Court of the United States decided the appeal of the City Railway Company adversely to that company and favorably to us. It was held that the rights of the Citizens' Company were at least good until 1901, and, therefore, the court considered that it was unnecessary to decide the question of our rights beyond that time. The court expressly declined to give any opinion upon the question of our company's rights after the expiration of the extension ordinance, but it confirmed the decree enjoining the City Railway Company from in any wise interfering with the occupying company.

This is the present status of one of the most notable legal struggles that has ever taken place in the courts of this country. It began, practically, the day after the writer became president in March, 1893, and has continued without cessation until the present time. In every instance, however, the company has been victorious in the maintenance of its legal rights. One of the later phases of this struggle has been the indictment and arrest of the officers and many of the employes of this company for alleged violation of the three-cent fare law. Under the injunction, however, entered by Judge Showalter, the company is collecting five-cent fares for each passenger, with privilege of free transfer.

It is to be hoped that the fresh support and strength which will be brought to the company by its new board of directors and new officers will enable it, now that the legal battle has been fought out and

won in the courts, to speedily reach a satisfactory adjustment of this most intricate problem.

Respectfully submitted,

AUGUSTUS L. MASON,  
President.

## RECORDS FROM THE CRAVATH RECORDER.

The accompanying engraving shows some of the alloy strips used in the Cravath recorder as they appear before and after use. It will be remembered from the description that appeared in our last issue that the record is made by a hot wire in the main motor circuit, melting a path through an alloy strip—the alloy being a mixture of lead and tin

CRAVATH RECORDER RECORDS.

which melts at a low temperature. The metal does not drip, but simply flows back from the wire, leaving the strip as shown in numbers 1 and 2. Number 3 shows a new strip. A rather curious phenomenon is that at each point the strip pauses in its descent a notch-like place is left by the hot wire. The distance between notches is usually very short with the best motorman and becomes longer as the men are more careless.

R. T. McDonald, president of the Ft. Wayne Electric Company, has been sued for \$50,000 by S. J. Hart of New Orleans, on account of an interview in which Mr. McDonald was alleged to have spoken in a derogatory manner of Mr. Hart's character.

**THE LEWISTON & YOUNGSTOWN FRONTIER RAILWAY.**

The Lewiston & Youngstown Frontier Electric Railway connects the villages of Lewiston and Youngstown, Niagara County, N. Y. The company was organized by a number of local capitalists in the summer of 1895, and after a number of surveys the road was finally located through private property between these villages, about one-quarter

FORT NIAGARA.

of a mile easterly from the River Road, so called, with the object of avoiding the destruction of property along the banks of the lower Niagara River, or occupying the highway.

The contract for the construction of the roadbed, ballasting, overhead work and fencing was let April 12, 1896, to Craige & Tench, Buffalo, N. Y., for the sum of \$63,500.

The road starts from the New York Central depot at

The right of way is 30 ft. in width and fenced throughout its entire length between the villages. There are no structures whatever on the line, with the exception of a few wooden box culverts and one trestle 48 ft. long and about 9 ft. high.

The road is single track of standard gage and has five turnouts in the course of the line with end switches at each end. In the two villages the track is laid with girder rails, 2 1/4 miles of 67-lb. and 1/2 mile of 87-lb. and in the country with 56-lb. T-rails, 4 1/2 miles. The Johnson Company furnished the rails and track fastenings and all the rails except the 87-lb. girders which were rolled by the Pennsylvania Steel Company. The ties are of cedar, 6 x 8 in. x 8 ft., spaced 2 ft. between centers. The line is ballasted with broken stone which is 6 in. deep under the ties.

R. W. Oliver furnished the overhead work at a cost of \$9,750. In the villages span work is used and in the country side pole bracket work. The trolley wire is No. 00 and there are nearly 24,000 ft. of No. 0000 stranded triple covered feed wire starting from Lewiston and reaching nearly to Youngstown. All poles and fence posts are painted olive green.

No power plant was constructed by this company, power being obtained from the plant of the Niagara Falls & Power Company, which is situated 7.17 miles distant from Lewiston. It is generated by one of the 1,000-h. p. generators situated in the new power house at the foot of the cliff, at a voltage of 550 volts. This is raised to 750 volts by being passed through a booster, and is conveyed to Lewiston over a 500,000 circular mil stranded copper wire, triple covered. This wire is strung on the poles of the "Gorge"

SCENES ON THE LEWISTON & YOUNGSTOWN FRONTIER RAILWAY.

Lewiston and runs up Center street to 5th street, thence northerly through 5th street to the village limits, thence through private lands to 3rd street, Youngstown, thence through Church street to Main street and to the United States Military Reservation, at the mouth of the Niagara River. There is also a branch in Lewiston from 5th street through Onondaga street to the New York Central freight station and a branch in Youngstown to the docks. The road is 7 1/4 miles long in all.

The country through which this road runs is extremely level and is in the heart of the Niagara fruit district, being largely devoted to the culture of apples, peaches and grapes.

Railway, located in the Niagara Gorge, and thus brought to Lewiston where it is connected with the trolley and feed wire above mentioned.

The equipment consists of four, eight bench open motor cars and two closed combination baggage and passenger cars seating 16 people, made by the J. G. Brill Company, Philadelphia. The combination cars have a vestibule on the passenger end, and the baggage compartment, which is 8 feet long, has sliding doors on each side and three drop sash in the front end allowing the motorman to occupy the baggage compartment when running that end forward, but there is no vestibule. All these cars are equipped with Brill eureka

maximum traction trucks, with 33-in. and 20-in. wheels. Each truck is equipped with one G. E. 1,000 motor, thus giving each car 2,000 lbs. horizontal tractive pull. The total cost of roadway, equipment, transmission line, land damages, etc., amounted to very nearly \$100,000.

After a number of delays, owing to the non-arrival of material, etc., the road was informally opened the latter part of August, 1896, and has been running ever since. The company contemplates a freight as well as a passenger service, and it is at present handling about 10 cars of freight per day, beside package freight. A steady passenger traffic is maintained between the points mentioned, which will undoubtedly increase during the summer.

The officers of the company are: L. D. Rumsey, president; H. C. Howard, vice-president and treasurer; F. R. March, attorney; Karl Evans, general passenger and freight agent, and R. B. Goodman, superintendent, all of Buffalo, New York.

The engineering work was in charge of Paul Voorhes, of Buffalo, who has constructed several other roads in the last four years, among them Buffalo & Williamsville Electric Railway and the Buffalo, Gardenville & Ebenezer Railway. During the thirteen years since his graduation at the Rensselaer Polytechnic, Mr. Voorhes has also been connected with several steam roads, notably with the New York Central as assistant.

#### OWNERSHIP OF UNCLAIMED ARTICLES

Some discussion has been aroused in New Jersey over the ownership of unclaimed articles lost in street cars. Nearly all of the street railway companies make some provision for holding the packages, umbrellas, etc., at some particular place so that the owners may come and claim them. This is nearly always done but when no owner can be found the question is to whom does the lost article belong? The custom is to return it to the conductor who turned it in. In New Jersey the state settles this question in the following manner. The law provides that the lost article may be sold after being held for three months and advertised. If, at the end of two years, no one has made claim to the ownership the money, less charges for storage, advertising and selling, shall be turned over to the state treasurer. Needless to say, New Jersey has not grown rich from these proceeds.

#### A REPAIR SHOP THAT PAYS.

About a year ago the Urbana & Champaign Electric Street Railway Company fitted up a repair shop with a drill press, a large lathe, a Q. & C. steel hack saw, emery wheels, grindstones, a circular saw and a forge with blower. President B. F. Harris, Jr., says that he considers the repair shop as one of the very best investments the company has ever made, and that the work can be done better and cheaper than elsewhere. With the tools at hand to do the work repairs were made in the earliest stages of deterioration instead of waiting until the parts fall to pieces. The cars are also painted and lettered in the shop. Lately, the plan has been adopted of transferring the letters, figures and ornaments instead of using the gold leaf in the usual way, thus getting a much handsomer effect at less expense than by the old method of hand lettering.

#### THE NEW ELYRIA & OBERLIN LINE.

The Cleveland, Beria & Elyria Railway is to be extended seven miles to Oberlin, but the extension is incorporated separately and will be known as the Elyria & Oberlin Electric Railway Company. F. T. Pomeroy, general manager of the new company, writes that franchises have been granted by both Oberlin and Elyria councils, and by the commissioners of Lorain county. The tracks will be laid on the principal streets of each town, and outside the corporate limits a private right of way has been secured. Within the city limits a deep T or girder rail will be laid and outside a 56 or 60-lb. rail will be used. What bonds are to be used has not yet been determined; in fact, the problem is still troubling the engineers. The new power house is to be built in Elyria, and with sufficient capacity to furnish current for the extension and for the western portion of the present lines. This will shorten the running time between Cleveland and Elyria about 15 minutes. The extension will make a total of 40 miles of track in the whole system. Some of the contracts have been let, and the work will be completed early in the fall.

#### THE ACCOUNTANTS' ASSOCIATION.

Secretary Brockway has mailed 900 copies of the constitution and by-laws, with application blanks, etc., to street railways in this country, Mexico and Canada, and already the returns are coming in. A very considerable addition to the initial membership is promised.

All members of the association and all interested persons are urged to send the secretary an expression as to what time of the year is best suited for future meetings. As reported in the April REVIEW this subject was fully discussed at the March meeting and while it was decided to hold the next meeting in October at the same date and place as the convention of the American Street Railway Association, it was understood and agreed that the matter would come up for settlement then. Many who voted for holding the next meeting in October are opposed to that date as the permanent one, believing it will be far better to meet in the spring and not at the same time and place as the American. Hence it is urged that a full expression be made to Secretary W. B. Brockway, Toledo, O., to whom inquiries for any information relating to the association may be addressed.

The committees appointed at Cleveland have already begun their work and the report will mark a big step in advance toward the work of standardizing accounts. Subjects for papers and assignments are being made, and the program will well repay every accountant in street railway work, for the time and expense to attend the meeting.

#### ATLANTA WILL CONTEST COMPULSORY TRANSFER.

Joel Hurt, president of the Atlanta Consolidated lines, has done as he said he would in case the transfer ordinance was passed by the city, and has taken the case to the United States court at New Orleans, where a restraining order against the city and the road was granted, preventing the putting into effect the ordinance until the court rules on the case. The company hopes to have the injunction made permanent.

**BUDAPEST UNDERGROUND ELECTRIC RAILWAY.**

We are indebted to the Railway World of London for the illustrations which we publish of the Underground Electric Railway in Budapest. This road extends from near the Danube river to the Park, 2.29 miles, and is laid in a tunnel under the Boulevard Waitzner and Andrassy street. Tunnel construction was necessary because the city absolutely refused to permit Andrassy street to be defaced by a street railway. The street was already inconveniently crowded by carriage traffic and foot passengers, and a surface railway could not

MOTOR CAR—BUDAPEST UNDERGROUND RAILWAY.

BOGIE TRUCK WITH 4-POLE MOTOR.

be added without rendering the blockade dangerous. The plans were prepared by Adolph Worner, technical director of the Electric Stadtbahn Company, and the work carried out under the direction of Messrs. Siemens & Halske.

Work was begun August 1894, and the line publicly opened May 26, 1896. The franchise is granted for 90 years, but the city reserves the right to buy the concession in 1940, when the surface line franchises expire, on announcing its intention two years in advance. The minimum rate of fare has been fixed at 5 cents for the entire distance, but

after 15 years the city may require a certain reduction to be made. After 20 years the city will receive from the company 1 per cent of the gross receipts for 10 years, 2 per cent for the next 10 years, 3 per cent for the next 10, 4 per cent for the next 10, and 5 per cent for the last 30 years of the concession. During the first 25 years the city is forbidden to grant any other transportation concessions of any kind between the center of the city and the Park.

The total depth which could be given to the tunnel and its foundations was limited to 16 ft. because of a large sewer which crosses the street at that depth. The thickness of the roof was fixed by the size of the girders necessary to sup-

port the surface roadway and the thickness of the pavement, and varies from 2 ft. 7 in. to 3 ft. 3 in. The foundation, though varying slightly, is also about 3 ft. 3 in. in depth, including the roadbed and rails, leaving 9 ft. 6 in. for interior depth. The inside width is 20 ft. The two tracks are of standard gage, 4 ft. 8 1/2 in. and 10 ft. 7 1/2 in. between centers. Columns are spaced 13 ft. 5 in. between centers, and carry twin longitudinal l-beam girders 12 1/2 in. deep under wood and 13.7 in. deep under stone paving. l-beams running transversely for the support of the pavement are spaced 3 ft. 3 in. apart, and vary in depth from 9 to 17 in. The transverse girders are covered by a bed of cement, which is 3 in. thick in the center of the street, and this latter is covered with several layers of felt smeared with hot asphalt, making the tunnel practically impervious to moisture. But to make sure, concrete conduits have been laid between each pair of rails, which will conduct any water that may leak in to cisterns, from which it can be pumped out.

The rails are of the Vignolles system. They are 4 1/2 in. high, weighing 50 lbs. per yard, and are in 30-ft. lengths. They are secured to iron cross ties by special clips and are inclined inward so as to bring the pressure of the tapered wheel tread in line with the rail web, as is the common practice on European steam roads.

The power station is near the park terminus of the road. It is equipped with two Siemens units, each supplying 11,000 amperes at 300 volts.

The cars are 36 ft. 4 in. long, 7 ft. 6 in. wide, 8 ft. 9 in. high and weigh 15 tons. The clearance between the car

BOILER ROOM—BUDAPEST UNDERGROUND RAILWAY.

and the ceiling is but 6 in., and between the curved girders which support the car body and the rail but 4 in.; at the sides it is 7.9 in. between the car and the outer wall and 3 ft. 1 in. between the two cars when passing.

The passenger compartment, that portion of the car body between the trucks, is divided into three parts, the two at the ends seat seven persons each and the middle one 40 persons. The end compartments for ladies and non-smokers are entered only through the middle one.

The stations are similar to the underground stations of London and Glasgow, and are very commodious. At the largest there is standing room for 1,000 persons. There are 11 stations, and only one car is permitted in the block between any two stations. The signal apparatus is entirely automatic and operated by the cars.

The service is performed by 20 cars, of which 14 are always in motion, giving a headway of 2 minutes. Trains run regularly from 6 a. m. to 11 p. m. at intervals of 3 minutes. From November 1, 1896, to January 15, 1897, 572,000 passengers were carried and 106,764 car-miles run.

### EXPERIMENTAL TRACK OF THE GENERAL ELECTRIC.

The encroachment of electric traction upon the field heretofore exclusively occupied by the steam locomotive has caused the General Electric Company to provide a special track to facilitate electric traction experiments. The track is laid along the Erie canal at Schenectady and comprises 6,700 ft. of the standard New York Central construction with 85-lb. T-rails. The first section of the line is a tangent of 2,415 ft., the second a series of short tangents and curves, and the third a tangent 2,730 ft. There are two 30-lb. conductor rails set on 8-in. treated ash blocks, running beside the track on the far side from the canal. The two conductor rails were installed for the purpose of experimenting

EXPERIMENTAL TRACK AT SCHENECTADY.

with alternating multiphase currents; for direct current experiments the two rails are connected in multiple. Both track and conductor rails are bonded with No. 0000 copper bonds. The feeder is a 500,000 c. m. insulated cable running along the track for 5,300 ft. The line is divided into three working sections, each controlled by its own switch and semaphore. When this switch is closed its section of conductor is made alive, and the movement of the switch handle sets the semaphore.

The experiments made so far have been carried on for the purpose of developing motors and systems of operation for elevated and surface steam roads. For the locomotive a

special 8-wheeled car is used which weighs 30 tons empty. It resembles a regular passenger coach and is so constructed as to give an unobstructed access to the two motor trucks. It is divided into three sections, a driving and testing compartment in front, a passenger division in the center, and a rear compartment for the air pump, tools, etc. The forward compartment is equipped with all the apparatus necessary to obtain a complete record of the performance under test. The resistances are suspended under the central compartment. The contact shoe is suspended by the two loose links from an iron casting on the end of an oak beam which projects from beneath the bolster of each truck.

During the test, when the photograph from which our illustration was reproduced was taken, the locomotive was equipped with four G. E. 2,000 motors rated at 125 h. p. each, one to each axle. A K16 series parallel controller was used. The first test made with the motor equipment was hauling four freight cars, loaded with pig iron, making a load of 121 tons. Later the locomotive was coupled to four passenger coaches which, with the motor car made a train of 130 tons. The total draw-bar pull was about 15,000 pounds. The tests have so far been attended with success and many interesting results will be derived from them.

### A LEVEL HEADED MAYOR.

One mayor has been discovered who has the courage of his convictions, and who is not afraid to express them. The Chicago Tribune recently published replies to questions it asked the mayors of several cities regarding their opinion of the Illinois Humphrey bill, then pending. Mayor H. P. Ford, of Pittsburg, said:

"Not knowing anything about the Humphrey bills I would not care to put my signature to an article on the subject. Generally speaking, I am opposed to the city and state supervision of street railways. The conditions in Chicago, where the ground is level, are different from what they are in Pittsburg, where the land is hills and hollows. I do not think the city should have the power to grant, extend, or annul franchises. When capitalists put their money in a road they do not know whether it will be a success. They have to risk their capital and take the responsibility. If the road proves a success the city shares in the benefit by getting improved transportation facilities and securing an increased taxable value on real estate.

"The city should not have the power to annul a franchise because a railway might be operated for ten years and not pay. Just about the time the stockholders began getting their money back it would not be right for the city to step in and annul their franchise. The men responsible for the creation of the road would quit heavy losers if this were done. The city should not be given a chance to build and operate street railways unless it has the money to do the work. The municipality might project a railroad that would lose money in its operation instead of making it. The taxpayers would have to foot the losses. Then, again, to build new lines the city would have to levy sufficient taxation to cover the cost and operation. This might be disastrous to the taxpayers and plunge some of them into bankruptcy. With private capital taking all the risks the city should give every encouragement in the way of franchises. If a road is not a success the city will not lose anything, as it would if it built the line."

## STREET RAILWAY LAW.

EDITED BY FRANK HUMBOLDT CLARK, ATTORNEY AT LAW, CHICAGO.

*Damages for Death of Minor.*

A girl, three years and eleven months old, having been left at home by her parents, in charge of an older sister, went upon the street and was killed by appellant's car; held that whether the parents were guilty of contributory negligence is a question of fact for the jury.

Under the circumstances of this case where the parents were working people and the child would probably have been a wage earner, the actual pecuniary loss could not exceed two thousand dollars.

In the opinion of the court, Shepard, P. J. said in part; "The appellee's intestate was a girl three years and eleven months old, in good health, and was run over and killed by a horse car, operated upon West Chicago avenue, by appellant. \* \* \* While it must be conceded that the witnesses for appellee did not agree, in some particulars, with one another, and sometimes on cross-examination did not adhere to an entirely consistent account of every detail testified to on direct examination, yet as to the main facts there can not, in fairness, be said to be an uncertainty, and from the whole evidence, the jury was justified in finding that the horse car driver was negligent. C. W. D. Ry. Co. v. Ryan, 31 Ill. App. 621, and 131 Ill. 474. Even though a child of such tender years goes upon the street and plays in the absence of her parents, having been left at home by her parents in the charge of an older sister, ten years of age, the law does not say that the parents are guilty of such contributory negligence as shall prevent a recovery for an accident to her from the negligence of another.

Whether the parents under such circumstances be guilty of contributory negligence, is a question of fact for the jury under proper instructions by the court. \* \* \* The objections urged against the instruction are that it omits the element of care due by the parents; that it is mandatory as amounting to coercion upon the jury upon using "must;" and that it omits to give to the jury any rule governing their assessment of damages. The instruction was had in every particular, except perhaps as to its mandatory form. T. W. & W. Ry. Co. v. Grable, 88 Ill. 441; City of Chicago v. Meyer, 18 Ill. 349; L. S. & M. S. Ry. Co. v. Pandey, 37 Ill. App. 203; C. E. & L. S. Ry. Co. v. Adamick, 33 Ill. App. 412; Garlan v. C. & N. W. R. R. Co., 82 Ill. App. 571 and the judgment would have to be reversed if that instruction were the only one in the case. But the appellant by instructions asked and given in its behalf, most amply cured all the defects in the one complained of.

Considering all the objections, the whole law of the case was sufficiently given to the jury. The verdict and judgment were for \$3,500, if we were permitted to consider anything more than the bare pecuniary loss to the next of kin, we could not say the verdict was for too much.

The parents were working people and worked away from home; the eldest sister was fifteen and was "living out;" the presumption is strong that if deceased had lived to a working age she would have joined the ranks of the wage earner, and if so, her parents would have been entitled to her earnings during her minority, such facts should be considered and when it be given its full weight, the result shows that the amount awarded is too large.

When the deceased is a minor and leaves parents entitled to his or her earnings, the law presumes a pecuniary loss, for which compensation may be given under the statute,

though, without the statute, no recovery whatever could be had. It was said in City of Chicago v. Scholten, 75 Ill. 468, and quoted approvingly in R. R. I. & St. L. R. R. Co. v. Delany, 82 Ill. 198, in such cases, the pecuniary loss may be estimated, for the fact proved common observation. The child was not old enough to apply any other of the elements there referred to, by applying what we have quoted to the case at bar, the death of a little girl almost four years old, the child of working people, and herself, presumably, as soon as her years would permit, we can not, by any calculation, conclude that the actual pecuniary loss exceeded \$2,000.

If, therefore, the appellee shall, within ten days, remit from the judgment recovered, all in excess of \$2,000, we will affirm the judgment for that sum, but otherwise the judgment will have to be reversed, and the cause remanded, and in both events, at the cost of appellee. Affirmed, if remittitur be made down to \$2,000, otherwise reversed and remanded.

(Appellate Court of Illinois, West Chicago Street Railroad Co. v. Scanlan Administrator, etc., 29 Chicago Legal News 224.)

[NOTE.—In the similar case of Calumet Electric Street Railway Co. v. Lewis Administrator, 29 Chicago Legal News 223, a girl two years and five months old running across the street to her father's house was run over and killed by an electric car when the car had gone less than its own length from the place of starting. The motorman did not see the child until she was in front of, almost under the car. The court found that from the time he did see her he was guilty of no negligence, but that he might have seen her sooner. In affirming a verdict against the company, the Appellate Court cites with approval the case of Chicago West Division Railway Co. v. Ryan, 31 Ill. App. 621, and 131 Ill. 474 on the questions of absence or negligence by the company and of care by the parents of the child.—ED.]

*Riding Between the Rails of Electric Railway on Bicycle—Duty of Motorman and Rider.*

A person riding between the rails of an electric railway upon a bicycle is held to be chargeable with the duty of looking out for and endeavoring to avoid danger from the electric cars; and the motorman seeing him is held entitled to assume up to the last moment that the rider will turn out of the way by increasing his speed or turning aside to avoid the danger.

(Supreme Court of California, Everett v. Los Angeles Consolidated Electric Railway Co., 34 Lawyers Reports Annotated 350.)

*Driving Upon Track in Front of Electric Car—Collision with Vehicle—Negligence of Motorman.*

In an action against a street railway company for injuries received in a collision with an electric car, it appeared that plaintiff, in order to pass a vehicle, drove upon the track of the defendant company and in a line with an approaching car some hundred feet in his rear, after going about thirty-five feet on the track he turned off and his wagon was struck by the approaching car, and it is held, that the plaintiff was not guilty of negligence in driving upon the track when the car was approaching at the rate of six miles per hour.

It appearing that the motorman had his car under control when within a wagon's length of the plaintiff, at which

time he increased the speed of the car so as to pass, he was guilty of negligence and an instruction that he recklessly ran into the wagon was not error.

(Supreme Court of Michigan, *Blakeslee v. Consolidated Street Railway Company*, 29 Chicago Legal News, 257.)

*Injury Caused by Several Wrong Doers—Liability of Each.*

The question with appellee is not which of the two railroad companies was most at fault, but is, did the appellant contribute to the injury she received. She sued both companies together, but at the trial dismissed her suit as to the city company, and took her verdict and judgment against appellant alone. Her right to do so is not questioned. The degree of fault, if there were any fault attachable to appellant, is immaterial so far as she is concerned. There was no evidence that tended to show that in a considerable degree at least, appellant was negligent in that its driver failed to see the cable train as he should have done, and he did not wait for it to pass, and appellee had her right of action against both or either of the wrong doers. Either one was responsible to her for the whole injury, and the degree of blame as between them was immaterial.

"When contributory action of all, accomplishes a particular result, it is unimportant to the party injured that one contributed much to the injury, and the other little; the one least guilty is liable for all because he aided in accomplishing all." *Cooley on Torts* (Sec. Ed.) 155. In the case of *St. Louis Bridge Co. v. Miller*, 138 Ill. 465, the court says: "Where several tort feasers have co-operated to the same end, either may be held for the entire tort. The fact that the injury could not have happened without the wrongful act of one is not a test of the non-responsibility of the other. A tort may be of such character as to require for its perpetration the concurrent action of several, so that if either one fail in part, the tort is not committed. In such case it may properly be said that but for the wrongful act of either of the tort feasers, the wrong could not have been committed. But the fact can not be argued in exoneration of the others."

(Appellate Court of Illinois, *West Chicago Street Railway Company v. Feldstein*, 29 Chicago Legal News, 216.)

*Action for Death of Child—Care to be Exercised Toward Minor—What may Excuse Heedlessness of Child.*

The duty of the appellant to exercise ordinary care, "That degree of care which, it is to be presumed, an ordinary careful and prudent person would exercise under the same relation and under the same circumstances," to avoid injuring a child upon the street, cannot be denied.

Her tender years and sex are to be taken into account in calculating the probable influence upon her fears in the loud ringing of the gong while the car was constantly coming nearer, and the way so obstructed.

Negligence and care are questions of fact for a jury. That she was a young girl running as fast as she could from the car, which was coming toward her, and that her path would soon be so narrowed that she might well be afraid to enter it, were obvious facts. While the duty of the appellant was not increased toward the child, her heedlessness in leaving a path of safety and going into danger may be excused by them.

The jury was justified in finding, in effect, that the car should not have been driven to pass her, as was the apparent purpose of the motorman, and that more respect should have

been had to the uncertainty of what such a child would rashly do under the surrounding circumstances.

The court is of the opinion that the question of the amount of damages is not before it for review.

(Appellate Court of Illinois. *Calumet Electric Railway Company v. Van Pelt*, 29 Chicago Legal News 197.)

## THE RIBBE STORAGE BATTERY.

Germany is the home of the practical storage battery and many efforts have been put forth to construct a battery suitable for street railway purposes. The latest product is a storage battery designed by Paul Ribbe, of Berlin, for which the inventor makes many claims of merit. The illustrations, which are from the London Electrical Engineer, represent the construction of the battery. The cell has a pasted plate for both positive and negative with celluloid separators. The lead frame work is shown to the left in cut and consists of a lead sheet, 0.35 in. thick with slots punched through it to hold the paste. In center of cut is shown the finished plate and cross section of the plate is represented on the right. The paste is applied only to those parts containing vertical slots and a thin sheet of celluloid is placed on either side of the

plates. The tubes of celluloid, A A, form vertical separating ribs between adjacent plates. The plate consists of a continuous lead core, a thin layer of active material on each side and a cover of celluloid, cemented at intervals through the grid. A car has been built for the London, Deptford & Greenwich Tramway Company and these batteries used. There are 140 cells to a car which gives a voltage of 280 and an ampere-hour capacity of 288. The weight of the batteries is about 6,150 lbs. and the inventor says that the storage capacity is 81 kilowatt-hours or enough to run the car for 20 hours.

Like other forms of storage batteries, good laboratory tests have been recorded but it has not yet proved itself durable enough for the severe service necessary for electric traction.

## FARE RESTORED TO FIVE CENTS AT SAVANNAH.

The Savannah (Ga.) Traction Company has given notice to its patrons that hereafter five cents will be the regular fare instead of three cents. This company, formerly called the Electric Railway Company, carried on a rate war with the City & Suburban Railroad Company and fares went as low as one-half cent, but through the intervention of the courts this was raised to three cents in 1895.

As both companies suffered greatly in their finances and neither gained any decisive victory by the war, each will be content to accept its share of patronage at the regular rate of fare.

## FIRE PROTECTION FOR STREET RAILWAYS.

The subject of fire protection falls naturally into three divisions, watchmen, apparatus and organization, and to these are to be added inspection and drill.

The most effective protection against fire is an efficient watchman, because if he properly attends to his duty, a fire, except as the result of an accident, such as an explosion, cannot get under sufficient headway to do serious damage. In conversation with a REVIEW representative, Fire Marshal Swenie of the Chicago fire department, in discussing watchmen, said that the mistake is often made of expecting too much of the men, and relying upon clocks or other time checks to see that the duty is properly attended to. For a man to watch all night and keep his senses alert is deemed impossible, and therefore the watchman should be relieved at the end of three or four hours. This, of course, would necessitate at least two men in the smallest plant. While the foregoing is true, it does not apply with the same force to street railway property, except the shops, because at barns, car houses and power stations there is always a regular force of men on duty until midnight or later and in some cases, where there are many cars to be cared for, all night.

The fire apparatus is usually installed at the instance of the fire underwriters, and the number of hydrants and extinguishers is regulated by an insurance inspector, and they are located in accordance with his recommendation.

The most important duty in connection with fire apparatus is to see that it is in good order and fit for use in the case of emergency. Too often the inspections of it, if made at all, are entirely perfunctory, and consist largely in observing that the particular thing inspected has not been carried off. As a rule, the city fire department makes inspections of all large buildings at regular intervals. In Chicago the captain and the lieutenant of each district make inspection of all buildings, other than dwelling houses, in the district at least once each year, the visits of the two officers being so timed as to be about six months apart. On these occasions notes of changes are made, and all valves hose, fire extinguishers, etc., carefully examined.

Lastly, there remains the organization among employes to be considered. The importance of having men skilled in the work required of them is nowhere greater than in this particular, because the best of apparatus is useless if the men do not know how to handle it. Any organization in general will have two objects—extinguishing the fire and rescuing the property in danger if the first is impracticable.

