SUPPLEMENT

TO THE THIRD EDITION OF THE

ENCYCLOPÆDIA BRITANNICA,

OR, A

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN TWO VOLUMES.

Illustrated with Fifty Copperplates.

By GEORGE GLEIG, LL. D. F. R. S. EDIN.

NON IGNORO, QUÆ BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUÆ NON OPTIMA, ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.—*CICERO.*

VOL. II.

Edinburgh:
PRINTED FOR THOMSON BONAR, PARLIAMENT-SQUARE;
BY *JOHN BROWN*, ANCHOR CLOSE, EDINBURGH.

1801.

SUPPLEMENT

TO THE

ENCYCLOPÆDIA BRITANNICA.

INCREMENT, is the ſmall increaſe of a variable quantity. Newton, in his Treatiſe on Fluxions, calls theſe by the name *Moments;* and obſerves, that they are proportional to the velocity or rate of increaſe of the flowing or variable quantities in an indefinitely ſmall time. He denotes them by ſubjoining a cypher o to the flowing quantity whoſe moment or increment it is; thus, xo the moment of x. In the doctrine of Increments, by Dr Brooke Taylor and Mr Emerſon, they are denoted by points below the variable quantities; as $\underset{\cdot}{x}$. Some have alſo denoted them by accents underneath the letter, as $\underset{'}{x}$; but it is now more uſual to expreſs them by accents over the ſame letter; as $\overset{'}{x}$.

METHOD OF INCREMENTS, a branch of Analytics, in which a calculus is founded on the properties of the ſucceſſive values of variable quantities, and their differences or increments.

The inventor of the method of increments was the learned Dr Taylor, who, in the year 1715, publiſhed a treatiſe upon it; and afterwards gave ſome farther account and explication of it in the Philoſ. Tranſ. as applied to the finding of the ſums of ſeries. And another ingenious and eaſy treatiſe on the ſame, was publiſhed by Mr Emerſon, in the year 1763. The method is nearly allied to Newton's Doctrine of Fluxions, and ariſes out of it. Alſo the Differential method of Mr Stirling, which he applies to the ſummation and interpolation of ſeries, is of the ſame nature as the method of increments, but not ſo general and extenſive.

INDETERMINATE PROBLEM. See ALGEBRA, Part I. Chap. VI. *Encycl.*

Diophantus was the firſt writer on indeterminate problems, which, after the publication of his work in 1621 by Bachet, employed much of the time of the moſt celebrated mathematicians in Europe. Afterwards ſuch problems were neglected as uſeleſs, till the public attention was again drawn to them by Euler and la Grange. The example of ſuch men was followed by Mr John Leſlie, a very eminent and ſelf-taught mathematician; who, in the ſecond vol. of the Tranſactions of the Royal Society of Edinburgh, has publiſhed an ingenious paper on indeterminate problems, reſolving them by a new and general principle. "The doctrine of indeterminate equations (ſays Mr Leſlie) has been ſeldom treated in a form equally ſyſtematic with the other parts of algebra. The ſolutions commonly given are devoid of uniformity, and often require a variety of aſſumptions. The object of this paper is to reſolve the complicated expreſſions which we obtain in the ſolution of indeterminate problems, into ſimple equations, and to do ſo, without framing a number of aſſumptions, by help of a ſingle principle, which, though extremely ſimple, admits of a very extenſive application.

"Let $A \times B$ be any compound quantity equal to another, $C \times D$, and let m be any rational number aſſumed at pleaſure; it is manifeſt that, taking equimultiples, $A \times m\,B = C \times m\,D$. If, therefore, we ſuppoſe that $A = mD$, it muſt follow that $mB = C$, or $B = \frac{C}{m}$. Thus two equations of a lower dimenſion are obtained. If theſe be capable of farther decompoſition, we may aſſume the multiples n and p, and form four equations ſtill more ſimple. By the repeated application of this principle, an higher equation, admitting of diviſors, will be reſolved into thoſe of the firſt order, the number of which will be one greater than that of the multiples aſſumed."

For example, reſuming the problem at firſt given, viz. to find two rational numbers, the difference of the ſquares of which ſhall be a given number. Let the given number be the product of a and b; then by hypotheſis, $x^2 - y^2 = ab$; but theſe compound quantities admit of an eaſy reſolution, for $\overline{x+y} \times \overline{x-y} = a \times b$. If, therefore, we ſuppoſe $x + y = ma$, we ſhall obtain $x - y = \frac{b}{m}$; where m is arbitrary, and if rational, x and y muſt alſo be rational. Hence the reſolution of theſe two equations gives the values of x and y, the numbers ſought, in terms of m; viz. $x = \frac{m^2a + b}{2m}$, and $y = \frac{m^2a - b}{2m}$.

INDUCTION, in logic, is that proceſs of the underſtanding by which, from a number of *particular* truths perceived by ſimple apprehenſion, and diligently compared together, we infer another truth which is always *general* and ſometimes *univerſal*. It is perhaps needleſs to obſerve, that in the proceſs of induction the truths to be compared muſt be of the ſame kind, or relate to objects having a ſimilar nature; for the mereſt tyro in ſcience knows that phyſical truths cannot be compared with moral truths, nor the truths of pure mathematics with either.

That the method of induction is a juſt logic, has been ſufficiently evinced elſewhere (ſee Logic, Part III. chap. V. and Philosophy, nº 73—78. *Encycl.*), and is now indeed generally admitted. It is even admitted by Britiſh philoſophers to be the only method of reaſoning by which any progreſs can be made in the phyſical ſciences; for the laws of Nature can be diſcovered only by accurate experiments, and by carefully noting the agreements and the differences, however minute, which are thus found among the phenomena apparently ſimilar. It is not, however, commonly ſaid that *induction* is the method of reaſoning employed by the mathematicians; and the writer of this article long thought, with others, that in pure geometry the reaſoning is ſtrictly *ſyllogiſtical*. Mature reflection, however, has led him to doubt, with Doctor Reid [*], the truth of the generally received opinion, to doubt even whether by categorical ſyllogiſms any thing whatever can be proved.

To the idolaters of Ariſtotle we are perfectly aware that this will appear an extravagant paradox; but to the votaries of truth, we do not deſpair of making it very evident, that for ſuch doubts there is ſome foundation.

We are led into this diſquiſition to counteract, in ſome degree, what we think the pernicious tendency of the philoſophy of Kant, which attempts have been lately made to introduce into this country. Of this philoſophy we ſhall endeavour to give ſomething like a diſtinct view in the proper place. It is ſufficient to obſerve here, that it reſts upon the hypotheſis, that "we are in poſſeſſion of certain notions *à priori*, which are abſolutely *independent of all experience*, although the *objects of experience* correſpond with them; and which are diſtinguiſhed by *neceſſity* and ſtrict *univerſality*." Theſe innate and univerſal notions, Kant conſiders as a ſet of *categories*, from which is to be deduced all ſuch knowledge as deſerves the name of ſcience; and he talks, of courſe, or at leaſt his Engliſh tranſlators repreſent him talking, with great contempt, of inductive reaſoning, and ſubſtituting ſyllogiſtic demonſtration in its ſtead.

As his categories are not familiar to our readers, we ſhall, in this place, examine ſyllogiſms connected with the categories of Ariſtotle, which are at leaſt more intelligible than thoſe of Kant, and which, being likewiſe general notions, muſt, in argument, be managed in the ſame way. Now the fundamental axiom upon which every categorical ſyllogiſm reſts, is the well known propoſition, which affirms, that "whatever may be predicated of a whole *genus*, may be predicated of every *ſpecies* and of every *individual* comprehended under that genus." This is indeed an undoubted truth; but it cannot conſtitute a foundation for reaſoning from the *genus* to the *ſpecies* or the *individual*; becauſe we cannot poſſibly know what can be predicated of the *genus* till we know what can be predicated of all the *individuals* ranged under it. Indeed it is only by aſcertaining, through the medium of induction, what can be predicated, and what not, of a number of individuals, that we come to form ſuch notions as thoſe of *genera* and *ſpecies*; and therefore, in a ſyllogiſm ſtrictly categorical, the propoſitions, which conſtitute the *premiſes*, and are taken for granted, are thoſe alone which are capable of proof; whilſt the concluſion, which the logician pretends to demonſtrate, muſt be evident to intuition or experience, otherwiſe the premiſes could not be known to be true. The analyſis of a few ſyllogiſms will make this apparent to every reader.

Dr Wallis, who, to an intimate acquaintance with the Ariſtotelian logic, added much mathematical and phyſical knowledge, gives the following ſyllogiſm as a perfect example of this mode of reaſoning in the firſt figure, to which it is known that all the other figures may be reduced:—

Omne animal eſt *ſenſu præditum.*
Socrates eſt *animal.* Ergo
Socrates eſt *ſenſu præditus.*

Here the propoſition to be demonſtrated is, that Socrates is endowed with ſenſe; and the propoſitions aſſumed as ſelf-evident truths, upon which the demonſtration is to be built, are, that "every animal is endowed with ſenſe;" and that "Socrates is an animal." But how comes the demonſtrator to know that "every animal is endowed with ſenſe?" To this queſtion we are not aware of any anſwer which can be given, except this, that mankind have agreed to call every being, which they perceive to be endowed with ſenſe, an *animal*. Let this, then, be ſuppoſed the true anſwer: the next queſtion to be put to the demonſtrator is, How he comes to know that *Socrates* is an *animal?* If we have anſwered the former queſtion properly, or, in other words, if it be eſſential to this genus of beings to be endowed with ſenſe, it is obvious that he can know that Socrates is an *animal* only by perceiving him to be *endowed with ſenſe;* and therefore, in this ſyllogiſm, the propoſition to be proved is the very firſt of the three of which the truth is perceived; and it is perceived intuitively, and not inferred from others by a proceſs of reaſoning.

Though there are ten categories and five predicables, there are but two kinds of categorical propoſitions, viz Thoſe in which the property or accident is predicated of the ſubſtance to which it belongs, and thoſe in which the *genus* is predicated of the *ſpecies* or *individual*. Of the former kind is the propoſition pretended to be proved by the ſyllogiſm which we have conſidered; of the latter, is that which is proved by the following:

Quicquid ſenſu præditum, eſt animal.
Socrates eſt ſenſu præditus. Ergo
Socrates eſt animal.

That this is a categorical ſyllogiſm, legitimate in mode and figure, will be denied by no man who is not an abſolute ſtranger to the very firſt principles of the Ariſtotelian logic; but it requires little attention indeed to perceive that it proves nothing. The impoſition of names is a thing ſo perfectly arbitrary, that the being, or claſs of beings, which in Latin and Engliſh is called *animal*, is with equal propriety in Greek called ζωον, and in Hebrew בפש. To a native of Greece, therefore, and to an ancient Hebrew, the major propoſition of this ſyllogiſm would have been wholly unintelligible; but had either of thoſe perſons been told by a man of known veracity, and acquainted with the Latin tongue, that every thing endowed with ſenſe was, by the Romans, called *animal*, he would then have underſtood the propoſition, admitted its truth without heſitation, and have

---

[*] Appendix to Vol. III of *Sketches of the Hiſtory of Man.*

henceforth known that Socrates and Moſes, and every thing elſe which he perceived to be endowed with ſenſe, would at Rome be called *animal*. This knowledge, however, would not have reſted upon demonſtrative reaſoning of any kind, but upon the credibility of his informer, and the intuitive evidence of his own ſenſes.

It will perhaps be ſaid, that the two ſyllogiſms which we have examined are improper examples, becauſe the truth to be proved by the former is ſelf evident, whilſt that which is meant to be eſtabliſhed by the latter is merely verbal, and therefore arbitrary. But the following is liable to neither of theſe objections:

All animals are *mortal.*
Man is *an animal;* therefore
Man is *mortal.*

Here it would be proper to aſk the demonſtrator, upon what grounds he ſo confidently pronounces all animals to be mortal? The propoſition is ſo far from expreſſing a ſelf evident truth, that, previous to the entrance of ſin and death into the world, the firſt man had ſurely no conception of mortality. He acquired the notion, however, by experience, when he ſaw the animals die in ſucceſſion around him; and when he obſerved that no animal with which he was acquainted, not even his own ſon, eſcaped death, he would conclude that all animals, without exception, are mortal. This concluſion, however, could not be built upon ſyllogiſtic reaſoning, nor yet upon intuition, but partly upon experience and partly on analogy. As far as his experience went, the proof, by induction, of the mortality of all animals was complete; but there are many animals in the ocean, and perhaps on the earth, which he never ſaw, and of whoſe mortality therefore he could affirm nothing but from analogy, *i. e.* from concluding, as the conſtitution of the human mind compels us to conclude, that Nature is uniform throughout the univerſe, and that ſimilar cauſes, whether known or unknown, will, in ſimilar circumſtances, produce, at all times, ſimilar effects. It is to be obſerved of this ſyllogiſm, as of the firſt which we have conſidered, that the propoſition, which it pretends to demonſtrate, is one of thoſe truths known by experience, from which, by the proceſs of induction, we infer the major of the premiſes to be true; and that therefore the reaſoning, if reaſoning it can be called, runs in a circle.

Yet by a concatenation of ſyllogiſms have logicians pretended that a long ſeries of important truths may be diſcovered and demonſtrated; and even Wallis himſelf ſeems to think, that this is the inſtrument by which the mathematicians have deduced, from a few poſtulates, accurate definitions, and undeniable axioms, all the truths of their demonſtrative ſcience. Let us try the truth of this opinion by analyſing ſome of Euclid's demonſtrations.

In the ſhort article PRINCIPLE (*Encycl.*), it has been ſhewn, that all our *firſt* truths are *particular*, and that it is by applying to them the rules of induction that we form general truths or axioms—even the axioms of pure geometry. As this ſcience treats not of real external things, but merely of *ideas* or *conceptions*, the creatures of our minds, it is obvious, that its definitions may be perfectly accurate, the induction by which its axioms are formed complete, and therefore the axioms themſelves *univerſal* propoſitions. The uſe of theſe axioms is merely to ſhorten the different proceſſes of geometrical reaſoning, and not, as has ſometimes been abſurdly ſuppoſed, to be made the *parents* or *cauſes* of *particular* truths. No truth, whether general or particular, can, in any ſenſe of the word, be the cauſe of another truth. If it were not true that all individual figures, of whatever form, comprehending a portion of ſpace equal to a portion comprehended by any other individual figure, whether of the ſame form with ſome of them, or of a form different from them all, are equal to one another, it would not be true that "things in *general*, which are equal to the ſame thing, or that magnitudes which coincide, or exactly fill the ſame ſpace," are reſpectively equal to one another; and therefore the firſt and eight of Euclid's axioms would be falſe. So far are theſe axioms, or general truths, from being the parents of particular truths, that, as conceived by us, they may, with greater propriety, be termed their *offſpring*. They are indeed nothing more than general expreſſions, comprehending all particular truths of the ſame kind. When a mathematical propoſition therefore is enounced, if the terms, of which it is compoſed, or the figures of which a certain relation is predicated, can be brought together and immediately compared, no demonſtration is neceſſary to point out its truth or falſehood. It is indeed intuitively perceived to be either comprehended under, or contrary to ſome known *axiom* of the ſcience; but it has the evidence of truth or falſehood in itſelf, and not in *conſequence* of that axiom. When the figures or ſymbols cannot be immediately compared together, it is then, and only then, that recourſe is had to demonſtration; which proceeds, not in a ſeries of ſyllogiſms, but by a proceſs of ideal menſuration or induction. A figure or ſymbol is conceived, which may be compared with each of the principal figures or ſymbols, or, if that cannot be, with one of them, and then another, which may be compared with it, till through a ſeries of well known intermediate relations, a compariſon is made between the terms of the original propoſition, of which the truth or falſehood is then perceived.

Thus in the 47th propoſition of the firſt book of Euclid's Elements, the author propoſes to demonſtrate the equality between the ſquare of the hypothenuſe of a right angled triangle, and the ſum of the ſquares deſcribed on the other two ſides; but he does not proceed in the way of categorical ſyllogiſms, by raiſing his demonſtration on ſome univerſal truth relating to the *genus* of *ſquares*. On the contrary, he proceeds to *meaſure* the three ſquares of which he has affirmed a certain relation; but as they cannot be immediately compared together, he directs the largeſt of them to be divided into two parallelograms, according to a rule which he had formerly aſcertained to be juſt; and as theſe parallelograms can, as little as the ſquare of which they are the conſtituent parts, be compared with the ſquares of the other two ſides of the triangle, he thinks of ſome intermediate figure which may be applied as a common meaſure to the ſquares and the parallelograms. Accordingly, having before found that a parallelogram, or ſquare, is exactly double of a triangle ſtanding on the ſame baſe and between the ſame parallels with it, he conſtructs triangles upon the ſame baſe, and between the ſame parallels with his parallelograms, and the ſquares of the ſides containing the right angle of the original triangle; and finding, by a proceſs formerly ſhewn to be juſt, that the triangles on the baſes of the parallelograms are preciſely equal to the triangles on the baſes of the ſquares, he perceives at once that the two parallelograms, of which the largeſt ſquare is compoſed, muſt be equal to the ſum of the two leſſer ſquares; and the truth of the propoſition is demonſtrated.

In the courſe of this demonſtration, there is not ſo much as one truth *inferred* from another by *ſyllogiſm*, but all are perceived in ſucceſſion by a ſeries of ſimple apprehenſions. Euclid, indeed, after finding the triangle conſtructed on the baſe of one of the parallelograms to be equal to the triangle conſtructed on the baſe of one of the ſquares, introduces an *axiom*, and ſays, "but the doubles of equals are equal to one another; *therefore* the parallelogram is equal to the ſquare." But if from this mode of expreſſion any man conceive the axiom or univerſal truth to be the *cauſe* of the truth more particular, or ſuppoſe that the *latter* could not be apprehended without a *previous* knowledge of the former, he is a ſtranger to the nature of evidence, and to the proceſs of *generalization*, by which axioms are formed.

If we examine the problems of this ancient geometrician, we ſhall find that the truth of them is proved by the very ſame means which he makes uſe of to point out the truth of his theorems. Thus, the firſt problem of his immortal work is, "to deſcribe an equilateral triangle on a given finite ſtraight line;" and not only is this to be done, but the method by which it is done muſt be ſuch as can be ſhewn to be incontrovertibly juſt. The ſides of a triangle, however, cannot be applied to each other ſo as to be immediately compared; for they are conceived to be immoveable among themſelves. A common meaſure, therefore, or ſomething equivalent to a common meaſure, muſt be found, by which the triangle may be conſtructed, and the equality of its three ſides afterwards evinced; and this equivalent Euclid finds in the *circle*.

By contemplating the properties of the circle, it was eaſy to perceive that all its *radii* muſt be equal to one another. He therefore directs two circles to be deſcribed from the oppoſite extremities of the given finite ſtraight line, ſo as that it may be the radius of each of them; and from the point in which the circles interſect one another, he orders lines to be drawn to the extreme points of the given line, affirming that theſe three lines conſtitute an equilateral triangle. To convince his reader of the truth of this affirmation, he has only to put him in mind, that from the properties of the circle, the lines which he has drawn muſt be each equal to the given line, and of courſe all the three equal to one another; and this mutual equality is perceived by ſimple apprehenſion, and not inferred by ſyllogiſtic reaſoning. Euclid, indeed, by introducing into the demonſtration his firſt axiom, gives to it the form of a ſyllogiſm: but that ſyllogiſm proves nothing; for if the equality of the three ſides of the triangle were not intuitively perceived in their poſition and the properties of the circle, the firſt axiom would itſelf be a falſehood. So true it is that categorical ſyllogiſms have no place in geometrical reaſoning; which is as ſtrictly experimental and inductive as the reaſoning employed in the various branches of phyſics.

But if this be ſo, how come the truths of pure geometry to be neceſſary, ſo that the contrary of any one of them is clearly perceived to be impoſſible; whilſt phyſical truths are all contingent, ſo that there is not one of them of which the direct contrary may not eaſily be conceived?

That there is not one phyſical truth, of which the contrary may not be conceived, is not perhaps ſo certain as has generally been imagined; but admitting the fact to be as it has commonly been ſtated, the apparent difference between this claſs of truths and thoſe of pure geometry, may be eaſily accounted for, without ſuppoſing that the former reſts upon a kind of evidence totally different from that which ſupports the fabric of the latter.

The objects of pure geometry, as we have already obſerved, are the creatures of our own minds, which contain in them nothing concealed from our view. As the mathematician treats them merely as meaſurable quantities, he knows, with the utmoſt preciſion, upon what particular properties the relation affirmed to ſubſiſt between any two or more of them muſt abſolutely depend; and he cannot poſſibly entertain a doubt but it will be found to have place among all quantities having the ſame properties, becauſe it depends upon them, and upon them alone. His proceſs of induction, therefore, by a ſeries of ideal meaſurements, is always complete, and exhauſts the ſubject; but in phyſical enquiries the caſe is widely different. The ſubjects which employ the phyſical enquirer are not his own ideas, and their various relations, but the properties, powers, and relations of the bodies which compoſe the univerſe; and of thoſe bodies he knows neither the ſubſtance, internal ſtructure, nor all the qualities: ſo that he can very ſeldom diſcover with certainty upon what particular property or properties the phenomena of the corporeal world, or the relations which ſubſiſt among different bodies, depend. He expects, indeed, with confidence, not inferior to that with which he admits a mathematical demonſtration, that any corporeal phenomenon, which he has obſerved in certain circumſtances, will be always obſerved in circumſtances exactly ſimilar; but the misfortune is, that he can very ſeldom be aſcertained of this ſimilarity. He does not know any one piece of matter *as it is in itſelf*; he cannot ſeparate its various properties; and of courſe cannot attribute to any one property the effects or apparent effects which proceed excluſively from it. Indeed, the properties of bodies are ſo cloſely interwoven, that by human means they cannot be completely ſeparated; and hence the moſt cautious inveſtigator is apt to attribute to ſome one or two properties, an event which in reality reſults perhaps from many. (See PHILOSOPHY and PHYSICS, *Encycl.*) This the geometrician never does. He knows perfectly that the relation of equality which ſubſiſts between the three angles of a plain triangle and two right angles, depends not upon the ſize of the triangles, the matter of which they are conceived to be made, the particular place which they occupy in the univerſe, or upon any one circumſtance whatever beſides their triangularity, and the angles of their corrolets being exactly right angles; and it is upon this power of diſcrimination which we have in the conceptions of pure geometry, and have not in the objects of phyſics, that the truths of the one ſcience are perceived to be neceſſary, while thoſe of the other appear to be contingent; though the mode of demonſtration is the

ſame

ſame in both, or at leaſt equally removed from categorical ſyllogiſms.

INERTIA. See DYNAMICS and IMPULSION in this *Supplement*.

INFLAMMATION has been ſufficiently explained in the *Encyclopædia*, and in the article CHEMISTRY in this *Supplement ;* but it cannot be improper, in this place, to give an account of ſome remarkable

Spontaneous INFLAMMATIONS, which, as different ſubſtances, are liable to them, have been, and may again be, the cauſe of many and great misfortunes

The ſpontaneous inflammation of eſſential oils, and that of ſome fat oils, when mixed with nitrous acid, are well known to philoſophers ; ſo alſo is that of powdered charcoal with the ſame acid (lately diſcovered by M. Prouſt), and thoſe of phoſphorus, of pyrophorus, and of fulminating gold. Theſe ſubſtances are generally to be found only in the laboratories of chemiſts, who are perfectly well acquainted with the precautions which it is neceſſary to take to prevent the unhappy accidents which may be occaſioned by them.

The burning of a ſtore houſe of ſails, which happened at Breſt in the year 1757, was cauſed by the ſpontaneous inflammation of ſome oiled cloths, which, after having been painted on one ſide, and dried in the ſun, were ſtowed away while yet warm ; as was ſhewn by ſubſequent experiments *.

Vegetables boiled in oil or fat, and left to themſelves, after having been preſſed, inflame in the open air. This inflammation always takes place when the vegetables retain a certain degree of humidity ; if they are firſt thoroughly dried, they are reduced to aſhes, without the appearance of flame. We owe the obſervation of theſe facts to MM. Saladin and Carette †.

The heaps of linen rags which are thrown together in paper manufactories, the preparation of which is haſtened by means of fermentation, often take fire, if not carefully attended to.

The ſpontaneous inflammation of hay has been known for many centuries ; by its means houſes, barns, &c. have been often reduced to aſhes. When the hay is laid up damp, the inflammation often happens ; for the fermentation is then very great. This accident very ſeldom occurs to the firſt hay (according to the obſervation of M. de Bomare), but is much more common to the ſecond ; and if, through inattention, a piece of iron ſhould be left in a ſtalk of hay in fermentation, the inflammation of that ſtalk is almoſt a certain conſequence. Corn heaped up has alſo ſometimes produced inflammations of this nature. Vanieri, in his *Prædium Rusticum*, ſays,

> *Quæ vero (gramina) nondum ſatis inſolata recondens*
> *Imprudens, ſubitis pariunt incendia flammis.*

Dung alſo, under certain circumſtances, inflames ſpontaneouſly.

In a paper, publiſhed in the *Repertory of Arts and Manufactures*, by the Rev. William Tooke, F. R. S. &c. we have the following remarkable inſtances of ſpontaneous inflammation. "A perſon of the name of Rüde, an apothecary at Bautzen, had prepared a pyrophorus from rye-bran and alum. Not long after he had made the diſcovery, there broke out, in the next village of Nauſlitz, a great fire, which did much miſchief, and was ſaid to have been occaſioned by the treating of a ſick cow in the cow-houſe. Mr Rüde knew, that the countrymen were uſed to lay an application of parched rye-bran to their cattle for curing the thick neck ; he knew alſo, that alum and rye bran, by a proper proceſs, yielded a pyrophorus ; and now he wiſhed to try whether parched rye-bran alone would have the ſame effect. Accordingly, he roaſted a quantity of rye-bran by the fire, till it had acquired the colour of roaſted coffee. This roaſted bran he wrapped up in a linen cloth; in the ſpace of a few minutes there aroſe a ſtrong ſmoke through the cloth, accompanied by a ſmell of burning. Not long afterwards the rag grew as black as tinder, and the bran, now become hot, fell through it on the ground in little balls. Mr Rüde repeated the experiment at various times, and always with the ſame reſult. Who now will any longer doubt, that the frequency of fires in cow-houſes, which in thoſe parts are moſtly wooden buildings, may not be occaſioned by this common practice, of binding roaſted bran about the necks of the cattle? The fire, after conſuming the cattle and the ſhed, communicates itſelf to the adjoining buildings ; great damage enſues ; and the ignorant look for the cauſe in wilful and malicious firing, conſequently in a capital crime."

The ſame author informs us, that in the ſpring of the year 1780, a fire was diſcovered on board a Ruſſian frigate lying in the road of Cronſtadt ; which, if it had not been timely extinguiſhed, would have endangered the whole fleet. After the ſevereſt ſcrutiny, no cauſe of the fire was to be found ; and the matter was forced to remain without explanation, but with ſtrong ſurmiſes of ſome wicked incendiary being at the bottom of it. In the month of Auguſt, in the ſame year, a fire broke out at the hemp-magazine at St Peterſburgh, by which ſeveral hundred thouſand poods ‡ of hemp and flax were conſumed. The walls of the magazine are of brick, the floors of ſtone, and the rafters and covering of iron ; it ſtands alone on an iſland in the Neva, on which, as well as on board the ſhips lying in the Neva, no fire is permitted. In St Peterſburgh, in the ſame year, a fire was diſcovered in the vaulted ſhop of a furrier. In theſe ſhops, which are all vaults, neither fire nor candle is allowed, and the doors of them are all of iron. At length the probable cauſe was found to be, that the furrier, the evening before the fire, had got a roll of new cere-cloth (much in uſe here for covering tables, counters, &c. being eaſily wiped and kept clean), and had left it in his vault, where it was found almoſt conſumed.

In the night between the 20th and 21ſt of April 1781, a fire was ſeen on board the frigate Maria, which lay at anchor, with ſeveral other ſhips, in the road off the iſland of Cronſtadt ; the fire was, however, ſoon extinguiſhed ; and, by the ſevereſt examination, little or nothing could be extorted concerning the manner in which it had ariſen. The garriſon was threatened with a ſcrutiny that ſhould coſt them dear ; and while they were in this cruel ſtate of ſuſpence, an order came from the ſovereign, which quieted their minds, and gave riſe to ſome very ſatisfactory experiments.

It having been found, upon juridical examination, as well as private inquiry, that in the ſhip's cabin, when the ſmoke appeared, there lay a bundle of matting, containing Ruſſian lamp-black prepared from fir-ſoot, moiſtened with hemp oil varniſh, which was perceived

---

* See Memoires de l'Academie de Paris, 1760.

† Journal de Phyſique, 1784.

‡ A pood conſiſts of 40 pounds Ruſs, or 36 Engliſh.

to have ſparks of fire in it at the time of the extinction, the Ruſſian admiralty gave orders to make various experiments, in order to ſee whether a mixture of hemp-oil varniſh and the forementioned Ruſſian black, folded up in a mat and bound together, would kindle of itſelf.

They ſhook 40 pounds of fir-wood ſoot into a tub, and poured about 35 pounds of hemp oil varniſh upon it; this they let ſtand for an hour, after which they poured off the oil. The remaining mixture they now wrapped up in a mat, and the bundle was laid cloſe to the cabin, where the midſhipmen had their birth. To avoid all ſuſpicion of treachery, two officers ſealed both the mat and the door with their own ſeals, and ſtationed a watch of four ſea officers, to take notice of all that paſſed the whole night through; and as ſoon as any ſmoke ſhould appear, immediately to give information to the commandant of the port.

The experiment was made the 26th of April, about 11 o'clock A. M. in preſence of all the officers named in the commiſſion. Early on the following day, about ſix o'clock A. M. a ſmoke appeared, of which the chief commandant was immediately informed by an officer: he came with all poſſible ſpeed, and through a ſmall hole in the door ſaw the mat ſmoking. Without opening the door, he diſpatched a meſſenger to the members of the commiſſion; but as the ſmoke became ſtronger, and fire began to appear, the chief commandant found it neceſſary, without waiting for the members of the commiſſion to break the ſeals and open the door. No ſooner was the air thus admitted, than the mat began to burn with greater force, and preſently it burſt into a flame.

The Ruſſian admiralty, being now fully convinced of the ſelf-enkindling property of this compoſition, tranſmitted their experiment to the Imperial Academy of Sciences; who appointed Mr Georgi, a very learned and able adjunct of the academy, to make farther experiments on the ſubject. Previous to the relation of theſe experiments, it is neceſſary to obſerve, that the Ruſſian fir-black is three or four times more heavy, thick, and unctuous, than that kind of painters black which the Germans call *kien-rahm*. The former is gathered at Ochta, near St Peterſburgh, at Moſco, at Archangel, and other places, in little wooden huts, from reſinous fir-wood, and the unctuous bark of birch, by means of an apparatus uncommonly ſimple, conſiſting of pots without bottoms ſet one upon the other; and is ſold very cheap. The famous fine German *kien-rahm* is called in Ruſſia *Holland's black*. In what follows, when raw oil is ſpoken of, it is to be underſtood of linſeed-oil or hemp oil; but moſt commonly the latter. The varniſh is made of five pounds of hemp oil boiled with two ounces and a half of minium. For wrapping up the compoſition, Mr Georgi made uſe of coarſe hemp-linen, and always ſingle, never double. The impregnations and commixtures were made in a large wooden bowl, in which they ſtood open till they were wrapped up in linen.

Three pounds of Ruſſian fir-black were ſlowly impregnated with five pounds of hemp-oil varniſh; and when the mixture had ſtood open five hours, it was bound up in linen. By this proceſs it became clotted; but ſome of the black remained dry. When the bundle had lain ſixteen hours in a cheſt, it was obſerved to emit a very nauſeous, and rather putrid, ſmell, not quite unlike that of boiling oil. Some parts of it became warm, and ſteamed much; this ſteam was watery, and by no means inflammable. Eighteen hours after the mixture was wrapped up, one place became brown, emitted ſmoke, and directly afterwards glowing fire appeared. The ſame thing happened in a ſecond and a third place, though other places were ſcarcely warm. The fire crept ſlowly around, and gave a thick, grey, ſtinking ſmoke. Mr Georgi took the bundle out of the cheſt, and laid it on a ſtone pavement; when, on being expoſed to the free air, there aroſe a ſlow burning flame, a ſpan high, with a ſtrong body of ſmoke. Not long afterwards there appeared, here and there, ſeveral chaps or clefts, as from a little volcano, the vapour iſſuing from which burſt into flame. On his breaking the lump, it burſt into a very violent flame, full three feet high, which ſoon grew leſs, and then went out. The ſmoking and glowing fire laſted for the ſpace of ſix hours; and afterwards the remainder continued to glow without ſmoke for two hours longer. The grey earthy aſhes, when cold, weighed five ounces and a half.

In another experiment, perfectly ſimilar to the foregoing, as far as relates to the compoſition and quantities, the enkindling did not enſue till 41 hours after the impregnation: the heat kept increaſing for three hours, and then the accenſion followed. It is worthy of remark, that theſe experiments ſucceeded better on bright days than on ſuch as were rainy; and the accenſion came on more rapidly.

In another experiment, three pounds of Ruſſian fir-black were ſlowly impregnated with three pounds of raw hemp-oil; and the accenſion enſued after nine hours.

Three quarters of a pound of German *rahm* were ſlowly impregnated with a pound and a half of hemp-oil varniſh. The mixture remained 70 hours before it became hot and reeking; it then gradually became hotter, and emitted a ſtrong exhalation; the effluvia were moiſt, and not inflammable. The reaction laſted 36 hours, during which the heat was one while ſtronger, and then weaker, and at length quite ceaſed.

Stove or chimney ſoot, moſtly formed from birch-wood ſmoke, was mingled with the above-mentioned ſubſtances and tied up; the compound remained cold and quiet.

Ruſſian fir-black, mixed with equal parts of oil of turpentine, and bound up, exhibited not the leaſt reaction or warmth.

Birch oil, mixed with equal parts of Ruſſian fir-black, and bound up, began to grow warm and to emit a volatile ſmell; but the warmth ſoon went off again.

From the experiments of the admiralty and of Mr Georgi, we learn, not only the deciſive certainty of the ſelf-accenſion of ſoot and oil, when the two ſubſtances are mixed under certain circumſtances, but alſo the following particulars:

Of the various kinds of ſoot, or lamp-black, the experiments ſucceeded more frequently and ſurely with the coarſer, more unctuous, and heavier, like Ruſſian painters black, than with fine light German *rahm*, or with coarſe chimney-ſoot. In regard to oils, only thoſe experiments ſucceeded which were made with drying oils, either raw or boiled. The proportions of the ſoots to the oils were, in the ſucceſsful experiments, very various; the mixture kindled with a tenth, a fifth, a third, Inflammation.

with an equal, and likewiſe with a double, proportion of oil. In general, however, much more depends on the mode of mixture, and the manipulation, and, as Mr Georgi often obſerved, on the weather; for in moiſt weather the bundles, after becoming warm, would frequently grow cold again.

The inſtances of ſpontaneous inflammation hitherto mentioned have been only of vegetable ſubſtances; but we have examples of the ſame thing in the animal kingdom. Pieces of woollen cloth, which had not been ſcoured, took fire in a warehouſe. The ſame thing happened to ſome heaps of woollen yarn; and ſome pieces of cloth took fire in the road, as they were going to the fuller. Theſe inflammations always take place where the matters heaped up preſerve a certain degree of humidity, which is neceſſary to excite a fermentation; the heat reſulting from which, by drying the oil, leads them inſenſibly to a ſtate of ignition; and the quality of the oil, being more or leſs deſiccative, very much contributes thereto.

The woollen ſtuff prepared at Sevennes, which bears the name of Emperor's ſtuff, has kindled of itſelf, and burnt to a coal. It is not unuſual for this to happen to woollen ſtuffs, when in hot ſummers they are laid in a heap in a room but little aired.

In June 1781, the ſame thing happened at a woolcomber's in a manufacturing town in Germany, where a heap of wool combings, piled up in a cloſe warehouſe ſeldom aired, took fire of itſelf. This wool had been by little and little brought into the warehouſe; and, for want of room, piled up very high, and trodden down, that more might be added to it. That this combed wool, to which, as is well known, rape-oil mixed with butter is uſed in the combing, burnt of itſelf, was ſworn by ſeveral witneſſes. One of them affirmed that, ten years before, a ſimilar fire happened among the flocks of wool at a clothier's, who had put them into a caſk, where they were rammed hard, for their eaſier conveyance. This wool burnt from within outwards, and became quite a coal; it was very certain that neither fire nor light had been uſed at the packing, conſequently the above fires aroſe from ſimilar cauſes. In like manner, very credible cloth-workers have certified, that, after they have bought wool that was become wet, and packed it cloſe in their warehouſe, this wool has burnt of itſelf; and very ſerious conſequences might have followed, if it had not been diſcovered in time.

Nay, there are inſtances, though they be but rare, of human bodies being conſumed by ſpontaneous inflammation. In the Philoſophical Tranſactions, and in the Memoirs of the Academies of Paris and Copenhagen, it is related that an Italian lady (the Counteſs Cornelia Bandi) was entirely reduced to aſhes, except her legs; that an Engliſh woman, called Grace Pitt, was almoſt entirely conſumed by a ſpontaneous inflammation of her viſcera: and, laſtly, that a prieſt of Bergamo was conſumed in the ſame manner. Theſe ſpontaneous inflammations have been attributed to the abuſe of ſpirituous liquors; but though the victims of intemperance are indeed very numerous, theſe certainly do not belong to that number.

The mineral kingdom alſo often affords inſtances of ſpontaneous inflammation. Pyrites heaped up, if wetted and expoſed to the air, take fire. Pitcoal alſo, laid in heaps, under certain circumſtances, inflames ſpontaneouſly. M. Duhamel has deſcribed two inflammations of this nature, which happened in the magazines of Breſt, in the years 1741 and 1757. Cuttings of iron, which had been left in water, and were afterwards expoſed to the open air, gave ſparks, and ſet fire to the neighbouring bodies. For this obſervation we are obliged to M. de Charpentier.

Inflammation || Ink.

The cauſes of theſe phenomena the chemiſt will aſſign; but they are here recorded as a warning to tradeſmen and others. It is evident, from the facts which have been related, that ſpontaneous inflammations being very frequent, and their cauſes very various, too much attention and vigilance cannot be uſed to prevent their dreadful effects. And conſequently it is impoſſible to be too careful in watching over public magazines and ſtorehouſes, particularly thoſe belonging to the ordnance, or thoſe in which are kept hemp, cordage, lampblack, pitch, tar, oiled cloths, &c. which ſubſtances ought never to be left heaped up, particularly if they have any moiſture in them. In order to prevent any accident from them, it would be proper to examine them often, to take notice if any heat is to be obſerved in them, and, in that caſe, to apply a remedy immediately. Theſe examinations ſhould be made by day, it not being adviſable to carry a light into the magazines; for when the fermentation is ſufficiently advanced, the vapours which are diſengaged by it are in an inflammable ſtate, and the approach of a light might, by their means, ſet fire to the ſubſtances whence they proceed. Ignorance of the fore-mentioned circumſtances, and a culpable negligence of thoſe precautions which ought to be taken, have often cauſed more misfortunes and loſs than the moſt contriving malice: it is therefore of great importance that theſe facts ſhould be univerſally known, that public utility may reap from them every poſſible advantage.

INFORMED Stars, or Informes Stellæ, are ſuch ſtars as have not been reduced into any conſtellation; otherwiſe called Sporades.—There was a great number of this kind left by the ancient aſtronomers; but Hevelius, and ſome others of the moderns, have provided for the greater part of them, by making new conſtellations.

Sympathetic INK is an old invention. Among the methods by which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal-duſt or ſoot.

> *Tuta quoque eſt, fallitque oculos, e lacte recenti*
> *Litera: carbonis pulvere tange, leges.*

It is obvious, that any other colourleſs and glutinous juice, which will hold faſt the black powder ſtrewed over it, will anſwer the purpoſe as well as milk; and therefore Pliny recommends the milky juice of certain plants to be uſed.

There are ſeveral metallic ſolutions perfectly colourleſs, or, at leaſt, without any ſtrong tint, which being wrote with, the letters will not appear until the paper be waſhed over with another colourleſs ſolution, or expoſed to the vapour of it; but among all theſe there is none which excites more aſtoniſhment, or from which naturaliſts can draw more concluſions, than that which conſiſts of a ſolution of lead in vegetable acid, and which by the vapour of arſenical liver of ſulphur becomes black, even at a conſiderable diſtance. This ink, which may

may be uſed by conjurors, proves the ſubtlety of vapour, and the poroſity of bodies; as the change or colouring takes place even when the writing is placed on the other ſide of a thin wall.

We knew before, that a ſolution of lead, treated in this manner, would anſwer the purpoſe of a ſympathetic ink (ſee that article *Encycl.*); but we did not know, nor do we yet believe, that the ſulphuric vapours will act upon the writing through *a wall.* Such, however, is the affirmation of Profeſſor Beckmann, who gives an account of a ſtill more wonderful ink from Peter Borel. This author, in a book called *Hiſtoriarum et obſervationum medico phyſic. centuriæ quatuor*, printed at Paris, firſt in 1653, and afterwards in 1657, gives a receipt for making this ink, which he calls *magnetic waters which act at a diſtance.* The receipt is as follows:

“ Let quick lime be quenched in common water, and while quenching, let ſome orpiment be added to it (this, however, ought to be done by placing warm aſhes under it for a whole day), and let the liquor be filtered, and preſerved in a glaſs bottle well corked. Then boil litharge of gold, well pounded, for half an hour with vinegar, in a braſs veſſel, and filter the whole through paper, and preſerve it alſo in a bottle cloſely corked. If you write any thing with this laſt water, with a clean pen, the writing will be inviſible when dry: but if it be waſhed over with the firſt water it will become inſtantly black. In this, however, there is nothing aſtoniſhing; but this is wonderful, that though ſheets of paper without number, and even a board, be placed between the inviſible writing and the ſecond liquid, it will have the ſame effect, and turn the writing black, penetrating the wood and paper without leaving any traces of its action, which is certainly ſurpriſing; but a fetid ſmell, occaſioned by the mutual action of the liquids, deters many from making the experiment. I am, however of opinion, that I could improve this ſecret by a more refined chemical preparation, ſo as that it ſhould perform its effect through a wall. This ſecret (ſays Borel) I received, in exchange for others, from J. Broſſon, a learned and ingenious apothecary of Montpelier.”

For making a ſympathetic ink of the fifth claſs mentioned in the *Encyclopædia*, the following proceſs by M. Meyer may be worthy of the reader's notice. It was entered upon in conſequence of a receipt for roſe-coloured ſympathetic ink ſhewn to him by a traveller. In that receipt cobalt was the principal ingredient, and therefore the firſt object was to procure cobalt; but M. Meyer, being unwilling to ſacrifice pure pieces of cobalt of any conſiderable ſize, made choice of one, which was viſibly mixed with biſmuth, iron, and quartz. He endeavoured to ſeparate the biſmuth as much as poſſible, and alſo the arſenic, if it ſhould contain any, by bringing it ſlowly to a red heat; and he ſucceeded pretty well, as the biſmuth flowed from it in abundance; and the arſenic, the quantity of which was ſmall, was volatiliſed: many globules of biſmuth ſtill adhered to it. By bringing it repeatedly to a red heat, and then quenching it in water, it was reduced to ſuch a ſtate as to be eaſily pulveriſed. Having poured nitrous acid upon the powder, he obtained by digeſtion a beautiful roſe red ſolution; the ſiliceous earth was ſeparated in the form of a white ſlime, and by diluting it with water there was depoſited a white powder, which was oxyd of biſmuth. The ſolution being filtered, he added to it a ſolution of potaſh, and obtained a precipitate inclining more to a yellow than to a red colour. He again poured over it a little of the nitrous acid, by which a part of the oxyd was re-diſſolved of a red colour: the remaining part, which had a dark brown colour, was oxyd of iron. From the ſolution, by the addition of potaſh, a precipitate was formed, which was now reddiſh. Having by this proceſs obtained it pure, that he might now prepare from it the wiſhed-for red ink, he diſſolved the waſhen pure oxyd of cobalt in different acids. That diſſolved in the nitrous acid with a mixture of nitre, gave a green ink like the common: that diſſolved in the ſulphurous acid, without the addition of ſalts, gave a reddiſh ink, which remained after it was expoſed to heat, and would not again diſappear, even when a ſolution of nitre was applied; and that diſſolved in the muriatic acid, gave a green ink, darker and more beautiful than the common. By diſſolving it, however, in the acetous acid, and adding a little nitre, he obtained what he had in view; for it gave, on the application of heat, an ink of a red colour, like that of the *roſa centifolia*, which again diſappeared when the paper became cold.

INORDINATE PROPORTION, is where the order of the terms compared is diſturbed or irregular. As, for example, in two ranks of numbers, three in each
rank, viz. in one rank, - - - 2, 3, 9,
and in the other rank, - - - 8, 24, 36,
which are proportional, the former to the latter, but in a different order, viz. - - 2 : 3 :: 24 : 36,
and - - 3 : 9 :: 8 : 24.
then, caſting out the mean terms in each rank, it is concluded that - - - - 2 : 9 :: 8 : 36,
that is, the firſt is to the 3d in the firſt rank,
as the firſt is to the 3d in the 2d rank.

INSECTS (See *Encycl.*). A number of non-deſcript little animals was diſcovered by La Martiniere the naturaliſt when accompanying Perouſe on his celebrated voyage of diſcovery. Theſe animals he called *inſects*, and to many of them he gave particular names. Of theſe we ſhall give his deſcription in this place, leaving our readers, as he has left his, to arrange them properly according to the Linnæan claſſification.

Plate XXX.

“ The inſect, which is figured N° 1. inhabits a ſmall priſmatic triangular cell, pointed at the two extremities, of the conſiſtence and colour of clear brittle ice; the body of the inſect is of a green colour, ſpotted with ſmall bluiſh points, among which are ſome of a golden tinge; it is fixed by a ligament to the lower part of its ſmall habitation: its neck is terminated by a ſmall blackiſh head compoſed of three converging ſcales, in the form of a hat, and encloſed between three fins, two of them large and channelled in the upper part (A) and one ſmall, ſemicircular (B). When it is diſturbed, it immediately withdraws its fins and its head into its cell, and gradually ſinks into the water by its own ſpecific gravity. Fig. 2. repreſents the under ſide of the priſm, ſhewing in what manner it is channelled, in order to allow free paſſage to the animal when it wiſhes to ſhut itſelf up in it. Fig. 3. repreſents the profile of the ſame. The movement carried on by the two larger fins, which are of a ſoftiſh cartilaginous ſubſtance, may be compared to that which would be produced by the two hands joined together in the ſtate of pronation, and forming, alternately, two inclined planes and one horizontal plane: it is by means of this motion that it ſupports itſelf on the top of the water, where it probably

bly feeds on fat and oily ſubſtances on the ſurface of the ſea." Our author found it near Nootka, on the north-weſt coaſt of America, during a calm.

Fig. 4. repreſents a collection of inſects, as our author calls them, conſiſting only of oval bodies, ſimilar to a ſoap bubble, arranged in parties of three, five, ſix, and nine: among them are alſo ſome ſolitary ones. Theſe collections of globules, being put into a glaſs filled with ſea water, deſcribed a rapid circle round the glaſs by a common movement, to which each individual contributed by ſimple compreſſion of the ſides of its body, probably the effect of the re-action of the air with which they were filled. It is not, however, eaſy to conceive how theſe diſtinct animals (for they may be readily ſeparated without deranging their economy) are capable of concurring in a common motion. "Theſe conſiderations (ſays our author), together with the form of the animal, recalled to my mind, with much ſatisfaction, the ingenious ſyſtem of M. de Buffon; and I endeavoured to perſuade myſelf, that I was about to be witneſs to one of the moſt wonderful phenomena of Nature, ſuppoſing that theſe molecules, which were now employed in increaſing or diminiſhing their number, or performing their revolutions in the glaſs, would ſoon aſſume the form of a new animal of which they were the living materials. My impatience led me to detach two from the moſt numerous group, imagining that this number might perhaps be more favourable to the expected metamorphoſis. I was, however, miſtaken. Theſe I examined with more attention than the reſt; and the following account is of their proceedings alone. Like two ſtrong and active wreſtlers, they immediately ruſhed together, and attacked each other on every ſide: ſometimes one would dive, leaving its adverſary at the ſurface of the water; one would deſcribe a circular movement, while the other remained at reſt in the centre; their motions at length became ſo rapid as no longer to allow me to diſtinguiſh one from the other. Having quitted them for a ſhort time, on my return I found them reunited as before, and amicably moving round the edge of the glaſs by their common exertions."

Fig. 5. repreſents a ſingular animal, which has a conſiderable reſemblance to a little lizard; its body is of a firm, gelatinous conſiſtence; its head is furniſhed on each ſide with two ſmall gelatinous horns, of which the two hindermoſt are ſituate the furtheſt inward: its body is provided with four open fan-like paws, and ſome appendages near the inſertion of the tail, and terminates like that of a lizard: the ridge of the back is divided the whole way down by a band of a deep blue; the reſt of the body, as well as the inſide of its paws, is of a bright ſilvery white. It appears to be very ſluggiſh in its motions; and when diſturbed by the finger, merely turned itſelf belly upwards, ſoon afterwards reſuming its former poſition. Fig. 6. repreſents it reverſed. Martiniere caught it during a calm at the landing place on the Baſhee Iſlands.

INSTITUTE is a name which has lately been ſubſtituted for *ſchool* or *academy*. Formerly *inſtitution*, in the propriety of the Engliſh language, was ſometimes uſed as a word of the ſame import with *inſtruction*; and now *inſtitute* is employed, eſpecially by the admirers of French innovations, to denote what had hitherto been called an academy. When royalty was aboliſhed in France, it would have been abſurd to continue the titles *Royal* Academy of Sciences, '*Royal* Academy of Inſcriptions, &c.; but inſtead of merely aboliſhing the word *royal*, and ſubſtituting *national* in its ſtead, it occurred to the fertile brain of Condorcet, to aboliſh the ſeven academies themſelves, or rather to melt them all down into one great academy; to which was given the appellation of the

National INSTITUTE, or *New Academy of Arts and Sciences*. This academy, founded on a decree of the new conſtitution, was opened on the 7th of December 1795, when BENEZECH, the then miniſter for the home department, attended, and the decree of foundation was read; which was to the following purport:

"The Academy of Arts and Sciences belongs to the whole republic, and Paris is its place of reſidence. Its employment is to aim at bringing all arts and ſciences to the utmoſt perfection of which they are capable. It is to notice every new attempt, and all new diſcoveries, and to keep up a correſpondence with all foreign literary ſocieties. And by the particular orders of the Executive Directory, its firſt ſtudies are to be directed to thoſe ſubjects which more immediately tend to the reputation and advantage of the French republic."

The academy is to conſiſt of 288 members, half of whom are to reſide in Paris, the other half in the departments; and to them is to be added a certain number of foreigners, as honorary members, confined at preſent to twenty-four.

The academy is divided into three claſſes, each claſs into ſections, each ſection to contain twelve members.

1ſt claſs. Mathematics and natural philoſophy. This claſs is divided into ten ſections. 1. Mathematics. 2. Mechanical arts. 3. Aſtronomy. 4. Experimental philoſophy. 5. Chemiſtry. 6. Natural hiſtory. 7. Botany. 8. Anatomy and animal hiſtory. 9. Medicine and ſurgery. 10. Animal œconomy, and the veterinary ſcience.

2d claſs. Morality and politics. This claſs conſiſts of ſix ſections. 1. Analyſis of ſenſations and ideas. 2. Morals. 3. Legiſlature. 4. Political economy. 5. Hiſtory. 6. Geography.

3d claſs. Literature and the fine arts. This claſs conſiſts of eight ſections. 1. Univerſal grammar. 2. Ancient languages. 3. Poetry. 4. Antiquities. 5. Painting. 6. Sculpture. 7. Architecture. 8. Muſic.

For each claſs a particular room in the Louvre is appropriated. No one can be a member of two claſſes at the ſame time, but a member of one claſs may be preſent at the meetings of any other. Each claſs is to print, yearly, an account of its tranſactions.

Four times a-year there are to be public meetings. On theſe occaſions, the three claſſes meet together. At the end of each year, they are to give a circumſtantial account to the legiſlative body of the progreſs made in that year in the arts and ſciences. The prizes given yearly by each claſs are to be publicly notified at certain times. The ſums requiſite for the ſupport of the inſtitution are to be decreed yearly by the legiſlative body, upon a requiſition made by the Executive Directory.

The firſt forty-eight members were choſen by the Executive Directory, to whom the choice of the remaining members was confided. To the members, reſidentiary in Paris, is reſerved the choice both of the department and the foreign members. On a vacancy in any claſs, three candidates are named by the claſs for the choice of the body at large.

Each claſs is to have, at its place of meeting, a collection of the products, both of nature and art, and a library, according to its particular wants.

The regulations of the inſtitution, with reſpect to the times of meeting, and its employments, are to be drawn up by the body at large, and laid before the legiſlative aſſembly.

The hall in which the body at large holds its meetings, forms part of the weſt wing of the Old Louvre, at preſent called the Muſeum It formerly went by the appellation of the Hall of Antiques (*Salle des Antiques*); and as long as the kings inhabited this part of the palace, was occupied by their guards, from which circumſtance it obtained the name of the Hall *des Cent Suiſſes.* It was likewiſe appropriated to banquets and entertainments, given by the court on gala days; and it was to this place that Henry IV. was conveyed, on his aſſaſſination by Ravaillac, in the *Rue de la Ferronnerie.*

It was built at the ſame time with the reſt of this part of the Louvre, about the year 1528, after the deſigns of Pierre Leſcot, abbot of Clagny. It is 144 feet in length, and 40 in breadth, and holds from 1000 to 1200 perſons. In order to adapt it to its new deſtination, the floor has been ſunk, which gives a greater air of lightneſs to the roof. In the centre ſtands a double table, in the form of a horſe-ſhoe, ſupported by ſphinxes, at which the members of the inſtitute take their ſeats. This table is ſurrounded by two tiers of benches, which are raiſed for the accommodation of ſpectators, who have likewiſe ſeats provided for them in the vaſt embraſures of the windows, and at each extremity of the hall.

Whether ſcience will be advanced by the ſeven royal academies having been melted into one, time muſt determine; but candour compels us to acknowledge, that the proceedings of the national inſtitute have hitherto been abundantly intereſting. Intimately connected with the national inſtitute is the French ſyſtem of

National INSTRUCTION, which is likewiſe novel, and therefore ſufficiently curious to deſerve notice in a Work of this kind. When the Chriſtian religion was aboliſhed in France, it was impoſſible to continue the univerſities and other ſeminaries which were founded by Chriſtians, and obliged by their conſtitution to teach, whether pure or not, the doctrines of Chriſtianity. They were accordingly all ſwept away, and a new ſyſtem of education planned, which was to be carried on in what they call

The Primary Schools.
The Central Schools.
The School of Health.
The School of Oriental Languages.
The Polytechnic School.
The National Inſtitute.
The Jury of Public Inſtruction.
The Commiſſion of Public Inſtruction.
The Legiſlative Committee of Inſtruction. And various other national eſtabliſhments for the improvement of particular ſciences.

The firſt degree of public inſtruction is to be met with in the *Ecoles Primarées*, eſtabliſhed by a decree of the convention of the ſecond *Pluvioſe*, in the ſecond year of the republic (A). Every diſtrict is furniſhed with one of theſe ſchools; the profeſſors or maſters in which are paid from the national treaſury; and to which every head of a family, without exception, is compelled by law to ſend its children for inſtruction. The ſubjects taught in theſe primary or elementary ſchools are divided into nine claſſes:

1*ſt*, Inſtructions connected with the phyſical and moral ſituation of children, prior to their entering into theſe ſchools. 2*d*, Similar inſtructions as a guide to teachers in the national ſchools. 3*d*, The arts of reading and writing. 4*th*, The elements of French grammar. 5*th*, Elements of arithmetic and geometry, with the theory of the new menſuration. 6*th*, The elements of geography. 7*th*, Explanations of the principal phenomena and productions of nature. 8*th*, Elements of agriculture. 9*th*, Elements of republican morals.