When requested to outline a fine organization among street railway employes which could be depended upon to render efficient aid to the regular department Chief Swenie said that because of the different conditions obtaining in each building a concrete scheme could scarcely be outlined. In general he laid down these rules: There must be a leader, one who will not be liable to get the "fire scare" and can be depended upon to hunt the fire and not lead in the retreat. The fire brigade should comprise only the employes who are regularly employed about the barn or car house, as they will be familiar with the premises and at hand when required. A set of signals agreed upon so that the location of the fire may be known when an alarm is turned into the office or other central point; a man at this point whose par-

ticular business it is to turn in an alarm to the city department. When an alarm is sounded the men should report to the barn foreman, or the person in charge at the barn, for directions. Frequent drills, which shall familiarize the men with the operation of the apparatus provided; at drills the apparatus as well as the men should be exercised.

Chief Bonner of the New York Fire Department advises as follows:

"In the large stables here, where a large number of horses are used and housed, there is a form of organization amongst the employes; upon a given signal, they are required to proceed to that point and render all necessary assistance in extinguishing the fire.

"The building is generally equipped with pails of water, fire extinguishers, or in other cases hogsheads, with pails submerged and ready for immediate use. This, in connection with a watch system and time detectors, is found to be very efficient when properly looked after. Of course the first duty of a watchman or others on discovering a fire in those great stables, is to send out a regular alarm for the city fire department; a special box for this purpose should be within the building, or within the immediate vicinity of the stables.

"Our officers make frequent inspections of these and other large buildings, such as hotels, music halls, theaters and large places of assemblage, or buildings covering large areas, with the view of becoming familiar with the building and its means of entrance, exits, stairways, etc., and see that all laws and regulations required by the department are strictly enforced, and to report from time to time any additional safeguards that may be required for the protection of life or property.

"The best plan of organizing a fire brigade for the protection of property would be to obtain the services of a thoroughly practical fireman and give him entire control of the men whom it is desired to use for this purpose, allow him to make the necessary inspections of the building, and assign such implements, extinguishers, etc., and posts for watch purposes as he may deem necessary. If he is the right caliber of a man he will report a plan of organization, commencing with a thorough system of watching, the supplying of implements, extinguishers, etc., and the assignment of the men under his charge, on a given assignment to any point within the building, let it be day or night. The system of watch duty ought to be supervised and provided with time detectors which should be located in the office where each tour of duty could be reported upon the card board and examined by the company upon the following day. This and other safeguards, such as may be suggested by the officer in charge of the department, I think would insure great safety, and possibly be the means of allowing a very large rebate on the amount of insurance."

Fire Marshal J. A. Archibald, of Cincinnati, writes as follows:

"It is customary in our department that the members and officers acquaint themselves with all buildings in their respective districts.

"We do not rely upon the employes of any company for any assistance, but these are at times of great assistance in locating the fire and assisting around the building.

"It would be an excellent idea to have an organized fire brigade at any plant of that kind. I would have plenty of water and good hose distributed in locations where it could be used to the best advantage, and would have picked men

from the employes and put them through a practical drill once a week. In a case of that kind they would not only be a great help to the fire department, but the chances would be they would put out the fires themselves without calling on their fire department."

When fire occurs the first duty is that of notifying the city department, and the second that of rescuing the property threatened, usually horses or cars. For handling cars, especially where the motive power is electricity, one or more cars used as switch engines may often be employed to advantage in hauling cars out of the barns, and one road has outlined such a scheme. In some places such an arrangement may be impossible, as in Indianapolis. There, when a fire occurs in any department of the street railway, the city fire department notifies the company to cut off the current from all lines in order to protect firemen from possible accidents with live wires.

The following replies to letters of inquiry to some of the largest street railway companies will indicate the precautions taken by them.

The Toledo Traction Company has no fire organization but employs regular watchmen with call boxes to American District Central Station. A scheme is outlined for switching cars out of barns in case of fire.

On the National Railway lines of St. Louis there is no organization among employes in the nature of a fire brigade and no drill. The buildings are all well supplied with lines of hose connected with water pipes, water tanks, buckets, etc. Daily inspections are made by the company, and also frequent inspections by the fire underwriters. The men are instructed to turn in an alarm and then use water buckets and hose and utilize all available men for running cars into the street.

One manager in writing of the matter concludes: "We have never had a fire, and being just like other mortals, our long immunity has, perhaps, made us careless in this regard."

The Market Street Railway of San Francisco up to the present has taken no precaution other than providing numerous hydrants and suitable hose. The red-wood used in building is much less inflammable than pine. This company contemplates a more thorough system however.

The Consolidated Tramway Company of Denver has no organization, but has its car houses protected by the Grinnell automatic sprinkler system, and in addition has stand pipes and fire plugs and Miller extinguishers.

The Lindell Railway Company, St. Louis, provides Babcock extinguishers, but has no drill. When an alarm is sounded on the fire bell the men report to the foreman, each taking the nearest extinguisher with him. Switching, etc., is at the discretion of the foreman.

J. E. Rugg, general superintendent of the West End Street Railway of Boston, replies to inquiries as follows:

"Our large car houses are equipped with stand pipes and roof nozzles, with fire underwriters standard hose and nozzles, also with fire buckets, axes, etc. A fire gong is connected with switchboards, by which an alarm can be sounded from different parts of the house.

"The car house men are organized into a fire brigade in charge of the foreman of mechanical department, each man being detailed for a particular duty.

"The men are not drilled regularly but are called out without previous notice.

"There is no special scheme outlined for running out cars in case of fire.

"At the sound of alarm the men respond instantly, assembling at a given point, and take their orders from the foreman.

"The fire equipment is inspected daily, being in charge of the foreman, and he is held responsible for it being in good working order."

The Union Traction Company, Philadelphia, has all of its stations thoroughly equipped with fire buckets filled with water, and fire hose attached to plugs and on reels ready for immediate use, but has no fire brigade or drill among employes. A fire inspector is employed whose duty it is constantly to visit the various stations to see that the apparatus is in good condition. The company carries no insurance except on leased property, and then not unless required by the terms of the lease.

The Twin City Rapid Transit Company has no fire organization and relies upon the service of watchmen, who are employed in all the stations.

The North and West Chicago Street Railroads employ watchmen and provide fire pails and buckets of sand for use in case of small fires, but have no fire organization among employes. The instructions are that a city alarm is to be turned in as soon as a fire is discovered, and every effort is made to have the alarm boxes placed near the principal buildings of the companies; in many cases they are placed on the walls of the barns or power houses.

The Montreal Street Railway Company has no regular fire organization. The superintendent, Mr. McDonald, says in regard to fire appliances: "In our main car shop and repair building, which is a three-story structure, we have a 3-in. water main running to the roof of the building and 300 ft. of hose attached to this, to reach any part of the roof in case of fire. Apart from this all parts of our shops are provided with sand and water pails that can be used at a moment's notice. In one of our stations, where we have several car sheds spread over a large area, we have a small hand reel that carries 500 ft. of hose, and we occasionally give our men who are waiting around the station a false alarm to accustom them to act quickly with this reel in case of fire."

The Chicago City Railway has a fire organization among the employes of each of its seven barns and also at the shops. Lindgren & Mahan stationary chemical machines, and Miller and Babcock extinguishers are placed according to the recommendations of the city fire department and the insurance inspectors, the number and location depending on the arrangements of the particular building. Fire hydrants are provided in all buildings; in the new Cottage Grove avenue car house they are spaced 50 ft. apart in one direction and 30 ft. in the other. Buckets of water are also placed at convenient intervals.

The fire brigade comprises all the men regularly employed in the barn, at the new barn there are about 20 men all the time both day and night, trainmen not being relied upon except as auxiliaries. Special watchmen are employed where there is no night force.

The barn foreman is the leader and is held responsible for the condition of extinguishers, etc., and for the men being acquainted with their respective duties. Each month the inspector visits all barns, opens and cleans all valves, inspects hose, tries the extinguishers, and in general satisfies himself by trial that all is in order. Notes are made of the condition of apparatus as found and a written report submitted to the electrical engineer by whom it is transmitted to the general manager.

Electric push buttons are placed in different parts of the barn. When fire is discovered the man's first duty is to push the nearest button, as directed, which signals the barn office as to the location of the fire; he then runs to a gong centrally located and sounds it. The men report for duty at once and are direct where to go, taking fire buckets and hose with them. When the alarm in the office is sounded the man on duty there turns in a city alarm at the nearest box.

This company organized its fire service in 1892, since which time seven fires have been extinguished without aid from the city department.

To illustrate the workings of this department, General Manager Bowen gave a REVIEW editor an order to turn in an alarm at the Cottage Grove car house. Presenting it to the barn foreman, he went quietly along until a point somewhat remote in the building was reached and then turning in an alarm waited to see if anything turned up. As the gong rang out its warning the score or more of workmen scattered through the building dropped their tools and in a moment he was surrounded with a phalanx armed with buckets, extinguishers and hose. When the boys discovered the cause of this excitement they looked as if they would like to turn the hose on somebody, but a "fire out" was sounded and the brigade returned to the more peaceful occupation of cleaning cars.

It appears that but little attempt has been made by the fire departments to have the railways cooperate with them, and what has been done in the way of fire service among employes has been at the instance of the companies themselves.

#### COPPER NEEDS NO PROTECTION.

The proposition to place a duty of one cent per pound on copper, as is proposed in the Dingley bill, is meeting with opposition from the Copper Producers' Association. The only copper that is imported comes to the smelting works to be refined or for separation of the precious metals contained in it. The United States has the greatest production of copper in the world, last year the output being 424,402,735 lbs. Of this about 252,000,000 lbs., valued at \$30,216,194, were exported. There are at present three copper producing districts in the United States, namely; Montana, from which 208,939,323 lbs. were mined; Lake Superior, 144,797,153 lbs., and Arizona, 70,666,259 lbs. It is noticed that the lake region no longer governs the supply. The Anaconda Copper Mining Company alone, produced 121,549,878 lbs., and the capacity of the Montana mines is being rapidly increased by the introduction of additional and improved machinery. The Arizona mines have been rapidly developed of late. It would seem that this profitable business is on a firm basis and can no longer be accounted an "infant industry."

The Consolidated, Pittsburg, recently took the wind out of a foolish suit, by going into court and confessing judgment for the five cents sued for by a passenger, whose transfer ticket was refused.

The Market street road, San Francisco, has caused the arrest and will prosecute under the anti-spitting law, a wealthy Californian, W. B. Bradbury, who persisted in expectorating in a street car after having been warned by the conductor to desist.

#### CONTINUOUS RAILS IN UNPAVED STREETS.

We all know of what great advantage the continuous rail has been to the street railways which have adopted it, and the low joint, the bete noire of the street railway manager, is no longer feared because it need no longer exist. By removing the hollows every 30 or 60 ft. into which each wheel fell, to be pulled out at the expense of the coal pile, the cost of power has been reduced, and also the cost of maintenance. The rail, the tie, the wheel, the truck and the passenger are all saved wear and tear. When it is suggested that the continuous rail would be of equal value in saving both the track and the rolling stock on steam roads, the answer is that on such roads the rail is above ground and exposed to all sudden changes of temperature; that it would contract and pull apart in winter and expand and buckle in summer; that on the street railways using the continuous rails, they are so buried in paved streets that less than 30 per cent of the surface is exposed and are laterally supported by the paving which prevents buckling. On

83-LB. RAILS IN 47TH STREET.

suburban roads also, where the tracks are laid in unpaved streets there has been considerable hesitancy about welding the rails, one company going so far as to consider the design of an expansion joint which could be laid at rather long intervals and thus provide for the expansion and contraction that it was presumed would occur.

We reproduce here photographs showing a piece of double track laid by the Chicago City Railway on 47th street between Western avenue and Kedzie avenue in July, 1896. This track is of standard street railway construction; 7-in. 83-lb. girder rails; oak ties spaced 28-in. between centers; wrought iron tie-rods every 7½ ft.; joints cast-welded by the Falk process. Tie plates with a brace which supports the rail on the outer side are used; there are four spikes at each end of each tie, the two on the inner side are driven through holes in the plate and grip the lower flange of the rail, those on the outer side are smaller and hold the tie plate only. This track is laid in an unpaved street on an embankment but little wider than the tracks. The space between the two tracks and between the rails is for the most part filled with loose dirt, in wet weather it is soft mud, into which the horses driven over the street sink clear down to

the ties, but the sides of the rails are in many places exposed for more than half their depth. This piece of track is one mile in length and has passed through the summer without a kink and the winter without a break.

The co-efficient of expansion of steel may be taken at .000066 per degree Fahrenheit, and the extreme range of temperature as 120 degrees, or the co-efficient for the total range as .0008. In a mile this amounts to over 4 ft. As the cars operating over this track did not find any such chasms it is fair to presume that the rails did not contract.

Assuming the joints to have been welded at the maximum temperature attained in summer, the rails would tend to contract .0008 of their length for a fall of temperature of 120°. The force necessary to prevent this is .0008 times the modulus of elasticity, which latter may most easily be defined as the stress necessary to stretch a bar of unit cross section to twice its original length, in the case of steel about 30,000,000 lbs. per sq. in. Thus the force necessary to prevent contraction is 24,000 lbs. per sq. in. or, since an 83-lb. rail has a sectional area of about  $8\frac{2}{3}$  sq. in., the total force is 208,000 lbs. This stress of 24,000 lbs. is well within the elastic limits for rails. Inasmuch as the modulus of elasticity is the ratio of unit stress to unit strain, the force necessary to prevent contraction is no more for a mile than for a foot; but this resisting force may be distributed, and applied uniformly throughout the length of the rail. The ties are 28 in. apart or 2,263 per mile, so that if at each tie the motion of the rail is resisted by a force of 92 lbs. no movement will result. Of course the track must be anchored at the ends in some manner or other, in this case it is so anchored by being connected to more track at the Western avenue end and to a piece of track in Kedzie avenue. The longer the rail the less is the resisting force per tie required to prevent motion and for 10 miles of track it would be only 9 lbs.

It is generally admitted that the buckling is more difficult to prevent than the contraction, and as the proper way of doing this Mr. Bowen suggests the rails should be welded at a comparatively high temperature so that nearly all the stresses to which the rails are subjected shall be those producing tension. This experience of the Chicago City Rail-

Oakland avenue, Milwaukee, laid with 60-lb. T-rails. The photograph was taken after four days exposure in June, 1896, the joints having been cast at night. This track is

SIX INCH 60-LB. T RAIL, OAKLAND AVENUE, MILWAUKEE.

covered by dirt to the heads of the rails; no joints have broken on this track.

### CARRYING BICYCLES.

Street railway managers are waking up to the fact that in many cities the carrying of bicycles on street cars is not only a possible source of revenue, but an accommodation which the public is beginning to demand. We have realized this trend from numerous letters, asking what is being done in other cities.

There are evidently cities where such accommodations are not much needed, but in others where the parks or other desirable riding streets can only be reached by passing over long stretches of bad riding, a good business can be carried. In San Francisco, as already illustrated in these pages, a device is attached to the front of each car which will carry two wheels. For these one regular fare is collected. All familiar with the topography of that city, and Butte, Montana, where wheels are carried, will realize the popularity of the scheme. But in other cities, not hilly, there are lines where bicycles can be hauled, not only in case of accident to the wheel, but where riders become tired, or are caught in rain and glad to return under cover. In New York city the elevated roads have put in operation several bicycle cars, converted from regular cars by taking out the seats and substituting a rack along one entire side; side seats extend along the other side. In these cars no one is allowed without a wheel, and no checks are given—each rider must watch

TRACK IN 47TH STREET, CHICAGO.

way will no doubt be of interest to those interurban roads which are seeking a solution of the low joint problem.

The third illustration is a view of a piece of track in

his own machine. On Sundays and specified holidays special bicycle cars are attached to trains running every twenty minutes between 155th and Rector streets, via the 9th avenue line, from 6:30 to 8:50 a. m. and from 4:30 to 6 p. m. This service was inaugurated Sunday, April 11, and promises to be very popular. A sign is carried reading "Bicycle Train."

Where street railways desire to inaugurate this traffic it would not be difficult to convert an old horse-car to the purpose, putting in racks with locks, using keys that cannot be removed when the rack is empty, and transporting the passengers in the regular car ahead. For good weather a flat-car can easily be constructed in the home shop of good length, and without any roof if desired.

### THE VARIED DUTIES OF MANAGING A SMALL ROAD.

We have always had a great deal of sympathy for the manager of the small road, and feel that frequently he out-generals, in his smaller operations, many a time, his brothers of the larger systems. It is obviously no easy task with small earnings, where every dollar must be made to count to give the service which he wants to give, but which the receipts do not warrant. In addition to this he must be practically the whole thing, and fill all the executive offices at once.

A bright young electrician who has had considerable experience on a large eastern road has been for the past year in charge of a small road in the west, and writing us of his experiences, says:

"When I come to think of the worry and care that have been mine during the past two years, I count my experience very valuable to me. I dare say it would have taken many years to have acquired the same ins and outs on a metropolitan road. The large street railways are divided into departments, and each department is under a separate head, but here a manager must act as superintendent, claim and purchasing agent, chief engineer, and sometimes a relief or extra on the cars; or, at other times must deal out comfort or charity to an afflicted widow whose husband your cars have killed; attend council meetings, secure legislation, and bear up proudly under the adverse criticism of a thankless public, which does not appreciate the efforts of its best friend. With the watchword, "Pay expenses or shut down," the past two years have found us heroically struggling to keep our heads above water. It has made me sick at heart at times to know that we ought to string more feeder wire, to find that the ground return was in bad shape, and re-bonding was necessary; hangers need replacing; air-brakes should be purchased (grades 1 per cent); that cars need repainting; whether to pay damage claims or stand suit; and buy a new engine for the power-house; repair faulty bridges—and only "chicken feed" in the till and a dwarfed bank account. Such are a few of the interesting problems I have had to face and work out, and I know you will rejoice with me that I have succeeded in paying expenses and made quite a number of improvements as well."

Such is the every day experience of many of our readers, and we offer these trials of our friend for the consolation of those in the same boat, on the ground that misery loves company. Let the manager of the many small roads which are working under conditions most adverse and unpromising take heart, and keep trying; there are doubtless others worse off.

### A NEW TIDE MOTOR.

Experiments are being continued in California to improve the old and unsuccessful types of wave motors so as to get a practical mechanism. A motor has been designed and is being built at the Union Iron Works, San Francisco, which the inventor, Mr. Schomberg of Los Gatos, believes will fulfill the requirements. In the model the force of a wave is transmitted to a piston which compresses the air in the cylinder into a large reservoir from which it can be used for driving any compressed air machinery. The apparatus is designed for a period of greatest calm and least swell as an ingenious system of pawls and ratchets with an automatic trip relieves the motor from any excessive strain due to very heavy swells. A wharf will be erected near Santa Cruz or Capitola this summer to test the new motor. Although no one has yet succeeded in working out the problem, it is such an inviting field and so full of possibilities, that it is to be hoped practical progress will soon be made.

### ELECTRIC MUTUAL CASUALTY ASSOCIATION.

At the annual meeting of the members of the Electric Mutual Casualty Association of Philadelphia, Pa., officers were elected as follows: President, W. B. Rockwell, Staten Island Midland Railway; vice-president and general attorney, Thomas B. Harned; treasurer, W. H. Clark, Bergen Traction Company and cashier of the Quaker City National Bank; secretary, William W. Wharton. In addition to the foregoing, the directors elected were N. Sumner Myrick, president Warren, Brookfield & Spencer Street Railway Company, Brookfield, Mass.; C. H. Stoll, president Belt Electric Line Company, Lexington, Ky.; Dr. H. B. Rockwell, medical director; W. S. Grant, Jr., president Geneva, Water-

W. W. WHARTON.

loo, Seneca Falls & Cayuga Lake Traction Company, Seneca Falls, N. Y. The association had a very successful experience in 1896 in avoiding accidents and adjusting claims, and commences the present year with every prospect for a successful career and rendering itself more necessary to its members than ever. The membership now comprises 40 of the most completely equipped suburban and interurban roads in the country, and a high standing is necessary for admission. The secretary, W. W. Wharton, who was elected at the last meeting of the association, was in December last appointed to that position, succeeding Newton Jackson. Mr. Wharton has long been identified with the insurance world, and is well qualified for the position.

An ice dam was formed beneath the falls at St. Cloud, Minn., recently, and caused the water in the Mississippi to back up in the canal leading to the power house of the City Street Car Company. This interfered with the turbines, and the plant was forced to shut down for a time.

## AN IMPROVEMENT FOR SAND CARS.

The Third Avenue Railroad Company, of New York, has two sand cars used exclusively for sanding and sweeping the tracks in wet weather. Four hoppers are on the car, and from these sand is deposited at the rear of the revolving brushes on a clean track. Some trouble was experienced in keeping the sand from packing in the neck of the hopper when it became damp. George H. Robertson, the twelve

year old son of Superintendent J. H. Robertson, designed a device by which this trouble is eradicated. As shown in the cut, a toothed wheel is revolved in the bottom of the hopper by a chain which is rotated by a collar on the wheel axle. This agitates the sand and prevents lumps from forming. A disconnecting clutch throws the mechanism in or out of gear. By this simple device but four men instead of eight are required on each car.

## EMERGENCY TELEPHONE SYSTEM.

The Simplex Interior Telephone Company of Cincinnati, has recently perfected an emergency street railway telephone system that may be installed at small cost. In its simplest form it comprises a metallic circuit from the power house or central station along the car route. The pole boxes are of iron, a trifle larger than the ordinary messenger call box, and the interior construction is such that the introduction of the conductor's transmitter automatically puts the same in circuit; there is also a ringing key for signaling central station. The conductor's instrument mounted in hard rubber, is small and easy to carry. The receiving station instrument comprises a relay, local alarm bell, and telephone instrument. Six cells of a good open circuit battery in the central station are sufficient to operate a line 10 miles long.

The wheelmen of Charleston, S. C., add insult to injury when they insist that the street railway provide a cinder path between its tracks, so bicyclists can ride out to the country. A liberal use of oyster shells would perhaps be better for the railway business.

## STREET RAILWAY PROBLEMS IN EUROPE.

Our readers will no doubt be interested in the questions proposed for discussion at the Tenth General Assembly of the Permanent International Tramway Union of Europe, which is to be held in Geneva in 1898. They are as follows:

## DIMENSIONS OF CARS.

What is the best relation, in tram cars, between the dimensions of the car body and of the platforms?

What type of car do you recommend for electric traction: 1. For underground or overhead trolley lines; 2. For storage battery lines?

## TRUCKS.

What are the advantages and disadvantages of using cars with bogie trucks for local traffic lines?

May not, by other arrangements, the reduction in dead weight be effected, in increasing the capacity of the rolling stock?

What is your experience with radial trucks?

## BRAKES.

What brakes do you recommend for the different systems of traction; 1. Animal; 2. Electric: (a) with motor car only; (b) with motor car and trailers; 3. Steam, compressed air, and gas motors.

## POWER HOUSES.

What, in general, is the proper choice of boilers and engines for a central station?

## BONDS.

What is the best electrical connection for the rails: 1. When laid flush with the pavement; 2. When projecting above the surface?

## SWITCHES.

What are the types of switches you use?

Do you consider that, for mechanical traction, switches with two moving points are preferable to those with one moving point?

## ACCUMULATORS.

What progress has been made with storage batteries for street railway traction?

1. As regards the construction, the capacity, and the reduction of the dead weight of the accumulators.

2. As regards the durability and the cost of maintenance.

3. As regards their practical and economical application to tramway traction.

## GENERAL.

What are the present actual advantages and disadvantages of the different systems of electric traction?

Have you new communications regarding mechanical motors for tramways?

## CARS HAVE RIGHT OF WAY AGAINST CYCLISTS.

In a suit brought against the Los Angeles Consolidated Electric Railway Company by one Everett, who was injured while riding a bicycle on the car track, the court held that it is a wheelman's duty to look out for and endeavor to avoid danger from the electric cars. The motorman has a right to assume up to the last moment that a rider who is between the rails will increase his speed or turn aside to avoid a collision.

### MAIL BOXES ON DES MOINES CARS.

The post office department has decided to test the use of street letter boxes on the cars of two lines of the Des Moines City Railway. The test will cover six months, and if at the end of that time proves satisfactory will be extended to all the lines, and to other cities where conditions are suitable. The Des Moines road affords an excellent test, as every car on the entire system passes the post office, and the boxes can be emptied each trip. The scheme was tried about 10 years ago on the Mt. Adams road in Cincinnati, and in one or two other cities but under the old horse car system was not as successful as it should be now with the quick trips made by electric cars. General Manager Hippe is to be congratulated on having his road selected.

Leading business men of St. Louis are urging the same service there.

### FRAUD CLAIM EXPOSED BY X-RAYS.

As the result of a collision of one of its cars with a car of another company, the City & Suburban Railway of Baltimore has recently had a suit entered against it for damages, by a passenger who claims to have had his arm broken, and in connection with which X-rays photographs will prove important evidence, if they have not already knocked out the case.

Although the collision was reported to be of a minor nature, the claim agent with due consideration of the consequences of such accidents, started at once to investigate. Early in his search he came to the business address of one of the passengers (a Jew) where he learned from his journeyman that the employer had met with an accident that morning and had gone to consult a doctor. In questioning these men, without revealing his business, the claim agent became suspicious, and started at once to track the party. He did not then succeed in locating the physician, but stumbled across a lawyer at whose office the claimant had already applied. From him was gained some valuable information. Two days later the claim was made by letter through another attorney. A meeting was arranged and the claimant appeared with his arm in plaster of paris splints, complaining of great suffering, and armed with a doctor's certificate which stated he was treating him for a broken ulna. The claim agent seemed credulous, and only to be anxious for a reasonable settlement, but made no offer. The claimant asked for \$2,000. When the company's surgeon examined the case he was met with the difficulty of the splints in his way, but he felt well satisfied from other indications that the arm had not been recently broken. How then to meet the contrary statements of the claimant's doctors became the question, in the event of a court trial. If claimant could be induced to submit to an X-rays examination the matter would be determined. To the claim agent's and doctor's plea of only wanting to be satisfied, the man consented to undergo the test, apparently in good confidence that he would escape detection. Appointment was then made with Professor Hamel, of the State Normal School laboratory and an outside surgeon of standing.

The first experiment, owing to movement of the patient while sitting, did not make a good court exhibit, although it satisfied the doctors that the arm was not broken. With much difficulty the claimant was induced to undergo a second trial. This resulted in a clearly defined reproduction

of the bones of hand and arm in normal condition; also showing in varying shadows the clothing, buttons and some trinkets placed in the field by the subject. As a result of the test one of the lawyers (for by this time there were three), dropped from his last offer of \$750.00 to \$25.00, but the company decided it would give nothing, and the claimant has since left Baltimore. It was afterwards learned that he had applied an acid to his arm to give it an inflamed appearance. An account of the exposure appeared in the daily papers, and the claim department has since heard that it has had a good effect upon a certain class of railway claimants.

### A CAR IN COVENTRY.

The illustration herewith is reproduced from a photograph showing one of the double-decked cars of the Coventry Electric Tramways Company, Coventry, England. Being a double-decker the trolley-stand must be of the form shown in order that the trolley may not interfere with the passen-

ELECTRIC TRAM CAR, COVENTRY, ENGLAND.

gers outside, and that the steps to the roof may be clear, the controllers must be set well back from the dash. These two features make the car look strange to American eyes, but the truck is quite familiar, as it should be, being one of the Peckham "extra long."

### TIME LIMIT IN DAMAGE AND DEATH CLAIMS.

The general assembly of Connecticut has passed a bill providing that no action for damages either by death or accident may be brought against any electric, horse, cable or steam railway company, unless written notice stating claims be given such company within four months of the time of the accident. The notice may be served on the secretary or any executive officer of the road.

The bursting of a steam pipe at the Depot street station near the foot of Price Hill, Cincinnati, caused a shut down of the engines and blocked the cars around Government square. Steam was soon up on another battery of boilers and the engines and generators started after an hour's delay.

### AN ABANDONED TROLLEY LINE.

There are some localities which cannot support electric roads, and when, regardless of conditions, tracks are laid and cars run with few patrons, the stockholders and investors are sure to come to grief. Such an ill-advised line was the Northern Electric Railway which made connections with the Cicero & Proviso electric road and Hanson Park, a suburb of Chicago. The Chicago, Milwaukee & St. Paul handled the suburban traffic in these sparsely settled suburbs. It was thought by some that an electric line connecting with the elevated or trolley roads to the center of the city would be profitable. In the spring of 1895 the track was laid for a part of the Northern Electric, but at the intersection of the C., M. & St. P. the railroad owned a strip of land 500 ft. wide. Upon this were laid 54 tracks

extending a short distance on each side of the street upon which the electric line ran.

To build a crossing over all these tracks was deemed too expensive for this small road, and tracks were laid to each side of the railroad crossing. Five cars were put in operation, the power being supplied from a dynamo in the Garden City Foundry. The receipts of the road amounted to about \$2 a day and the expenses \$24. When the cold weather came the system was frozen up and went into hibernation for the winter. The following spring the cars were run for a time, but financial prospects were no brighter than the previous season, and the service was abandoned. The illustration from the Chicago Chronicle shows the dilapidated condition of all that remains of the system. Small boys and junk men soon had the trolley wire down and the cars dismantled. The rest of the ruin was wrought by the elements. The remains stand as a monument to injudicious plans and blasted hopes, and a warning to those who think a fortune is made when a trolley line is built.

### AMERICAN TRADE IN EUROPE.

Albert Herbert, of Boston, in addressing the National Association of Manufacturers, recently said:

We have had some experience with foreign trade. In the last few years one-third of our entire force of 1,200 men has been working on foreign trade, nearly all European, and in England we did it in this way.

First, we found that the circumstances over there are very similar to what they are here. Those people have the same

tongue, and American advertising reached them, and they responded just as quickly to advertising as in this country. In addition to that, we sent over first-class American salesmen and established offices in the principal cities on the other side. We found those people were just as quick as we are—and I believe a little quicker—to take hold of a first-class American article over there.

In other words, the way to reach that trade over there is to advertise the same thing that we advertise here, first-class advertising when it is required, and back it up by first-class salesmen, sent from this side to start the thing over there. I think that in two years from this time most of our business will be done in Europe.

### RECENT DECISIONS IN CONNECTICUT.

The supreme court of Connecticut has recently decided the question of whether a street railway constitutes an additional burden in the street in the negative. Unfortunately the court was divided in its opinion so that a change of one in the judges may result in a reversal of the rule in similar suits which will certainly be brought in the event of such a change occurring. The only similar case that has ever been before the court was decided in 1857, the road being a steam railroad, and it was held that an additional servitude was created. A few years later a lower court held that no new servitude was imposed by a street railway, and the case was not appealed. Being thus able to approach the question unhampered by a mass of precedents the decision was on different lines from what it would have been had the law been well settled.

The majority opinion was written by Judge S. E. Baldwin and concurred in by two of the other four judges. The court says, in part:

"It is the prevailing doctrine in the United States, and was settled, as respects this case, in the case of *Imlay vs. Union Branch Railway Company*, 26 Conn., 249, that the location of an ordinary steam railroad upon a highway imposes an additional burden upon the soil, for which the owner of the fee is entitled to demand the compensation. \* \* \* The essence of the decision was that the grant of a railway franchise by the legislature, authorizing the occupation of land subject to a highway in such a manner as substantially to interfere with the proper uses of a highway, or substantially to change them by introducing another, not practically identical with the original ones, was the bestowal of a power, the exercise of which charged the land with a new servitude."

This opinion cites the preamble of one of the early statutes of the state which declares the fit maintenance of highways in a "fit posture" for passage "according to the several occasions that occurred," is necessary for man and beast and a profit and advantage for the people. The court holds that this statement of principles requires that the public easements for highway purposes must have "originally contemplated all such improvements in structure and grade as occasions occurring in consequence of the advance and growth of the country, and particularly of populous and growing cities shall make necessary."

Continuing, the Judge says:

"Whoever holds property subject to a public trust holds it subject to the same extent to public control. The owner of the fee in a highway holds his estate subject to a public right, which is equally, and for similar reasons, subject to public control so far as may be necessary to protect the public in the full enjoyment of whatever belongs to them. This power of control resides primarily in the general assembly. It is their judgment that street railroads furnish a proper means of accommodating public travel on highways; and the judicial depart-

ment of the government will not pronounce charters granted for their construction to be invalid because they make no provision for additional compensation to the owners of the soil, unless forced to the conclusion that to give them effect would necessarily sanction the invasion of private right.

"But as yet there is a substantial identity in many particulars between the use of a highway by an electric car and that by an ordinary vehicle, both moving upon the same grade. \* \* \* New York is the only state in which the courts have accepted the position that a railroad, designed for the transportation of passengers, or passengers and property, and not operated by steam, imposes a new servitude on the soil of a city or village street; and this conclusion is there rested on the ground that the railway company has a right of an exclusive character to the use of its tracks, which is, to a certain extent, paramount to the general public right to travel. \* \* \* No grant of any power of eminent domain is to be found in the charter of the Newington Tramway Company. If, therefore, the franchise to construct a street railway, which it assumes to grant, cannot be exercised in case of objection on the part of any of the abutting land owners, without the aid of compulsory proceedings, it must fail of effect, and fail because the charter is in conflict with the constitution, in that it purports to allow the taking of private property for public use without just compensation."

While thus holding that there is not of necessity an increased servitude because of a street railway being laid in the street, it is also plainly pointed out that speed, construction and operation may be abused and thus special servitudes arise.

The opinion of the minority is by Judge Hamersly, the youngest on the bench in point of time, and concurred in by Chief Justice Andrews, the oldest. The argument by them is that at common law the rights of the abutting owner in the highway are subject only to well defined easements of a public character, and that the street railway is in the nature of an illegal private occupancy, or a trespass which sounds in damages.

Another case of interest is that decided by Judge Wheeler of the Superior Court in regard to a trolley line from Shelton to Stratford, which in connection with other trolley roads would have joined Bridgeport with Ansonia and Derby, and closely paralleled a division of the New York, New Haven & Hartford. When such a parallel is proposed, it is necessary to have a ruling from a judge of the Superior Court that the line is of public necessity, and Judge Wheeler in deciding this point, rules that there can be no public necessity for "speculative" roads. He says:

"If it should appear that the applicant is bankrupt and that the road will exist on paper, that its promoters were but speculators intending to hawk the franchise about the state, no public interest could be conserved by such a road, and I don't think that the public convenience and necessity would require such a road. Under the statutes the intentions to build such a road must be proven."

If this decision is sustained in the Supreme Court it will inure to the advantage of all legitimate street railway enterprises, protecting them from a very common species of blackmail.

## ELECTRICAL REPAIRS ON CITY VS. SUBURBAN ROADS.

A rather peculiar fact which is hard to account for has been observed by the manager of a large system which has some lines reaching into the heart of a great city and others which do simply a suburban business. On the suburban lines straight runs of half a mile or more at full speed are common, while on the city lines the traffic is as heavy as any place in the world. The power station records show, as would be expected, that the city lines take from 25 to 30 per

cent more current per car-mile than do the suburban because of the power used in accelerating cars. However, in the matter of repairs, the proportion of expense is almost exactly the reverse; that is, the armature repairs are higher per car-mile on the suburban than on the city lines. The rolling stock is the same in the two classes of service. It would naturally be thought that the armature repairs would be greatest on those lines which used the most current per car-mile. However it would hardly be good logic or common sense to reason that the more current a car uses the less will be its electrical repairs; nor does it follow that a reduction in the amount of power used by the city lines would not be accompanied by a reduction in repairs on the city lines. There is, evidently, some special destructive force at work on the suburban lines that is not felt on the city lines. The fact is hard to account for, and the REVIEW would be pleased to learn of the experiences of any roads similarly situated, in order that further light may be thrown on the matter. The high speed lines would naturally be expected to cause more mechanical wear on the motors than slower speed, and it has been suggested that perhaps the mechanical strains on the armature windings are at the bottom of the electrical repairs. The fact that the motors are in parallel a greater proportion of the time on the suburban lines, and are, therefore, both subjected to the full potential a greater proportion of the time has also been offered as an explanation.

## FOR DRAINING GROOVE RAILS.

Our illustrations shows a perspective view and a section of a rail patented in England by W. H. S. Dawson, and manufactured by Askham Bros. & Wilson, of Sheffield, designed to drain groove rails on tramways. The drain rail is of crucible cast steel and is usually 8 ft., 6 in. long, though made in shorter lengths and also in curved sections. Except at the drain box it is of the same section as the grooved girder rails and is fished to the latter at the ends when laid.

A slot 12 in. long is cast in the groove of the rail casting through which the water flows to the sewer, a drain of 4-in. earthenware tiles being laid. Adjacent to this slot and covering the drain, a box with removable lid is provided so that the drain may be easily cleaned, though this is seldom necessary. The rail is in use on tramways in Bradford, Leeds, Huddersfield and Wigan, where considerable difficulty has been experienced from water flowing along the rails and eventually getting into the joints and under the bottom flanges causing more rapid deterioration.

## NO DAMAGES FOR DOGS.

George F. Frances brought suit for \$5,000 against the North Chicago Street Railroad Company on account of his large St. Bernard dog being killed by a cable car. The jury decided for the company.

The Nassau Benevolent Association has been organized by the employees of the Nassau lines, Brooklyn.

## ONE REMEDY FOR BROKEN WHEELS.

Managers that are searching for the mysterious cause of numerous broken wheels and who are on the point of blaming the wheel maker or adopting a heavier wheel for future use may find something to interest them in the experience of a small city road, which recently by a heroic method of treatment succeeded in solving the broken wheel problem. The road was one nearly free from curves but abounding in crossings. The wheels being on maximum traction trucks under long heavy cars, were subjected to heavy stress at special work. Finally after much search for the cause of the difficulty and much argument with the wheel maker, the motormen were notified that men turning in broken wheels would be expected to pay for them. That was the end of the broken wheel difficulty on that road. It is unnecessary to state that the motormen now run over rough special work more carefully than formerly.

## OWNERSHIP OF THE CALUMET ELECTRIC RAILWAY, CHICAGO.

On April 19, Judge Showalter, of the United States Circuit Court, approved an agreement between J. C. McKeon, receiver for the National Bank of Illinois, and Farson, Leach & Co., who financed the Calumet road, by which title to \$183,800 of the \$500,000 capital stock, and to \$2,846,000 of the \$3,000,000 outstanding bonds is transferred to the bank in satisfaction of sundry doubtful promissory notes, assets of the bank. The bank also expects to secure some of the remaining stocks and bonds, and perhaps all of it. Farson, Leach & Co. release all claims on the road; but in the event of its sale prior to April 1, 1900, are to receive one-twelfth of the net proceeds. The receiver for the bank will advance the necessary funds to operate the road and keep the property in first-class condition. No changes in the management or policy are contemplated. As a result of the approval of this agreement, the case in equity of the National Bank of Illinois against the creditors, for debts secured by the Calumet stock and bonds is dismissed.

## ACCIDENTS IN MASSACHUSETTS, NEW YORK AND PENNSYLVANIA.

The table taken from the annual report of the Board of Railroad Commissioners of Massachusetts, is intended to exhibit as fully as may be the actual as well as the comparative risk of injury in connection with street railway operation. The years 1896 and 1895 are compared with the year 1888, which is the last year in which the operation was wholly by horse-power, in order to show, so far as the data furnished by the companies will permit, the relative dangers attending the use of horse and electric power. The report continues:

"The comparison thus made will be the more satisfactory as regards fatal injuries, since it must be presumed that these have always been fully reported. Without going into particulars, it may be said that the proportion of passengers and employes killed during the last two years of electric operation appears by the table to have been on the whole about the same as with the use of horse power in 1888, while the ratio of persons killed on the street to total mileage

operated, round trips and car-miles run, has not been materially larger.

"The ratio of non-fatal accidents or injuries appears by the table to have been considerably greater the last two years than in 1888. To just what extent this is due, to the fuller reports of slight accidents which have been made in the later years, as before mentioned, it is impossible to say. The greater speed of the electric service undoubtedly contributes to accidents of this class, especially to the large proportion of accidents, most of them slight, which result from attempting to take or leave a car, or from falling or being thrown from a car, while the car is in motion. In all kinds of locomotion speed is attained with some sacrifice of safety, and nowhere more so than on the street railway. Any high degree of railway speed is absolutely incompatible with the safety of other street travel.

"The record of the last two years indicates, however, that on the street railway lines of this state only one out of 32,500,000 passengers is likely to meet with fatal casualty, and but one out of 275,000 passengers will receive any injury, however slight; and that cars are run on an average about 30,000 miles without mishap of any sort to passenger, employe, traveler on the street, or other person."

## ACCIDENTS IN MASSACHUSETTS.

PASSENGERS CARRIED, ETC.	1888.*	1895.	1896.

\* Operation wholly by horse power.

The detailed report of accidents in Massachusetts showed that the West End road of Boston, with about one-half the passengers and one-half the car-miles run in the state, had

about the same proportion of accidents to passengers and to employes, but nearly three-quarters of the accidents to "other persons;" it had one-half the fatal accidents and three-quarters of those not fatal.

From the report of the New York Railroad Commissioners for 1896 the second table has been compiled, showing the accidents on mechanical traction lines in New York in 1896, and the ratio of the persons killed, injured, etc., to the passengers carried, miles of track, and car-miles.

### ACCIDENTS IN NEW YORK, 1896.

Passengers carried.....	569,680,943
Average number of employes (including officials).....	21,782
Miles of single track.....	1,485.17
Car-miles run.....	111,403,286

	Killed.	Injured.
<b>Passengers</b> .....	<b>13</b>	<b>192</b>
Ratio to all passengers.....	1 to 43,129,308	1 to 2,920,109
Ratio to miles of track.....	1 to 114.24	1 to 7.73
Ratio to car-miles.....	1 to 8,569,484	1 to 580,225
<b>Employes</b> .....	<b>4</b>	<b>40</b>
Ratio to all employes.....	1 to 3,639	1 to 545
Ratio to miles of track.....	1 to 247.53	1 to 37.13
Ratio to car-miles.....	1 to 18,567,214	1 to 2,785,082
<b>Other persons</b> .....	<b>56</b>	<b>169</b>
Ratio to miles of track.....	1 to 26.52	1 to 8.78
Ratio to car-miles.....	1 to 1,988,987	1 to 659,191
<b>Total</b> .....	<b>75</b>	<b>401</b>
Ratio to miles of track.....	1 to 19.80	1 to 3.79
Ratio to car-miles.....	1 to 1,485,377	1 to 277,814

The third table is from the report of the Secretary of Internal Affairs of Pennsylvania. This report does not give the car-miles run, so that the ratios of killed and injured to the car-miles can not be computed.

### ACCIDENTS IN PENNSYLVANIA IN 1896.

Passengers carried.....	376,502,551
Total number of employes.....	8,394
Miles of single track operated.....	1,561.89

	Killed.	Injured.
<b>Passengers</b> .....	<b>32</b>	<b>532</b>
Ratio to all passengers.....	1 to 11,765,705	1 to 1,053,912
Ratio to miles of track.....	1 to 48.81	1 to 2.94
<b>Employes</b> .....	<b>10</b>	<b>67</b>
Ratio to all employes.....	1 to 839	1 to 125
Ratio to miles of track.....	1 to 156.89	1 to 23.31
<b>Other Persons</b> .....	<b>76</b>	<b>394</b>
Ratio to miles of track.....	1 to 20.55	1 to 3.66
<b>Total</b> .....	<b>118</b>	<b>993</b>
Ratio to miles of track.....	1 to 13.24	1 to 1.57

The Massachusetts table is particularly valuable as showing the decreased liability of accident with mechanical traction.

It is evident that there must be considerable difference as to what accidents are reported in these three states; in Massachusetts the ratio of passengers injured to passengers killed is 111, while in New York it is 12, and in Pennsylvania 17. This indicates that the reported injuries in the latter states were much more serious than the average injury reported in Massachusetts.

The ratios for the number of persons killed indicate that it is about four times as dangerous for a passenger to ride on street cars in Pennsylvania as in New York, and three times as dangerous as in Massachusetts. For "other

persons" the fatal liability is about as 1 in Massachusetts to 3 1/3 in New York and 4 1/3 in Pennsylvania.

On the steam railroads in these states the number of passengers killed and injured were as follows:

	Mass.	N. Y.	Pa.
Passengers carried.....	111,620,051	179,315,449	128,334,166
Passengers killed.....	10	18	37
Passengers injured.....	79	196	834
Ratio of killed to total carried.....	1 to 11,162,005	1 to 9,963,081	1 to 3,468,499
Ratio of injured to total carried.....	1 to 1,413,037	1 to 914,874	1 to 141,887

It is apparent that in proportion to the passengers carried, there are on an average for these three states but 2/3 as many passengers killed on the street railways as on the steam roads. As the danger to passengers on steam roads is known to be slight, and considering that the street railways operate in streets, the showing of fatal accidents to passengers on them is very favorable indeed.

In Massachusetts there were relatively 5 times as many passengers injured on the street roads as on the steam roads, which is further ground for believing that in this state many trivial injuries on the street railways are reported. In New York the steam roads injured relatively 3.2 times as many passengers, and in Pennsylvania 7.4 times as many, as did the street roads. The average for the three states is the same as the average killed—2/3 as many, relatively, on the street roads as on the steam roads.

## SNOW PLOW FOR THE SOUTHWESTERN MISSOURI.

The illustration shows a snow plow of novel design built for the Southwestern Missouri Electric Railway Company by the Freeman Foundry & Machine Works of Joplin, Mo. It consists of a share of heavy steel boiler plate mounted on

SNOW PLOW—SOUTHWESTERN MISSOURI ELECTRIC RAILWAY.

a 1-wheel truck, which is coupled to and pushed ahead of the car. The plow is fitted with a lever for raising and lowering the share. During the last winter this plow was used over the entire system of the company and proved to be very servicable.

Contrary to newspaper report the Oakland (Cal.) Consolidated has not made a 1-cent fare, but has put on sale a commutation book of 25 rides for a dollar, which is primarily designed for use by students at the state university.

## ALUMINUM CONDUCTORS.

The recent reduction in the price of aluminum has caused electrical engineers to do some figuring as to the relative cost and conductivity of the metal in comparison with copper. It can be seen that aluminum gives promise of coming into commercial use as a conductor of electricity. The production of copper seems to be inadequate to the present demand. In fact the visible supply is barely equal to three months' consumption. This is due to the extensive application of electricity in every branch of industry. Especially is the demand a growing one in England and on the Continent, because of the development there of electric traction. The price of Lake copper, with a gradually rising market, is 12 cents per pound. Careful tests have been made recently with aluminum of 99.66 per cent purity, and a conductivity of 63.1 per cent was found as compared with copper. The specific gravity of rolled aluminum is 2.63 and that of copper is 8.93. With this conductivity and specific gravity, weight for weight, aluminum will conduct 2.14 times as much current as copper. At present quotations for copper, aluminum will be a competitor whenever the price is reduced to 25.68 cents per pound. In view of the fact that aluminum sold for \$12.00 a pound 10 years ago, and can be purchased for 32 cents per pound in England today, and with the ever increasing facilities for cheap production in large quantities, it seems reasonable that the metal can soon be purchased for 25 or even 20 cents per pound.

At first aluminum was produced by the sodium process, but this chemical method was quite tedious and expensive on account of the great stability of the compounds. Chemical methods were abandoned, the separation of the metal by electrolysis being the only commercial process. At the works of the Pittsburg Reduction Company at Niagara Falls, the Hall process is used, which consists of dissolving alumina in a molten bath composed of the fluoride of aluminum and the fluoride of some metal more electro-positive than aluminum. Bauxite, an oxide found in extensive deposits in Georgia and Alabama, is best suited for the reduction. It is composed of the following elements: Alumina, 59 per cent; water, 32 per cent; titanic acid, 4 per cent; silica, 3 per cent, and oxide of iron, 2 per cent. This is obtained cheaply, and is delivered to the works direct from the deposits in the South. The crude ore is crushed and washed. With cryolite added as a solvent it is placed in pots which are arranged in series with a low potential circuit of great current carrying capacity. The resistance of the metal mass is such as to give a very high temperature. In each pot is a carbon cylinder which is the positive electrode or anode and the lining of the pot, with the metal deposited, is the other electrode. The aluminum is deposited in the bottom of the vessel by this electrolytic action in a molten mass, and is then drawn off and a new supply of material added.

Cryolite has nearly the same specific gravity as molten aluminum, and for this reason is not an ideal solvent, but its high heat of formation protects it from being decomposed in the electrolytic process, and its solvent powers are greater than any other substance that has been tried. These pots are in constant operation, and as there is little depreciation they seldom need renewal. Noxious gases are prevented by the use of special chemical solvents which are used in dissolving the alumina with a certain strength of current.

Direct currents must be used in this process which necessitates the use of rotary transformers to convert the two-phase alternating current into a direct current of 160 volts. After the aluminum has been drawn off in iron ladles the ingots are sent to the company's works at New Kensington, Pa., where the metal is cast, rolled or hammered into commercial forms.

Since 1886 no less than 16 plants have been started for the manufacture of aluminum and of these only five remain, the rest succumbing to adverse litigation. These firms are the Pittsburg Reduction Company in the United States, the British Aluminum Company in England, the Aluminum Industrie Actiengesellschaft in Switzerland, the Société Electro-Metallurgique and the Société Industrielle d'Aluminium in France. In 1895 these factories turned out 2,528,960 lbs. of aluminum, whereas 10 years previously less than 7,000 lbs. were consumed. The capacity has increased with great rapidity, the Pittsburg Reduction Works alone with its new plant having an output of 3,500,000 lbs. annually.

At the works of this company aluminum has been used for conductors both to the upper and the lower plants. At the upper works, currents of from 8,000 to 10,000 amperes at 160 volts are carried over bars one half to one inch in thickness and 12 in. wide, bolted together with aluminum rivets. Mr. Hunt, president of the company, says that there is less corrosion at the joints and that the present lines give better service than the copper bars which have been used and are still employed in part of the line. At the lower works, in conducting the current from the power station to the pot room on the upper bank of the Niagara river, aluminum rods are used which are 350 ft. in length and  $\frac{3}{8}$  in. in diameter. The rods are connected to the bus bars at one end, running from the generators, and at the other end to the large bars carrying current to the pot-room line by having the ends of these  $\frac{3}{8}$ -in. rods upset into a large aluminum plate which is designed to make the connection between the rods which are the conductors up the bank and the pot room line. About 500 of these rods are used in this way, and are bare.

There are some objections to the use of aluminum in line work, the most fertile source of trouble being with the joints. Joints are difficult to solder though it is stated that the use of a solution of ammonia will greatly facilitate the operation. Galvanic action is liable to take place between the solder and the conductor, but these defects can doubtless be remedied in practice. The greater bulk of the aluminum conductors would make them more difficult to handle than copper, the cost of insulation will be increased and the insulation resistance diminished. However, for trolley wire the greater size with equal weight will facilitate suspension, give greater strength to the line, better contact to the trolley and a less per cent of depreciation. Aluminum has a tensile strength of 25,000 lbs. per sq. in. which is about the same as copper. It likewise has nearly the same temperature coefficient but is not so easily corroded. Some of the alloys of aluminum are of commercial value, though they do not possess the low specific gravity that is such a desirable feature of the pure metal. Many novelties and small utensils are made of aluminum and its use is constantly finding broader application. Should it become available as a conductor of electricity, the effect will be far reaching for in many cases it would be preferable to copper.

## TO THE PYRAMIDS BY ELECTRICITY.

(From Our Own Correspondent, Cairo, Egypt.)

Cairo, if not a city of magnificent distances, is at least a city of magnificent contrasts. There, in striking juxtaposition, are squalor and luxury rubbing shoulder with one another, whilst savagery and barbarism are check by jowl with an advanced form of civilization. Along the streets of Masr-el-Kahira pass all types of vehicles, the well-appointed broughams of wealthy pashas, humble bullock wagons laden with burdens of veiled village women; stately camels with Beduin riders fresh from the desert, bicycles steered by dames in the regulation wheeling costume, donkey boys in blue galabeyahs, bestriding their animals and flourishing their sticks over their heads, and hacks and carriages, called in the vernacular "ariboyahs," with red tarboushed drivers. Motley as the throng is to those multifarious conveyances was added last summer another kind of conveyance, which has to a large extent revolutionized the street traffic of Cairo. Electric tram lines, operated from an over-head trolley, intersect the principal thoroughfares of the capital of Egypt. From the building devoted to the mixed tribunals run the trim, well-kept electric cars, conveying passengers to Abasiyeh, the site of the English cavalry barracks; to Boulak; to Masr-el-Atiqua or Old Cairo; to Bab-el-Luk, and to the Citadel where the famous—or rather infamous—massacre of the Mamelukes took place. Their success is partly evidenced by the rise in the price of the shares of the Societé Anonyme des Tramways du Cairo, from the nominal value of \$100 to \$150.

Curiously enough, none of the shares are held by the native population of Egypt, and on the organization of the company some little dissatisfaction was thereby caused, since many of the wealthier Egyptians desired to invest capital in a local enterprise. Nevertheless, the general public has taken kindly to the new means of transit, and the cars are daily crowded with the turbaned

KASER-EL-NIL BRIDGE.

Arabs, and the black, shapeless bundles whose kernel is an Egyptian woman. Of course, at first a few Arabs were killed by the trams, because an Arab takes some time to grasp the fact that the ting-ting of the bell is an imperative injunction for him to get out of the way. Only 20 have, however, been killed, which is a notable fact to the credit of the native motormen. The success of the trams is further attested by the fact that last year the number of licenses applied for by ostahs or the drivers of hack carriages has been decreased by one-third, and that the donkey boys have decreased in like proportion—in some respects a regrettable fact. There is a further evidence of the popularity of the electric trams in the projected tramway to the Pyramids, for which a concession has been granted by the Egyptian government to the above named company.

The tramway will be commenced in May, and it is anticipated that the cars will be running during the early part of the next year. It will be about seven miles long, and will start from the Kaser-el-Nil bridge, whose poodle-like

ROAD TO THE PYRAMIDS, WHICH THE TRAMWAY WILL FOLLOW.

lions wear an expression of idiotic complacency, and will terminate at Mena House, the famous hotel near the Pyramids. The estimated cost of the undertaking is \$300,000. One of the little difficulties in the way of the undertaking is the narrowness of the bridge called the English bridge, in contradistinction to the Kaser-el-Nil bridge, which was built by the French. The company is required to build on the side of the existing bridges for the tram line and to construct a small foot-way on the other side of the bridge for foot-passengers. The undertaking, however, presents no great difficulty, as the arm of the Nile crossed by the bridge is of

no great width. There is a further requirement, this being that the trams shall not interfere with the avenue of acacia trees which line the road to the Pyramids.

As is the case with the other lines in Cairo, the projected line will be operated on the overhead trolley system, and the power will be derived from Boulak. As the Kaser-el-Nil bridge, or rather one portion of the bridge, is open at a stated time of the day in order to admit of the passage of the dahabeyahs, the cable is carried under the Nile at this point and thence over the bridge. The system is that of the so-called Union Electricaets Gesellschaft of Berlin, which is the same as that of the General Electric Company.

PALM GROVE AT GIZEH.

The poles supporting the trolley wire were in the case of existing lines made in the United States, but as to the forthcoming line they are at present being made in France. The cars are to be made in Belgium; open cars will be used in summer and closed cars in winter. Each car will contain six garden seats, while there will be a compartment set apart for the harem. The wheels are to be made, as for the other cars of the company, by Miller & Co. of Edinburgh. The service will be an hourly one, and there is no doubt whatever that from a financial point of view the success of the scheme is assured. All the material for the line is already in Cairo, and the work is not likely to be stopped by any hitch. There is to be in the first instance a single line, which will no doubt accommodate the traffic, at all events for some time. There will, however, be no difficulty in constructing a double line if needful in a very short time.

Of course, from an engineering point of view, there is no special interest in the line to the Pyramids. The road is perfectly flat and there are no difficulties to be overcome which cannot be readily surmounted. On the other hand, from a picturesque point of view, the road along which the trams will pass is eminently interesting. The contrast between the avenue of trees, with its passing throng of quaintly attired, bronzed Arabs in bright blue robes, or in yellow, purple or striped garments, and the arid desolation of the desert glaringly yellow in its sterility, is great indeed. But this is not the attraction of the traveler. Attention is always fixed on the huge masses of stone which loom up in the distance, seeming to be very near, but which are apparently no nearer after three miles of the road have been traversed than at the outset.

It is, artistically speaking, a huge mistake to destroy the old world aspect and the orientalism of the road to the Pyramids by anything so shockingly modern as the electric tram, which must inevitably jar the aesthetic sensibilities of the cultured traveler.

Still the tram will be by no means a bad thing from a practical point of view, and as usual in this prosaic age aestheticism must give way to utility.

#### TROLLEY WIRES AND POLES IN ST. LOUIS.

The annual report of A. J. O'Reilly, supervisor of the city lighting department, of St. Louis, for the fiscal year ending April 13, 1896, shows:

The miles of streets on which electric cars are operated are 187, on which are laid 332 miles of track. The miles of trolley wires are 344, and the number of poles in public streets, used for railway work is 13,630; poles in parks 123. Only three cases of electrolysis were reported during the year and these were quite insignificant. Electric light wires caused the death of four persons and three horses; five cases of fire were reported from electric wires; and three persons were killed from gas explosions, while two more were asphyxiated.

There were 267 reports of electric light wires "down" and 100 reports of span, trolley and guard wires repaired.

New York's rapid transit act has been declared constitutional by the Court of Appeals, in the suit brought by the Sun newspaper to enjoin the city officials from paying out funds for the enterprise.

## REPAINTING OLD CARS.

BY CHARLES KOONS.

## PART I.

The subject of repainting old cars is quite a broad one, and the systems in vogue are still broader, and often varied in ways and methods. Every painter likes to be original and says his way is the best, and even after he does settle down upon a regular system he is never satisfied, but keeps continually changing, from the fact that here and there some one will be found who has improved this and that way of doing things. It is a progressive trade in any way one wishes to look at it. New colors demand certain treatment to make them show up and wear; varnishes, shellacs, fillers and stains need constant attention and study also.

The numerous new substitutes for this paint and that paint that are constantly being brought forward have to be tested by the practical painter before he feels justified in using them. It is not the wise painter that takes anyone's word for anything in the painting business. If he did there would be chaos in his work, and there would be nothing but trouble from start to finish in all that he did. He must know his oils, japans and varnishes thoroughly, their working qualities and their natures, and be well posted on the strength and drying of his paint mixtures.

The labeled three and four day paint coat and varnish is out of the race just now and has to be used in the one and two day limit, and sometimes sooner. It takes some thought.

The modes of a few years back will not answer for the rush of the present; instead of two weeks, now it is days, and then one cannot do the work soon enough for some people.

The question of service is not considered so much now as formerly, but how soon can it be put through, the quicker the better for some of the hustlers of street railways. With many of them the least attention is paid to this part of the work, hence the rush and hurry that is continually being urged with the painting, which ought to have plenty of time. It has been too often the case that street railway managers look upon the repainting of street cars as needed only when other work is necessary, and not before, and then only a short time is given the painter to jump at his work and throw it on almost any way; if he don't get sufficient paint on to do the work right it has to go anyway, and he has to do the best he can.

This makes it very bad and disagreeable for the painter, as he wants to do good work always, but is often hindered by this kind of treatment. It also keeps him from using the proper material, and as a result he cannot do the work satisfactorily to himself or to his employer. The work, as a rule, in such cases is run out, looking bad and only half finished, and, of course, will not give the service that it should, or would give if better done.

There is no other department that is so hurried in its work and handicapped by the want of proper time. The blacksmith may take all the time he cares to, the woodworker is never through with a job until he has patched up every hole in the car, and even the electrician goes about his work as if he had all summer to do it in, but lo the poor painter has to hedge in on somebody's time in order to get half a show. And he is asked before he has hardly commenced, when he will finish the job. But there are some managers that have

due respect for well painted and fresh looking cars, and have arranged things accordingly, and more, they give the master painter all the freedom he requires in repainting; and as the rolling stock never receives too much paint it is the proper thing to do.