Next to the primary ſchools in rank and conſequence are the *Ecoles Centrales*, which were eſtabliſhed by a decree of the Convention of the ſeventh *Ventoſe* in the third year. They are ſituated in the capital of every department, bearing the proportion of one central ſchool to 300,000 inhabitants. In theſe ſchools the republican youths are taught the ſciences, and their application in real life. In each of them are profeſſors for the following branches:

1. For mathematics. 2. Experimental philoſophy and chemiſtry. 3. Natural hiſtory. 4. Agriculture and commerce. 5. Logic and metaphyſics. 6. Political economy and legiſlation. 7. The philoſophical hiſtory of nations. 8. The art of healing. 9. Arts and manufactures. 10. Univerſal grammar. 11. The belles lettres. 12. The ancient languages. 13. The modern languages. 14. The fine arts.

Each central ſchool is furniſhed with an extenſive public library—a botanic garden—a cabinet of natural hiſtory—an apparatus for experimental philoſophy—and a collection of machines and models connected with the arts and manufactures.

The profeſſors of each ſchool hold, every month, a public ſitting, in which conferences are held relative to ſubjects connected with the improvement of letters, the ſciences, and the arts, which are the moſt beneficial to ſociety.

The object in the eſtabliſhment of the primary and central ſchools was, the general inſtruction of all claſſes of the citizens; and it being incompatible with the perfect completion of that important purpoſe, to expect from them the propagation of particular branches of ſcience, it became neceſſary to eſtabliſh other literary and ſcientific academies.

Accordingly, the French government have founded, 1*ſt*, Schools of health (*les ecoles de ſante*), in Paris, Straſburgh, and

---

(A) We would tranſlate this chronological jargon into the language of Chriſtian Europe, were we not perſuaded that the French calendar, the French conſtitution, and the French inſtitutes, will have the ſame duration as we truſt in God not a long duration. For *Pluvioſe*, and the other fantaſtical names of months introduced into this article, ſee REVOLUTION, *Encycl.* nº 184.

and Montpelier, where medicine and ſurgery are ſtudied; which ſchools are affirmed, by thoſe who find nothing wrong in France, to be the moſt perfect of their kind, as well as new and unparalleled models for ſuch inſtitutions.

2*d*, Two ſchools for Oriental languages, in the national library, and in the college of France.

3*d*, The Polytechnic ſchool in Paris, or central ſchool for the direction of public works. This eſtabliſhment is very generally admired and conſidered as a model for imitation. It contains more than 400 young perſons, previouſly educated in the mathematics, and the majority of them intended for engineers in various lines; and they labour under the immediate direction of their tutors nine hours every day. It occupies the principal part of the *Palais de Bourbon* in Paris, and is furniſhed with a large collection of inſtruments and models. The journal of the Polytechnic ſchool, which is publiſhed by the bookſellers Regent and Bertrand at Paris, is a perfectly original work, and admirably calculated to convey uſeful information.

Of the national inſtitute a ſufficient account has been given in the preceding article. We proceed therefore to the jury of public inſtruction (*Le Jury Central d'Inſtruction*), of which the principal buſineſs is to ſuperintend the primary and central ſchools. It appoints the profeſſors in theſe ſchools, and examines into their conduct. Like the legiſlative body it is renewed by a third every half year. When they have choſen a profeſſor for a central ſchool, they ſubmit their choice to the department; and, in caſe of diſapprobation, they make another appointment. To this jury of public inſtruction the profeſſors in the central ſchools are amenable for all miſconduct connected with their offices; it may expel them, but all its deciſions muſt be ſubmitted for confirmation to the tribunal of the department.

There is alſo eſtabliſhed at Paris a ſupreme council, called The Commiſſion of Public Inſtruction, to which is entruſted the whole executive department. The preſervation of the national monuments, of public libraries, muſeums, cabinets, and valuable collections; the ſuperintendance of all the ſchools and the modes of inſtruction; all new inventions and ſcientific diſcoveries; the regulation of weights and meaſures; national ſtatiſtics and political economy, are all placed under the authority of this ſupreme commiſſion. For the commodious and regular execution of ſo many complicated branches of buſineſs, there is a large office, called *Le Secretariat*, which is divided into three departments.

1. For the regulation of the different kinds of inſtruction; of the modes of education in the ſchools; and for the choice of elementary books. 2. For weights and meaſures; inventions and diſcoveries; libraries and bibliography; muſeums, works of art, and literary rewards and encouragements. 3. For theatres, national feaſts, republican inſtitutions, and the erection of monuments.

As all public eſtabliſhments require the ſuperintendance and occaſional correction of the legiſlature, in addition to that of their own immediate executive authority, it has been deemed neceſſary to appoint a permanent committee of inſtruction in the legiſlative body, to provide ſuch ſums as may be neceſſary for the preſervation and improvement of this ſyſtem of inſtruction. This legiſlative committee are inveſted with due authority for theſe purpoſes. Their objects are preciſely the ſame as thoſe of the commiſſion of public inſtruction above deſcribed, only with this difference, that the latter ſuperintends the execution of exiſting laws, whilſt the former receives and improves them, or propoſes new ones. This committee is divided into three departments, as is the commiſſion, with exactly the ſame arrangement of their reſpective labours. The committee being charged with the enaction of all new laws, its members, with a view to obtain accurately all the requiſite information relative to the numerous branches of the arts, have procured from the legiſlative body the appointment of a *commiſſion temporaire des arts* to be annexed to them, and to meet in the ſame houſe with them; which temporary commiſſion is divided into ſixteen claſſes: viz. 1. For Zoology; 2. Botany; 3. Mineralogy; 4. Phyſics; 5. Chemiſtry; 6. Anatomy; 7. Machinery; 8. Geography; 9. Artillery and Fortification; 10. Medals and Antiquities; 11. Bibliography; 12. Painting; 13. Architecture; 14. Sculpture; 15. Bridges and Cauſeways; and, 16. Muſical Inſtruments.

The improvements of the national literary and ſcientific eſtabliſhments are numerous and important.

1*ſt*, By a decree of the convention of the 11th *Prairial*, in the ſecond year, it was enacted, that means ſhould be adopted by which every poſſible advantage might be derived from the botanic gardens of the republic, in Turkey and other foreign countries. This politic decree clearly tended to render France, in the language of the reporter, *L'abregé de tous les climats, et l'entrepôt de l'Europe.* "The epitome of every climate, and the magazine of Europe." Thoſe plants which thrive between the tropics may be cultivated in the ſouth of France; and thoſe which are the produce of northern climates, may be cultivated in the northern departments; by which means, France will be in poſſeſſion of all foreign plants and drugs, without the exportation of ſpecie.

2*d*, The National Bibliography was decreed in the ſitting of 22d *Germinal*, in the ſecond year. It conſiſts of a complete catalogue of books of all deſcriptions, the property of the nation; it was then aſcertained, that the republic poſſeſſed more than ten millions of books. The titles of them were to be adjuſted by actual compariſons; the manuſcripts to be regiſtered ſeparately; anonymous productions were to be arranged according to their ſubjects; and thoſe of known authors in the alphabetical order of the names. The ſeveral editions to be claſſed according to their dates: and what may be deemed more important, this French National Bibliography will contain a dictionary of anonymous books, as well as thoſe publiſhed under fictitious names, a deſideratum in the republic of letters.

3*d*, The annihilation of all *patois*, or dialects, decreed in the ſitting of the 16th *Prairial*, in the ſecond year. Notwithſtanding the univerſality of the French language, and that it was excluſively ſpoken in the majority of the inland departments, yet there exiſted thirty various dialects in France. It is more aſtoniſhing that Rozier had remarked, that between one neighbouring village and another, there was ſo conſiderable a difference in the dialect, that the inhabitants could not underſtand each other; and the vineſtock had thirty different names. The naturaliſt, Villars, has ſtated, that in the nomenclature of vegetables, in the departments, he had only met with an hundred which had a common appellation.

Inſtitute.

4*th*, The eſtabliſhment of the *Conſervatoire des Arts et Métiers*, was decreed in the ſitting of the 8th of *Vendemiaire*, in the third year. This conſiſts of a ſpacious hall, in the form of an amphitheatre, and contains the inſtruments and the models of machinery connected with the arts, and a deſcription of their uſes, with every book relating to them. Annexed to this eſtabliſhment are three expoſitors and a draughtſman, who explain to the ſtudents the uſe of each inſtrument, and who regiſter every new diſcovery, which is preſented to the *Bureau de Conſultation*, to the lyceum of arts, the *ci-devant* academy of ſciences, or to the board of commerce.

5*th*, The eſtabliſhment of the board of longitnde was decreed in the ſitting of the 7th of *Meſſidor*, third year. It was certainly a diſgrace under the monarchy, that an aſtronomical and nautical eſtabliſhment, which had already proved ſo beneficial to Great Britain, ſhould not have been adopted in France. In conſequence of this decree, the French board is now as complete as the Engliſh. It conſiſts of ten members, and has under its juriſdiction the national obſervatory at Paris, and all the aſtronomical inſtruments belonging to the republic. It correſponds with foreign aſtronomers; delivers public lectures on aſtronomy and navigation; and its proceedings are annually recited in a public ſitting.

6*th*, The general ſchool of the Oriental languages was eſtabliſhed by a decree of the 10th of *Germinal*, in the fourth year. This ſchool adjoins to the national library, and all the books and manuſcripts relative to Oriental literature are depoſited in it.

7*th*, The national muſeum of antiquities was decreed in the ſitting of 20th of *Prairial*, fourth year. A ſchool of this deſcription was ſucceſsfully eſtabliſhed at Vienna, by Eckel; at Gottingen, by Heyne; at Leipſick, by Erneſt; and even at Straſburgh, by the celebrated Oberlin: Paris was, however, without one. This national archeology, or ſcience of antiquity, is divided into nine different claſſes: inſcriptions, characters, ſtatues, *bas reliefs*, ſculptures, paintings, moſaics, medals, civil, religious, and military inſtruments. This extenſive eſtabliſhment is under the direction of two principal profeſſors; *le Conſervateur Profeſſeur, et le Conſervateur Bibliothecaire*. The province of the former is to deliver public lectures on the ſeveral branches of antiquities, to teach the theory of medals and engravings, the hiſtory of the arts among the ancients, &c. The duties of the latter are merely of a bibliographical nature.

8*th*, The new modelling of the Grand National Library, was decreed in the ſitting of 25th *Vendemiaire*, in the fourth year. By virtue of this decree, the place of librarian in chief was ſuppreſſed, and the whole eſtabliſhment placed under a *conſervatoire* of eight members; of whom two were appointed for the ſuperintendance of printed books; two for manuſcripts; two for antiquities; and two for engravings. From theſe a temporary director is annually choſen, who ſuperintends the whole acts occaſionally as preſident of this aſſembly, and maintains a regular correſpondence with the conſtituted authorities relative to the concerns of the library.

9*th*, The augmentation of the Muſeum of Natural Hiſtory, formerly called *Le Jardin Royal des Plantes*. This eſtabliſhment was decreed the 15th *Brumaire*, third year, upon a report of Thibadeau, in the name of the committee of Public Inſtruction. Beſides the addition of large rooms, and various other buildings, there are new collections of natural curioſities and productions; and the library is much increaſed. It is open to the public three times a week. At ſtated periods all the naturaliſts in Paris deliver courſes of lectures in the various branches of natural hiſtory. The muſeum is ſaid to have received greater improvements from this augmentation than from all the labours of Buffon, or from its foundation, ſince the time of Tournefort.

10*th*, The *Ecole des Mines* was eſtabliſhed in the *Hotel des Monnaies*, and has for its direction the naturaliſt Le Sage. This inſtitution is unrivalled in Europe; and the collection of mineralogical curioſities ſurpaſſes whatever can be conceived.

11*th*, The ſociety of natural hiſtory in Paris, deſervedly claſſes among thoſe which have rendered the greateſt ſervices to the cauſe of ſcience ſince the revolution. A lecture of public inſtruction is held every ten days, which is generally given by one of the members, and which is open to all the lovers of natural hiſtory. Premiums are propoſed for diſſertations; one of which, by the late C. Herman, jun. (whoſe early deceaſe was a great loſs to the republic of letters) on the *apterous* claſs of inſects, may be ſaid to conſtitute an epocha in the annals of natural hiſtory. The ſociety has publiſhed a volume of memoirs, in folio, entitled, "*Tranſactions of the Society of Natural Hiſtory*." It has likewiſe erected a ſtatue to the great Linnæus, in the national garden of plants; and, at the period when every public inſtruction was ſuſpended, gave lectures on the different branches of ſcience belonging to its department. Several intelligent and ſkilful navigators, among others thoſe ſent in ſearch of the unfortunate La Pérouſe, as well as thoſe which accompanied Buonaparte on his romantic expedition to Egypt, were members of this ſociety.

This ſtatement of facts relative to the preſent ſtate of public inſtruction, the ſciences, the arts, and the progreſs of national literature in France, has been taken from a miſcellany, of which the principal writers are well acquainted with what is doing in that diſtracted country. They call it a ſublime ſyſtem; and ſeem to conſider the increaſe of the national library, the improvement of the botanic gardens, and the diſcoveries that have been made by the different ſchools or inſtitutes, as furniſhing a demonſtration that the republican government is more favourable to the advancement of ſcience, than the monarchical, whether abſolute or limited. But it ſhould not be forgotten, that this ſyſtem is yet in its infancy; and that in proſecuting new ſchemes, all men, and more eſpecially Frenchmen, are actuated by an enthuſiaſm which gradually cools as their purſuits become familiar. We ſhall therefore venture to predict, that the different ſchools will not diſplay ſuch ardour ſeven years hence as they do at preſent; and that if the republican government continue a dozen of years in France, the progreſs of ſcience in that country will not be more rapid than it was under the monarchy. We muſt remember, too, that the French libraries, muſeums, and picture galleries, have been improved by means which the morals of other governments do not employ—by rapine and robbery.

That ſomething may be learned from this ſyſtem to improve the modes of education in other countries, we admit; and it is for that reaſon that we have inſerted an account of it. But if it contains ſomething worthy of imitation, it contains likewiſe much to be ſhunned. We do not think it conſiſtent with the *rights of man* to *compel* parents to ſend their children to be educated in *particular* ſchools; eſpecially in ſchools where not only religious inſtruction is omitted, but where, there is reaſon to believe, that the profeſſors are at pains to raze all religious impreſſions from the youthful mind. In a nation denying the truth of Chriſtianity, it is not to be ſuppoſed that the Chriſtian religion will be publicly taught; but in a nation of philoſophers, as the French call themſelves, it might have been expected that the laws of religious toleration would have been ſo far regarded, that Chriſtian parents would not have been *compelled* to ſend their children to *antichriſtian* ſchools! But it is not Chriſtianity alone that is neglected in this *ſublime* ſyſtem of education. Though the legiſlative body has ſome time ago decreed that there is a God, there is not in any one of thoſe ſchools the ſmalleſt care taken to inſtruct the republican youth in the principles even of natural religion! We might indeed have looked for it under the title *Metaphyſics*, had not the conſtitution of the National Inſtitute taught us, that French metaphyſics attend to nothing but the analyſis of ſenſations and ideas. Yet the legiſlators might have liſtened on this ſubject to a republican as ſound as themſelves, and who was likewiſe no friend to ſuperſtition. "Nam et Majorum inſtituta tueri ſacris, ceremoniiſque retinendis ſapientis eſt. Non ſolum ad religionem pertinet, ſed etiam ad *civitatis* ſtatum, ut ſine iis, qui ſacris publice præſunt, religioni privatæ ſatisfacere non poſſunt." *Cicero de Nat. Deorum.*

INSURANCE, in law and commerce, though an excellent inſtitution, is not of high antiquity. The oldeſt laws and regulations concerning inſurance, with which the indefatigable Beckmann is acquainted, are the following:

On the 28th of January 1523, five perſons appointed for that purpoſe drew up at Florence ſome articles which are ſtill employed on the exchange at Leghorn. Theſe important regulations, together with the preſcribed form of policies, which may be conſidered as the oldeſt, have been inſerted, in Italian and German, by Magens, in his Treatiſe on Inſurance, average, and bottomry, publiſhed at Hamburgh in 1753.

There is ſtill preſerved a ſhort regulation of the 25th May 1537, by the Emperor Charles V. reſpecting bills of exchange and inſurance, in which the ſtrictly fulfilling only of an agreement of inſurance is commanded.

In the year 1556, Philip II. king of Spain, gave to the Spaniſh merchants certain regulations reſpecting inſurance, which are inſerted by Magens, with a German tranſlation, in his work before-mentioned. They contain ſome forms of policies on ſhips going to the Indies.

In the year 1598, the *Kamer von aſſurantie*, chamber of inſurance, was eſtabliſhed at Amſterdam. An account of the firſt regulations of this inſurance office may be ſeen in Pontanus's Hiſtory of the city of Amſterdam, and in other works.

In the year 1600, regulations reſpecting inſurance were formed by the city of Middelburg in Zealand.

It appears that the firſt regulations reſpecting inſurances in England, which may be ſeen in *Anderſon's Hiſtory of Commerce*, were made in the year 1601. We find by them, that inſurers had before that period conducted themſelves in ſuch a manner, that the utmoſt confidence was repoſed in their honeſty, and that on this account few or no diſputes had ariſen.

Of the various policies for inſurance in England, a pretty accurate account will be found in the *Encyclopædia*; but there is one of them, of which our account muſt be acknowledged to be now defective. This is,

INSURANCE on lives; which is a policy that has greatly increaſed, in conſequence of its utility being more generally underſtood. Of the two offices for life aſſurances, noticed in that article, the former, entitled the *Amicable Society*, has extended the number of its ſhares to 4000; but, as we have already obſerved, the nature of the inſtitution is too limited to become of general importance. The latter, entitled, the *Society for Equitable Aſſurances on Lives and Survivorſhip*, is undoubtedly one of the moſt important inſtitutions of the kind, as will appear by the following account, with which we have been favoured by an obliging correſpondent, and upon the accuracy of which our readers may depend:

The members of the equitable ſociety, finding, in June 1777, that their affairs were in a flouriſhing ſituation, reſolved to reduce their annual premiums one tenth; and in 1782, adopted new tables agreeable to the probabilities of life at Northampton, in lieu of thoſe they had hitherto uſed, formed from the London bills of mortality. But though it was evident, that the new tables were much better adapted for aſſuring promiſcuouſly perſons reſiding in the country, or in large towns, it was thought proper, for greater ſecurity, to make an addition of 15 per cent. to the real value of the aſſurances, as computed from the table of mortality at Northampton; and with the view of making an adequate compenſation to the aſſured for their former payments, which had been ſo much higher than would be required by the new rates, an addition was made to their claims of L.1 : 10s. per cent. for every premium they had paid. The conſequence of theſe meaſures proved highly favourable to the ſociety; for its buſineſs increaſed ſo faſt, that in 1785 it was nearly doubled; the ſums aſſured amounting to upwards of L.720,000. At this period, the favourable reſult of a minute and very laborious inveſtigation of the ſtate of the ſociety, induced them to take off the 15 per cent. charged upon the premiums in 1782, and make a further addition to the claims of L.1 per cent. for every payment made prior to the 1ſt January 1786. A ſtill greater increaſe of ſucceſsful buſineſs determined them, in 1791, to make another addition of L.1 per cent. to the claims; and in the following year, a further addition of L.2 per cent.; by which the claims upon aſſurances of the year 1770 were more than doubled; and thoſe of an earlier date increaſed in a ſtill higher proportion. By theſe advantages to its members, and the honourable and truly equitable manner in which the concerns of the ſociety are tranſacted, the augmentation of their buſineſs has been ſo great, that on the 31ſt December 1794, the ſums aſſured (without including the additions made to them) amounted to upwards of L.3,000,000; and on the 31ſt December 1795, to about L.4,000,000.

The rates of aſſurance, as reduced to their real values in 1786, and according to which the ſociety now tranſact buſineſs, are as follows :

Sum Aſſured £. 100.

Age.	*One Year.*			*Seven Years.*			*Whole Life.*		
15	£. 0	17	11	£. 1	2	11	£. 1	18	7
20	1	7	3	1	9	5	2	3	7
25	1	10	7	1	12	1	2	8	1
30	1	13	3	1	14	11	2	13	4
35	1	16	4	1	18	10	2	19	10
40	2	0	8	2	4	1	3	7	11
45	2	6	8	2	10	10	3	17	11
50	2	15	1	3	0	8	4	10	10
55	3	5	0	3	12	0	5	6	4
60	3	18	1	4	7	1	6	7	4
65	4	15	2	5	10	10	7	16	9

The other offices in London for the aſſurance of lives are, the *Royal Exchange Aſſurance*, the *Weſtminſter Society*, and the *Pelican Life Office*.

The corporation of the *Royal Exchange Aſſurance* was empowered to aſſure lives by its ſecond charter, dated 29th April 1721; but the original object of the company being ſea aſſurances, and the true principles of aſſuring on lives being at that time little underſtood, this branch of their buſineſs was at firſt comparatively ſmall : they generally required a premium of five or ſix guineas per cent. without any regard to the age ; and the aſſurance, which was uſually for a ſmall ſum, was ſeldom for a greater term than one year. In this manner they continued to aſſure upon lives till the end of the year 1783, when the increaſing importance of this part of their buſineſs, which they had ſome years felt, induced them to adopt a regular table of rates of aſſurance, according to the Northampton regiſters of mortality, but with a greater addition to the real values than had been made by the "Society for Equitable Aſſurances on Lives and Survivorſhip." This was thought proper, from the conſideration that the aſſurers with the Royal Exchange company are not in any caſe liable to a call upon them beyond the premium they engage to pay, and have the ſecurity of the capital and funds of the company ariſing from the other branches of their buſineſs ; however, the company, finding themſelves ſucceſsful in their life aſſurances, determined, in 1790, to reduce their premiums ; and in 1797 made a ſtill greater reduction, by which they are brought very near to thoſe above ſtated. This company have agents in all the principal towns of Great Britain, and are impowered to aſſure lives in all parts of the world.

The *Weſtminſter Society* was eſtabliſhed in 1792, for aſſuring lives, and granting annuities. Their terms are nearly the ſame as thoſe of the Royal Exchange Aſſurance ; but not being a corporate body, every perſon aſſuring ſigns a declaration, that he accepts the joint ſtock of the ſociety as his ſecurity.

The *Pelican Life Office* was inſtituted in 1797, by ſome of the principal proprietors of the Phœnix Fire Office. The rates which they have publiſhed vary conſiderably from thoſe of the other offices ; but whether they are founded on more juſt principles, time and experience muſt determine. This ſociety alſo makes a new ſpecies of aſſurance, by way of endowment for daughters, or for children generally, when they ſhall attain the age of twenty-one years.

INTEGRAL CALCULUS, in the new analyſis, is the reverſe of the differential calculus, and is the finding of the integral from a given differential ; being ſimilar to the inverſe method of fluxions, or the finding the fluent to a given fluxion. See FLUXIONS, *Encycl.*

INTEREST, is the allowance given for the uſe of money by the borrower to the lender, and is either *ſimple* or *compound*. The method of computing both intereſts is explained in the article ALGEBRA, (*Encycl.*) page 427, &c. ; and the ſubject of ſimple intereſt is again reſumed in ARITHMETIC, (*Encycl.*) n° 20. The application of the canons for the computation of compound intereſt, to the value of annuities, the only caſe in which that intereſt is allowed by the laws of this country, may be ſeen in the articles ANNUITY and SURVIVORSHIP, (*Encycl.*) ; where various tables are given to facilitate the different computations. Some of our readers, however, have expreſſed a wiſh to have the rule for computing compound intereſt ſo ſtated, as to be underſtood by thoſe who are unacquainted with algebraic ſymbols. Their wiſh may be eaſily gratified.

The general formula $S = p\,R^t$ anſwers for the amount of any ſum, whether the intereſt be payable yearly, half-yearly, quarterly, or daily. Let R denote the amount of one pound for the firſt payment, and t the number of payments, the unit being from the commencement till the firſt payment is due ; alſo, let l denote the logarithm of any quantity before which it is wrote; then, from the known property of logarithms, the theorem may be expreſſed thus, $l.\,S = l.\,p + l.\,R \times t$.

Required the amount of L. 250 at 5 per cent. compound intereſt, for 12 years, reckoning the intereſt payable yearly, half-yearly, quarterly, and daily ?

Yearly. $p = 250,\ R = 1{\cdot}05,\ t = 12.$

$$\begin{array}{r}
0{\cdot}0211893 = l.\,R \\
12 \\
\hline
{\cdot}2542716 = l.\,R \times t. \\
2{\cdot}3979400 = l.\,p. \\
\hline
\end{array}$$

$$l.\,S = 2{\cdot}6522116 - \text{L. } 448 : 19 : 3\tfrac{1}{4} = \text{Amount.}$$

$$\begin{array}{r}
250 \\
\hline
198 : 19 : 3\tfrac{1}{4} = \text{Comp. intereſt.}
\end{array}$$

Half yearly, $p = 250,\ R = 1{\cdot}025,\ t = 24.$

$$\begin{array}{r}
0{\cdot}0107239 = l.\,R. \\
24 \\

205 : 11 : $3\frac{1}{2}$ = Intereſt.

INTERPOLATION, in the modern algebra, is uſed for finding an intermediate term of a ſeries, its place in the ſeries being given. See ALGEBRA and SERIES, *Encycl.*

The method of interpolation was firſt invented by Mr Briggs, and applied by him to the calculation of logarithms, &c. in his Arithmetica Logarithmica, and his Trigonometria Britannica; where he explains, and fully applies, the method of interpolation by differences. His principles were followed by Reginal and Mouton in France, and by Cotes and others in England. Wallis made uſe of the method of interpolation in various parts of his works; as his arithmetic of infinites, and his algebra, for quadratures, &c. The ſame was alſo happily applied by Newton in various ways: by it he inveſtigated his binomial theorem, and quadratures of the circle, ellipſe, and hyperbola. See Wallis's Algebra, chap. 85. &c. Newton alſo, in lemma 5. lib. 3. Princip. gave a moſt elegant ſolution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the ſubſequent propoſition, applied the ſolution of this problem to that of finding, from certain obſerved places of a comet, its place at any given intermediate time. And Dr Waring, who adds, that a ſolution ſtill more elegant, on ſome accounts, has been ſince diſcovered by Meſſ. Nichol and Stirling, has alſo reſolved the ſame problem, and rendered it more general, without having recourſe to finding the ſucceſſive differences. *Philoſ. Tranſ.* vol. 69. part 1. art. 7.

INTERSCENDENT, in algebra, is applied to quantities, when the exponents of their powers are radical quantities. Thus $x^{\sqrt{2}}$, $x^{\sqrt{a}}$, &c. are interſcendent quantities.

INTERSTELLAR, a word uſed by ſome authors to expreſs thoſe parts of the univerſe that are without and beyond the limits of our ſolar ſyſtem.

INTRADOS, the interior and lower ſide, or curve, of the arch of a bridge, &c. In contradiſtinction from the extrados, or exterior curve, or line on the upper ſide of the arch. See ARCH in this *Suppl.*

INVOLUTION and EVOLUTION, are terms introduced into geometry by the celebrated Mr Huyghens, to expreſs a particular manner of deſcribing curvilineal ſpaces which occurred to him when occupied in the improvement of his noble invention of pendulum clocks. Although he was even aſtoniſhed at the accuracy of their motion, and they ſoon ſuperſeded all balance clocks, he knew that the wide vibrations were ſomewhat ſlower than the narrow ones, and that a circle was not ſufficiently incurvated at the ſides to render all the vibrations iſochronous. The proper curve for this purpoſe became an intereſting object. By a moſt accurate inveſtigation of the motions of heavy bodies in curved paths, he diſcovered that the cycloid was the line required. Lord Brouncker had diſcovered the ſame thing, as alſo Dr Wallis. But we do not imagine that Huyghens knew of this; at any rate, he has the full claim to the diſcovery of the way of making a pendulum oſcillate in a cycloidal arch. It eaſily occurred to him, that if the thread by which the pendulum hangs be ſuſpended between two curved cheeks, it would alternately lap on each of them in its vibrations, and would thus be raiſed out of the circle which it deſcribes when ſuſpended from a point. But the difficulty was to find the proper form of thoſe cheeks. Mr Huyghens was a moſt excellent geometer, and was poſſeſſed of methods unknown to others, by which he got over almoſt every difficulty. In the preſent caſe there was fortunately no difficulty, the means of ſolution offering themſelves almoſt without thought. He almoſt immediately diſcovered that the curve in queſtion was the ſame cycloid. That is, he found, that while a thread unwinds from an arch of a cycloid, beginning at the vertex, its extremity deſcribes the complementary arch of an equal cycloid. Thus he added to this curve, already ſo remarkable for its geometrical properties, another no leſs curious, and infinitely exceeding all the others in importance.

The ſteps by which this property was diſcovered are ſuch direct emanations from general principles, that they immediately excited the mind of Mr Huyghens, which delighted in geometry, to proſecute this method of deſcribing or transforming curve lines by evolution. It is ſurpriſing that it had not ere this time occurred to the ancient geometers of the laſt century, and particularly to Dr Barrow, who ſeems to have racked his fancy for almoſt every kind of motion by which curve lines can be generated. Evolution of a thread from a curve is a much more obvious and conceivable geneſis than that of the cycloid invented by Merſennus, or that of the conchoid by Nicomedes, or thoſe of the conic ſections by Vieta. But except ſome vague expreſſions by Ptolemy and Gaſſendus, about deſcribing ſpirals

Involution.

by a thread unlapped from a cylinder, we do not recollect any thing of the kind among the writings of the mathematicians; and it is to Huyghens alone that we are indebted for this very beautiful and important branch of geometry. It well deſerves both of theſe epithets. The theorems which conſtitute the doctrines of evolution are remarkable for their perſpicuity and neatneſs. Nothing has ſo much contributed to give us clear notions of a very delicate ſubject of mathematical diſcuſſion, namely curvature, and the meaſure and variations of curvature. It had become the ſubject of very keen debate; and the notions entertained of it were by no means diſtinct. But nothing can give ſuch a preciſe conception of the difference of curvature, in the different parts of a cycloid or other curve, as the beholding its deſcription by a radius continually varying in length. This doctrine is peculiarly valuable to the ſpeculator in the higher mechanics. The intenſity of a deflecting force is eſtimated by the curvature which it induces on any rectilineal motion; and the variations of this intenſity, which is the characteriſtic of the force, or what we call its nature, is inferred from the variations of this curvature. The evolution and involution of curve lines have therefore great claim to our attention. But a Work like ours can only propoſe to exhibit an outline of the ſubject; and we muſt refer our readers to thoſe eminent authors who have treated it in detail. Varignon, in the Memoirs of the French Academy for 1706, has been at immenſe pains to preſent it in every form; James Bernoulli has alſo treated the ſubject in a very general and ſyſtematic manner. Some account is given of it in every treatiſe of fluxions. We recommend the original work of Mr Huyghens in particular; and do not heſitate to ſay, that it is the fineſt ſpecimen (of its extent) of phyſico-mathematical diſcuſſion that ever has appeared. Huyghens was the moſt elegant of all modern geometers; and both in the geometrical and phyſical part of this work, *De Horologio Oſcillatorio*, he has preſerved the utmoſt rigour of demonſtration, without taking one ſtep in which Euclid or Apollonius would not have followed him.

> ———— *juvat integros accedere fontes*
> *Atque haurire.*

Such authors form the taſte of the young mathematician, and help to preſerve him from the almoſt mechanical procedure of the expert ſymbolical analyſt, who arrives at his concluſion without knowing how he gets thither, or having any notions at all of the magnitudes of which he is treating.

There are two principal problems in this doctrine.

I. To aſcertain the nature of the figure generated by the evolution of a given curve.

II. To determine the nature of the curve by whoſe evolution a given curve may be generated.—We ſhall conſider each of theſe in order, and then take the opportunity which this ſubject gives of explaining a little the abſtruſe nature of curvature, and its meaſures and variations, and take notice of the opinions of mathematicians about the preciſe nature of the angle of contact.

Plate XXXI.

The curve line ABCDEF (fig. 1.) may be conſidered as the edge of a crooked ruler or mould; a thread may be ſuppoſed attached to it at F, and then lapped along it from F to A. If the thread be now led away from A, keeping it always tight, it is plain that the extremity A muſt deſcribe a curve line A*bcdef*, and that the detached parts of the thread will always be tangents to the curve ABCDEF. In like manner will the curve line F*d′c′b′*A′ be deſcribed by keeping the thread faſt at A, and unlapping it from the other end of the mould

This proceſs was called by Mr Huyghens the EVOLUTION of the curve ADF. ADF is called the EVOLUTE. A*df* was named by him the CURVE BY EVOLUTION. It has been ſince more briefly termed the EVOLUTRIX, or unlapper. It has alſo been called the INVOLUTE; becauſe, by performing the proceſs in the oppoſite direction *fd*A, the thread is lapped up on the mould, and the whole ſpace ADF*fd*A is folded up like a fan. The detached parts C*c*, D*d*, or C*c′*, D*d′*, &c. of the thread, are called RADII OF THE EVOLUTE; perhaps with ſome impropriety, becauſe they rather reſemble the momentary radii of the evolutrix. We may name them the EVOLVED RADII. The beginning A of evolution may be conſidered as the vertex of the curves, and the ends F and *f* may be called the TERMS.

There is another way in which this deſcription of curve lines may be conceived. Inſtead of a thread F*f* gradually lapped up on the mould, we may conceive F*f* to be a ſtraight edged ruler applied to the mould, and gradually rolled along it without ſliding, ſo as to touch it in ſucceſſion in all its points. It is evident, that by this proceſs the point *f* will deſcribe the curve *fd*A, while the point F deſcribes the other curve F*da*. This way of conceiving it gives a great extenſion to the doctrine, and homologates it with that geneſis of curve lines by which cycloids of all kinds are deſcribed, and which we may diſtinguiſh by the name of PROVOLUTION. For it is plain, that the relative motions of the points A and *b* are the ſame, whether the ruler *b*B*b′* roll on the mould ABF, or the mould roll on the ruler: but there will be a great difference in the form of the line traced by the deſcribing point, if we ſuppoſe the plane on which it is traced to be attached to the rolling figure. Thus, when a circle rolls on a ſtraight line, a point in its circumference traces a cycloid on the plane attached to the ſtraight line, while the point of the ſtraight line which quitted the circle deſcribes on the plane attached to the circle another line; namely, the involute of the circle. This mode of deſcription allows us to employ a curved ruler in place of the ſtraight one *b*B*b′*; and thus gives a vaſt extenſion to the theory. But at preſent we ſhall confine ourſelves to the employment of the ſtraight line *b*B*b′*, only keeping in mind, that there is an intimate connection between the lines of evolution and of provolution.

By the deſcription now given of this proceſs of evolution and involution, it is plain,

1. That the evolution is always made from the convex ſide of the evolute.

2. That the evolved radii B*b*, C*c*, D*d*, &c. are reſpectively equal to the arches BA, CA, DA, &c. of the evolute which they have quitted; and that *b*B*b′*, *c*C*c′*, *d*D*d*, &c. are always equal to the whole arch ADF.

3. That any point B of the lapped up thread deſcribes during its evolution a curve line B$\gamma\delta\varepsilon\phi$ parallel to *bcdef*; becauſe theſe curves are always equidiſtant from each other.

4. That if the thread extend beyond the mould as a tangent to it, the extremity α will deſcribe a parallel or equidiſtant

equidiſtant curve $\alpha\beta\gamma\delta\epsilon\varphi$, lying without A$bcdef$. From this it appears that B$\gamma\delta\epsilon\varphi$ is the complete evolutrix of FEDCB, while $bdcef$ is the evolutrix of that arch, and the added tangent Bb. In like manner, the lapped up thread ADF, with the added part Fφ', deſcribes the evolutrix $\varphi'\epsilon'\delta'\gamma'\beta'$ A′.

5. If from any point C of the evolute there be drawn lines Cb, Cc, Cd, Ce, &c. to the evolutrix, thoſe which are more remote from the vertex are greater than thoſe which are nearer. Draw Bb, cC, dD, eE, touching the evolute. Cb is leſs than CB + Bb; that is (2), than Cc. Again, DC + Cc is equal to Dd, which is leſs than DC + Cd. Therefore Cc is leſs than Cd. Now let Ce cut Dd in r. Then er + rDE is greater than eE. But eE is equal to dr + rDE. Therefore er is greater than dr; and er + rC is greater than dr + rC, which is greater than cC. Therefore eC is greater than cC.

6. Hence it follows, that a circle deſcribed round any point of the evolute, with a radius reaching to any point of the evolutrix, will cut the evolutrix in that point, and be wholly within it on the ſide remote from the vertex, and without it on the ſide next the vertex.

7. The evolved radius cuts every arch of the evolutrix perpendicularly, or a right line drawn through the interſection at right angles touches the evolutrix in that point. Through any point d draw the line mdt at right angles to dD. The part of it md next to the vertex is wholly without the curve, becauſe it is without the circle deſcribed round the centre D; and this circle is without the evolutrix on that ſide of d which is next the vertex (6). Any point t on the other ſide of d is alſo without the curve. For let teE be another evolved radius, cutting Dd in n: then nd is leſs than nt, becauſe ndt is a right angle by conſtruction; and therefore ntd is acute. But becauſe En + nD are greater than ED, En + nd are greater than ED + Dd, that is, than Ee, and nd is greater than ne. Therefore, ſince it is leſs than nt, it follows that ne is much leſs than nt, and t lies without the curve. Therefore the whole line mdt is without the curve, except in the point d. It therefore touches the curve in d, and the radius Dd cuts it at right angles in that point. By the ſame reaſoning, it is demonſtrated, that all the curves Abdf, $\alpha\beta\delta\varphi$, A′$b'd'f'$, $\alpha'\beta'\delta'\varphi'$, are cut perpendicularly by the tangents to the evolute. Alſo all theſe curves interſect the evolute at right angles in their vertexes

It follows from this propoſition, that from every point, ſuch as s, or i, or o, &c. in the ſpace AOF comprehended by the evolute and its extreme tangents AO, FO, two perpendiculars may be drawn to the evolutrix Adf; and that from any point in the ſpace within the angle Aof only one perpendicular can be drawn; and that no perpendicular can be drawn from any point on the other ſide of ADF. Apollonius had obſerved theſe circumſtances in the conic ſections, but had not thought of marking the boundary formed by the evolute ADF. Had he noticed this, he would certainly have diſcovered the whole theory of evolution, and its importance in ſpeculative geometry.

It alſo follows from this propoſition, that if a curve A$bcdef$ is cut by the tangents of ABCDEF at right angles in every point, it will be deſcribed by the evolution of that curve: For if the evolutrix, whoſe vertex is A, be really deſcribed, it will coincide with Abcd in A, and have the ſame tangent; it therefore does not deviate from it, otherwiſe their tangents would ſeparate, and would not both be at right angles with the lines touching the evolute. They muſt therefore coincide throughout.

8. The arches bcd and $\beta\gamma\delta$, intercepted by the ſame radii Bb and Dd, may be called *concentric*; and the angles contained between the tangents drawn thro' their extremities are equal. Thus the angle $\lambda\pi o$ is equal to lpo: but although equidiſtant, parallel, and containing the ſame angle between their tangents and between their radii, they are not ſimilar. Thus, the arch $\alpha\beta$ has a curvature at α that is the ſame with that of any circle whoſe radius is equal to Aα; but the curvature at A is incomparable with it, and unmeaſurable. The ſame may be ſaid of the curvatures at β and at B.

9. If a circle udz be deſcribed round the centre D with the radius Dd, it both touches and cuts the evolutrix in the point d, and no circle can be deſcribed touching the curve in that point, and paſſing between it and the circle udz: For ſince it touches the curve in d, its centre muſt be ſomewhere in the line dD perpendicular to mdt. It cannot be in any point n more remote from d than D is; for it would paſs without the arch du, and be more remote than du from the arch dc of the evolutrix. On the other ſide, it would indeed paſs without the arch dz, which lies within the arch de of the evolutrix: but it would alſo paſs without the curve. For it has been already demonſtrated (7) that nd is greater than ne; and the curve would lie between it and the circle dz.

Thus it appears, that a circle deſcribed with the evolved radius approaches nearer to the curve, or touches it more cloſely, than any other circle; all other circles either interſect it in meaſurable angles, or are within or without the curve on both ſides of the point of contact. This circle udz has therefore the ſame curvature with the curve in the point of contact and coaleſcence. It is the EQUICURVE CIRCLE, the circle of equal curvature, the OSCULATING CIRCLE (a name given it by Leibnitz). The evolved radius of the evolute is the RADIUS OF CURVATURE of the evolutrix, and the point of the evolute is the CENTRE OF CURVATURE at the point of contact with the evolutrix. The evolute is the geometrical locus of all the centres of curvature of the evolutrix.

This is the moſt important circumſtance of the whole doctrine of the involution and evolution of curve lines. It is aſſumed as a ſelf evident truth by the precipitant writers of elements. It is indeed very like truth: For the extremity of the thread is a momentary radius during the proceſs of evolution; and any minute arch of the evolute nearer the vertex muſt be conceived as more incurvated than the arch at the point of contact, becauſe deſcribed with ſhorter radii: for the ſame reaſon, all beyond the contact muſt be leſs incurvated, by reaſon of the greater radii. The curvature at the contact muſt be neither greater nor leſs than that of the circle. But we thought it better to follow the example of Huyghens, and to eſtabliſh this leading propoſition on the ſtricteſt geometrical reaſoning, acknowledging the ſingular obligation which mathematicians are under to him for giving them ſo palpable a method of fixing their notions on this ſubject. When the evolute of a curve is given, we have not only a clear view of the geneſis of the curve, with a neat and accurate mechanical method of deſcribing it, but alſo a diſtinct comprehenſion of the whole curvature, and a connected view of its gradual variations.

We ſpeak of curvature that is greater and leſſer; and every perſon has a general knowledge or conception of the difference, and will ſay, that an ellipſis is more curve at the extremities of the tranſverſe axis than any where elſe. But before we can inſtitute a compariſon between them with a preciſion that leads to any thing, we muſt agree about a meaſure of curvature, and ſay what it is we mean by a double or a triple curvature. Now there are two ways in which we may conſider curvature, or a want of rectitude: We may call that a double curvature which, in a given ſpace, carries us twice as far from the ſtraight line; or we may call that a double curvature by which we deviate twice as much from the ſame direction. Both of theſe meaſures have been adopted; and if we would rigidly adhere to them, there would be no room for complaint: but mathematicians have not been ſteady in this reſpect, and by mixing and confounding theſe meaſures, have frequently puzzled their readers. All agree, however, in their firſt and ſimple meaſures of curvature, and ſay, that the curvature of an arch of a circle is as the arch directly, and as the radius inverſely. This is plainly meaſuring curvature by the deflection from the firſt direction. In an arch of an inch long, there is twice as much deflection from the firſt direction when the radius of the circle is of half the length. If the radius is about 57¼th inches, an arch of one inch in length produces a final direction one degree different from the firſt. If the radius is 114½ inches, the deviation is but half of a degree. The linear deflection from the ſtraight path is alſo one half. In the caſe of circles, therefore, both meaſures agree: but in by far the greateſt number of caſes they may differ exceedingly, and the change of direction may be greateſt when the linear deviation is leaſt. Flexure, or change of direction, is, in general, the moſt ſenſible and the moſt important character of curvature, and is underſtood to be its criterion in all caſes. But our proceſſes for diſcovering its quantity are generally by firſt diſcovering the linear deviation; and, in many caſes, particularly in our philoſophical inquiries, this linear deviation is our principal object. Hence it has happened, that the mathematician has frequently ſtopped ſhort at this reſult, and has adapted his theorems chiefly to this determination. Theſe differences of object have cauſed great confuſion in the methods of conſidering curvature, and led to many diſputes about its nature, and about the angle of contact; to which diſputes there will be no end, till mathematicians have agreed in their manner of expreſſing the meaſures of curvature. At preſent we abide by the meaſure already given, and we mean to expreſs by curvature or flexure the change of direction.

This being premiſed, we obſerve, that the curvature of all theſe curves of evolution where they ſeparate from their evolutes, is incomparable with the curvature in any other place. In this point the radius has no magnitude; and therefore the curvature is ſaid to be infinitely great. On the other hand, if the evolved curve has an aſſymptote, the curvature of the evolutrix of the adjacent branch is ſaid to be infinitely ſmall. Theſe expreſſions becoming familiar, have occaſioned ſome very intricate queſtions and erroneous notions. There can be little doubt of their impropriety: For when we ſay, that the curvature at A is infinitely greater than at α, we do not recollect that the flexure of the whole arch A *b* is equal to that of the whole arch α β, and the flexure at A muſt either make a part of the whole flexure, or it muſt be ſomething diſparate.

The evolutrix A *b c d f* (fig. 2.) of the common equilateral hyperbola exhibits every poſſible magnitude of curvature in a very ſmall ſpace. At the vertex A of the hyperbola it is perpendicular to the curve; and therefore has the tranſverſe axis A φ A″ for its tangent. The curvature of the evolutrix at A is called infinitely great. As the thread unlaps from the branch ABC, its extremity deſcribes A *b c*. It is plain, that the evolutrix muſt cut the aſſymptote φ H at right angles in ſome point G, where the curvature will be what is called infinitely ſmall; becauſe the centre of curvature has removed to an infinite diſtance along the branch AF of the hyperbola. This evolutrix may be continued to the vertex of the hyperbola on the other ſide of the aſſymptote, by cauſing the thread to lap upon it, in the ſame way that Mr Huyghens completed his cycloidal oſcillation. Or we may form another evolutrix α β γ δ φ γ′ δ′ β′ A″, by lengthening the thread from G to φ, the centre of the hyperbola, and ſuppoſing that, as ſoon as the curve A δ φ is completed, by unlapping the thread from the branch ABC, another thread laps upon the hyperbola A″ F″. This laſt is conſidered as a more geometrical evolution than the other: For the mathematicians, extending the doctrine of evolution beyond Mr Huyghens's reſtriction to curves which had their convexity turned one way, have agreed to conſider as one continued evolution whatever will complete the curve expreſſed by one equation. Now the ſame equation expreſſes both the curves AF and A″F″, which occupy the ſame axis AA″. The cycloid employed by Huyghens is, in like manner, but one continuous curve, deſcribed by the continued provolution of the circle along the ſtraight line, although it appears as two branches of a *repeated* curve. We ſhall meet with many inſtances of this ſeemingly compounded evolution when treating of the ſecond queſtion.

Since the arch A *b d* G contains every magnitude of curvature, it appears that every kind of curvature may be produced by evolution. We can have no conception of a flexure that is greater than what we ſee at A, or leſs than what we ſee at G; yet there are caſes which ſeem to ſhew the contrary, and are familiarly ſaid, by the greateſt mathematicians, to exhibit curvatures infinitely ſmaller ſtill. Thus, let ABC (fig. 3.) be a conical parabola, whoſe parameter is AP. Let AEF be a cubical parabola, whoſe parameter is AQ. If we make AQ to AD as the cube of AP to the cube of AQ, the two parabolas will interſect each other in the ordinate DB. For, making AP $= p$, and AQ $= q$, and calling the ordinate of the conic parabola y, that of the cubic parabola z, and the indeterminate abſciſſa AD x, we have

$$p^3 : q^3 = q : x, = q^3 : z^3, \text{ and } p : q = q : z;$$

but $q : p = q : p$; therefore, by compoſition,

$$p^2 : q^2 = q^2 : p\,x = q^2 : y^2, \text{ and } p : q = q : y;$$

therefore $z = y$, and the parabolas interſect in B.

Now, becauſe in all parabolas the ordinates drawn at the extremity of the parameters are equal to the parameters,

meters, the interſections q and p will be in a line A qp, which makes half a right angle with the axis AP. Therefore, when AQ is greater than AP, the point q is without the conical parabola, and the whole arch of the cubical parabola cut off by the ordinate DB is alſo without it: but when AQ is leſs than AP, q is within the conical parabola, as is alſo the arch q B. Therefore the remaining arch BEA is without it, and is therefore leſs incurvated at A. An endleſs number of conical parabolas of ſmaller curvature may be drawn by enlarging AP; yet there will ſtill be an arch AEB of the cubical parabola which is without it, and therefore leſs incurvated. Therefore the curvature of a cubical parabola is leſs than that of any conical parabola: It is ſaid to be infinitely leſs, becauſe an infinity of cubical parabolas of *ſmaller curvature* than AEB may be drawn by enlarging AQ.

It may be demonſtrated in the ſame manner, that a paraboloid, whoſe ordinates are in the ſubbiquadrate ratio of the abſciſſæ, has an infinitely ſmaller curvature at the vertex than the cubical parabola. And the curvature of the paraboloid of the next degree is infinitely leſs than this; and ſo on continually. Nay, Sir Iſaac Newton, who firſt took notice of this remarkable circumſtance, demonſtrates the ſame thing of an endleſs ſucceſſion of paraboloids interpoſed between any two degrees of this ſeries. *Neque novit* (ſays he) *natura limitem.*

If this be the caſe, all curves cannot be deſcribed by evolution; for we have no conception of a radius of curvature that is greater than a line without limit. The theory of curvilineal motions delivered in the article DYNAMICS muſt be imperfect, or there muſt be curve lines which bodies cannot deſcribe by any powers of nature. The theory there delivered profeſſes to teach how a body can be made to deſcribe the cubical parabola, and many other curves which have theſe infiniteſimal curvatures; and yet its demonſtrations employ the radius of curvature, and cannot proceed without it. We profeſs ourſelves obliged to an attentive reader (who has not favoured us with his name) for making this obſervation. It merits attention.

There muſt be ſome paralogiſm or miſconception in all this language of the mathematicians. It does not neceſſarily follow from the arch AEB lying without the arch AIB, that it is leſs incurvated at A; it may be more incurvated between A and B. Accordingly we ſee, that the tangent BT of the conical parabola is leſs inclined to the common tangent AV than the tangent B t of the cubical parabola is; and therefore the flexure of the whole arch AEB is greater than that of the whole arch AIB; and we ſhall ſee afterwards, that there is a part of AEB that is more incurvated than any part of AIB. There is nothing correſponding to this unmeaning and inconceivable ſucceſſion of ſerieſes of magnitudes of one kind, each of which contains an endleſs variety of individuals, and the greateſt of one ſeries infinitely leſs than the ſmalleſt of the next, &c.; there is nothing like this demonſtrated by all our arguments. In none of theſe do we ever treat of the curvature at A, but of a curvature which is *not* at A. At A we have none of the lines which are indiſpenſably neceſſary for the demonſtration. Beſides, in the very ſame manner that we can deſcribe a cubical parabola, and prove that it has an arch lying without the conical parabola, we can deſcribe a circle, and demonſtrate that it has alſo an arch lying without the parabola. Theſe infiniteſimal curvatures, therefore, are not warranted by our arguments, nor does it yet appear that there are curves which cannot be deſcribed by evolution. We are always puzzled when we ſpeak of infinites and infiniteſimals as of ſomething preciſe and determinate; whereas the very denomination precludes all determination. We take the diſtinguiſhing circumſtance of thoſe different orders for a thing clearly underſtood; for we build much on the diſtinction. We conceive the curvature of the cubical parabola as verging on that of the common parabola, and the one ſeries of curvatures as beginning where the other ends. But Newton has ſhewn, that between theſe two ſerieſes an endleſs number of ſimilar ſerieſes may be interpoſed. The very names given to the curvature at the extremities of the hyperbolic evolutrix have no conceptions annexed to them. At the vertex of the hyperbola there is no line, and at the interſection with the aſſymptote there is no curvature. Theſe unguarded expreſſions, therefore, ſhould not make us doubt whether all curves may be deſcribed by evolution. If a line be incurvated, it is not ſtraight. If ſo, two perpendiculars to it muſt diverge on one ſide, and muſt converge and meet on the other in ſome point. This point will lie between two other points, in which the two perpendiculars touch that curve by the evolution, of which the given arch of the curve may be deſcribed. Finally (which ſhould decide the queſtion), we ſhall ſee by and bye, that the cubic, and all higher orders of paraboloids, may be ſo deſcribed by evolution from curves having aſſymptotic branches of determinable forms.

Such are the general affections of lines generated by evolution. They are not, properly ſpeaking, peculiar properties; for the evolutrixes may be any curve lines whatever. They only ſerve to mark the mutual relations of the evolutes with their evolutrixes, and enable us to conſtruct the one, and to diſcover its properties by means of our knowledge of the other. We proceed to ſhew how the properties of the evolutrix may be determined by our knowledge of the evolute.

This problem will not long occupy attention, being much limited by the conditions. One of the firſt is, that the length of the thread evolved muſt be known in every poſition: Therefore the length of the evolved arch muſt, in like manner, be known; and this, not only *in toto*, but every portion of it. Now this is not univerſally, or even generally the caſe. The length of a circular, parabolic, hyperbolic, arch has not yet been determined by any finite equation, or geometrical conſtruction. Therefore their evolutrixes cannot be determined otherwiſe than by approximation, or by compariſon with other magnitudes equally undetermined. Yet it ſometimes happens, that a curve is diſcovered to evolve into another of known properties, although we have not previouſly diſcovered the length of the evolved arch. Such a diſcovery evidently brings along with it the rectification of the evolute. Of this we have an inſtance in the very evolution which gave occaſion to the whole of this doctrine; namely, that of the cycloid; which we ſhall therefore take as our firſt example.

Let ABC (fig. 5.) be a cycloid, of which AD is the axis, and AHD the generating circle, and AG a tangent to the cycloid at A, and equal to DC. Let

BKE touch the cycloid in B, and cut AG in K. It is required to find the ſituation of that point of the line BE which had unfolded from A?

Draw BH parallel to the baſe DC of the cycloid, cutting the generating circle in H, and join HA. Deſcribe a circle KEM equal to the generating circle AHD, touching AG in K, and cutting BK in ſome point E. It is known, by the properties of the cycloid, that BK is equal and parallel to HA, and that BH is equal to the arch A *h* H. Becauſe the circles AHD and KEM are equal, and the angles HAK and AKE are equal, the chords AH and KE cut off equal arches, and are themſelves equal. Becauſe BHAK is a parallelogram, AK is equal to HB; that is, to the arch A *h* H, that is, to the arch K *m* E. But if the circle KEM had been placed on A, and had rolled from A to K, the arch diſengaged would have been equal to AK, and the point which was in contact with A would now be in E, in the circumference of a cycloid AEF, equal to CBA, having the line AG, equal and parallel to DC, for its baſe, and GF, equal and parallel to DA, for its axis. And if the diameter KM be drawn, and EM be joined, EM touches the cycloid AEF.

Cor. The arch BA of the cycloid is equal to twice the parallel chord HA of the generating circle: For this arch is equal to the evolved line BKE: and it has been ſhewn, that EK is equal to KB, and BE is therefore equal to twice BK, or to twice HA. This property had indeed been demonſtrated before by Sir Chriſtopher Wren, quite independent of the doctrine of evolution; but it is given here as a legitimate reſult of this doctrine, and an example of the uſe which may be made of it. Whenever a curve can be evolved into another which is ſuſceptible of accurate determination, the arch of the evolved curve is determined in length; for it always makes a part of the thread whoſe extremity deſcribes the evolutrix, and its length is found, by taking from the whole length of the thread that part which only touches the curve at its vertex.

This geneſis of the cycloid AEF, by evolution of the cycloid ABC, alſo gives the moſt palpable and ſatisfactory determination of the area of the cycloid. For ſince BE is always parallel to AH, AH will ſweep over the whole ſurface of the ſemicircle AHD, while BE ſweeps over the whole ſpace CBAEF; and ſince BE is always double of the ſimultaneous AH, the ſpace CBAEF is quadruple of the ſemicircle AHD. But the ſpace deſcribed in any moment by BK is alſo one-fourth part of that deſcribed by BE. Therefore the area GAEF is three times the ſemicircle AHD; and the ſpace DHABC is double of it; and the ſpace CBAG is equal to it.

Sir Iſaac Newton has extended this remarkable property of evolving into another curve of the ſame kind to the whole claſs of epicycloids, that is, cycloids formed by a point in the circumference of a circle, while the circle rolls on the circumference of another circle, either on the convex or concave ſide; and he has demonſtrated, that they alſo may all be rectified, and a ſpace aſſigned which is equal to their area (See *Principia.* B. I. prop. 48. &c.). He demonſtrates, that the whole arch is to four times the diameter of the generating circle as the radius of the baſe is to the ſum or difference of thoſe of the baſe and the generating circle. We recommend theſe propoſitions to the attention of the young reader who wiſhes to form a good taſte in mathematical reſearches; he will there ſee the geometrical principles of evolution elegantly exemplified.