If all of the car painters could use their own judgment in the matter there would not be so many dilapidated cars on our public streets, and instead of the heavy expense per car, for painting every two or three years, caused by the paint and varnish being allowed to perish entirely before giving attention, there would be a thorough going over every year, with a touch of color here and there, and a re-varnishing of the car throughout, in this way there would be no need of repainting a properly painted car except every three or four years. A re-touch and varnish every year saves the expense of repainting every two years. A car that is painted properly will do, if re-touched and varnished once every twelve months for at least three years, and with some colors longer. There is economy in this kind of management because it saves painting one time in three.

Cars that run two years without either painting or varnishing become so cracked up that the only thing that can be done with them is to burn off the paint and re-paint them from the bottom up. Whereas, if the car were re-touched and varnished every year the paint would be preserved and kept intact for at least three or four years, and then repainting would not require nearly as much work as to burn off the paint clear down to the wood.

The varnish preserves the paint and the paint protects and keeps the wood and iron from decay; now if there is no renewing of the varnish every year the paint is exposed and it must give way, and then there is nothing left to keep the car from rotting. The life of the very best varnish made is not over one year, and if not refreshed in that time it is bound to crack. When varnish once cracks it opens up and allows the elements to go still farther, and it is only a question of a short time when the paint will also begin to crack, and then it is a quick process of destruction for everything, varnish, paint and the outside wood and iron exposed.

There is another feature about re-touching and varnishing a car every year. It gives a chance to remedy other defects, for instance one of the worst things to start decay in a street car is the opening of the joints at the corners, and the loosening of screws and nails in every part. This necessarily lets in the rain and dampness, and as a consequence decay soon starts in these places. When this destroyer once has a foot hold there is nothing to prevent it eating its way into more vital parts, thus causing the car to become weakened just through a little matter of neglect.

About once a year these things need attention, when the car is brought in to re-touch and varnish the car builder needs to look over the car and carefully examine every joint and tighten every loose screw or, which is better, replace every loose one with a larger size. The painter in his re-touching always touches and thoroughly goes over these parts, putting and filling up and painting them well and then when the coat of new varnish is put on over this it is ready for another year's run. It is the old story that a stitch in time saves nine, which will be thoroughly proved to any manager if he will give the method a trial.

This, however, is only a prelude to my subject, but is a necessary preparation for the hints and pointers that may follow. In repainting a car the first thing necessary for a painter is to find out how badly the old varnish surface has

cracked. If it has not gone too long and the under paint coating is not affected, it is not necessary to burn it off, but only to wash it down clean with water then take the finishing coat of varnish off with ammonia, using it just strong enough to soften the outside coat, and no more, as the under coat or rubbing varnish that is used in colors must not be softened unless the cracks run clear through all of the varnish, which is unusual unless it is caused by improper painting or bad material. If the cracks are deeper than the varnish and color, the surface must be rubbed down with block pumice stone; after all the varnish is taken off with ammonia, if the cracks are still deeper and run down clear through the under coatings to the priming then there is only one thing to do, that is to burn the old paint off. After which sand and clean down smooth, and free the surface from any of the old paint; unless this is done the repainting will crack again wherever there is any of the old paint left on. This is lifeless stuff after it has gone this far, and the only thing to be done is to get rid of it at any cost. It is often the case that old cracks have not gone any deeper than the color coat, and if this is the case a careful rubbing with block pumice stone will be sufficient to bring out the cracks and level it down to start again with a coat of lead, or a guide coat as we call it. It is nothing more than lead colored up something near the color to be used.

After this coat of lead is thoroughly dry the surface is ready for the putty and plaster of which there will be quite a lot, for the reason that all the former holes, low places and cracks, through the use of ammonia, have been softened and brought down below the regular surface, and these must be all gone over again and filled up level. After the putty becomes dry the whole car is ready for a thoroughly close sanding with No. 1 sand paper. When this is done properly the car is ready for the color coats. Another system which is a very good one, is to give on top of the putty a coat of rough stuff, and rub down with block pumice stone to a level surface. One is about as cheap as the other although the former is the quicker, saving one day's time. In the matter of the painter's health the latter system is preferred on account of doing away with the dust arising from sand papering the lead and putty, which is very injurious.

Another very good way of removing old paint is to use an eradicator, of which there are quite a number on the market. Great care should be taken in using these strong preparations; they should be used by experts who know all about working them, as the tendency is to leave them on too long in certain parts and then there is trouble, as they are made up with solutions of lye, strong soda and most anything in that line that will destroy the paint.

When some parts of the old paint stick a little closer than the rest, and will not come off by using the eradicator, a putty knife or coarse sand paper should be brought into use as a continual coating of the eradicator over the same spot, has a tendency to calcine the wood, as it were, and make the surface so that nothing will stick to it; this is one result of its use and it should be handled with the greatest of care to save trouble and the usual paint and varnish deviltries.

The matter of using color is brought down to the painters judgment; he has had experience in the use of everyone's brand of this and that color, and through that knowledge he surely knows which is best adapted for his use.

There is quite a difference in the various japan colors that are on the market; no two can be alike unless they are ground in the same japan, and then the chances are that one

will be a little different from the other in fineness, and it often happens that the shade from the same pigment is different through the grinding.

Some colors should not be ground in japan, as that medium has a tendency to darken the tint and cause it to turn and fade quicker than it would if ground in varnish. In dark colors it doesn't matter, but in light delicate tints the lighter the medium in color, the cleaner and brighter will the color be when finished. The style in color for painting the modern street car runs in sectional tastes, as every city has a peculiar fad of its own for street car painting, in some dark reds seem to be the only colors used, while other cities go to the other extreme and use the light yellows and whites. In others the tendency is to follow the steam car style and paint all over one color, this makes a very heavy looking street car, especially when the color is dark, although a more economical style could not be devised.

The usual custom is to paint the main panels and letter board with the top ends and dashboard the main color of the car, and then the window framing and the concaves a lighter shade, this adds a little more life and variety to the car, as well as making it appear lighter than it would if painted one color all over.

There is quite a difference in the degree and quality of the colors that may be used in either the dark or light color, and it is poor economy to use cheap colors. The cheap dark colors having a tendency to turn and spot while the lighter shades either turn dark or dim away to no color. Another point against using cheap material in the way of colors is that they will not allow re-touching and varnishing every year, but if the car is to be made to look anything like a fresh painted car the cheap colored paint will have to be cut down and re-coated, while the substantial color will stand re-touching and varnishing two or three times before it needs repainting. This is a saving of one in three in the matter of labor and material, and in the continued expense of keeping the cars looking fresh and clean.

In re-touching good color the tendency is not so much for constant changing. When the color has taken on its old look it generally stays at one point, if it is protected, and can be easily matched anytime afterward. This is not the case with the cheap colors, as they are the ones that are so easily affected by the elements, which cause them to turn and fade, sunlight being their worst enemy.

This can be easily proved by coating panels two or three days apart and exposing each coat to the sun; each day will show a different cast of color with the cheap colors but with good reliable material the changes are not perceptible but come after long wear and exposure if at all.

In another issue we shall take up the permanency of colors used for street car work.

## FIRE DEPARTMENT HAS RIGHT OF WAY.

It has been decided in the case before Justice Dickey of the Supreme Court of New York that fire engines have the right of way over trolley cars as well as other conveyances.

The suit was brought by a fireman against the Atlantic Avenue Railroad Company of Brooklyn, on account of injuries sustained from a collision between a trolley car and a fire engine. It was previously decided that a trolley repair wagon has no right of way, the only vehicles with such a privilege being an ambulance and the fire department engines and wagons.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

Two students of the senior class of the Case School of Applied Science, Cleveland, are now conducting experiments under the direction of Professor Benjamin on the bursting of small fly-wheels. The wheels are driven by a steam turbine, the speed being determined by observing the tone. The first wheel tested was 15 $\frac{1}{8}$  in. in diameter, and burst at a speed of 6,250 r. p. m. A timber bomb-proof surrounding the wheel was demolished.

\* \* \*

The reason why the best is the cheapest in cylinder oils, as in other things, is well brought out by Albert A. Cary in the Engineering Magazine. When oil is fed into the steam much of it enters the cylinder mechanically suspended in the steam in the form of minute globules, and the remainder as vapor. As of course only the unvaporized oil is available for lubrication, the greater the portion vaporized the greater the quantity that must be fed to the cylinder to secure the necessary lubrication. The cheaper grades of cylinder oils are generally composed of a mixture of mineral oil (which has not been sufficiently deprived of its most volatile constituents) with some animal or vegetable oil, added to increase the viscosity. These last named oils vaporise at comparatively low temperatures, and are not therefore fitted for use in cylinders with high pressure steam.

### Test of a 300-H. P. Steam Turbine.

The illustration, for which we are indebted to the Scientific American, shows a 300-h. p. De Laval steam turbine, now in successful operation in the 12th street station of the Edison Electric Illuminating Company, New York City.

In this type of motor steam is conducted from the initial pressure through nozzles to a lower final pressure with consequent increase in volume and velocity; the nozzles are made divergent at the ends so that considering the increasing velocity of the steam, the cross section of the tube is such as to just provide for the increasing volume. The turbine shown has eight such nozzles; when it is desired to reduce the power developed some of them may be closed. The wheel case is near the left end looking at the picture, with the stems of the valves controlling the nozzle openings projecting from it.

The turbine wheel is 29.5 in. in diameter, and runs at 9,000 r. p. m., the speed of the buckets being 1,160 ft. per second. The blades are ranged around the periphery and are milled out of the solid steel spokes of which the wheel is built up. The blades forming the buckets are curved in cross section and made very thin at the edges; a steel band surrounds the periphery and prevents the steam jet from escaping over the front edge of the buckets. At the left of the wheel case is the exhaust chamber which is connected to a surface condenser; at the right is the gearing box. In

the gearing box are a pinion and two gears of such proportion as to reduce the speed from 9,000 to 750 r. p. m. The shafts of the two gears extend through the box and operate two 100-k. w. Desrozier dynamos working on the three wire system. The teeth on the pinion and gears are double helicoidal, inclined both ways from the center at an angle of 45° so that there is no end thrust on the shaft.

As in all De Laval turbines the shaft of the turbine wheel is sufficiently flexible to bend and permit the wheel to revolve about its center of gravity. A centrifugal governor driven from one of the dynamo gear shafts regulates the speed by varying the supply of steam admitted to the steam chest, through a balanced valve in the top.

The following are the published results of the tests for which we are indebted to J. W. Lieb, Jr., general manager of the Edison Electric Illuminating Company. The results of

300-H. P. DE LAVAL STEAM TURBINE.

four tests of one hour each are tabulated below; in these the steam entered the turbine chamber at a pressure of about 147 lbs.:

No. of jets in use.	Average load.		Average watts.		Per cent of full load.	Vacuum ins.	Steam per e. h. p. per hour. Lbs.
	+ Amp.	Amp.	+	-			
2	153.78	147.15	18,707	18,283	18.50	27.00	27.35
4	433.60	455.80	54,156	57,886	56.02	26.43	20.22
6	700.85	718.65	87,746	91,268	89.51	26.07	19.75
7	771.94	787.33	97,418	100,856	99.14	25.70	19.95

A six-hour test made with a steam pressure of 155 lbs. gave results as follows: Dynamo output 127.25 volts and 692.45 amperes and 128.26 volts and 709.18 amperes. Total water from air pump, 27,763 lbs. Average water per electrical horse-power-hour, 19,275 lbs. Average water per brake horse-power-hour (allowing an efficiency of .90 for the dynamos), 17,348 lbs.

Tests on the Parsons compound turbine, recently made at Newcastle, England, are said to have shown water consumptions of 17.28, 20.00 and 22.01 lbs. per electrical horse-power-hour, the steam pressure being 70 lbs. and the speed 9,400 r. p. m.

If these very surprising figures on water consumption, (equal to or better than the compound engine) can be duplicated elsewhere, the steam engine has found a rival indeed. Such a low economy as this was scarcely to be expected, as the experiments on a 10-h. p. De Laval turbine at Purdue University, the results of which were published some time since by Professor Goss, showed a water rate of 46.6 lbs. per brake h. p. per hour when the turbine was developing 10.3 h. p., the initial steam pressure being 126.3 lbs. per sq. in.

### The Wellington Series Engine.

On April 8 the Engineering News published a description of the Wellington series engine, involving an "absolutely new process in thermodynamics," and believed to be "entitled to rank among the greatest of original creations in the field of the transformation of heat into mechanical energy."

The diagram, Fig. 1, illustrating the arrangement is reproduced from the Engineering News, after adding the temperatures of the several boilers and condensers. The series engine as indicated, consists of five engines, each having its separate tubular boiler and surface condenser. At one end of the series is a "heater," and at the other a "cooler." A "circulating fluid" is caused to flow from the heater through the boilers of the several engines, through the cooler, and back to the heater through the several condensers, by a suitable pump not shown in the diagram. The "circulating fluid" imparts heat to the "boilers" and abstracts it from the condensers. Each of the five engines draws steam from its own boiler and exhausts into its own condenser.

In the original description it was assumed that the circulating fluid leaves each boiler with its temperature reduced 56°F. below its temperature when entering; that the engines

FIGURE 1.

all use steam for the working fluid; and that in passing through each condenser the temperature of the circulating fluid is raised 47.6° F. It was further supposed that the steam pressure in each boiler is that due a temperature 10° less than that of the circulating fluid at its exit from that boiler, and that the same difference exists in each condenser between the temperature of its contents and the temperature of the circulating fluid leaving it. It was assumed, however, that the temperature of the contents of the condenser was 10° less than that of the circulating fluid instead of 10° greater, but this was probably only a blunder of the editor, since not even a Wellington condenser can be expected to transmit heat from a lower to a higher temperature.

In the discussion which follows we propose to show, that waiving all questions as to the series engine being a mechanical monstrosity, that practically the use of a circulating fluid is absurd, that the same heat applied to a single multi-cylinder engine will give 50 per cent more work, and that it is cheaper to throw away the heat abstracted from the exhaust steam by the condenser than to save it by the means adopted in the series engine.

The thermodynamic efficiency of the Wellington series engine depends solely upon the temperature at which the circulating fluid leaves the "heater," and upon that at which it enters the cooler. Leaving the heater at 500° and entering the cooler at 220° the series engine shown in Fig. 1 has the thermodynamic efficiency,  $(500-220) \div (500+461.2) = .2913$ .

But this efficiency can only be realized on the assumption that there are an infinite number of engines in the series, and

FIGURE 2.

that each works in a Carnot cycle, receiving heat from the circulating fluid as it passes along one side and restoring a portion of the heat as it returns on the other. Fig. 2 will serve to indicate a perfect series engine.

Since there are an infinite number of engines the heat that each receives from the circulating fluid will lower the temperature of the latter by an infinitesimal amount, so that each of the small engines will receive all its heat at the maximum temperature and reject it at the minimum. The efficiency of each small engine is the same and equals  $(220-50) \div (220+461.2)$ ; but as all the heat not appearing as work is returned to the circulating fluid by the small engines their range of working is unimportant.

All the heat given to the small engines by the circulating fluid is transformed into work or is returned to it, so that the efficiency of the latter is the ratio of what it gives the small engines to what it might give, i. e.,  $(500-220) \div (500+461.2) = .2913$ , as before stated.

A single engine working in a Carnot cycle would give the same result.

The temperature at which the heat is rejected is limited to 32° when water is the working fluid; but it may be assumed that 50° is as low as the temperature of the working fluid may be reduced.

Since it is impossible to have an infinite number of engines in the series let us reduce the number to say five, and let those

five each work in a Carnot cycle. Also let the specific heat of the circulating fluid be unity. Fig. 3 will represent such an engine.

Each small engine will receive heat at say the temperature of the circulating fluid as it leaves the boiler of that engine. Let the efficiency of each engine be .18. Then the lower limit for the engine E is  $.82x(220 + 461.2) = 558.6^\circ$  or  $97.4^\circ$  F. The engine E rejects  $.82x(276 - 220) = 45.9$  thermal units. Hence the temperature of the circulating fluid must be  $97.4^\circ - 45.9^\circ = 51.5^\circ$  when it leaves the cooler, in order not to become hotter than  $97.4^\circ$  when leaving condenser E, and thus reduce the working range and the efficiency. The temperature when entering the heater will be  $51.5^\circ + .82x(500 - 220) = 281.1^\circ$ .

The heat transformed into work by the five engines is  $280x.18 = 50.4$  thermal units, but  $50.4 \div (500 - 281.1) = .2302$ , while the thermodynamic efficiency is .2913. The difference is the loss due to the necessity of cooling the circulating fluid below the temperature of the condenser E, that is, with an infinite series the temperature at which the circulating fluid returned to the heater would be  $45.9^\circ$  higher. The full line in Fig. 3 shows the actual temperature of the circulating fluid and the dotted line the higher temperature that we would get in the infinite series engine.

Thus it is apparent that if we have a series engine composed of five perfect engines working in Carnot cycles between the temperatures  $500^\circ$  and  $220^\circ$  we shall get but  $\frac{2}{3}$  as much work from it as from a non-series engine working in a Carnot cycle.

Fig. 4 shows what will happen if we continue to reduce the number of cylinders in series. For two in series with the heater heating the circulating fluid to  $500^\circ$ , and the cooler cooling it to  $80^\circ$  there would be absolutely no heat transformed into work.

Now, in order to compare the performance of the "series" and the "non-series" engines: Let each engine receive dry and saturated steam at the higher temperature indicated; let the steam be expanded adiabatically in a non-conducting cylinder until the condenser temperature is reached and then exhausted into the latter; no clearance, compression, cylinder condensation or radiation losses are, for the present, considered. The circulating fluid is a matter of indifference but let it be water. In the description it was stated that it might be a gas; but we submit that the efficiency of the Wellington boiler is then no greater than that of any other boiler of the of the same material and dimensions. Let there be no gap between the boiler and engine nor between the engine and condenser temperatures. In other words, we substitute engines working steam in non-conducting cylinders for the Carnot cycle engines of Fig. 3. Fig. 1 shows the temperature limits of this engine.

Under the foregoing conditions each engine will receive heat equal to that given out by the circulating fluid in falling  $56^\circ$  in temperature, which will be slightly different for the different engines, because of the varying specific heat of the "circulating fluid," water.

Peabody's and Thurston's steam tables were used and the results, considering one pound of the "circulating fluid" for the five engines, and for a non-series engines N working between the temperatures  $500^\circ$  and  $200^\circ$  are given below:

Engine.	Heat to each engine. B. T. U.	Transformed into work. B. T. U.	Range of temperature Degrees.	Ratio of expansion.	Efficiency of steam. Per cent.
A	50.3	9.37	156	5.7	.1580
B	38.4	9.56	149.5	6.8	.1637
C	57.8	9.67	142	8.5	.1673
D	57.3	9.77	133.7	11.1	.1766
E	56.4	9.79	125	15.2	.1736
Total	220.7	48.16			.2182
N	220.7	56.70	380	26.4	.2569

The total heat for the series engine is not the total of the heat supplied to the several engines by the circulating fluid but the heat supplied to one pound of the latter by the heater, and is, of course, the same for the series and the non-series engines.

Other calculations show that if a drop of  $10^\circ$  be allowed between each boiler and engine and between each engine and condenser, other assumptions remaining unchanged, the work from 220.7 B. T. U. given to the circulating fluid will be 43.01 instead of 48.16 B. T. U.

Now we observe that the engine N has a temperature range of  $280^\circ$  and 26.4 expansions, so that it might be a compound engine with a temperature range of  $140^\circ$  in each cylinder. Suppose that the 18 per cent more work given out by the non-series engine is all lost because of the drop in the receiver pressure when the engine is compounded. We then have theoretically, the same amount of work for both engines, but the series engine comprises five cylinders, with an average temperature range of  $141^\circ$  in each, and six pumps, while the non-series engine comprises two cylinders with temperature ranges of  $140^\circ$ , and at most two pumps.

It is thus apparent that the losses due to compression, clearance, radiation and cylinder condensation will be, in actual engines, much greater in the series than in the non-series engine.

However, the series engine requires a "cooler" which shall cool the circulating fluid to  $48.3^\circ$ , and it is but fair to supply the non-series engine with a similar cooler. Cold water is abundant, and we may safely assume that in the non-series engine the lower limit of temperature is  $140^\circ$ .

This engine working steam in a non-conducting cylinder would give us, with an expenditure of 220.7 B. T. U., 77.4 B. T. U. transformed into work. The temperature range is  $360^\circ$ , the number of expansion 137, the efficiency of steam .3234.

Working over this range in a quadruple expansion engines we have a temperature range of  $90^\circ$  in each cylinder, as against  $141^\circ$  in the series engine, and one less cylinder.

Also since in the example we have allowed no temperature drop between boilers and engines and between engines and condensers in the series engine which would further reduce the work from it by more than 10 per cent., we may safely take the losses from all causes as being no greater in the quadruple expansion than in the series engines.

Hence, the efficiency of steam in the series engine may be taken as .218, as against .323 in the non-series, that is, the latter has 50 per cent greater efficiency.

Referring to the editorial comments of the Engineering News under the caption "The Story of a Great Invention," there are a few points that may be mentioned:

It was stated that "Mr. Wellington perceived that its practical success would depend on the invention of an entirely new form of heat transferring apparatus." We presume

that this refers to the boiler, but as the "heater" in the series engine has all the functions of the boiler in the ordinary plant and must itself have a source of heat, it is not apparent why the "heater" should not transfer heat to steam instead of to hot water. In any event that which heats the heater must leave it at a temperature in excess of the latter, with consequent loss.

The same applies to a Wellington series engine receiving its heat from the jacket of a gas engine, why not generate vapor and work it to better advantage in a "non-series" engine? The use of liquids with a low boiling point is not new, (see Rankine's Steam Engine, p. 444) but if we expand much below the lower limit of engine E it would soon be necessary to erect a refrigerating plant (driven by a steam engine) to condense the volatile gas.

The prediction was made that, if a practical success, the Wellington engine promises the highest economy in the conversion of heat into work of any heat engine ever made. Having shown that the maximum efficiency of this engine to be about two-thirds that of a non-series engine working between the same limits, we do not have any faith in the prediction, and think that our contemporary should have given the "discovery of this absolutely novel process in thermodynamics" to the world on April 1, or else permitted it to quietly rest in the "wild-cat cage."

## THE OPERATION OF A HIGH PRESSURE MULTIPLE EXPANSION STEAM PLANT.

BY FREDERICK L. RAY.

In building a steam plant where the latest and best machinery of all kinds is used, it is expected that the most economical results will follow the installation. These expectations are not always realized, but the experience will cause no backward movement in improved appliances, but rather an energetic effect to better the appliances and make the plant as it should be, a money making investment.

Vertical engines with three or four expansions are to be found on land as well as on sea, and why should they not be, for if they are a paying investment on the sea, with proper consideration as to their importance, they should be on land. Multiple expansion engines, as a rule, are run condensing, but may, with profit, be run non-condensing in connection with an exhaust steam heating system where coal is costly and a good price can be obtained for steam heating. When the steam heating is installed in connection with the plant, the double system of piping is needed in order that no more engines than necessary shall exhaust into the heating system. Especially does this apply in the fall and spring when there is very little heating to be done. There should be two exhaust mains of the same size, which are connected across on top with gate valves on vertical pipe over each main. This enables the operator to throw steam to the atmosphere or the heating system, and effects a saving by running the engines without back pressure when the exhaust is not needed for heating. A condensing system can be operated in connection with a steam heating system if water for that purpose is convenient and cheap. With a condensing system and a heating system in connection with a lighting plant, where the right conditions prevail, there is no reason why the highest economy should not be obtained. A plant of this kind would depend upon the conditions under

which it must operate. To make the heating system pay, the plant must be close to the center of distribution of heating, and for a condensing plant to be highly successful it must be close to a large supply of water. With these conditions prevailing, there is no reason why a plant of this kind should not be a financial success. It is desirable, if possible, to return all water of condensation from the steam heating mains to the boilers, especially so if hard water is used, as a little water of condensation will go a great ways towards improving bad water for boilers.

There are several systems of exhaust steam heating. In some of these the water of condensation is returned to the boilers, where it is used over again. In others, all water is drawn off at the heating service pipe main, where it is trapped to the sewer, after passing through what is known as a cooling coil, and goes to waste after having given up the most of its heat. To the careful engineer it would appear that if it be practicable to return this water to the boiler, it should be done. Almost without exception it will be found that the exhaust system feed water heater is used in connection with steam plants. Now, if heating and condensing apparatus be installed in the plant, an exhaust steam heater is useless, because all the engines which are not on the heating system will be run condensing. The exhaust steam heater would be replaced by a fuel economizer, with which a much higher temperature of feed water can be obtained, and still use a product that is continually going to waste. With an economizer of an ample size for the work, it is no trouble to get feed water at a temperature of 250° to 527° F. This is not exceptionally high when the steam pressure is 200 pounds, but can be attained in every day actual practice. Where the steam pressure is lower it would not be possible to get so high a temperature in the economizer. It is generally considered that with such a high temperature in the economizer, where bad water is in use, that it would be but a short time until the pipes would be scaled so badly that no heat could be transmitted through them. Such is not the case, as with very bad water the writer has had no trouble along this line. There is precipitation, of course, but it fails to the bottom, and while in a soft state can be blown out to the sewer. When the conditions are such that no other water can be had for the boilers but that which is highly impregnated with scale forming salts, devices must be used that will purify the water before it enters boiler. These devices are usually settling tanks, exhaust steam heaters, economizers, and live steam purifiers. Where space is valuable, settling tanks are out of the question. Where the plant is running condensing the exhaust steam heater is of no value, but there is no time when the economizer and the live steam purifier cannot be brought into effective service. The economizer uses nothing but the heat which otherwise would go to waste, and if properly constructed there need be no loss in draft. The purifier will cause no loss but by radiation, and there need be but very little of this if the purifier is properly covered by a good non-conductor. All devices for use under 200 pounds per square inch must be made extra heavy, or especially for that service. A good common wrought iron pipe will work satisfactorily under this pressure, but no cast iron fittings of any kind should be used, unless they are extra heavy, as they will leak, and at all times be a source of danger.

Let all flanges be faced and have plenty of bolts. All valves and fittings above three inches should be flanged, as it adds greatly to the convenience of the making up and

taking down of pipe and fittings. A good steam joint is one that will not leak, and if it does leak, there should be no chance for enough steam or water to blow out to cause any damage, or obstruct the working of the plant. Such a joint would be made of some soft rubber and lead composition, such as Jenkins, or Usudurian sheet packing, which when hot, will soften so that the joint can be screwed up almost iron to iron. This joint may leak just a little when it is cold, or when it is warming up, but when it is hot it will be tight. It is often the practice to use some thick gasket, or rubber composition, or asbestos. This will not do under high steam pressure, as there would be danger of a piece blowing out, and if it did, it would mean the shutting down of a part of the machinery, or perhaps all the plant, depending on where it was located. The ideal joint for high pressure is that in which the metal comes up iron to iron, or nearly so. More allowance must be made for the expansion and contraction of piping under high pressure, because of the higher temperature. All flanges for pipe should be beveled slightly on the inside; the pipe screwed hard into the flange and through it a short distance; then it

to give them strength. The disadvantage of steel in comparison with brass is that it will rust, but with proper application of graphite, there need be no trouble from this source. A rising spindle is to be preferred over others that are stationary, for the rising spindle always indicates whether the valve is open or shut. A good valve will be made so that the stem can be packed regardless of whether the valve is open or shut. This is an important consideration in an electric lighting plant, as it is a serious matter to be compelled to shut down a part of the plant to pack the valve stem.

Composition discs of soft metal or rubber, will not answer for high pressure valves, as they are not to be relied on, and, almost without exception, it will be found impossible to shut steam off some time when it is necessary to do so. Nothing can serve the purpose better than a good bronze seat and disc. If they leak they can be repaired and made as good as new. Brass body valves of large sizes are not satisfactory for high pressures as made, for, on account of the expensive character of the metal, these are made of light weight. This is their great fault, and they twist and bend and expand so that they leak at the disc, and at the thread on the pipe. Of course if they were made heavier, there could be no objection to them, but this would prohibit their manufacture in competition with cast iron body valves. One of the most important valves around a steam plant is the blow-off valve. If it leaks, one can soon blow tons of coal into the sewer, so to speak, and to keep it tight under high pressure has always been an interesting problem. Thanks to the inventive genius of an American mechanic, we have today a blow-off valve made for any pressure, which, when it leaks, can be repaired.

All water of condensation should be returned to the boiler automatically, and this can be done by the return trap as shown in the illustration. The separators on the engines and all steam mains are connected to a receiver in the basement, from which the water is returned to the boiler as fast as it comes to the receiver. Where separators are placed on the pipe close to the boilers, as shown in the cut, the condensation and entrained water will return to the boiler automatically. The condensation pipe should be connected below the water line in the boiler, and should have a vertical check in the pipe close to the separator, to prevent the water coming from the boiler to the separator, if from any cause it should attempt to rise. The separator should be placed between the main stop valve and the boiler, so that when the boiler is off this separator will be off also. All pipes and fittings should be covered with the best non-conductor of heat to be had, for steam at 200 pounds pressure will soon radiate a great amount of heat. Covering pipes also makes them safer, as it prevents to a great extent the sudden expansion and contraction that occurs where it is exposed to all the various changes of temperature. Live steam purifiers should be covered. If they are not, there will be trouble from leaks at the rivets, and especially at horizontal seams. In putting on the purifier, great care should be exercised in regard to heating all parts gradually. The method of doing this is to turn steam on very slowly, and finally get boiler pressure. While heating it in this manner there will be considerable water form in bottom. This must be drained off through the blow-off, which should be opened a little when steam is first turned on. If this water is allowed to accumulate in the bottom, there will be an unequal expansion that will require the services of a boiler maker at once. The bottom should be kept dry while putting purifier on. When

is cut off and riveted. This will make a joint that will last as long as any other part of the plant, but if at any time one of these joints should leak, no attempt should be made to caulk it, as it is impossible to make a caulked wrought and cast iron joint hold under 200 pounds steam pressure. There is nothing around a steam plant more satisfactory than plenty of good pure graphite. A little of this mixed with oil will prevent pipe joints from sticking, and bolts from rusting, and it is useful in a thousand ways. There are no valves made today, extra heavy or otherwise, that can be opened under 200 pounds steam pressure, without injury to themselves, except they be a by-pass to first equalize the pressure. A good gate valve for high pressure will have removable seats that are not screwed, but are driven in, so that they can be removed for repairs. A globe valve also, should have a driven seat. Globe valves can be reset without taking the seat from the valve, or the valve from the pipe, with a portable valve reseating machine, a number of which are in the market. Valves should have steel spindles

thoroughly heated, the gravity valve opened and the water turned in, the purifier is ready for work.