We may juſt obſerve, before quitting this claſs of curves, that many writers, even of ſome eminence, in their compilations of elements, give a very faulty proof of the poſition of the tangent of a curve deſcribed by rolling. They ſay, for example, that the tangent of the cycloid at E is perpendicular to KE; becauſe the line KE is, at the moment of deſcription, turning round K as a momentary centre. This, to be ſure, greatly ſhortens inveſtigation; and the inference is a truth, not only when the rolling figure is a circle rolling on a ſtraight line, but even when any one figure rolls on another. Every point of the rolling figure really *begins* to move perpendicularly to the line joining it with the point of contact. But this geneſis of the arch E *e*, by the evolution of the arch B *b*, ſhews that K is by no means the centre of motion, nor HK the radius of curvature. Nor is it, in the caſe of epicycloids, trochoids, and many curves of this kind, a very eaſy matter to find the momentary centre. The circle KEM is both advancing and turning round its centre; and theſe two motions are equal, becauſe the circle does not ſlide but roll, the detached arch being always equal to the portion of the baſe which it quits. Therefore, drawing the tangents E *g*, M *g*, and completing the parallelogram E *f* M *g*, E *f* will repreſent the progreſſive motion of the centre, and E *g* the motion of rotation. EM, the motion compounded of theſe, muſt be perpendicular to the chord EK.

The inveſtigation that we have given of the evolutrix of the cycloid has been ſomewhat peculiar, being that which offered itſelf to Mr Huyghens at the time when he and many other eminent mathematicians were much occupied with the ſingular properties of this curve. It does not ſerve, however, ſo well for exemplifying the general proceſs. For this purpoſe, it is proper to avail ourſelves of all that we know of the cycloid, and particularly the equality of its arch BA to the double of the parallel chord HA. This being known, nothing can be more ſimple than the determination of the evolutrix, either by availing ourſelves of every property of the cycloid, or by adhering to the general proceſs of referring every point to an abſciſſa by means of perpendicular ordinates. In the firſt method, knowing that BE is double of BK, and therefore KE equal to HA, and KA = BH, = H *h* A, = K *m* E, we find E to be the deſcribing point of the circle, which has rolled from A to K. In the other method, we muſt draw EN perpendicular to AG; then, becauſe the point E moves, during evolution, at right angles to BE, EK is the normal to the curve deſcribed, and NK the ſubnormal, and is equal to the correſponding ordinate H I of the generating circle of the cycloid ABC. This being a characteriſtic property of a cycloid, E is a point in the circumference of a cycloid equal to the cycloid ABC.

Or, laſtly, in accommodation to caſes where we are ſuppoſed to know few of the properties of the evolute, or, at leaſt, not to attend to them, we may make uſe of the fluxionary equation of the evolute to obtain the fluxionary equation of the evolutrix. For this purpoſe, take a point *e* very near to E, and draw the evolving radius *b e*, cutting E *f* (drawn parallel to the baſe DC) in *o*; draw *e n* parallel to the axis of the evolute, cutting

ting E o in v; alſo draw $b\,h\,i$ parallel to the baſe, and B d perpendicular to it. If both curves be now referred to the ſame axis CGF, it is plain that B b, B d, and $d\,b$ are ultimately as the fluxions of the arch, abſciſs, and ordinate of the evolute, and that Ee, $e\,v$, and v E, are ultimately as the fluxions of the arch, abſciſſa, and ordinate of the evolutrix. Alſo the two fluxionary triangles are ſimilar, the ſides of the one being perpendicular, reſpectively, to thoſe of the other. If both are referred to one axis, or to parallel axes, the fluxion of the abſciſſa of the evolute is to that of its ordinate, as the fluxion of the ordinate of the evolutrix is to that of its abſciſſa. Thus, from the fluxionary equation of the one, that of the other may be obtained. In the preſent caſe, they may be referred to AD and FG, making CG equal to the cycloidal arch CBA. Call this a; AI, x; IB, y; and AB, or EB, z. In like manner, let F t be $= u$, t E $= v$, and FE $= w$; then, becauſe $DH^2 = DA^2 - AH^2$, and DA and AH are the halves of CF and BE, we have $DH^2 = \frac{a^2 - z^2}{4}$. Alſo $DI = \frac{DH^2}{DA} = \frac{a^2 - z^2}{4 \times \frac{1}{2} a}, = \frac{a^2 - z^2}{2\,a}$. But DI = F t. Therefore F t, or u, $= \frac{a^2 - z^2}{2\,a}$. Alſo $\dot{w} = \frac{\dot{u}\ \dot{z}}{\dot{y}}$, by what was ſaid above, that is, $\dot{w} = \frac{a\ \dot{u}}{\sqrt{a^2 - z^2}}$, $= \frac{a\,\dot{u}}{\sqrt{2\,a\,u}}$. Therefore we have $\dot{w} : \dot{u}\ (= a : \sqrt{2\,a\,u}) = \sqrt{\tfrac{1}{2}a} : \sqrt{u} = \sqrt{GF} : \sqrt{F\,t}$, which is the analogy competent to a cycloid whoſe axis is GF = DA.

It is not neceſſary to inſiſt longer on this in this place; becauſe all theſe things will come more naturally before us when we are employed in deducing the evolute from its evolutrix.

When the ordinates of a curve converge to a centre, in which caſe it is called a radiated curve, it is moſt convenient to conſider its evolutrix in the ſame way, conceiving the ordinates of both as inſiſting on the circumference of a circle deſcribed round the ſame centre. Spirals evolve into other ſpirals, and exhibit ſeveral properties which afford agreeable occupation to the curious geometer. The equiangular, logarithmic, or loxodromic ſpiral, is a very remarkable example. Like the cycloid, it evolves into another equal and ſimilar equiangular ſpiral, and is itſelf the evolutrix of a third. This is evident on the ſlighteſt inſpection. Let C $r\,q\,p$ (fig. 6.) be an equiangular ſpiral, of which S is the centre; if a radius SC be drawn to any point C, and another radius SP be drawn at right angles to it, the intercepted tangent CP is known to be equal to the whole length of the interior revolutions of the ſpiral, though infinite in number. If the thread CP be now unlapped from the arch C $r\,q$, it is plain that the firſt motion of the point P is in a direction PT, which is perpendicular to PC, and therefore cuts the radius PS in an angle SPT, equal to the angle SCP; and, ſince this is the caſe in every poſition of the point, it is manifeſt that its path muſt be a ſpiral PQR, cutting the radii in the ſame angle as the ſpiral C $r\,q\,p$. James Bernoulli firſt diſcovered this remarkable property. He alſo remarked, that if a line PH be drawn from every point of the ſpiral, making an angle with the tangent equal to that made by the radius (like an angle of reflection correſponding with the incident ray SP), thoſe reflected rays would all be tangents to another ſimilar and equal ſpiral I v H; ſo that PH = PS. S and H are conjugate foci of an infinitely ſlender pencil; and therefore the ſpiral I v H is the cauſtic by reflection of RQP for rays flowing from S. If another equal and ſimilar ſpiral $x\,v\,y$ roll on I v H, its centre z will deſcribe the ſame ſpiral in another poſition $w\,u\,z$. All theſe things flow from the principles of evolution alone: and Mr Bernoulli traces, with great ingenuity, the connection and dependence of cauſtics, both by reflection and refraction, of cycloidal, and all curves of provolution, and their origin in evolution or involution. A variety of ſuch repetitions of this curve (and many other ſingular properties), made him call it the SPIRA MIRABILIS. He deſired that it ſhould be engraved on his tombſtone, with the inſcription EADEM MUTATA RESURGO, as expreſſive of the reſurrection of the dead. See his two excellent diſſertations in *Act.* Erudit. 1692, March and May.

Another remarkable property of this ſpiral is, that if, inſtead of the thread evolving from the ſpiral, the ſpiral evolve from the ſtraight line PC, the centre S will deſcribe the ſtraight line PS. Of this we have an example in the apparatus exhibited in courſes of experimental philoſophy, in which a double cone deſcends, by rolling along two rulers inclined in an angle to each other (ſee *Graveſande's* Nat. Phil. I. § 210). It is pretty remarkable, that a rolling motion, ſeemingly round C, as a momentary centre, ſhould produce a motion in the ſtraight line SP; and it ſhews the inconcluſiveneſs of the reaſoning, by which many compilers of elements of geometry profeſs to demonſtrate, that the motion of the deſcribing point S is perpendicular to the momentary radius. For here, although this ſeeming momentary radius may be ſhorter than any line that can be named, the real radius of curvature is longer than any line that can be named.

But it is not merely an object of ſpeculative geometric curioſity to mark the intimate relation between the geneſis of curves by evolution and provolution; it may be applied to important purpoſes both in ſcience and in art. Mr M'Laurin has given a very inviting example of this in his account of the Newtonian philoſophy; where he exhibits the moon's path in abſolute ſpace, and from this propoſes to inveſtigate the deflecting forces, and *vice verſa.* We have examples of it in the arts, in the formation of the pallets of pendulums, the teeth of wheels, and a remarkable one in Meſſrs Watt and Boulton's ingenious contrivance for producing the rectilineal motion of a piſton rod by the combination of circular motions. M. de la Hire, of the Academy of Sciences at Paris, has been at great pains to ſhew how all motions of evolution may be converted into motions of provolution, in a memoir in 1706. But he would have done a real ſervice, if, inſtead of this ingenious whim, he had ſhewn how all motions of provolution may be traced up to the evolution which is equivalent to them. For there is no organic geneſis of a curvilineal motion ſo ſimple as the evolution of a thread from a curve. It is the primitive geneſis of a circle; and it is in evolution alone that any curvilineal motion is comparable with circular motion. A given curve line is an individual, and therefore its primitive organical geneſis muſt alſo be individual. This is ſtrictly true of evolution. A parabola

bola has but one evolute. But there are infinite motions of provolution which will deſcribe a parabola, or any curve line whatever; thereſore theſe are not primitive organical modes of deſcription. That this, however, is the caſe, may be very eaſily ſhewn. Thus let ABCD (fig. 7.) be a parabola, or any curve; and let *a b c d* be any other curve whatever. A figure E *m l k h i* may be found ſuch, that while it rolls along the curve *a b c d*, a point in it ſhall deſcribe the parabola. The proceſs is as follows: Let B *b*, C *c*, D *d*, &c. be a number of perpendiculars to the parabola, cutting the curve *a b c d* in ſo many points. The perpendiculars may be ſo diſpoſed that the points *a*, *b*, *c*, &c. ſhall be equidiſtant. Now we can conſtruct a triangle E *e h* ſo, that the three ſides E *e*, *eh*, and *h* E, ſhall be reſpectively equal to the three lines E *e*, *e f*, F *f*. In like manner may the whole figure be conſtructed, having the little baſes of the triangles reſpectively equal to the ſucceſſive portions of the baſe A *b c d*, and the radii equal to the perpendiculars B *b*, C *c*, D *d*, &c. Let this figure roll on this baſe *c*. While the little ſide *e k* moves from its preſent poſition, and applies itſelf to *e f*, the point E deſcribes an arch E ε of a circle round the centre *e*, and, falling within the parabola, is ſomewhere between E and F. Then continuing the provolution, while the next ſide *h i* turns round *f* till *i* applies to *g*, the point E deſcribes another arch ε F *o* round *f*, firſt riſing up and reaching the parabola in F, when the line *h* E coincides with *f* F, and then falling within the parabola till the point *h* begin to riſe again from *f* by the turning of the rolling figure round the point *g*. Reverſing the motion, the ſides *i h*, *h e*, *e k*, &c. apply themſelves in ſucceſſion to the portions *g f*, *f e*, *e d*, &c. of the baſe, and the point E deſcribes an undulating line, conſiſting of arches of circles round the ſucceſſive centres *g*, *f*, *e*, &c. Theſe circular arches all touch the parabola in the points G, F, E, &c. and ſeparate from it a little internally. By diminiſhing the portions of the baſe, and increaſing the number of the triangular elements of the rolling figure without end, it is evident that the figure becomes ultimately curvilineal inſtead of polygonal, and the point E continues in the parabola, and accurately deſcribes it. It is now a curvilineal figure, having its elementary arches equal to the portions of the baſe to which they apply in ſucceſſion, and the radii converging to E equal to the perpendiculars intercepted between the curve ABCD and the baſe. It may therefore be accurately conſtructed.

It is clear, that practical mechanics may derive great advantage from a careful ſtudy of this ſubject. We now ſee motions executed by machinery which imitate almoſt every animal motion. But theſe have been the reſult of many random trials of *wipers*, *ſnail-pieces*, &c. of various kinds, repeatedly corrected, till the deſired motion is at laſt accompliſhed. But it is, as we ſee, a ſcientific problem, to conſtruct a figure which ſhall certainly produce the propoſed motion; nor is the proceſs by any means difficult. But how ſimple, in compariſon, is the production of this motion by evolution. We have only to find the curve line which is touched by all the perpendiculars B *b*, C *c*, D *d*, &c. This naturally leads us to the ſecond problem in this doctrine, namely, to determine the evolute by our knowledge of the involute: a problem of greater difficulty and of greater importance, as it implies, and indeed teaches, the curvature of lines, its meaſure, and the law of its variation in all particular caſes. The evolute of a curve is the geometrical expreſſion, and exhibition to the eye, of both theſe affections of curve lines.

Since the evolved thread is always at right angles to the evolutrix and its tangent, and is itſelf always a tangent of the evolute, it follows, that all lines drawn perpendicular to the arch of any curve, touch the curve line which will generate the given curve by evolution. Were this evolved curve previouſly known to us, we could tell the preciſe point where every perpendicular would touch it; but this being unknown, we muſt determine the points of contact by ſome other method, and by this determination we aſcertain ſo many points of the evolute. The method purſued is this: When two perpendiculars to the propoſed curve are not parallel (which we know from the known poſition of the tangents of our curve), they muſt interſect each other ſomewhere on that ſide of the tangents where they contain an angle leſs than 180°. But when they thus interſect, one of them has already touched the evolute, and the other has not yet reached it. Thus let *b s*, *e s* (fig. 1.) be the two perpendiculars: being tangents to the evolute, the point *s* of their interſection muſt be on its convex ſide, and the unknown points of contact B and E muſt be on different ſides of *s*. Theſe are elementary truths.

Let *e* E approach toward *b* B, and now cut it in *x*. The contact has ſhifted from E to D, and *x* is ſtill between the contacts. When the ſhifting perpendicular comes to the poſition ι C, the interſection is at *i*, between the contacts B and C. And thus we ſee, that as the perpendiculars to the involute gradually approach, their contacts with the evolute alſo approach, and their interſection is always between them. Hence it legitimately follows, that the ultimate poſition of the interſection (which alone is ſuſceptible of determination by the properties of the involute) is the poſition of the point of contact, and therefore determines a point of the evolute. The problem is therefore reduced to the inveſtigation of this ultimate interſection of two perpendiculars to the propoſed curve, when they coaleſce after gradually approaching. This will be beſt illuſtrated by an example: Therefore let ABC (fig. 8.) be a parabola, of which A is the vertex, AH the axis, and AV one-half of the parameter; let BE and CK be two perpendiculars to the curve, cutting the axis in E and K, and interſecting each other in *r*; draw the ordinates BD, CV, and the tangent BT, and draw BF parallel to the axis, cutting CK in F, and CN in O.

Becauſe the perpendiculars interſect in *r*, we have $r\mathrm{E} : \mathrm{EB} = \mathrm{EK} : \mathrm{BF}$. If therefore we can diſcover the ratio of EK to BF, we determine the interſection *r*. But the ratio of EK to BF is compounded of the ratio of EK to BO, and the ratio of BO to BF. The firſt of theſe is the ratio of equality; for DE and VK are, each of them, equal to AV, or half the parameter. Take away the common part VE, and the remainders EK and DV are equal, and DV is equal to BO; therefore $\mathrm{EK} : \mathrm{BF} = \mathrm{BO} : \mathrm{BF}$; therefore $r\mathrm{E} : r\mathrm{B} = \mathrm{BO} : \mathrm{BF}$, and (by diviſion) $\mathrm{BE} : \mathrm{E}r = \mathrm{FO} : \mathrm{OB}$. Now let the point C continually approach to B, and at laſt unite with it. The interſection *r* will unite with a point of contact N on the evolute. The ultimate ratio of FO to OB, or of $f o : o\mathrm{B}$, is evidently that of ED to DT, or ED to 2DA; therefore BE : EN = ED : 2DA, or as half the parameter to twice the abſciſſa. Thus have we determined a point of the evolute; and we may, in like manner, determine as many as we pleaſe.

But we wiſh to give a general character of this evolute, by referring it to an axis by perpendicular ordinates. It is plain that V is one point of it, becauſe the point E is always diſtant from its ordinate DB by a line equal to AV; and therefore, when B is in A, E will be in V, and *r* will coincide with it. Now draw VP and NQ perpendicular to AH, and NM perpendicular to VP; let EB cut PV in *t*: then, becauſe AV and DE are equal, AD is equal to VE, and VE is equal to one-half of DT. Moreover, becauſe BD and NQ are parallel, DE : EQ = BE : EN = DE : DT; therefore DT = EQ, and VE = $\frac{1}{2}$EQ, and therefore = $\frac{1}{3}$VQ; therefore V*t* is $\frac{1}{3}$ of M*t*, and $\frac{1}{2}$MV. This is a characteriſtic property of the evolute. The ſubtangent is $\frac{3}{2}$ of the abſciſſa; in like manner, as in the common parabola, it is double of the abſciſſa. We know therefore that the evolute is a paraboloid, whoſe equation is $a x^2 = y^3$; that is, the cube of any ordinate MN is equal to the parallelopiped whoſe baſe is the ſquare of the abſciſſa VM, and altitude a certain line VP, called the parameter. To find VP, let CR be the perpendicular to the parabola in the point where it is cut by the ordinate at V; draw the ordinate RS of the paraboloid, and RG perpendicular to AH. Then it is evident, from what has been already demonſtrated, that VK is $\frac{1}{2}$ of KG, and $\frac{1}{3}$ of VG; therefore KG^2 = 4VK^2, and (in the parabola) VC^2 = 2VK^2. Alſo, becauſe KV : VC = KG : GR, we have GR^2 = 2KG^2 = 8VK^2; therefore VP × RG^2 = 8VP × VK^2. But VG^3 = 27VK^3, = 27VK × VK^2; therefore, becauſe in the paraboloid VP × VS^2, = SR^3, or VP × RG^2 = VG^3, we have 8VP × VK^2 = 27VK × VK^2, and 8VP = 27VK; or VK : VP; that is, AV : VP = 8 : 27; or VP = $\frac{27}{8}$ AV, or $\frac{27}{16}$ of the parameter of the parabola ABC. The evolute of the conical parabola is the curve called the ſemicubical parabola, and its parameter is $\frac{27}{16}$ of the conical parabola.

This inveſtigation is nearly the ſame with that given by Huyghens, which we prefer at preſent to the method generally employed, becauſe it keeps the principle of inference more cloſely in view.

Mr Huyghens has deduced a beautiful corollary from it. Since the parabola ABC is deſcribed by the evolution of the paraboloid VNR, the line RC is equal to the whole evolved arch RNV, together with the redundant tangent line AV. If therefore we take from CR a part Cκ equal to the redundant AV, the remainder κR is equal to the arch RNV of the paraboloid. We may do this for every poſition of the evolved radius, and thus obtain a ſeries of points V, β, γ, δ, ε, of the evolutrix of the paraboloid. We have even an eaſier method for obtaining the length of any part of the arch of the paraboloid, without the previous deſcription of the parabola ABC. Suppoſe P*y* the arch of the paraboloid, and *yz* the tangent; make P*z* = $\frac{8}{27}$ of the parameter, and deſcribe the arch P*uu* of a circle; then draw from every tangent *yz* a parallel line *xv*, cutting the circle in *u*. The length of the arch *y*P is equal to *yz* + *uv*. The celebrated author congratulates himſelf, with great juſtice, on this neat exhibition of a right line equal to the arch of a curve, without the employment of any line higher than the circle. It is the ſecond curve that has been ſo rectified, the cycloid alone having been rectified by plain geometry a very few years before by Sir Chriſtopher Wren. It is very true, and he candidly admits it, that this very curve had been rectified before by Mr William Neill, a young gentleman of Oxford, and favourite pupil of Dr Wallis; as alſo by Mr Van Heuraet, a Dutch gentleman of rank, and an eminent mathematician. But both of theſe gentlemen had done it by means of the quadrature of a curve, conſtructed from the paraboloid after the manner of Dr Barrow, *Lect. Geom.* XI. Nor was this a ſolitary diſcovery in the hands of Mr Huyghens, as the rectification of the cycloid had been in thoſe of Sir Chriſtopher Wren; for the method of inveſtigation furniſhed Mr Huyghens with a general rule, by which he could evolve every ſpecies of paraboloid and hyperboloid, two claſſes of curves which come in the way in almoſt every diſcuſſion in the higher geometry. He obſerves, that the ratio of B*f* to E*e*, being always compounded of the ratios of B*f* to B*o*, and of B*o*, or D*d*, to E*e*; and the ultimate ratio of B*f* to B*o* being that of TE to TD, which is given by the nature of the paraboloid, we can always find the ratio of BE to BN, if we know that of D*d* to E*e*. In all curves, the ratio of D*d* to E*e* (taken indefinitely near), is that of the ſubtangent to the ſum of the ſubtangent and ordinate of a curve conſtructed on the ſame abſciſſa, having its ordinates equal to the ſubnormals DE, *de*, VK, &c. In the conic ſections the ratio is conſtant, becauſe the line ſo conſtructed is a ſtraight line; and, in the parabola, it is parallel to the axis. See farther properties of it in Barrow's *Lect. Geom.* XI.

From this inveſtigation, Mr Huyghens has deduced the following beautiful theorem:

Let *a* be the parameter of the paraboloid, *x* its abſciſſa, and *y* its ordinate; and let the equation be $a^n x^n = y^{m+n}$; let the radius of the evolute meet the tangent through the vertex A in Z. We ſhall always have BN = $\frac{n}{m}$ BE + $\frac{m+n}{m}$ BZ. Thus,

$$\text{If}\ \left.\begin{array}{l} a\,x = y^2 \\ a^2 x = y^3 \\ a\,x^2 = y^3 \\ a\,x^3 = y^4 \\ a^3 x = y^4 \end{array}\right\}\ \text{then BN} = \left\{\begin{array}{l} \text{BE} + 2\,\text{BZ} \\ \tfrac{1}{2}\text{BE} + \tfrac{3}{2}\text{BZ} \\ 2\,\text{BE} + 3\,\text{BZ} \\ 3\,\text{BE} + 4\,\text{BZ} \\ \tfrac{1}{3}\text{BE} + \tfrac{4}{3}\text{BZ}. \end{array}\right.$$

&c. &c.

This is an extremely ſimple and perſpicuous method of determining the radius of the evolute, or radius of curvature; and it, at the ſame time, gives us the rectification of many curves. It is plain that every geometrical curve may be thus examined, becauſe the ſubnormals DE, VK are determined; and therefore their differences are determined. Theſe differences are the ſame with the differences of D*d* and E*e*; and therefore the ratio of D*d* to E*e* is determined; that is, the ſubſidiary curve now mentioned can always be conſtructed.

There is a ſingular reſult from this rule, which would hardly have been noticed, if the common method for determining BN had alone been employed. The equation of the paraboloid is ſo ſimple, that the increaſe of the ordinates and diminution of curvature ſeem to keep pace together; yet we have ſeen that, in the vertex of the cubical parabola, the curvature is leſs than any circular curvature that can be named. In the legs, the curvature certainly diminiſhes as they extend farther;

there muſt therefore be ſome intermediate point where the curvature is the greateſt poſſible. This is diſtinctly pointed out by Mr Huyghens's theorem. The evolute of this paraboloid (having $a^2x = y^3$) is a curve ONRNQ (fig. 9.) conſiſting of two branches RO, and RQ, which have a common tangent in R; the branch RQ has the axis AE for its aſſymptote. The thread unfolding from OR, its extremity, deſcribes the arch BC, and then, unfolding from RQ, it deſcribes the ſmall arch CB′A. When B′ is extremely near A, the thread has a poſition B′N′E, in which B′N is very nearly ½BE. At C, if CE be biſected in G, GR is $\frac{3}{2}$ of CZ. Here CR the radius of curvature is the ſhorteſt poſſible. The evolutes of all paraboloids conſiſt of two ſuch branches, if $m + n$ exceeds 2.

Such is the theory of evolution and involution as delivered by Mr Huyghens about the year 1672. It was cultivated by the geometers with ſucceſs. Newton prized it highly, and gave a beautiful ſpecimen of its application to the deſcription, rectification, and quadrature of epicycloids, trochoids, and epicycles of all kinds. But it was eclipſed by the fluxionary geometry of Newton, which included this whole theory in one propoſition, virtually the ſame with Mr Huyghens's, but more comprehenſive in its expreſſion, and much more ſimple in its application. Adopting the unqueſtionable principle of Mr Huyghens, that the evolved thread is the radius of a circle which has the ſame flexures with the curve, the point of the evolute will be obtained by finding the length of the radius of the equicurve circle. The formula for this purpoſe is given in the article FLUXIONS of the *Encyclopædia Britannica*; but is incorrectly ſtated $= \frac{\overline{a+4}|^{\frac{3}{2}}}{2\sqrt{a}}$, inſtead of $\frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. The theorem alſo from which it is deduced $\left(r = \frac{\dot{z}^2}{-\dot{x}\ddot{y}}\right)$ is incorrectly printed, and is given without any demonſtration, thereby becoming of very little ſervice to the reader. For which reaſon, it is neceſſary to ſupply the defect in this place.

Therefore let AbcdEf (fig. 10.) be a circle, of which C is the centre, and ACE a diameter; let the points b, c, d, of the circumference be referred to this diameter by the equidiſtant perpendicular ordinates bi, cg, dk; draw the chords bc, cd, producing dc till it meet the ordinate bi in a, produce cg to the circle in f, and join bf, df; draw bh, cm, perpendicular to the ordinates; then bh, cm, hc, md, bc, cd, are ultimately proportional to the firſt fluxions of the abſciſſa AE, the ordinate cg, and the arch Ac; alſo ab, the difference between dm and ch is ultimately as the ſecond fluxion of the ordinate. The triangle abc is ſimilar to bdf; for the angle abc is equal to the alternate angle bcf, which is equal to bdf, ſtanding on the ſame ſegment. The angle acb is equal to bfd, ſtanding on the ſegment bcd; therefore the remaining angles bac and dbf are equal; therefore $ab : bc = bd : df = \frac{1}{2} bd : \frac{1}{2} df$. Now let the ordinates bi and dk continually approach the ordinate cg, and at laſt unite with it; we ſhall then have bc ultimately equal to $\frac{1}{2} bd$, and cg ultimately equal to $\frac{1}{2} df$. Therefore, ultimately, $ab : bc = bc : cg$, and $cg = \frac{bc^2}{ab}$.

Let u, v, w, repreſent the variable abſciſſa, ordinate, and arch. We have, for the fluxionary expreſſion of the ordinate of the equicurve circle, $v = \frac{\dot{w}^2}{-\ddot{v}}$ ($\ddot{v}$ muſt have the negative ſign, becauſe, as the arch increaſes, $\dot{v}$ diminiſhes). In the next place, it is evident that, ultimately, $bh : bc = cg : c$C, and $c\text{C} = \frac{cg \times bc}{bh}$. If r be the radius of the equicurve circle, we have $\dot{u} : \dot{w} = v : r$, and $r = \frac{v\dot{w}}{\dot{u}}$. But we had $v = \frac{\dot{w}^2}{-\ddot{v}}$. Subſtitute this in the preſent equation, and we obtain $r = \frac{\dot{w}^3}{-\dot{u}\ddot{v}}$. Laſtly, obſerve that $\dot{w}^2 = \dot{u}^2 + \dot{v}2$, and $\dot{w} = \sqrt{\dot{u}^2 + \dot{v}^2} = \overline{\dot{u}^2 + \dot{v}^2}|^{\frac{1}{2}}$. Therefore $\dot{w}^3 = \overline{\dot{u}^2 + \dot{v}^2}|^{\frac{3}{2}}$ and we have $r = \frac{\overline{\dot{u}^2 + \dot{v}^2}|^{\frac{3}{2}}}{-\dot{u}\ddot{v}}$, as the moſt general fluxionary expreſſion of the radius of a circle, in terms of the ſine, coſine, and arch.

When a curve and a circle have the ſame curvature, it is not enough that the firſt fluxions of their abſciſſæ, ordinates, and arches, are the ſame. This would only indicate the poſition of their common tangent. They muſt have the ſame deflection from that tangent. This is always equal to half of the ſecond fluxion of the ordinate. Therefore the circle and curve muſt have the ſame ſecond fluxion of their ordinates. Therefore let DbcdF be any curve coinciding with, or oſculated by, the circle Abcd. Let its axis be DG, parallel to the diameter AE; and let cn be its ordinate. Let Dn be $= x$, $cn = y$, and $bc = z$. We have $\dot{x}$, $\dot{y}$, $\dot{z}$, reſpectively equal to $\dot{u}$, $\dot{v}$, $\dot{w}$. Therefore the radius of the oſculating circle is $r = \frac{\dot{z}^3}{-\dot{x}\ddot{y}}$ or $r = \frac{\overline{\dot{x}^2 + \dot{y}^2}|^{\frac{3}{2}}}{-\dot{x}\ddot{y}}$, for all curves whatever. (We recommend the careful peruſal of the celebrated 2d corollary of the 10th propoſition of the 2d book of Newton's Principia, where the firſt principles of this doctrine are laid down with great acuteneſs.)

Inſtead of ſuppoſing the ordinates equidiſtant, and conſequently $\dot{x}$ invariable, we might have ſuppoſed the ordinates to increaſe by equal ſteps. In this caſe y would have had no ſecond fluxion. The radius would then be $= \frac{\dot{z}^3}{\dot{y}\ddot{x}}$. Or, laſtly, we might ſuppoſe (and this is very uſual) the arch z to increaſe uniformly. In this caſe $r = \frac{\dot{z}\dot{y}}{\ddot{x}}$: For becauſe $\dot{x}^2 + \dot{y}^2 = \dot{z}^2$, by taking the fluxion of it, $2\dot{x}\ddot{x} + 2\dot{y}\ddot{y} = 0$, and $\ddot{y} = \frac{\dot{x}\ddot{x}}{\dot{y}}$; and therefore $r = \frac{\dot{z}^3}{\dot{y}\ddot{x} - \dot{x}\ddot{y}}, = \frac{\dot{z}^3}{\dot{y}\ddot{x} + \frac{\dot{x}^2\ddot{x}}{\dot{y}}}, = \frac{\dot{y}\dot{z}^3}{\dot{y}^2 + \dot{x}^2 \times \ddot{x}}, = \frac{\dot{y}\dot{z}}{\ddot{x}}$.

Having thus obtained the radius of curvature, and conſequently a point of the evolute, we determine its form

form by reference to an abſciſs, without much farther trouble: It only requires the drawing Cp perpendicular to the axis of the propoſed curve, and giving the values of Cp and Dp. If we ſuppoſe $\dot x$ conſtant, then, cC being $= \frac{\dot z^3}{-\dot x \ddot y}$, we have Dp $(= Dn + gc, = Dn + \frac{\dot y}{\dot z} \times cC) = x + \frac{\dot y \dot z^2}{-\dot x \ddot y}$; and pC $(= cg - cn, = \frac{\dot x}{\dot z} \times cC - cn) = \frac{\dot z^2}{-\ddot y} - y$. But if we ſuppoſe $\dot y$ conſtant; then, cC being $= \frac{\dot z^3}{\dot y \ddot x}$, we have $Dp = x + \frac{\dot z^2}{\ddot x}$, and $pC = \frac{\dot x \dot z^2}{\dot y \ddot x} - y$. And if $\dot z$ be conſtant, then, cC being $= \frac{\dot y \dot z}{\ddot x}$, we ſhall have $Dp = x + \frac{\dot y^2}{\ddot x}$, and $pC = \frac{\dot x \dot y}{\ddot x} - y$.

Theſe formulæ are ſo many general expreſſions for determining both the curvature of the propoſed curve and the form of its evolute. They alſo give us the rectification of the evolute; becauſe cC is equal to the evolved arch, or to that arch, together with a conſtant part, which was a tangent to the evolute at its vertex, in thoſe caſes where the involute has a finite curvature at its vertex; as in the common parabola.

Let us take the example of the common parabola, that we may compare the two methods. The equation of this is $ax = y^2$, or $a^{\frac{1}{2}} x^{\frac{1}{2}} = y$. This gives $\dot y = \frac{1}{2} a^{\frac{1}{2}} \dot x x^{-\frac{1}{2}}, = \frac{a^{\frac{1}{2}} \dot x}{2 x^{\frac{1}{2}}}$, and (making $\dot x$ conſtant) $\ddot y = -\frac{1}{2} \times \frac{1}{2} a^{\frac{1}{2}} \dot x^2 x^{-\frac{3}{2}} = \frac{-a^{\frac{1}{2}} \dot x^2}{4 x^{\frac{3}{2}}}$. Wherefore $\dot z \ (= \sqrt{\dot x^2 + \dot y^2}) = \frac{\dot x}{2} \sqrt{\frac{4x + a}{x}}$, and the radius of curvature $\left(= \frac{\dot z^3}{-\dot x \ddot y}\right) = \frac{\overline{a + 4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. At the vertex, where $x = 0$, the formula becomes $= \frac{1}{2} a$. Again, $Dp \left(= x + \frac{\dot y \dot z^2}{-\dot x \ddot y}\right)$ becomes $\frac{1}{2} a + 3x$; and therefore $Vp = 3x$, = the abſciſſa of our evolute. Likewiſe cp, its ordinate, $\left(= \frac{\dot z^2}{-\ddot y} - y\right) = \frac{4x^{\frac{3}{2}}}{\sqrt{a}}$; and $Cp^2 = \frac{16x^3}{a}$; and $Cp^2 \times a = 16x^3$. But $Vp = 3x$, and $Vp^3 = 27x^3$. Therefore $Cp^2 \times \frac{1}{16}$th $a = x^3, = \frac{1}{27}$th Vp^3, and $\frac{27}{16}$ths $a \times Cp^2 = Vp^3$. Therefore the evolute VC is a ſemicubical parabola, whoſe parameter is $\frac{27}{16} a$, as was ſhewn by Mr Huyghens. The arch VC is $= \frac{\overline{a + 4x}|^{\frac{3}{2}}}{2\sqrt{a}} - \frac{1}{2} a$.

We ſhall give one other example, which comprehends the whole claſs of paraboloids. Their general equation is $y = ax^n$. This gives us $\dot y = nax^{n-1}\dot x$, and $\ddot y = n \times \overline{n-1} \times ax^{n-2}\dot x^2$; therefore $\dot z$ $(= \sqrt{\dot x^2 + \dot y^2}) = \dot x\sqrt{1 + n^2a^2x^{2n-2}}$; $Cc \left(= \frac{\dot z^3}{-\dot x \ddot y}\right) = \frac{\overline{1 + n^2a^2x^{2n-2}}|^{\frac{3}{2}}}{-n \times \overline{n-1} \times ax^{n-2}}$; $Dp \left(= x + \frac{\dot y \dot z^2}{-\dot y \dot x}\right) = x - \frac{x + n^2a^2x^{2n-1}}{n-1}$; $Cp \left(= \frac{\dot z^2}{\ddot y} - y\right) = \frac{1 + \overline{2n-1} \times na^2x^{2n-2}}{-\overline{n-1} \times nax^{n-2}}$; and $DV = -\frac{n^2a^2o^{2n-1}}{n-1}$

This laſt formula expreſſes the radius of curvature at the vextex D, or the redundant part of the thread, by which it exceeds the arch VC of the evolute. If $n = \frac{1}{2}$, the formula becomes $\frac{a^2}{2}$: but if n be greater than this, VC will be $= o$; and if it be leſs, VC will be infinite. Hence it appears, that the radius of curvature at the vertex of a curve is a finite quantity only in the caſes where the firſt or naſcent ordinates are in the ſubduplicate ratio of their abſciſſæ. In all other caſes, the curvature is incomparable with that of any circle, being either what is called infinite (when n is greater than $\frac{1}{2}$) or nothing (when it is leſs).

We ſcruple not to ſay, that the method of Mr Huyghens is more luminous, more pleaſing to the imagination of a geometer, than this; and in all the caſes which occurred to us in our employment of it, it ſuggeſted more ready conſtructions, with the additional ſatisfaction of exhibiting, in a continuous train, what the *ſymbolical* method, proceeding by the fluxionary calculus, only indicates by points. We muſt alſo obſerve, that the ſubſidiary curve employed by Huyghens, having its ordinates equal to the ſubnormals of the involute under examination, is the geometrical expreſſion of that function of the involute which gives the ſecond fluxions $\ddot y$ and $\ddot x$ of the ordinate and abſciſſa. The young mathematician will find no difficulty in conſtructing this curve *in every caſe;* whereas we imagine that he will not find it a light matter to conſtruct the final equations of the ſymbolic method *almoſt in any caſe.* At the ſame time, the all-comprehending extent of the latter method, and the numberleſs general theorems which it ſuggeſts to the expert analyſt, give it a moſt deſerved preference, and make it almoſt an indiſpenſable inſtrument for all who would extend our phyſico-mathematical ſciences.

In the employment of the geometry of curve lines, eſpecially in the doctrine of centripetal forces, it is uſual to conſider the ordinates, not as inſiſting on a rectilineal abſciſſa, but as diverging from a centre. This is alſo the uſual way of conceiving all ſpirals and evolutrixes of curves which include ſpace; in ſhort, all RADIAL curves. The proceſs for finding their evolute, or their radius of curvature, is ſomewhat different from that hitherto exhibited; but it is more ſimple. Thus, let GPM (Fig. 10.) be the elliptical path of a planet, of which S is the focus. We require PC, the radius of curvature in the point P. Let Pp be a very ſmall arch. Draw the radii SP, Sp, the tangents PT, pt; and

and draw ST perpendicular to PT, cutting pt in t; and Po perpendicular to Sp. Let the arch GP be $= z$, the radius SP $= y$, and the perpendicular ST $= p$. Then, it is plain, that Pp, op, Tt, are ultimately proportional to $\dot{z}, \dot{y}, \dot{p}$. The triangles PC$p$, and T$pt$ or TPt are alſo ultimately ſimilar; as alſo the triangles PST and poP. Therefore, ultimately,

$$\text{T}t : \text{P}p = \text{PT} : \text{PC}$$

alſo $$\text{P}p : po = \text{PS} : \text{PT}$$

therefore $\text{T}t : po = \text{PS} : \text{PC}$, or, $\dot{p} : \dot{y} = y : r$, and $r = \frac{y\dot{y}}{\dot{p}}$; an expreſſion of the radius of curvature, extremely ſimple, and of eaſy application.

The logarithmic or equiangular ſpiral PQR (fig. 6.) affords an eaſy example of the uſe of this formula. The angle SPT, which the ordinate makes with the curve, is everywhere the ſame. Therefore let a be our tabular radius, and b the ſine of the angle SPT. We have $\text{ST} = \frac{by}{a}$; and therefore PC $\left(= \frac{y\dot{y}}{\dot{p}}\right) = \frac{ay\dot{y}}{b\dot{y}} = \frac{ay}{b}$. This is to SP or y in the conſtant ratio of a to b, or of SP to ST: that is, ST : SP = SP : PC, the triangles SPT and PCS are ſimilar, the angles at P and C equal, and C is a point of an equiangular ſpiral pyr round the centre S.

It is not meant that the conſtruction pointed out by this theory of involution, expreſſed in its moſt general and ſimple form, is always the beſt for finding the centre of the equicurve circle. Our knowledge of, or attention to, many other properties of the curve under conſideration, beſides thoſe which ſimply mark its relation to an abſciſs and ordinate, muſt frequently give us better conſtructions. But evolution is the natural geneſis of a line of varying curvature. Moreover, in the moſt important employment of mathematical knowledge, namely, mechanical philoſophy, it is well known, that the moſt certain and comprehenſive method of ſolving all intricate problems is by reference of all forces and motions to three co-ordinates perpendicular to each other. Thus, without any intentional ſearch, we have already in our hands the very fluxionary quantities employed in this doctrine; and the expreſſion which it gives of the radius of curvature requires only a change of terms to make it a mechanical theorem.

Thus have we conſidered the two chief queſtions of evolution and involution. We have done it with as cloſe attention to geometry as poſſible, that the reader's mind may become familiar with the *ipſa corpora* while acquiring the elementary knowledge, which is to be employed more expeditiouſly afterwards by the help of the ſymbolical analyſis. Without ſuch ideas in the mind, the occupation is oftentimes as much diveſted of thought as that of an expert accountant engaged in complex calculations; the attention is wholly turned to the rules of his art.

It now remains to conſider a little the nature of this curvature of which ſo much has been ſaid, and about which ſo many obſcure opinions have been entertained. We mentioned, in an early part of this article, the unwarranted uſe of the terms of infinite and infiniteſimal magnitude as applicable to curvature, and ſhewed its impropriety by the inconſiſtences into which it leads mathematicians. Nothing threw ſo much light on this ſubject as Mr Huyghens's Geometry of Evolution; and we ſhould have expected that all diſputes would have been ended by it. But this has not been the caſe; and even the moſt eminent geometers and metaphyſicians, ſuch as the Bernoullis and Leibnitz, have given explanations of orders of curvature that can have no exiſtence, and explanations of that coaleſcence which obtains between a curve line and its equicurve circle, which are not warranted by juſt principles.

Theſe errors (for ſuch we preſume to think them) aroſe from the method employed by the geometers of laſt century for obtaining a knowledge of the magnitude and variation of curvature. The ſcrupulous geometers of antiquity deſpaired of ever being able to compare a curve with a right line. The moderns, although taught by Des Cartes to define the nature of a curve by its equation, allowed that this only enabled them to exhibit a ſeries of points through which it paſſed, and to draw the polygon which connects theſe points, but gave no information concerning the continuous *incurvated* arches, of which the ſides of the polygon are the chords. They could not generally draw a tangent to any point, or from any point; but they could draw a chord through any two points. Des Cartes was the firſt who could draw a tangent. He contrived it ſo, that the equation which expreſſes the interſections of the curve with a circle deſcribed round a given centre ſhould have two equal roots. This indicates the coaleſcence of two interſections of the common chord of the circle and the curve. Therefore a perpendicular to the radius ſo determined muſt touch the curve in the point of their union. This was undoubtedly a great diſcovery, and worthy of his genius. It naturally led the way to a much greater diſcovery. A circle may cut a curve in more points than two: It may cut a conic ſection in four points; all expreſſed by one equation, having four roots or ſolutions. What if three of theſe roots ſhould be equal? This not only indicates a cloſer union than a mere contact, but alſo gives indication of the flexure of the intervening arch. For, before the union, the interſections were in the arch both of the curve and of the circle; and therefore the diſtinction between the union of two and of three interſections muſt be of the ſame kind with that between a ſtraight line and an arch of *this* circle. The flexure of a circle being the ſame in every part, it becomes a proper index; and therefore the circle, which is determined by the coaleſcence of three interſections, was taken as the meaſure of the curvature in that point of the curve, and was called the CIRCLE OF CURVATURE, the EQUICURVE CIRCLE. There is a certain progreſs to this coaleſcence which muſt be noticed. Let ABD (fig. 4.) be a common parabola, EBF a line touching it in B, and BO a line perpendicular to EBF. Taking ſome point O in the other ſide of the axis for a centre, a circle may be deſcribed which cuts the curve in four points a, b, c, and d. By enlarging the radius, it is plain that the points a and b muſt ſeparate, as alſo the points c and d. Thus, the points b and c approach each other, and at laſt coaleſce in a point of contact B, with the parabola, and with its tangent. In the mean time, a and d have retired to A and D. If we now bring the centre O nearer to B, the new circle will fall wholly within the laſt circle ABD; and therefore both

A and D will again approach to each other, and to B, which ſtill continues a point of contact. It is plain that A will approach faſter to B than D will do. At length, the centre being in o, the point A coaleſces with B, and we obtain a circle ϵ B δ, touching the curve in B, and cutting it in δ: Conſequently the arch B ϵ δ is wholly within, and B ϕ δ is wholly without the parabola; and the circle both touches and cuts the parabola in B. Here is certainly a cloſer union, at leaſt on the ſide of a. But perhaps a farther diminution of the circle may bring it cloſer on the ſide of D. Join B δ. Let a ſmaller circle be deſcribed, touching the parabola in B, and cutting it in ϕ. Draw $\phi\, c$ parallel to δ B. It may be demonſtrated that the new circle cuts the parabola in c. Now the arch between c and ϕ being without the parabola, the arch B C muſt be within it; and therefore this circle is within the parabola on both ſides of B, and is more incurvated than the parabola. We have ſeen, that a circle greater than ϵ B δ is without the parabola on both ſides of B; and therefore is leſs incurvated than the parabola. Therefore the individual circle ϵ B δ is neither more nor leſs curve than the parabola in the point B. Therefore the circle indicated by the coaleſcence of three interſections is properly named the equicurve circle; and, ſince we meaſure all curvatures by that of a circle, it is *properly* the circle of curvature, and its radius is the radius of curvature.

Had B been the vertex of the axis, every interſection on one ſide of B would have been ſimilar to an interſection on the other, and there would always have been two pairs of roots that are equal; and therefore when three interſections coaleſce, a fourth alſo coaleſces, and the contact is ſaid to be ſtill cloſer.

What has now been ſhewn with reſpect to a conic ſection is true of every curve. When two interſections coaleſce, there is a common tangent; when three coaleſce, there is an equal curvature, and no other circle can paſs between this circle and the curve. There cannot be a coaleſcence of four interſections, except when the diameter is perpendicular to the ordinates, and thoſe are biſected by the diameter.

Mr Leibnitz, who valued himſelf for metaphyſical refinement, and never fails to claim ſuperiority in this particular, notices the important diſtinction between a ſimple contact and this cloſer union, in a very well written diſſertation, publiſhed in the *Acta Eruditorum*, July 1686. He calls the contact of equal curvatures an OSCULATION, and the circle of equal curvature the OSCULATING CIRCLE, and delivers ſeveral very judicious remarks with the tone of a maſter and inſtructor. He alſo ſpeaks of different degrees or orders of oſculation, each of which is infinitely cloſer than the other, as a thing not remarked by geometers. But Sir Iſaac Newton had done all this before. The firſt twelve propoſitions of the *Principia* had been read to the Royal Society ſeveral years before, and were in the Regiſters. The *Principia* had received the imprimatur of the Society in July 1686; but was almoſt printed before that time. In the Scholium to the 11th Lemma, is contained the whole doctrine of contact and oſculation; and in the lemma and its corollaries, is crowded a body of doctrine, which has afforded themes for volumes. The author glances with an eagle's eye over the whole proſpect, and points out the prominent parts with the moſt compreſſed brevity; but with ſufficient preciſion for marking out the more important objects, and particularly the different orders of curvature. This lemma and its corollaries are continually employed in the twelve propoſitions already mentioned. In 1671 he had written the firſt draught of his method of fluxions, where this doctrine is ſyſtematically treated; and Mr Collins had a copy of it ever ſince 1676. It is well known that Leibnitz, when in London, had the free peruſal of the Society's records, and information at all times by his correſpondence with the ſecretary Oldenburgh and Mr Collins. His conduct reſpecting the theorems concerning the elliptical motion of the planets, and the reſiſtance of fluids, leave little room to doubt of his having availed himſelf in like manner of his opportunity of information on this ſubject. He gives a much better account of the Newtonian doctrine on this ſubject than in thoſe other inſtances, it being more ſuited to his refining and paradoxical diſpoſition.

In this and another diſſertation, he conſiders more particularly the nature of evolution, and of that oſculation which obtains between the evolutrix and the circle deſcribed by the evolved radius. He ſays, that it is equivalent to two ſimple contacts, each of which is equivalent to two interſections. An oſculation produced in the evolution of a curve is therefore equivalent to four interſections. And he adviſes, with an air of authority, the mathematicians to attend to theſe remarks, as leading them into the receſſes of ſcience. He is miſtaken, however; and the liſtening to him would prevent us from forming a juſt notion of oſculation, and from conceiving with diſtinctneſs the ſingular fact of a circle both touching and cutting a curve in the ſame point. James Bernoulli loſt his friendſhip, becauſe he preſumed to ſay that the preſence of four interſections in an oſculation is not warranted by the equation expreſſing thoſe interſections.

Mr Leibnitz was miſled by the way in which he had conſidered the oſculation in the evolution of curves. It merits attention. From any point within the ſpace ADFOA (fig. 1.), two perpendiculars may be drawn to the evolutrix A $b\,d\,f$; and therefore two circles may be deſcribed round that point, each touching the curve. Each contact is the union of two interſections. Therefore, as the centre approaches the evolute, the contacts approach each other, and they unite when the centre reaches the evolute. Therefore the oſculation of evolution is equivalent to four interſections.

But when two ſuch circles are deſcribed round a point s, ſo as that both may touch the evolutrix A $a\,f$, the point s is in the interſection of one evolved radius with the *prolongation* of another. The contact at the extremity b of the prolonged radius b B is an exterior contact, and the arch of the circle croſſes the evolutrix, from without inwards, in ſome point more remote from A. The contact at the extremity e of the radius e E is an interior contact; and if $e\,s$ be greater than the ſtraight line EA, the arch of this circle croſſes the curve, from within outwards, in ſome point nearer to A. Thus each contact is accompanied by an interſection on the ſide next the other contact, ſometimes beyond it, and ſometimes between the contacts. As the contacts approach, the interſections alſo approach, ſtill retaining their characters as interſections, as the contacts ſtill continue contacts. Alſo the circle next to A croſſes from without inwards, and that next to f croſſes from within outwards. They retain this character to the laſt; and when the contacts coaleſce, the two circles coaleſce over their whole circumference, ſtill, however, croſſing the curve in the ſame direction as before; that is, without the curve on the ſide of A, and within it on the ſide of *f*. The contacts unite as contacts, and the interſections as interſections. Thus it is that the oſculating circle both touches and interſects the curve in the ſame point.

At *f* the oſculation is indeed cloſer than anywhere elſe. The variation of curvature is leſs there than anywhere elſe, becauſe the radius changes more ſlowly. It is this circumſtance that determines the cloſeneſs of contact. If a circle oſculates a curve, it has the ſame curvature. If this curvature does not change in the vicinity of the contact, the curve and circle muſt coincide; and the deviation of the circle (the curvature of which is everywhere the ſame) from the curve muſt proceed entirely from the variation of its curvature. This, therefore, is the important circumſtance, and is indeed the characteriſtic of the figure as a curve line; and its other properties, by which the poſition of its different parts are determined, may be aſcertained by means of the *variation* of its curvature, as well as by its relation to co-ordinates. Of this we have a remarkable inſtance at this very time. The orbit of the newly diſcovered planet has been aſcertained with tolerable preciſion by means of obſervations made on its motions for three years. In this time it had not deſcribed the 20th part of its orbit; yet the figure of this orbit, the poſition of its tranſverſe axis, the place and time of its perihelion, were all determined within 100dth part of the truth by the *obſerved variation* of its curvature. It therefore merits our attention in the cloſe of this article. We know of no author who has treated the ſubject in ſo inſtructive a manner as Mr M‘Laurin has done, by exhibiting the theorem which conſtitutes Newton's 11th lemma in a form which points this out even to the eye (ſee *M‘Laurin's Fluxions*, Chap. xi. § 363, &c.). We earneſtly recommend this work to the young geometer, as containing a fund of inſtruction and agreeable exerciſe to the mathematical genius, and as greatly ſuperior in perſpicuity and in ideas which can be treaſured up and recollected, when required, to the greateſt part of the elaborate performances of the eminent analyſts of later times. By expreſſing every thing geometrically, the author furniſhes us with a ſort of picture, which the imagination readily reviews, and which exhibits in a train what mere ſymbols only give us a momentary glimpſe of.

“ As, of all right lines which can be drawn through a given point in the arch of a curve, that alone is the tangent which touches the arch ſo cloſely that no right line can paſs between them; ſo, of all circles which touch a curve in a given point, that circle alone has the ſame curvature which touches it ſo cloſely that no circle can paſs between them. It cannot coincide with the arch of the curve; and therefore the above condition is ſufficient for making it equicurve. As the curve ſeparates from the tangent by its flexure or curvature, it ſeparates from the equicurve circle by its *change* of curvature; and as its curvature is greater or leſs according as it ſeparates more or leſs from its tangent, ſo the variation of its curvature is greater or leſs according as it ſeparates more or leſs from its equicurve circle. There can be but one equicurve circle at one point of a curve, otherwiſe any other circle deſcribed between them through that point will paſs between the curve and the equicurve circle.

“ When two curves touch each other in ſuch a manner that no circle can paſs between them, they muſt have the ſame curvature; becauſe the arch which touches one of them ſo cloſely that no circle can paſs between them, muſt touch the other in like manner. But circles may touch the curve in this manner, and yet there may be indefinite degrees of more or leſs intimate contact between the curve and its equicurve circle.” This is ſhewn by the ingenious author in a ſeries of propoſitions, of which a very ſhort abridgment muſt ſuffice in this place.

Let any curve EMH (fig. 11.), and a circle ERB, touch a right line ET on the ſame ſide at E. Let any right line TK, parallel to the chord EB of the circle, meet the tangent in T, the curve in M, and a curve BKF (which paſſes through B) in K. Then, if $MT \times TK$ be everywhere equal to TE^2, the curvature of EMH in the point E is the ſame as that of the circle ERB; and the contact of EM and ER is ſo much the cloſer the ſmaller the angle is which is contained at B between the curve BKF and the equicurve circle BQE.

Let TK meet the circle in R and Q. Then, becauſe $RT \times TQ = TE^2$, it muſt be $RT \times TQ = MT \times TK$; and $RT : MT = TK : TQ$. The line BKF may have any form. It may croſs the circle BQR in B, as in the figure. It may touch it, or touch EB, &c. Let us firſt conſider what ſituations of the point M correſpond with the poſition of K, in that part of the curve BKF which lies without the circle BRE. Let TK move toward EB, always keeping parallel to it, till it coincide with it, or even paſs it. Then, while the point K deſcribes KB, it is evident that ſince TK is greater than TQ, TM muſt be leſs than TR, and the point M muſt always be found between T and R. The arch ME of the curve muſt be nearer to the tangent than the arch RE of the circle. If any circle be now deſcribed touching TE in E, and cutting off from EB a ſmaller chord than EB, it is clear that the whole of this ſegment muſt be within the ſegment BRE; therefore this ſmaller circle does not paſs between ERB and the curve EMH. But ſince we ſee that the curve lies without the circle, in the vicinity of E, perhaps a greater circle than ERB may paſs between it and the curve. A greater circle, touching at E, muſt cut off a chord greater than EB. Let E*r b* be ſuch a circle, cutting EB in *b*, and TQ in *q*. T*q* is neceſſarily greater than TQ. For ſince *b* is beyond B, and the arch BKF lies in the angle QB*b*, the circle E*r q* muſt croſs the curve FKB in ſome point; ſuppoſe F. Then while K is found in the arch FB, the point *q* muſt be beyond K, or T*q* muſt be greater than TK. Now $Tr \times Tq = TE^2, = TM \times TQ$. Therefore $TM : Tr = Tq : TQ$. Therefore T*q* being greater than TQ, T*r* muſt be leſs than TM, and the point *r* muſt lie without the curve, and the arch E*r* does not paſs between EMH and the circle ERB. In like manner, on the other ſide of EB, it will appear, that when the curve BK′F′ falls within the circle which touches EMH in E, and cuts off the chord EB, the arch of the curve correſponding to the arch BKF′, lying within the circle, alſo lies within the circle. For TK′ being leſs than TQ′, TM′ is greater than TR′, and the curve is within

within the circle. And, by ſimilar reaſoning, it is evident that a circle cutting off a greater chord falls without both the circle ER′B and the curve, and that a circle leſs than ER B muſt neceſſarily leave ſome part of the curve BK′F′ without it; and therefore TK′ will be greater than T*q*′, and the correſponding point *r*′ muſt be without the curve. All circles therefore touching TE in E fall without both ER and EM, or within them both, according as they cut off from EB a chord greater or leſs than EB, and no circle can paſs between them when the rectangle $MT \times TK$ is always equal to ET^2, and the focus of the point K paſſes through B; that is, ERB is the equicurve circle at E.

This corroborates the ſeveral remarks that we have made on the circumſtance of a circle touching and cutting a curve in the ſame point. No other circle can be made to paſs between it and the curve, and it therefore has the ſame curvature. This may therefore be taken as a ſufficient indication of the equicurve circle; the character peculiarly aſſured to it by the nature of evolution. It muſt be noted, however, that the curve is ſuppoſed to have its concavity in the vicinity of the contact turned all the ſame way. For if the contact be in a point of contrary fluxure, even a ſtraight line will both touch and cut it in that point.

The reader cannot but remark, that MK is always the chord of a circle touching TE in E, and paſſing through M.

Let E*m* be another curve, touching TE in E, ſuch, that the conjugate curve *k*B, which always gives $Tm \times Tk = TE^2$, alſo paſſes through B. Then, by what has now been demonſtrated, the two curves EM and E*m* have the ſame equicurve circle ERB, and conſequently the ſame curvature in E. Then, becauſe the rectangles $RT \times TQ$, $MT \times TK$, and $mT \times Tk$, are equal, we have $Tm : TM = TK : Tk$. Therefore if the arch B*k* paſs between BK and BQ, the curve E*m* muſt paſs between the curve EM and the circle ER. E*m* muſt therefore have a cloſer contact with ER than EM has with it; and the ſmaller the angle QBK is which is contained between the curve and its equicurve circle, the cloſer is the contact of the curve EM and its equicurve circle ER. Thus the length of the chord EB determines the *magnitude* or degree of curvature at E, when compared with another; and the angle contained between the equicurve circle and the conjugate curve BKF determines the cloſeneſs of the contact of the curve with its equicurve circle (the angle TEB being ſuppoſed the ſame in both).

It appears, from the proceſs of demonſtration, that the curve EMH falls without or within the equicurve circle according as its conjugate curve BKF does. Alſo, when BKF cuts BQR, HME alſo cuts it. But if FQB is on the ſame ſide of QB on both ſides of the interſection B, the curve HME is alſo on the ſame ſide of it on both ſides of the contact E. It is alſo very clear, that the contact or approach to coaleſcence between the curve and its circle of curvature, is ſo much the cloſer as the conjugate curve BKF comes nearer to the adjoining arch of this circle. It muſt be the cloſeſt of all when KB touches QB, and it muſt be the leaſt ſo when KB touches EB, or has EB for an aſſymptote. The ſpace QBK is a ſort of magnified picture of the ſpace MER; and we have a ſenſible proportion of TQ to TK as the repreſentation of the proportion of TM to TR, quantities which are frequently evaneſcent and inſenſible. When QBK is a finite angle, that is, when the tangents of BQ and BK do not coincide, the angle QBK can be meaſured. But no rectilineal angle can be contained as an unit in the curvilineal angle MER. They are incommenſurable, or incomparable. Let the curve KB touch the circle QB without cutting it. This angle is equally incomparable with the former QBK; yet it has a counterpart in MER. This muſt be incomparable with the former in the ſame manner; for there is the ſame proportion between the individuals of both pairs. Thus it appears plainly, that there are curvilineal angles incomparable with each other. Yet are they magnitudes of one kind; becauſe the ſmalleſt rectilineal angle muſt certainly contain them both; and one of them contains the other. But, further, there may be indefinite degrees of this coaleſcence or cloſeneſs of contact between a curve and a circle. The firſt degree is when the ſame right line touches both. This is a *ſimple contact*, and may obtain between any curve and any circle. The next is when EMH and ERB have the ſame curvature, and when the conjugate curve FKB interſects the circle QB in any aſſignable angle. This is an *oſculation*. The third degree of contact, and ſecond of oſculation, is when the curve KB touches the circle QB, but not ſo as to oſculate. The fourth degree of contact, and third of oſculation, is when KB and QB have the ſame curvature or oſculate in the firſt degree of oſculation. This gradation of more and more intimate contact, or (more properly ſpeaking) of approximation to coaleſcence, may be continued without end, "*neque novit natura limitem*," the contact of EM and ER being always two degrees cloſer than that of BK and BQ. Moreover, in each of thoſe claſſes of contact there may be indefinite degrees. Thus, when EM and ER have the ſame curvature, the angle QBK admits of indefinite varieties, each of which aſcertains a different cloſeneſs of contact at E. Alſo, though the angle QBK ſhould be the ſame, the contact at E will be ſo much the cloſer the greater the chord EB is.

For $TR : TM = TK : TQ$
Therefore $RM : TR = KQ : KT$
Or $RM : KQ = TR : TK; = TR \times TQ : TK \times TQ, = TE^2 : TK \times TQ$.

Therefore, when TE is given, RM (which is then the meaſure of the angle of contact) is proportional to KQ directly, and to the rectangle $TK \times TQ$ inverſely; and when KQ is given, RM is leſs in proportion as $KT \times TQ$ is greater. In the very neighbourhood of E and B, it is plain that $KT \times TQ$ is very nearly equal to EB^2, and therefore ultimately $RM : KQ = ET^2 : EB^2$.

It will greatly aſſiſt our conception of this delicate ſubject, if we view the origin of theſe degrees of contact as they are generated by the evolution of lines. A thread evolving from a polygon EDCBA (fig. 13.) deſcribes with its extremity *a* a line *e d b c a*, conſiſting of ſucceſſive arches of circles united in ſimple contacts. If it evolve from any continuous curve CBA, after having evolved from the lines ED, BC, the arch *cb* will be united with the circular arch *dc* by oſculation of the firſt degree. If any other curve FC touch this evolute in a ſimple contact, and if the two curves FCBA and DCBA are both evolved, they will touch each other in a ſimple oſculation in that point where they have the ſame radius. If FC touches DC in a ſimple oſculation, the evolved curves will touch in an oſculation of the ſecond degree; and, in general, the oſculation of the two generated curves is a degree cloſer than that of their evolutes; and in each ſtate of one of the oſculations, there is an indefinite variety of the other, according to the length of its radius of curvature. All this is very clear; and ſhews, that theſe degrees of contact do not indicate degrees of curvature, one of which infinitely exceeds another; for they are all finite.

The reader will do well to remark, that the magnitude, which is the ſubject of the above proportions, which is really of the ſame kind in them all, and conſidered as ſuſceptible of various degrees and orders of infiniteſimals, is not curvature, but lineal extenſion. It is RM, the ſubtenſe of the angle of contact MER. It is the linear ſeparation from the tangent, or from the equicurve circle. It is, however, uſually conſidered as the meaſure of curvature, or the proportions of this line are given as the proportions of the curvature. This is inaccurate; for curvature is unqueſtionably a change of direction only. As this line has generally been the intereſting object in the refined ſtudy of curve lines, eſpecially in the employment of it in the diſcuſſions of mechanical philoſophy, it has attracted the whole attention, and the language is now appropriated to this conſideration. What is called, by the moſt eminent mathematicians, variation of curvature, is, in fact, variation of the ſubtenſe of the angle of contact But it is neceſſary always to diſtinguiſh them carefully.

Variation of curvature is the remaining object of our attention.

Curvature is uniform in the circle alone. When the curvature of the arch EMH (fig. 11.) decreaſes as we recede from E, the arch, being leſs deflected from its primitive direction ET than the arch ER, muſt ſeparate leſs from the line ET, or muſt fall without the arch ER. The more rapidly its curvature decreaſes, the deſcribing point muſt be left more without the circle. It muſt be the contrary, if its curvature had increaſed from E toward M. It may change its curve equably or unequably. If equably, there muſt be a certain uniform rate, which would have produced the ſame final change of direction in a line of the ſame length, bending it into the uniformly incurvated arch of a circle. It is not ſo obvious how to eſtimate a rate of variation of curvature; and authors of eminence have differed in this eſtimation. Sir Iſaac Newton, who was much intereſted in this diſcuſſion, in his ſtudies on univerſal gravitation, ſeems to have adopted a meaſure which beſt ſuited his own views; and has been followed by the greater number. He gives a very clear conception of what he means, by ſtating what he thinks a caſe of an invariable rate of variation. This is the equiangular ſpiral, all the arches of which, comprehended in equal angles from the centre, are perfectly ſimilar, although continually varying in curvature. He calls this a curve EQUABLY VARIABLE, and makes its rate of variation (eſtimated in that ſenſe in which it is uniform) the meaſure of the rate of variation in all other curves. Let us ſee in what reſpect its variation of curvature is conſtant. It may be deſcribed by the evolution of the ſame ſpiral in another poſition (ſee fig. 6.), and the ratio between the radius of the evolute and that of the evolutrix is always the ſame; or (which amounts to the ſame thing) the arch of the evolutrix bears to the evolved arch of the evolute a conſtant ratio. The curvature of the ſpiral changes more rapidly in the ſame proportion as the ratio of the evolved arch to the arch of the evolutrix generated by it is greater, or as it cuts the radii in a more acute angle. Theſe arches may be infiniteſimal; therefore the fraction $\frac{\text{fluxion of evolute}}{\text{fluxion of evolutrix}}$ expreſſes the rate of the variation of curvature in this ſpiral. Now let *abcd* (fig. 13.) be any other curve, and ABCD its evolute; let *p* be the centre of curvature at the point B of the evolute, and B*o* the evolved arch; draw the radii *p*B, *po*, B*m*, *on*; join *pm*, and draw B*q* perpendicular to *pm*. It is evident that *mn* and B*o* have the ſame ratio with B*m* and B*p*; and that theſe two ſmall arches may be conceived as being portions of the ſame equiangular ſpiral (perhaps in another poſition), of which *q* is the centre; and that *p* is in the curve of another of the ſame. For $qp : q\text{B} = q\text{B} : q\text{M}, = p\text{B} : \text{B}m$; therefore the ratio of theſe infiniteſimal arches *mn* and B*o* will expreſs the rate of variation in any curve. This is evidently equivalent to ſaying, that the variation of curvature is proportional to the fluxion of the radius of curvature directly, and the fluxion of the curve inverſely. For *mn* and B*o* are ultimately as thoſe fluxions, and $\frac{\text{B}o}{mn}$ is equivalent to $\frac{-\dot{r}}{\dot{z}}$, where *z* is the arch of the ſpiral, and *r* the evolved radius of the other. Accordingly, this is the enunciation of the INDEX OF VARIATION given by Newton (See Newton's Fluxions, Prob. VI. § 3). Therefore, what Newton calls a uniform variation of curvature, is not an increaſe or diminution by equal arithmetical differences, but by equal proportions of the curvature in every point. The variation of curvature in ſimilar points of ſimilar arches is ſuppoſed to be the ſame.

It is evident that this ratio is the ſame with that of radius to the tangent of the angle *pm*B, or of 1 to its tabular tangent. The tangent therefore of this angle correſponding to any point of a curve is the meaſure of the variation of curvature in that point. Now it may be ſhewn (and it will appear by and bye), that the fluxion of TK in fig. 11. or the ultimate value of KQ, is always $\frac{2}{3}$ds of the fluxion of the radius of curvature. Therefore the tangent of the angle QBK is always $\frac{2}{3}$ds of that of *pm*B; and therefore the angle QBK, which we have ſeen to be an index of the cloſeneſs of contact, is alſo the index of the variation of curvature (See *M'Laurin*, § 386.).

Sir Iſaac Newton has given ſpecimens of the uſe of this meaſure in a variety of geometrical curves, by means of a general expreſſion of $\frac{\dot{r}}{\dot{z}}$. Thus, in the curve ABC (fig. 8.), let AB be $= z$, AD $= x$, DB $= y$, BN $= r$, and BE $= p$; we have $\frac{\text{N}n}{\text{B}b} = \frac{\dot{r}}{\dot{z}}$. Now DB : BE $= y : p, = \text{D}d : \text{B}b, = \dot{x} : \dot{z}$. Therefore $\dot{z} = \frac{p\dot{x}}{y}$, and $\frac{\dot{r}}{\dot{z}} = \frac{y\dot{r}}{p\dot{x}}$. Now, in every curve which we can expreſs by an equation, we can obtain all theſe quantities p, y, $\dot{r}$, and $\dot{z}$, and can therefore obtain the meaſure

of

Involution.

of the variation of curvature. It is alſo deſerves particular notice, that this inveſtigation of $\frac{\dot{r}}{\dot{z}}$ is equivalent with finding the centre and radius of curvature of the evolute, by which the curve under conſideration is generated; or with finding the centre q (fig. 13.) of an equiangular ſpiral, which will touch our curve in m, its evolute in B, and the evolute of the evolute in p, if put into different poſitions when neceſſary. This leads to very curious ſpeculations, for which, however, we have no room It has been ſaid, for inſtance, that the curvature at the interſection of a cycloid with its baſe is infinitely greater than that of any circle. If the evolution of the cycloid begin from this point, the curvature of its evolutrix will be infinitely greater ſtill upon the ſame principles; and we ſhall have one infinitely greater than this by evolving it. Yet all theſe infinites, multiplied to infinity, are contained in the central point of every equiangular ſpiral! In like manner, there are evolutrixes which coincide with a ſtraight line, and others of infinitely greater rectitude, and ſtill they are curves. Can this have any meaning? And can it be reconciled with the legitimate reaſoning from the ſame principles, that all theſe curvatures and angles of contact are producible by evolution; and that they may be, and certainly are every day deſcribed, by bodies moving in free ſpace, and acted on by accelerating forces directed to different bodies?

The parabola (conical) is the moſt ſimple of all the lines of unequably varying curvature, and becomes a very good ſtandard of compariſon. In the parabola ABC (fig. 8.) let the parameter be $2a$. The equation is then $2ax = y^2$; DE $= a$; p, or BE $= \sqrt{a^2+y^2}$ DQ $= a + 2x$ (by what was formerly demonſtrated). Moreover, DB : BE = DQ : BN; and BN $= \frac{pa+2px,}{a} = r$. Theſe equations give $2a\dot{x} = 2y\dot{y}, = 2p\dot{p}$; and $\frac{a\dot{p}+2x\dot{p}+2p\dot{x}}{a} = \dot{r}$. Now making $\dot{x} = 1$, and reducing the equations, we obtain $\dot{y} = \frac{a}{y}$; $\dot{p} = \frac{y\dot{y}}{p} = \frac{a}{p}$; and $\dot{r} = \frac{a\dot{p}+2x\dot{p}+2p}{a}$.

With theſe values of $\dot{y}, \dot{p}, \dot{r}$, we obtain a numerical value of $\frac{y\dot{r}}{p}$ moſt readily. Thus, in order to obtain the index of variation of curvature in the point where the ordinate at the focus cuts the parabola, make $a = 1$. Then $2x = y^2$; $x = \frac{1}{2}$, $y\ (= \sqrt{2x}) = 1$; $\dot{y}\left(= \frac{a}{y}\right) = 1$; $p\ (= \sqrt{a^2+y^2}) = \sqrt{2}$; $\dot{p}\left(= \frac{a}{p}\right) = \sqrt{\frac{1}{2}}$, and $\dot{r}\left(= \frac{a\dot{p}+2x\dot{p}+2p}{a}\right) = \sqrt{2} \times 3$. Therefore $\frac{y\dot{r}}{p} = 3, =$ the index of variation in the point B when D is the focus of the parabola; that is to ſay, the fluxion of the radius of curvature is three times the fluxion of the curve.

Involution.

The index of variation, where the ordinate is equal to the parameter, is had by making $x = 2$. This gives $y = 2$; $\dot{y} = \frac{1}{2}$; $p = \sqrt{5}$; $\dot{p} = \sqrt{\frac{1}{5}}$, and $\dot{r} = 3\sqrt{5}$. Wherefore $\frac{y\dot{r}}{p} = 6$, which is the index of variation. Moreover, ſince $\dot{p}$ and $\dot{r}$ are in a conſtant ratio, it appears that the index of variation of curvature in the parabola is proportional to the ordinate y. It is always $= 6\,\frac{\text{ordinate}}{\text{parameter}}$; and thus, with very little trouble, we can deſcribe the evolute of its evolute, *i e.* of the ſemicubical parabola.

In like manner, it may be ſhewn, that in all the conic ſections $\frac{\dot{r}}{\dot{z}}$ is always proportional to the rectangle of the ordinate DB and the ſubnormal DE, or to DB × DE. In the parabola, whoſe equation is $2ax = y^2$, we have $\frac{\dot{r}}{\dot{z}} = \frac{3y}{a}$. In an ellipſe, whoſe equation is $2ax - bx^2 = y^2$, we have $\frac{\dot{r}}{\dot{z}} = \frac{3-3b}{a} \times$ DB × DE, and in the hyperbola, whoſe equation is $2ax + bx^2$, $\frac{\dot{r}}{\dot{z}}$ is $= \frac{2+3b}{a} \times$ DB × DE. This ratio, in all the three ſections, is always as the tangent of the angle contained between the diameter and the normal at the point of contact. By this we may compare them with a parabola. In the cycloid at the point E (fig. 5) $\frac{\dot{r}}{\dot{z}}$ is $=$ tan. ∠ EKM, &c. &c.

All theſe things may be traced in the obſervations made on fig. 11. and 12. When the angle BET is a right angle, the angle KBQ indicates it directly, its tangent being always $= \frac{2\dot{r}}{3\dot{z}}$. It is eaſy alſo to ſee, that when the curve EMH is a parabola, the line BKF is a ſtraight line parallel to ET. It is alſo plain, that by the ſame ſteps that we proved that no circle can paſs between this parabola and its equicurve circle ERB, ſo no other parabola can paſs between them. Indeed the ſame reaſoning will prove that no curve of the ſame kind can paſs between any curve and its oſculating circle. In many caſes, it is more eaſy to reaſon from the curvature of a curve, by comparing it with an equicurve parabola than with an equicurve circle; particularly in treating of the curvilineal motions of bodies in free ſpace, actuated by deflecting forces.

If EMH be an ellipſe or hyperbola, BKF is another ellipſe or hyperbola (*M'Laurin*, § 373.)

WE have thus endeavoured to introduce our readers into this curious branch of ſpeculative geometry. An introduction is all that can be expected from a work of this kind. We have enlarged on particular points, in proportion as we thought that the notions entertained on the ſubject were inadequate, or even vague and indiſtinct; and we hope that ſome may be incited to acquire clearer conceptions by going to the fountain head. We conclude, by recommending to the young geometer the peruſal of the Fluxions of Sir Iſaac Newton, after

after he has read M'Laurin's Chapter with care. He will probably be ſurpriſed and delighted with ſeeing the whole compreſſed by a maſter's hand into ſuch narrow compaſs with ſuch beautiful perſpicuity.

JOAN D' ARC, the maid of Orleans, has been variouſly characteriſed; but all now agree, that ſhe was worthy of a better fate than the horrid death ſhe was doomed to die. (See JOAN *d'Arc*, *Encycl.*). But did ſhe actually die that death? An ingenious writer in the *Monthly Magazine* has proved, we think, that ſhe did not.

The biſhop of Beauvais (ſays he) is accuſed by all parties of treachery and trick in the conduct of the trial: it was his known propenſity to gain his ends by ſtratagem, craft, manœuvre, fraud, dexterity. He ſeeks out, and brings forward, ſuch teſtimony only as relates to eccleſiaſtical offences, and then hands over the deciſion to the ſecular judges, whoſe clemency he invokes. Joan ſays to him publicly, "You * *promiſed* to reſtore me to the church, and you deliver me to my enemies." The intention of the biſhop, then, muſt have been, that the ſecular judges, for want of evidence, ſhould ſee no offence againſt the ſtate; as the clerical judges, notwithſtanding the evidence, had declined to ſee any againſt the church. A fatal ſentence was, however, pronounced; and the fulfilment of it entruſted to the eccleſiaſtical authorities. Immediately after the *auto da fé*, one of the executioners ran to two friars, and ſaid, "that he had never been ſo ſhocked at any execution, and that the Engliſh had built up † a ſcaffolding of plaſter (*un echafaud de platre*) ſo lofty, that he could not approach the culprit, which muſt have cauſed her ſufferings to be long and horrid." She was, therefore, by ſome *unuſual* contrivance, kept out of the reach and obſervation even of the executioners.

Some time after, when public commiſeration had ſucceeded to a vindictive bigotry, a woman appeared at Metz ‡, who declared herſelf to be Joan of Arc. She was everywhere welcomed with zeal. At Orleans, eſpecially, where Joan was well known, ſhe was received with the honours due to the liberatreſs of the town. She was acknowledged by both her brothers, Jean and Pierre d'Arc. On their teſtimony ſhe was married by a gentleman of the houſe of Amboiſe, in 1436. At their ſolicitation her ſentence was annulled in 1456. The Pariſians, indeed, long remained incredulous: they muſt elſe have puniſhed thoſe eccleſiaſtics, whoſe humanity, perhaps, conſpired with the biſhop of Beauvais to withdraw her from real execution down a central chimney of brick and mortar; or, as the executioner called it, a ſcaffolding of plaſter. The king, for the woman ſeems to have ſhunned no confrontation, is ſtated to have received her with theſe words: "*Pucelle, m'amie, ſoyez la tres bien revenue, au nom de Dieu.*" She is then ſaid to have communicated to him, kneeling, the artifice practiſed. Can this woman be an impoſtor? Our author thinks not, and appeals to Voltaire, who, in his proſe works, ſeems willing to allow that ſhe was not, as is too commonly imagined, one of thoſe half inſane enthuſiaſts, employed as tools to work upon the vulgar; whom the one party endeavoured to cry up as a propheteſs, and the other to cry down as a witch; but that ſhe was a real heroine, ſuperior to vulgar prejudice, and no leſs remarkable by force of mind than for a courage and ſtrength unuſual in her ſex. This opinion is certainly countenanced by her behaviour in adverſity, and during her trial, which was firm without inſolence, and exalted without affectation.

JONES (Sir William), who was ſtyled by Johnſon the moſt enlightened of men, was the ſon of William Jones, Eſq; one of the laſt of thoſe genuine mathematicians, admirers, and contemporaries of Newton, who cultivated and improved the ſciences in the preſent century. Our author was born on the 28th of September 1746, and received his education at Harrow ſchool, under the care of Dr Robert Sumner, whom he has celebrated in an eulogium which will out-laſt braſs or marble. We are told that he was a claſs-fellow with Dr Parr, and at a very early age diſplayed talents which gave his tutor the moſt promiſing expectations, and which have ſince been amply juſtified. From Harrow he was ſent to Univerſity college, Oxford, where the rapidity and elegance of his literary acquiſitions excited general admiration; while a temper, ardently generous, and morals perfectly irreproachable, procured him teſtimonies of the moſt valuable eſteem. The grateful affection which he always cheriſhed for that venerable ſeat of learning, did as much honour to his ſenſibility, as Oxford herſelf has received by enrolling him among the number of her ſons.

In the twenty-third year of his age he travelled through France, and reſided ſome time at Nice, where he employed himſelf very differently from moſt other young men who make what is called the tour of Europe. *Man*, and the influence of various forms of *government*, were the principal objects of his inveſtigation; and in applying the reſult of his inquiries to the ſtate of his own country, he mingled the ſolicitudes of the Patriot with the honeſt partialities of an Engliſhman.

Mr Jones's firſt literary work was a tranſlation into French of a Perſian manuſcript, entitled "*Hiſtoire de Nadir Shah, connu ſous le nom de Thahmas Kuli Khan, Empereur de Perſe,*" in two vols. 4to; the hiſtory of which performance we ſhall give in his own words: "A great northern monarch, who viſited this country a few years ago, under the name of the Prince of Travendal, brought with him an eaſtern manuſcript, containing the life of Nadir Shah, the late ſovereign of Perſia, which he was deſirous of having tranſlated in England. The ſecretary of ſtate, with whom the Daniſh miniſter had converſed upon the ſubject, ſent the volume to me, requeſting me to give a literal tranſlation of it in the French language; but I wholly declined the taſk, alledging for my excuſe the length of the book, the dryneſs of the ſubject, the difficulty of the ſtyle, and chiefly my want both of leiſure and ability to enter upon an undertaking ſo fruitleſs and ſo laborious. I mentioned, however, a gentleman, with whom I had not then the pleaſure of being acquainted, but who had diſtinguiſhed himſelf by a tranſlation of a Perſian hiſtory, and was far abler than myſelf to ſatisfy the king of Denmark's expectations. The learned writer, who had other works upon his hands, excuſed himſelf on the account of his many engagements; and the application to me was renewed. It was hinted, that my compliance would be of no ſmall advantage to me at my entrance into life; that it would procure me ſome mark of diſtinction which might be pleaſing to me; and, above all, that it would be a reflec-

tion upon this country, if the king ſhould be obliged to carry the manuſcript into France. Incited by theſe motives, and principally by the laſt of them, unwilling to be thought churliſh or moroſe, and eager for the bubble reputation, I undertook the work, and ſent a ſpecimen of it to his Daniſh Majeſty; who returned his approbation of the ſtyle and method, but deſired that the whole tranſlation might be perfectly literal, and the oriental images accurately preſerved. The taſk would have been far eaſier to me, had I been directed to finiſh it in Latin; for the acquiſition of a French ſtyle was infinitely more tedious; and it was neceſſary to have every chapter corrected by a native of France, before it could be offered to the diſcerning eye of the public, ſince in every language there are certain peculiarities of idiom, and nice ſhades of meaning, which a foreigner can never learn to perfection. But the work, how arduous and unpleaſing ſoever, was completed in a year, not without repeated hints from the ſecretary's office that it was expected with great impatience by the Court of Denmark." The tranſlation of the Hiſtory of Nadir Shah was publiſhed in the ſummer of the year 1770, at the expence of the tranſlator; and forty copies upon large paper were ſent to Copenhagen; one of them bound with uncommon elegance for the king himſelf, and the others as preſents to his courtiers*.

What marks of diſtinction our author received, or what fruits he reaped for his labour, he has not thought proper to diſcloſe; but if any dependence is to be placed on common fame, the reward beſtowed upon him for this laborious taſk conſiſted only in the thanks of his Daniſh Majeſty, and the honour of being enrolled in the Royal Society of Copenhagen. That diſtinction was indeed accompanied with a letter, recommending the learned tranſlator to the patronage of his own ſovereign; but, in the interim, his friend Lord Dartmouth, who was to have delivered it, had reſigned his office of ſecretary of ſtate, and the letter, we are told, was never preſented.

There is reaſon to think, that this early and ſevere diſappointment made a deep impreſſion on his mind, and induced him to renounce the muſes for a time, and to apply himſelf with aſſiduity to the ſtudy of juriſprudence. This we think apparent, from the ſtyle in which he writes of his return from the continent, and of the death of his beloved preceptor Dr Sumner.

"When I left Nice, (ſays he) where I had reſided near ſeven months, and after traverſing almoſt all France, returned to England, I moſt ardently deſired to paſs ſeveral years more in the ſtudy of polite literature; as then, I thought, I might enter into public life, to which my ambition had always prompted me, more mature and prepared: but with this fruit of my leiſure, either fortune, or rather Providence, the diſpoſer of all human events, would not indulge my ſloth; for on a ſudden, I was obliged to quit that very literature to which, from my childhood, I had applied myſelf; and he who had been the encourager and aſſiſtant of my ſtudies, who had inſtructed, taught, formed me ſuch as I was, or if I am any thing at all, Robert Sumner, within a year after my return, was ſnatched away by an untimely death (a)."

In 1771 Mr Jones publiſhed *Diſſertation ſur la Literature Orientale*, 8vo, and this was followed by *Lettre à Monſieur A** Du P***, dans laquelle eſt compris l'Examen de ſa Traduction des Livres attribues à Zoroaſtre*, 8vo. The diſſertation offered a favourable ſpecimen of the author's abilities as a linguiſt and as a critic; and the letter contained a ſpirited vindication of the univerſity of Oxford, from the very ſcurrilous reproaches, in which its incompetency in Oriental literature was aſſerted by the illiberal tranſlator of the ſuppoſed works of the Perſian philoſopher.

In the ſame year he gave to the public, "A Grammar of the Perſian language," 4to, and at the ſame time propoſed to republiſh Meninſki's Dictionary, with improvements from *De Labroſſee's Gazophylacium Linguæ Perſarum*, and to add in their proper place an Appendix ſubjoined to Gehaunagnire's Perſic Dictionary. The Grammar has been found extremely uſeful, and has

* *Preface to the Hiſtory of Nadir Shah*, 1773.

(a) As a ſpecimen of our author's latinity, we ſubjoin the epitaph on Dr Sumner, which is affixed to the wall of the ſouth tranſept of Harrow church.

Ingenii, virtutis triſte reliquit deſiderium, ſubitâ, eheu! atque immaturâ
Morte correptus prid. Id. Sept. A. D.
1771, Æt. 41.

has been reprinted ſeveral times; but the deſign of the Dictionary, though an object of even national importance, for want of due encouragement was obliged to be laid aſide.

In 1772 he publiſhed "Poems; conſiſting chiefly of Tranſlations from the Aſiatic Languages. To which are added two Eſſays; 1. On the Poetry of the Eaſtern Nations. 2. On the Arts commonly called Imitative," 8vo, which in 1777 he republiſhed with the addition of ſome Latin Poems, every way worthy of their author. On the 18th June 1773, he took the degree of Maſter of Arts, and the ſame year publiſhed "The Hiſtory of the Life of Nadir Shah, King of Perſia. Extracted from an Eaſtern Manuſcript, which was tranſlated into French by order of his Majeſty the King of Denmark. With an Introduction, containing, 1. A Deſcription of Aſia according to the Oriental Geographers. 2. A ſhort Hiſtory of Perſia from the earlieſt Times to the preſent Century: And an Appendix, conſiſting of an Eſſay on Aſiatic Poetry, and the Hiſtory of the Perſian Language. To which are added Pieces relative to the French Tranſlation," 8vo. Our author having at this period determined to ſtudy the law as a profeſſion, and to relinquiſh every other purſuit, our readers will not be diſpleaſed with the following extract, relating to this reſolution, which concludes the preface to the hiſtory now under conſideration:

"To conclude; if any eſſential miſtakes be detected in this whole performance, the reader will excuſe them, when he reflects upon the great variety of dark and intricate points which are diſcuſſed in it; and if the obſcurity of the ſubject be not a ſufficient plea for the errors which may be diſcovered in the work, let it be conſidered, to uſe the words of Pope in the preface to his juvenile poems, that there are very few things in this collection which were not written under the age of five-and-twenty: moſt of them indeed were compoſed in the intervals of my leiſure in the South of France, before I had applied myſelf to a ſtudy of a very different nature, which it is now my reſolution to make the ſole object of my life. Whatever then be the fate of this production, I ſhall never be tempted to vindicate any part of it which may be thought exceptionable; but ſhall gladly reſign my own opinions, for the ſake of embracing others, which may ſeem more probable; being perſuaded, that nothing is more laudable than the love of truth, nothing more odious than the obſtinacy of perſiſting in error. Nor ſhall I eaſily be induced, when I have diſburdened myſelf of two other pieces which are now in the preſs, to begin any other work of the literary kind; but ſhall confine myſelf wholly to that branch of knowledge in which it is my chief ambition to excel. It is a painful conſideration, that the profeſſion of literature, by far the moſt laborious of any, leads to no real benefit or true glory whatſoever. Poetry, ſcience, letters, when they are not made the ſole buſineſs of life, may become its ornaments in proſperity, and its moſt pleaſing conſolation in a change of fortune; but if a man addicts himſelf entirely to learning, and hopes by that, either to raiſe a family, or to acquire, what ſo many wiſh for, and ſo few ever attain, an honourable retirement in his declining age, he will find, when it is too late, that he has miſtaken his path; that other labours, other ſtudies, are neceſſary; and that unleſs he can aſſert his own independence in active life, it will avail him little to be favoured by the learned, eſteemed by the eminent, or recommended even by kings. It is true, on the other hand, that no external advantages can make amends for the loſs of virtue and integrity, which alone give a perfect comfort to him who poſſeſſes them. Let a man, therefore, who wiſhes to enjoy, what no fortune or honour can beſtow, the bleſſing of ſelf-approbation, aſpire to the glory given to Pericles by a celebrated hiſtorian, of being acquainted with all uſeful knowledge, of expreſſing what he knows with copiouſneſs and freedom, of loving his friends and country, and of diſdaining the mean purſuits of lucre and intereſt: this is the only career on which an honeſt man ought to enter, or from which he can hope to gain any ſolid happineſs."

The next year he publiſhed *Poeſeos Aſiaticæ Commentariorum Libri Sex, cum Appendice: ſubjicitur Limon, ſeu Miſcellaneorum Liber*, 8vo; and purſuing his purpoſe of applying to the ſtudy of the law, we hear no more of him from the preſs (except the new edition of his Poems), until the year 1779. In this interval he was called to the bar, and attended Weſtminſter hall and the Oxford circuit, where he obtained but little buſineſs. He was however appointed a commiſſioner of bankrupts by Lord Bathurſt, who is ſuppoſed to have intended to exert his intereſt to procure his nomination to the bench in the Eaſt Indies.

He publiſhed in this year, "The ſpeeches of Iſeus, in cauſes concerning the law of ſucceſſion to property at Athens; with a preparatory diſcourſe, notes critical and hiſtorical, and a Commentary, 4to." In this valuable work, the talents of the ſcholar, the critic, and the lawyer, combine to elucidate a very important part of juriſprudence; for, "though deep reſearches into the legal antiquities of *Greece* and *Rome* (as he obſerves in his Commentary) are of greater uſe to ſcholars and contemplative perſons, than to lawyers and men of buſineſs; though Bracton and Lyttleton, Coke and Rolle, are the proper objects of our ſtudy; yet the ableſt advocates, and wiſeſt judges, have frequently embelliſhed their arguments with learned alluſions to antient caſes; and ſuch alluſions, it muſt be allowed, are often uſeful, always ornamental; and, when they are introduced without pedantry, never fail to pleaſe." The work was dedicated in a ſtyle of reſpectful gratitude to his patron Lord Bathurſt.

In the year 1780, we find our author a candidate to repreſent in parliament the univerſity of Oxford. He had for ſome time reſided but little in the univerſity, and therefore laboured under ſome diſadvantages; but he did not meanly court the ſupport of any man. In a paper, which was circulated on that occaſion, his friends, who were numerous, declare, that they have "neither openly ſolicited, nor intend openly to ſolicit, votes for Mr Jones within the Univerſity itſelf, becauſe he will never become the inſtrument of diſturbing the calm ſeat of the Muſes, by conſenting to any ſuch ſolicitation for himſelf or for any man whatever. His own applications have been, are, and will be, confined to thoſe only who have profeſſed a regard for him, *and who have no votes themſelves*: the Maſters of Arts in a great univerſity, whoſe prerogative is cool reaſon and impartial judgment, muſt never be placed on a level with the voters of a borough, or the freeholders of a county. Even in proceeding thus far, he does not ſet the example, but follows it; and his friends would never have printed any paper, if they had not thought themſelves juſtified by the conduct of others.

"For the firſt and the laſt time, they beg leave to ſuggeſt, that no exertions muſt be ſpared by thoſe who, either perſonally or by reputation, approve the character of Mr Jones; into which, both literary and political, as well as moral, his friends deſire and demand the ſtricteſt ſcrutiny. For his univerſity he began early to provoke, and poſſibly to incur, the diſpleaſure of great and powerful men: For his univerſity he entered the liſts with a foul-mouthed and arrogant Frenchman, who had attacked Oxford in three large volumes of miſrepreſentation and ſcurrility: For his univerſity he reſigned, for a whole year, his favourite ſtudies and purſuits, to ſave Oxford the diſcredit of not having one of her ſons ready to tranſlate a tedious Perſian manuſcript. To Oxford, in ſhort, he is known to be attached by the ſtrongeſt poſſible ties; and only regrets the neceſſity of abſenting himſelf from the place in which of all others he moſt delights, until the event of the preſent competition ſhall either convince him that he has toiled in vain as a man of letters, or ſhall confer on him the greateſt reward to which he can aſpire. The unavoidable diſadvantage of being ſo late propoſed, and the reſpectable ſupport with which he is now honoured, will ſecure him in all events from the leaſt diſgrace." The application was unſucceſsful, chiefly becauſe his own college had fixed upon another candidate, from a perſuaſion that the immediate appointment of Mr Jones to a ſeat, then vacant on the bench of judges in India, was morally certain.

The riots of that year gave occaſion to another publication of our author, entitled, "An Inquiry into the legal Mode of ſuppreſſing Riots; with a conſtitutional Plan of future Defence," 8vo; and in 1781 he publiſhed "An Eſſay on the Law of Bailments," 8vo, a very maſterly treatiſe, which did great honour to his legal abilities. In this laſt work he inculcates the neceſſity of deeply exploring the grounds of the common law; and ſpeaking of Blackſtone, (he ſays) "his commentaries are the moſt correct and beautiful outline that ever was exhibited of any human ſcience; but they alone will no more form a lawyer, than a general map of the world, how accurately and elegantly ſoever it may be delineated, will make a geographer."

In this year he likewiſe recalled his muſe in an Ode on the nuptials of Lord Viſcount Althorpe, who had been his pupil, to Miſs Lavinia Bingham. This beautiful little poem is preſerved in the European Magazine for January 1785, and we think in other periodical publications.

From many circumſtances which might be collected together, it would appear that our author at this juncture did not coincide in opinion with thoſe who had the direction of government, nor did he approve the meaſures at that period adopted.—With theſe ſentiments he ſeems to have been ſelected as a proper perſon to be introduced as a member of the Conſtitutional Society. Could he have foreſeen the degeneracy of ſuch aſſociations, there is reaſon to believe that he would have declined what he condeſcended to accept as an honour; for though an ardent friend to liberty, he was an enemy to theoretical innovation, and declares, in a letter to the ſecretary, that by the term conſtitution, he underſtands "the great ſyſtem of public, in contradiction to private and criminal law, which compriſes all thoſe articles which Blackſtone arranges, in his firſt volume, under the rights of perſons, and of which he gives a perſpicuous analyſis. Whatever then relates to the rights of perſons, either abſolute rights, as the enjoyment of liberty, ſecurity, and property, or relative, that is, in the public relations of magiſtrates and people, makes a part of that majeſtic whole, which we properly call the conſtitution. This conſtitutional or public law is partly unwritten, and grounded upon immemorial uſage, and partly written or enacted by the legiſlative power; but the unwritten, or common law, contains the true ſpirit of our conſtitution: the written has often moſt unjuſtifiably altered the form of it; the common law is the collected wiſdom of many centuries, having been uſed and approved by ſucceſſive generations; but the ſtatutes frequently contain the whims of a few leading men, and ſometimes of the mere individuals employed to draw them."

In 1782 he publiſhed "The Mahomedan Law of Succeſſion to the Property of Inteſtates, in Arabic, with a verbal Tranſlation and explanatory Notes." 4to.

At length the poſt of one of the judges in the Eaſt Indies, which had been kept vacant five years, was determined upon being filled up; and our author, on the 4th March 1783, was appointed to that ſtation, and on the 20th received the honour of knighthood. On the 8th of April he married Miſs Shipley, eldeſt daughter of the Biſhop of St Aſaph, and almoſt immediately embarked for the Indies. He had previouſly publiſhed "The Moallakat; or, Seven Arabian Poems, which were ſuſpended on the Temple at Mecca, with a Tranſlation and Arguments." 4to. To this it was intended to add a preliminary diſcourſe and notes.—The former to compriſe obſervations on the antiquity of the Arabian language and letters; on the dialects and characters of Himyar and Koraiſh, with accounts of ſome Himyarick poets; on the manners of the Arabs in the age immediately preceding that of Mahomed; on the temple at Mecca, and the Moallakat, or pieces of poetry ſuſpended on its walls or gate; laſtly, on the lives of the Seven Poets, with a critical hiſtory of their works, and the various copies or editions of them preſerved in Europe, Aſia, and Africa. The latter to contain authorities and reaſons for the tranſlation of controverted paſſages; to elucidate all the obſcure couplets, and exhibit or propoſe amendments of the text; to direct the reader's attention to particular beauties, or point out remarkable defects; and to throw light on the images, figures, and alluſions of the Arabian poets, by citations either from writers of their own country, or from ſuch of our European travellers as beſt illuſtrate the ideas and cuſtoms of Eaſtern nations. This diſcourſe and the notes have not yet appeared. At his departure for the eaſtern world, he left, in manuſcript, with his brother-in-law the Dean of St Aſaph, a little tract, entitled "The Principles of Government, in a Dialogue between a Scholar and a Peaſant." This celebrated dialogue being afterwards publiſhed by the Dean, and widely circulated by the ſociety for conſtitutional information, the Dean was proſecuted for publiſhing a libel, and, if our memory deceives us not, was found guilty.

Sir William Jones now dropt for ever all concern in party politics, and applied himſelf to purſuits more worthy of his talents. During his voyage to India, he conceived the idea of the Aſiatic Society, of which an account has been given under the title SOCIETIES (*Encycl.*), and of whoſe reſearches five volumes, replete with much curious information, are now before the public. But ardently as his mind was attached to general literature and ſcience, he was by no means inattentive to the profeſſional duties of his high ſtation. He had indeed, to uſe his own expreſſion, an “ undiſſembled fondneſs for the ſtudy of juriſprudence *;” and in the character of a judge, diſplayed the profound knowledge and irreproachable integrity, which, before his promotion, pervaded his reaſonings as a lawyer, and governed his conduct as a man. Unfortunately the intenſe ardour of application, which produced his frequent contributions to the ſtock of human knowledge, added to the unfavourable influence of the climate, greatly impaired his health. On this account, after a reſidence of about fifteen years in India, he made preparations for returning to England; but death interpoſed; and this illuſtrious ornament of ſcience and virtue was taken from the world on the 27th of April 1794, in the 48th year of his age. “ It is to the ſhame of ſcepticiſm (as one of his biographers well obſerves), to the encouragement of hope, and to the honour of genius, that this great man was a ſincere believer in the doctrines of Chriſtianity, and that he was found in his cloſet in the attitude of addreſſing his prayer to God.” We ſhall give his character as it was drawn by Sir John Shore, Baronet, (now Lord Teignmouth) in a diſcourſe delivered at a meeting of the Aſiatic Society, held on the 22d of May 1794.

“ His capacity for the acquiſition of languages has never been excelled. In Greek and Roman literature, his early proficiency was the ſubject of admiration and applauſe; and knowledge of whatever nature, once obtained by him, was ever afterwards progreſſive. The more elegant dialects of modern Europe, the French, the Spaniſh, and Italian, he ſpoke and wrote with the greateſt fluency and preciſion; and the German and Portugueſe were familiar to him. At an early period of life his application to Oriental literature commenced; he ſtudied the Hebrew with eaſe and ſucceſs; and many of the moſt learned Aſiatics have the candour to avow, that his knowledge of Arabic and Perſian was as accurate and extenſive as their own; he was alſo converſant in the Turkiſh idiom, and the Chineſe had even attracted his notice ſo far as to induce him to learn the radical characters of that language, with a view perhaps to farther improvements. It was to be expected, after his arrival in India, that he would eagerly embrace the opportunity of making himſelf maſter of the Sanſcrit; and the moſt enlightened profeſſors of the doctrines of Brahma confeſs with pride, delight, and ſurpriſe, that his knowledge of their ſacred dialect was moſt critically correct and profound. The Pandits, who were in the habit of attending him, could not, after his death, ſuppreſs their tears for his loſs, nor find terms to expreſs their admiration at the wonderful progreſs he had made in their ſciences.

“ Before the expiration of his twenty-ſecond year, he had completed his Commentaries on the Poetry of the Aſiatics, although a conſiderable time afterwards elapſed before their publication; and this work, if no other monument of his labours exiſted, would at once furniſh proofs of his conſummate ſkill in the Oriental dialects, of his proficiency in thoſe of Rome and Greece, of taſte and erudition far beyond his years, and of talents and application without example.

“ But the judgment of Sir William Jones was too diſcerning to conſider language in any other light than as the key of ſcience, and he would have deſpiſed the reputation of a mere linguiſt. Knowledge and truth were the objects of all his ſtudies, and his ambition was to be uſeful to mankind; with theſe views he extended his reſearches to all languages, nations, and times.

“ Such were the motives that induced him to propoſe to the government of India, what he juſtly denominated a work of national utility and importance, the compilation of a copious Digeſt of Hindu and Mahomedan Law, from Sanſcrit and Arabic originals, with an offer of his ſervices to ſuperintend the compilation, and with a promiſe to tranſlate it. He had foreſeen, previous to his departure from Europe, that without the aid of ſuch a work, the wiſe and benevolent intentions of the legiſlature of Great Britain, in leaving to a certain extent the natives of theſe provinces in poſſeſſion of their own laws, could not be completely fulfilled; and his experience, after a ſhort reſidence in India, confirmed what his ſagacity had anticipated, that without principles to refer to, in a language familiar to the judges of the courts, adjudications amongſt the natives muſt too often be ſubject to an uncertain and erroneous expoſition, or wilful miſinterpretation of their laws.

“ To the ſuperintendance of this work, which was immediately undertaken at his ſuggeſtion, he aſſiduouſly devoted thoſe hours which he could ſpare from his profeſſional duties. After tracing the plan of the Digeſt, he preſcribed its arrangement and mode of execution, and ſelected from the moſt learned Hindus and Mahomedans fit perſons for the taſk of compiling it: flattered by his attention, and encouraged by his applauſe, the Pandits proſecuted their labours with chearful zeal to a ſatiſfactory concluſion. The Molavees have alſo nearly finiſhed their portion of the work; but we muſt ever regret, that the promiſed tranſlation, as well as the meditated preliminary diſſertation, have been fruſtrated by that decree, which ſo often intercepts the performance of human purpoſes.

“ During the courſe of this compilation, and as auxiliary to it, he was led to ſtudy the works of Menu, reputed by the Hindus to be the oldeſt and holieſt of legiſlators; and finding them to compriſe a ſyſtem of religious and civil duties, and of law in all its branches, ſo comprehenſive and minutely exact, that it might be conſidered as the Inſtitutes of Hindu Law, he preſented a tranſlation of them to the government of Bengal. During the ſame period, deeming no labour exceſſive or ſuperfluous that tended in any reſpect to promote the welfare or happineſs of mankind, he gave the public an Engliſh verſion of the Arabic Text of the Sirajiyah or Mahomedan Law of Inheritance, with a Commentary. He had already (as has been obſerved) publiſhed in England a tranſlation of a tract on the ſame ſubject by another Mahomedan lawyer, containing, as his own words expreſs, ‘ a lively and elegant Epitome of the Law of Inheritance of Zaid.’

“ To

---

* *Law of Bailments.*

"To theſe learned and important works, ſo far out of the road of amuſement, nothing could have engaged his application but that deſire which he ever profeſſed, of rendering his knowledge uſeful to his nation, and beneficial to the inhabitants of theſe provinces.

"I ſhould ſcarcely (continues Lord Teignmouth) think it of importance to mention, that he did not diſdain the office of editor of a Sanſcrit and Perſian work, if it did not afford me an opportunity of adding, that the latter was publiſhed at his own expence, and was ſold for the benefit of inſolvent debtors. A ſimilar application was made of the produce of Sirajiyah."

But nothing exhibits the large graſp of Sir William Jones's mind in ſo ſtriking a point of view as a paper in his own hand writing, which came into Lord Teignmouth's poſſeſſion after his death. It was intitled DESIDERATA, and propoſed for inveſtigation the following ſubjects relating to the eaſtern world.

India.—1. The ancient geography of India, &c. from the Puranas. 2. A botanical deſcription of Indian plants, from the Coſhas, &c. 3. A grammar of the Sanſcrit language, from Panini, &c. 4. A dictionary of the Sanſcrit language, from the 32 original vocabularies and Niructi. 5. On the ancient muſic of the Indians. 6. On the medical ſubſtances of India, and the Indian art of medicine. 7. On the philoſophy of the ancient Indians. 8. A tranſlation of the Veda. 9. On ancient Indian geometry, aſtronomy, and algebra. 10. A tranſlation of the Puranas. 11. A tranſlation of the Mahabbara and Ramayan. 12. On the Indian theatre, &c. &c. 13. On the Indian conſtellations, with their mythology, from the Puranas. 14. The hiſtory of India before the Madomedan conqueſt, from the Sanſcrit Caſhmir Hiſtories.

Arabia.—15. The hiſtory of Arabia before Mahomed. 16. A tranſlation of the Hamaſa. 17. A tranſlation of Hariri. 18. A tranſlation of the Facahatul Khulafa. Of the Caſiah.

Perſia.—19. The hiſtory of Perſia, from authorities in Sanſcrit, Arabic, Greek, Turkiſh, Perſian ancient and modern, Firdauſi's Khroſrau nama. 20. The five poems of Nizami, tranſlated in proſe. 21. A dictionary of pure Perſian Je changire.

China.—22. A tranſlation of Shi-cing. 23. The text of Can-fu-tſu, verbally tranſlated.

Tartary.—24. A hiſtory of the Tartar nations, chiefly of the Moguls and Othmans, from the Turkiſh and Perſian.

"We are not authoriſed (ſays his Lordſhip) to conclude, that he had himſelf formed a determination to complete the works which his genius and knowledge had thus ſketched; the taſk ſeems to require a period beyond the probable duration of any human life; but we, who had the happineſs to know Sir William Jones; who were witneſſes of his indefatigable perſeverance in the purſuit of knowledge, and of his ardour to accompliſh whatever he deemed important; who ſaw the extent of his intellectual powers, his wonderful attainments in literature and ſcience, and the facility with which all his compoſitions were made—cannot doubt, if it had pleaſed Providence to protract the date of his exiſtence, that he would have ably executed much of what he had ſo extenſively planned."

We have already enumerated attainments and works which, from their diverſity and extent, ſeem far beyond the capacity of the moſt enlarged minds; but the catalogue may yet be augmented. To a proficiency in the languages of Greece, Rome, and Aſia, he added the knowledge of the philoſophy of thoſe countries, and of every thing curious and valuable that had been taught in them. The doctrines of the Academy, the Lyceum, or the Portico, were not more familiar to him than the tenets of the Vedas, the myſticiſm of the Sufis, or the religion of the ancient Perſians; and whilſt, with a kindred genius, he peruſed with rapture the heroic, lyric, or moral compoſitions of the moſt renowned poets of Greece, Rome, and Aſia, he could turn with equal delight and knowledge to the ſublime ſpeculations or mathematical calculations of Barrow and Newton. With them alſo he profeſſed his conviction of the truth of the Chriſtian religion; and he juſtly deemed it no inconſiderable advantage, that his reſearches had corroborated the multiplied evidence of Revelation, by confirming the Moſaic account of the primitive world.

In his eighth anniverſary diſcourſe to the Aſiatic Society, he thus expreſſes himſelf: "Theological inquiries are no part of my preſent ſubject; but I cannot refrain from adding, that the collection of tracts which we call, from their excellence, the Scriptures, contain, independently of a divine origin, more true ſublimity, more exquiſite beauty, purer morality, more important hiſtory, and finer ſtrains both of poetry and eloquence, than could be collected within the ſame compaſs from all other books that were ever compoſed in any age, or any idiom. The two parts, of which the Scriptures conſiſt, are connected by a chain of compoſitions, which bear no reſemblance in form or ſtyle to any that can be produced from the ſtores of Grecian, Indian, Perſian, or even Arabian learning; the antiquity of theſe compoſitions no man doubts, and the unſtrained application of them to events long ſubſequent to their publication, is a ſolid ground of belief that they were genuine predictions; and conſequently inſpired."

There were, in truth, few ſciences in which he had not acquired conſiderable proficiency; in moſt, his knowledge was profound. The theory of muſic was familiar to him; nor had he neglected to make himſelf acquainted with the intereſting diſcoveries lately made in chemiſtry; "and I have heard him (ſays Lord Teignmouth) aſſert, that his admiration of the ſtructure of the human frame had induced him to attend for a ſeaſon to a courſe of anatomical lectures, delivered by his friend the celebrated Hunter."

His laſt and favourite purſuit was the ſtudy of botany, which he originally began under the confinement of a ſevere and lingering diſorder, which with moſt minds would have proved a diſqualification from any application. It conſtituted the principal amuſement of his leiſure hours. In the arrangements of Linnæus, he diſcovered ſyſtem, truth, and ſcience, which never failed to captivate and engage his attention; and from the proofs which he has exhibited of his progreſs in botany, we may conclude that he would have extended the diſcoveries in that ſcience.

It cannot be deemed uſeleſs or ſuperfluous to inquire by what arts or method he was enabled to attain to a degree of knowledge almoſt univerſal, and apparently beyond the powers of man, during a life little exceeding 47 years.

The faculties of his mind, by nature vigorous, were improved by conſtant exerciſe; and his memory, by habitual practice, had acquired a capacity of retaining whatever had once been impreſſed upon it. To an unextinguiſhed ardour for univerſal knowledge, he joined a perſeverance in the purſuit of it which ſubdued all obſtacles; his ſtudies began with the dawn, and, during the intermiſſions of profeſſional duties, were continued throughout the day; reflection and meditation ſtrengthened and confirmed what induſtry and inveſtigation had accumulated. It was a fixed principle with him, from which he never voluntarily deviated, not to be deterred by any difficulties that were ſurmountable from proſecuting to a ſucceſsful termination what he had once deliberately undertaken.

But what appeared more particularly to have enabled him to employ his talents ſo much to his own and the public advantage, was the regular allotment of his time, and a ſcrupulous adherence to the diſtribution which he had fixed; hence all his ſtudies were purſued without interruption or confuſion. He collected information, too, from every quarter; juſtly concluding, that ſomething might be learned from the illiterate, to whom he liſtened with the utmoſt candour and complacency.

Lord Teignmouth, addreſſing himſelf to the Aſiatic Society, ſays, "Of the private and ſocial virtues of our lamented Preſident, our hearts are the beſt records. To you who knew him, it cannot be neceſſary for me to expatiate on the independence of his integrity, his humanity, probity, or benevolence, which every living creature participated; on the affability of his converſation and manners, or his modeſt, unaſſuming deportment: nor need I remark, that he was totally free from pedantry, as well as from arrogance and ſelf-ſufficiency, which ſometimes accompany and diſgrace the greateſt abilities. His preſence was the delight of every ſociety, which his converſation exhilarated and improved; and the public have not only to lament the loſs of his talents and abilities, but that of his example.

"To him, as the founder of our inſtitution, and whilſt he lived its firmeſt ſupport, our reverence is more particularly due. Inſtructed, animated, and encouraged by him, genius was called forth into exertion, and modeſt merit was excited to diſtinguiſh itſelf. Anxious for the reputation of the Society, he was indefatigable in his own endeavours to promote it, whilſt he cheerfully aſſiſted thoſe of others. In loſing him, we have not only been deprived of our brighteſt ornament, but of the guide and patron, on whoſe inſtructions, judgement, and candour, we could implicitly rely." Though theſe are the ſentiments, not only of Lord Teignmouth, but, we believe, of every man of letters, we truſt there is ſtill left in Bengal a ſufficient love of letters and of ſcience to carry on the plan which was formed by the genius of Sir William Jones.