To keep a water gauge glass intact under 200 pounds pressure is one of the present impossibilities. They will last for, say from one moment to sometimes as much as a week or two, but no reliance can be placed in them. Nothing but a very short glass, such as are used in automatic lubricators, will stand this pressure. A glass of any length is soon destroyed, either by an explosion or by a white coating, which renders it unfit for use. All shapes and makes of glass fail under this pressure, when they experience so many extreme changes of temperature. A good chain pull self-closing gauge cock is the best practice possible at present, but let us hope that in the near future there will be improvements that will be satisfactory, for to know where the water is in some kinds of boilers, will soon wear out the best of gauge cocks, and a fireman's will.

Coal should be handled as much as possible by machinery. Ashes should be handled by machinery also. Ashes should be lifted and carried to their destination, and under no circumstances should dragging them be tried, for it has not been successfully accomplished. Mechanical stokers should be used because they are a smoke preventative, and more than that, at least 25 per cent more work may be had from the same boiler than with hand firing. There will be better results from the economizer, for there will not be so much smoke, and necessarily not so much soot, and certainly a higher temperature for the gases in the economizer. There can be of course, a great many arrangements for handling coal and ashes at a modern steam plant, all of which should be as simple as possible, for all devices soon wear out, and if very complicated, there will soon be a great deal of trouble and expense. A rule to build on in this case would read something like this: Fill car with coal from bin in basement; elevate car to top of bin, dump and repeat the operation. Coal to leave bin through a spout to place on the floor, if hand fired, and to hopper, if mechanical stoker is used. Handle ashes in the same manner by a car, when they can be drawn from the bin and carted away.

So far, this paper has been dealing with boiler appliances, but now we shall, for a little while at least, treat of the engine.

Triple expansion engines run just the same as any other, and require the same good care to get good results. A vertical triple expansion engine may, and usually does, have more pieces in it than a Corliss engine, but it is no more complicated to the intelligent engineer. To secure good results, one must have high steam pressure and dry steam at all times, or the first result noticed will be that the work is not done. This means loss all around, uneconomical engines and poor service to consumers.

Belt transmission is slowly but surely being displaced by direct connected engines and dynamos. This is as it should be in a triple expansion plant, for why should one go to the expense of saving at the engine, while still losing on the belted machinery. If a triple expansion engine have dry steam at high pressure and be direct connected to the work, it will deliver the work to the line with as little expenditure of coal as it is possible for it to be done. In handling high steam pressures special care must be given to all piston packing, as there is always a tendency to leak at any pressure, and once fairly started, great damage is soon done.

As is generally supposed, cylinder oil must stand a very high fire test for use in cylinders under high pressure, but

there is no trouble in getting an oil to do the work nicely. A vertical engine from the very nature of its design requires very little oil as compared with others, which have heavy pistons and unbalanced valves. Direct connected engines and dynamos for arc lighting and street railway work, must be perfectly insulated one from the other. This point is not so important in alternating current machines. In the arc lighting stations of today, where it is the practice to use from 4,000 to 6,000-volt machines, the greatest precaution is necessary to prevent loss to life. The machines are carefully insulated from the earth. The floor is such that if the frame of machine should be grounded, there would be no harm come to the attendant if he should touch it, and as an extra precaution, rubber mats are spread about the machinery on the floor. All terminal boards are covered with glass or fibre. The insulating couplings between engines and dynamos are sometimes made of wood, fibre or raw hide. Veneered wood has served as well as anything. It should be soft and tough and thoroughly seasoned. Fibre is good, but is objectionable because of its tendency to warp out of shape and also because so very hard. Raw hide is a good flexible coupling, but it is not nearly so good as wood or fibre. Either one of these must be kept tight, and no lost motion permitted, or the coupling will soon be destroyed.

In conclusion, it may be said, that the high pressure multiple expansion steam plants of today are features of modern engineering, and they have come to stay. They are advances along the line of practical engineering, wherein it has been demonstrated that the higher the pressure and the more expansions, the higher the economy will be. We are told that 200 pounds steam pressure is the limit of practical engineering today. Perhaps it is, but who can tell us what the morrow will bring forth. The 20th century may bring us a practice of steam engineering, of which we cannot dream now. If it be in the line of present developments, the advance will be towards higher pressures and more expansions. What will this mean? Why, greater engines, stronger material, and appliances; greater knowledge of how to apply and safely handle this machinery under these conditions. Such may be our future, and why not help to make it.

---

#### SAFETY GATE DAMAGE CASE.

---

The cars in St. Paul and Minneapolis have been equipped for several months with safety gates operated by the motor-man, who does not open them until the car has come to a full stop and who closes them before starting. The effect on the accident list has been most marked, and the management are confident of saving many thousands yearly.

Suit was recently brought by a woman passenger, who claimed injuries caused by the gate closing as she was boarding the car. The company made its defense largely on a demonstration of the gate, a full sized model of which was installed in the court room and operated before the jury. The result was so evident and convincing that the sudden closing of the gates could not inflict any great physical injury that the jury found for the defendant within 30 minutes.

---

The footboards, on the summer cars of the Metropolitan Street Railway of Kansas City, are to be removed to prevent passengers from jumping on and off the cars while in motion.

**HARDIE COMPRESSED AIR LOCOMOTIVE.**

In the REVIEW for April were given the data obtained with the two motor cars on the Hardie compressed air system which have been operating on the 125th street line in New York City for several months past. The illustration herewith, for which we are indebted to the Railway Age, shows the locomotive which is to have a trial on the Manhattan Elevated. In general appearance this machine much resembles the ordinary steam locomotive. The space usually occupied by the boiler, however, is taken up by the storage tanks for the air and by the reheater. On this locomotive

HARDIE COMPRESSED AIR LOCOMOTIVE.

the air is stored in 36 tubes of Mannesmann rolled steel, they are 9 in. in diameter and of varying lengths, from 13½ to 21 ft. The charging pressure is 2,000 lbs. per sq. in. The air is led from these tanks through the reheater, in which water is stored at an initial temperature of 350°F., and after passing through three reducing valves is admitted to the cylinders at a pressure of 150 lbs. The working cylinders are 13½x20 in. The American Air Power Company, which controls the Hardie patents has erected a compressing plant for charging at 100 Greenwich street. It is expected that this locomotive will haul 5 cars and make a run of 13 miles between charges.

**THE ECONOMY OF CONTRACTING FOR REPAIRS.**

M. R. McAdoo, the general manager of the road at Paterson, N. J., is the author of several original ideas which he has put into successful operation. For the last two years he has specially watched and studied the question of repairs, and has concluded that many of the usual repairs about a street railway can be more cheaply secured by contract work than in the good old way of the company's men on yearly pay roll. Thus far he has carried it out on track work and the repainting of open cars.

Formerly the best he was able to get out of 12 men and 1 foreman, on raising joints, was 5 miles for an entire summer's work. This was accomplished at an expense of \$18 per day, the foreman receiving \$3 and the men \$1.25 each. Last year Mr. McAdoo tried the contract plan on the following basis: For 35 cents per joint, the contractor was to expose a rail joint, remove three ties if necessary, replace, fill and tamp; remove bond wires if necessary, raise joint,

tighten fish plates; all to the satisfaction of the company's inspector. The company replaces the paving. It would not seem that much of a job could be done on a pair of joints for 70 cents, and Mr. McAdoo says it can't, or is not, with men working for the company direct. The contractor, on the other hand, divides the work out frequently as piece-work, and the result is the men are practically working for themselves—with the usual result. In this way the entire system of 35 miles was gone over last summer, at an expense no greater than the company had previously been paying for 5 miles. The scheme is well worth study.

Another line of contract work was repainting his open cars this spring. There is little fancy work, and this was left to the company's master painter to do with his own men. But the roofs and floors and running boards were let out. The contract called for one coat on the roof, three on the floor and foot-boards, the work and material to be furnished at a price of \$2 per car; and performed in a manner satisfactory to the master painter. The question most naturally arising is that the paint must have been mighty poor stuff; but the explanation is the labor was done by a cheaper grade of painters than the regulation \$3-a-day man, and yet was good enough for the purpose. The cars were from 23 to 35 ft. in length. The fact that outsiders can come in and make contract, and fulfill the same, at the prices named, is sufficient to warrant some careful thinking.

**SAN MATEO TROLLEY ROAD TO BE IMPROVED.**

About a year ago the San Francisco & San Mateo Railway was purchased at a sheriff's sale for \$300,000 by J. A. Buck, Nicholas Ohlandt and the Spreckels brothers. The road cost nearly three times that sum, but its sale was forced by a foreclosure suit. The mortgagors failed to redeem, and, having secured the property, the present company expects to greatly improve the system. The 13 miles of track will be relaid with 84-lb. rails, new cars will be purchased, the feeder lines enlarged and an outlet to Market street secured. The new officers are: A. B. Spreckels, president; J. A. Buck, vice-president; Walter Gibson, treasurer, and W. Clayton, secretary. J. D. Spreckels is the fifth director.

**RE-TURNING TROLLEY WHEELS.**

Charles E. Moore, master mechanic of the Chicago City Railway, has quite recently devised a method for re-turning trolley wheels on a milling machine instead of a lathe, with the result that only four minutes are needed to do the work that formerly required 20 minutes. A small sprocket wheel is fixed on the shaft that ordinarily is used only for giving a vertical feed to the table, and a similar sprocket also attached to the head of the milling machine, these two being connected by a chain when turning trolley wheels. A special 10-tooth cutter with a suitable form of tooth is mounted on the cutting arbor, the wheel to be turned mounted on the head, the latter placed in position, and a single revolution of the head suffices to true up the wheel. The speed of revolution of the cutter is about 160 times that of the head.

Atlanta (Ga.) city council passed an ordinance requiring the company to issue transfers on one fare.

## THE USE OF BED PLATES IN CONCRETE TRENCH CONSTRUCTION.

The president of a western road writes us as follows:

Referring to the STREET RAILWAY REVIEW, I notice the article on new track construction at Kansas City, page 140, March issue, and also the article on concrete work in track construction, page 73, February issue.

In the latter article, reference is made to the REVIEW for January, in which F. A. Little presented figures on concrete foundations, based on the construction of nearly 50 miles of track in Detroit. Our company has eight blocks of double track road, which was laid on wooden stringers, they in turn being laid on wooden cross ties. The work was imperfectly done before the road came under the present management, and since we have ascertained that the wooden stringers, as well as the ties, have become badly decayed, and that the track is spreading, there being practically nothing but the granite blocks to hold it in position. As the street has been paved with concrete and asphaltum, we wish to reconstruct the same by taking out the granite blocks, and the old rails, throwing out the wooden stringers, cutting off the old ties, and practically doing that kind of trench work referred to in the above issues of your journal. We think of using the Johnson rail, Section 83, No. 275, weighing 83 lbs. to the yard, and laying the same on a bed of cement concrete, to be laid in the bottom of the trench. We expect to use cross tie-rods, say every 10 feet, and bed the rails in cement, the construction being similar to that shown in Fig. 1, page 73 of your February issue. We may use granite blocks on both sides of the rail, instead of one side, as shown in said illustration.

We would like to know if it would be desirable to use bed plates under the ends of the rails, where they join, and if so, what size and thickness. We believe the Detroit company laid its rails on concrete foundations, omitting the wooden cross ties, as shown in Fig 2, to be used in new track construction at Kansas City.

We would like to know what its experience has been, as to whether the rail resting on the concrete made too rigid and solid a foundation or not. Unless the rails should settle at the ends, breaking the concrete, would there be any advantage in using a bed plate? How thick should the concrete be underneath the base of the rail? The soil underneath the tracks referred to is principally sand, having been filled into a depth of some eight or ten feet above the natural surface of the soil.

If there is any information on this subject, in addition to that already published in the numbers of the STREET RAILWAY REVIEW above referred to, you would confer a favor by informing us of the same.

Reply by F. A. Little, C. E., Detroit.

Your communication relative to "trench" work at hand. In reply we will say that we think, under the conditions stated in the letter, that trench work as has been previously described in the REVIEW, will give them the best of results.

We consider it necessary to use bed plates under the joints, to avoid the possibility of the breaking of the concrete. In the Detroit work we used  $5\frac{1}{2} \times 24 \times \frac{3}{8}$ -in. plates and channel iron of the same dimensions with 1-in. flanges, the base of the rail resting in the channel. Either one answers the purpose, channel iron being the easier to place in position.

We believe that a beam of concrete 8 in. deep and 12 in.

wide is sufficient under the base of the rail, provided the soil upon which it rests is firm, but if the soil is soft, and of a yielding nature, it needs a wider base, tapering towards the base of the rail, so that the trench through the asphalt shall be no wider than the convenient placing of the track in place requires.

In the February issue of the REVIEW, Fig. 1, page 73, the rail is shown as resting directly upon the concrete beam. While not wishing to criticise any method of construction, but judging from our own experience, we would say, better construction can be obtained by laying a 6-in. course of concrete, or so as to be 2 in. below the base of the rail, and let that "set" for four or five days before beginning track laying. In this way we have 2 in. of space between the base of rail and the concrete, which allows for the placing of the rail to the exact grade irrespective of any irregularities in the laying of the concrete, and also leaving room to work the grouting under the rail. We used oak "shims" for blocking the rail to grade.

It is true that concrete makes a very rigid and solid foundation, but we do not consider this an objection, when the slight additional rumbling sound made by the cars running over it is greatly overbalanced by the smoothness of its riding qualities, and not only this, but it is a satisfaction to railway companies to know that they have a track, laid at a moderate cost (compared with tie construction under the same conditions), that is going to last as long as the rail, which we believe possible with concrete properly laid.

In conclusion we can say that the track laid by the Detroit Railway in trenches, using a concrete beam 6 in. in depth and 12 in. in width, and grouting around the rail and 2 in. beneath it, using tie-rods every 10 ft., and bed plates under the joints, after withstanding the frosts of two winters, and a traffic of cars from two to four minutes apart, 18 hours per day, for two years, is in a condition at least 25 per cent better than the tracks laid with oak ties on a 6-in. concrete foundation, but using no tie-rods and extra support for the joints.

## SPLICING SMALL CARS.

BY W. H. PELTON.

While the writer was in charge of the railway shops of a well-known company the management became imbued with the long car idea, and there was some work done which may be of interest to readers of the REVIEW. The equipment consisted at that time of short, panel-body cars, as shown in Fig. 1, each car equipped with two 30-h. p. motors; and while it was imperative that the old equipment be not scrapped, it was equally imperative that we have double-truck cars. As a result it was decided to form one 32-ft. car from two 16-footers, and to operate it with the four 30-h. p. motors taken from the short cars.

The two bodies were set on horses in the shop, the back end was removed from one and the front end from the other, and the corner posts and end sills ripped in half. Then the two bodies were butted together and fastened with  $\frac{5}{8}$ -in. carriage bolts, placed so as to be out of sight. A few heavy wood screws were used under the window strips, and the sills were reinforced with  $\frac{1}{2}$ -in. iron plates extending  $\frac{1}{4}$  ft. each way from the splice. While this work was in progress the old panels and water rails had been removed so

that it was possible to set a piece of southern pine,  $4\frac{1}{2} \times 12$  in.  $\times 32$  ft. on each side of the car, flush with the bottoms of the sills, and to bolt through the sills at intervals of about

FIG. 1.

22 in., using  $5\frac{3}{8}$ -in. bolts, with cast washers on the pine side. The old sills were of oak. On each side of the splice two rods of  $3\frac{1}{4}$ -in. round iron went clear through the car body. The  $4\frac{1}{2} \times 12$ -in. was framed at the top to fit the curvature

to hold it there. The  $2 \times 8$ -in. pieces are 14 in. from the roof at center of car.

The four motors are operated with an ordinary controller, wired so that on the series notches the motors are working two in series and two in parallel, and on the multiple notches, four in parallel. Whenever it is necessary for the wiring to go below the floor it is placed in an iron-armored "interior conduit."

The Hunt air-brake is used, and the arrangement of the brake levers on the car body is such as to give extreme flexibility (see Fig. 4.) The brake is worked from an independent electric compressor.

The steps were formed by cutting risers from  $1\frac{1}{8}$ -in. iron and riveting two of the old single steps in position to form one double step.

The trucks were set well apart, so as to avoid an extreme overhang on curves. This threw the front truck so far forward that the sand-rigging was placed in front of the back truck; the sand valves from the two small cars being connected by a rocker shaft so as to sand both rails.

In writing this article it was not the purpose to describe an ideal car. But this makeshift may, for a very little money, furnish some other road with a few good-looking, durable, easy-riding cars, capable of handling a very heavy traffic.

of the posts. A section through a post is shown in Fig. 2. After putting in the truss rods the car was sided with round-corner white wood,  $1\frac{1}{2} \times 1\frac{3}{4}$  in.

The form-trussing used is shown in Fig. 3. This form of double truss effectually prevents the sagging of any part of the car body, no matter how loaded. The under truss was placed just inside the car sills, and covered by the seats. The over truss was let into the  $4\frac{1}{2} \times 12$ -in., and held close to the siding, in order to have the necessary rise and not prevent the lowering of the windows near the center of the car. The under truss was so placed as to secure a good bearing on the old car as well as the new car sills.

In closing the roof, finishing the sign-board, water-rail, etc., care was used to break joints wherever possible, but even then, owing to the lightness of the frame and carlines, the roof would barely support its own weight, not to mention a heavy trolley stand, and the hob-nail shoes of a 190-pound "inspector." The form of truss adopted may be seen in Fig. 5. Two pieces of Southern pine, each  $2 \times 8$  in., extend the length of the roof and into an angle of  $\frac{1}{2}$ -in. iron at each end. Two rods,  $3\frac{1}{4}$  in.  $\times 32$  ft. 5 in., pass through these angles with double nuts on each end. With this device it is possible to give the roof any desired camber and

Some may object to side seats in a car of this style. They are not pretty, but please to remember that the seating capacity is just about the same as with cross seats in a car of the same size, while the standing room is vastly greater,

FIG. 5.

and a car of this sort can be loaded or unloaded at a rate that would be utterly impossible with any of the cross-seat cars known to the writer. One of these cars, 32 ft. long by

7 ft. wide over all, will seat comfortably 44 to 48 persons, and will handle without undue crowding loads of 100 to 110.

These are the exact dimensions of the car shown in Fig. 5, and the writer has seen a load of 134 persons on that car, exclusive of children and dead-heads; probably 156 or 158 in all. That time it was crowded.

The four motors may lead to some extra work and some expense. But they render every pound in the entire car available for traction and on a slipping rail, or on an upgrade, a car will come up to speed in from one-half to one-third the time that it can with a two-motor double truck equipment. The difference is more than noticeable on a clear level rail.

It was also shown by ammeter readings that a car in going around the loop referred to above would use for a given speed 36 to 38 amperes with four motors; 88 to 92 amperes with two motors in one truck or 54 to 56 amperes with one motor in each truck. The same would undoubtedly be found in any one of the curves on the line, the ratios depending on the radius of the curve, and would be more clearly shown in starting from a dead stop in a curve. And every extra horse power spent in this way means not only a loss of power but it means the destruction of the car wheels, of the special work, and to a smaller extent of the trucks and car body. In double truck work four motors have their advantages. I shall be pleased to answer any enquiries addressed in care of the REVIEW.

#### DISTRIBUTION OF RESISTANCE BETWEEN CONTROLLER POINTS.

When series-parallel control first came into use but little subdivision of resistance between controller points was made, the usual arrangement being to divide the resistance into two parts, half of which was to cut out on the second point of the controller, and all was out on the third point. But very little resistance was used when the motors were thrown in parallel. The tendency more recently has been to subdivide the resistance more, so as to prevent the tendency to jerk when the controller is turned from one point to another. Theoretically, when the resistance on a certain type of motor equipment has been once properly fixed by the manufacturer, there should be no further trouble. But practically it is often the case that the resistance in circuit on some points of the controller does not seem to be properly proportioned to the work to be done. On numerous equipments which have come under the writer's notice but very little effect in the way of acceleration seems to be obtained on some of the controller points, while on the next points above those spoken of the car gives a jerk, showing that the resistance was too much on the point below. For example, on a certain type of car the first point is often hardly sufficient to make the car move, and when the controller is put on the second point there is almost invariably a jerk, no matter how long and patiently the motorman waits on the first point. The effect of having such an arrangement is practically to induce the motorman never to wait for acceleration on the first point. If the first point gave a good acceleration there would be less temptation to leave it too soon. On other equipments the opposite fault is found, that of having in circuit so little resistance on the first point that it is hard to start a car without slipping the wheels. The obvious remedy for all such defects is to pay more attention

to the subdivision of the starting resistance when a set of cars is first equipped.

#### KEYSTONE PORTABLE VOLTMETERS.

The illustration shows a portable voltmeter recently placed on the market by the Keystone Electrical Company of Philadelphia, which is recommended as more fully meeting the requirements of practical use. In the construction nothing is incorporated that is subject to deterioration, and being calibrated, they may be relied upon to maintain their accuracy. The system is such that there is no magnetic lag

and no error due to self-induction, therefore they are independent of frequency variations of the alternating current. The instruments are dead-beat without the use of a mechanical brake, and each is provided with a reversing switch for use with direct currents; these two features will be appreciated by busy users. These voltmeters are listed in ranges from 12 to 700 volts, single and double scales, so that all classes of work are provided for. They are mounted in mahogany cases in which separate compartments are provided for the pair of flexible leads included with each instrument.

#### REDUCED FARES CONSIDERED BY THE INTERSTATE COMMERCE COMMISSION.

The stockholders of the Chevy Chase & Kensington Electric Railroad Company are also the stockholders of the Chevy Chase Land Company. The latter company sold railroad tickets at half the regular fare to those who purchased land from it or who were patrons at the company's hotel. Complaints were made to the interstate commerce commission and a decision was rendered. The commission holds that the two companies are distinct and that no discrimination was practised by the railroad company and the common ownership was not a means of evading legal obligations. The discrimination of the land company in the sale of tickets for the benefit of its business is not a subject for correction by the commission.

**BICYCLES REDUCE WAGES IN ROCHESTER**

The lines in Rochester, N. Y., are paying the penalty for the large amount of excellent paving done there in the past few years. The constantly increasing use of bicycles during eight months in the year has made very appreciable inroads upon the earnings of the company, which has been forced, though the action has been deferred as long as possible, to order a cut of 10 per cent in wages.

**HE STOLE LIGHT.**

An enterprising inhabitant of Gloucester, Mass., who knew too much about electricity for his own good, tapped one of the feeder lines of the Gloucester street railway and lighted his house from it. After enjoying the privilege of free and brilliant illumination for about a month the company discovered the leak in its line and put a stop to it without ceremony. The wire was cut, attached to the company's wagon and pulled out of the man's house.

**GOOD CHANCE TO TRY MUNICIPAL OWNERSHIP.**

It is not often that a street railway system, with all the appliances, may be had for the asking, but such is the case with the little city of Woodland, Cal. Dr. T. Ross, president of the Woodland Street Railway Company, offers to give to the city the entire service, with tracks, cars, horses and car house, providing the city will maintain and operate the system for at least five years. The board of trustees hesitate about accepting the gift until some expression is made by the citizens of Woodland.

**MEASURING TRACK WITH A BICYCLE.**

The manager of a small road recently remarked to C. L. Wight, secretary of the Toledo Traction Company, that he was bothered in getting some track measurements, and did not want to go to the expense of having it chained. That's easy, replied Mr. Wight, if you do not need the measurement down to a few inches all you have to do is to run a bicycle over the route, riding in the middle of the track, and note the starting and finishing figures of the cyclometer on the wheel. To make doubly sure let two riders go over the route, or the same one two or three times, and take the average distance recorded. It can be quickly done, will not cost anything, and will give results sufficiently accurate for many purposes.

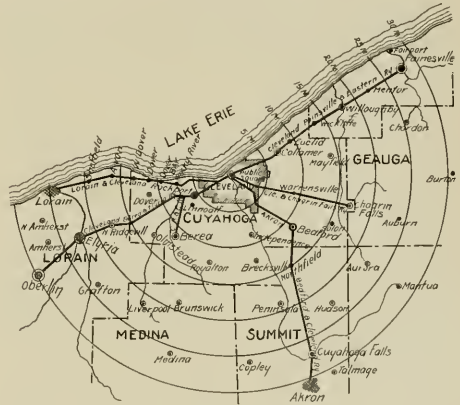

**CITY GUIDE BOOK FOR ATLANTA.**

The Atlanta (Ga.) Consolidated Railway Company has recently published a very attractive pamphlet, giving a condensed time table, describing some of the most pleasant places around Atlanta to visit and containing a fund of general information. The 18 miles of lines extend to the suburban towns of Decatur, Pittsburg, Edgewood, Kirkwood and Inman Park. Fort McPherson, the government post and reservation, Grant Park, Lakewood Park and Brisbane Park are all pleasant places for a trip on the trolley cars. A few hints are given to the patrons of the company

in reference to getting on and off the cars and in dealing with the conductor. The good will of the railway company to its patrons is manifest by this request: "Suggestions from patrons or friends of the road as to the betterment of its service, or on any other points, will be gladly received, and where possible such suggestions will be adopted, provided they prove to be in the interest of the public and the company." Advertising on two pages of the circular paid for its publication.

**CLEVELAND SUBURBAN SYSTEMS.**

The accompanying map shows the electric suburban or interurban railways which connect Cleveland with a score of the towns and villages lying within a radius of 30 miles of the city. Even at the present time the electric suburban transportation facilities enjoyed by Cleveland are more complete than can be found elsewhere, and a glance at the number of towns in the vicinity not so served makes it evident that there is ample opportunity for the construction of

feeders for and extensions to the existing lines. The electric lines all terminate at the public square in Cleveland, and by thus being of more convenient access to the public are able to compete with the steam roads even in the matter of time. The fares to Painesville and Akron are 80 cents and \$1.00, as against \$1.15 and \$1.90 charged by the steam roads. The lines now in operation serve 16 towns with an aggregate population of 66,000; the Lorain & Cleveland line and the extension to Oberlin, now building, will increase this figure to nearly 100,000. During the month of March the Akron, Bedford & Cleveland carried 31,200; the Cleveland, Painesville & Eastern 36,400, and the Cleveland, Berea & Elyria 23,500 passengers.

Foreclosure proceedings against the Columbus (Ohio) Central Railway Company have been instituted by the trustee of the bond mortgage. This action will likely prevent the establishment of the freight service contemplated. The company has always done a certain amount of hauling between Columbus and Westerville, charging at the rate of \$4.00 per car and allowing one hour for loading and unloading at each end of the run. An extension of this service was planned but will hardly be carried out.

**Interesting Bits of Information from all Parts of the Country,  
Boiled Down for Busy Readers.**

Springfield, Mass., will do its street sprinkling with electric car sprinklers.

The Lindell Railway Company of St. Louis has purchased the Midland Street Railway and the Clayton & Delmar Railroad.

In Milwaukee a judgment of \$11,981 has been paid a 6-year-old boy who lost an arm and a leg by being run over three years ago.

The Rochester, N. Y., railway has been ordered to discontinue the hanging of signs from span wires, whether for charitable or other purposes.

Owing to the sudden death of R. M. Fernal, the principal owner and president of the Eureka (Cal.) Street Railway Company, the cars have stopped running and as the road is in a bad financial condition, there is little prospect of operation being resumed.

A Chicago justice refused to fine a man arrested for spitting in a street car, on the grounds that the law under which the arrest was made was unconstitutional; but stated he would have imposed a fine had the offender been booked on a charge of "disorderly conduct."

B. F. Harris, Jr., the successful young president of the railway, electric lighting, gas and water works properties, at Champaign and Urbana, Ill., has consolidated them all into one company called the Urbana & Champaign Railway, Gas & Electric Company. Mr. Harris is president of the new company.

The city council of Los Angeles, Cal., passed a resolution to prevent the erection of poles or the stringing of wires in the business section of the city. It further required that all poles and wires in the "conduit district" must be removed within a year. An exception was made in favor of electric railway poles and wires.

A loan of \$100,000 was made by the Union Trust Company of San Francisco, to the San Diego Electric Railway Company for 40 years at five per cent interest. A mortgage has been given on all the property, real and personal, including franchises, power houses, cars, railroads, and all that may be built within the next 40 years.

A terrific explosion occurred in the tunnel of the London Underground Railway, severely injuring 10 persons and wrecking a passenger car. It was supposed that the accident resulted from an explosion of accumulated gas or else it was due to the placing of a bomb in the tunnel by some one wishing to destroy the station near by.

An ordinance was introduced to forbid the aldermen from receiving passes over the Superior (Wis.) Rapid Transit Railway. Several of the members stated that they had enjoyed the privilege of free rides for the past two years

and did not care to be deprived of it now. The bill was laid on the table for the new council to consider.

An alderman of Port Angeles not long since was greatly exercised over a paving problem and vigorously championed wood in a speech, closing as follows: "Gentlemen, I consider it our bounden duty to degrade and pave these streets. By putting our heads together we can at least construct a wooden pavement. By so doing our posteriors will forever bless us."

The reports of the Brooklyn Heights and the Brooklyn, Queens County & Suburban Railroad Companies, of the Brooklyn Rapid Transit system for the quarter ending March 31, 1897, show earnings of \$959,703; operating expenses, \$644,947; fixed charges and taxes, \$449,343. Exclusive of taxes operating cost 67.20 per cent of earnings. The deficit is \$75,161 against \$128,981 for same period in 1896.