JONESIA, is a very handſome middling-ſized ramous tree, found in gardens about Calcutta. In the Sanſcrit it is called *As'óca*, and in the Bengaleſe *Ruſſuck*; but the name Joneſia was given to it by the Aſiatic Society, who conſecrated it to the memory of their firſt preſident Sir William Jones. It is thus deſcribed by Dr Roxburgh, a member of that ſociety:

"*Calyx*, two leaved, corol, one petaled, piſtil-bearing; baſe of the tube impervious; ſtamens long, aſcending, inſerted into the margin of a glandulous nectarial ring, which crowns the mouth of the tube, the uppermoſt two of which more diſtant; ſtyle declining. *Legume* turgid. *Trunk* erect, though not very ſtraight. *Bark* dark brown, pretty ſmooth. *Branches* numerous, ſpreading in every direction, ſo as to form a moſt elegant ſhady head. *Leaves* alternate, abruptly feathered, ſeſſile, generally more than a foot long; when young pendulous and coloured. *Leaflets* oppoſite, from four to ſix pair, the lowermoſt broad lanced, the upper lanced; ſmooth, ſhining, firm, a little waved, from four to eight inches long. *Petiole* common, round, and ſmooth. *Stipule* axillary, ſolitary; in fact a proceſs from the baſe of the common petiole, as in many of the graſſes and monandriſts, &c. *Umbels* terminal and axillary; between the ſtipule and branchlet, globular, crowded, ſubſeſſile, erect. *Bracts*, a ſmall hearted one under each diviſion of the umbel. *Peduncle* and pedicles ſmooth, coloured. *Flowers* very numerous, pretty large; when they firſt expand they are of a beautiful orange colour, gradually changing to red, forming a variety of lovely ſhades; fragrant during the night. *Calyx* perianth, below two-leaved, leaflets ſmall, nearly oppoſite, coloured, hearted, bracte-like, marking the termination of the pedicel, or beginning of the tube of the corol. *Corol* one-petalled, funnel-form; tube ſlightly incurved, firm, and fleſhy, tapering towards the baſe (club funnel-ſhaped) and there impervious; border four parted; diviſion ſpreading, ſuborbicular; margins moſt ſlightly woolly: one third the length of the tube. *Nectary*, a ſtimeniferous and piſtiliferous ring crowns the mouth of the tube. *Stamens*, filaments generally ſeven; and ſeven muſt, I think, be the natural number; viz. three on each ſide, and one below, above a vacancy, as if the place of an eighth filament, and is occupied on its inſide by the piſtil; they are equal, diſtinct, aſcending, from three to four times longer than the border of the corol. *Anthers* uniform, ſmall, incumbent. *Piſtil*, germ oblong, pediceled; pedicel inſerted into the inſide of the nectary, immediately below the vacant ſpace already mentioned; ſtyle nearly as long as the ſtamens, declining; ſtigma ſimple. *Pericarp*, legume ſcimeter-formed, turgid, outſide reticulated, otherwiſe pretty ſmooth; from ſix to ten inches long, and about two broad. *Seeds* generally from four to eight, ſmooth; grey, ſize of a large cheſnut."

The Joneſia flowers at the beginning of the hot ſeaſon, and its ſeeds ripen during the rains. The plants and ſeeds were originally brought to Calcutta from the interior parts of the country, where it is indigenous. *N. B.* Many of the flowers have only the rudiment of a piſtil. In Plate XXX. A is a branchlet of the natural ſize. B, A ſingle flower a little magnified; *a a* the calyx. C, A ſection of the ſame, exhibiting four of the ſtamens, 1 1 1 1 the piſtil 2, and how far the tube is perforated. D, A ſimilar ſection of one of the abortive flowers; 3 is the abortive fiſtil. E, The ripe legume opening near the baſe, natural ſize. *Note*, The ſpace between the *b* and *c* marks the original tube of the coral. F, One of the ſeeds, natural ſize. G, The baſe of the common petiole, with its ſtipule; *a a*, the petioles of the lower pair of leaflets.

JOOTSI-SIMA, a ſmall flat iſland, which is ſeparated from Cape Nota in Japan by a channel about five leagues wide. Its circumference does not exceed two leagues; it is well wooded, of an agreeable aſpect, and well inhabited. Perouſe, who ſailed round it, remarked from the quarter-deck of his ſhip ſome conſiderable edifices between the houſes of the inhabitants; and hard

Journals, Joyſt.

hard by a ſort of caſtle, at the ſouth-weſt point of the iſland, he diſtinguiſhed ſome gibbets. He does not, however, affirm that thoſe gibbets were for the execution of criminals; for, as he obſerves, it would be ſingular enough if the Japaneſe, whoſe cuſtoms are ſo different from ours, were in this point to reſembles us ſo nearly. He repreſents the iſland as ſurrounded with dreadful breakers; at the diſtance of a league and a half from which, he had conſtantly 60 fathoms, with rocky bottom. He places the iſland (differently, according to the editor of his voyage, from all other geographers) in latitude 37° 51′ north, and in Long. 135° 20′ eaſt from Paris.

JOURNALS, the title of periodical publications. See *Encyclopædia*. The principal Britiſh Journals are: *The Hiſtory of the Works of the Learned*, begun at London in 1699. *Cenſura Temporum*, in 1708. About the ſame time there appeared two new ones; the one under the title of *Memoirs of Literature*, containing little more than an Engliſh tranſlation of ſome articles in the foreign Journals, by M. de la Roche; the other, a collection of looſe tracts, intitled, *Bibliotheca Curioſa*, or a Miſcellany. Theſe, however, with ſome others, are now no more, but are ſucceeded by the *Annual Regiſter*, which began in 1758; the *New Annual Regiſter*, begun in 1780; the *Monthly Review*, which began in the year 1749, and gives a character of all Engliſh literary publications, with the moſt conſiderable of the foreign ones: the *Critical Review*, which began in 1756, and is nearly on the ſame plan: as alſo the *London Review*, by Dr Kenrick, from 1775 to 1780; *Maty's Review*, from Feb. 1782 to Aug. 1786; the *Engliſh Review*, begun in Jan. 1783; and the *Analytical Review*, begun in May 1788, dropt in 1798, and revived in 1799, under the title of the *New Analytical Review*; but again dropt after two or three months trial: the *Britiſh Critic*, begun in 1792, and ſtill carried on with much ſpirit and ability: the *Anti-Jacobin Review and Magazine*, commenced in 1798, for the meritorious purpoſe of counteracting the pernicious tendency of French principles in politics and religion: the *New London Review*, January 1799: *A Journal of Natural Philoſophy, Chemiſtry, and the Arts*, which was begun in 1797 by Mr Nicholſon, and has been conducted in ſuch a manner, that it is one of the moſt valuable works of the kind to be found in any language: the *Philoſophical Magazine*, begun in 1798 by Mr Tilloch, and carried on upon much the ſame plan, and with much the ſame ſpirit, as Nicholſon's Journal.

Beſides theſe, we have ſeveral monthly pamphlets, called *Magazines*, which, together with a chronological ſeries of occurrences, contain letters from correſpondents, communicating extraordinary diſcoveries in nature and art, with controverſial pieces on all ſubjects. Of theſe, the principal are thoſe called the *Gentleman's Magazine*, which began with the year 1731; the *London Magazine*, which began a few months after, and has lately been diſcontinued; the *Univerſal Magazine*, which is nearly of as old a date; the *Scotch Magazine*, which began in 1739, and is ſtill continued; the *European Magazine*; and the *Monthly Magazine*, a miſcellany of much information, but not of good principles.

JOYST or Jeyst, the ſecond month of the Bengal year.

Irrational ‖ Iron.

IRRATIONAL Numbers or *Quantities*, are the ſame as *ſurds*, for which ſee Algebra, *Encycl.*

IRREDUCIBLE Case, in algebra, is uſed for that caſe of cubic equations where the root, according to Cardan's rule, appears under an impoſſible or imaginary form, and yet is real.

It is remarkable that this caſe always happens, *viz.* one root, by Cardan's rule, in an impoſſible form, whenever the equation has three real roots, and no impoſſible ones, but at no time elſe.

If we were poſſeſſed of a general rule for accurately extracting the cube root of a binomial radical quantity, it is evident we might reſolve the irreducible caſe generally, which conſiſts of two of ſuch cubic binomial roots. But the labours of the algebraiſts, from Cardan down to the preſent time, have not been able to remove this difficulty. Dr Wallis thought that he had diſcovered ſuch a rule; but, like moſt others, it is merely tentative, and can only ſucceed in certain particular circumſtances.

IRON, is by much the moſt uſeful of all the metals, as has been ſufficiently proved under the article Iron, *Encycl.* and under Chemistry in this *Supplement*. The word is again introduced here, becauſe it affords us an opportunity of laying before our readers ſome valuable obſervations by Chaptal on the uſe of the *oxyds* of iron in dyeing cotton.

"The oxyd of iron has ſuch an affinity for cotton thread, that if the latter be plunged in a ſaturated ſolution of iron in any acid whatever, it immediately aſſumes a chamoy yellow colour, more or leſs dark, according to the ſtrength of the liquors. It is both a curious and eaſy experiment, that when cotton is made to paſs through a ſolution of the ſulphat of iron, rendered turbid by the oxyd which remains ſuſpended in the liquor, it will be ſufficient to dip the cotton in the bath to catch the laſt particle of the oxyd, and to reſtore to the liquor the tranſparency it has loſt. The ſolution, then, which before had a yellowiſh appearance, becomes more or leſs green, according as it is more or leſs charged.

"The colour given to cotton by the oxyd of iron becomes darker, merely by expoſure to the air; and this colour, ſoft and agreeable when taken from the bath, becomes harſh and ochry by the progreſſive oxydation of the metal. The colour of the oxyd of iron is very faſt: it reſiſts not only the air and water, but alſo alkaline leys, and ſoap gives it ſplendour without ſenſibly diminiſhing its intenſity. It is on account of theſe properties that the oxyd of iron has been introduced into the art of dyeing, and been made a colouring principle of the utmoſt value.

"In order that the oxyd of iron may be conveniently applied to the cotton thread, it is neceſſary to begin by effecting its ſolution; and, in this caſe, acids are employed as the moſt uſeful ſolvents. Dyers almoſt everywhere make a myſtery of the acid which they employ; but it is always the acetous, the ſulphuric, the nitric, or the muriatic. Some of them aſcribe great differences to the ſolution of iron by the one or the other acid; but, in general, they give the preference to the acetous. This predilection appears to be founded much leſs on the difference of the colours that may be communicated by the one or the other ſalt, than on the different degrees of corroſive power which each exerciſes on the ſtuff. That of the ſulphat and muriat is ſo great, that if the ſtuff be not waſhed when it comes from the bath, it will certainly be burnt; whereas ſolutions by the acetous, or any other vegetable acid, are not attended with the like inconvenience.

"Iron appears to be at the ſame degree of oxydation in the different acids, ſince it produces the ſame ſhade of colour when precipitated; and any acid ſolvent may be employed indiſcriminately, provided the nature of the ſalt, and the degree of the ſaturation of the acid, be ſufficiently known; for the ſubſequent operations may be then directed according to this knowledge, and the inconveniences which attend the uſe of ſome of theſe ſalts may be prevented. This, without doubt, is a great advantage which the man of ſcience enjoys over the mere workman, who is incapable of varying his proceſs according to the nature and ſtate of the ſalts which he employs.

"1. If the ſulphat of iron, or any other martial ſalt, be diſſolved in water, and cotton be dipped in the liquid, the cotton will aſſume a chamoy colour, more or leſs dark according as the ſolution is more or leſs charged. The affinity of the cotton to the iron is ſo great, that it attracts the metal, and takes it in a great meaſure from the acid by which it was diſſolved.

"2. If the iron of a pretty ſtrong ſolution be precipitated by an alkaline liquor that ſhews five or ſix degrees (by the areometer of Baumé), the reſult will be a greeniſh blue magma. The cotton macerated in this precipitate aſſumes at firſt an unequal tint of dirty green; but mere expoſure to the air makes it in a little time turn yellow, and the ſhade is very dark.

"It is by ſuch, or almoſt ſimilar proceſſes, that dyers communicate what is called among workmen an *ochre* or *ruſt colour*. But theſe colours are attended with ſeveral inconveniences to the artiſt: 1. Strong ſhades burn or injure the cloth: 2. This colour is harſh, diſagreeable to the eye, and cannot be eaſily united with the mild colours furniſhed by vegetables."

To avoid theſe inconveniences, our author made ſeveral attempts, which led him to the following practice: He treads the cotton cold in a ſolution of the ſulphat of iron, marking three degrees; he wrings it carefully, and immediately plunges it in a ley of potaſh at two degrees, upon which he has previouſly poured to ſaturation a ſolution of the ſulphat of alumine: the colour is then brightened, and becomes infinitely more delicate, ſoft, and agreeable. The ſulphat no longer attacks the tiſſue of the ſtuff; and after the cotton has been left in the bath for four or five hours, it is taken out to be wrung, waſhen, and dried. In this manner we may obtain every ſhade that can be wiſhed, by graduating the ſtrength of the ſolutions. This ſimple proceſs, the theory of which preſents itſelf to the mind of every chemiſt, has the advantage of furniſhing a colour very agreeable, exceedingly fixed, and, above all, extremely economical. He employs it with great advantage in dyeing nankeens, as it has the property of reſiſting leys. It becomes brown, however, by the action of aſtringents.

M. Chaptal made ſeveral attempts to combine this yellow with the blue of indigo, in order to obtain a durable green; but as they were all unſucceſsful, he infers that there is not a ſufficient affinity between the blue of indigo and the oxyds of iron. He found that theſe oxyds, on the other hand, combine very eaſily with the red of madder, and produce a bright violet or plum colour, the uſe of which is as extenſive as beneficial in the cotton manufactory. But if we ſhould confine ourſelves to apply theſe two colours to cotton, without having employed a mordant capable of fixing the latter, the colour would not only remain dull and diſagreeable by the impoſſibility of brightening it, but it would ſtill be attended with the great inconvenience of not reſiſting leys. We muſt begin, then, by preparing the cotton as if to diſpoſe it for receiving the Adrianople red; and when it has been brought to the operation of galling, it is to be paſſed through a ſolution of iron, more or leſs charged, according to the nature of the violet required: it is then to be carefully waſhed, twice maddered, and brightened in a bath of ſoap.

When a real velvety rich violet is required, it is not to be paſſed through the ſolution of iron till it has been previouſly galled; the iron is then precipitated in a bluiſh oxyd, which, combined with the red of madder, gives a moſt brilliant purple, more or leſs dark according to the ſtrength of the galling and of the ferruginous ſolution. It is very difficult to obtain an equal colour by this proceſs; and in manufactories, an equal violet is conſidered as a maſter-piece of art. It is generally believed, that it is only by well-directed manipulations that it is poſſible to reſolve this problem, of ſo much importance in dyeing. But I am convinced (ſays our author), that the great cauſe of the inequality in this dye is, that the iron depoſited on the cotton receives an oxydation merely by expoſure to the air, which varies in different parts of it. The threads which are on the outſide of the hank are ſtrongly oxydated, while thoſe in the inſide, removed from the action of the air, experience no change. It thence follows, that the inſide of the hank preſents a weak ſhade, while the exterior part exhibits a violet almoſt black. The means to remedy this inconvenience is, to waſh the cotton when it is taken from the ſolution of iron, and to expoſe it to the madder moiſt. The colour will become more equal and velvety. The ſolvents of iron are almoſt the ſame for this colour as for the yellow colour already mentioned.

The following obſervation may ſerve to guide the artiſt in brightening the violet on his cotton. The red of madder and the oxyd of iron depoſited on the ſtuff determine the violet colour. This colour becomes red or blue, according as either of the principles predominates. The dyer knows by experience how difficult it is to obtain a combination which produces the tone of colour deſired, eſpecially when it is required to be very full, lively, and durable. This object, however, may be obtained, not only by varying the proportions of the two colouring principles, but alſo by varying the proceſs of brightening. The only point is to be acquainted with the two following facts; that the ſoda deſtroys the iron, while the ſoap, by ſtrong ebullition, ſeizes in preference the red of the madder. Hence it is, that the colour may be inclined to red or blue, according as you brighten with one or the other of theſe mordants. Thus, cotton taken from the madder dye, when waſhed and boiled in the brightening liquor with $\frac{3}{10}$ths of ſoap, will give a ſuperb violet; whereas you will obtain only a plum colour in treating it with ſoda.

The oxyd of iron precipitated on any ſtuff unites alſo very advantageouſly with the fawn colour furniſhed by aſtringents; and by varying the ſtrength of mordants, an infinity of ſhades may be produced. In this caſe, it is leſs a combination or ſolution of principles than the ſimple mixture or juxta-poſition of the colouring bodies on the ſtuff. By means of a boiling heat, we may combine, in a more intimate manner, the oxyd of iron with the aſtringent principle; and then it is brought to the ſtate of black oxyd, as has been obſerved by Berthollet. It is poſſible alſo to embrown theſe colours, and to give them a variety of tints, from the bright grey to the deep black, by merely paſſing the cottons impregnated with the aſtringent principle thro' a ſolution of iron. The oxyd is then precipitated itſelf by the principle which is fixed on the ſtuff.

An obſervation, which may become of the utmoſt value for the art of dyeing, is, that the moſt uſual aſtringent vegetables all furniſh a yellow colour, which has not much brilliancy, but which has ſufficient fixity to be employed with advantage. This yellow colour is brightened in the ſeries of vegetables, in proportion as the aſtringent principle is diminiſhed, and the vivacity of the colour is augmented in the ſame proportion. It is difficult, then, to obtain yellow colours which are at the ſame time durable and brilliant. Theſe two valuable qualities are to each other in an inverſe ratio; but it is poſſible to unite the colouring principles in ſuch a manner as to combine ſplendour with fixity. Green oak bark unites perfectly with yellow weed, and ſumach with green citron. It is by this mixture that we may be able to combine with the oxyd of iron vegetable colours, the ſplendour of which is equal to their durability.

Our author concludes his obſervations with cautioning the dyer againſt ſubſtituting ſumach and the bark of the alder tree or oak for gall when dyeing cotton red. "I can ſafely aſſert (ſays he), that it is impoſſible to employ theſe as ſubſtitutes, in whatever doſes they may be uſed. The colour is always much paler, poorer, and leſs fixed. I know that the caſe is not the ſame in regard to dyeing wool and ſilk, in which it may be employed with ſucceſs; and in giving an account of this difference, I think the cauſe of it may be found in the nature of the gall-nuts. 1. The acid which they excluſively contain, as Berthollet has proved, facilitates the decompoſition of the ſoap with which the cottons have been impregnated, and the oil then remains fixed in their tiſſue, and in a greater quantity, as well as in a more intimate combination. 2. The gall-nuts, which owe their development to animal bodies, retain a character of animaliſation, which they tranſmit to the vegetable ſtuff, and by theſe means augment its affinities with the colouring principle of the madder; for it is well known of what utility animal ſubſtances are to facilitate this combination. This animaliſation becomes uſeleſs in operating upon woollen or ſilk."

JUAN DE FUCA, a celebrated ſtrait on the north-weſt coaſt of America, was ſurveyed by Captain Vancouver in the Diſcovery ſloop of war, with a view to aſcertain whether it leads to any communication between the North Pacific and the North Atlantic Oceans. As they advanced within the opening of the ſtrait, their progreſs was greatly retarded by the number of inlets into which the entrance branched in every direction; and moſt of theſe were examined by the boats, which were frequently abſent from the ſhips on this ſervice for ſeveral days together. In the midſt of their labours, they were ſurpriſed by the ſight of two Spaniſh veſſels of war, employed, like themſelves, in ſurveying this inlet, the examination of which had been begun by them in the preceding year. Meaſures of mutual aſſiſtance were concerted between the captains of the two nations for the proſecution of the ſurvey, in which each agreed to communicate to the other their diſcoveries. Not one of the many arms of the inlet, nor of the channels which they explored in this broken part of the coaſt, was found to extend more than 100 miles to the eaſtward of the entrance into the ſtrait. After having ſurveyed the ſouthern coaſt, on which ſide a termination was diſcovered to every opening, by following the continued line of the ſhore, they were led to the northward, and afterward towards the north-weſt, till they came into the open ſea through a different channel from the ſtrait of Juan de Fuca, by which they had commenced this inland navigation.

Thus it appeared, that the land forming the north ſide of that ſtrait is part of an iſland, or of an archipelago, extending nearly 100 leagues in length from S. E. to N. W.; and on the ſide of this land moſt diſtant from the continent is ſituated Nootka Sound. The moſt peculiar circumſtance of this navigation is the extreme depth of water, when contraſted with the narrowneſs of the channels. The veſſels were ſometimes drifted about by the currents during the whole of a night, cloſe to the rocks, without knowing how to help themſelves, on account of the darkneſs, and the depth being much too great to afford them anchorage.

In the courſe of this ſurvey, the voyagers had frequent communications with the natives, whom they met ſometimes in canoes and ſometimes at their villages. In their tranſactions with Europeans, they are deſcribed as "well verſed in the principles of trade, which they carried on in a very fair and honourable manner." In other reſpects they were leſs honeſt. At one village 200 ſea otter ſkins were purchaſed of them by the crews of the veſſels in the courſe of a day; and they had many more to ſell in the ſame place, as alſo ſkins of bears, deer, and other animals. One party of Indians whom they met had the ſkin of a young lioneſs; and theſe ſpoke a language different from that uſed in Nootka Sound. Veniſon was ſometimes brought for ſale; and a piece of copper, not more than a foot ſquare, purchaſed one whole deer and part of another. Among other articles of traffic, two children, ſix or ſeven years of age, were offered for ſale. The commodities moſt prized by the natives were fire-arms, copper, and great coats. Beads and trinkets they would only receive as preſents, and not as articles of exchange. Many of them were poſſeſſed of fire-arms. In one part it is related, that after a chief had received ſome preſents, "he, with moſt of his companions, returned to the ſhore; and, on landing, fired ſeveral muſkets, to ſhew, in all probability, with what dexterity they could uſe theſe weapons, to which they ſeemed as familiarized as if they had been accuſtomed to fire-arms from their earlieſt infancy."

The dreſſes of theſe people, beſides ſkins, are a kind of woollen garments; the materials compoſing which are explained in the following extract;

"The dogs belonging to this tribe of Indians were numerous, and much reſembled thoſe of Pomerania, though, Juan.

though, in general, ſomewhat larger. They were all ſhorn as cloſe to the ſkin as ſheep are in England; and ſo compact were their fleeces, that large portions could be lifted up by a corner without cauſing any ſeparation. They were compoſed of a mixture of a coarſe kind of wool, with very fine long hair, capable of being ſpun into yarn. This gave Captain Vancouver reaſon to believe, that their woollen clothing might in part be compoſed of this material mixed with a finer kind of wool from ſome other animal, as their garments were all too fine to be manufactured from the coarſe coating of the dog alone."

Of other animals alive, deer only were ſeen in any abundance by our people.

The number of inhabitants computed to be in the largeſt of the villages or towns that were diſcovered, did not exceed 600. Captain Vancouver conjectured the ſmall-pox to be a diſeaſe common and very fatal among them. Many were much marked; and moſt of theſe had loſt their right eye. Their method of diſpoſing of their dead is very ſingular.

"Baſkets were found ſuſpended on high trees, each containing the ſkeleton of a young child; in ſome of which were alſo ſmall ſquare boxes filled with a kind of white paſte, reſembling (ſays our author) ſuch as I had ſeen the natives eat, ſuppoſed to be made of the ſaranne root; ſome of theſe boxes were quite full, others were nearly empty, eaten probably by the mice, ſquirrels, or birds. On the next low point ſouth of our encampment, where the gunners were airing the powder, they met with ſeveral holes in which human bodies were interred, ſlightly covered over, and in different ſtates of decay, ſome appearing to have been very recently depoſited. About half a mile to the northward of our tents, where the land is nearly level with high water mark, a few paces within the ſkirting of the wood, a canoe was found ſuſpended between two trees, in which were three human ſkeletons.

"On each point of the harbour, which, in honour of a particular friend, I called *Penn's Cove*, was a deſerted village; in one of which were found ſeveral ſepulchres, formed exactly like a centry box. Some of them were open, and contained the ſkeletons of many young children tied up in baſkets: the ſmaller bones of adults were likewiſe noticed, but not one of the limb bones could here be found; which gave riſe to an opinion, that theſe, by the living inhabitants of the neighbourhood, were appropriated to uſeful purpoſes; ſuch as pointing their arrows, ſpears, or other weapons."

However honourably theſe people have been repreſented in their conduct as traders, it appeared on ſeveral occaſions that it was unſafe to depend on their goodwill alone: and ſome inſtances occurred, of their making every preparation for an attack, from which they deſiſted only on being doubtful of the event; yet immediately on relinquiſhing their purpoſe, they would come with the greateſt confidence to trade, appearing perfectly regardleſs of what had before been in agitation. The boats, as already noticed, were frequently at a great diſtance from the ſhips; and on ſuch occaſions, when large parties of Indians have firſt ſeen them, they generally held long conferences among themſelves before they approached the boats; probably for the purpoſe of determining the mode of conduct which they judged it moſt prudent to obſerve. Captain Vancouver places the entrance of the ſtrait of Juan de Fuca in 48° 20′ N. Lat. and 124° W. Long.

Jugglers.

JUGGLERS are a kind of people whoſe profeſſion has not been often deemed either reſpectable or uſeful. Profeſſor Beckmann, however, has undertaken their defence; and in a long and learned chapter in the third volume of his *Hiſtory of Inventions*, pleads the cauſe of the practiſers of legerdemain; rope-dancers; perſons who place their bodies in poſitions apparently dangerous; and of thoſe who exhibit feats of uncommon ſtrength. All theſe men he claſſes under the general denomination of *Jugglers;* and taking it for granted (ſurely upon no good grounds) that every uſeful employment is full, he contends, that there would not be room on the earth for all its preſent inhabitants did not ſome of them practiſe the arts of *Juggling*.

"Theſe arts (ſays he) are indeed not unprofitable, for they afford a comfortable ſubſiſtence to thoſe who practiſe them; but their gain is acquired by too little labour to be hoarded up; and, in general, theſe roving people ſpend on the ſpot the fruits of their ingenuity; which is an additional reaſon why their ſtay in a place ſhould be encouraged. But farther, it often happens, that what ignorant perſons firſt employ, merely as a ſhow, for amuſement or deception, is afterwards ennobled by being applied to a more important purpoſe. The machine with which a Savoyard, by means of ſhadows, amuſed children and the populace, was by Liberkühn converted into a ſolar microſcope; and, to give one example more, the art of making ice in ſummer, or in a heated oven, enables gueſts, much to the credit of their hoſteſs, to cool the moſt expenſive diſhes. The Indian diſcovers precious ſtones, and the European, by poliſhing, gives them a luſtre.

"But, if the arts of juggling ſerved no other end than to amuſe the moſt ignorant of our citizens, it is proper that they ſhould be encouraged for the ſake of thoſe who cannot enjoy the more expenſive deceptions of an opera. They anſwer other purpoſes, however, than that of merely amuſing: they convey inſtruction in the moſt acceptable manner, and ſerve as an agreeable antidote to ſuperſtition, and to that popular belief in miracles, exorciſm, conjuration, ſorcery, and witchcraft, from which our anceſtors ſuffered ſo ſeverely."

Surely this reaſoning, as well as the cauſe in which it is brought forward, is unworthy of the learning of Beckmann. It is indeed true, that jugglers ſpend their money freely, and that their arts afford them the means of ſubſiſtence; but it is very ſeldom, as our author muſt know, that they ſubſiſt either comfortably or innocently. Is it innocent to entice the ignorant and labouring poor, by uſeleſs deceptions, to part with their hard-earned pittance to idle vagabonds? or is the life of thoſe vagabonds comfortable, when it is paſſed amid ſcenes of the moſt grovelling diſſipation? Jugglers ſpend indeed their money, for the moſt part, on the ſpot where it is gained; but they ſpend it in drunkenneſs, and other ſeducing vices, which corrupt their own morals and the morals of all with whom they aſſociate; and therefore their ſtay in a place ſhould certainly *not* be encouraged. Could it be proved that the ſolar microſcope would never have been invented, had not a Savoyard juggler contrived a ſimilar machine to amuſe children and the rabble, ſome ſtreſs might be laid on the ſervice which ſuch wretches

have

have rendered to ſcience: but where is the man that will ſuppoſe the philoſophy of Bacon and Newton to reſt upon the arts of juggling? or who conſiders the refinements of ſcience as of equal value with the morals of the people? There is, at the moment in which this article is drawing up, a fellow exhibiting, before the windows of the writer's chamber, the moſt indecent ſcenes by means of puppets, and keeping the mob in a conſtant roar. Is he innocently employed? or will any good man ſay that there is not room for him in the armies which on the Continent are fighting in the cauſe of God and humanity?

Our author endeavours to ſtrengthen his reaſoning by proving, which he does very completely, the antiquity of juggling. "The deception (ſays he) of breathing out flames, which at preſent excites, in a particular manner, the aſtoniſhment of the ignorant, is very ancient. When the ſlaves in Sicily, about a century and a half before our æra, made a formidable inſurrection, and avenged themſelves in a cruel manner for the ſeverities which they had ſuffered, there was amongſt them a Syrian named Eunus, a man of great craft and courage, who, having paſſed through many ſcenes of life, had become acquainted with a variety of arts. He pretended to have immediate communication with the gods; was the oracle and leader of his fellow ſlaves; and, as is uſual on ſuch occaſions, confirmed his divine miſſion by miracles. When, heated by enthuſiaſm, he was deſirous of inſpiring his followers with courage, he breathed flames or ſparks among them from his mouth while he was addreſſing them. We are told by hiſtorians, that for this purpoſe he pierced a nut-ſhell at both ends, and, having filled it with ſome burning ſubſtance, put it into his mouth and breathed through it.

"This deception, at preſent, is performed much better. The juggler rolls together ſome flax or hemp, ſo as to form a ball about the ſize of a walnut; ſets it on fire; and ſuffers it to burn till it is nearly conſumed; he then rolls round it, while burning, ſome more flax; and by theſe means the fire may be retained in it for a long time. When he wiſhes to exhibit, he ſlips the ball unperceived into his mouth and breathes through it; which again revives the fire, ſo that a number of weak ſparks proceed from it; and the performer ſuſtains no hurt. provided he inſpire the air not through the mouth but the noſtrils.

"For deceptions with fire the ancients employed alſo naphtha, a liquid mineral oil, which kindles when it only approaches a flame. (See NAPHTHA, *Encycl.*) Galen informs us, that a perſon excited great aſtoniſhment by extinguiſhing a candle and again lighting it, without any other proceſs than holding it immediately againſt a wall or a ſtone. The whole ſecret of this conſiſted in having previouſly rubbed over the wall or ſtone with ſulphur. But as the author, a few lines before, ſpeaks of a mixture of ſulphur and naphtha, we have reaſon to think that he alludes to the ſame here. Plutarch relates how Alexander the Great was aſtoniſhed and delighted with the ſecret effects of naphtha, which were exhibited to him at Ecbatana. The ſame author, as well as Pliny, Galen, and others, has already remarked, that the ſubſtance with which Medea deſtroyed Creuſa, the daughter of Creon, was nothing elſe than this fine oil. She ſent to the unfortunate princeſs a dreſs beſmeared with it, which burſt into flames as ſoon as ſhe approached the fire of the altar. The blood of Neſſus, in which the dreſs of Hercules, which took fire likewiſe, had been dipped, was undoubtedly naphtha alſo; and this oil muſt have been always employed when offerings caught fire in an imperceptible manner.

"In modern times, perſons who could walk over burning coals or red-hot iron, or who could hold red-hot iron in their hands, have often excited wonder. But laying aſide the deception ſometimes practiſed on the ſpectators, the whole of this ſecret conſiſts in rendering the ſkin of the ſoles of the feet and hands ſo callous and inſenſible, that the nerves under them are ſecured from all hurt, in the ſame manner as by ſhoes and gloves. Such calloſity will be produced if the ſkin is continually compreſſed, ſinged, pricked, or injured in any other manner. Thus do the fingers of the induſtrious ſempſtreſs become horny by being frequently pricked; and the caſe is the ſame with the hands of fire-workers, and the feet of thoſe who walk bare footed over ſcorching ſand.

"In the month of September 1765, when I viſited (ſays our author) the copper-works at Aweſtad, one of the workmen, for a little drink money, took ſome of the melted copper in his hand, and after ſhewing it to us, threw it againſt a wall. He then ſqueezed the fingers of his horny hand cloſe to each other; put it a few minutes under his arm-pit, to make it ſweat, as he ſaid; and, taking it again out, drew it over a ladle filled with melted copper, ſome of which he ſkimmed off, and moved his hand backwards and forwards. very quickly, by way of oſtentation. While I was viewing this performance, I remarked a ſmell like that of ſinged horn or leather, though his hand was not burnt. It is highly probable, that people who hold in their hands red hot iron, or who walk upon it, as I ſaw done at Amſterdam, but at a diſtance, make their ſkin callous before, in the like manner. This may be accompliſhed by frequently moiſtening it with ſpirit of vitriol; according to ſome the juice of certain plants will produce the ſame effect; and we are aſſured by others, that the ſkin muſt be very frequently rubbed, for a long time, with oil, by which means, indeed, leather alſo will become horny*."

Our author then proves, in a very learned manner, that all theſe tricks were of high antiquity; that the Hirpi, who lived near Rome, jumped through burning coals; that women were accuſtomed to walk over burning coals at Caſtabala in Cappadocia, near the temple dedicated to Diana; that the exhibition of balls and cups (ſee LEGERDEMAIN, *Encycl.*) is often mentioned in the works of the ancients; that in the third century, one Firmus or Firmius, who endeavoured to make himſelf emperor in Egypt, ſuffered a ſmith to forge iron on an anvil placed on his breaſt; that rope-dancers with balancing poles are mentioned by Petronius and others; and that the various feats of horſemanſhip exhibited in our circuſes paſſed, in the thirteenth century, from Egypt to the Byzantine court, and thence over all Europe.

JUNGLE, in Bengal, waſte land, or land covered with wood and brambles.

* *Haller, Elementa Phyſiolog.*

K.

Kaarta.

KAARTA, a kingdom in Africa, through which Mr Park paſſed in his route from the Gambia to the Niger. He deſcribes the country as conſiſting either of ſandy plains or rocky hills; but, from his account, the level part ſeems to be the moſt extenſive. The natives are negroes, of whom many, though converted to the Mahomedan faith, or rather to the ceremonial part of the Mahomedan religion, retain all their ancient ſuperſtitions, and even drink ſtrong liquors. They are called Johers or Jowers, and in Kaarta form a very numerous and powerful tribe. One of theſe men undertook to conduct our author to Kemmoo, the capital of the kingdom, and alarmed him not a little by his ſuperſtitious ceremonies.

"We had no ſooner (ſays Mr Park) got into a dark and lonely part of the firſt wood, than he made a ſign for us to ſtop, and taking hold of a hollow piece of bamboo, that hung as an amulet round his neck, whiſtled very loud, three times. I confeſs I was ſomewhat ſtartled, thinking it was a ſignal for ſome of his companions to come and attack us; but he aſſured me that it was done merely with a view to aſcertain what ſucceſs we were likely to meet with on our preſent journey. He then diſmounted, laid his ſpear acroſs the road, and having ſaid a number of ſhort prayers, concluded with three loud whiſtles; after which he liſtened for ſome time, as if in expectation of an anſwer, and receiving none, told us we might proceed without fear, for there was no danger."

White men were ſtrangers in the kingdom of Kaarta; and the appearance of our author had on ſome of the natives the effect which ignorant people, in this country, attribute to ghoſts. "I had wandered (ſays he) a little from my people, and being uncertain whether they were before or behind me, I haſtened to a riſing ground to look about me. As I was proceeding towards this eminence, two negro horſemen, armed with muſkets, came galloping from among the buſhes: on ſeeing them I made a full ſtop; the horſemen did the ſame, and all three of us ſeemed equally ſurpriſed and confounded at this interview. As I approached them their fears increaſed, and one of them, after caſting upon me a look of horror, rode off at full ſpeed; the other, in a panic of fear, put his hand over his eyes, and continued muttering prayers until his horſe, ſeemingly without the rider's knowledge, conveyed him ſlowly after his companion. About a mile to the weſtward, they fell in with my attendants, to whom they related a frightful ſtory: it ſeems their fears had dreſſed me in the flowing robes of a tremendous ſpirit; and one of them affirmed, that when I made my appearance, a cold blaſt of wind came pouring down upon him from the ſky like ſo much cold water."

At Kemmoo our traveller was graciouſly received by the king; who honeſtly told him, however, that he could not protect him, being then engaged in war with the king of BAMBARRA (ſee SEGO in this *Supplement*); but he gave him a guard to JARRA, the frontier town of the neighbouring kingdom of Ludamar. The origin and iſſue of this war between Kaarta and Bambarra, of which Mr Park gives a full account, ſhews the folly of attempting to liberate the negroes from ſlavery till civilization and Chriſtianity be introduced into Africa. Major Rennel places Kemmoo, the capital of Kaarta, in 14° 15′ N. Lat. and 7° 20′ W. Lon.

Kabobiquas.

KABOBIQUAS, a nation in ſouth Africa, who had never ſeen a white man till 1785, that they were viſited by M. Vaillant. Intimation had been given of his approach by ſome of the tribes through whoſe country he had previouſly paſſed; and every thing that had been ſaid of his colour, his fuſees, and his equipage, bore the character of the moſt enthuſiaſtic exaggeration. The curioſity of the people was wound up to the higheſt pitch; and as ſoon as they ſaw his company at a diſtance, the whole horde quitted the kraal, and ran with eagerneſs to meet him. Not being able to believe their eyes in regard to what they ſaw, they endeavoured to obtain more ſatisfaction by touching him. They felt his hair, hands, and almoſt every part of his body. His beard, above all, aſtoniſhed them to an inconceivable degree. More than thirty perſons came in ſucceſſion, and half unbuttoned his clothes. They all imagined him to be a hairy animal; and ſuppoſed, without doubt, that his body was covered with hair as long as that on his chin; but finding this not to be the caſe, they were aſtoniſhed, and confeſſed, with the openneſs of ſavages, that they had never ſeen the like in any man of their country. The little children, terrified at his appearance, hid themſelves behind their mothers. When he attempted to lay hold of any of them, in order to careſs them, they ſent forth loud cries, as a child would do in Europe who ſhould ſee a negro for the firſt time.

The grown up people, however, were ſoon reconciled to his appearance, and even the children were bribed by ſmall bits of ſugar candy. The chief of the horde ſhowed him every mark of attachment. He was a man advanced in life, and of a majeſtic figure. He wore a long mantle, which hung from his ſhoulders to the ground, and which, formed of four jackal ſkins joined together, was bordered at the ſides with that of a hyæna. His left hand wanted two joints of the little finger, which, he ſaid, were amputated in his infancy to cure him of a ſevere illneſs.

This cuſtom of ſavages, who, to relieve a man from pain, add new ſufferings to his evils, affords a vaſt field for reflection. Mr Paterſon, another African traveller, tells us, that he obſerved inſtances of the ſame practice among a horde at the mouth of Orange-river; which is not improbable. However abſurd a cuſtom may be, ſavage tribes, when they are neighbours, may borrow it from each other; but that it ſhould be common among the iſlanders of the South Sea, who, ſince their country was firſt inhabited, had never ſeen ſtrangers before Cook and Bougainville, is truly aſtoniſhing. Our author was very deſirous of interrogating minutely the people of the horde on this ſubject. He wiſhed alſo to propoſe ſome queſtions to them reſpecting other cuſtoms, which appeared ſingular; but difficulties increaſed the more he advanced into the country. The Kabobiquas ſpoke a particular language; and this dialect, though accompanied with the clapping noiſe of the Hottentots, was underſtood only by the Koraquas, who, on account of their vicinity, kept up ſome intercourſe with them. The caſe was the ſame with the language of the Koraquas, in regard to their neighbours the Nimiquas; and nothing reached our author's ear till it had paſſed through four different mouths. The conſequence was, that when he aſked any thing, the anſwer had frequently no relation to the queſtion; and for this inconveniency no remedy could be found.

The ſame deſire for trinkets to ornament their dreſs prevailed among the Kabobiquas as among the other hordes which Vaillant had viſited; and in one day he purchaſed twenty oxen for things of that kind of no value. The chief, however, had ſet his affections on a razor; and juſt when our author and he were treating about it, a ſhot was fired near them, which was inſtantly followed by the moſt frightful cries. "Ruſhing inſtantly from my tent (ſays M. Vaillant) to enquire what was the cauſe of this noiſe, I ſaw a Kabobiqua flying as faſt as he could from one of my hunters, while, at the diſtance of a hundred paces farther, three men were making the moſt lamentable clamour, and near them was a young girl lying on the ground. I made a ſignal to my hunter to approach me; but the report of the ſhot, and the howling of the three men, had already ſpread alarm throughout the horde. Some cried out treachery; others ran to their arms; and I now imagined that I was about to be maſſacred, with my whole company, and that I ſhould be obliged to arm them in my defence. My ſituation was the more critical, as neither I, nor any perſon in the kraal, knew what was the cauſe of this confuſion; and if I had known, how could I have explained it?

"Under this embarraſſment, I took the chief by the hand, and advanced with him towards the horde. Fear was painted in his countenance; tears began to drop from his eyes; and he ſpoke to me with great vivacity. He imagined, no doubt, that he was betrayed. He complained to me, and accuſed my people of perfidy; yet he readily followed me.

"As I was without arms, and preſented myſelf with the chief, I was received with confidence, and my appearance ſeemed, in ſome meaſure, to calm their perturbation. My people, who had ſeen me direct my courſe towards the kraal, haſtened thither after me, to protect me; and their number overawed the multitude. At length the whole myſtery was cleared up, and we learned what had occaſioned the tumult.

"A Kabobiqua having met one of my hunters, who was returning with his fuſee, wiſhed to examine it, and begged him to ſhew it to him. In handling it, however, he accidentally touched the trigger; it inſtantly went off; and the ſavage, frightened by the unexpected exploſion, threw down the fuſee, and ran away as faſt as he could.

"At that time, three men of the horde and a young girl happened unluckily to be ſtanding, at the diſtance of a hundred paces, in the direction of the piece. The latter received a ſingle grain of ſhot in the cheek; and the others a few grains in the legs and thighs. The author of the misfortune confirmed this explanation; tranquillity was ſoon reſtored; the ſavages depoſited their arms; and I was ſurrounded only by friends as before.

"Nothing remained but to enquire into the ſtate of the wounded, and to give them every aſſiſtance in my power. Without loſs of time, therefore, I repaired, ſtill accompanied by the chief, to the place where they were. By the way we met the young girl, who was returning from the kraal, bathed in tears. The cauſe of her uneaſineſs was a grain of lead, which had, however, penetrated ſo little, that I forced it out by only preſſing the part with my fingers. With regard to the three men, they lay rolling on the ground, howling in a moſt frightful manner, and exhibiting every ſymptom of deſpair.

"I was aſtoniſhed at their conſternation, and could not conceive how men inured to ſufferings ſhould be ſo much affected by a few ſmall punctures, the pain of which could have ſcarcely drawn tears from an infant. They at length told me the cauſe of their wailings. Theſe ſavages, accuſtomed to poiſon their arrows, imagined that I had in like manner poiſoned the lead with which they were wounded. They had, therefore, given themſelves up as loſt, and expected in a few moments to expire."

It was with great difficulty that our author could convince them that they had nothing to fear. He ſhewed them in the fleſh of his own leg a dozen of ſhots of lead; but they were not ſatisfied till one of the moſt intelligent of his Hottentots, taking from his ſhot bag a few grains of lead, and ſhewing them to the three men, immediately ſwallowed them. This concluſive argument produced the deſired effect. The cries of the wounded men inſtantly ceaſed; ſerenity again appeared in their faces; and their wounds were no more mentioned.

The Kabobiquas have neither the flat noſe nor plump cheeks of the Hottentots. Their ſkin alſo has not that baſtard colour, which, being neither black nor white, renders them odious to both races; nor do they beſmear their bodies with thoſe diſguſting fat ſubſtances, on account of which one cannot approach them without being bedaubed with their filth, or acquiring an offenſive ſmell. In ſtature they are as tall as the Caffres, and their colour is equally black. Their hair, which is exceedingly ſhort, and much curled, is ornamented with ſmall copper buttons, arranged with great art and ſymmetry. Inſtead of that apron made of a jackal's ſkin, employed by the Hottentot to cover what modeſty bids him conceal, the Kabobiquas uſe a round piece of leather, the edge of which is ornamented with a ſmall indented circle of copper, and which is divided into different compartments by rows of glaſs beads of various colours, all proceeding from the centre, and diverging towards the circumference, like the rays in our images of the ſun.

This kind of veil is made faſt to the groin by means of a girdle; but as it is only four inches in diameter, as it is deranged by the ſmalleſt movement, and as they give themſelves little uneaſineſs reſpecting ſuch accidents, it is very ill ſuited to the purpoſe for which it is applied. During the great heats, this ſmall and almoſt uſeleſs apron is the only covering on their bodies. Its being ſo readily diſplaced, enabled our author to aſcertain that they do not practice circumciſion; but it ſeemed to ſhow alſo, that, in regard to modeſty, their ideas are very different from ours.

Though they go thus almoſt entirely naked, their manners, inſtead of being licentious, are remarkably chaſte,

chaſte. No females can be more prudent or more reſerved than their women; and whether from refinement of coquetry, or the effect of prudence, they do not tattoo their faces like their huſbands and fathers. They do not even follow their example in ornamenting their hair with copper buttons; and they always go bare-legged, though moſt of them wear ſandals.

Their dreſs conſiſts of an apron that reaches only half down the thigh; a kroſs which, paſſing under the arm-pits, is tied on the breaſt; and a long mantle like that of the men. The mantle is made of ſkins not deprived of the hair; and the kroſs of tanned leather, prepared like that uſed for gloves in Europe.

With regard to glaſs beads, they wear them as bracelets. They form them alſo into necklaces, which deſcend in different rows to the pit of the ſtomach; and they ſuſpend from their girdles ſeveral ſtrings of them, which fall down their thighs below the apron.

Theſe ornaments being very durable, the habit of ſeeing them renders the women almoſt indifferent to the pleaſure of poſſeſſing them. Thoſe they procured from our author afforded at firſt great ſatisfaction, on account of their novelty. But when he ſhewed them ſciſſars and needles, they gave the preference to theſe articles; and this choice does honour to the good ſenſe of the Kabobiqua ladies. Like their chief, they ſet a higher value on utility than ornament.

Before our author's arrival among them, the Kabobiquas were acquainted with the uſe of tobacco through the means of ſome of the tribes more contiguous to the Cape. It was, however, a luxury which they could ſeldom enjoy; and ſo indifferent were they about it, that if it were not brought to them, they would not go a ſtep to procure it. This indifference, about an article which is eagerly ſought for by all the tribes of Hottentots, ſeemed to ſhew that there are traits in the character of the Kabobiquas which diſtinguiſh them from their ſouthern neighbours. The caſe was the ſame as to ſtrong liquors, on which they ſet no great value; and though there were among them ſome few individuals diſpoſed to reliſh them, the greater number abſolutely refuſed them.

" If the contents of my flaſks (ſays Vaillant) gave them little ſatisfaction, they were, however, much captivated with the flaſks themſelves. Theſe tranſparent bottles excited their admiration in the higheſt degree. They called them *ſolid water*; for, notwithſtanding the heat of the climate, theſe ſavages had ſeen ice on the ſummits of the mountains by which they are ſurrounded; and they entertained no doubt that the glaſs of my flaſks was water, which I had rendered ſolid by magic, and which I prevented their fires from melting. As it was impoſſible for me to explain this matter, I did not attempt to undeceive them: and beſides, with what advantage would it have been attended? I ſuffered them, therefore, to continue in their error, and contented myſelf with conferring on them an obligation, by giving them all the empty bottles for which I had no uſe.

" On their part, they vied with each other in ſhewing their generoſity towards me; and I muſt indeed allow, that I never ſaw a nation ſo diſintereſted. Every night they brought to my camp a conſiderable quantity of milk; and they never came to ſpend the evening with my people, without bringing ſome ſheep to regale them. I have ſeen many of them give away gratuitouſly, and without receiving any thing in return, part of their herds and their flocks; and, when I departed, there were many perſons in my caravan who poſſeſſed both ſheep and oxen, which they had received as a pure gift."

With this benevolent diſpoſition, the Kabobiquas have alſo a martial character. Their weapons are poiſoned arrows, and a lance with a long iron point, but different from the aſſagay of the Hottentots. In battle, their defenſive armour conſiſts of two bucklers; the one of a ſize ſufficient to cover the whole body of the combatant; the other much ſmaller. They are both made of ſkins exceedingly thick, and proof againſt arrows.

The courage which the Kabobiquas diſplay in combat is particularly exerciſed in their hunting excurſions, and, above all, againſt carnivorous animals. Intrepid, however, as it may be to attack the elephant and the rhinoceros, theſe ſpecies of animals are not objects of their vengeance; becauſe, living upon graſs and herbs, they have nothing to apprehend from them, either for themſelves or their cattle. But the tiger, lion, hyæna, and panther, being enemies of a different kind, they declare againſt them implacable war, and purſue them without remiſſion.

Of the ſpoils of theſe deſtructive animals they form their bucklers, girdles, ſandals, kroſſes, mantles, &c. They conſider it as a mark of honour to wear them; and they ſet a much higher value upon them than upon the ſkin of the rhinoceros or of the elephant. If they ſometimes hunt the latter, it is only as objects of food; and they employ to catch them thoſe concealed pits, which are the uſual ſnares of the Hottentots: but this method, which requires both patience and labour, is very little ſuited to a people ſo brave and enterpriſing as the Kabobiquas.

As they poſſeſs ſo bold and reſolute a character, one might be induced to believe that they are ferocious and intractable. Among all the African nations, however, which our author viſited, he never knew one that ſo much practiſed obedience and ſubordination.

The chief here is not, as in other tribes, a principal among his equals; he is a ſovereign in the midſt of his ſubjects, a maſter ſurrounded by his ſlaves. A word, a geſture, or a look, is ſufficient to procure him obedience. Whatever be his orders, they are never contradicted; and the caſe is the ſame in every particular family. What the chief is to the horde, the father is to his children. His commands are abſolute; and he exerciſes regal power at home, while he obeys elſewhere.

Though the tribe was very numerous, the wiſdom with which it was ruled, and the good order that prevailed, announced, in the man by whom it was governed, an intelligence ſuperior to that of all the ſavages our author had before ſeen; for he had not then viſited the Houzouanas. The habitation of this chief was ſuited to his ſupreme dignity. It was, indeed, a hut only, like thoſe of his ſubjects, and, like them, covered with the ſkins of animals; but it was much larger, as well as more elevated; and around it were ſix others, occupied by his family, and deſtined for them alone.

The natural dryneſs of the country inhabited by the Kabobiquas obliges them to dig wells, for their own uſe as well as for their cattle; but as the ſame cauſe often dries up theſe wells, they are then forced to remove, and to ſeek elſewhere a ſoil more abundant in ſprings; for Fiſh-River, though conſiderable in the rainy ſeaſon, is often, during the great heats, entirely deſtitute of water.

The long journeys which theſe too frequent emigrations compel them to undertake, and the intercourſe which they thence have with other nations, muſt neceſſarily inſpire them with ideas unknown to the ſettled tribes; and it would not be unnatural to ſuppoſe, that to this extenſion of ideas are they indebted for that ſuperiority of intelligence which elevates them above their neighbours.

Of the religion of the Kabobiquas, our author talks very inconſiſtently, and like a true philoſopher of the French ſchool. "Of all the African nations (ſays he), they are the only people among whom I found any idea, however confuſed a one, of the exiſtence of a Deity. I do not know whether it be from their own reflection, or the communications of other tribes, that they have acquired this ſublime knowledge, which would alone bring them near to a level with poliſhed nations; but they believe, as far as I have been able to learn from my people, that beyond the ſtars there exiſts a Supreme Being, who made and who governs all things. I muſt however obſerve, that on this ſubject their ideas are vague, barren, and unproductive. They have no conception of the future exiſtence of the ſoul, or of rewards and puniſhments in another life; in ſhort, they have neither worſhip, ſacrifices, ceremonies, nor prieſts, and are total ſtrangers to what we call religion."

This is impoſſible. A people believing in a Supreme Being, who made and who governs all things, *may* indeed be without *ſacrifices*, *ceremonies*, and *prieſts*; but ſuch a people cannot avoid *wiſhing*, that the Being who governs all things may protect them. Such a wiſh is a prayer; and ſurely he who prays is no ſtranger to religion. M. Vaillant places the country of the Kabobiquas between 23° and 25° S. Lat. and 16° 25′ and 19° 25′ Lon. eaſt from Paris.

KAJAAGA, an African kingdom, called by the French *Gallam*, is bounded on the ſouth-eaſt and ſouth by Bambouk; on the weſt, by Bondou and Foota Torra; and on the north, by the river Senegal. The air and climate (ſays Mr Park) are more pure and ſalubrious than at any of the ſettlements towards the coaſt; the face of the country is every where interſperſed with a pleaſing variety of hills and valleys; and the windings of the Senegal river, which deſcends from the rocky hills of the interior, make the ſcenery on its banks very pictureſque and beautiful.

The inhabitants are called Serawoollies, or (as the French write it) *Seracolets*. Their complexion is a jet black: they are not to be diſtinguiſhed in this reſpect from the Jaloffs.

The government is monarchical; and the regal authority, from what I experienced of it, ſeems to be ſufficiently formidable. The people themſelves, however, complain of no oppreſſion; and ſeemed all very anxious to ſupport the king in a conteſt he was going to enter into with the ſovereign of Kaſſon. The Serawoollies are habitually a trading people; they formerly carried on a great commerce with the French in gold and ſlaves, and ſtill maintain ſome traffic in ſlaves with the Britiſh factories on the Gambia. They are reckoned tolerably fair and juſt in their dealings, but are indefatigable in their exertions to acquire wealth, and they derive conſiderable profits by the ſale of ſalt and cotton cloth in diſtant countries. When a Serawoolli merchant returns home from a trading expedition, the neighbours immediately aſſemble to congratulate him upon his arrival. On theſe occaſions the traveller diſplays his wealth and liberality, by making a few preſents to his friends; but if he has been unſucceſsful, his levee is ſoon over; and every one looks upon him as a man of no underſtanding, who could perform a long journey, and (as they expreſs it) *bring back nothing but the hair upon his head*.

Their language abounds much in gutturals, and is not ſo harmonious as that ſpoken by the Foulahs: it is, however, well worth acquiring by thoſe who travel through this part of the African continent; it being very generally underſtood in the kingdoms of Kaſſon, Kaarta, Ludamar, and the northern parts of Bambara. In all theſe countries the Serawoollies are the chief traders.

Joag, the frontier town of this kingdom as you enter it from Piſania, may be ſuppoſed, on a groſs computation, to contain two thouſand inhabitants. It is ſurrounded by a high wall, in which are a number of port holes, for muſquetry to fire through in caſe of an attack. Every man's poſſeſſion is likewiſe ſurrounded by a wall; the whole forming ſo many diſtinct citadels; and amongſt a people unacquainted with the uſe of artillery, theſe walls anſwer all the purpoſes of ſtronger fortifications. To the weſtward of the town is a ſmall river, on the banks of which the natives raiſe great plenty of tobacco and onions. Mr Park was in this town plundered of half his effects by order of the king, becauſe forſooth he had neglected to pay the accuſtomed duties before he entered the kingdom; and it required a good deal of addreſs to prevent himſelf and his attendants from being made ſlaves; a ſtate to which the law, it was ſaid, condemned them for the commiſſion of this unintended crime. He was at laſt reſcued from Joag by a nephew of the king of Kaſſon. Joag is placed by Major Rennel in 14° 25′ N. Lat. and 9° 46′ W. Lon.

KAINSI is the name given by the Hottentots to a particular ſpecies of antelope, of which, according to Vaillant, no author has yet given a perfect deſcription. It is called by the Dutch *klip-ſpringer*, on account of the eaſe with which it leaps from rock to rock; and indeed of all the antelopes there is no one equal to it in agility. It is about the ſize of a kid of a year old, and of a yellowiſh grey colour; but its hair has this peculiarity, that, inſtead of being round, pliable, and firm, like that of moſt other quadrupeds, it is flat, harſh, and ſo little adherent to the ſkin, that the ſlighteſt friction makes it fall off. Nothing is more eaſy, therefore, than to deprive this animal of its hair: dead or alive it is the ſame; to rub, or even to touch the animal, is ſufficient. Another peculiarity of this ſingular hair is its being extremely fragile; ſo that if you take a tuft of it between your fingers, and twiſt it with the other hand, it will break like the barbs of a feather. This property, however, belongs not excluſively to the hair of the kainſi; for our author ſays he has obſerved it in the hair of other quadrupeds, which in the ſame manner live among the rocks.

This antelope differs from the other ſpecies alſo in the ſhape of the foot, which, inſtead of being pointed

Kainſi,
Kamtſchatka.

like theirs, is rounded at the end; and as it is always accuſtomed, both in leaping and walking, to tread with the point of the hoof, without reſting at all on the heel, it leaves a print diſtinguiſhable from that of any other antelope in Africa. Its fleſh is exquiſitely flavoured, and much ſought after, particularly by the hunters.

The chace of the kainſi is very amuſing. It is true, it is ſcarcely poſſible to hunt it down with dogs, as it ſoon eſcapes them by means of its inconceivable agility, and gets out of their reach on the point of ſome detached rock, where it will remain whole hours ſafe from all purſuit, and ſuſpended, as it were, above the abyſs. But in this ſituation it is excellently placed for the arrow or the ball of the huntſman; who is commonly certain of ſhooting it at pleaſure, though he is not always able to come at it when killed. We ſhall give our author's account of a chace of the kainſi in his own words.

"I was hunting (ſays he) one of theſe animals, when, from the nature of the place, it found itſelf ſo preſſed by my dogs, as to be on the point of being run down and taken. There were apparently no means of eſcape; ſince before it was a vaſt perpendicular rock, by which its courſe was neceſſarily ſtopped. In this wall, however, which appeared to me perfectly ſmooth, was a little ridge, projecting at moſt not above *two inches*, which the kainſi quickly perceived, and, leaping upon it, to my great aſtoniſhment kept itſelf *firm* (A). I imagined, that at any rate it muſt ſoon tumble down; and my dogs, too, ſo fully expected it, that they ran to the bottom of the rock, to be ready to catch it when it fell. To haſten its fall, I endeavoured to haraſs it, and make it loſe its equilibrium; and for this purpoſe I pelted it with ſtones. All at once, as if gueſſing my deſign, it collected its whole ſtrength, bounded over my head, and, falling a few paces from me, darted away with the utmoſt ſpeed. Notwithſtanding the rapidity of its flight, it would have been eaſy for me to have ſhot it; but its leap had ſo ſurpriſed and amuſed me, that I gave it its life." This was generous, if the ſtory be true.

KAMTSCHATKA is inhabited by a people, who are repreſented in the *Encyclopædia* as poſſeſſing almoſt every quality that can diſgrace human nature. We think it incumbent upon us to acknowledge, in this place, that a much more favourable picture of them is drawn by La Perouſe who viſited Kamtſchatka in September 1787. The Ruſſian governor made the commodore and his officers remark the promiſing appearance of ſeveral ſmall fields of potatoes, of which the ſeed had been brought from Irkoutſk a few years before; and purpoſed to adopt mild, though infallible means, of making farmers of the Ruſſians, Coſſacks, and Kamtſchadales. The ſmall-pox in 1769 ſwept away three-fourths of the individuals of the latter nation, which is now reduced to leſs than four thouſand perſons, ſcattered over the whole of the peninſula; and which will ſpeedily diſappear altogether, by means of the continual mixture of the Ruſſians and Kamtſchadales, who frequently intermarry. A mongrel race, more laborious than the Ruſſians, who are only fit for ſoldiers, and much ſtronger, and of a form leſs diſgraceful to the hand of nature, than the Kamtſchadales, will ſpring from theſe marriages, and ſucceed the ancient inhabitants. The natives have already abandoned the *yourts*, in which they uſed to burrow like badgers during the whole of the winter, and where they breathed an air ſo foul as to occaſion a number of diſorders. The moſt opulent among them now build *iſbas*, or wooden houſes, in the manner of the Ruſſians. They are preciſely of the ſame form as the cottages of our peaſants; are divided into three little rooms; and are warmed by a brick ſtove, that keeps up a degree of heat (B) inſupportable to perſons unaccuſtomed to it. The reſt paſs the winter, as well as the ſummer, in *balagans*, which are a kind of wooden pigeon-houſes, covered with thatch, and placed upon the top of poſts twelve or thirteen feet high, to which the women as well as the men climb by means of ladders that afford a footing very inſecure. But theſe latter buildings will ſoon diſappear; for the Kamtſchadales are of an imitative genius, and adopt almoſt all the cuſtoms of their conquerors. Already the women wear their hair, and are almoſt entirely dreſſed, in the manner of the Ruſſians, whoſe language prevails in all the *oſtrogs*; a fortunate circumſtance, ſince each Kamtſchadalian village ſpoke a different jargon, the inhabitants of one hamlet not underſtanding that of the next. It may be ſaid in praiſe of the Ruſſians, that though they have eſtabliſhed a deſpotic government in this rude climate, it is tempered by a mildneſs and equity that render its inconveniences unfelt. They have no reproaches of atrocity to make themſelves, like the Spaniards in Mexico and Peru. The taxes they levy on the Kamtſchadales are ſo light, that they can only be conſidered as a mark of gratitude towards the ſovereign, the produce of half a day's hunting acquitting the impoſts of a year. It is ſurpriſing to ſee in cottages, to all appearance more miſerable than thoſe of the moſt wretched hamlets in our mountainous provinces, a quantity of ſpecies in circulation, which appears the more conſiderable, becauſe it exiſts among ſo ſmall a number of inhabitants. They conſume ſo few commodities of Ruſſia and China, that the balance of trade is entirely in their favour, and that it is abſolutely ceſſary to pay them the difference in rubles. Furs at Kamtſchatka are at a much higher price than at Canton; which proves, that as yet the market of Kiatcha has not felt the advantageous effect of the new channel opened in China.

Kamtſchatka.

Our author compares Kamtſchatka, with reſpect to climate and ſoil, to the coaſt of Labrador in the vicinity of the Straits of Belle-Iſle; but the men, like the animals, are there very different. The Kamtſchadales appeared to him the ſame people as thoſe of the bay of Caſtries, upon the coaſt of Tartary. Their mildneſs and their probity are the ſame, and their perſons are very little different. They ought then no more to be compared to the Eſquimaux Indians, than the ſables of Kamtſchatka to the martins of Canada.

The Greek religion has been eſtabliſhed among the Kamtſchadales without perſecution or violence, and with extraordinary facility. The vicar of Paratounka is the ſon of a Kamtſchadale and of a Ruſſian woman. He delivers his prayers and catechiſm with a tone of feeling very

---

(A) This we think incredible.

(B) Not leſs than thirty degrees of Reaumur's thermometer.

very much to the taſte of the aborigines, who reward his cares with offerings and alms, but pay no tythes. The canons of the Greek church permitting prieſts to marry, we may conclude that the morals of the country clergymen are ſo much the better. “ I believe them, however (ſays Perouſe), to be very ignorant ; and do not ſuppoſe, that for a long time to come they will ſtand in need of greater knowledge. The daughter, the wife, and the ſiſter of the vicar, were the beſt dancers of all the women, and appeared to enjoy the beſt ſtate of health. The worthy prieſt knew that we were good Catholics, which procured us an ample aſperſion of holy water ; and he alſo made us kiſs the croſs that was carried by his clerk : theſe ceremonies were performed in the midſt of the village. His parſonage-houſe was a tent, and his altar in the open air ; but his uſual abode is Paratounka, and he only came to St Peter and St Paul's to pay us a viſit.”

The people of Kamtſchatka have inured themſelves to the extremes of heat and cold. It is well known, that their cuſtom in Europe, as well as in Aſia, is to go into vapour baths, come out covered with perſpiration, and immediately roll themſelves in the ſnow. The *oſtrog* of St Peter had two of theſe public baths, into which our author went before the fires were lighted. They conſiſt of a very low room, in the middle of which is an oven conſtructed of ſtones, without cement, and heated like thoſe intended to bake bread. Its arched roof is ſurrounded by ſeats one above another, like an amphitheatre, for thoſe who wiſh to bathe, ſo that the heat is greater or leſs according as the perſon is placed upon a higher or lower bench. Water thrown upon the top of the roof, when heated red hot by the fire underneath, is converted inſtantly into vapour, and excites the moſt profuſe perſpiration. The Kamtſchadales have borrowed this cuſtom, as well as many others, from their conquerors ; and ere long the primitive character that diſtinguiſhed them ſo ſtrongly from the Ruſſians will be entirely effaced.

Our author deſcribes the bay of Avatſcha as the fineſt, the moſt convenient, and the ſafeſt, that is to be met with in any part of the world. The entrance is narrow, and ſhips would be forced to paſs under the guns of the forts that might be eaſily erected. The bottom is mud, and excellent holding ground. Two vaſt harbours, one on the eaſtern ſide, the other on the weſtern, are capable of containing all the ſhips of the French and Engliſh navy. The rivers of Avatſcha and Paratounka fall into this bay, but they are choaked up with ſand-banks, and can only be entered at the time of high water. The village of St Peter and St Paul is ſituated upon a tongue of land, which, like a jetty made by human art, forms behind the village a little port, ſhut in like an amphitheatre, in which three or four veſſels might lie up for the winter. The entrance of this ſort of baſon is more than twenty-five toiſes wide ; and nature can afford nothing more ſafe or commodious. On its ſhore the governor propoſed to lay down the plan of a city, which ſome time or other will be the capital of Kamtſchatka, and perhaps the centre of an extenſive trade with China, Japan, the Phillippines, and America. A vaſt pond of freſh water is ſituated northward of the ſite of this projected city ; and at only three hundred toiſes diſtance run a number of ſtreamlets, the eaſy union of which would give the ground all the advantages neceſſary to a great eſtabliſhment. Of theſe advantages Mr Kaſloff underſtood the value ; “ but firſt (ſaid he a thouſand times over) we muſt have bread and hands, and our ſtock of both of them is very ſmall.” He had, however, given orders, which announced a ſpeedy union of the other *oſtrogs* to that of St Peter and St Paul, where it was his intention immediately to build a church. By obſervation, St Peter and St Paul was found to be in 53° 1′ N. Lat. and 156° 30′ E. Long. from Paris.

KANEM, is the name given by Edriſi to the kingdom of Bornou in Africa, of which the reader will find ſome account in the *Encyclopædia Britannica.* In ſome particulars, however, that account is incorrect. The kingdom of Bornou or Kanem muſt extend farther eaſt and farther north than it is there ſaid to do ; for according to the lateſt and beſt accounts, its capital ſtands in Lat. 24° 32′ Long. 22° 57′. The empire is ſaid to be very extenſive ; and if it be true, as we learn from the proceedings of the African Aſſociation, that its ſovereign is more powerful than the Emperor of Morocco, the people cannot be ſuch abſolute brutes, as we have repreſented them in the article referred to ; for the ſovereign of brutes would have no power. The truth, however is, that very little is yet known in Europe of Bornou or its inhabitants.

KANT (Immanuel), Royal Profeſſor of Morals and Metaphyſics in the Univerſity of Königſberg, is conſidered by his admirers as the greateſt philoſopher that Germany ever produced. Were we to form an eſtimate of his merits from the different views that have been given in Engliſh of his celebrated ſyſtem, we certainly ſhould not conſider him as entitled to that character ; for thoſe views are obſcured by new and uncouth terms, and are altogether wrapt up in a ſtyle which approaches nearer to jargon than to the luminous compoſition of a man who thinks with clearneſs and preciſion. We readily admit, that it is very difficult to tranſlate a novel ſyſtem of metaphyſics from one language into another ; for the tranſlator, to perform his taſk properly, muſt be not only a complete maſter of both languages, but alſo a profound metaphyſician ; and not one of the tranſlators or abridgers of the works of Kant into our language appears to us poſſeſſed of both theſe qualities. Deſpairing, from our ſcanty knowledge of the German language, of performing ourſelves what ſo many others have failed to perform, we have applied for aſſiſtance to an illuſtrious Frenchman, who has reſided many years in Germany, who is maſter of both languages, who is a profound metaphyſician, and whoſe name, were we at liberty to publiſh it, would reflect luſtre upon our Work. From him we have reaſon to expect a clear and comprehenſive view of the *Critical PHILOSOPHY*, as Kant terms his ſyſtem ; but ſhould we be diſappointed of our expectation, we ſhall, under that title, lay before our readers a *ſpecimen* of the ſyſtem from the different views of it which have been publiſhed in our own tongue.

KANTUFFA, a ſpecies of thorn peculiar to Abyſſinia, is thus deſcribed by Mr Bruce : The branches ſtand two and two upon the ſtalk ; the leaves are diſpoſed two and two likewiſe, without any ſingle one at the point, whereas the branches bearing the leaves part from the ſtalk : at the immediate joining of them are two thick thorns placed perpendicular and parallel alternate-

Kantuffa, Kaſſon.

ly; but there are alſo ſingle ones diſtributed in all the interſtices throughout the branch.

The male plant has a one-leaved perianthium, divided into five ſegments, and this falls off with the flower. The flower is compoſed of five petals, in the middle of which riſe ten ſtamina or filaments, the outer row ſhorter than thoſe of the middle, with long ſtigmata, having yellow farina upon them. The flowers grow in a branch, generally between three and four inches long, in a conical diſpoſition, that is, broader at the baſe than the point. The inſide of the leaves are a vivid green, in the outſide much lighter. It grows in form of a buſh, with a multitude of ſmall branches riſing immediately from the ground, and is generally ſeven or eight feet high. Our author ſaw it when in flower only, never when bearing fruit. It has a very ſtrong ſmell, reſembling that of the ſmall ſcented flower called mignionet, ſown in vaſes and boxes in windows, or rooms, where flowers are kept.

Our author repreſents the kantuffa as ſo very troubleſome, that it renders travelling through ſome places of Abyſſinia almoſt impoſſible. The ſoldier ſcreens himſelf from it by a goat's, a leopard's, or a lion's ſkin thrown over his ſhoulder, of which it has no hold. As his head is bare, he always cuts his hair ſhort before he goes to battle, leſt his enemy ſhould take advantage of it; but the women, wearing their hair long, and the great men, whether in the army or travelling in peace, being always clothed, it never fails to incommode them, whatever ſpecies of raiment they wear. If their cloak is fine muſlin, the leaſt motion againſt it puts it all in rags; but if it is a thick, ſoft cloth, as thoſe are with which men of rank generally travel, it buries its thorns, great and ſmall, ſo deep in it, that the wearer muſt either diſmount and appear naked, which to principal people is a great diſgrace, or elſe much time will be ſpent before he can diſengage himſelf from its thorns. In the time when one is thus employed, it rarely fails to lay hold of you by the hair, and that again brings on another operation, full as laborious, but much more painful, than the other. A proclamation is therefore iſſued, every year immediately before the king commences any march, in theſe words; "Cut down the kantuffa in the four quarters of the world; for I do not know where I am going." The wild animals, both birds and beaſts, eſpecially the Guinea fowl, know how well it is qualified to protect them. In this ſhelter, the hunter in vain could endeavour to moleſt them, were it not for a hard-haired dog, or terrier of the ſmalleſt ſize, who being defended from the thorns by the roughneſs of his coat, goes into the cover, and brings them and the partridges alive one by one to his maſter.

KASSON, a populous kingdom in North Africa, of which the capital *Kooniakary* is placed by Major Rennel in 14° 33′ N. Lat and 8° 43′ W. Lon. The king who reigned when Mr Park was in the country was extremely kind to our traveller, though his ſon plundered him unmercifully, like other rapacious chiefs of that ſavage country. From the top of a high hill, at ſome diſtance from the capital, "I had (ſays Mr Park) a moſt enchanting proſpect of the country. The number of towns and villages, and the extenſive cultivation around them, ſurpaſſed every thing I had yet ſeen in Africa. A groſs calculation may be formed of the number of inhabitants in this delightful plain, by conſidering, that the king of Kaſſon can raiſe four thouſand fighting men by the ſound of his war drum."

Kaſſon.

At Teeſee, a large unwalled town, where our author reſided for ſome days, he had an opportunity of obſerving the cuſtoms of the inhabitants, who conſiſted partly of Pagans and partly of Buſhreens, *i. e.* of negroes converted to Mahomedaniſm. Though theſe people poſſeſs both cattle and corn in abundance, rats, moles, ſquirrels, ſnakes, locuſts, &c. are eaten without ſcruple by the higheſt and loweſt. Another cuſtom, ſtill more extraordinary, is, that no woman is allowed *to eat an egg*. This prohibition, whether ariſing from ancient ſuperſtition, or from the craftineſs of ſome old Buſhreen who loved eggs himſelf, is rigidly adhered to; and nothing will more affront a woman of Teeſee than to offer her an egg. The cuſtom is the more ſingular, as the men eat eggs without ſcruple in the preſence of their wives, and Mr Park never obſerved the ſame prohibition in any other of the Mandingo countries.

Our author was preſent at a palaver held by the governor of Teeſee on a very extraordinary occaſion; of which we ſhall give his account at full length, becauſe it ſhows how free men are reduced to ſlavery in North Africa. "The caſe was this. A young man, a Kafir, of conſiderable affluence, who had recently married a young and handſome wife, applied to a very devout Buſhreen, or Muſſulman prieſt, of his acquaintance, to procure him ſaphies for his protection during the approaching war. The Buſhreen complied with the requeſt; and in order, as he pretended, to render the ſaphies more efficacious, enjoined the young man to avoid any nuptial intercourſe with his bride for the ſpace of ſix weeks. Severe as the injunction was, the Kafir ſtrictly obeyed; and without telling his wife the real cauſe, abſented himſelf from her company. In the mean time it began to be whiſpered at Teeſee, that the Buſhreen, who always performed his evening devotions at the door of the Kafir's hut, was more intimate with the young wife than he ought to be. At firſt, the good huſband was unwilling to ſuſpect the honour of his ſanctified friend, and one whole month elapſed before any jealouſy roſe in his mind; but hearing the charge repeated, he at laſt interrogated his wife on the ſubject, who frankly confeſſed that the Buſhreen had ſeduced her. Hereupon the Kafir put her into confinement, and called a palaver upon the Buſhreen's conduct. The fact was clearly proved againſt him; and he was ſentenced to be ſold into ſlavery, or to find two ſlaves for his redemption, according to the pleaſure of the complainant. The injured huſband, however, was unwilling to proceed againſt his friend to ſuch extremity, and deſired rather to have him publicly flogged before the governor's gate. This was agreed to, and the ſentence was immediately executed. The culprit was tied by the hands to a ſtrong ſtake; and a long black rod being brought forth, the executioner, after flouriſhing it round his head for ſome time, applied it with ſuch force and dexterity to the Buſhreen's back, as to make him roar until the woods reſounded with his ſcreams. The ſurrounding multitude, by their hooting and laughing, manifeſted how much they enjoyed the puniſhment of this old gallant; and it is worthy of remark, that the number of ſtripes was preciſely the ſame as are enjoined by the Moſaic law, *forty, ſave one*."

The method of converting the negro nations to the

Kaſſon.

religion of the Arabian Impoſtor is a very ſingular one; and Mr Park ſaw the whole people of Teeſee converted in an inſtant. During his reſidence in that town an embaſſy of ten people belonging to Almami Abdulkader, king of Foota Torra, a country to the weſt of Bondou, arrived at Teeſee; and deſiring Tiggity Sego the governor to call an aſſembly of the inhabitants, announced publicly their king's determination, to this effect: "That unleſs all the people of Kaſſon would embrace the Mahomedan religion, and evince their converſion by ſaying eleven public prayers, he (the king of Foota Torra) could not poſſibly ſtand neuter in the preſent conteſt, but would certainly join his arms to thoſe of Kajaaga." A meſſage of this nature, from ſo powerful a prince, could not fail to create great alarm; and the inhabitants of Teeſee, after a long conſultation, agreed to conform to his good pleaſure, humiliating as it was to them. Accordingly, one and all publicly offered up eleven prayers, which were conſidered a ſufficient teſtimony of their having renounced Paganiſm, and embraced the doctrines of the Prophet.

Our author relates a ſtory, which we cannot refuſe ourſelves the pleaſure of inſerting, becauſe it exhibits a very pleaſing picture of the affection and gratitude of the Pagan negroes. In his train was a blackſmith, who had lived ſome years on the Gambia, and who now returned to his own country *Kaſſon*. "Soon after we came in ſight of Jumbo, his native town (ſays Mr Park), his brother, who had by ſome means been appriſed of his coming, came out to meet him, accompanied by a ſinging man: he brought a horſe for the blackſmith, that he might enter his native town in a dignified manner; and he deſired each of us to put a good charge of powder into our guns. The ſinging man now led the way, followed by the two brothers; and we were preſently joined by a number of people from the town, all of whom demonſtrated great joy at ſeeing their old acquaintance the blackſmith, by the moſt extravagant jumping and ſinging. On entering the town, the ſinging man began an extempore ſong in praiſe of the blackſmith, extolling his courage in having overcome ſo many difficulties; and concluding with a ſtrict injunction to his friends to dreſs him plenty of victuals.

"When we arrived at the blackſmith's place of reſidence, we diſmounted and fired our muſkets. The meeting between him and his relations was very tender; for theſe rude children of nature, free from reſtraint, diſplay their emotions in the ſtrongeſt and moſt expreſſive manner. Amidſt theſe tranſports, the blackſmith's aged mother was led forth, leaning upon a ſtaff. Every one made way for her; and ſhe ſtretched out her hand to bid her ſon welcome. Being totally blind, ſhe ſtroked his hands, arms, and face, with great care, and ſeemed highly delighted that her latter days were bleſſed by his return, and that her ears once more heard the muſic of his voice. From this interview I was fully convinced, that whatever difference there is between the Negro and European in the conformation of the noſe and the colour of the ſkin, there is none in the genuine ſympathies and characteriſtic feelings of our common nature.

"During the tumult of theſe congratulations, I had ſeated myſelf apart, by the ſide of one of the huts, being unwilling to interrupt the flow of filial and parental tenderneſs; and the attention of the company was ſo entirely taken up with the blackſmith, that I believe none of his friends had obſerved me. When all the people preſent had ſeated themſelves, the blackſmith was deſired by his father to give them ſome account of his adventures; and ſilence being commanded, he began; and after repeatedly thanking God for the ſucceſs that had attended him, related every material occurrence that had happened to him from his leaving Kaſſon to his arrival at the Gambia; his employment and ſucceſs in thoſe parts; and the dangers he had eſcaped in returning to his native country. In the latter part of his narration, he had frequently occaſion to mention me; and after many ſtrong expreſſions concerning my kindneſs to him, he pointed to the place where I ſat, and exclaimed, *aſſille ibi ſiring*, "ſee him ſitting there." In a moment all eyes were turned upon me; I appeared like a being dropped from the clouds; every one was ſurpriſed that they had not obſerved me before; and a few women and children expreſſed great uneaſineſs at being ſo near a man of ſuch an uncommon appearance. By degrees, however, their apprehenſions ſubſided; and when the blackſmith aſſured them that I was perfectly inoffenſive, and would hurt nobody, ſome of them ventured ſo far as to examine the texture of my clothes; but many of them were ſtill very ſuſpicious; and when by accident I happened to move myſelf, or look at the young children, their mothers would ſcamper off with them with the greateſt precipitation. In a few hours, however, they all became reconciled to me." With theſe worthy people our author ſpent the greater part of two days in feaſting and merriment; the blackſmith accompanied him to the capital; and declared, that he would not leave him while he reſided there.

Kaſſon, Keate.

KEATE (George, Eſq; F. R. S.), deſcended of an ancient and honourable family, was born about the year 1729 or 1730, and received his education at Kingſton ſchool, under the Rev. Mr Woodeſon. From thence he went to Geneva, where he reſided ſome years; and during his ſtay there, became acquainted with Voltaire, with whom he continued to correſpond many years after he returned to England. After finiſhing the tour of Europe, he ſettled as a ſtudent in the Inner Temple, was called to the bar, and ſometimes attended Weſtminſter Hall; though he did not meet with encouragement enough to induce his perſeverance in his profeſſion, nor indeed does it ſeem probable that he had ſufficient application for it. His firſt literary performance was "Ancient and Modern Rome," a poem, written at Rome in the year 1755, printed in the year 1760, and received with conſiderable applauſe. The next year he publiſhed "A Short Account of the Ancient Hiſtory, Preſent Government, and Laws, of the Republic of Geneva, 8vo." This work was compiled during the author's reſidence at Geneva; is a very uſeful one; and is dedicated to Monſieur de Voltaire; to whom he ſays, "When I reflect, that it was in this Republic, whoſe government I have attempted to deſcribe, that I was firſt introduced to your acquaintance; when memory renews the hours of ſocial mirth and refined entertainment which your hoſpitality and converſation afforded me—I cannot but rejoice in this occaſion of expreſſing my gratitude; proud that, as your friendſhip diſtinguiſhed the author of theſe pages in a foreign country, your name may at home adorn his labour."

Keate.

It was at one time the intention of Voltaire to tranſlate this account into French, though he afterwards relinquiſhed the deſign.

The next year, 1762, he produced an "Epiſtle from Lady Jane Gray to Lord Guildford Dudley:" and in 1763, "The Alps," a poem; the ſubject of which comprehends all that chain of mountains known under the general name of the Alps, extending from Italy to Germany, and from France to Tyrol, by whatever denomination they are particularly diſtinguiſhed. Of all the poetical works of Mr Keate, this is intitled to the higheſt praiſe for truth of deſcription, elegance of verſification, and vigour of fancy.

Continuing to employ the preſs, in 1764 he publiſhed "Netley Abbey," which he afterwards, in 1769, enlarged and reprinted: and, in 1765, produced "The Temple Student, an Epiſtle to a Friend;" humourouſly rallying his own want of application to the ſtudy of the law, his preference of the belles lettres, and his conſequent want of ſucceſs in his profeſſion. The death of Mrs Cibber in 1766, of whoſe merits as an actreſs he entertained the higheſt opinion, gave occaſion for a poem to her memory, which celebrates her excellent performances on the ſtage, and laments the loſs the theatre would ſuſtain by her death.

In February 1769, he married Miſs Hudſon; and about the ſame time publiſhed "Ferney; an Epiſtle to M. de Voltaire" In this poem, after praiſing with energy the various beauties of his friend's poetical works, he introduces the following panegyric on Shakeſpeare:

> Yes! jealous wits may ſtill for empire ſtrive,
> Still keep the flames of critic rage alive:
> Our Shakeſpeare yet ſhall all his rights maintain,
> And crown the triumphs of Eliza's reign.
> Above controul, above each claſſic rule,
> His tut'reſs Nature, and the world his ſchool,
> On ſoaring pinions borne, to him was given
> Th' ærial range of Fancy's brighteſt heav'n;
> To bid wrapt thought o'er nobleſt heights aſpire,
> And wake each paſſion with a muſe of fire.
> Revere his genius. To the dead be juſt,
> And ſpare the laurels that o'erſhade the duſt.
> Low ſleeps the bard, *in cold obſtruction laid*,
> Nor aſks the chaplet from a rival's head.
> O'er the drear vault, Ambition's utmoſt bound,
> Unheard ſhall Fame her airy trumpet ſound!
> Unheard alike; nor grief nor tranſport raiſe
> The blaſt of cenſure, or the note of praiſe!
> As Raphael's own creation grac'd his hearſe,
> And ſham'd the pomp of oſtentatious verſe,
> Shall Shakeſpeare's honours by himſelf be paid,
> And Nature periſh ere his pictures fade.

This eulogium on Shakeſpeare, in an an epiſtle to Voltaire, who had laboured ſo long and ſo ſtrenuouſly to detract from the merit of our immortal bard, ſhews that Mr Keate had not given up his judgment to the ſage of Ferney. How the old and envious ſophiſter would reliſh his friend's conduct, may be eaſily conceived. His feelings were certainly very different from thoſe of the mayor and burgeſſes of Stratford, when, in conſequence of this panegyric on their townſman, they complimented Mr Keate with a ſtandiſh, mounted with ſilver, made out of the famous Mulberry tree planted by Shakeſpeare.

Keate.

In 1773, he publiſhed "The Monument in Arcadia," a dramatic poem, built on the picture of Pouſſin, mentioned by Abbé du Bos in his "Critical Reflections on Poetry and Painting."

In 1779, Mr Keate produced one of his moſt ſucceſsful works, intitled "Sketches from Nature; taken and coloured in a Journey to Margate," 2 vols, 12mo. This performance, allowing it to be, as it really is, an imitation of Sterne's "Sentimental Journey;" yet contains ſo many pleaſing delineations of life, ſo many ſtrokes of humour, and ſo much elegance of compoſition, that few will heſitate to give it the preference to any other of Sterne's imitators.

In 1781, he collected his poetical works in two vols, 12mo, and added ſeveral new pieces not before printed. The principal of theſe was "The Helvetiad," a fragment, written at Geneva in the year 1756. In the preface to this performance he gives the following account of it: "During a long ſtay I many years ſince made at Geneva, I viſited moſt of the principal places in Switzerland. The many ſublime ſcenes with which nature hath enriched this romantic country; the tranquillity and content with which every individual enjoys his property; and, above all, that independence of mind which is ever the reſult of liberty—animated me with ſuch veneration for the firſt authors of that freedom, whoſe figures are recorded to poſterity either by ſculpture or painting in the public parts of the towns thro' thoſe little ſtates, that my enthuſiaſm betrayed me into a deſign of writing a poem on this ſingular revolution; the argument of which I had divided into *ten cantos*, beginning the work with the oppreſſions of the Houſe of Auſtria, and cloſing it with the battle of Mongarten; by which thoſe injured people finally renounced its uſurpation, and formed among themſelves thoſe various confederacies that ended in the great union and alliance of the preſent *thirteen cantons*. When I had ſettled the whole plan of this work, I occaſionally, as I found a diſpoſition in myſelf, took up any part of the poem which at the moment moſt invited my thoughts: and enjoying at this time ſuch an intercourſe with M. de Voltaire as afforded me a conſtant acceſs to him, I acquainted him with my intention, ſhewing him the argument I had drawn out for the conduct of the whole deſign. He kept it a few days; and, in returning it, told me, that he thought the great object of the piece, the epiſodes connected with the hiſtory, together with the ſcenery of the country, preſented ſubject matter whereon to form a fine poem; "but the time (added he) which ſuch an undertaking will require, I would rather counſel you to employ on ſubjects that might more engage the public attention; for ſhould you devote yourſelf to the completion of your preſent deſign, the Swiſs would be much obliged to you, without being able to read you, and the reſt of the world care little about the matter." Feeling the force and juſtneſs of the remark, Mr Keate laid aſide his plan, and probably never reſumed it. In the ſame year, 1781, he publiſhed "An Epiſtle to Angelica Kauffman."

A few years after, he became engaged in a long and vexatious law-ſuit, in conſequence of the neglect (to ſay the leaſt of it) of an architect who profeſſed himſelf to be his friend; the particulars of which it is of no importance to detail. At the concluſion of the buſineſs, he ſhewed that his good humour had not forſaken him:

Keate. And in 1787 he gave to the public the principal circumſtances of his caſe in a performance, intitled, "The Diſtreſſed Poet, a ſerio-comic Poem, in three Cantos," 4to, with ſome pleaſantry, and without any acrimony.

His laſt work did infinite honour to his head and his heart, as well as to the liberality of the bookſeller for whom on the title-page it was ſaid to be publiſhed. In the year 1782, the Antelope packet was ſhipwrecked on the Pelew iſlands, where the commander, Captain Wilſon, and his crew lived ſome time before they could get off. On his return to England, the Captain was, for ſome reaſon or other, refuſed the command of another ſhip; and, as we have been informed, he was reduced to a ſtate much the reverſe of affluence. Theſe circumſtances being communicated to Mr Keate, who was ſtruck with admiration of the manners of the inhabitants of the Pelew iſlands (See PELEW ISLANDS, *Encycl.*), he offered to draw up, for the benefit of Captain Wilſon, a narrative of the occurrences which took place during that officer's reſidence among ſo ſingular a people. This he executed in "An Account of the Pelew Iſlands, ſituated in the Weſtern Part of the Pacific Ocean: compoſed from the Journals and Communications of Captain Henry Wilſon and ſome of his Officers, who in Auguſt 1783 were there ſhipwrecked, in the Antelope, a Packet belonging to the Honourable the Eaſt India Company," 4to; a work written with great elegance, compiled with much care, and which, if embelliſhed (as it has been inſinuated) with facts better calculated to have found a place in a novel than a genuine narrative, muſt be aſcribed to the miſinformation of thoſe who were actors in the ſcene, and muſt firſt have deceived before they obtained credit. We mention this report as it has come to us, without any attempt either to eſtabliſh or refute it. We ſhall only add, that if the charge is well founded, Mr Keate (who undertook the taſk on the moſt diſintereſted principle, and derived no advantage whatever from the work) was too ſturdy a moraliſt to have had any hand in the impoſition.—The manuſcript was offered to Mr Dodſley for 300 guineas; but he heſitated to give for it ſo large a price, when another bookſeller undertook to publiſh the work for the benefit of Mr Wilſon; and, we have reaſon to believe, paid to that gentleman, within the compaſs of a year, triple the ſum for which the manuſcript had been offered to Dodſley. Such conduct reflects honour on the London trade.

Beſides the pieces already mentioned, Mr Keate was the author of many Prologues and Epilogues, ſpoken at Mr Newcomb's ſchool at Hackney. He adapted his friend Voltaire's "Semiramis" to the ſtage; but this was ſuperſeded in 1777 at Drury Lane, by a worthleſs tranſlation of as worthleſs an author, one Captain Ayſcough; but neither this nor the author are deſerving of any further notice.

We ſhall conclude by obſerving, that Mr Keate's life paſſed without any viciſſitudes of fortune; he inherited an ample eſtate, which he did not attempt to increaſe otherwiſe than by thoſe attentions which prudence dictated in the management of it. He was hoſpitable and beneficent, and poſſeſſed the good-will of mankind in a very eminent degree. For the laſt year or two, his health viſibly declined; but on the day he died, it appeared to be ſomewhat mended. His death was ſudden, on the 27th of June 1797. He left one daughter, married in 1796 to John Henderſon, Eſq; of the Adelphi. At the time of his death, Mr Keate was a Bencher of the Temple, and a very old member of the Royal and Antiquary Societies, of both of which he had been frequently elected one of the council.

Kennicott. KENNICOTT (Dr Benjamin) was a man of ſuch eminence in the learned world, that every thing relating to him muſt be generally intereſting. In the biographical ſketch of him publiſhed in the *Encyclopædia*, we have acknowledged ourſelves unacquainted with the rank and character of his parents; but this information has been ſince ſupplied by a very candid and well-informed writer in the Monthly Magazine; and as it is accompanied with circumſtances peculiarly honourable to the Doctor, and ought therefore to be preſerved, we ſhall inſert it in this place.

"The parents of Dr Kennicott (ſays this writer) were honeſt characters: His father was the pariſh clerk of Totneſs, and once maſter of a charity ſchool in that town. At an early age young Kennicott ſucceeded to the ſame employ in the ſchool, being recommended to it by his remarkable ſobriety and premature knowledge. It was in that ſituation he wrote the verſes to the honourable Mrs Courtney, which recommended him to her notice, and that of many neighbouring gentlemen. They, with a laudable generoſity, opened a ſubſcription to ſend him to Oxford.

"He ſoon there diſtinguiſhed himſelf, as is well known. As a teſtimony of the truth of the above ſtatement, the following is a copy of an inſcription written by Dr Kennicott, and engraved on the tomb of his father and mother. The writer of this article has tranſcribed it from the original in the church-yard of Totneſs. The tomb is more elegant than perſons in their ſituation are accuſtomed to have erected, and was thought, perhaps, by the envious to be ſomewhat oſtentatious. A perſonal knowledge of the Doctor induces the writer of this article to think, that it was rather the tribute of a good and grateful mind, and of the pious reverence and love which he entertained for the authors of his being.

As Virtue ſhould be of good report,
ſacred
be this humble Monument
to the Memory of
BENJAMIN KENNICOTT, Pariſh-Clerk of Totneſs,
and ELIZABETH his Wife:
The latter
an Example of every Chriſtian Duty;
The former,
animated with the warmeſt Zeal,
regulated by the beſt good ſenſe,
and both conſtantly exerted
for the Salvation of himſelf and others.
Reader!
Soon ſhalt thou die alſo;
and as a Candidate for Immortality
ſtrike thy breaſt and ſay,
Let me live the life of the Righteous,
that my laſt end may be like his.
Trifling are the dates of Time
where the ſubject is Eternity.
Erected
by their Son, B. Kennicott, D. D.
Canon of Chriſt-Church, Oxford.

"It is ſaid, that when Dr Kennicott had taken orders, he came to officiate in his clerical capacity in his native

native town. When his father as clerk proceeded to place the ſurplice on his ſhoulders, a ſtruggle enſued between the modeſty of the ſon and the honeſt pride of the parent, who inſiſted on paying that reſpect to his ſon which he had been accuſtomed to ſhew to other clergymen: to this filial obedience was obliged to ſubmit. A circumſtance is added, that his mother had often declared ſhe ſhould never be able to ſupport the joy of hearing her ſon preach; and that on her attendance at the church for the firſt time, ſhe was ſo overcome as to be taken out in a ſtate of temporary inſenſibility."

KERMES (ſee *Coccus Ilicis*, Encycl.) has been proved by Profeſſor Beckmann to have been uſed as a dye from very remote antiquity. "All the ancient Greek and Latin writers, he ſays, agree, that kermes, called by the latter *coccum*, perhaps alſo *coccus*, and often *granum*, were found upon a low ſhrubby tree, with prickly leaves, which produced acorns, and belonged to the genus of the oak; and there is no reaſon to doubt that they mean *coccum ilicis*, and that low ever green oak, with the prickly leaves of the holly (*aquifolium*), which is called at preſent in botany *quercus ilex*. This aſſertion appears more intitled to credit, as the ancients aſſign for the native country of this tree places where it it is ſtill indigenous, and produces kermes.

"I am inclined (continues our author) to believe, that the art of employing kermes to dye a beautiful red colour was diſcovered in the Eaſt at a very early period; that it was ſoon ſo much improved as to excel even the Tyrian purple; and that it contributed to cauſe the proper purple to be at length abandoned. From the coſtly red dyes extolled ſo much by the Hebrew writers, and which, according to the opinion of learned commentators, were made from kermes, I ſhall not venture to adduce any proofs, as I am not acquainted with the Oriental languages to examine their accounts with accuracy; but I have found a paſſage in Vopiſcus, which ſeems to render my conjecture very probable. That author informs us, that the king of Perſia ſent to the Emperor Aurelian, beſides other articles of great value, ſome woollen cloth, which was of a much coſtlier and brighter purple colour than any that had been ever ſeen in the Roman empire, and, in compariſon of which, all the other purple cloth worn by the Emperor and the ladies of the court appeared dull and faded. In my opinion, this cloth, which was of a beautiful purple red colour, was not dyed with the liquor of the murex, but with kermes. This idea was indeed not likely to occur to the Romans, who were acquainted only with the purple of the murex, and who had leſs experience in the arts in general than in that of robbing and plundering, or who, at any rate, in that reſpect were inferior to the Orientals. The Roman emperors cauſed this ſuppoſed purple to be ſought for in India by the moſt experienced dyers; who, not being able to find it, returned with a vague report that the admired Perſian purple was produced by the plant ſandix. I am well aware, that ſome commentators have ſuppoſed that the ſandix was our madder. Heſychius, however, ſays, very confidently, that the *ſandix* is not a plant, but a kind of ſhrubby tree, which yields a dye like the *coccus*. The Roman dyers, perhaps prejudiced in favour of the murex, made that only the object of their ſearch; and their labour proving fruitleſs, they might have heard ſomething of kermes, or the kermes-oak, which they did not fully underſtand. Our dyers, even at preſent, believe many falſe accounts reſpecting the dye-ſtuffs which they uſe daily."

The uſe of kermes in dyeing ſeems to have been continued through every century. In the middle ages, as they are called, we meet with kermes under the name of *vermiculus* or *vermiculum*; and on that account cloth dyed with them was called *vermiculata*. Hence the French word *vermeil*, and its derivative *vermilion*, as is well known, had their extraction; the latter of which originally ſignified the red dye of kermes, but it is now uſed for any red paint, and alſo for fine pounded cinnabar.

KHAS, in Bengal, lands taken into the hands of government, oppoſed to the management of Zemindars or farmers. See ZEMINDAR in this *Supplement*.

KHALSA, in Bengal, ſometimes with the addition of *Shereefah*, the department of land and revenues; the exchequer.

KHERAJE, in Bengal, ſignifies ſtrictly the tribute paid by a conquered country: it is alſo uſed for revenue in general.

KHIDMUT, office, attendance, employment, ſervice.

KHIDMUTGAR, a waiting man.

KHISMUT, portion or diviſion.

KHOMAR, or COMAR, a Zemindar's demeſne land.

KING-POST, or KING-*Piece*, is a piece of timber ſet upright in the middle, between two principal rafters, and having ſtruts or braces going from it to the middle of each rafter. See ROOF, *Encycl.*; and CARPENTRY, *Suppl.*

KIPPIS (Andrew, D. D. F. R and A. S.), was born at Nottingham, March 28 (O. S.) 1725. His father, a reſpectable tradeſman of that town, was deſcended from the Rev. Benjamin King of Oakham, Rutlandſhire, an ejected miniſter; and his mother, Ann Ryther, was the grand-daughter of the Rev. John Ryther, who was ejected from the church of Fernby, in the county of York. In the year 1730, he loſt his father, and went to reſide with his grandfather, Andrew Kippis of Seaford in Lincolnſhire. He received his claſſical education at the grammar ſchool in that town; but what contributed moſt to his future eminence, was the friendſhip of the Rev. Mr Merrival, who was equalled by few of his contemporaries in various branches of learning, particularly in his acquaintance with the claſſics, his knowledge of ancient and modern hiſtory, and his refined taſte in the belles lettres. Dr Kippis frequently ſaid, that it was impoſſible for him to expreſs his obligations to this friend of his youth. In 1741 he removed to Northampton, and commenced his academical ſtudies under Dr Doddridge. After a reſidence of five years at the academy, he was invited by ſeveral congregations to become their miniſter. Though he was preſſed to ſettle at Dorcheſter, and had been choſen their miniſter, he gave the preference to an invitation from Boſton in Lincolnſhire, where he went to reſide in September 1746. Here he continued four years; and in November 1750, accepted the paſtoral charge of a congregation at Dorking in Surry. The congregation meeting in Princes-ſtreet Weſtminſter, having been without a miniſter about two years, he was choſen, in June 1753, to ſucceed the Rev. Dr Obadiah Hughes. On the 21ſt of September

ber following, he married, at Boſton, Miſs Elizabeth Bott, one of the daughters of Mr Iſaac Bott, a merchant of that place; and in the month of October fixed his reſidence in Weſtminſter. In June 1767, he received the degree of D. D. from the univerſity of Edinburgh, on the unſolicited recommendation of the late learned Profeſſor Robertſon. He was elected a member of the Society of Antiquaries on the 19th of March 1778; and on the 17th of June 1779, he was choſen a Fellow of the Royal Society. In both Societies he had the honour of being in the council two years.

Dr Kippis was eminently diſtinguiſhed for the virtues and accompliſhments which form the chief ornaments of private life. With a ſuavity of manners and urbanity of behaviour peculiarly attractive, he united that knowledge of men and books which rendered his converſation uncommonly entertaining and inſtructive to the circle of his acquaintance and friends. As a miniſter, he was not leſs eminent for his profound acquaintance with every branch of theology than for the happy manner in which he applied it to the improvement of thoſe who attended his miniſtry. His ſermons were remarkable for perſpicuity, elegance, and energy; and his elocution was unaffected and very impreſſive, particularly at the cloſe of his diſcourſes. But the ſuperior powers and vigour of mind which he derived from nature, and which he had cultivated with unremitting diligence and peculiar ſucceſs, were not to be confined to the narrow limits of private life and the duties of the paſtoral charge, however important; they were deſigned for more extenſive and important ſervices to his country and to mankind. The intereſts of literature, ſcience, and religion, have received from the exertion of his talents as a writer the moſt eſſential advantages. His firſt efforts in literature were made in the Gentleman's Magazine, a periodical publication called the Library, and the Monthly Review; to each of which he contributed many important articles, eſpecially in the hiſtorical and philological departments of the laſt. He was the author of three important tracts, viz "A Vindication of the Proteſtant Diſſenting Miniſters, &c." "Obſervations on the late Conteſts in the Royal Society;" and "Conſiderations on the Treaty with America, &c." His improved edition of Dr Doddridge's Lectures is a work of great value; and "The Hiſtory of Knowledge, Learning, and Taſte, in Great Britain," prefixed to the New Annual Regiſter, merits, and has received, the approbation of the public. He publiſhed at different times ſeveral ſingle ſermons; among which, that on the death of his friend the Rev. Mr Laugher, is intitled to very high praiſe. The greater part of theſe he republiſhed, with other practical diſcourſes, in the year 1794: but the work which, next to the ſtudies immediately connected with his office as a Chriſtian miniſter, engaged his principal attention, and by which he has long been diſtinguiſhed, is, the improved edition of the "*Biographia Britannica.*" In this great national publication, the comprehenſiveneſs and powers of his mind, the correctneſs of his judgment, the vaſt extent of his information, his indefatigable reſearches and unremitting aſſiduity, his peculiar talent of appreciating the merits, and analyzing the labours of the moſt eminent writers, and his unſhaken integrity, unbiaſſed fidelity, and impartial deciſion on the characters of the philoſopher, ſtateſman, poet, ſcholar, and divine, are ſtrongly diſplayed, and univerſally acknowledged. His ſtyle, formed on the models of Sir William Temple and the claſſical Addiſon, is remarkable for its perſpicuity, elegance, and purity; and gives a peculiar luſtre to the rich ſtores of knowledge treaſured in the volumes now publiſhed. This work has given him a high rank among the literati of his country, and will carry down his name with diſtinguiſhed reputation to poſterity. He died on the 8th October 1795.

KOL-QUALL, the Abyſſinian name of a tree, which ſome botaniſts have ſuppoſed to be the EUPHORBIA *Officinarum* of Linnæus. Mr Bruce, who gives the only deſcription of the Kol quall that we have ſeen, is of a different opinion: for which he aſſigns two reaſons; the firſt is, that the flower, which he ſays is roſaceous, is compoſed of ſeveral petals, and is not companiform; and the ſecond, that it produces no ſort of gum, either ſpontaneouſly or upon inciſion. We muſt acknowledge, that we entertain ſome doubts whether our author was at due pains to aſcertain this fact; and theſe doubts are ſuggeſted by his own hiſtory of the tree. His deſcription is not very perſpicuous, and therefore, leſt we ſhould miſrepreſent his meaning, we ſhall give it in his own words:

"The firſt thing that preſented itſelf was the firſt ſhoot of this extraordinary tree. It was a ſingle ſtalk, about ſix inches meaſured acroſs, in eight diviſions, regularly and beautifully ſcolloped and rounded at the top, joining in the centre at three feet and a half high. Upon the outſide of theſe ſcollops were a ſort of eyes or ſmall knots, out of every one of which came five horns, four on the ſides and one in the centre, ſcarce half an inch long, fragil, and of no reſiſtance, but exceedingly ſharp and pointed. Its next proceſs is to put out a branch from the firſt or ſecond ſcollop near the top, others ſucceed from all directions; and this ſtalk, which is ſoft and ſucculent, of the conſiſtence of the aloe, turns by degrees hard and ligneous, and after a few years, by multiplying its branches, aſſumes the form of a tree, the lower part of which is wood, the upper part, which is ſucculent, has no leaves; theſe are ſupplied by the fluted, ſcolloped, ſerrated, thorny ſides of its branches. Upon the upper extremity of theſe branches grow its flowers, which are of a golden colour, roſaceous, and formed of five round or almoſt oval petala; this is ſucceeded by a triangular fruit, firſt of a light green with a ſlight caſt of red, then turning to a deep crimſon, with ſtreaks of white both at top and bottom. In the inſide it is divided into three cells, with a ſeed in each of them; the cells are of a greeniſh white, the ſeed round, and with no degree of humidity or moiſture about it; yet the green leaves contain a quantity of bluiſh watery milk almoſt incredible.

"Upon cutting two of the fineſt branches of a tree in its full vigour, a quantity of this iſſued out, which I cannot compute to be leſs than four Engliſh gallons; and this was ſo exceedingly cauſtic, that though I waſhed the ſabre that cut it immediately, the ſtain has not yet left it.

"When the tree grows old, the branches wither, and, in place of milk, the inſide appears to be full of powder, which is ſo pungent, that the ſmall duſt which I drew upon ſtriking a withered branch, ſeemed to

Koona, Koraquas

threaten to make me ſneeze to death, and the touching of the milk with my fingers excoriated them as if ſcalded with boiling water; yet I everywhere obſerved the wood-pecker piercing the rotten branches with its beak, and eating the inſects, without any impreſſion upon its olfactory nerves.”

If what is milk in a young tree be a dry powder in one that is old, is it not probable that the milk might by evaporation be reduced to the conſiſtence of gum, and that the kol quall may be at moſt but a variety of the *euphorbia officinarum?* From our author's obſervation, the kol quall appeared to thrive beſt on poor, ſandy, ſtony earth, at no great diſtance from the ſea. The Abyſſinians employ the milky juice in tanning to take off the hair from the ſkins, and they make no other uſe whatever of the tree.

KOONA, a ſpecies of ECHITES (for which ſee *Encycl.*), very common in the woods of North Africa. It is a ſhrub, of which the leaves, when boiled with a ſmall quantity of water, yield a thick black juice, into which the negroes dip a cotton thread. This thread they faſten round the iron of their arrows, in ſuch a manner that it is almoſt impoſſible to extract the arrow when it has ſunk beyond the barbs, without leaving the iron and the poiſoned thread in the wound. The poiſon of the koona is ſaid to be very deadly.—*Park's Travels.*

KORAQUAS, a tribe of Hottentots inhabiting a diſtrict of South Africa, which M. Vaillant places on the confines of the Nimiqua country (See NIMIQUAS, *Suppl.*). When our author viſited them, the whole tribe was aſſembled for the election of a chief: and not agreeing among themſelves, ſome blood had been ſhed, and much more would have been ſhed, had they not unanimouſly made choice of him. When he firſt joined them, the whole horde paid attention to nothing but their quarrel. To ſee their warmth, one might have ſuppoſed that their election was a matter of importance to the whole world, and that the fate of mankind was about to depend on their chief. All ſpoke at the ſame time; each endeavoured to drown his neighbour's voice by his own; their eyes ſparkled with fury; and amidſt this confuſion, while they threatened each other in turns, the noiſe they made became truly dreadful.

Unarmed, and without any precaution, though ſurrounded by this enraged multitude, our author walked calmly along in the midſt of them; and when he reached the kraal, he ordered his tent to be immediately formed, as if he had been ſurrounded by friends and relations. This appearance, raiſed ſuddenly, and as if by magic, before the eyes of the horde, with his fuſees, horſes, and tent, objects which were all new to them, filled them with admiration. Men, women, and children, motionleſs, and with their mouths wide open, all ſtood looking at them with profound ſilence. Anger, hatred, and every violent paſſion, ſeemed by their countenances to be extinguiſhed, and to have given place to more tranquil emotions, to ignorant ſurpriſe, and ſtupid aſtoniſhment. Infancy is naturally curious; it is ſtruck with every thing it ſees; and the ſavage, in this reſpect, is only a grown-up child. As theſe ſavages ſeemed to wiſh that he would permit them to examine more cloſely whatever excited their admiration, he readily condeſcended to gratify their deſire. They approached, ſurveyed, and handled every thing. But the principal object of general curioſity was his perſon. They ſeemed as if they would never be ſatisfied with looking at his dreſs. They pulled off his hat, that they might the better examine his hair and his beard, which were long. They even half unbuttoned his clothes; and ſurpriſed to ſee his ſkin white, each felt it, as if deſirous to aſcertain that what they ſaw was real.

Koraquas.

This comedy continued till the evening; and at length, when the moment of ſeparation arrived, M. Vaillant cauſed to be hinted to the whole company, that if, two hours after ſun-riſe next morning, they ſhould not be agreed reſpecting the choice of a chief, he would immediately leave them. He added, however, that if, on the other hand, they came and preſented to him a chief, elected by general conſent, he would then load them all with preſents, and beſtow on him a diſtinction which would raiſe him above all his equals, and render the horde one of the moſt celebrated in the whole country. “But what was my ſurpriſe (ſays he) when I learned the ſame evening, that on my head the burden of the crown was depoſed!” He acquieſced, however; aſſuring them, that if they would promiſe to be obedient, he would give them the only chief worthy of ruling them, and of making them happy.

By his interpreters he had learned, that the choice of the majority leaned towards one Haripa, a man about 40 years of age; tall, well made, exceedingly ſtrong, and conſequently formed by nature for ruling the feeble multitude. He therefore named Haripa chief; and the people appearing to approve of his choice, he commanded ſilence, and cauſing the new monarch to approach, placed on his head, with great ſolemnity, a Dutch grenadier cap, of which the copperplate on the front was ornamented with the arms of Holland. This ſymbol, *viz.* a lion rampant, having in one of his fore-paws ſeven arrows, and in the other a naked ſabre, could not fail to pleaſe the ſavages, as it exhibited a repreſentation of the weapons peculiar to them, and of the moſt formidable animal of their country. They teſtified their admiration in the moſt expreſſive manner; and imagined that, ſuperior to kings, the white man during the night had by magic made this crown, merely to adorn their chief, and to afford them pleaſure. Vaillant then affixed to the ſkin, which formed Haripa's dreſs, ſeveral rows of glaſs beads; gave him a girdle made of a ſtring of very large ones; ornamented his arms with tin bracelets, and ſuſpended from his neck a ſmall padlock, ſhaped like a butterfly, the key of which had been loſt. Such padlocks, made in the form of animals of every kind, are very common at the Cape. They come from China; and are brought to Africa by the captains of the Company's ſhips which trade in the Indian ſeas.

During the ceremony of inſtallation, the whole horde, dumb and motionleſs through admiration, ſeemed loſt in ecſtacy. Haripa himſelf, though highly gratified, did not dare to make the leaſt movement, and obſerved a gravity altogether riſible. When the inauguration was finiſhed, and he was completely dreſſed, our author preſented him with a mirror, that he might enjoy the ſatiſfaction of ſurveying his own figure. He then ſhewed him to the people, who expreſſed their joy by ſhouts and applauſes without end.

“Ye honeſt hearts (ſays M. Vaillant), who peruſe this account, behold what it coſt me to reſtore peace among

among

among a whole tribe, and to prevent them from deſtroying each other!" From this moment concord was re-eſtabliſhed; univerſal joy prevailed through the horde; and they inſtantly began their dancings, which continued for three days and three nights without intermiſſion. They killed for this feſtival ſeveral fat ſheep, and even two oxen; an extraordinary and truly aſtoniſhing magnificence among a people who, when they barter one of their daughters for a cow, think they have made an excellent bargain.

Our author, wiſhing to purchaſe ſome oxen for his waggons, bought them at the price of a nail the ox; and thoſe who had the good fortune to make ſuch an exchange were highly ſatisfied with their bargain. Nails and ſmall bits of iron were indeed of real value to them, to point the arrows and aſſageys with which they ſhot the antelopes that abound in their country, and conſtitute much of their food. Like other ſavages, the Koraquas were ready to pilfer, and appropriate to their own uſe whatever they found pleaſing, or ſuited to their purpoſes. They attempted to carry away ſome of our author's effects, even before his face; and to prevent their rapacity, he was obliged either to watch over, or to depoſit them in ſome place of ſafety.

The Koraquas are much taller than the Hottentots of the colonies, though they appeared evidently to be deſcended from the ſame race, having the ſame language and cuſtoms with their neighbours the NIMIQUAS (ſee that article), who are certainly of Hottentot extraction.

As the exceſſive dryneſs of the country renders ſprings very rare, the Koraquas would be unable to inhabit it, had they not found the means of remedying this ſcarcity of water. For this purpoſe they dig in the earth a kind of ciſterns or rather wells, to which they deſcend gradually by ſteps; and theſe people are the only African nation among whom our author ever found the ſame mark of induſtry.

As their wells always contain little water, and as none is to be loſt, they take care to ſecure it even from the birds, by cloſing up the mouth of the hole with ſtones and the branches of trees; ſo that, unleſs one knows the ſpot, it is impoſſible to find it. They go down into it every day, to fetch up as much water as may be neceſſary for the conſumption of their people and cattle. They draw it in a kind of veſſels made of hollowed wood, and pour it into the ſkins of buffaloes or giraffes, placed in a concave form on the ground to hold it; but they diſtribute it with the utmoſt parſimony, and never draw more than they abſolutely have occaſion for.