Calumet Electric Railway stockholders, May 4, elected John Farson, president; Charles R. Corwith, vice-president, and H. B. White, secretary and treasurer. During the year ending April 30 the road earned all operating expenses and a surplus of \$10,000. A short extension of the company's Lake avenue line will be made by Receiver John C. McKeon.

The Baltimore & Ohio Railroad Company has extended the electric equipment of its Belt Line at Baltimore a distance of two miles, to Waverly. Hereafter freight trains will be drawn to that point by the powerful electric locomotives. The object of the extension is to do away with the smoke nuisance, and to enable rapid transit over the heavy grades.

More trouble has been experienced on the Brooklyn bridge from broken axles on the electric cars. Although the axles are of the best make on the market and are the same size as are used on many of the steam roads, yet the company has decided to get new axles one-half-inch larger in diameter. It is thought that not enough allowance has been made at the curves in the width of the gauge and that the trouble will not cease until this defect is remedied.

G. A. Wheeler, general manager of the Love Electric Traction Company, states that this company has purchased the franchise rights of the General Electric Railway of Chicago, and will proceed to build the road as soon as it is possible to complete the preliminary arrangements. The offices of the two companies are at 955 Old Colony building, Chicago, but there are no signs of the preparation visible there. Mr. Wheeler declines to make any statements as to when contracts will be let.

Conductor H. E. Miller, of the Frederick & Middletown Electric Railway, lost his life and wrecked a freight car through his disobedience of the company's orders. On the Catocitic mountain line the motor car sometimes leaves a freight car at the top of the mountain to be loaded and proceeds on to Middletown. Conductor Miller was in charge of such a car and decided to run it down the mountain by gravity. He soon lost control of it and at the crossing at the foot of the mountain it jumped the track, shattered a trolley pole and stopped in a newly plowed field, the conductor being impaled on a post.

The Mahoning Valley lines at Youngstown, O., have been equipped with the Buffalo fender.

A "Tramway Technical Exhibition" is to be held in Hamburg, Germany, August 5 to 9, with a general meeting on the 6th and 7th.

The first car over the extension of the street railway to the Soldiers' Home four miles north of LaFayette, Ind., is scheduled to run on May 16.

On May 1 the employes of the Akron, Bedford & Cleveland were notified that the rate of wages would thereafter be 20 cents instead of 17 cents per hour.

Wages on the Duryea line of the Pittsburg Traction Company were, on May 15, reduced from \$1.70 to \$1.50 per day. It is not expected that other lines will be affected.

The Consolidated and North Side roads of Pittsburg have modified their recent orders so as not to discriminate against workmen carrying tools so long as the burden is a reasonable one.

J. T. Windrim was chosen president of the Holmesburg, (Pa.) Tacony & Frankfort Electric Railway Company, F. F. Bell, vice-president, and James Pollock a member of the board of directors.

Charles A. Bien, superintendent of the Akron & Cuyahoga Falls Rapid Transit Company, was struck by a trolley pole while working on the top of a disabled car. His injuries were quite serious.

An electrical stamp canceling machine has been placed on the street railway postal car running on the Mission street line in San Francisco. Power is furnished by a small motor taking current from the line.

The transfer office of the Capitol Traction Company in front of the Treasury, Washington, D. C., was set on fire by the explosion of a coal oil stove. Two printing outfits for transfers were burned together with other property making a loss of \$1,000.

Martin Lane of Philadelphia, was chosen president of the Portsmouth (Va.) Street Railway in place of Gen. J. K. Siegfried, deceased; C. W. Wilson of Pottsville, Pa., was elected secretary. The other officers and directors were re-elected. The board decided to change the lines to a trolley system.

Another "revolution in street railway propulsion" is threatened, this time by the Atmospheric Railway & Power Company of Baltimore. The cars are to be propelled by atmospheric pressure, a more or less perfect vacuum being formed by steam power behind the piston which is connected to the car axle.

The Consolidated Road at Butte, Montana, has received from the city a new franchise which permits it to continue the operation of its cable lines or a change to trolley at such time as desired within three years. The proposed change would be made with a view of having one power station do the work now performed by two.

Suit to recover \$10,000 deposited as security to guarantee the construction of its electric road according to terms of the franchise was brought by the Peekskill, State Camp & Mohegan Railroad at Peekskill, N. Y. Judge Dykman has just decided that as the railroad company failed to keep its agreement its deposit was forfeited.

F. L. Wanklyn, general manager of the Toronto Street Railway Company, has gone to Montreal to assume charge of the Montreal road during the absence of James Ross, vice-president, and Granville Cunningham, general manager, who sailed for England May 8 to superintend the construction of the new electric line in Birmingham.

The annual meeting of the stockholders of the Winona (Minn.) Street Railway & Electric Light Company, was held in Boston and the following officers chosen: A. Perry, president; R. T. Payne, vice-president; A. Burr, secretary and treasurer, and S. B. Livermore, general manager. Except Mr. Livermore the officers are all Boston men.

The following officers have been chosen for the Lafayette (Ind.) Street Railway Company; W. G. Griffith of Philadelphia, president; Paul M. Elsasser of Philadelphia, vice-president; J. T. Henderson, secretary and treasurer, and E. B. Gunn, general manager. The new board of directors consists of W. G. Griffith, P. M. Elsasser, J. L. Jones, J. M. Kennedy, T. J. Levering, H. W. Moore and J. L. Caldwell.

The Harrisburg, (Pa.) Traction Company has been selling tickets 25 for \$1.00, but has been compelled to stop it on account of the misuse made of such tickets by the merchants of the city. The store-keepers offered tickets as a premium for each bill of goods purchased and this practice became so general that the four cent fare became the basis instead of five cents. The traffic did not justify such a reduction and the tickets have been withdrawn.

E. C. McCloy, who is a member of the American Tribune Soldiers Colony, at Fitzgerald, Ga., writes that it is desired to interest someone in the promotion of a street railway in that city, which in two years has grown to 6,000 population, and the founders expect will reach 20,000 in 5 years. Two steam roads, with three more in sight, and a navigable river furnish excellent transportation and a rich country and facilities for manufacture promise a bright future.

The Southwest Missouri Electric Railway has passed out of the hands of the Harrisburg, Pa., stockholders and is now controlled by local capitalists of Carthage, Mo. Robert Moore, Wm. McMillen, W. E. Hall and Isaac Perkins are the new directors; D. R. Goucher was chosen president; C. F. McElroy, secretary, and F. H. Fitch, superintendent. This is an interurban, 32 miles in length, and runs through Carthage, Cartersville, Webb City, Joplin and Galena, Kan.

What promised to be a serious fire in the car barn of the Consolidated Street Railway Company of Grand Rapids, Mich., was narrowly averted. It is supposed that a live coal from a stove in one of the cars dropped on the floor and set fire to it. The fire rapidly spread, but as soon as the heat was great enough to act on the automatic fire extinguishers, eight of them began to spray water on the flames and materially assisted the fire department in confining the damage to one car.

## POWER STATION CONTROVERSEY IN CHICAGO.

Engineers, like doctors and lawyers, often disagree, but it is astonishing in these days to find men who term themselves engineers saying that in properly designed boilers plants, economizers are no good, that simple cylinder engines are more economical and better adapted to street railway work than compound condensing engines; that dynamos driven by means of rope transmission, are more desirable, reliable and economical than direct driven units, and so on; such however, is the case according to an article which appears in the May issue of the Street Railway Journal.

In the first place economizers are a valuable adjunct to any boiler plant, whether well designed or not, and is it not a fact that 99 per cent of the engineers in the old country and in this are firm believers in them. In some instances they give better results than in others, according to the class of boiler and method of setting. For example, in the case of a battery of Galloway or similar boilers where the gases from the furnaces are kept in contact with the boiler by means of flues 100 ft. long, before they enter the main flue leading to the stack you will find the gases at a lower temperature than in the case of return tubular or water tube boilers. However, in such a case, the gases by being passed through an economizer, would raise the temperature of the feed water from 100 deg. to 120 deg. Fahr., as shown by the reports of the chief engineer of the Manchester Steam Users' Association, England, abstracts of which have been given from time to time in the engineering papers. Wherever they have been installed in connection with electric or other plants in this country, they have been found economical, and although the first cost may seem a trifle heavy, yet in a short time they will prove by results given in actual work, that it is a profitable investment. As a large number of plants which have been equipped with economizers have been designed by engineers of high standing and good reputation, and are generally considered very good from a mechanical standpoint, I would ask Mr. Pierce and his colleagues if these have been properly designed and installed, and if they can suggest any improvements in them. Such information would be beneficial to the engineering fraternity at large.

Coming to the question of engines, Mr. Hill tells us that simple non-condensing engines for street railway work are the most economical for his company, but why this particular company more than any other engaged in the same class of work. It is an acknowledged fact, not from 24 hour test results, but from continuous working in large stations from one end of the year to the other, that compound condensing and non-condensing engines are more economical than single cylinder condensing and non-condensing engines respectively. As a practical proof of this statement, compare the coal bills of plants having the different classes of engines; also look at the number of plants where extensions and alterations have been made, and you will find the simple engine has given place to the compound, either with or without condensers, and further look at the number of boilers installed in one case as compared with those in the other. From a theoretical point any engineer having a thorough knowledge of heat and the expansive properties of steam, combined with the principles of engine design, can verify the above statement.

One objection against direct coupling is the want of elas-

ticity, which in case of sudden and heavy overloading might cause a breakdown, but why cannot engines for street railway work be designed on the same lines regarding strength as those in the mercantile marine service, which are subject to far heavier shocks and loads, especially in very rough weather, and seldom give out. If possible in one case it can surely be done in the other, especially when one type of engine is controlled by a governor and the other is not.

Regarding generators, Mr. Hill lays great stress on the accidents caused where direct coupled units have been used. Have not accidents without number been caused by the bursting of fly-wheels in belted plants, not only demolishing the engines and building, but killing several persons outright and damaging property far beyond their own walls? Again, fires have been caused by short circuits in belted plants with no crane or direct coupled unit in sight, the cause of the fire often being located a mile or more from the central station. Mention is made of a plant with compound condensing engines and direct coupled units having lost two armatures whilst a third was being repaired, tying up the road. It strikes me forcibly that the plant in question may have been too small for its work, and as one armature had become disabled the load was too great for the other two, and by overloading they gave out. Such cases as this have occurred in other plants, and have often been due to insufficient capacity, neglect and shortsightedness by not keeping the machinery in proper repair and working order. As to the Western avenue plant in Chicago there must be something radically wrong with the design of the machines to necessitate this continued tinkering, otherwise why have not the same troubles occurred in other plants belonging to the same company?

I fail to see how it is necessary to disconnect the generators to repair the engines in a direct coupled plant except in case of a fractured shaft, for as a rule the shaft and its bearings are the only parts immediately connected with the generators, and you could remove the rest of the engine without disturbing these. In case of re-babbiting the boxes, as engines are now designed, it is necessary in any case to lift the shaft slightly so as to remove the box.

Mr. Hill says the frictional load is from two to four per cent less. Does he refer to the main bearings alone, or the frictional load the engine has to overcome as a whole, including the rope driving gear and its adjuncts? Furthermore, does he refer to the friction when the engine is running the dynamos with no load or when running with a full load?

A good return tubular boiler will give results as good as many of the water tube class, but can you raise steam as rapidly with them; are they as safe as the water tube class; don't they take up more room for an equal horse power, and when one of a battery explodes three or four others follow suit from some unknown cause; and how often we read of these accidents with loss of life and property, whilst an occasional tube only may need replacing in the other. In case of emergency and having to feed with cold water, how many shell boilers have cracked and leaked on their lower surfaces, whilst a water tube has done its work irrespective of hot or cold water. The New Haven Railroad may have used the return tube boilers, but at the same time it installed direct driven units as being better and more economical than any other.

Under the head of "Operation" Mr. Hill says that the Edison Electrical Company of Paterson, is using rope

drives for its arc machines, and that it has the most economical plant in America. But he does not mention that it has four cross-compound condensing engines with direct coupled units for the electric railway work, and two similar engines and dynamos for the three wire incandescent system, whilst it has two cross-compound condensing engines for driving the arc lighting machinery, and furthermore, all the boilers are of the water tube type. These are the elements which make it such an economical plant.

English engineers are also quoted in connection with this matter, but electric traction is little known in England, and in the matter of lighting they are away behind their American cousins. The Englishman, although a pioneer in steam railroading and navigation, has allowed other nations to go ahead in the development of electricity. There are many reasons for this, one of which is they are subject to very severe and exacting laws and not allowed to put up poles, string wires and lay down tracks when and where they please; again, they do not rush into new enterprises without due consideration and deliberation, and expect a fair return for the money they invest. What they have done in electrical work has been well carried out and in a substantial manner; but large direct connected units are almost unknown to them, perhaps the only example of this class of work being that done by Ferranti, at Deptford, near London. However, they like to have a plant symmetrical in all respects and do not care to mix up different styles in the same station, and this may have had something to do with the Liverpool plant. In lighting plants they have adopted small direct driven units very extensively and are still moving in the same direction.

In conclusion Mr. Hill gives a table of building and power costs of certain plants in Chicago and makes a comparison between them and his own. Putting first cost aside, for the cheapest plant is not always the best and most economical, I should think the best thing he could do so as to make a comparison is to measure all the water supplied to his boilers, weigh all the coal carefully, and have a recording wattmeter on his switchboard, then only can he tell what his plant is doing; but as done at present, by taking half hourly readings, no man on earth can tell what the actual output is, nor can he tell what the boilers are doing relatively to fuel consumption and evaporation. When this is done he can find out the cost of fuel per kilowatt-hour, which is the factor all practical men consider today in judging whether a plant is economical or not.

A case has recently been brought to the writer's attention in Mr. Hill's own city, where a comparatively small railway plant installed a direct coupled unit and thereby dispensed with the running of three single corliss condensing engines with a saving of some seven to ten tons of coal in the twenty-four hours. There are other plants all over the country which show results in the same direction.

I think enough has been written on this matter to convince any practical man which of the two systems is the best.

A PRACTICAL ENGINEER.

The many friends of W. B. Allen, for a long time general sales agent of the Brownell Car Company, will be pleased to learn of his appointment to the very desirable position of secretary to the president of the board of public improvements, St. Louis. The appointment is for four years at a good salary.

## CALIFORNIA STATE ASSOCIATION.

The Street Railway Association of California held its second annual meeting at the California Hotel, San Francisco, May 6. A discussion of railway matters occupied the day, vice-president S. B. McLenegan presiding, and in the evening a banquet was served.

Among those present were: S. B. McLenegan, E. P. Vining, M. B. Stein, H. H. Lynch, E. M. Van Frank, Ira Bishop, E. P. Vandercook, C. Gustafson, J. W. Harris, A. W. Barran, J. C. Skinner, S. L. Foster, H. A. Iddings, G. H. Fairchild, W. Clayton, G. A. Loring, J. P. Burk of San Jose, F. W. Ely of Santa Cruz, George T. Smith, C. P. Gilbert of Sacramento, Fred C. White, F. A. Ross of Sacramento, F. W. Woodward and J. F. Burke of Los Angeles and L. A. Lighthipe.

## ELECTRICITY FOR CALIFORNIA STEAM ROAD.

No little interest will attach to the announcement of President Huntington of the Southern Pacific, that his company has under consideration the conversion of its steam line between San Francisco and San Jose, a distance of 50 miles, from steam to electricity. There is a large passenger travel between the city and the Santa Clara valley, and a growing necessity for frequent train service, and the plans contemplate half hourly trains. The change will not be made before next year, but will in all probability be put under way then.

## WRECK IN PORTLAND, ORE.

A very serious accident occurred at Portland, Ore., on the morning of April 27, which it is claimed was primarily caused by running down grade at an excessive speed. A car on the Mount Tabor line was approaching Span's slough, which is at the bottom of a long grade, at a high speed and in passing a jog in the track the front axle was broken, causing the car to leave the track. At the slough the car broke through the bridge railing and plunged into the water. There were 34 persons on the car, three of whom were killed and several injured, some of them seriously.

## MASON AT INDIANAPOLIS RESIGNS.

A. L. Mason, for the past four years president of the Citizens' Street Railway, Indianapolis, resigned on May 8, going to Philadelphia in person to tender his resignation, which was accepted.

Shickle, Harrison & Howard iron works, St. Louis, have a constantly increasing demand for motor gears, and in addition to old customers are steadily adding new ones. One of the orders being filled this month is for 500 steel gears for the Chicago City Railway.

The E. T. Burrows Company, Portland, Me., announces two new styles of curtain fixtures for street cars, making four styles now manufactured for this trade, and which gives a selection which meets every possible requirements. The Burrows shades are rapidly becoming the standard for street railways, thousands of them being in use on the best roads in all parts of the country.

## NEW PUBLICATIONS.

We acknowledge the receipt of the catalog of the Scoville Place School, Oak Park, Ill., of which W. J. Cooke, vice-president of the McGuire Manufacturing Company, is president.

Thomas G. Grier has just published a revised edition of his "Note Book of Wiring Tables," which treats in a very thorough manner the systems of calculating the sizes and the methods of wiring.

The April 29 issue of *Lighting*, of London, was a special "fittings" number with an extended article on electric lighting in house decoration, which is handsomely illustrated and will be found very interesting.

The W. J. Johnston Company has sent out a new catalog of electrical books published by this firm and some pamphlets giving an outline of the contents of the *Electrical World* during the past year. The excellence and variety of the Johnston publications are well known.

The yearly catalog of Worcester Polytechnic Institute has just been issued giving an outline of the five courses of study, three of which are in engineering. In the electrical engineering department attention is given to the design and testing of street railway apparatus and lectures, illustrated by stereoptican views, are delivered by Prof. H. B. Smith.

The last catalog of Purdue University, Lafayette, Ind., has been received. The technical courses are especially strong in electrical and railroad engineering. The electrical laboratory is equipped for the study of different kinds of apparatus and machines in commercial use. Several street car motors are mounted with series parallel controllers and prony brakes to absorb the power. Prof. W. E. Goldsborough gives a course on the design of street railway apparatus.

Catalog No. 28, issued by the Murray Iron Works Company of Burlington, Ia., is an illustrated book of 72 pages descriptive of its Sioux corliss engines, formerly known as the Sioux City, and as such receiving an award for excellent workmanship at the World's Fair. It is apparent from the list of the users of the Sioux engines that they are very well adapted to street railway and electric lighting service, reference being made to 50 such companies. A catalog will be sent to those interested on application.

The W. J. Johnson Company has just published two books of much value to electrical engineers. "Theory and Calculation of Alternating Current Phenomena" is the title of an exhaustive treatise on that subject by C. P. Steinmetz, assisted by Ernst J. Berg. It is a book of 425 pages written in a terse and mathematical style, with many formulæ and curves. A knowledge of the fundamentals of the theory of alternating currents and electrical terminology is presupposed and Mr. Steinmetz ably discusses the phenomena of resistance, inductance, capacity, reactance, admittance, conductance, susceptance, etc., with reference to alternating current apparatus. Price, \$2.50.

Dr. Louis Bell is the author of "Electric Power Transmission, a Practical Treatise for Practical Men" and it is as its

name indicates, a book full of suggestions and an accumulation of facts from operating plants. It is not mathematical and clearly states the elemental principles of electricity, so that it does not take an engineer to follow the author in his treatment of the subject. Transmission by alternating and direct currents, current reorganizers, prime movers, both steam and hydraulic, the construction and operation of lines and power house, and lastly the commercial aspect are all topics handled in a lucid and pleasing manner. The book is profusely illustrated. Price, \$2.50.

We have received from Monsieur Guyer-Zeller, of Zurich, the chairman of the Jungfrau Railway Syndicate, a portfolio of information regarding the "Jungfraubahn," the electric railway which is to bring the summit of this incomparable mountain within three and one-half hours of the Little Scheidegg. After a thorough consideration of the engineering problems involved and of the sanitary and æsthetic objections urged against the enterprise, a concession was granted M. Guyer-Zeller in December, 1894. Subscriptions to the \$1,200,000 of bonds and the \$800,000 of stock are now being received; it is the desire of the Syndicate to interest American and English capital to the extent of one-quarter of the total.

A new edition of the "Pocket Handbook" of useful information, relating to lead covered electric cables and insulated wires, has been published by the Standard Underground Cable Company. It is a book of 182 pages containing many rules, diagrams and tables which will be of value to electrical engineers. The question of electrolysis is discussed and results of laboratory and commercial practice given. Directions are furnished for conduit and cable laying and jointing, the application of protective devices, location of faults, and solutions of many problems, troublesome to electricians. The book is in a neat and convenient form with a handy index. It is a souvenir worthy of the company and makes a valuable addition to a technical library.

"Materials of Construction" by J. B. Johnson is probably the most comprehensive treatise which has been published on this subject. Professor Johnson has for many years been an earnest student of engineering subjects and in this work has culled the most valuable developments from a vast number of sources, and his position as director of the testing laboratory of Washington University, St. Louis has afforded opportunity for special work. The four parts of the book comprise a synopsis of the principles of mechanics underlying the laws of the strength of materials, the manufacture and general properties, the methods of testing, and the mechanical properties as determined by tests. The care taken to incorporate the latest data available makes the work particularly valuable to the practising engineer who has not the time to make his own researches. Published by John Wiley & Sons, New York; large octavo, 800 pages; price \$6.00, postpaid.

An arrangement has been made by the surface and elevated roads with the board of trustees of the New York & Brooklyn bridge for bridge charges. The companies are to pay five cents a round trip for each car operated across the structure and for each passenger such a sum as will be determined later by the directors.

## WATER POWER FOR SANTA CRUZ.

Coal is very expensive in California, some of it being shipped all the way from Australia, so that when a water power is developed near where power is needed it is more valuable than in the eastern states. The Big Creek transmission is the latest project of this kind to be completed. Big Creek is a stream of considerable magnitude, having its source in the Coast Range and emptying into the Pacific ocean. The fall available for power is 926 ft. and the volume of water is sufficient to give a minimum capacity of 500 h. p., but this will be increased to 1,000 h. p. by building a reservoir. By constructing a flume 18 x 30 in. and 11,000 ft. in length a pressure of 400 pounds at the turbine is secured.

A 250-h. p. Pelton water-wheel, 42 in. in diameter, runs a 150-k. w. Westinghouse, two-phase generator. Perhaps no other one thing has been a greater source of trouble in a water-power plant, with a fluctuating load such as is required for a small street-railway system, than the governing

BIG CREEK POWER HOUSE.

apparatus for the water wheels. This problem has been solved by the installation of a Replogle electric governor. The speed regulation is as good as could be desired, as there is very little change from no load to full load. The cut, from a photograph furnished by F. W. Swanton, the principal promoter of the system, shows the power house, which is a wooden structure. The entire plant was completed in 58 working days, about the quickest time ever made on this kind of work.

The current is conducted to two 75-k. w. transformers at 1,100 volts, and the pressure is raised to 11,000 volts for transmission, and at the same time is converted into a three phase current by the Scott system. Two lines extend 18 miles to Santa Cruz, one of three No. 8, B. & S., wires for the street railway circuit, and three No. 5, B. & S., for lighting service. The line consists of redwood poles, 30 ft. long, and set approximately 30 to the mile. Each pole carries two cross arms for the two power circuits and a bracket for a telephone line. The wires for the power circuits are transposed at every pole to avoid self-induction, and the telephone line at every fifth pole, and no difficulty is experienced in carrying on a conversation between the power house and Santa Cruz, 18 miles distant.

At the Santa Cruz sub-station the voltage is transformed down to 1,100 for lighting and street railway purposes. The street railway lines were run by horses from 1882 to 1893,

when electric traction was installed. The current was supplied from one 80-h. p. and one 90-h. p. generator of the General Electric multipolar type. These same machines are used, but the engines have been replaced by a Tesla motor, made by the Westinghouse Company. The motor was started April 9 and has been running with satisfaction since, even under the most exacting service that the road demands.

## AUTOMATIC LUBRICATION.

A liberal supply of oil fed automatically to the working parts of an engine, contributes wonderfully to smooth, quiet running, and relieves the engineer from the drudgery of watching and re-filling a lot of oil cups. The cut illustrates the system applied to the American Ball engines now building at Bound Brook, N. J.

The characteristic features of this system include a positive circulation of oil from an external storage tank into which the oil is strained on its return from the engine frame, and an entire separation of the water from the oil, by means of a tight bulkhead near the cylinder end of engine frame.

SIDE VIEW OF ENGINE.

A simple pump placed in the storage tank, and actuated from the rock shaft, circulates the oil through suitable pipes and discharge nozzles, to the stationary working surfaces, from where it flows by gravity or centrifugal force to the crank pin and cross head pins through oil holes and channels, provided for that purpose, and thence by gravity back to the storage tank, on entering which it passes through a fine gauze strainer located in the tank.

To insure an abundant supply of oil at the discharge nozzles, the pumping capacity is made to exceed the maximum requirement, and the surplus oil escaping through a relief valve falls back into the storage tank. To provide against possible derangement of the pump, a gravity receptacle is arranged to be instantly attached to the system, as an emergency supply.

The reports of the receiver for the Metropolitan Elevated Railroad, Chicago, show that from January 20 to February 28, the number of passengers carried was 1,732,949, or 44,434 per day; and for March 1,482,161, or 17,812 per day. It is probable that this increase is due to Sunday traffic.

The Cayuga Lake Electric Road suffered the loss of a mile and half of copper ground wire last January. The thieves were caught, brought to Seneca Falls and upon pleading guilty, were sent to the county jail for three months. The wire was recovered, but was cut up into very short lengths.

## FOREIGN FACTS.

The Board of Trade has permitted the running speed between Dublin and Dalkey to be reduced 10 minutes and the eight miles is now made in 70 minutes.

The lines of the Dublin & Lucan Tramways Company are to be changed to a single track trolley system. A power house is to be erected and rolling stock purchased.

The Leeds tramway lines are being improved and additional equipment added. An order for 10 new trailer cars has been placed and these are to be mounted on Brill trucks.

The damage to the sea-going car of the Brighton & Rottingdean line from the storm last winter was not so serious as was anticipated. It has been repaired and is again in operation.

The Taunton, England, Town Council is considering an application from the Taunton & West Somerset Electric Railways & Tramways Company which wishes to construct a trolley line in the borough.

The Halifax tramway committee has recommended the adoption of the overhead trolley system and is at work on the details. It was recommended that electric lights on the trolley poles be substituted for the present lighting system.

J. H. Madden, U. S. consul at Smyrna, Turkey, writes that there are but two street railways in that province and these are both in the city of Smyrna. These lines are of small importance as the Turks feel little need of rapid locomotion.

The Bury, Rochdale & Oldham Tramway Company has decided to equip the Rochdale branch of the company's lines with electricity and arrangements to that effect have been made with the borough authorities. The trolley system is to be adopted.

The Belgian Government has decided to make a trial of electric locomotives on the state railroad running from Brussels to Tervueren, a distance of nine miles. The speed is to be 31 miles an hour on the level and 18 going up the steep grades. Storage batteries are to be tried at first.

The Highways Committee of the London County Council has reported favorably on the application of the London, Deptford & Greenwich Tramways Company, to operate for one year Ribbe's electric accumulator street cars on the Rotherhithe New road, between Raymouth road and the canal bridge, Old Kent road.

Information is received from the Imperial & Royal Land Bank, of Vienna, that the horse tramway of Linz is to be changed to an electric line and an extension is to be made up a neighboring mountain, the continual ascent being 10.5 per cent. The single track mileage will be 5.75 miles long. There will be 17 motor and 15 trailer cars on the line and the power house capacity is to be about 1,500 h. p.

A London syndicate has been formed for the purpose of building a system of light railways on the island of Angelsey to carry both freight and passengers. The local authorities have been favorably disposed towards the project

and permission has been granted to run the lines along the main roads, with single tracks and turn-outs at suitable intervals. The company will be capitalized at £140,000.

The Tramway Committee in Glasgow after a report by the chairman that the expense of working was from 2 to 4 cents per car-mile for electricity as against 16 cents per car-mile for horses, adopted the following resolution: "That an overhead electric system of tramway traction be applied to the Springburn route, (three miles) and that the co-operation of the Watching and Lighting Departments be secured to have the route lit by electricity from the same source."

The Imperial Tramways Company, Bristol, England, desiring to find a remunerative re-investment for the proceeds of some Dublin shares recently sold, has made provisional arrangements to acquire 4,000 £10 preference, and 4,000 £10 ordinary shares of the London United Tramways. This latter company, of which J. Clifton Robinson, London, is managing director, owns and operates about nine miles of track in the west end of London, and has in the last two years paid 6 per cent on preference and 8 per cent on ordinary shares.

The Public Works Committee, of Birmingham, after visiting Bristol, Blackpool, Paris, Rouen, Brussels, Vienna, Budapest, Dresden, Berlin, Hamburg and Bremen, has returned and made a report to the council. It recommends the electric conduit system in preference to any other on account of its insulated return and greater safety. Prices quoted to the committee in Berlin for a mile of conduit were but 25 per cent higher than for the trolley. The tramways company, in anticipation of a favorable report for the trolley lines, had placed some orders for trolley equipment which will have to be withdrawn if the decision of the committee stands.

In a recently published report the directors of the Hanover tramway system advocated the extension of the storage battery system in preference to the trolley and gave figures to substantiate their judgment. Storage battery cars are run in the center of the city and trolley lines extend into the suburbs. The cost of maintenance has been accurately determined and found to be about two cents per car-mile for storage battery over the trolley but the directors think that the battery cars have advantages which more than compensate for this difference. As soon as the necessary arrangements can be made the whole system will be equipped with the battery cars.

Another street tramway committee is to make an extended tour of inspection. After considerable discussion with the city council of Douglas, Isle of Man, the Douglas Southern Company offered to pay the expenses of the traction committee, the town clerk and the borough surveyor in a trip to London, Paris, Frankfurt, Dresden, Berlin, Hamburg, Cologne, Brussels, Liege, Rouen, Bristol and Prescot. It would seem that, as this field has been pretty well covered by the tramway committees of other English cities and all of them have recommended some form of trolley traction, this long jaunt is unnecessary. However the report of this committee will be awaited with interest. The tramways company is improving its roadbed and making some extensions to its lines in anticipation of a heavy summer's traffic.