Notwithſtanding this ſtrict economy, the wells often become dry; and in that caſe the horde is obliged to remove to ſome other place. Among all the weſtern tribes, therefore, there are none who lead ſo wandering a life as the Koraquas: the conſequence of which is, that, as they often change their abode, and acquire new neighbours, they muſt, in ſome meaſure, adopt the cuſtoms of the nations near which they fix their reſidence. Some tribes of them greaſe themſelves like the Hottentots; while others tattoo their face, breaſt, and arms, after the manner of the Caffres. It is, however, to be remarked, that the ſame colour is not employed by all the Koraquas; each has his own, according as caprice may direct him in his choice, and it generally varies every day; which renders, as one may ſay, the inhabitants of the ſame horde ſtrangers to each other, and gives them a motley appearance, as if they were dreſſed for a maſquerade.

KRISHNA or CRISNA, is an eaſtern river of conſiderable magnitude, which is very little known in Europe. We have the following account of it, and its tributary waters, and the countries through which it flows, in Mr Pennant's View of Hinduſtan:

"From Gangapatam, on the northern mouth of the Pennar, the land runs due north as far as Mottapilli, when it forms a ſtrong curve toward the eaſt; the point of which is one ſide of the great river Criſna, in about lat. 15° 43′. Its Delta, which winds round as far as Maſulipatam, is not conſiderable. This river annually overflows a vaſt tract of country, like the Indus on the weſtern ſide of this empire, and like all the other great rivers on this extenſive coaſt. The Criſna riſes from the foot of the weſtern Ghauts, and not more than 45 miles from Severndrug, on the weſtern coaſt. There is another branch to the eaſt, that riſes ſtill more northerly. On that ſide is Sattara, a ſtrong fortreſs, the capital of the Mahratta ſtate in the time of the rajahs of Sivaji's race. It was taken by him in 1673, and found to be the depoſitory of immenſe treaſure; at that time it belonged to the king of Vijapur: it was afterwards uſed by the Mahrattas as the lodgment of their riches, and alſo as a retreat for the more defenceleſs inhabitants of Puna, and other open towns, in time of potent invaſions.

"The river continues deſcending to the eaſt. In latitude 17° is Meritch, a ſtrong fortreſs, with a Jaghirdar territory, conquered from its owner by Hyder. In lat. 16° 45′, a ſmall river diſcharges itſelf into the Criſna from the north. It would not be worth mentioning, but that Pannela, a fortreſs of vaſt ſtrength, was made by Sumbuji, the profligate ſon of Sivaji, his reſidence juſt before his ſurpriſal in 1689, betrayed by Cablis Khan, the vile inſtrument of his pleaſures, corrupted by Aurengzebe. His extravagant love of women brought on him ruin. Informed by Cablis that a Hindu of rank and great beauty was on the road to be delivered by her parents to her huſband, according to the cuſtom of the Hindus, he inſtantly put himſelf at the head of a ſmall body of horſe to carry off the prize, and ordered Cablis to follow at a diſtance for his protection, in caſe of accidents in that hoſtile time. The traitor had given notice to Aurengzebe of this expedition, who, ſending a body of cavalry, ſurpriſed Sumbuji juſt as he had diſperſed the nuptial proceſſion.

"Into the north ſide of the Criſna, in lat. 16° 20′, falls the great river Bima, after a courſe of 350 miles. It riſes at the head of the weſtern Ghauts, parallel to Chaul in the Concan, and not above 50 miles from the ſea. It deſcends rapidly towards the ſouth-eaſt. In lat. 17° 40′ it receives a ſmall river from the weſt, on the ſouthern banks of which ſtands Vijapur, the capital of the famous kingdom of the ſame name, now poſſeſſed by the Mahrattas, but once governed by its own monarchs, till conquered by Aurengzebe in 1686. It was of great extent, and reached to the weſtern ſea, where it poſſeſſed the ports of Dabul, Vingorla, and Carapatan.

"The capital Vijapur is ſome leagues in circuit, ſeated in a fine but naked country, well watered. It makes a ſingular appearance from an adjacent eminence, filled with numbers of ſmall domes, and one of a majeſtic ſize.

ſize. It was once a city of great ſplendour, and filled with palaces, moſques, mauſoleums, and public and private buildings of great magnificence; many of them are fallen to ruin, and give melancholy proofs of its former ſplendour. I ſhall not attempt to detail them. The palaces of the kings, and accommodations for their attendants, were within a vaſt fort, ſurrounded with a ditch 100 yards wide; the depth appeared to be great, but is now filled with rubbiſh: within the fort is the citadel. Tavernier ſays, that the great ditch was filled with crocodiles, by way of garriſon, to prevent all acceſs by water. Lieutenant Moor has his doubts about this, imagining that there never was any water in this foſs. That ſuch garriſons have exiſted I doubt not. I have read in Purchas, that in Pegu the foſſes of fortified places were ſtocked with thoſe tremendous animals, not only to keep out enemies, but to prevent deſertion. This practice has certainly been of great antiquity in ſome parts of India: Pliny mentions it as uſed in a fair city of the Horatæ, a people I cannot trace.

“ The Criſna, above and below its conflux with the Bima, is fordable; and a few miles below its channel is 600 yards wide, made horrid with the number and rudeneſs of the variouſly formed rocks, which are never covered but in the rainy ſeaſon.

“ The Tungbuddra is another vaſt branch of the Criſna. It falls into it in lat. 16° 25′, and originates extremely ſouth, from a doubtful fountain. Towards its lower part it divides into three or four ſmall branches, which riſe remote from each other; the moſt ſouthern is the Curga Naïr's country; the moſt northern from the head of the Ghauts oppoſite to Onor, and ſcarcely 20 miles from the ſea. What muſt give this river great celebrity, is its having had on its banks, in lat. 15° 22′, the ſplendid city of Vijanagar. Feriſhta ſays, that it was founded in 1344 by Belaldeo king of the Carnatic, which in thoſe days included the whole peninſula. It was viſited by Cæſar Frederick a Venetian traveller, in 1565, and found deſerted and ruinous, having been ſacked by four confederated Mahomedan princes two years before, on which its monarch had retired to Penuconda. Frederick ſays that its circumference was 24 miles. Mr Rennel has given us a view of its preſent ſtate from Lieutenant Emitt, who viſited it in 1792.

“ The ruins of Vijanagar are in the little Sircar of Anagundi, which does not extend above 20 miles around this vaſt city. It is very ſingular, that that little Sircar is now poſſeſſed by a lineal deſcendant of Rama Rajah, the laſt great monarch of Vijanagar, and its attendant nations Canarine and Malabar, united 700 years before under the rule of Criſna Deva. Tippu wiſhed to reſerve this little tract to himſelf, for the ſatisfaction of generouſly reſtoring to the deſcendant the ſmall relique of the great empire of his anceſtors. He is denied the title of Rajah, inſtead of which he has the diminutive Raïl beſtowed on him. This is ſuitable to his revenues, which do not exceed two lacs of rupees, or 25,000 *per annum*, with the empty regality of a mint at Anagundi.” In the remainder of its courſe the Criſna offers nothing remarkable.

KUARA, is a beautiful tree, which grows in the ſouth and ſouth-weſt parts of Abyſſinia. With the ebony it is almoſt the only wood of the province of Kuara, of which it bears the name; but Mr Bruce aſſures us, that it is very frequent in all the countries where there is gold. “ It is (ſays he) what naturaliſts call *a Corallodendron*, probably from the colour of its flowers or of its fruit, both equal in colour to coral. Its fruit is a red bean, with a black ſpot in the middle of it, which is incloſed in a round capſula or covering, of a woody nature, very tough and hard. This bean ſeems to have been in the earlieſt ages uſed for a weight of gold among the Shangalla, and, where that metal is found, all over Africa; and by repeated experiments, I have found that, from the time of its being gathered, it varies very little in weight, and may perhaps have been the very beſt choice that therefore could have been made between the collectors and buyers of gold.

“ I have ſaid this tree is called kuara, which ſignifies the ſun. The bean is called *carat*, from which is derived the manner of eſteeming gold as ſo many carats fine. From the gold country in Africa it paſſed to India, and there came to be the weight of precious ſtones, eſpecially diamonds; ſo that to this day in India we hear it commonly ſpoken of gold or diamonds, that they are of ſo many carats fine or weight. I have ſeen theſe beans likewiſe from the Weſt-Indian iſlands. They are juſt the ſame ſize, but, as far as I know, are not yet applied to any uſe there.”

This is a very different account of the origin of the term CARAT from what we have given in the *Encyclopædia*; but the reader will judge for himſelf between the two.

KUMI, the name of an iſland between Japan and China, of which Perouſe writes in the following terms: “ On the 5th of May, at one o'clock in the morning, we made an iſland, which bore north-north eaſt of us; we paſſed the reſt of the night, ſtanding off and on, under an eaſy ſail, and at day-break I ſhaped my courſe ſo as to run along the weſt coaſt of this iſland, at the diſtance of half a league. We ſounded ſeveral times without finding bottom. We were ſoon ſatisfied that this iſland was inhabited, for we ſaw fires in ſeveral places, and herds of oxen grazing on the ſea-ſhore. When we had doubled its weſt point, which is the moſt beautiful and beſt inhabited ſide, ſeveral canoes put off from the ſhore in order to obſerve us. They ſeemed to be extremely in fear of us; their curioſity cauſed them to advance within muſket ſhot, and their diſtruſt made them immediately flee away with ſpeed. Our ſhouts, geſtures, ſigns of peace, and the ſight of ſome ſtuffs, at length determined two of the canoes to come alongſide of us. I made each of them a preſent of a piece of nankeen and ſome medals. It was evident that theſe iſlanders had not left the coaſt with any intention of trafficking with us, for they had nothing to offer in exchange for our preſents; they only faſtened to a rope a bucket of freſh water, making ſigns to us, that they ſtill thought themſelves in our debt, but that they were going aſhore to fetch proviſion, which they expreſſed by putting their hand into their mouth. Before coming alongſide the frigate, they placed their hands upon their breaſt, and raiſed their arms towards the ſky: theſe geſtures were repeated by us, and then they reſolved to come on board; but it was with a want of confidence, which was ſtrongly expreſſed in their countenance during the whole time. They nevertheleſs invited us to approach the land, giving us to underſtand, that we ſhould there want for nothing. Theſe iſlanders

Kumi, Kuriles.

are neither Japaneſe nor Chineſe, but, ſituate between theſe two empires, they ſeem to partake of both people. Their covering was a ſhirt and a pair of cotton drawers Their hair, tucked up on the crown of the head, was rolled round a needle, which ſeemed to us to be gold : each of them had a dagger, the handle of which was gold alſo. Their canoes were made out of hollowed trees, and they managed them very indifferently. I could have wiſhed to land upon this iſland, but as we had brought the ſhip to, in order to wait for theſe canoes, and as the current ſet to the northward with extreme rapidity, we had drifted a great way to leeward, and our efforts to reach it would perhaps have been in vain : beſides, we had not a moment to loſe, and it was of the higheſt importance to us to get out of the Japan ſeas before the month of June ; a period of ſtorms and hurricanes, which render theſe ſeas the moſt dangerous in the whole world.

"It is clear, that veſſels which might be in want would readily provide themſelves with proviſion, wood, and water, in this iſland, and perhaps even carry on a little trade ; but as it is not more than three or four leagues in circumference, there is no great probability that its population exceeds four or five hundred perſons; and a few gold needles are not of themſelves a proof of wealth." Our author, by obſervation, found the latitude of Kumi to be 24° 33′ north ; its longitude 120° 56′ eaſt from Paris.

KURILES, are a cluſter of iſlands, of which ſome account has been given under the word Kuril, in the *Encyclopædia*. In addition to that article, the following particulars are worthy of notice : Of the 21 iſlands belonging to Ruſſia, which are diſtinguiſhed from each other, not by names, but by numbers, four only are inhabited, viz. thoſe which are called the firſt, the ſecond, the thirteenth, and the fourteenth. The laſt two may indeed be counted only as one, becauſe the inhabitants all paſs the winter upon N° 14, and return to N° 13 to paſs the ſummer months. The others are entirely uninhabited, the iſlanders only landing there occaſionally from their canoes for the ſake of hunting foxes and otters. Several of theſe laſt mentioned iſlands are no better than large rocks, and there is not a tree on any one of them. The currents are very violent between the iſlands, particularly at the entrance of the channels, ſeveral of which are blocked up by rocks on a level with the ſea. The population of the four inhabited iſlands amounts at moſt to 1400 ſouls. The inhabitants are very hairy, wear long beards, and live entirely upon ſeals, fiſh, and the produce of the chace. When viſited by M. Perouſe, they had juſt been exempted for ten years from the tribute uſually paid to Ruſſia, becauſe the number of otters on their iſlands is very much diminiſhed. Theſe poor people are good, hoſpitable, and docile, and have all embraced the Chriſtian religion. The more ſouthern and independant iſlanders ſometimes paſs in canoes the channels that ſeparate them from the Ruſſian Kuriles, in order to give ſome of the commodities of Japan in exchange for peltries.

L.

Labdaſſeba, Laboratory.

LABDASSEBA, a tribe of ſavage Arabs who inhabit the deſart of Sahara in Africa. They are the moſt powerful of all thoſe tribes except the Ouadelims ; and they reſemble theſe ſo much in every thing, that we ſhall give an account of the manners of both under the title Ouadelims, and of their country under that of Sahara.

LABORATORY, is an apparatus ſo neceſſary to the chemiſt, that every contrivance to render it more convenient, or to leſſen the expence of it, muſt contribute greatly to the advancement of ſcience. The abilities of *Morveau* alias *Guyton*, and the ſucceſs with which he has proſecuted the ſtudy of chemiſtry, are well known ; and therefore his different methods of ſaving time and expence in making chemical experiments muſt be worthy of the notice of younger chemiſts.

In the ſecond volume of the Memoirs of the Ancient Academy of Dijon, we have a deſcription by him of a box containing a kind of portable laboratory, compoſed of a lamp with three wicks, diſpoſed in the figure of an equilateral triangle, to form an internal current of air, with ſupports for the different veſſels of digeſtion, diſtillation, evaporation, &c. He made a ſolution of ſilver with common aqua fortis and the metal in an alloyed ſtate, which anſwered very well as a re-agent, without having occaſion for any other utenſils but this box and apothecary's phials, which are every where to be found.

Laboratory.

This apparatus, however, was confined in its application, and he ſoon thought of improving it. He conſtructed a lamp, on the principles of Argand, with three concentric circular wicks, each having an interior and exterior current of air. The effect ſurpaſſed his expectations with regard to the intenſity of the heat ; but it was difficult to prevent the deſtruction of the hard ſolder round the wicks ; and the glaſs retorts were frequently melted at the bottom, and disfigured. It was attended with other inconveniences, and the quantity of oil conſumed was great.

A ſhort time afterwards, it occurred him to ſubſtitute, inſtead of the glaſs chimney of Argand's lamp, a cylinder of copper with an indented part or ledge a few millimetres (ſee Revolution, *Encycl.* n° 183.) above the flame, to perform the office of the indented chimney of glaſs, and by that means to render it practicable to raiſe the wick to a certain height without ſmoaking. This cylinder has three branches like a chaffing-diſh. By this apparatus two or three decilitres of water (about half an Engliſh wine pint) may be brought to boil in a copper or glaſs veſſel in about ſix or ſeven minutes. It has ſerved for a number of operations ; but it was not till after he had obſerved the degree of heat obtained from the lamp in its ordinary ſtate, and particularly ſince he had ſubſtituted inſtead of the metallic tube a chimney of glaſs cut off at the length of three centimetres (rather more than one Engliſh inch) above the contraction, that he perceived all the advantages it was capable of affording; and that by means of a moveable ſupport for the reception of the different veſſels, which may be fixed at pleaſure by a thumb-ſcrew, this lamp furnace, at the ſame time that it gives light, and conſequently without any additional expence, may with facility be uſed for almoſt every one of the operations of chemiſtry; ſuch as digeſtions, ſolutions, cryſtallizations, concentrations; the rectification of acids; diſtillations on the ſand-bath, or by the naked fire; incinerations of the moſt refractory reſidues; analyſes with the pneumatic apparatus, or of minerals by the ſaline fuſion, &c. "I have not (ſays he) hitherto met with any exception but for complete vitrifications and cupellations; for even the diſtillations to dryneſs may be performed with ſome precautions, ſuch as that of transferring the matter into a ſmall retort blown by the enameller's lamp, and placing its bottom on a little ſand-bath in a thin metallic diſh." The ſupport here mentioned is ſimply a copper ring eight centimetres (3,15 inch.) in diameter, which is raiſed or lowered by ſliding on a ſtem of the ſame metal. Nothing more was required but to adapt it to the ſquare iron ſtem which paſſes through the reſervoir of the lamp. The connection is made by a piece of wood, in order that leſs of the heat might be diſperſed. As the lamp itſelf is capable of being moved on its ſtem, it is eaſy to bring it nearer or remove it at pleaſure from the veſſels, which remain fixed; a circumſtance which, independent of the elevation or depreſſion of the wick, affords the means of heating the retorts by degrees, of moderating or ſuppreſſing the fire inſtantly, or of maintaining it for ſeveral hours at a conſtant or determinate intenſity, from the almoſt inſenſible evaporation of cryſtallizable ſolutions to the ebullition of acids; properties never poſſeſſed by the athanor, of which chemiſts have boaſted ſo much. The advantage of theſe will be properly valued by thoſe operators who know that the moſt experienced and the moſt attentive chemiſts meet with frequent accidents, by which both their veſſels and the products of their operations are loſt for want of power in the management of the fire."

For the analyſis of ſtones, ſuch as the cryſtals of tin, the ſhortened chimney of glaſs is to be uſed; and the proceſs is to be begun by placing the mixture in a capſule of platina or ſilver $2\frac{3}{4}$ inches in diameter. This capſule is to be placed on the ſupport, and the heat regulated in ſuch a manner, that ebullition ſhall take place without throwing any portion of the matter out of the veſſel. As ſoon as its contents are perfectly dry, they are to be transferred into a very thin crucible of platina, of which the weight is about $252\frac{1}{2}$ grains Engliſh, and its diameter one inch and three-fourths. This crucible reſts on a ſmall ſupport of iron-wire, which ſerves to contract the ring; and the wick being at its greateſt elevation, with the ring lowered to the diſtance of $9\frac{3}{4}$ inches from the upper rim of the chimney, Guyton produced, in leſs than twenty minutes, the ſaline fuſion to ſuch a degree, that from the commencement of the operation the decompoſition proceeded as far as to 0.70 of the mineral. The ſame apparatus, that is to ſay, with the ſhortened chimney, ſerves for oxidations, incinerations, torrefactions, and diſtillations to dryneſs.

In ſuch operations as require a leſs heat, he leaves the lamp with its large chimney abſolutely in the ſame ſtate as when it is uſed for illumination; and by raiſing and lowering either the ring which ſupports the veſſel, or the body of the lamp if the veſſels be fixed in communication with others, he graduates the heat at pleaſure. Vinegar diſtils without interruption at $2\frac{1}{3}$ inches Engliſh from the upper termination of the chimney, that is to ſay, $7\frac{1}{2}$ inches Engliſh from the flame. Water is made to boil in eight minutes, at the ſame height, in a glaſs veſſel containing one wine pint Engliſh, and is uniformly maintained at the diſtance of $8\frac{2}{3}$ inches from the flame.

"I muſt not in this place (ſays our author) omit to mention a ſlight obſervation which this proceſs has afforded, becauſe it may lead to uſeful applications, and tends to point out one great advantage of this method of operating; namely, that an infinity of circumſtances may be perceived, which might not even be ſuſpected when the whole proceſs is carried on within a furnace. I have remarked, as did likewiſe ſeveral of my colleagues who were then preſent, that a column of bubbles conſtantly roſe from a fixed point of the retort on one ſide of the bottom. We were of opinion, that ſome particle of matter was in that place incorporated with the glaſs, which had a different capacity for heat from that of the reſt of the glaſs. In order to verify this conjecture, I endeavoured the following day to diſtil the ſame quantity of the ſame water in the ſame retort, after having introduced a button of cupelled ſilver, weighing nine decigrammes ($20\frac{1}{2}$ grains). At the commencement of the operation there was a ſmall ſtream of bubbles from the ſame point as before; but a ſhort time afterwards, and during the whole remaining time of operating, the largeſt and moſt inceſſant ſtream of bubbles roſe from the circumference of the button, which was often diſplaced by the motion; and in proportion to the time the product of the diſtillation was ſenſibly greater. Whence we may conclude, that metallic wires or rods, diſtributed through a maſs of water required to be kept in a ſtate of ebullition, and placed a little below its ſurface, would produce, without any greater expence of fuel, nearly the ſame effect as thoſe cylinders filled with ignited matter which are made to paſs through the boilers."

We have related this fact in Guyton's own words, or at leaſt in a faithful tranſlation of them; and we are far from calling it in queſtion, for it is a fact which has been often obſerved; but we think his inference from it too haſtily drawn. It is not conceivable that heat can be more rapidly conveyed through a maſs of liquid by the conducting power of metal, than by a free circulation; but we agree with what ſeems to be Mr Nicholſon's opinion *, that the thin ſtratum of water beneath the button becomes more ſuddenly and violently elaſtic than elſewhere, and therefore riſes regularly to the ſurface. The whole of this phenomenon the reader will find explained in our article STEAM (*Encycl.*), n° 10. But this is a digreſſion.

We return therefore to Guyton's laboratory, of which the reader will form a diſtinct notion from plate XXXIII. where fig. 1. repreſents the whole apparatus ready mounted for diſtillation, with the tube of ſafety and a pneumatic receiver. A is the body or reſervoir of the uſual lamp of Argand, with its ſhade and glaſs chimney. The lamp may be raiſed or lowered at pleaſure by means of the thumb ſcrew B, and the wick riſes and

---

* *Journal*, Auguſt 1798, note, page 212.

and falls by the motion of the ſmall toothed wheel placed over the waſte cup. This conſtruction is moſt convenient, becauſe it affords the facility of altering the poſition of the flame with regard to the veſſels, which remain fixed; and the troubleſome management of bended wires above the flame for the ſupport of the veſſels is avoided, at the ſame time that the flame itſelf can be brought nearer to the matter on which it is intended to act. D, a ſupport conſiſting of a round ſtem of braſs, formed of two pieces which ſcrew together at about two thirds of its height. Upon this the circular ring E, the arm F, and the nut G ſlide, and are fixable each by its reſpective thumb-ſcrew. The arm alſo carries a moveable piece H, which ſerves to ſuſpend the veſſels in a convenient ſituation, or to ſecure their poſition. The whole ſupport is attached to the ſquare iron ſtem of the lamp by a piece of hard wood I, which may be fixed at any required ſituation by its ſcrew. K repreſents a ſtand for the receivers. Its moveable tablet L is fixed at any required elevation by the wooden ſcrew M. The piece which forms the foot of this ſtand is fixed on the board N; but its relative poſition with regard to the lamp may be changed by ſliding the foot of the latter between the pieces OO. P, another ſtand for the pneumatic trough. It is raiſed or lowered, and fixed to its place, by a ſtrong wooden ſcrew, Q. R is a tube of ſafety, or reverſed ſyphon, which ſerves, in a great meaſure, to prevent the bad effects of having the veſſels either perfectly cloſed, or perfectly open. Suppoſe the upper bell-ſhaped veſſel to be nearly of the ſame magnitude as the bulb at the lower end of the tube, and that a quantity of water, or other ſuitable fluid, ſomewhat leſs than the contents of that veſſel, be poured into the apparatus: In this ſituation, if the elaſticity of the contents of the veſſels be leſs than that of the external air, the fluid will deſcend into the bulb, and atmoſpheric air will follow and paſs through the fluid into the veſſels: but, on the contrary, if the elaſticity of the contents be greater, the fluid will be either ſuſtained in the tube, or driven into the bell-ſhaped veſſel; and if the force be ſtrong enough, the gaſeous matter will paſs through the fluid, and in part eſcape.

Fig. 2. Shews the lamp furnace diſpoſed to produce the ſaline fuſion; the chimney of glaſs ſhortened; the ſupport D turned down; the capſule of platina or ſilver S placed on the ring very near the flame.

Fig. 3. The ſame part of the apparatus, in which, inſtead of the capſule, a very thin and ſmall crucible of platina T is ſubſtituted, and reſts upon a triangle of iron wire placed on the ring.

Fig 4. Exhibits the plan of this laſt diſpoſition.

LACERTA, in aſtronomy. See ASTRONOMY, nº 406. *Encycl.*

LACMUS, a dye ſtuff prepared by the Dutch from the LICHEN ROCELLA, which ſee in this *Supplement*.

LACSHA, the Indian name of the lac inſect, which has been deſcribed in the *Encyclopædia* under the title COCCUS, *Species* 5. Since that article was publiſhed, a deſcription of that inſect, which is more to be depended upon, has been given to the world in the ſecond volume of the Aſiatic Reſearches. It is by Mr Roxburgh, ſurgeon on the Madras eſtabliſhment, and was communicated to the Society by Dr James Anderſon phyſician at Fort St George, who obſerves, that Mr Roxburgh's diſcovery will bring the lacſha as a genus into the claſs *Hemiptera* of Linnæus.

"Some pieces of very freſh-looking lac (ſays Mr Roxburgh) adhering to ſmall branches of mimoſa cinerea, were brought me from the mountains on the 20th of November 1789. I kept them carefully, and to-day, the 4th of December, fourteen days from the time they came from the hills, myriads of exceedingly minute animals were obſerved creeping about the lac and branches it adhered to, and more ſtill iſſuing from ſmall holes over the ſurface of the cells: other ſmall and perforated excreſcences were obſerved with a glaſs amongſt the perforations, from which the minute inſects iſſued, regularly two to each hole, and crowned with ſome very fine white hairs. When the hairs were rubbed off, two white ſpots appeared. The animals, when ſingle, ran about pretty briſkly, but in general they were ſo numerous as to be crowded over one another. The body is oblong, tapering moſt towards the tail, below plain, above convex, with a double, or flat margin: laterally on the back part of the thorax are two ſmall tubercles, which may be the eyes: the body behind the thorax is croſſed with twelve rings: legs ſix; feelers (antennæ) half the length of the body, jointed, hairy, each ending in two hairs as long as the antennæ: rump, a white point between two terminal hairs, which are as long as the body of the animal. The mouth I could not ſee. On opening the cells, the ſubſtance that they were formed of cannot be better deſcribed, with reſpect to appearance, than by ſaying it is like the tranſparent amber that beads are made of: the external covering of the cells may be about half a line thick, is remarkably ſtrong, and able to reſiſt injuries: the partitions are much thinner: the cells are in general irregular ſquares, pentagons and hexagons, about an eighth of an inch in diameter, and one quarter deep: they have no communication with each other. All thoſe I opened during the time the animals were iſſuing, contained in one half, a ſmall bag filled with a thick red jelly-like liquor, replete with what I take to be eggs: theſe bags, or utriculi, adhere to the bottom of the cells, and have each two necks, which paſs through perforations in the external coat of the cells, forming the fore-mentioned excreſcences, and ending in ſome very fine hairs. The other half of the cells have a diſtinct opening, and contain a white ſubſtance, like ſome few filaments of cotton rolled together, and numbers of the inſects themſelves ready to make their exit. Several of the ſame inſects I obſerved to have drawn up their legs, and to lie flat: they did not move on being touched, nor did they ſhew any ſigns of life with the greateſt irritation.

" *December* 5. The ſame minute hexapedes continue iſſuing from their cells in numbers: they are more lively, of a deepened red colour, and fewer of the motionleſs ſort. To-day I ſaw the mouth: it is a flattened point about the middle of the breaſt, which the little animal projects on being compreſſed.

" *December* 6. The male inſects I have found to-day: a few of them are conſtantly running among the females moſt actively: as yet they are ſcarce more, I imagine, than one to 5000 females, but twice their ſize. The head is obtuſe; eyes black, very large; antennæ clavated, feathered, about ⅔ds the length of the body: below the middle an articulation, ſuch as thoſe in the legs: colour between the eyes a beautiful ſhining green: neck very ſhort: body oval, brown: abdomen oblong, the length of body and head: legs ſix: wings membranaceous, four, longer than the body, fixed to the ſides of the

the thorax, narrow at their inſertions, growing broader for ⅔ds of their length, then rounded; the anterior pair is twice the ſize of the poſterior: a ſtrong fibre runs along their anterior margins: they lie flat, like the wings of a common fly when it walks or reſts: no hairs from the rump: it ſprings moſt actively to a conſiderable diſtance on being touched: mouth in the under part of the head: maxillæ tranſverſe. To-day the female inſects continue iſſuing in great numbers, and move about as on the 4th.

"*December* 7. The ſmall red inſects ſtill more numerous, and move about as before: winged inſects, ſtill very few, continue active. There have been freſh leaves and bits of the branches of both *Mimoſa Cinerea* and *Corinda* put into the wide mouthed bottle with them: they walk over them indifferently, without ſhewing any preference, or inclination to work or copulate. I opened a cell whence I thought the winged flies had come, and found ſeveral, eight or ten, more in it, ſtruggling to ſhake off their incumbrances: they were in one of thoſe utriculi mentioned on the 4th, which ends in two mouths, ſhut up with fine white hairs, but one of them was open for the exit of the flies; the other would no doubt have opened in due time: this utriculus I found now perfectly dry, and divided into cells by exceeding thin partitions. I imagine, before any of the flies made their eſcape, it might have contained about twenty. In theſe minute cells with the living flies, or whence they had made their eſcape, were ſmall dry dark coloured compreſſed grains, which may be the dried excrements of the flies."

LAMANON (Robert Paul), of the academy at Turin, correſpondent of the Academy of Sciences at Paris, and member of the Muſeum in the ſame city, was born at Salon in Provence, in 1752, of an old and reſpectable family. Being a younger ſon, he was deſtined for the church, and ſent to Paris to complete his theological ſtudies; but getting acquainted with the philoſophers (as they called themſelves), he ſoon loſt all reliſh for the ſtudy of theology, and devoted himſelf to the phyſical ſciences, eſpecially thoſe of chemiſtry and mineralogy. Into the church, however, he got, and roſe to the dignity of canon; but by the death of his father and elder brother, having acquired the right of directing his own future exertions, he haſtened to quit a profeſſion, towards which he felt no partiality.

A prelate, then in high favour at court, hearing of Lamanon's intention of quitting his office of canon, offered him a conſiderable ſum, to induce him to reſign in favour of one of his dependents. The chapter of Arles, replied our young eccleſiaſtic, did not ſell me my benefice, I ſhall therefore reſtore it in the ſame manner that I received it. This conduct was certainly meritorious; and his eulogiſt *Ponce* mentions another trait of his character, which ſets him in a very amiable point of view; he refuſed to accept of his paternal inheritance, otherwiſe than as an equal ſharer with his brothers and ſiſters.

Thus liberated from the trammels of his former profeſſion, Lamanon applied himſelf with uncommon ardour to ſtudy. Eager to raiſe the awful veil that conceals from our eyes the ſecrets of nature; perſuaded, that even the greateſt genius only amuſes itſelf with falſe ſyſtems in the ſilence of a cabinet; convinced of the neceſſity of much and various obſervation, and of ſurpriſing Nature, as it were, in the very fact, in order to penetrate into the ſublimity of her operations;—our young philoſopher travelled through Provence and Dauphine, and ſcaled the Alps and Pyrenees. At the ſight of theſe vaſt natural laboratories the bent of his mind burſt forth inſtantaneouſly: he climbed to the ſummit of rocks, and explored the abyſs of caverns, weighed the air, analyſed ſpecimens, and, in his ardent fancy, having attained the ſecrets of creation, he formed a new ſyſtem of the world. On his return home, he applied with additional intereſt to the ſtudy of meteorology, mineralogy, natural philoſophy, and the other branches of the hiſtory of nature.

Whilſt he was meditating a viſit to Paris for the purpoſe, as his eulogiſt expreſſes himſelf, of converſing with the luminaries of ſcience, the inhabitants of the commune of Salon, having loſt a cauſe againſt their lord, unanimouſly elected Lamanon, with whoſe integrity and abilities they were well acquainted, to go and ſolicit of the council the repeal of an unjuſt decree that had been obtained by partiality. The reply of the young philoſopher on this occaſion is an additional proof of his uncommon diſintereſtedneſs. "As I intend (ſaid he) to go to Paris on buſineſs of my own, I cannot think of accepting your offer of 24 livres daily pay: a twelfth of this ſum will cover the extraordinary expences of the journeys that I ſhall be obliged to make to Verſailles on your account." He had the ſatisfaction of complete ſucceſs in the buſineſs thus undertaken.

Having ſatisfied his curioſity in Paris, he went over to England. During the paſſage, though much incommoded by ſea ſickneſs, and in imminent hazard of being overwhelmed by the tumbling waves of a very ſtormy ſea, he cauſed himſelf to be tied to the main-maſt, in order to contemplate at leiſure ſo grand and fearful a ſpectacle. The burſts of thunder, the howling of the wind, the brilliancy of the lightning, the glancing of the ſpray which covered him every moment, theſe objects, ſo terrible to an ordinary man, threw him into a kind of mental intoxication, and he has often declared, that this day was the moſt exquiſite of his whole life.

Convinced that the friendſhip of an eminent man elevates the ſoul, excites generous emulation, and becomes an additional ſtimulus to one whoſe delight is ſtudy, and whoſe moſt preſſing want is an object on which to place his affection, Lamanon anxiouſly endeavoured to merit the regard of CONDORCET, ſo well known by his talents, his impieties, his rebellion, and his misfortunes. This academician, juſtly conſidering that an apoſtate prieſt would be ready to join the conſpiracy of the philoſophiſts againſt the altar and the throne, received Lamanon with diſtinction, and at length admitted him to his moſt intimate friendſhip.

During the three ſucceſſive years that Lamanon ſpent at Paris, he followed with care the track of thoſe learned ſocieties, of which he had been elected a member. He became at this period, together with Count de Gebelin, and ſome other philoſophers and artiſts, one of the founders of the Muſeum, the greater part of the members of which are now reunited in the open ſociety of ſciences, letters, and arts, at Paris. Among the different papers of his that were read at various meetings of theſe ſocieties, Ponce mentions with particular approbation what he calls *a notice* of Adam de Crapone, an eminent hydraulic engineer; a memoir on the Cretins; a memoir on the theory of the winds; a treatiſe on the alteration in the courſe of rivers, particularly the Rhone; and another on an enormous bone belonging to to ſome cetaceous fiſh, that was dug up at Paris in laying the foundations of a houſe in the *rue Dauphine*. We have not ſeen theſe memoirs; but as their author was the friend of Condorcet, and fancied that he had attained the ſecrets of creation, we can eaſily conceive their tendency.

Having reſolved again to reviſit Switzerland and Italy, Lamanon firſt went to Turin, where he allied himſelf to the learned of that country. During his ſtay there, the brilliant novelty diſcovered by Montgolfier was occupying the attention of all the philoſophers of Europe. Lamanon, deſirous of making ſome experiments of this kind himſelf, aſcended in a balloon from the city of Turin; but not perceiving in this diſcovery, which had at firſt highly intereſted him, an object of public utility; not foreſeeing, that one day, on the plains of Fleurus, it would be the cauſe of rallying and eſtabliſhing victory under the ſtandards of France, he returned to his favourite occupations. Purſuing his route from Piedmont, he viſited Italy, and returned by Switzerland, where he explored the Alps and aſcended the ſummit of Mont Blanc: thence returning, loaden with the ſpoils of the countries which he had traverſed, to Provence, he employed himſelf in the arrangement of the intereſting fruits of his journey.

Of the ſcrupulous exactneſs of his obſervations, his eulogiſt gives the following inſtance: "Being convinced that the plain of Crau, divided by the channel of the Durance, had formerly been a lake, he wiſhed to be abſolutely aſſured of it. For this purpoſe he collected a ſpecimen of each of the ſtones that are to be found in this vaſt plain; the number of theſe he found to amount to nineteen; then tracing the courſe of the river towards its head, near the frontiers of Savoy, he obſerved, that above each junction of the tributary ſtreams with the Durance, the variety of pebbles diminiſhed. Afterwards aſcending the current of each of theſe ſmaller ſtreams, he diſcovered on their banks the original rock of every pebble that overſpreads the plain of Crau; thus inconteſtably proving, that this plain was anciently a lake formed by the waters of the Durance, and the ſtreams that fall into it. If all philoſophers (ſays our author) would conduct their examinations with equal preciſion, certain hypotheſes, more brilliant than ſolid, would not find ſo many admirers; the charm of imagination, and the graces of ſtyle, would not ſo often encroach upon the impreſcriptible rights of nature and truth."

To citizen Ponce this appears a demonſtration of Lamanon's theory; but we cannot ſay that it does ſo to us. It may be a kind of proof, though not a demonſtration, that in ſome convulſion of nature, ſtones had been rolled from the rock, and the plain of Crau, for a time, overflowed by the Durance; but it ſurely furniſhes no evidence of that plain's having ever been *a permanent lake*. It *may* have been ſo; but ſuch inveſtigations as this will not guard philoſophers againſt the deluſions of favourite hypotheſes.

It was at the time when Lamanon was preparing for the preſs his great work on the *Theory of the Earth*, that the French government conceived the vaſt project of completing the diſcoveries of Captain Cook: the academy of ſciences was entruſted with the care of ſelecting men capable of rectifying our notions of the ſouthern hemiſphere, of improving hydrography, and advancing the progreſs of natural hiſtory. Condorcet, not knowing any one better qualified for this laſt department than Lamanon, wrote to him an invitation to ſhare the danger and glory of this great enterprize. He accepted with eager tranſport a propoſal that fulfilled his higheſt expectations, haſtened to Paris, refuſed in a conference with the miniſter the ſalary that was offered, took a haſty leave of his friends, and departed for Breſt.

On the 1ſt of Auguſt 1785, the armament ſet ſail under the orders of La Perouſe, an experienced commander, whoſe patriotiſm and ſcientific zeal were equal to his courage and good ſenſe, and who had already merited the public confidence. The philoſophers of all Europe were in expectation of thoſe uſeful diſcoveries, the probable fruit of the zeal and talents employed in the expedition. The beginning of the voyage was proſperous. After various delays, and a multitude of obſervations, the two veſſels arrived at the iſland of Maouna, one of the ſouthern Archipelago. The impatient Lamanon, eager to aſſure himſelf of the truth of the publiſhed accounts of that country, debarked with Langle, the ſecond in command. At the moment of their return, the natives, in hopes of booty, which had been excited by the number of preſents that they had received, ſeized upon the boats, and attacked the party. The French were obliged to have recourſe to arms for ſelf defence, and a deſperate combat enſued. Lamanon, Langle, and ten of the two boats crews, fell a ſacrifice to the fury of theſe barbarians.

Thus periſhed Lamanon, a young man ardent in the purſuits of ſcience, to a high degree diſintereſted, and a zealot in what he thought the cauſe of liberty. He refuſed the ſalary which was allotted to him when he was appointed to this unfortunate expedition; for "if I do not feel ſatisfied (ſaid he) on board the veſſel; if my inclination or curioſity lead me to quit the ſhip,—I ſhould be unhappy if any power in the world had acquired the right of preventing me."

According to M. Ponce, Lamanon ſeemed born to bring about a revolution in ſcience: the depth of his ideas, the energy of his character, the ſagacity of his mind, united to that lively curioſity that can draw inſtruction out of any thing, and leaves nothing unexplored, would have led him to the moſt valuable diſcoveries. In perſon he was tall; and to great vivacity and expreſſion of feature added prodigious ſtrength and activity; in a word, Nature formed him with ſuch care, as if ſhe had intended him for one of thoſe few who are deſtined to great exploits. His ſtyle was nervous, often poetical, without loſing ſight of propriety, and the language of ſentiment might frequently be diſcovered in the midſt of ſtrong and ſtriking expreſſions; and if he wanted the exquiſitely dazzling poliſh of diction, he was eminently gifted with the preciſion of logical reaſoning, which commands attention and enforces perſuaſion.

LAMP (ſee *Encycl.*) is an inſtrument compriſing three articles which demand our attention, *viz.* the oil, the wick, and the ſupply of air. It is required that the oil ſhould be readily inflammable, without containing any fetid ſubſtance which may prove offenſive, or mucilage, or other matter, to obſtruct the channels of the wick. Mr Nicholſon ſays *, that he knows of no proceſs by which oils can be meliorated for this purpoſe, except that of waſhing with water containing acid or alkali. Either of theſe is ſaid to render the mucilage of animal oils more ſoluble in water; but acid is to be preferred, becauſe

---

* *Journal*, vol. i. n° 2.

because it is leſs diſpoſed to combine with the oil itſelf. Perhaps oil might be deprived of all fetid ſmell in burning, by being made to paſs through Collier's filtering apparatus, deſcribed under the word FILTER in this *Suppl.*

The office of the wick appears to be chiefly, if not ſolely, to convey the oil by capillary attraction to the place of combuſtion. As the oil is conſumed and flies off, other oil ſucceeds, and in this way a continued current of oil and maintenance of the flame are effected. But as the wicks of lamps are commonly formed of combuſtible matter, it appears to be of ſome conſequence what the nature and ſtructure of this material may be. It is certain that the flame afforded by a wick of ruſh differs very conſiderably from that afforded by cotton; though perhaps this difference may, in a great meaſure, depend on the relative dimenſions of each. And if we may judge from the different odour in blowing out a candle of each ſort, there is ſome reaſon to ſuſpect that the decompoſition of the oil is not effected preciſely in the ſame manner in each. We have alſo ſome obſcure accounts of prepared wicks for lamps, which are ſtated to poſſeſs the property of facilitating the combuſtion of very impure oils, ſo that they ſhall burn for many hours without ſmoke or ſmell.

The economical wicks of M. Leger, concerning which a report was preſented to the Academy at Paris in 17[illegible]2 by Condorcet, Lavoiſier, and De Milly, were compoſed of cotton of different ſizes and forms, namely, round and flat, according to the uſe they were intended to ſerve. They were covered with a fat ſubſtance, of a ſmell not diſagreeable, but feebly aromatic. From the trials of theſe commiſſaries it was aſcertained: 1. That they afforded a clearer flame, with leſs undulation. 2. That they conſumed ſomewhat leſs oil; and, 3. That they poſſeſſed the remarkable property of affording neither ſmell nor ſmoke, however common the oil made uſe of. When uſing a lamp with a flat wick, we have ourſelves found a piece of clean cotton ſtocking anſwer the purpoſe better than the cotton wicks which are ſold in the ſhops.

The acceſs of air is of the laſt importance in every proceſs of combuſtion. When a lamp is fitted up with a very ſlender wick, the flame is ſmall, and of a brilliant white colour: if the wick be larger, the combuſtion is leſs perfect, and the flame is brown: a ſtill larger wick not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatiliſed matter, which does not become ignited until it has aſcended towards the point. When the wick is either very large or very long, part of this matter eſcapes combuſtion, and ſhews itſelf in the form of coal or ſmoke. The different intenſity of the ignition of flame, according to the greater or leſs ſupply of air, is remarkably ſeen by placing a lamp with a ſmall wick beneath a ſhade of glaſs not perfectly cloſed below, and more or leſs covered above. While the current of air through the glaſs ſhade is perfectly free, the flame is white; but in proportion as the aperture above is diminiſhed, the flame becomes brown, long, wavering, and ſmoky; it inſtantly recovers its original whiteneſs when the opening is again enlarged. The inconvenience of a thick wick has been long ſince obſerved, and attempts made to remove it; in ſome inſtances, by ſubſtituting a number of ſmall wicks inſtead of a larger; and in others, by making the wick flat inſtead of cylindrical. The moſt ſcientific improvement of this kind, though perhaps leſs ſimple than the ordinary purpoſes of life demand, is the well known lamp of Argand, deſcribed in the *Encyclopædia.*

Much has been ſaid of this lamp, and great praiſe laviſhed on the inventor. It cannot indeed be denied that it was a very pretty invention, nor have we the ſlighteſt wiſh to detract from the merit of M. Argand; but truth compels us to ſay, that the ſame thought had occurred to others as early as to him, and that lamps had been conſtructed on his principles long before he had publiſhed an account of his lamp to the world (A).

Many ingenious men have endeavoured to determine the moſt economical method of lighting up large halls and workhouſes by means of different lamps and candles; and when the expence of tallow and oil is conſidered, it will be admitted that they could not employ their time in a manner more beneficial to the poor and the induſtrious. Among others, Count Rumford and M. Haſſenfratz have turned their attention to this ſubject; and the reſults of their inveſtigations are worthy of notice. To the Count, a method occurred for meaſuring the relative quantities of light emitted by lamps of different conſtructions, which is at once ſimple and accurate. It is as follows:

Let the two burning lamps, or other lights to be compared, be called A and B; and let them be placed at equal heights upon two light tables, or moveable ſtands, in a darkened room; let a ſheet of clean white paper be equally ſpread out, and faſtened upon the wainſcot, or ſide of the room, at the ſame height from the floor as the lights; and let the lights be placed overagainſt this ſheet of paper, at the diſtance of ſix or eight feet from it, and ſix or eight feet from each other, in ſuch a manner, that a line drawn from the centre of the paper, perpendicular to its ſurface, ſhall biſect the angle formed by lines drawn from the lights to that centre; in which caſe, conſidering the ſheet of paper as a plane ſpeculum, the one light will be preciſely in the line of reflection of the other.

This may be eaſily performed, by actually laying a piece of a looking-glaſs, ſix or eight inches ſquare, flat upon the paper, in the middle of it; and obſerving, by means of it, the real lines of reflection of the lights from that plane, removing it afterwards, as ſoon as the lights are properly arranged. When this is done, a ſmall cylinder of wood, about $\frac{1}{4}$th of an inch in diameter, and ſix inches long, muſt be held in a vertical poſition, about two or three inches before the centre of the ſheet of paper, and in ſuch a manner, that the two ſhadows of the cylinder, correſponding to the two lights, may be diſtinctly ſeen upon the paper.

If theſe ſhadows ſhould be found to be of unequal denſities, which will almoſt always be the caſe, then that light whoſe correſponding ſhadow is the denſeſt muſt be removed farther off, or the other muſt be brought nearer to the paper, till the denſities of the ſhadows appear to be exactly equal; or, in other words, till the denſities of the rays from the two lights are equal *at the ſurface of the paper;* when, the diſtances of the lights from

---

(A) One of theſe was employed in the college of Glaſgow, by the lecturer on chemiſtry, ſo long ago as 1766.

from the centre of the paper being meaſured, the ſquares of thoſe diſtances will be to each other as the real intenſities of the lights in queſtion at their ſources.

If, for example, the weaker light being placed at the diſtance of four feet from the centre of the paper, it ſhould be found neceſſary, in order that the ſhadows may be of the ſame denſity, to remove the ſtronger light to the diſtance of eight feet from that centre, in that caſe, the real intenſity of the ſtronger light will be to that of the weaker as 8^2 to 4^2; or as 64 to 16; or 4 to 1; and ſo for any other diſtances.

It is well known, that when any quality proceeds from a centre in ſtraight lines in all directions, like the light emitted by a luminous body, its intenſity at any given diſtance from that centre will be as the ſquare of that diſtance inverſely; and hence it is clear, that the intenſities of the lights in queſtion, at their ſources, muſt be to each other as the ſquares of their diſtances from that given point *where their rays uniting are found to be of equal denſity*. For, putting $x =$ the intenſity of B, if P repreſents the point where the rays from A and from B meeting are found to be of equal denſity or ſtrength, and if the diſtance of A from P be $= m$, and the diſtance of B from the ſame point P $= n$; then, as the intenſity of the light of A at P is $= \frac{x}{m^2}$, and the intenſity of the light of B at the ſame place $= \frac{y}{n^2}$, and as it is $\frac{x}{m^2} = \frac{y}{n^2}$ by the ſuppoſition, it will be $x : y :: m^2 : n^2$.

That the ſhadows being of equal denſity at any given point, the intenſities of the illuminating rays muſt of neceſſity be equal at that point alſo, is hence evident, that the total abſence of light being perfect blackneſs, and the ſhadow correſponding to one of the lights in queſtion being deeper or fainter, according as it is more or leſs enlightened by the other, when the ſhadows are equal, the intenſities of the illuminating rays muſt be equal likewiſe.

In removing the lights, in order to bring the ſhadows to be of the ſame denſity, care muſt be taken to recede from, or advance towards, the centre of the paper in a ſtraight line, ſo that the one light may always be found exactly in the line of reflection of the other; otherwiſe the rays from the different lights falling upon the paper, and conſequently upon the ſhadows, at different angles, will render the experiment fallacious.

When the intenſity of one ſtrong light is compared with the intenſities of ſeveral ſmaller lights taken together, the ſmaller lights ſhould be placed in a line perpendicular to a line drawn to the centre of the paper, and as near to each other as poſſible; and it is likewiſe neceſſary to place them at a greater diſtance from the paper than when only ſingle lights are compared.

In all caſes, it is abſolutely neceſſary to take the greateſt care that the lights compared be properly trimmed, and that they burn clear and equally, otherwiſe the reſults of the experiments will be extremely irregular and inconcluſive. It is aſtoniſhing what a difference there is in the quantities of light emitted by the ſame candle, when it burns with its greateſt brilliancy, and when it has grown dim for want of ſnuffing. But as this diminution of light is progreſſive, and as the eye inſenſibly conforms to the quantity of light actually preſent, it is not always taken notice of by the ſpectators; it is nevertheleſs very conſiderable, in fact, as will be apparent to any one who will take the trouble to make the experiment; and ſo great is the fluctuation in the quantity of light emitted by burning bodies, lamps, or candles, in all caſes, even under the moſt favourable circumſtances, that this is the ſource of the greateſt difficulties which our author met with in determining the relative intenſities of lights by the method here propoſed.

To aſcertain by this method the comparative denſities, or intenſities, of the light of the moon and of that of a candle, the moon's direct rays muſt be received upon a plane white ſurface, at an angle of incidence of about 60°, and the candle placed in the line of the reflection of the moon's rays from this ſurface; when the ſhadows of the cylinder, correſponding to the moon's light and to that of the candle, being brought to be of equal denſity, by removing the candle farther off, or bringing it nearer to the centre of the white plane, as the occaſion may require, the intenſity of the moon's light will be equal to that of the candle *at the given diſtance of the candle from the plane*.

To aſcertain the intenſity of the light of the heavens, by day or by night, this light muſt be let into a darkened room through a long tube blackened on the inſide, when its intenſity may be compared with that of a candle or lamp by the method above deſcribed.

The Count, however, has contrived an apparatus for aſcertaining the intenſity of the ſun's light, compared with the light emitted by any artificial illuminator, with much greater accuracy than it can be done by this ſimple method. That apparatus we ſhall deſcribe under the title PHOTOMETER in this *Supplement*; and in the mean time we proceed to lay before our readers the reſults of his experiments as they relate to economy in the production of artificial light.

1
Of the relative quantities of oil conſumed, and of light emitted, by an Argand's lamp, and by a lamp on the common conſtruction, with a riband wick.

The brilliancy of Argand's lamp is not only unrivalled, but the invention is in the higheſt degree ingenious, and the inſtrument uſeful for many purpoſes; but ſtill, to judge of its real merits as an illuminator, it was neceſſary to know whether it gives more light than another lamp *in proportion to the oil conſumed*. This point he determined in the following manner:

Having placed an Argand's lamp, well trimmed, and burning with its greateſt brilliancy, before his *photometer*, and over againſt it a very excellent common lamp, with a riband wick about an inch wide, and which burnt with a clear, bright flame, without the leaſt appearance of ſmoke, he found the intenſities of the light emitted by the two lamps to be to each other as 17956 to 9063; the denſities of the ſhadows being equal when, the Argand's being placed at the diſtance of 134 inches, the common lamp was placed at the diſtance of 95,2 inches, from the field of the photometer.

Both lamps having been very exactly weighed when they were lighted, they were now (without being removed from their places before the photometer) cauſed to burn with the ſame brilliancy juſt 30 minutes; they were then extinguiſhed and weighed again, and were found to have conſumed of oil, the Argand's lamp $\frac{253}{8192}$, and the common lamp $\frac{161}{8192}$, of a Bavarian pound.

Now, as the quantity of light produced by the Argand's gand's lamp, in this experiment, is to the quantity produced by the common lamp as 17956 to 9063, or as 187 to 100, while the quantity of oil conſumed by the former is to that conſumed by the latter only in the ratio of 253 to 163, or as 155 to 100, it is evident that the quantity of light produced by the combuſtion of a given quantity of oil in an Argand's lamp is greater than that produced by burning the ſame quantity in a common lamp, in the ratio of 187 to 155, or as 100 to 85.

The ſaving, therefore, of oil which ariſes from making uſe of an Argand's lamp inſtead of a common lamp, in the production of light, is evident; and it appears, from this experiment, that that ſaving cannot amount to leſs than fifteen *per cent.* How far the advantage of this ſaving may, under certain circumſtances, be counterbalanced by inconveniences that may attend the making uſe of this improved lamp, our author does not pretend to determine.

2
Of the relative quantities of light emitted by an Argand's lamp and by a common wax candle.

The Count made a conſiderable number of experiments to determine the relative quantities of light emitted by an Argand's lamp and a common wax candle; and the general reſult of them is, that a common Argand's lamp, burning with its uſual brightneſs, gives about as much light as nine good wax-candles; but the ſizes and qualities of candles are ſo various, and the light produced by the ſame candle ſo fluctuating, that it is very difficult to aſcertain, with any kind of preciſion, what a common wax-candle is, or how much light it ought to give. He once found that his Argand's lamp, when it was burning with its greateſt brilliancy, gave twelve times as much light as a good wax candle $\frac{3}{4}$ths of an inch in diameter, but never more.

3
Of the fluctuations of the light emitted by candles.

To determine to what the ordinary variations in the quantity of light emitted by a common wax-candle might amount, he took ſuch a candle, and, lighting it, placed it before the photometer, and over againſt it an Argand's lamp, which was burning with a very ſteady flame; and meaſuring the intenſity of the light emitted by the candle from time to time, during an hour, the candle being occaſionally ſnuffed when it appeared to ſtand in need of it, its light was found to vary from 100 to about 60. The light of a wax-candle of an inferior quality was ſtill more unequal; but even this was but trifling, compared to the inequalities of the light of a tallow-candle.

An ordinary tallow-candle, of rather an inferior quality, having been juſt ſnuffed, and burning with its greateſt brilliancy, its light was as 100; in eleven minutes it was but 39; after eight minutes more had elapſed, its light was reduced to 23; and in ten minutes more, or twenty-nine minutes after it had been laſt ſnuffed, its light was reduced to 16. Upon being again ſnuffed, it recovered its original brilliancy, 100.

4
Of the relative quantities of bees-wax, tallow, olive-oil, rape-oil, and linſeed-oil, conſumed in the production of light.

In order to aſcertain the relative quantities of bees wax and of olive-oil conſumed, in the production of light, the Count proceeded in the following manner: Having provided an end of a wax-candle of the beſt quality, ,68 of an inch in diameter, and about four inches in length, and a lamp with five ſmall wicks, which he had found upon trial to give the ſame quantity of light as the candle, he weighed very exactly the candle and the lamp filled with oil, and then, placing them at equal diſtances (forty inches) before the field of the photometer, he lighted them both at the ſame time; and, after having cauſed them to burn with preciſely the ſame degree of brightneſs *juſt one complete hour*, he extinguiſhed them both. and, weighing them a ſecond time, he found that 100 parts of wax and 129 parts of oil had been conſumed.

Hence it appears, that the conſumption of bees wax is to the conſumption of olive-oil, in the production of the ſame given quantity of light, as 100 is to 129.

In this experiment no circumſtance was neglected that could tend to render the reſult of it concluſive; care was taken to ſnuff the candle very often with a pair of ſharp ſciſſars, in order to make it burn conſtantly with the ſame degree of brilliancy; and the light of the lamp was, during the whole time, kept in the moſt exact equilibrium with the light of the candle, which was eaſily done by occaſionally drawing out, a little more or leſs, one or more of its five equal wicks. Theſe wicks, which were placed in a right line, perpendicular to a line drawn from the middle wick to the middle of the field of the photometer, were about $\frac{1}{10}$th of an inch in diameter each, and $\frac{1}{4}$th of an inch from each other; and, when they were lighted, their flames united into one broad, thin, and very clear, white flame, without the leaſt appearance of ſmoke.

In order to aſcertain the relative conſumption of olive-oil and rape-oil, in the production of light, two lamps, like that juſt deſcribed, were made uſe of; and, the experiment being made with all poſſible care, the conſumption of olive-oil appeared to be to that of rape-oil, in the production of the ſame quantity of light, as 129 is to 125.