## NEW TYPES OF LIGHTNING ARRESTERS.

To be effective in conducting away high potential discharges generated in overhead lines by atmospheric disturbances, the lightning arresters must have a less resistance across the spark gaps than has the insulation of the appara-

For higher voltage the number of gaps is increased, exhaustive tests showing that for an 11,000-volt, 5,000-h. p. line there should be 14 gap spaces.

The cuts show the connections for these two types.

## DAMAGE SUIT FOR FAILURE TO DELIVER COPPER.

In the supreme court of New York, a case was disposed of last week which has been in litigation some time; the settlement being reached by a discontinuance of the suit of the Okonite Company against Holmes, Booth & Haydens.

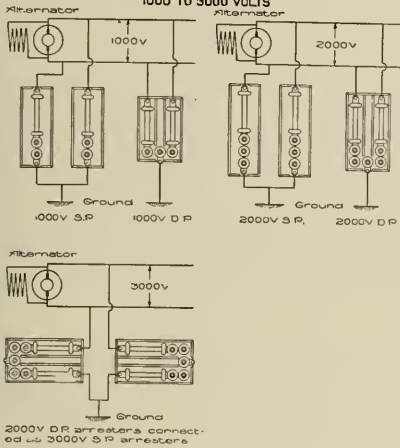

The complaint showed that in June 1895, Holmes, Booth & Haydens sold to the Okonite Company 300,000 lbs. copper at 12½ cents, and after delivering 50,509 lbs. stopped further delivery. The Okonite Company then in September 1895 purchased elsewhere the balance of the copper at 14 cents, and sued Holmes, Booth & Haydens for the difference, about \$4,500. Holmes, Booth & Haydens denied the contract. An order discontinuing the suit was entered in the clerk's office on April 21, and on inquiry it is understood that Holmes, Booth & Haydens paid the Okonite Company about \$2,800 for a settlement.

## J. G. WHITE & COMPANY.

A new corporation, the J. G. White & Company, has been organized under the laws of the state of New York, with a fully paid capital of \$100,000. It succeeds to the business of the White-Crosby Company, of 29 Broadway, New York, and of Baltimore. When the White-Crosby Company was organized it was intended that Oscar T. Crosby, who had just severed his connection with the General Electric Company, would engage actively in the business, but his health was in a precarious condition from overwork. A trip to Europe was taken for rest and recuperation. Upon his return, Mr. Crosby became largely interested in a street railway in Washington, and later organized a light and power company, which has grown into a large and flourishing institution. This and other local interests absorbing all his time, it was deemed best to reorganize the White-Crosby Company. The new company was organized under the laws of New York instead of those of West Virginia, and it was decided to adopt the name by which the company had previously been known, although the "company" was merely nominal.

J. G. White was graduated at the State Pennsylvania College in 1882, and obtained the degree of Ph. D. at Cornell in 1885. For two years Mr. White taught physics in the University of Nebraska, and at the end of that time formed the Western Engineering Company, with headquarters at Lincoln, Neb. In this enterprise he was joined by D. C. Jackson, now professor of electrical engineering at the University of Wisconsin, and H. J. Ryan, professor of electrical engineering at Cornell University. This company was sold to the United Edison Manufacturing Company in the spring of 1890. Mr. White made an agreement with the Edison Company to become its exclusive agent, on a commission basis, for the United States, in making contracts for the construction of and equipment of electrical railways. Later in the year he formed the J. G. White Company, and conducted the business alone until the formation of the White-Crosby Company in May, 1894.

CONNECTIONS OF WIRT ALTERNATING CURRENT SHORT GAP LIGHTNING ARRESTERS 1000 TO 3000 VOLTS

tus to be protected, which in railway armatures is usually sufficient to withstand a voltage of 3,000. The perfected arrester for use with 500-volt continuous currents adopted by the General Electric Company is known as type M-D and has a spark gap of  $\frac{1}{2}$  in., which a 2,000 volt current will bridge. The gap is in a strong magnetic field so that the arc is at once blown out. To limit the current a low non-inductive resistance is placed in circuit.

The Wirt alternating current short gap arresters, made by this company, have been especially designed to operate effectively with very small gap spaces. For 1,000 volt circuits there is a single  $\frac{1}{2}$ -in. spark gap between two metal cylinders 2 in. in diameter and 2 in. long. One cylinder is connected to the overhead line and the other to the ground and a low non-inductive graphite resistance placed in circuit. The combined action of the metal cylinders and non-inductive resistance prevents the heating of the cylinders when the lightning discharge passes and the formation of gas which would enable the alternator to maintain an arc. The arc itself is extinguished by the reversal of the alternating current.

This firm, under the various titles above mentioned, has equipped electric railways in Spokane, Wash.; Salt Lake City, Utah; Sherman, Texas, and in many other cities and towns. During the past five years the contract work in Baltimore alone amounted to \$3,000,000. The transmission line for the Cataract Construction Company, between Niagara Falls and Buffalo, and a large part of the work on the Buffalo & Niagara Falls Electric Railway has been completed by this company. It has at the present time contracts for the complete construction and equipment of the street railways of Charleston, S. C., including all buildings, power plant, track, overhead equipment, and other details; the changing of the "Blue Line" of the Baltimore City Passenger Railway Company from cable to trolley; the electrical engineering for a large transmission plant to be located near Helena, Mont., power for which is to be obtained from the Missouri river; the building of extensions for the Norwalk Tramway Company, Norwalk, Conn., as well as other similar work.

Mr. White is one of the pioneers in the electric railway construction business, and the new corporation will have the full benefit of his long and varied experience.

---

### PERSONAL.

J. J. Boudreau has been made general roadmaster of the Hartford street Railway.

Howard Abel succeeds Robert Laughlin as a director of the Lake Street Elevated of Chicago.

Charles W. Stevens resigned as superintendent of the Chester & Derry (Mass.) and accepted a position with the Lowell, Lawrence & Haverhill road.

W. D. Ray, manager of the railway at Everett, Wash., is anything but an ex-Ray, but has recently made some very interesting experiments with X-ray apparatus.

Russell B. Harrison, president of the Terre Haute Electric Railway Company, attended the Grant monument dedication parade in New York and acted as aid to Gen. Dodge.

Pierre Jay has been elected president of the Second Avenue Railroad Company in place of John D. Crimmins, who has held the office since the Metropolitan interests acquired control.

President Beckley, of the Rochester (N. Y.) street railway, has voluntarily reduced his own salary from \$6,000 to \$1,000, and raised that of Manager Nichol from \$4,000 to \$6,000.

C. E. Flynn, formerly of Peoria, Ill., and now general manager of the Carbondale (Pa.) Traction Company, visited Chicago friends and the REVIEW on his recent western trip.

E. J. Martyn, a member of the firm, and P. D. Armour's confidential man, died suddenly in this city. He was a director in the Metropolitan road, Kansas City, a man of fine executive ability and very popular.

W. D. Calder, superintendent of the Seattle & Rainier Beach line, was out on reconstruction work for two days and nights without rest, and fainting from exhaustion fell and badly cut his head on the iron work.

Capt. T. T. Johnson, of Fort Wayne, Ind., succeeds Col. J. R. Cook as superintendent of the street railway at Ironton, O. Capt. Johnson is a man of wide experience in street railway matters, and is well qualified to fill his new position.

H. J. Quigg, general manager of the Staten Island Electric Railroad, has resigned that position to go with the Erie Railroad, with which he was connected from 1891 to 1893. Mr. Quigg has suffered from ill health the past year and hopes to be benefitted by the change.

Robert Chappell resigned the presidency of the Galesburg (Ill.) Electric Motor & Power Company, and Fred Seacord was chosen by the board of directors as his successor. H. F. Arnold also handed in his resignation as secretary, but no action was taken to fill the vacancy.

At the annual meeting of the Peckham Motor Truck & Wheel Company, the Hon. C. H. Duell, of Syracuse, N. Y., was elected vice-president in place of H. C. Loap, of Kingston. Mr. Duell has the reputation of being one of the best patent lawyers in the United States, and his experience will be of great value to the company.

John N. Beckley, who for several years past has been president of the Rochester (N. Y.) Railway, and who has served with marked ability both his own company and the American Street Railway Association, has resigned in order to devote his whole time to other and, to him, more important interests. He will continue on the board.

John I. Beggs, who has long been identified with electric work and who was manager of the Chicago office of the Edison Company up to the time of consolidation, and recently general manager of the Cincinnati Edison Electric Company, has been appointed general manager of the Milwaukee Electric Railway & Lighting Company, and has entered on his new duties.

---

### OBITUARY.

We announce with regret the very sudden death on April 22, of apoplexy, of Edward F. Bradford, of the Bradford Belting Company, Cincinnati.

Wm. W. Cross, formerly president of the Brockton, Mass., Street Railway Company, died recently of heart trouble. He was a prominent business man and interested in several lines of industry in Brockton which has always been his home.

Gustav Sutro, who has been a prominent business man of San Francisco and one largely interested in street railways, died in that city. He purchased the Omnibus Railroad Company and connected it with the Cliff House and Ferris system. In this he was associated with his cousin, ex-Mayor Adolph Sutro as well as in many other business enterprises.

The Massachusetts committee on street railways has voted to report a bill providing that after 1898 cars shall be vestibuled in winter.

The Halberstaedt (Germany) Street Railway, a horse line, earned a 3½ per cent dividend on the capital stock of \$52,000 in the year 1895-6.

**Alabama.**

MONTGOMERY, ALA.—Right to build, operate and maintain a branch line on McDonough street has been granted the Montgomery Street Railroad Company.

**California.**

SANTA ANA, CAL.—The Santa Ana & Orange Motor Company's bid of \$10 for the street railway franchise has been accepted.

MONTEREY, CAL.—The Pajaro Extension Railway Company has been incorporated to construct an electric railway in Monterey county. Capital stock, \$100,000; incorporators, Claus Spreckels, W. C. Waters and John L. Koster.

PASADENA, CAL.—Action on the Terminal Railway Company's application for a franchise has been postponed until May 17. The judiciary committee has agreed upon the conditions to be imposed, but opines that it would be inexpedient to advertise the franchise for sale until the new law relating thereto should go into effect, as it will, May 12.

**Canada**

WINDSOR, ONT.—The council of Sandwich West has granted a franchise to the Windsor, Amherstburg & Lake Erie Railway Company for an electric line through the town requiring construction to begin immediately. The company has given a \$10,000 bond to comply with the conditions.

MONTREAL, QUE.—The Montreal and Southern Counties Railway Company is being organized to construct 150 miles of electric railway to connect Montreal and the south shore with the counties of Chambly, Vercheres, Ronville, St. Hyacinthe, Laprairie, Brown, Shefford, Stanstead, and Sherbrooke. A. F. Corriveau is promoting the scheme with the assistance, it is said, of New York capitalists. The capital of the company is placed at \$2,000,000.

**Chicago.**

CHICAGO.—The Calumet, Blue Island & Harvey Street Railroad Company has petitioned the county commissioners for a 20-year franchise to construct a single or double track road over certain streets in the towns of Bremen and Thornton. The company will carry passengers, mail, express and baggage. Consents have been obtained from the required frontage.

CHICAGO.—Charles S. Leeds, promoter of the Suburban Electric Railroad, has filed a bill for an accounting from the directors of the company and Naugle, Holcomb & Co., also for a receiver for the railroad, and the Suburban Construction Company, and an injunction to restrain Naugle, Holcomb & Co., from disposing of any of the stock and bonds in their possession, alleging that if not restrained they would deprive him of all interest in the enterprise.

CHICAGO, ILL.—Receiver McKeon, of the National Bank of Illinois, has taken possession of the Calumet Electric Railway. Farson, Leach & Co., are released from all obligations. In exchange for 4,835 shares of stock and 2,843 bonds, the receiver returns to Farson, Leach & Co., the note for \$3,000,000, bearing their indorsement. The receiver is to furnish all the money needed to keep the road in operation and to develop and keep the roadway in repair, and to charge 6 per cent interest thereon.

**Connecticut.**

BETHANY, CONN.—Talcott H. Russell and E. P. Arvine are interested in the Woodbridge & Bethany Electric Railroad Company, which has applied to the railroad commissioners for a franchise.

HARTFORD, CONN.—The bill to charter the New Haven & East Haven River Railroad Company has passed the senate. This com-

pany will extend the New Haven Street Railway from its present terminus in East Haven to Cosy Beach and Mansfield Grove. A bill has also passed to incorporate the Branford Electric Railway Company.

**Delaware.**

REHOBOTH, DEL.—W. B. Welling, of New York, asks the assembly to grant a charter to the Delaware Central Railroad, which desires to build a trolley line from Seaford to Rehoboth, a distance of 30 miles.

DOVER, DEL.—P. A. B. Widener, William L. Elkins, John Edward Addicks, Peter L. Cooper and Richard Colchens are the incorporators of a new electric railway company which is to build a road from Chester via Claymont, through the city of Wilmington and connect with the New Castle Electric Railway.

**Florida.**

PENSACOLA, FLA.—Captain W. H. Northup, receiver of the Pensacola Terminal Company, states that at a recent meeting of security holders at Baltimore it was decided to equip with electricity, "the experiments with compressed air not having been satisfactory." To perfect title the property will be sold under the former order of Judge Swayne of the United States court. As soon as the sale is made the work on the extension will be pushed to completion.

**Georgia.**

ATHENS, GA.—The Athens Street Railway Company has purchased the electric lighting plant of the Athens Manufacturing Company and now controls all the commercial lighting of Athens.

ATLANTA, GA.—The Atlanta & Douglasville Railway Company has been formed to build 25 miles of electric railway. The capital is placed at \$375,000, and among those interested are Charles G. Wetter, president Builder's Exchange, Philadelphia, and L. Galloway, of Decatur, Ga.

**Illinois.**

GALESBURG, ILL.—Citizens of Knoxville have subscribed \$8,000 and Galesburg will probably give \$2,000 to make the \$10,000 bonus asked by Fred Seacord and Robert Chapel for their proposed electric railroad to connect Galesburg and Knoxville.

AURORA, ILL.—Manager Belden, of the Aurora & Geneva Railway, has begun condemnation proceedings for right of way along the river south of Geneva. Mr. Belden says: "From the present outlook, cars will run over our Geneva branch by June 1, and there is no immediate prospect of any delay in the work, which is now so well under way."

AURORA, ILL.—At a meeting, April 28, of the recently incorporated Aurora, Yorkville & Morris Electric Railway Company, at the office of Aldrich, Winslow & Worcester, the following officers were elected: President, Vine A. Watkins, of Chicago; vice-president, U. P. Hord, of Aurora; secretary, F. D. Winslow, of Aurora; and treasurer, F. B. Watson, of Aurora. The remaining director is H. L. Tracy, of Columbus, O. Several eastern capitalists, members of the syndicate, were in attendance at the meeting and expressed the belief that the work of construction would begin early this summer. Nearly all the right of way has been secured along the country route following the west river road. The road will probably enter Aurora on both sides of the river, the main line branching at Montgomery.

**Indiana.**

LAFAYETTE, IND.—Superintendent Guhn of the Lafayette Street Railway, is estimating the cost of an extension, which may be made if satisfactory to the eastern stockholders.

**Iowa.**

FT. DODGE, IA.—The electric railway company has been granted an extension of time until November 1, 1898, in which to have the road built and running.

CEDAR FALLS, IA.—Having been granted a franchise for a street railway to be operated by compressed air, gas, or electricity, C. W. McElyea is visiting eastern cities to investigate those systems of traction.

BURLINGTON, IA.—A syndicate of Boston capitalists including Edwin G. Innis and E. J. K. Noyes, has purchased the Burlington Electric Railway at sheriff's sale. The new owners intend to expend \$100,000 at once on new tracks, cars and improvements. An extension 3 miles in length will be built to West Burlington.

**Kansas.**

LEAVENWORTH, KAN.—City Treasurer Amos A. Fenn and E. A. Kelly are organizing a company to procure a franchise and construct and operate an electric railway in opposition to the Leavenworth Electric Street Railway.

**Kentucky.**

FRANKFORT, KY.—No bids were received on April 22, when the Capital Street Railway was offered for sale by United States Commissioner T. N. Lindsey.

COVINGTON, KY.—A street railway to be operated by gasoline motors is proposed by city engineer Weaver of Ludlow. The contemplated line would be ten miles in length, connecting Erlanger with the Cincinnati, Newport & Covington Electric Railway at Ludlow.

LOUISVILLE, KY.—The Metropolitan Railway Company, which was recently incorporated, offers \$75,000 a year for the street car privileges of Louisville. The fare is to be 4 cents, with 8 tickets for 25 cents. The charter of the Louisville Railway Company, which operates all the lines expires September 28, of this year.

**Maine.**

PORTLAND, ME.—The Portland & Cape Elizabeth Electric Railway Company will soon extend its double track through Broadway to Pickett street, in readiness for summer excursion traffic to Willard Casino.

**Maryland.**

BALTIMORE, MD.—The Central Railway has petitioned the council for right to lay tracks on Milton avenue and Canton avenue.

NORTH EAST, MD.—The North East Electric Railway Company, which was incorporated some time ago to build a line from Rising Sun through North East to the Elk River, held a meeting at North East, April 17, and elected the following officers: James Mallen, of Conshohocken, Pa., president; George W. Cosden, of North East, secretary and treasurer; J. C. Carhart, of Zion, Md., corresponding secretary.

BALTIMORE, MD.—The ordinance extending the time for completing the Edmondson Avenue, Catonsville & Ellicott City Electric Railway has been signed by Mayor Hooper. The company recently elected the following officers. President, George Yakel; vice-president, John Hubner; treasurer, Louis Yakel; secretary, William L. Layfield, general manager; W. Kesley Schoepf; directors—John Hubner, David M. Newbold, Bernard N. Baker, W. K. Schoepf, Louis Yakel, N. L. Layfield and George Yakel. It is stated that work on the road will be resumed in a few weeks.

**Massachusetts.**

HOLYOKE, MASS.—The Holyoke Street Railway Company has accepted the franchises recently granted for various extensions.

BOSTON, MASS.—A site for a power house costing \$400,000 has been purchased at Boylston street by the West End Street Railway Company.

NEWBURYPORT, MASS.—The Plum Island Electric Street Railway Company has been incorporated to build four miles of road. Incorporators, Charles Odell of Salem, and C. Fred Dennis of Newburyport.

AMHERST, MASS.—The Amherst-Sunderland Street Railway Company has selected a site for its power station. The steam plant will be supplied and erected by the H. M. Holt Boiler & Engine Company of Boston.

WORCESTER, MASS.—Matthew J. Whittall and Alfred Thompson, of Worcester, on April 23 purchased the Blackstone Valley Electric Railroad for \$31,000 at receiver's sale. The purchasers have not yet decided what to do with the property.

ATTLEBORO, MASS.—The Norton & Attleboro Street Railway Company has been incorporated to construct 5.5 miles of electric road. Capital stock, \$40,000; incorporators, D. E. Saunders, Salem, Mass.; L. C. Powers, Somerville, Mass.; and Albert A. Babb, Malden, Mass.

NEWBURYPORT, MASS.—Stockholders of the People's Electric Railway, which is soon to be built from Newburyport to West Newbury, recently elected Charles Odell, of Salem, president; Rufus H. Brown, of Peabody; Thomas H. Johnson, of Salem; C. C. G. Thornton, of Boston; Chas. H. Odell, of Salem; Thomas Smith, A. R. Smith, of West Newbury, directors.

PITTSFIELD, MASS.—Directors of the Pittsfield Electric Street Railway have appointed a committee to look into the matter of building their own power plant. The Pittsfield Electric Company, which now supplies current, finds its capacity overtaxed, but declines to install additional engines and generators, unless given a contract for a series of years. It is estimated that a new plant will cost \$20,000 or more.

**Michigan.**

PONTIAC, MICH.—The Oakland Electric Railway Company, by Secretary Strathearn Hendrie, will apply for a franchise to operate in Pontiac.

ALGONAC, MICH.—Citizens have voted to give the Detroit & St. Clair River Electric Railroad Company right of way over the principal street.

MONROE, MICH.—The Johnson & Jacobson Company, of Detroit has accepted their franchise and will begin work at once on the electric road in Monroe.

HOLLAND, MICH.—Work will begin at once on the new road of the Holland & Saugatuck Electric Railway Company. It is expected cars will be running by August 1.

BENTON HARBOR, MICH.—Forrester & Westcott, it is said, will take the contract to build the electric road to Eastman Springs, for which Seely McCord was recently granted a franchise.

ST. JOSEPH, MICH.—James Brooks has been appointed receiver of the St. Joseph & Lake Shore Street Railway upon application of the Royal Trust Company, Chicago, which holds a \$30,000 mortgage.

DETROIT, MICH.—Construction of the Oakland Railway extension from Birmingham to Pontiac has begun under the supervision of John Busbee, superintendent of the Wyandotte & Detroit River Electric Railway. It is expected cars will be running by June 15.

BAY CITY, MICH.—Two combination summer and winter cars will be purchased by the Consolidated Street Railway Company. The beach cars will be equipped with Westinghouse in place of Sprague motors. After completing the relaying of the Center avenue line work will be begun on the Essexville line and be completed by August 1 at the latest.

**Minnesota.**

DULUTH, MINN.—The Minnesota Point Street Railway Company made a voluntary assignment April 15, to Paul Sharvy. The immediate cause of the assignment was the inability of the company to pay a note for \$6,700 held by Charles Pettengill, and which is past due.

**Missouri.**

ST. LOUIS, MO.—The Missouri Railroad Company's 3 lines have been bought by the owners of the Lindell system.

ST. LOUIS, MO.—A bill has been introduced in the house of delegates granting franchises to the Central Street Railway Company. The St. Louis & Suburban asks leave to abandon its branch line to Forest Park and run a line in the opposite direction.

ST. LOUIS, MO.—The Hamilton syndicate power-house was damaged by fire on the night of April 16. The machinery suffered no damage, beyond that caused by water, one of the generators having its insulation somewhat weakened. It is estimated the loss will not exceed \$3,000.

### New Hampshire.

EXETER, N. H.—Directors of the Exeter Street Railway Company have been authorized to contract for the construction of their road to Hampton.

### New Jersey.

CAMDEN, N. J.—The ordinance granting the Camden & Suburban Railway Company permission to lay 1.5 miles of track in Haddonfield will be passed May 12.

HADDONFIELD, N. J.—The West Jersey Traction ordinance, which has hung fire for over two years, has been passed by the newly elected borough commissioners.

NEWARK, N. J.—A map showing seven miles of proposed extensions has been filed with the secretary of state by the Passaic & Newark Electric Railway company.

LONG BRANCH, N. J.—The Long Branch Electric Railway Company, has been incorporated to operate 1.75 miles of road in Long Branch. Capital stock, \$150,000; incorporators, Frank P. Killen, Bernard Mahon, Jacob Lorsch, James J. McInerney, C. E. Patterson, Harry W. Green and Chas. Morris.

BRIDGETON, N. J.—The Bridgeton & Millville Traction Company, which recently acquired the South Jersey Traction property at master's sale, at its first meeting, May 3, elected the following directors: C. Hartman Kuhn, president; Stephen Greene, vice-president; Walter H. Bacon, secretary and treasurer; Aaron Fries, Bloomfield H. Minch, Lawrence Johnson, and Frank S. Lewis.

### New York.

BUFFALO, N. Y.—The Crosstown Street Railway Company, May 3, filed its acceptance of the franchise recently granted to lay its tracks on six streets and avenues.

OLEAN, N. Y.—Superintendent Pierce, of the Olean, Rock City & Bradford Electric Railway, has purchased 4 high pressure boilers of 600-h. p. for the proposed new line.

ALBANY, N. Y.—The trustees of Greenbush Village have passed an ordinance granting a franchise to the Albany Railway to construct and operate an electric railway in Greenbush.

HUDSON, N. Y.—The reorganized Hudson Electric Railway Company has elected William A. Harder, Jr., president; R. W. Evans, vice-president, and Augustus McKinstry, secretary and treasurer.

MAYVILLE, N. Y.—C. C. Minton, of the Mayville State Bank, has been elected treasurer of the Westfield, Mayville Electric Railroad Company. He believes the road will be built inside of two months.

PENN YAN, N. Y.—The state railroad commission, April 14, granted the Penn Yan, Keuka Park & Branchport Electric Railroad Company permission to build its line between Penn Yan and Branchport

ORISKANY, N. Y.—Ties and rails have been distributed over the route of the Suburban Railway Company between Whitesboro and Summit Park, Oriskany. The electric road is expected to be open for travel on Memorial Day.

BROOKLYN, N. Y.—Citizens of Flushing met recently and resolved that necessary permission for building a trolley line through Bayside in accordance to the route decided upon at this meeting be granted the New York & North Shore Railway Company.

RIVERHEAD, N. Y.—Consents have been obtained for the electric road which Riverhead, Quogue & Southampton Railroad Company proposes to build through Flanders to Quogue and the Ocean beach. The capital is on hand and construction is soon to begin.

BUFFALO, N. Y.—Permission to build and operate a surface road over various streets is asked by the Tonawanda Electric Railway Company. George P. Smith asks that he be allowed to lease the franchise of the Tonawanda Street Railroad to the same company.

NEW YORK, N. Y.—Plans for a 3-story brick car and power house have been filed by the Metropolitan Street Railway Company. The plant, costing \$200,000, will be erected on Lenox avenue, to care for the increasing traffic in Harlem and to relieve the Lexington avenue power station.

ALBANY, N. Y.—The Hudson Electric Railway Company has been incorporated to operate the reorganized Hudson Electric Railway. Capital, \$50,000; directors, William H. Lamb, R. Rainey, P. S. Johnson, R. W. Evans, W. A. Harder, S. Thompson, W. M. Brownell, C. S. Rogers and J. E. Gillette.

PORT JERVIS, N. Y.—A trolley road is to be built by the Port Jervis Electric Street Railway Company, which has recently been incorporated with \$70,000 capital stock. The directors are Lafe Pence and George McKibben, of New York, and S. D. Lake, A. C. Haines, George A. Elston, J. E. Wickham, J. E. March, and Theodore Shay, of Port Jervis.

SYRACUSE, N. Y.—A franchise will be asked of the Salina town board to permit the construction of an electric railway through the town. The line would connect with the Lakeside Electric Railway and extend to Liverpool. Among those interested are Valentine Bond, George Shaver, George Riechberg and Thomas Holleran, of Liverpool, and John Kaufman, of Syracuse.

NEW YORK, N. Y.—The Rapid Transit Underground Railroad Company has been incorporated with the object of obtaining the contract to build the underground road for the city and subsequently operating it under lease. The incorporators are Carlton H. Reeve, Cornelius V. Sidell, John Bogart, John Acker, David L. Hough, John F. O'Rourke, Thomas Allen and Robert H. Sherwood of this city, and Nelson S. Eastman of Summit, N. J.

FAR ROCKAWAY, N. Y.—The Ocean Electric Railway Company has been incorporated to build five miles of electric railway over two routes. Headquarters will be at Far Rockaway. Capital stock, \$50,000; directors, Daniel F. Lewis, Louis E. Robert and Henry A. Van Keuren, of Brooklyn, and Samuel B. Lawrence, John B. Summerfield, William H. Chesebrough, Jr., Henry M. Haviland, Francis P. Lowrey and Armitage Mathews, of New York.

HAMBURG, N. Y.—The Hamburg Railway Company has ordered 600 tons of steel rails to complete the trolley line between Blasdell and Hamburg. The Buffalo, Hamburg & Orchard Park Railway Company has elected the following officers: Directors, W. W. Wheatley, Arthur W. Hickman, John A. Donaldson, Ernest Wende, Lester J. Chase, Willis J. Gregory, U. L. Upson, Frank W. Everett, George R. Vaughn, William J. Wright and Dr. Loren F. Bliss. Mr. Upson says work will begin in July.

WESTFIELD, N. Y.—The Westfield, Mayville & Chautauqua Motor Railway Company has been incorporated to build the electric line already reported in the DAILY BULLETIN. The charter provides for 15 miles of road, to be operated by any power other than steam. Capital stock, \$150,000; directors, John C. Minton, of Burlington, Ia.; James V. Minton, Waldo L. Minton, Harry S. Minton, Harlow W. Gibbs, Willis U. Baldwin, and William L. Minton, of Westfield; Charles C. Minton and Clarence R. Cipperly, of Mayville.

CORNING, N. Y.—J. D. Nares, of Corning, writes us that the Savona Valley & Lake Keuka Railway to connect with the Rochester division of the Erie Railway at Savona, and run through the towns of Savona, Bradford, Tyrone, Weston and Wayne, terminating at Keuka, the summer resort of Lake Keuka, a distance of 18 miles, then connecting with a ferry system crossing Lake Keuka to Gibson and Pulteney, a distance of two miles. The road is to be standard gage, and run all classes of passenger and freight cars, and to be run by electric power. The power house will be located at Bradford, N.

Y., about middle distance of the road. The power plant will be heavy, as the freight service will be heavy. Also the passenger service is expected to very large in the summer and fall season. The Chenango Engineering Company, of Binghamton, N. Y., is now at work on surveys and maps. Work will be let about May 15, 1897.

**BUFFALO, N. Y.**—The Buffalo, Niagara River & Grand Island Railway Company has been incorporated with a capital stock of \$30,000, to operate a street surface electric road from the city of Buffalo to the dock of the Buffalo & Grand Island ferry on the Niagara river in the town of Tonawanda. The directors are: Donoto A. Crage, William E. Tench, George A. Ricker, J. M. Metcalf, Herbert P. Bissell, George C. Riley, James Murphy, Charles W. Ricker and Frank W. Carr, all of Buffalo. The projector of the road is William E. Tench, of the firm of Crage & Tench, of this city, the builders of the Gorge road.

**BUFFALO, N. Y.**—The Buffalo & Depew Railway Company was incorporated May 1 to build an air line connecting the villages of Depew and Lancaster with Buffalo. The road will be built for rapid transit; cars are expected to cover the 7.25 miles distance in 15 minutes. The right of way is private, and was surveyed four years ago by George A. Ricker. The enterprise has no connection with the Buffalo Railway or Traction Company. Capital stock, \$100,000; directors, William B. Cutter, Augustin Smith, George A. Ricker, John H. Baker, Herbert P. Bissell, J. Henry Metcalf, George C. Riley, James Murphy and Frederick M. Turner, all of Buffalo.

**LIBERTY, N. Y.**—The Liberty & Jeffersonville Electric Railroad Company will be organized to build a line between the two towns. Citizens have subscribed \$20,000 in aid of the enterprise. Frank Lober has subscribed for \$34,600 of the 36,000 capital stock, Thomas Loomis, of New York, Charles W. Wilfert, Conrad Metzger and Charles Homer, of Jeffersonville, having taken one share apiece. Right of way has been donated, and poles have been purchased. Rails will be purchased of the O. & W. Railroad. The power house will be located at Youngsville and equipped with a 150-h. p. engine. The construction of the road will be supervised by the Pierce & Miller Engineering Company, of New York.

### Ohio.

**EAST LIVERPOOL, O.**—The East Liverpool Railway Company has been incorporated with \$300,000 capital stock.

**CINCINNATI, O.**—The Cincinnati Consolidated Street Railway Company is considering a new line to Norwood.

**CINCINNATI, O.**—A new franchise was granted May 1, by the county commissioners, to the Cincinnati & Miami Valley Traction Company.

**OBERLIN, O.**—The city council has granted a franchise for the extension of the Cleveland & Elyria Electric Railway. Work is to begin at once.

**HAMILTON, O.**—J. C. Hooven, president of the Cincinnati & Hamilton Electric Railway Company, has applied for right of way over Hamilton streets.

**ST. MARYS, O.**—The Lima & Piqua Electric Street Railroad Company, of St. Marys, has changed its name and location to Lima & Piqua Railroad Company, of Sidney.

**PAINESVILLE, O.**—Charles H. Moody, of Painesville, has been granted a franchise by the Lake county commissioners to build and operate an electric road between Painesville and Fairport.

**ELYRIA, O.**—Lorain County Commissioners have granted the Cleveland & Elyria Electric Road Company a franchise to build their road to Oberlin, eight miles from Elyria. If they are granted a franchise by the Oberlin council the work of construction will begin at once.

**BUCYRUS, O.**—W. E. Haycox, president of the Buckeye Traction Company, on May 1 filed with the county commissioners a bond of \$3,000, binding the company to begin the construction of the Bucyrus & Galion Electric Railway by June 1. It is hoped to have trains running by September 1.

**NEWARK, O.**—The Equitable Trust Company, of Chicago, filed a cross petition in the United States court April 13, in the suit of Reinhart Scheidler vs. the Newark & Granville Electric Railway Company, setting up the fact that they hold mortgages on the property to its full value, and asking for a receiver.

**CLEVELAND, O.**—The Osborne Engineering Company is making a final survey of the proposed electric road from Akron to Cleveland. The line will run through Brighton, Parma, Royalton, West Richfield, Bath, Ghent, Montrose and Fairmont. It is said contracts for construction will be let within six weeks.

**ALLIANCE, O.**—The Stark Electric Railway Company has been incorporated to build and operate a line between Alliance and Waynesburg, via Canton; also a branch between Alliance and Salem. Capital stock, \$10,000; incorporators, J. B. G. Roberts, Clement R. Jones, C. B. Gibson, R. R. Jacob and T. F. Williams. Headquarters will be at Waynesburg.

**DAYTON, O.**—Stockholders of the Dayton, Spring Valley & Wilmington Transit Company, met at Spring Valley and elected the following officers for the ensuing year. President and general manager, J. M. Wilson; secretary, J. H. Racer; treasurer, John R. Barrett; vice-president, Wallace Berryhill; superintendent, F. H. Talbot; directors, F. H. Talbot, J. B. Pence, J. M. Wilson and J. Fremont Stump.

**CLEVELAND, O.**—Stockholders of the Cleveland, Canton & Southern Railroad are figuring upon the substitution of electric for steam power. The cost of the change and the result have been closely determined. At present the company is insolvent, but it is said to be on the eve of reorganization. Their contemplated adoption of electricity is being hastened by the approaching completion of the Cleveland & Chagrin Falls Electric Railway, which expects to make passenger rates that will capture all the Chagrin Falls travel to Cleveland, thus depriving the Canton & Southern, the only steam road reaching Chagrin Falls, of considerable business.

### Oregon.

**SALEM, ORE.**—The Salem & Suburban Railway Company has been incorporated to operate the Salem Motor Railway purchased by F. R. Anson. Capital stock, \$5,000; incorporators, E. P. McCormack, F. R. Anson, F. H. Page and D. S. Tutbill.

**ASTORIA, ORE.**—The Astoria & Suburban Railway Company has been incorporated to build a road from mouth of Walluski river to the head of tide water on John Days river, and from Astoria to the ocean beach, via Warrenton and Flavel. Capital stock, \$30,000; incorporators, J. W. Conn, F. W. Newell and W. A. Sherman.

### Pennsylvania.

**MCKEESPORT, PA.**—The Corry Avenue Street Railway Company has been incorporated to construct 1.5 miles of electric railway. Capital stock, \$10,000.

**CONNELLSVILLE, PA.**—A branch line to Vanderbilt, three miles in length, will be built by the Conneltsville, New Haven & Leisenring Street Railway Company.

**PITTSBURG, PA.**—The West Newton & Northern and the Second Avenue Electric Railway Companies are rival applicants for right of way through West Newton.

**PITTSBURG, PA.**—Belleverson has at last granted a franchise to the Second Avenue Traction Company of Pittsburg for a line connecting with Charleroi, Monongahela and Belleverson.

**UNIONTOWN, PA.**—The Uniontown Street Railway Company has been thrown into the hands of the sheriff on the suit of William G. Freeman, of Cadiz, O., who holds a claim for \$5,000.

**DOYLESTOWN, PA.**—A six month's extension of time to build has been granted the Bucks County Railway Company. The ordinance of the East Penn Traction Company has passed its second reading.

**PHILADELPHIA, PA.**—The New Philadelphia & Bristol Electric Railway has gone into operation. The completed portion is 7 miles in length. Owing to the opposition of the Pennsylvania Railroad there is a gap in the line at Crocyden.

**COLUMBIA, PA.**—William B. Given, receiver of the Pennsylvania Traction Company, will buy one mile of track material, 4.5 miles of feeder wire, eight cars with 50-h. p. equipment, 300-h. p. engine, two 350-h. p. boilers, and a 260-k. w. generator.

**PITTSBURG, PA.**—The Beechwood Street Railway Company has been incorporated to build 2.5 miles of road in Pittsburgh. Capital stock, \$15,000; incorporators, Peter Shields, Frank McCann, Daniel R. Deely, Charles Donnelly and John F. Steel.

**TITUSVILLE, PA.**—A bill granting a franchise to the Titusville Electric Traction Company, on April 15, was passed second and third readings by the Hydetown council. The company's surveyors have about completed their labors under the direction of Secretary M. B. Dunham.

**PITTSBURG, PA.**—Residents of Squirrel Hill are collecting a bonus of \$50,000 to induce the Consolidated Traction Company to extend its lines to their section. The property owners have obtained a charter for a road which they will turn over to the company together with the bonus.

**MONONGAHELA, PA.**—J. J. Rankin, secretary of the Valley Electric Street Railway Company, writes us: "We expect to be in the market very soon for an entire equipment, and the construction of 18 miles of road. Would like to have addresses of parties in the construction and supply business."

**SOUTH BETHLEHEM, PA.**—President Hugh E. Crilley, of Allentown, reports that the Hellertown town council has finally granted the South Bethlehem & Hellertown Electric Railway Company right of way in that borough. After obtaining right of way between the two places application will be made for a franchise in South Bethlehem.

**PITTSBURG, PA.**—Stockholders of the Troy Hill & Reserve Township Street Railway Company, it is said, will hand over their project to any company that will undertake to build a line into Reserve township. Right of way has been obtained and other preliminary work valued at \$30,000 has been done. It is expected that the North Side Traction Company or the Allegheny & Millvale Company will accept the offer.

**MCDONALD, PA.**—Citizens held an enthusiastic meeting at McDonald recently, in favor of the Carnegie & Cannonsburg Electric Railway. It was agreed to form a company with \$250,000 capital. A committee of three men each from McDonald, Noblestown, Oakdale, Venice and Cannonsburg was appointed to obtain right of way and solicit subscriptions. Edward McDonald, banker, of McDonald, is at the head of the committee.

**TAMAQUA, PA.**—The street railway project, noticed from time to time in the DAILY BULLETIN, has been finally organized at Lehigh as the Lansford & Tamaqua Street Railway Company, with the following directors: President, Frank P. Spiese, of Tamaqua; secretary and treasurer, James McGready, of Summit Hill; superintendent and manager, W. D. Zehner, of Lansford; Daniel Shepp, of Tamaqua, and L. A. Riley, of Philadelphia.

**PITTSBURG, PA.**—President James Callery of the Second Avenue Company announces that the Pleasant Valley line will undergo extensive improvements this summer. Three hundred thousand dollars is to be expended for a new power house to replace the Taggart steel structure and for the relaying of steel girder tracks. The road will also be equipped with new cars. Calhoun Park is to be improved by the adding of new features, and Oak Park, on the line of the West End line, will be beautified.

## Rhode Island.

**WOONSOCKET, R. I.**—President Ray, of the Woonsocket Street Railway has been appointed a committee of one to arrange for the extension of the road.

**PROVIDENCE, R. I.**—The Providence & Taunton Electric Railroad Company will petition the cities of Taunton, Rehoboth, Dighton and Seekonk for right of way.

## South Carolina.

**ORANGEBURG, S. C.**—J. E. Bull writes us that the Orangeburg City Horse Railway is offered for sale.

**CHARLESTON, S. C.**—The Charleston City Railway Company has notified the secretary of state of its intention to increase its capital stock from \$100,000 to \$850,000. The extension of its charter for 50 years will also be petitioned for.

**CHARLESTON, S. C.**—The Summerville Street Railway Company has been incorporated to construct and operate a horse car line in Summerville. Capital stock, \$50,000; incorporators, J. S. Lawrence, of Baltimore, and Philip H. Gadsden, of Charleston.

**GREENVILLE, S. C.**—J. S. Lawrence and others of Charleston, have been granted a 37-year franchise on condition that they build within 12 months four miles of electric railway in Greenville. Work is to begin in about two months. Mr. Lawrence and his friends have just completed an electric road in Charleston.

## Tennessee.

**KNOXVILLE, TENN.**—Bondholders ask the appointment of a receiver for the Johnson City & Carnegie Street Railway Company.

## Texas.

**SHERMAN, TEX.**—Operation of the College Hills & Park Lines electric, has permanently ceased.

**GALVESTON, TEX.**—The Galveston & Houston Electric Railway Company has been incorporated with \$150,000 capital stock.

**SHERMAN, TEX.**—Extensions to Fairview and west are proposed by the street railway company. The company also proposes to go into the business of supplying power, light and heat.

## Virginia.

**PORTSMOUTH, VA.**—The Portsmouth Street Railway Company has contracted for the electrical equipment of 6 miles of its line. Later extensions will be made to Gilmerston and the Norfolk & Western Railroad. The North Portsmouth Electric Railway Company has applied for right of way over certain streets, having deposited \$1,000 to guarantee performance of contract.

**NORFOLK, VA.**—The application of the Port Norfolk Railway for the use of additional streets in order to reach South Portsmouth has been granted by the city council. The company agrees to pay \$20 per year for the use of each street, \$40 tax for each car, lay 7-in. girder rail on paved streets and put up a \$5,000 indemnity bond. Work is to begin in 30 days and be completed in 6 months.

## West Virginia.

**WHEELING, W. VA.**—The Suburban Electric Railway Company has been incorporated with \$500 capital by N. E. Whittaker, George W. Woods and Charles M. Fissel, of Wheeling.

## Wisconsin.

**OSHKOSH, WIS.**—A mortgage for \$200,000 has been given by the new Citizens' Traction Company to the Security & Trust Company, of New York.

**MILWAUKEE, WIS.**—C. R. Gether asks the village board of Whitefish Bay to grant a franchise for a street railway to connect with the northern terminus of the dummy line.

**MADISON, WIS.**—The Wisconsin Inland Lakes & Chicago Electric Railway Company has been incorporated in Wisconsin. This company has been undergoing promotion for a year past. Capital stock, \$5,000,000; directors, Bayard Taylor, William J. Marks, Jesse B. Barton and George E. C. Johnson, all of Chicago, and F. K. Bryant, of Princeton, Ill.

**WAUKESHA, WIS.**—Stockholders of the North Greenfield & Waukesha Electric Railway met in Milwaukee recently to decide upon arrangements for beginning construction. While the exact route in Waukesha has not been fixed, the company will in about two weeks apply to the Waukesha council for a franchise. S. I. Henderson, of North Greenfield is the chief promoter.

The Bradford Belting Company being incorporated, the death of Mr. Bradford will not interfere with the business continuing as heretofore.

Frank J. Sprague of New York has been awarded the contract to furnish controllers for the cars of the South Side Elevated Railroad Company, Chicago.

Erbeck Brothers of Homestead, Pa., have received the contract to construct 4 miles of electric road for the Brad-dock & Homestead Street Railway Company.

Abendroth & Root, of New York, manufacturers of the well known Root improved water tube boiler, have removed their western office from 1422 to 1539 Monadnock building, Chicago.

Hildreth & Co., of New York, have received the contract to build the extension of the Hartford, Manchester & Rockville Tramway to Rockville, Conn., including a bridge at Talcottville.

Dixon's traction belt dressing is recommended by electrical experts as a means of preventing the belt from slipping and thus generating electricity with a consequent loss of power and danger of fire.

The New Haven Car Register Company, New Haven, Conn., is in receipt of a remarkably large number of orders for its 1897 model register, which contains a number of valuable improvements.

Harold P. Brown's elastic copper amalgam rail bond has been adopted by the Hamilton Street Railway Company, of Hamilton, Ont., where it is proving a decided success. It is used in streets paved with asphalt.

The Griffin Wheel Company, of Chicago, reports a very busy state of affairs in its street car department. The company's new foundries at Tacoma, Wash., are now in full running order and turning out street car wheels.

The Edward P. Allis Company, Milwaukee, is building a 1,200-h. p. cross compound condensing engine for the Citizens road, Memphis, and another of the same size and type for the New York & Staten Island Electric Company.

A. O. Schoonmaker, of New York and Chicago, has gotten out some new mica segments for G. E. 800 motors. These segments have greater breath, giving greater wearing capacity. They are the Billings & Spencer type of form 6.

Garton-Daniels Electric Company, Keokuk, Ia., reports total sales for March as far in excess of the same month last year, and that orders are coming in even beyond its expectations. The improved arresters are making fine records.

The Brownell Car Company, of St. Louis, Mo., is building three convertible cars for the Janesville Street Railway Company, Janesville, Wis. A portion of the equipment required for the new power plant will be furnished by the General Electric Company.

The Partridge Carbon Company, of Sandusky, O., is running its factory to its full capacity to meet the demand for brushes for motors and generators. Foreign trade is being developed by this company with promise of its attaining considerable proportions.

The New York Electrical Works, 161 Washington street, New York, manufacturers of trolley fittings have issued an illustrated catalog showing different types of section insulators, crossings, suspensions, span wire fittings, strain insulators, ears, splicers, etc., made by them.

The Citizens Traction Company of Oshkosh, Wis., has awarded the contract for the construction of its new electric road to the Electrical Installation Company of Chicago. The contract for the special work has been given to the Falk Manufacturing Company of Milwaukee.

A big contract was recently captured by the American Electrical Works, of Providence R. I. It will furnish \$350,000 worth of electric railway feeders and other supplies to the Consolidated Street Railway Company, of Cincinnati, O., to be used in converting the cable lines into electric roads.

The American Electric Traction Company has been incorporated under the laws of New Jersey, with headquarters in New York. The company will acquire control of and manufacture the John McCleod electric railway patents. Of the \$500,000 authorized capital \$1,000 has been paid in.

W. R. Brixey, of New York and Chicago, has opened an office at suite 1507 Marquette building, Chicago, under the management of J. B. Wallace, where he is prepared to meet his old trade. A full line of Day's Kerite, feeder wire, etc., will also be carried in stock at the storeroom, 141 South Clinton street.

The Forest City Electric Works, at Cleveland, were damaged by fire on the night of April 12. Fortunately the machines received no injury, the destruction being confined to the belting, pulleys, etc. The debris has been removed, and the company is filling promptly all orders for roll-drop commutator bars.

Eugene Munsell & Co., of New York and Chicago, report considerable improvement in their business. Their western trade especially is rapidly increasing, which would indicate that their customers appreciate the establishment of a western branch carrying a full stock of Indian amber mica for insulation purposes.

The Ball Engine Company, Erie, Pa., has lately installed engines for the electric lighting plants of the Wauwatosa County Insane Asylum, Wisconsin, and the Chicago Public Library. This latter plant comprises 5 direct connected units aggregating 900 h. p.; the Chicago Edison Company furnished the dynamos.

The Central Electric Company, of Chicago, has designed new material for overhead construction which is well worthy examination. The company is preparing to place on the market at a very low price a full line of high grade railway motor bearings. Trolley wheels are now sold in large quantities to railway companies which use no other wheel.

The Buckeye Engine Company, of Salem, O., has opened an office in Manufacturers Record building, Baltimore, which will be under the management of J. W. Taylor, who is well known in the machinery line in the east. The territory, covered by this agency will be Maryland, Virginia, the Carolinas, East Tennessee, Georgia and Florida.

The Forest City Electric Company of Cleveland, O., has issued a very neat little pamphlet on "Rail Bonding" which is profusely illustrated. The evolution of bonding is briefly described and some pointers on the methods to be used are given. The merits of the flexible, protected rail bonds made by this company are set forth in a convincing manner.

The Swarts Metal Refining Company has moved to No. 20 North Desplaines street, corner of Eagle, where it will have greatly improved facilities. This company, a few years ago almost unknown, has built up a successful business both at home and abroad by fair dealing with its customers, and fortunate purchases which make low quotations possible.

Edward Smith & Co., 45 Broadway, New York, manufacturers of preservative compounds for various building materials, have recently reprinted a paper on the subject of "Preservative Coatings for Iron Work," read before the New England Railroad Club by A. H. Sabin. The pamphlet will prove very interesting to those who have to deal with the problems discussed.

The extensive engine works of McIntosh, Seymour & Co., at Auburn, N. Y., are very busy and business has increased to such an extent as to necessitate an addition to the already large plant. The new building under construction is 80 x 160 ft. and is being pushed to completion as rapidly as possible. In addition to orders already on the books a very gratifying amount of new work is in prospect.

The Providence fender has been adopted by the city council of Syracuse, N. Y., for use on the cars of the Rapid Transit Company. A special committee of the council traveled extensively to inspect the life-saving appliances employed in different cities. It was only after viewing 40 other fenders that the committee selected the "Providence," made by the Consolidated Car Fender Company of Providence, R. I.

The Standard Underground Cable Company, of Pittsburgh, Pa., has issued a handbook giving full information and complete price lists of materials used in underground cable construction. The book, which was compiled by Joseph W. Marsh, is well illustrated, with diagrams as well as rules for making all kinds of cable connections. For the convenience of customers the telegraphic code of the Standard Company is added.

The Milwaukee Electric Railway & Light Company advises us that it has just closed a contract with the Park Manufacturing Company for welding 7,000 joints, and that

the number will probably be increased to 10,000 or 12,000. A large number of these joints will be used on new track to be laid in unpaved streets, as the results on the Oakland avenue line proved so satisfactory. The greater part, however, are for raising old joints.

The Columbia Incandescent Lamp Company, St. Louis, makes a specialty of lamps for street railway service and furnishes for headlights and decorative car lighting round bulb lamps which are carefully made to consume the same amount of energy as the ordinary lamps used in the car, and so may be burned in series with them. These lamps may be had with frosted, or superficially colored globes, or with genuine colored ruby or opal glass.

The general sales office of the Walker Company, formerly at 253 Broadway, is now located in the new building on the northwest corner of Wall & Nassau streets, New York city. The Walker Company has taken an entire floor in this new building. Increased business has necessitated these large and more centrally located quarters. The Walker Company is to be congratulated for its enterprise which is indicated by this change of location.

Alfred G. Hathaway, of Cleveland, O., is enjoying a good demand for the Murrey brake in his own city, and its fame is spreading. Among recent orders he has equipped all the cars of the new Cleveland & Chagrin Falls Electric Railway. Soon he will place his brake on the Cleveland & Elyria Electric Railway. A contract has just been closed with the Detroit & St. Clair River Electric Railway Company for 14 sets of brakes. Companies operating double truck cars are especially well pleased with the Murrey brake.

Two large orders received within the past week, one from Japan and the other from Mexico, for Walker cars, evidences the fact that the fame of this car as a support for trolley wires has extended beyond the bounds of the United States, where its reputation is already widespread. The Ohio Brass Company, sole manufacturer of this article, has recently brought out several modified forms of the car used on straight line suspension which are adapted for feeder, strain and splicing purposes, so that the trolley wire can be equipped with Walker cars throughout. These several new designs will be illustrated in the new supplemental catalog soon to be issued.

Warren Hill & Co. call the attention of the trade to their improved ticket punches, which have been on the market for four years and give the best of satisfaction. These were designed upon a new principle with the idea of securing a punch adapted to all tickets in use and at the same time not imitate other punches. The die is carefully protected by a stripper and the steel joint piece is of large size and accurately fitted, so that the die can not get dulled. The  $\frac{5}{16}$  punch has a reach of  $1\frac{1}{8}$  in., and the  $\frac{3}{16}$  punch has a reach as great as  $2\frac{1}{2}$  in.; any die is made to order and over 300 are kept in stock. Communications should be addressed to the manager, John B. Holaday, 171 Pearl street, Hartford, Conn.

The Northern Pacific railroad annual, "Wonderland," has been issued by Charles S. Fee, general passenger agent, and is in every way up to the high standard of previous years. Beautifully illustrated with ever interesting views of the

mountain lands of the far West, and a text full of historic and instructive explanation, the brochure will be a welcome addition to the library table everywhere. The front cover displays a view of the great falls of the Yellowstone, in colors. A copy will be sent to any address on receipt of 6 cents in stamps, which is the amount of postage required to mail it. Many a guide book sold for one dollar is less interesting and attractive. Requests may be sent to C. S. Fee, G. P. Agent, St. Paul.

The American Engine Company, of Bound Brook, N. J., has just begun the shipment of its new direct-connected generating plants, in which the American-Ball engine is combined with the new line of 6-pole generators. The company is now installing a 75-k. w. plant at No. 7 East 17th street, New York, in the building of Deitch Brothers, and a 35-k. w. plant in the building of the Evening Wisconsin, of Milwaukee. In addition to this it has orders from the Philadelphia Inquirer for a 100-k. w. plant; the Buffalo Evening News, a 35-k. w. plant; the Phelps Publishing Company, of Springfield, Mass., two 35-k. w. plants; the New York Tribune, a 75-k. w. plant, and the World's Dispensary Medical Association, of Buffalo, a 25-k. w. plant.

The engineering staff of the Standard Air-Brake Company has been increased by the addition of Edward H. Dewson, Jr. with whom General Manager Wessels lately closed a contract for a term of years. Mr. Dewson brings to the company a ripe experience. He entered upon his new field on April 26th. Mr. Dewson has been long and favorably known in connection with his work while with the General Electric Company in its engineering department, and in connection with locomotive practice and the superintendency of one of the western lines. He has for some time filled the position of master mechanic of the Pratt & Letchworth Company, Buffalo, and is thoroughly posted on the mechanical arts and will find full scope for his ability in his new field.

At the annual meeting of the stockholders of the Standard Air-Brake Company, New York, the following directors were elected: Henry Seligman, Edward J. Wessels, Albert Strauss, Leopold Wallach, Theodore Seligman and D. F. Meyer. The company has closed contracts with the Dighton, Somerset & Swansea Street Railway Company of Taunton, Mass., the Commonwealth Avenue Street Railway Company of Boston, and through its foreign agents, for air-brakes for the Continent. Advices have been received as to the successful opening of an extension at Sydney, N. S. W., on which heavier motor cars equipped with the Standard brakes are used. The company is also supplying a complete working outfit to the Pennsylvania State College for its experimental line.

The Mica Insulator Company, 218 Water street, New York, has lately added to its already extensive plant at Schenectady, some new machines of special construction which mill micaite plates to very exact thickness. The special plates for commutator segments are gaining a stronger hold than ever. They are guaranteed not to ooze cement whatever temperature a commutator may reach in practice. Considering the mechanical difficulties contended with, to reach the present high state of perfection, high compliments are due the company. The improvement in business reported

is very encouraging, because the mica business is one of the best barometers, and without a doubt this company has during the past year of depression placed itself in a position to reap the full benefits of the business improvement which is just dawning.

As a result of recent experiments with compressed air motors on the Eckington & Soldiers Home Railroad at Washington, D. C., it has been decided to equip the road with these cars. Fifteen of them will be placed on the line to Brookland as soon as they can be constructed. Receiver Schoepf says the tests have been entirely satisfactory. The car now in operation has carried eighty-seven passengers one way and thirty the other, making 107 on the round trip, with 25 per cent of reserve force in the reservoirs, or 500 pounds out of the 2,000 pounds with which the reservoirs were charged with starting. "The car has already run over 1,000 miles on the Eckington tracks," said Mr. Schoepf, in conclusion, "and has hauled over 4,500 passengers, and not yet has a dollar been spent on it for maintenance or renewals. I consider this a fine showing."

The Vilter Manufacturing Company of Milwaukee, Wis., has recently closed contracts for supplying refrigerating machinery and Corliss engines as follows: Maumee Brewing Company, Toledo, O., one 25-ton refrigerating machine; Indiana Brewing Association, Marion, Ind., one double 100-ton refrigerating plant; Theodore Hamm Brewing Company, St. Paul, one 100-ton machine; Centennial Brewing Company, Butte, Mont., one 35-ton plant; Estrell a de Oro, City of Mexico, one 10-ton plant and brewery outfit; Schwartzschild & Sulzberger Company, Kansas City, one 200-ton machine; Ouemmi & Siebert Refrigerating Machine Company, St. Louis, one 50-ton and one 5-ton machine; Christ, Abtau, Germantown, Pa., one 5-ton machine; H. Piper, Chicago, one 2-ton machine; A. Trostel & Sons, Milwaukee, one 2 1/2 x 42-in. engine; William Larsen & Company, Green Bay, Wis., one 12 x 30-in. engine.

Boody & Wheeler of Philadelphia have been awarded the contract to construct 25 miles of electric railway between Trenton, N. J., and Doylestown, Pa., for the East Penn Traction Company. The line will pass through Morrisville, Yardley, Newtown, Writestown, Pineville, Buckingham and Mechanics Valley. The contract provides for a stone-ballasted roadbed, equipped with the latest improved cars and motors and power-house machinery, including boilers, engines, generators, ample car-barns, and everything complete to operate the road. Double-truck, 8-wheel 34-ft. cars with two 30-h. p. motors to each car, will be used. Work will begin immediately at Morrisville, opposite Trenton, and at Doylestown and be carried on in both directions. The road will be along the side of the public highway and there are no physical difficulties to be encountered. The grades are light and there are no important bridges except at Morrisville. It is expected to have the road built and in operation between Morrisville and Yardley within a few months, and to Doylestown inside of one year.

The consolidation of the Oakland, California, lines which was well under way a few months ago, at which time it looked as though an English syndicate would purchase them all, has fallen through and the deal is entirely off.

# Removal Notice.

We beg to announce that we have removed from the Betz Building, to 10 So. Tenth Street, Philadelphia, where we have established a large and commodious warehouse. We now have in stock a full line of material manufactured by the well-known Companies we represent, together with a Full and Complete Stock of Electric Railway Material and Supplies for immediate shipment. Our facilities for handling our rapidly increasing business are now strictly first-class.

MAYER & ENGLUND,

10 South Tenth St.

Philadelphia, Pa.

## THE NEW STEEL MOTOR.

Street railway motors, entirely enclosed and constructed of steel, were first designed and built by the Steel Motor Company, of Johnstown, Pa. On account of the strength, lightness and durability of these motors they met with much favor. This company has lately constructed and tested a new motor, known as No. 22, which combines the best features desired in a railway motor. As shown in the cut, the motor is cylindrical in form and enclosed in a water and dust proof case. The whole construction is of steel, and is so compact in design that it is claimed to be lighter for a given output than any heretofore produced.

There are four poles, each having an individual field coil which is interchangeable with the others. They are wound on special forms and are insulated with special material of such a character that deterioration in ordinary service is prevented. The poles are of laminated wrought iron with serrated face, this for giving great mechanical strength and a high efficiency. The illustration shows the lower half of the field frame dropped down with the armature retained in it. However, the armature may be kept in the upper half if desired, thus permitting easy access to all parts.

The armature is of the ordinary drum type, and is very simple in its construction. It contains a smaller number of slots than any armature manufactured, and into which are inserted machine-wound coils which are thoroughly insulated with special material and are waterproof. The armature is well ventilated. The design is such that a very short time

NEW STEEL MOTOR.

is required to rewind the armature, and this feature will be especially appreciated when quick repairs are required. The armature core is hollowed to prevent sparking at excessive loads and to provide means for a rapid circulation of air.

The commutator is of the undercut bar type, and is simplified by the number of bars used. The armature leads and commutator bars are tinned for electrical connection and the use of solder is avoided. The brush holders are identical and interchangeable, and are independent of each other and their position on the commutator is fixed. No adjustment is necessary, and they may be removed or replaced without opening the motor. The motors are arranged for nose, yoke and side bar suspension. The armature bearings are interchangeable. They project outside the motor frame, providing a ready means for slinging the armature. Oil wipers are provided which prevent grease from getting into the motor.

These motors are made in sizes from 25 h. p. up to 100 h. p., and are suitable for urban, interurban and elevated railway service. The parts are all interchangeable and as few and simple as can be designed.

### WHERE WILL YOU SPEND THE SUMMER?