The experiment being afterwards repeated with olive-oil and very pure linſeed-oil, the conſumption of olive-oil appeared to be to that of linſeed-oil as 129 to 120.

The experiment being twice made with olive oil and with a tallow candle; once when the candle, by being often ſnuffed, was made to burn conſtantly with the greateſt poſſible brilliancy, and once when it was ſuffered to burn the whole time with a very dim light, owing to the want of ſnuffing; the reſults of theſe experiments were very remarkable.

When the candle burnt with a clear, bright flame, the conſumption of the olive oil was to the conſumption of the tallow as 129 is to 101: but when the candle burnt with a dim light, the conſumption of the olive-oil was to the conſumption of the tallow as 129 is to 229. So that it appeared, from this laſt experiment, that the tallow, inſtead of being nearly as productive of light in its combuſtion as bees wax, as it appeared to be when the candle was kept conſtantly well ſnuffed, was now, when the candle was ſuffered to burn with a dim light, by far leſs ſo than oil.

But this is not all; what is ſtill more extraordinary is, that the very ſame candle, burning with a long wick, and a dim light, actually conſumed *more tallow* than when, being properly ſnuffed, it burnt with a clear, bright flame, and gave near *three times as much light.*

To be enabled to judge of the relative quantities of light actually produced by the candle in the two experiments, it will ſuffice to know, that in order to counterbalance this light at the field of the *photometer*, it required, in the former experiment, the conſumption of 141 parts, but in the latter only the conſumption of 64 parts, of olive-oil. But in the former experiment 110, and

and in the latter 114, parts of tallow were actually found to be conſumed. Theſe parts were 8192ths of a Bavarian pound.

From the reſults of all the foregoing experiments, it appears that the relative expence of the undermentioned inflammable ſubſtances, in the production of light, is as follows:

		Equal Parts in Weight.
Bees wax.	A good wax-candle, kept well ſnuffed, and burning with a clear, bright flame, - - -	100
Tallow.	A good tallow candle, kept well ſnuffed, and burning with a bright flame, - - - - -	101
	The ſame tallow-candle, burning very dim for want of ſnuffing,	229
Olive-oil.	Burnt in an Argand's lamp, - -	110
	The ſame burnt in a common lamp, with a clear, bright flame, without ſmoke, - - - - -	129
Rape-oil.	Burnt in the ſame manner, - - -	125
Linſeed-oil.	Likewiſe burnt in the ſame manner, - - - - - - -	120

With the foregoing table, and the prices current of the therein mentioned articles, the relative prices of light produced by thoſe different materials may very readily be computed.

In the year 1795, Mr J. H. Haſſenfratz was employed by the French government to make a ſeries of experiments to determine the moſt economical method of procuring light from the different combuſtible ſubſtances uſually employed for that purpoſe. The materials of his experiments were, wax, ſpermaceti, and tallow candles, fiſh-oil, oil of coleſeed, and of poppy ſeeds. In uſing theſe oils, both the Argand and common lamps were employed. The wicks of the latter were round, containing thirty-ſix cotton threads. The tallow and ſpermaceti candles were mould, ſix to the pound. The wax candles five to the pound. Mr Haſſenfratz uſed the ſame method with Count Rumford for determining the comparative intenſity of the lights.

Count Rumford, as we have ſeen, uſed the Argand lamp as a ſtandard for compariſon; but as the intenſity of its light varies according to the height of the wick, Mr Haſſenfratz preferred a wax-candle, making uſe of it ſoon after it was lighted. When two luminous bodies, of different intenſities, are put in compariſon with each other, the ſhadows are of two colours. That from the weakeſt light is blue, and from the ſtrongeſt, red. When the lights of two different combuſtible bodies are compared, they are either red or blue in a compound ratio of the colour and intenſity. Thus in comparing the ſhadows from different luminous bodies, they will be red or blue reſpectively, in the following order:

Light of the ſun.
——- of the moon.
——- of Argand lamps.
——- of tallow-candles.
——- of wax ditto.
——- of ſpermaceti ditto.
——- of common lamps.

That is to ſay, when a body is illuminated by the ſun and by any other luminous ſubſtance, the ſhadow of the former is red, and of the latter, blue. In like manner, the ſhadow from an Argand lamp is red, when placed by that of a tallow-candle, which is blue.

The following table will ſhew, according to Mr Haſſenfratz, the proportional diſtance that different luminous bodies ſhould be placed at to produce an equally intenſe ſhadow from the ſame object. The ſecond column gives the proportional intenſity of each light, which is known to be in proportion to the ſquares of the diſtances of luminous bodies giving the ſame depth of ſhadow. The third column ſhews the quantity of combuſtible matter conſumed in the hour by each mode of giving light, which Mr Haſſenfratz calculates from the average of many repeated experiments.

		Diſtance.	Intenſity.	Quantity conſumed per hour	Quantity required for equal intenſities.
Argand lamps with	Oil of poppy ſeed	10	10.000	23	23
	— of fiſhes	10	10.000	23.77	23.77
	— of cole-ſeed	9.246	8.549	14.18	16.59
Common lamps with	Oil of cole-ſeed	6.774	4.588	8.81	19.2
	— of fiſhes	6.524	4.550	9.14	20.06
	— of poppy-ſeed	5.917	3.501	7.03	20.14
Spermaceti candle		5.917	3.501	9.23	26.37
Old tallow-candle		5.473	2.995	7.54	25.17
New ditto		5.473	2.995	8.23	27.48
Wax candle		4.275	1.827	9.54	53

The relative quantity of combuſtible matter required to produce *equal* lights at equal diſtances, may be obtained by a ſimple rule of proportion from the above data. Thus, if a given intenſity of light, expreſſed by 3.501, has been produced by a conſumption of 9.23 of ſpermaceti in the hour, the ſame luminous body will produce a light of 10.000, by conſuming in the ſame time a quantity of ſpermaceti $= \frac{10.000 \times 9.23}{3.501} = 26.37.$— Therefore we may add to the table a fourth column, expreſſing the quantity of combuſtible which each body muſt conſume to produce a light of 10.000.

From what has been laid down, it will alſo appear that the number of lights required to produce a given light, will be as follows: To produce a light equal to 100 Argand lamps, burning poppy-ſeed oil, it will require

100 Argand lamps with fiſh-oil.
117 Ditto do. with cole ſeed oil
218 Common lamps with cole-ſeed oil
219 Ditto do. with fiſh oil
285 Ditto do. with poppy-ſeed oil
285 Spermaceti candles
333 Tallow ditto
546 Wax ditto.

Mr Haſſenfratz next takes notice of the comparative price of theſe articles; by which he finds, that in Paris the moſt expenſive light is that produced from wax-candles; and the moſt *economical*, that from oil of cole-ſeed, burned in Argand lamps.

The chief difference between the Argand and common lamp is, that in the latter much of the oil is volatilized without combuſtion, and hence the unpleaſant ſmell which it produces; whereas in the former, the heat is ſo great at the top of the wick, that all the oil is decompoſed in paſſing through, the diſpoſition of the wick allowing the free acceſs of air to aſſiſt combuſtion. It ſhould therefore follow, that the Argand lamp conſumes leſs fuel to produce a given light than the common lamp, and this, as we have ſeen, is the opinion of Count Rumford. Yet (Mr Haſſenfratz obſerves) there are two circumſtances that prevent the full effect of the complete combuſtion in the Argand lamp. The one is, that the glaſs cylinder abſorbs a part of the rays of light as they paſs through; the other, that the column of light proceeding from the inner ſurface of the wick, is, in part, loſt, by being obliged to paſs through that from the outer ſurface. Count Rumford allows the firſt cauſe of diminution of light, and eſtimates it at .1854, but not the latter. The author of this memoir, in repeating Count Rumford's experiments, aſſerts, that when two candles are placed ſo that the light of the one is obliged to paſs through that of the other, the ſum of the light ſo produced is not ſo ſtrong as when they are placed ſide by ſide; for in the firſt caſe, a part of the hindmoſt light is abſorbed by the foremoſt.

LANCASHIRE. In the account which we have given of that county in the *Encyclopædia*, an obliging correſpondent has pointed out to us ſome miſtakes. He aſſures us, that the ſea coaſt, where we underſtood the atmoſphere to be loaded with ſuch exhalations as produce malignant and intermitting fevers, is remarkably healthy; and he ſpeaks from experience, having lived on that coaſt for forty years. He aſſures us likewiſe, that the Duke of Bridgewater's inland navigation was begun ſoon after, if not before, the year 1736, and that he (the writer), ſo early as 1764, was one of a party who ſailed up the ſough or edit a conſiderable way to ſee how the coals were worked. The ſame correſpondent has pointed out a few miſtakes in our account of

LANCASTER, the capital of the county. "That town (he ſays) carries on no trade whatever with North America, but a very conſiderable one with Jamaica and the other Weſt India iſlands, in veſſels of from 100 to 500 tons burthen. It exports to theſe iſlands all ſuch Britiſh manufactures as they have occaſion for, Iriſh linens, and ſalted proviſions of all kinds, ſuch as Iriſh beef, pork, butter, &c. It trades alſo to the Baltic, Portugal, Hamburgh, &c. to a large amount; and ſome of its ſhips with their cargoes have of late been worth from L. 60 to L. 80,000 ſterling. It has, however, no communication by water with the rivers Merſey, Dee, &c. as we have ſaid; the canal reaching as yet no farther than to near Preſton in Lancaſhire." The communication with theſe rivers is indeed intended to be completed; but whether the ſcheme be practicable is, according to our correſpondent, very uncertain.

LANTERN (See *Encycl.*). Sir George Staunton informs us, that of the Chineſe lanterns, ſome were ſuch as we have deſcribed, *viz.* compoſed of thin ſilk gauze, painted or wrought in needle-work with figures of birds, inſects, flowers, or fruit, and ſtretched on neat frames of wood. Others, however, were very different, being entirely made of horn. Theſe were ſo thin and tranſparent, that they were taken at firſt for glaſs; a material to which, for this purpoſe, the horn is preferred by the Chineſe, as cheaper, lighter, leſs liable to accident, and, in caſe of accident, more eaſily repaired; many of them were about two feet in the diameter, and in the form of a cylinder, with the ends rounded off, and the edges meeting in the point to which the ſuſpending cords were tied. Each lantern conſiſted of an uniform piece of horn, the joints, or ſeams, being rendered inviſible by an art found out by the Chineſe; among whom, the vaſt number of ſuch lanterns uſed in their dwelling houſes and temples, as well as on the occaſions of their feſtivals and proceſſions, have led to many trials for improving their conſtruction. The horns generally employed are thoſe of ſheep and goats. The uſual method of managing them, according to the information obtained upon the ſpot, is to bend them by immerſion in boiling water, after which they are cut open and flattened; they then eaſily ſcale, or are ſeparated into two or three thin laminæ or plates. In order that theſe plates ſhould be made to join, they are expoſed to the penetrating effect of ſteam, by which they are rendered almoſt perfectly ſoft. In this ſtate the edges of the pieces to be joined are carefully ſcraped and ſlanted off, ſo as that the pieces overlapping each other ſhall not together exceed the thickneſs of the plate in any other part. By applying the edges, thus prepared, immediately to each other, and preſſing them with pincers, they intimately adhere, and incorporating, form one ſubſtance, ſimilar in every reſpect to the other parts; and thus uniform pieces of horn may be prepared to almoſt any extent. It is a contrivance little known elſewhere, however ſimple the proceſs appears to be; and perhaps ſome minute precautions are omitted in the general deſcription, which may be eſſential to its complete ſucceſs.

Such lanterns as theſe would be very proper for military ſtore houſes; and Rochon of *the National Inſtitute* was employed, ſince the commencement of the preſent war, to make them, if he could, for the marine ſtorehouſes of France. While he was thus engaged, however, it occurred to him, that he might ſupply the preſſing wants of the navy without horn, merely by filling up the interſtices of wire-cloth with fine tranſparent glue. In carrying this thought into execution, he at firſt tinned the iron wires of the ſieve cloth he made uſe of; but afterwards found it more convenient, in every reſpect, to give it a ſlight coating of oil paint to preſerve it from ruſt. The glue he made uſe of was afforded by boiling the clippings of parchment with the air-bladders and membranes of ſea fiſh; materials which he uſed, not from any notion that they were preferable to iſinglaſs, but becauſe they were the cheapeſt he could procure. He added the juice of garlic and cyder to his compoſition, in ſuch proportions as he found to communicate great tenacity, and ſomewhat more of tranſparence than it would have poſſeſſed without them. Into this tranſparent and very pure glue or ſize he plunged his wire cloth, which came out with its interſtices filled with the compound. It is requiſite that the ſize ſhould poſſeſs a determinate heat and conſiſtence, concerning which experience alone muſt guide the operator.

When this prepared wire cloth is fixed in the lantern, it muſt be defended from moiſture by a coating of pure drying linſeed oil; but even in this ſtate it is not fit to be expoſed to the weather. The eaſe with which theſe lanterns are repaired in caſe of accident, by a ſlight coating of glue, is pointed out as a great advantage by the inventor; who likewiſe informs us, that they were uſed in the expedition to Ireland as ſignal lanterns, though contrary to his wiſhes.

LAPIS Fungifer, a ſpecies of earth found near Rome, Naples, and Florence, of which the following account is taken from the *New Tranſactions of the Royal Academy of Sciences at Stockholm* for the year 1797: Near Naples the lapis fungifer is found in the chalk-hills like a white ſtalactites, intermixed with a great many fine roots of ſhrubs; and near Florence there is a ſpecies of it, conſiſting of hardened turf, which is dug up near volcanoes. The author made experiments with a piece procured from Italy, and found that 100 parts contain from 45 to 46 ſiliceous earth, 23 argillaceous earth, 7 calcareous earth, and 20 calx of iron, with ſome white magneſia and vegetable alkali. It is well known, that when this friable ſpecies of ſtone is preſerved in cellars and moiſtened with water, it produces abundance of eatable muſhrooms, which in Italy are highly eſteemed and brought to the firſt tables. Hence the origin of its name.

LARDIZABALA, a new genus of plants belonging to the *diœcia hexandria* of Linnæus. It is a native of Chili, and is thus deſcribed in Perouſe's Voyage, from drawings ſent to France by La Martiniere. The leaves are alternate, on footſtalks inflated at their baſe. Each leaf is bi-ternate, that is to ſay, it is divided into three leaflets, each of which is again ſubdivided into three oval ſharp-pointed folioles, which, when young, are entire, but afterwards become obſcurely lobed. The flowers, diſpoſed in ſimple and pendent cluſters, grow towards the top of the ſtem and of the branches in the axillæ of the leaves. The plant is diœcius. At the baſe of each cluſter of bloſſoms are two ſmall, rounded, oval, floral leaves.

Plate XXX.

Male Flower.—*Calyx* formed of ſix expanding leaves, oblong-oval, and obtuſe, of which the three outermoſt are the largeſt. *Corolla* compoſed of ſix ſharp lanceolated petals, oppoſite to, and ſhorter than, the leaves of the calyx. A cylinder riſes from the centre of the flower of the length of the petals, terminated by ſix oblong bilocular anthers, which open from below.

Female Flower.—*Calyx*, ſimilar to that of the male flower, but larger. *Corolla* inſerted beneath the piſtil compoſed of ſix petals, rarely entire, but generally bifid or trifid at their ſummit: ſhorter than the leaves of the calyx. *Stamina* ſix, having the ſame inſertion as the corolla; filaments diſtinct, broad, very ſhort, ſurrounding the piſtil; *anthers*, ſix, upright, oblong, acuminated, barren. *Seed bud*, cells, from three to ſix, oblong, gibbous on the outſide, of nearly the length of the corolla; ſtyles none; ſtigmata, ſitting, oblong, permanent. *Berries*, equal in number to the cells, oblong, acuminated (divided into ſix cells, containing ſeveral angular ſeeds. *Flora Peruviana*).

The general character of the lardizabala evidently places this new genus among the family of the *meniſpermæ*, to which it is related by its climbing ſtalk, its bunches of diœcious flowers, by its ſix petals, ſtamina, and leaves of its calyx, by its piſtil, compoſed of from three to ſix cells, which contain as many ſeeds. It differs from the known genera of this order only in its fruit, which, inſtead of being monoſpermous, contains ſeveral ſeeds. This character, which requires the introduction of a new ſection into the *meniſpermæ*, ſtrengthens the relation of this family to the next order of the *anonæ*. In fact, the greater part of the genera of the anonæ, as they have in the ſame flower ſeveral fruits, with numerous ſeeds, differ in this particular from all the genera of the meniſpermæ; and by placing between them the lardizabala, we eſtabliſh a natural tranſition. In order to confirm theſe reſemblances, it only remains to examine the inſide of the fruit, and particularly the ſtructure of the ſeeds. Thoſe of the meniſpermæ are reniform, at leaſt on the inſide, incloſed in a hinged pericarpium, and containing in their upper part a very ſmall dicotyledonus embryo. The characters that we have given of the lardizabala render probable a ſimilar ſtructure in its ſeeds.

LARMIER, in architecture, a flat ſquare member of the cornice below the cimaſium, and jets out fartheſt; being ſo called from its uſe, which is to diſperſe the water, and cauſe it to fall at a diſtance from the wall, drop by drop, or, as it were, by tears; *larme* in French ſignifying a tear.

LATUS Primarium, a right line drawn through the vertex of the ſection of a cone, within the ſame, and parallel to the baſe.

Latus Rectum. See *Conic Section*, Encycl.

Latus Tranſverſum of the hyperbola, is the right line between the vertices of the two oppoſite ſections, or that part of their common axis lying between the two oppoſite cones.

LAVA. In addition to the obſervations of Sir William Hamilton, Bergmann, Formes, and Dalmieu, on the compoſition of different lavas, which have been given in the *Encyclopædia*, we cannot refuſe ourſelves the pleaſure of noticing, in this place, thoſe of Sir James Hall. From a number of well-deviſed experiments, Sir James thinks himſelf warranted to conclude, that lava and whinſtone are intrinſically the ſame ſubſtance; and that their apparent differences ariſe wholly from the circumſtances under which they have paſſed from a liquid to a ſolid ſtate. The lavas, it is well known, have been cooled rapidly in the open air, and the whins (according to Dr Hutton's theory, which Sir James ſeems willing to adopt) ſlowly in the bowels of the earth.

Though we are far from adopting that theory in all its parts, to which we think inſuperable objections may be made (ſee Earth, *Encycl.* nº 120), we admit, that the experiments of Sir James Hall go far to eſtabliſh the identity of lava and whinſtone. Theſe experiments were made upon ſeven different ſpecies of whinſtone and ſix lavas, of which four were broken from the currents of Etna and Veſuvius by Sir James himſelf. Each of the original whinſtones was reduced, by fuſion and ſubſequent rapid cooling, to a ſtate of perfect glaſs. This glaſs, being again placed in the furnace, was ſubjected to a ſecond fuſion. The heat, being then reduced to a temperature generally about 28° of Wedgewood, was maintained ſtationary for ſome hours; when the crucible was either immediately removed, or allowed to cool with the furnace. The conſequence was, that in every caſe the ſubſtance had loſt the character of glaſs, and by cryſtallization had aſſumed in all reſpects that of an original whinſtone. It muſt be owned, that in moſt caſes the new production did not exactly reſemble the particular original from which it was formed, ed, but ſome other original of the ſame claſs; owing to accidental varieties in the mode of refrigeration, and to chemical changes which unavoidably took place during the proceſs. In the caſe, however, of the rock of Edinburgh caſtle, and of that of the baſaltic columns of Staffa, the artificial ſubſtances bear a complete reſemblance to their originals, both in colour and texture.

The lavas were now treated in the ſame way, and were each, by fuſion and rapid cooling, reduced, as the whinſtones had been, to glaſs. This glaſs, when fuſed again and cooled ſlowly, yielded the ſame kind of cryſtallized, ſtony, or earthy maſſes, completely reſembling an original whin or lava.

Although the internal ſtructure of lava was thus accounted for, yet Sir James was embarraſſed with the ſtate of its external ſurface; which, though cooled in contact with the open air, is ſeldom or never vitreous, holding an intermediate ſtation between glaſs and ſtone; but this difficulty was removed by a circumſtance which took place in the courſe of theſe experiments. It was found, that a ſmall piece of glaſs of any of the lavas, or of ſeveral of the whins, being introduced into a muffle, the temperature of which was at any point between the 20th and the 22d degree of Wedgewood's ſcale, the glaſs became quite ſoft in the ſpace of one minute; but, being allowed to remain till the end of a ſecond minute, it was found to have become hard throughout in conſequence of a rapid cryſtallization, to have loſt its character of glaſs, and to have become by 12 or 14 degrees more infuſible, being unaffected by any heat under 30, though the glaſs had been fuſible at 18° or at 16°. This accounted for the ſcoria on the ſurface of lavas; for the ſubſtance even at the ſurface, being in contact with the flowing ſtream, and ſurrounded with heated air, could not cool with exceſſive rapidity: and the experiment ſhews, that ſhould any part of the maſs, in deſcending heat, employ more than one or two minutes in cooling from 22 to 20, it would infallibly loſe its vitreous character.

Independently of any alluſion to ſyſtem or to general theory, Sir James Hall flatters himſelf that theſe experiments may be of ſome importance, by ſimplifying the hiſtory of volcanoes; and, above all, by ſuperſeding ſome very extraordinary, and, he conceives, unphiloſophical opinions advanced with regard to volcanic heat, which has been ſtated as poſſeſſing very little intenſity, and as acting by ſome occult and inconceivable influence, or with the help of ſome inviſible agent, ſo as to produce liquidity without fuſion. Theſe ſuppoſitions, which have been maintained ſeriouſly by ſome of the moſt celebrated naturaliſts in Europe, have originated from the difficulty of accounting for the ſtony character of lavas when compared with that of glaſs, which they aſſume in conſequence of fuſion in our furnaces. But now he hopes we may be relieved from the neceſſity of ſuch violent efforts of imagination, ſince the phenomena have been fully accounted for by the ſimple, though unnoticed, principle of refrigeration, and have been repeated again and again with eaſe and certainty in a ſmall chamber furnace.

LAVOISIER (Antoine Laurent), was born in Paris on the 26th of Auguſt 1743. His father, who directed his education, was opulent, and ſpared no coſt for his improvement. The youth ſhewed a decided taſte for the phyſical ſciences. In 1764, government having propoſed an extraordinary premium for the beſt and cheapeſt mode of lighting the ſtreets of a large city, Lavoiſier obtained the gold medal; and his memoir, full of nice inveſtigation, was printed by the Academy. Into that body he was received on the 13th May 1768, in ſpite of a formidable oppoſition; and to its ſervice he ever after devoted his labours, and became one of its moſt uſeful aſſociates and coadjutors.

His attention was ſucceſſively occupied with every branch of phyſical and mathematical ſcience. The pretended converſion of water into earth, the analyſis of gypſum in the neighbourhood of Paris, the cryſtallization of ſalts, the effects produced by the *grande de loupe* of the garden of the Infanta, the project of bringing water from l'Yvette to Paris, the congelation of water, and the phenomena of thunder and the aurora borealis—all occupied his attention.

Journeys, undertaken in concert with Guettard into every diſtrict of France, enabled him to procure numberleſs materials towards a deſcription of the lithological and mineralogical empire; theſe he arranged into a kind of chart, which wanted little of being completed. They ſerved alſo as a foundation for a more laborious work of his on the revolutions of the globe, and the formation of *Couches de la Terre;* a work of which two beautiful ſketches are to be ſeen in the Memoirs of the French Academy for 1772 and 1787. All the fortune and all the time of Lavoiſier were devoted to the culture of the ſciences; nor did he ſeem to have a preponderating inclination for any one in particular, until an event, ſuch as ſeldom occurs in the annals of the human mind, decided his choice, and attached him thenceforth excluſively to chemiſtry—a purſuit which has ſince rendered his name immortal.

The important diſcovery of gaſes was juſt announced to the philoſophical world. Black, Prieſtley, Scheele, Cavendiſh, and Macbride, had opened to phyſiologiſts a ſort of new creation; they had commenced a new era in the annals of genius, which was to become equally memorable with thoſe of the compaſs, printing, electricity, &c.

It was about the year 1770 that Lavoiſier, ſtruck with the importance and grandeur of this diſcovery, turned his attention to this inexhauſtible fountain of truths, and inſtantly perceived, by a kind of inſtinct, the glorious career which lay before him, and the influence which this new ſcience would neceſſarily have over the whole train of phyſical reſearches. Of thoſe who had preceded him, the moſt indefatigable experimenter was Prieſtley: but facts the moſt brilliant remained frequently unproductive in his hands; on every occaſion he was ready to frame ſome crude hypotheſis, which as haſtily he abandoned. Lavoiſier was imbued with the true ſpirit of inductive philoſophy; his obſervations, eminently preciſe and luminous, always pointed to general views. In 1774, he publiſhed his chemical opuſcules, which contained a very neat hiſtory of all that had been done with reſpect to gaſes, and concluded with the author's capital experiments, by which it was proved, that metals, in calcination, derive their augmentation of weight from the abſorption of air. Soon afterward, he ſhewed, in oppoſition to Prieſtley, that nitrous acid is compoſed of air; a remark, of which the importance appeared in the ſequel. His ingenuity as a chemiſt was now ſo well known, that in 1776 Turgot employed him to inſpect the manufacture of gun-powder. He introduced ſome valuable improvements, and, ſuppreſſing the odious viſits in queſt of the materials of ſaltpetre, he yet quintupled its produce. The gun powder would now carry 120 toiſes, when formerly it would not reach 90. This ſuperiority was indeed acknowledged in the laſt war.

It had been alleged, that by frequent diſtillation water is converted into earth. This queſtion Lavoiſier reſolved in 1778, having ſhewn that the earthy ſediment was owing to the continual eroſion of the internal ſurface of the retort. In that ſame year he made a more intereſting diſcovery; namely, that the reſpirable portion of the atmoſphere is a conſtituent principle of all acids, and which he therefore denominated *oxygen;* a moſt important fact, and the firſt great ſtep towards the new chemiſtry; which the compoſition of water, aſcertained in 1783, triumphantly completed.

Lavoiſier poſſeſſed deciſive advantages over his contemporaries; he ſtudied a geometrical accuracy of inveſtigation; and his wealth enabled him to make experiments on a large ſcale, and to uſe inſtruments of the moſt perfect conſtruction. He was able to hold in his houſe, twice every week, aſſemblies, to which he invited every literary character that was moſt celebrated in geometrical, phyſical, and chemical, ſtudies; in theſe inſtructive *converſationes,* diſcuſſions, not unlike ſuch as preceded the firſt eſtabliſhment of academies, regularly took place. Here the opinions of the moſt eminent literati in Europe were canvaſſed; paſſages the moſt ſtriking and novel, out of foreign writers, were recited and animadverted on; and theories were compared with experiments. Here learned men of all nations found eaſy admiſſion; Prieſtley, Fontana, Blagden, Ingenhouſz, Landriani, Jacquin, Watt, Bolton, and other illuſtrious phyſiologiſts and chemiſts of England, Germany, and Italy, found themſelves mixed in the ſame company with La Place, La Grange, Borda, Couſin, Meunier, Vandermonde, Monge, Morveau, and Berthollet. Happy hours paſſed in theſe learned interviews, wherein no ſubject was left uninveſtigated that could poſſibly contribute to the progreſs of the ſciences, and the amelioration and happineſs of man. One of the greateſt benefits reſulting from theſe aſſemblages, and the influence of which was ſoon afterwards felt in the academy itſelf, and conſequently in all the phyſical and chemical works that have been publiſhed for the laſt twenty years in France, was the agreement eſtabliſhed in the methods of reaſoning between the natural philoſophers and the geometricians. The preciſion, the ſeverity of ſtyle, the philoſophical method of the latter, was inſenſibly tranſfuſed into the minds of the former; the philoſophers became diſciplined in the tactics of the geometricians, and were gradually moulded into their reſemblance.

It was in the aſſemblage of theſe talents that Lavoiſier embelliſhed and improved his own. When any new reſult from ſome important experiment preſented itſelf, a reſult which threatened to influence the whole theory of the ſcience, or which contradicted theories till then adopted, he repeated it before this ſelect ſociety. Many times ſucceſſively he invited the ſevereſt objections of his critical friends; and it was not till after he had ſurmounted their objections, to the conviction and entire perſuaſion of the ſociety; it was not till after he had removed from it all myſtery and obſcurity, that he ventured to announce to the world any diſcovery of his own.

At length he combined his philoſophical views into a conſiſtent body, which he publiſhed in 1789, under the title of *Elements of Chemiſtry;* a book which is a moſt beautiful model of ſcientific compoſition, clear, logical, and elegant. It would be foreign to our purpoſe to attempt an expoſition of the principles, or to expatiate on the merits, of this celebrated ſyſtem; which, within the ſpace of a very few years, has been almoſt univerſally adopted, and which, if not the genuine interpretation of nature, approaches as near to it as the preſent ſtate of knowledge will permit. See CHEMISTRY in this *Supplement.*

The laſt, but not the leaſt uſeful, of Lavoiſier's philoſophical reſearches, on the Perſpiration of Animals, was read to the Academy on the 4th May 1791, and of which part was publiſhed in the volume for 1790. He found, by ſome delicate experiments, made in conjunction with Seguin, that a man in 24 hours perſpires 45 ounces; that he conſumes 33 ounces of vital air; that he diſcharges from the lungs 8 cubic feet of carbonic acid gas, of which one-third is carbon and two-thirds are oxygen; that the weight of water diſcharged from the lungs amounts to 23 ounces, of which 3 are hydrogen and 20 oxygen, excluſive of 6 ounces of water already formed, loſt in pulmonary perſpiration. Theſe diſcoveries were directed to the improvement of medicine.

We have mentioned the aſſiſtance which Lavoiſier received while he was digeſting his new ſyſtem of chemiſtry; but we muſt add, that to him pertains excluſively the honour of a founder. His own genius was his ſole conductor, and the talents of his aſſociates were chiefly uſeful in illuſtrating diſcoveries he himſelf had made; he firſt traced the plan of the revolution he had been a long time conceiving; and his colleagues had only to purſue and execute his ideas.

In the twenty volumes of the Academy of Sciences, from 1772 to 1793, are 40 memoirs of Lavoiſier, replete with all the grand phenomena of the ſcience; the doctrine of combuſtion, general and particular; the nature and analyſis of atmoſpherical air; the formation and fixation of elaſtic fluids; the properties of the matter of heat; the compoſition of acids; the augmentation of the ponderoſity of burnt bodies; the decompoſition and recompoſition of water; the diſſolution of metals; vegetation, fermentation, and animalization. For more than 15 years conſecutive, Lavoiſier purſued, with unſhaken conſtancy, the route he had marked out for himſelf, without making a ſingle falſe ſtep, or ſuffering his ardour to be damped by the numerous and increaſing obſtacles which conſtantly beſet him.

Many were the ſervices rendered by Lavoiſier, in a public and private capacity, to manufactures, to the ſciences, and to artiſts. He was treaſurer to the Academy after Buffon and Tillet, and introduced economy and order into the accounts. He was alſo a member of the Board of Conſultation, and took an active ſhare in whatever was going forwards. When the new ſyſtem of meaſures was agitated, and it was propoſed to determine a degree of the meridian, he made accurate experiments on the expanſion of metals, and conſtructed a metalline thermometer. By the National Convention he was conſulted on the means of improving the manufacture of aſſignats, and of increaſing the difficulties of forging them.

Like a good citizen, Lavoiſier turned his thoughts to political economy. Between the years 1778 and 1785, he allotted 240 *arpents* in the Vendômois to experimental agriculture, and increaſed the uſual produce by one-half. In 1791, he was invited by the Conſtituent Aſſembly to digeſt a plan for ſimplifying the collection of the taxes. This gave occaſion to an excellent report, afterwards printed with the title of *Territorial Riches of France*. At this time, alſo, he was appointed commiſſioner of the national treaſury, in which he effected ſome beneficial reforms.

During the horrors of the Robeſpierrean dictatorſhip, Lavoiſier told La Lande that he foreſaw he ſhould be ſtripped of his property, but that he would work for his bread. The profeſſion of apothecary would have ſuited him the beſt. But his doom was already fixed. On the 8th of May 1794, confounded with 28 farmers general, he ſuffered on the ſcaffold, merely becauſe he was rich!

Lavoiſier was tall, and of a graceful, ſprightly appearance. He was mild, ſociable, obliging, and extremely active; and in his manners he was unaffectedly plain and ſimple. Many young men, not bleſſed with the gifts of fortune, but incited by their genius to woo the ſciences, have confeſſed their obligations to him for pecuniary aid; many, alſo, were the unfortunate whom he relieved in ſilence, and without the oſtentation of virtue. In the communes of the department of the *Loir* and *Char*, where he poſſeſſed conſiderable eſtates, he would frequently viſit the cottages of indigence and diſtreſs; and long will his memory be cheriſhed there. But his reputation, influence, virtues, and wealth, gave him a great preponderance, which unfortunately provoked the jealouſy of a crew of homicides, who made a ſport of ſacrificing the lives of the beſt of men to a ſanguinary idol.

This great and good man married, in 1771, Marie-Anni Pierette Paulze, daughter of a farmer general; a woman whoſe wit and accompliſhments conſtituted the charm of his life; who aſſiſted him in his labours, and even engraved the figures of his laſt work.

LEAD. See that article (*Encycl.*), and CHEMISTRY-*Index* in this *Supplement*. It is well known, that lead generally contains a portion of ſilver, and ſometimes of gold; and that there are occaſions, particularly in aſſaying, when it is of importance to have it freed from theſe metals. For accompliſhing theſe purpoſes different proceſſes have been propoſed; but the following by Pet. Jac. Hjelm, as it is the leaſt expenſive, promiſes to be the moſt uſeful:

LITHARGE (ſee *Encycl.*) was the ſubſtance on which this chemiſt made his experiments, and his principal object was to free it from all mixture of ſilver. This was accompliſhed in the following manner: He placed a crucible, in which half a pound of litharge found good room, and which was fitted with a cloſe cover, in a wind-furnace filled with dead coals. He then put into the crucible a mixture of four ounces of potaſh and the ſame quantity of powder of flint. When the whole was well melted by ſtrengthening the draught, and making the coals glow, he took off the cover, and laid hold of the crucible with a pair of tongs, in order to take it out, and to ſuffer this very fuſible glaſs to cover the inſide of the crucible, to ſecure it from the glaſs of the lead which he meant to melt in it. The ſuperfluous glaſs was poured out; the crucible again placed on its foot, and half a pound of litharge thrown into it with a ſhovel. The cover was placed upon it while the litharge was melting; and when it was thoroughly glowing and fluid, charcoal duſt was ſifted into the uncovered crucible through a ſieve, ſo that the ſurface of the litharge was completely covered with it. This immediately produced an efferveſcence, and the riſing of bubbles, by means of the ſeparation of the air occaſioned by the reduction of the lead. During this proceſs, the cover was put on, and a few coals thrown into the furnace: when theſe were burnt, every thing in the crucible was quiet, and the melted maſs was poured into a warm conical mould. The crucible was then again filled with half a pound of the ſame kind of litharge, and put into the furnace, and charcoal duſt was ſeveral times ſifted over the melted ſurface, till it was well covered before the maſs was thrown out, a ſufficient ſpace being every time left for the efferveſcence. The firſt maſs had, in the mean time, become cool, and, on examination, contained four ounces of lead at the bottom, and litharge at the top. When this litharge was reduced with potaſhes and wine ſtone, the lead thence obtained, which weighed 23 ounces, was found to contain leſs than one-half grain of ſilver in the pound. In the ſecond maſs there was found ſomewhat more than ſix ounces of lead, which contained all the ſilver that had been before mixed with the litharge, becauſe in the lead which had been reduced from the litharge in the above manner, there were no perceptible traces of ſilver. This lead was then melted over a ſlow fire, and caſt into bars, which were rolled ſmooth, and formed into maſſes of a known weight, to be uſed for aſſaying gold and ſilver, and for other purpoſes of the ſame kind. All theſe meltings were made in one crucible, which, according to every appearance, remained unhurt. If the ſame experiments were made with red lead, the like reſult would infallibly follow.

With the ſame view of obtaining lead free from ſilver, he melted, in the like manner, half a pound of white lead, which produced half an ounce of lead When the litharge ſtanding over it was revived, the lead obtained was ſtill found to contain too much ſilver. He therefore precipitated another half pound of white lead by charcoal powder, after the lead that fell from it had been ſeparated; and then it produced, by reviving, a maſs of lead without any mixture of ſilver.

LEDYARD (—— ——), the celebrated, though unfortunate, traveller, was a native of North America, but of what province we have not learned. We are equally ignorant of the year of his birth, and the rank of his parents; but have no reaſon to think that they were opulent. From his early youth he diſplayed a ſtrong propenſity to viſit unknown and ſavage countries; and to gratify that propenſity, he lived for ſeveral years with the American Indians, whoſe manners and habits he ſeemed in ſome degree to have acquired. Afterwards he ſailed round the world with Captain Cook in the humble ſtation of a corporal of marines; and on his return, he determined to traverſe the vaſt continent of America, from the Pacific to the Atlantic Ocean.

This deſign being fruſtrated by his not obtaining a paſſage to Nootka Sound, he determined to travel over land to Kamſchatka. With this view he went over to Oſtend, with only ten guineas in his pocket, and proceeded by the way of Denmark and the Sound to the capital of Sweden, and endeavoured to croſs the Gulph of Bothnia on the ice; but finding, when he came to the middle, that the water was not frozen, he walked round the gulph to Peterſburgh. Here he found himſelf without ſtockings or ſhoes; but procured relief from the Portugueſe ambaſſador, and obtained leave to proceed with a detachment of ſtores to Yakutz. He made this journey of ſix thouſand miles, and there met Mr Billengs, an Engliſhman, whom he had known on board Captain Cook's ſhip. From thence he went to Oczakow, on the coaſt of the Kamſchatka Sea; but being too late to embark that year, returned to Yakutz to winter. Here he was, on ſome ſuſpicion, ſeized, conveyed on a ſledge through Northern Tartary, and left on the frontiers of the Poliſh dominions. In the midſt of poverty, rags, and diſeaſe, he however reached Koningſburg, where he found friends that enabled him to reach England.

On his arrival in London, he waited on Sir Joſeph Banks, on whoſe credit he had, in his diſtreſs, received at different times 25 guineas. Sir Joſeph communicated to him the views of the African Aſſociation, and pointed out the route in which they wiſhed Africa to be explored. On his engaging at once in the enterpriſe, Sir Joſeph aſked him when he would be able to ſet out. "To-morrow morning," replied Ledyard, without heſitation. At this interview the preſident of the Royal Society declares, that he was ſtruck with the figure of the man, the breadth of his cheſt, the openneſs of his countenance, and the rolling of his eye. Though ſcarcely exceeding the middle ſize, his figure indicated great ſtrength and activity. Deſpiſing the accidental diſtinctions of ſociety, he ſeemed to regard no man as his ſuperior; but his manners, though coarſe, were not diſagreeable. His uncultivated genius was original and comprehenſive. From the native energy of his mind, he was adventurous, curious, and unappalled by dangers; while the ſtrength of his judgment united caution with energy. The track pointed out to him was from Cairo to Senaar, and thence weſtward in the latitude and ſuppoſed direction of the Niger.

He was not ignorant, that the taſk aſſigned him was arduous and big with danger; but inſtead of ſhrinking from it, he ſaid, on the day of his departure, "I am accuſtomed to hardſhips; I have known both hunger and nakedneſs to the utmoſt extremity of human ſuffering; I have known what it is to have food given me as charity to a madman; and I have at times been obliged to ſhelter myſelf under the miſeries of that character to avoid a heavier calamity. My diſtreſſes have been greater than I ever owned, or ever will own to any man. Such evils are terrible to bear, but they never yet had power to turn me from my purpoſe. If I live, I will faithfully perform, in its utmoſt extent, my engagement to the Society: and if I periſh in the attempt, my honour will be ſafe; for death cancels all bonds."

After receiving his inſtructions and letters of recommendation, this intrepid traveller ſailed from London on the 30th of June 1788; and in 36 days arrived at Alexandria. Proceeding to Cairo, where he arrived Auguſt the 17th, he viſited the ſlave markets, and converſed with the travelling merchants of the caravans. Theſe ſources of information, generally neglected by travellers, enabled him to obtain, at a very ſmall expence, more correct information concerning the African nations and their trade, the poſition of places, the nature of the country, the manner of travelling, &c. than could have been eaſily obtained by any other method. He thus learned, that the Arabs of the deſert have an invincible attachment to liberty, though it is ſingular that they have no word to expreſs liberty in their language. The Mahomedans of Africa are a trading, ſuperſtitious, and warlike ſet of vagabonds. He ſaw near 200 black ſlaves expoſed to ſale, who had been brought from the interior parts of Africa; their appearance ſavage, but not like priſoners of war; they had head ornaments, and their hair plaited in detached plaits of great length. Another parcel, which had come from Darfoor, were moſtly women; and the beads, and ſome other ornaments which they wore, were Venetian. They were well formed, quite black, had the true Guinea face, and curled hair. Mr Ledyard was informed, that the king of Senaar was a merchant, and concerned in the caravans; that 20,000 negro ſlaves are imported into Egypt annually. Among ſome Senaar ſlaves, he ſaw three of a bright olive colour, but their heads uncommonly formed, the forehead the narroweſt, longeſt, and moſt protuberant he ever ſaw.

The Senaar caravan is the moſt rich; that of Darfoor is not equally ſo, though it trades with almoſt the ſame commodities. Beſides ſlaves, theſe are gum, elephants teeth, camels, and oſtrich-feathers; for which are received in exchange trinkets, ſoap, antimony, red linen, razors, ſciſſars, mirrors, and beads. Wangara, to which the caravans alſo trade, was repreſented to Mr Ledyard as a kingdom producing much gold; but the king ſeems to intermeddle with commerce as well as the potentate of Senaar; for in order to deceive ſtrangers, and prevent them from gueſſing at the extent of his riches, he was reported to vary continually the gold uſed in barter, which it is his province to regulate, and of which he iſſues at one time a great quantity, and at others little or none. A caravan goes from Cairo to Fezzan, which they call a journey of fifty days; and as the caravans travel about 20 miles a day, the diſtance muſt be about 1000 miles; from Fezzan to Tombuctoo is 1800 miles; from Cairo to Senaar about 600 miles.

Such was the information which Mr Ledyard derived from the merchants of the caravans in Egypt; but when he was about to verify it by his own obſervations, and had announced to the Aſſociation that his next diſpatch would be dated from Senaar, he was ſeized with a bilious complaint, which fruſtrated the ſkill of the moſt eminent phyſicians, and put a period to his travels and his life at Cairo. It is needleſs to ſay how much his death was regretted, or how well he was qualified for the arduous enterpriſe in which he had engaged. The perſon who, with ſuch ſcanty funds, could penetrate the frozen regions of Tartary, ſubſiſt among their churliſh inhabitants, and ingratiate himſelf with the ferocious Moors of Egypt, could hardly have failed to obtain a kind reception from the gentle and hoſpitable Negro, had no untoward circumſtance intervened. At Senaar, indeed, his riſk would have been great; and Mr Bruce was decidedly of opinion, that a man ſo poorly attended as Mr Ledyard, could never have made his eſcape from that treacherous and ferocious people.

The obſervations of this accurate obſerver on the female character, though they have been repeatedly quoted in other works, are well intitled to a place here; and with them we ſhall conclude this ſketch of his life: "I have always (ſays he) remarked, that women in all countries are civil and obliging, tender and humane; that they are ever inclined to be gay and cheerful, timorous and modeſt; and that they do not heſitate, like man, to perform a generous action. Not haughty, not arrogant, not ſupercilious; they are full of courteſy, and fond of ſociety; more liable, in general, to err than man; but in general alſo more virtuous, and performing more good actions than he. To a woman, whether civilized or ſavage, I never addreſſed myſelf, in the language of decency and friendſhip, without receiving a decent and friendly anſwer. With man it has often been otherwiſe. In wandering over the barren plains of inhoſpitable Denmark, through honeſt Sweden, and frozen Lapland, rude and churliſh Finland, unprincipled Ruſſia, and the wide ſpread regions of the wandering Tartar; if hungry, dry, cold, wet, or ſick, the women have ever been friendly to me, and uniformly ſo. And to add to this virtue (ſo worthy the appellation of benevolence), theſe actions have been performed in ſo free and kind a manner, that if I was dry, I drank the ſweeteſt draught; and if hungry, I eat the coarſeſt morſel with a double reliſh." For a fuller account of *Ledyard*, ſee *The Tranſactions of the African Aſſociation*, or *A View of the Late Diſcoveries in Africa.*

Hyperbolic LEGS, are the ends of a curve line that partakes of the nature of the hyperbola, or having aſymptots.

LEMINGTON Priors, is a village two miles eaſt of the town of Warwick, famous for its mineral waters. One ſalt ſpring, which riſes near the church yard, has been long known, as well as another which riſes in the bed of the river; but the moſt remarkable ſpring was diſcovered in the year 1790. The waters of both ſprings have been analyzed with great accuracy by William Lambe, M. A. late Fellow of St John's colledge, Cambridge, who has given us the following ſynoptical table of the ſubſtances contained in them:

Gaſeous Fluids contained in a Wine gallon in Cubic Inches.

	WATER OF THE NEW SPRING.	WATER OF THE OLD SPRING.
Hepatic gas -	*Too ſmall to be meaſured.*	*Too ſmall to be meaſured.*
Azotic gas -	3.5	3
Carbonic acid gas	.5	—

Solid contents of a Wine-gallon in Grains.

	WATER OF THE NEW SPRING.	WATER OF THE OLD SPRING.
Carbonat of iron	·75	
Oxyds of iron and mangaueſe -	—	*Too ſmall to be weighed.*
Oxygenated muriat of iron and manganeſe - -	*Unknown, but very ſmall.*	*Unknown, but very ſmall.*
Sulphur - - -	*Unknown, but very ſmall.*	—
Muriat of magneſia	11.5	58
Muriat of ſoda	430	330
Sulphat of ſoda	152	62
Sulphat of lime	112	146

In the courſe of his experiments, for which we muſt refer to the original memoir, in Tranſactions of the Mancheſter Society, Mr Lambe thinks he diſcovered the origin of the *muriatic acid.* He found a coincidence, very unexpected, between the hepatiſed ſolution of iron and the oxygenated muriat of iron. "I had almoſt concluded (ſays he), from the reſemblance between the properties of this ſalt and the phenomena of the water, that the water contains this very ſalt. Now, I conclude, that they contain a matter, be it what it may, produced by the action of hepatic gas on iron. But they are the very ſame facts which form the baſis, upon which each ſeparate inference is built. Does it not follow, then, as a neceſſary conſequence, that the hepatiſed ſolution itſelf contains a muriat of iron highly oxygenated, and that therefore *in this proceſs muriatic acid is generated?* This concluſion ſeemed authoriſed by reaſon, and experiment has confirmed it."

LEMNISCATE, the name of a curve in the form of the figure of 8.

LEMON juice, is an article of ſuch harmleſs luxury, and in ſome caſes of ſuch real utility, that many of our readers will be pleaſed to know a ſimple method by which they may obtain it in great purity. In the article Chemistry (*Suppl.*), nº 476, we have ſhewn from Scheele and Dizé, how to obtain the citric acid perfectly pure, and in the form of cryſtals; but here we mean nothing more than to ſhew how it may be completely ſeparated from that ſlimy ſubſtance with which it is always mixed in the lemon, without allowing it time to ſpoil or to acquire any diſagreeable taſte during the ſeparation. This we are enabled to do by M. Brugnatelli, who, in the 2d volume of the *Annali di Chimia*, informs us, that he expreſſed in the common manner the juice of perfectly ripe lemons, and ſtrained it through a piece of linen. In half an hour he ſtrained it again, to free it from a little ſlimy matter which had ſettled at the bottom of the veſſel. He then added to the juice a certain quantity of the ſtrongeſt ſpirit of wine, and preſerved the mixture for ſome days in a well-corked bottle. During that time there was a conſiderable depoſit, which to all appearance was of a ſlimy nature, and which he ſeparated by filtering paper. If the fluid was too thick to paſs through the filter, he diluted it again with ſpirit of wine. After this operation, the depoſit remained on the paper, which was entirely covered with it; and he obtained, in the veſſel placed below, the pureſt acid of lemons combined with ſpirit of wine.

If it be required to obtain the acid perfectly pure, nothing is neceſſary but to ſeparate from it the ſpirit of wine, which can be beſt effected by evaporation. The acid of the lemons aſſumes, after it has been freed from the ſpirit of wine and the moiſture combined with it, a yellowiſh colour, and becomes ſo ſtrong, that by its taſte it might be conſidered as a mineral acid.

It is not neceſſary to evaporate the ſpirit of wine in a cloſe veſſel, if the experiment is made only on a ſmall ſcale; nor is there any danger that in open veſſels any of the acid will be loſt, as it is too fixed to be volatiliſed by the ſame degree of heat at which ſpirit of wine evaporates. This acid has peculiar properties, which deſerve farther examination.

LENSES (ſee Lens and Dioptrics, *Encycl.*), are either blown or ground.

Blown Lenses are uſed only in the ſingle microſcope; and

and the uſual method of making them has been to draw out a fine thread of the ſoft white glaſs called *cryſtal*, and to convert the extremity of this into a ſpherule by melting it at the flame of a candle. But this glaſs contains lead, which is diſpoſed to become opake by partial reduction, unleſs the management be very carefully attended to. We are informed, however, by Mr Nicholſon, that the hard glaſs uſed for windows ſeldom fails to afford excellent ſpherules. This glaſs is of a clear bright green colour when ſeen edgewiſe. A thin piece was cut from the edge of a pane of glaſs leſs than one-tenth of an inch broad. This was held perpendicularly by the upper end, and the flame of a candle was directed upon it by the blow-pipe at the diſtance of about an inch from the lower end. The glaſs became ſoft, and the lower piece deſcended by its own weight to the diſtance of about two feet, where it remained ſuſpended by a thin thread of glaſs about one five-hundredth of an inch in diameter. A part of this thread was applied endwiſe to the lower blue part of the flame of the candle without the uſe of the blow-pipe. The extremity immediately became white-hot, and formed a globule. The glaſs was then gradually and regularly thruſt towards the flame, but never into it, until the globule was ſufficiently large. A number of theſe were made; and being afterwards examined, by viewing their focal images with a deep magnifier, proved very bright, perfect, and round. This, as the ingenious author obſerves, may prove an acceptable piece of information to thoſe eminent men (and there are many ſuch), whoſe narrow circumſtances, or remote ſituations, are obliged to have recourſe to their own ſkill and ingenuity for experimental implements.

Ground LENSES, are ſuch as are ground or rubbed into the deſired ſhape, and then poliſhed. Different ſhapes have been propoſed for lenſes; but in the article OPTICS, nº 251 (*Encycl.*), it has been ſhewn that, after all, the ſpherical is the moſt practically uſeful. By many of the methods of grinding, however, the artificer, with his utmoſt care, can only produce an approximation to a truly ſpherical figure; and, indeed, gentlemen have, for the moſt part, nothing to depend on for the ſphericity of the lenſes of their teleſcopes, but the care and integrity of the workmen. In the 41ſt volume of the Tranſactions of the Royal Society of London, a machine is deſcribed by Mr Samuel Jenkins, which, as it is contrived to turn a ſphere at one and the ſame time on two axes, cutting each other at right angles, will produce the ſegment of a true ſphere merely by turning round the wheels, and that without any care or ſkill in the workmen. The following deſcription of this machine will enable our readers fully to comprehend its conſtruction, and the mode of uſing it: A is a globe covered with cement, in which are fixed the pieces of glaſs to be ground. This globe is faſtened to the axis, and turns with the wheel B. C is the braſs cup which poliſhes the glaſs: this is faſtened to the axis, and turns with the wheel D. The motion of the cup C, therefore, is at right angles with the motion of the globe A; whence it follows demonſtrably, that the pieces of glaſs ground by this double motion muſt be formed into the ſegments of ſpheres.

Plate XXXII.

LEO X. is a pontiff to whom learning, and art, and ſcience, are ſo deeply indebted, that not to give a ſketch of his life and character, in a Work of this kind, would be an unpardonable omiſſion. A character of him is indeed given in the *Encyclopædia*; but it is ſo far from the truth, that it is difficult to conceive the prejudices under which he muſt have laboured by whom ſuch a libel was drawn up.

Leo, whoſe name, before his elevation to the pontificate, was *Giovanni de Medici*, was the ſecond ſon of Lorenzo de Medici, juſtly ſtyled the Magnificent. In the life of that great man publiſhed in this *Supplement*, the reader will ſee by what means, and for what purpoſe, he got Giovanni raiſed to the dignity of cardinal at ſo early a period of life; and in the elegant work of Roſcoe, to which we there refer, he will find ſuch inſtructions of Lorenzo to the cardinal as muſt have made a deep impreſſion on his youthful mind.

Speaking of his promotion, Lorenzo ſays, "The firſt thing that I would ſuggeſt to you, is, that you ought to be grateful to God, and continually to recollect that it is not through your merits, your prudence, or your ſolicitude, that this event has taken place, but through his favour, which you can repay only by a *pious*, *chaſte*, and *exemplary life*; and that your obligations to the performance of theſe duties are ſo much the greater, as in your *early years* you have given ſome *reaſonable expectation* that your riper age may produce ſuch fruits. It would indeed be highly diſgraceful, and as contrary to your duty as to my *hopes*, if at a time when others diſplay a greater ſhare of reaſon, and adopt a better mode of life, you ſhould forget the *precepts of your youth*, and forſake the path in which you have *hitherto trodden*."—"I well know (continues Lorenzo), that as you are now to reſide at Rome, that ſink of all iniquity, the difficulty of conducting yourſelf by theſe admonitions will be increaſed. The influence of example is itſelf prevalent; but you will probably meet with thoſe, who will particularly endeavour to corrupt and incite you to vice; becauſe, as you yourſelf may perceive, your early attainment of ſo great a dignity is not obſerved without envy, and thoſe who could not prevent your receiving that honour, will ſecretly endeavour to diminiſh it, by inducing you to forfeit the good eſtimation of the public."—"You are not unacquainted with the great importance of the character which you have to ſuſtain; for you well know, that all the Chriſtian world would proſper if the cardinals were what they ought to be; becauſe in ſuch a caſe there would always be a good pope, upon which the tranquillity of Chriſtendom ſo materially depends."

As this was a confidential letter from Lorenzo to his ſon, the firſt of theſe extracts furniſhes very ſufficient evidence, that Giovanni had been at leaſt a well behaved boy, diligent in his ſtudies, and regular in his conduct; and without ſuppoſing him remarkably religious, the admonitions of ſuch a father, aided by his own ambition and love of letters, would ſurely guard him againſt ſuch groſs licentiouſneſs as that of which he is accuſed in the *Encyclopædia*. How much he revered his father, is apparent from the letter which he wrote to his brother immediately after Lorenzo's death. "What a father (ſays he) have we loſt! How indulgent to his children! Wonder not, then, that I grieve, that I lament, that I find no reſt. Yet, my brother, I have ſome conſolation in reflecting that I have thee, whom I ſhall always regard in the place of a father." Surely this is not the language of a groſs ſenſualiſt, or of one who could ſoon forget the ſalutary admonitions of ſuch a parent as Lorenzo de Medici. But it is needleſs to infer the decency of his character by ſuch reaſonings as theſe. The ſtory publiſhed in the *Encyclopædia*, of the manner in which the Cardinal de Medici obtained the tiara, cannot poſſibly be true. The reader, who ſhall turn to the article Pope in that Work, will find that the conclave, when fitted up for an election, is ſo large a place, that we may ſafely affirm, that had the cardinal's ulcer diſcharged matter ſo fetid as to *poiſon all the cells*, the aſſertion of the phyſicians would have been verified, and that in the then ſtate of the healing art, the new pope could not have ſurvived a month. Let it be remembered, too, that Leo, at his acceſſion, was not 30, but 37 years of age, and that he had long ruled in Florence with ſovereign ſway by the ſame means which had upheld the authority of his father. The follies of youth, therefore, had he ever been remarkable for ſuch follies, muſt have been over with him; and in ſuch a ſtate as Florence he could not have maintained the authority of Lorenzo, without exhibiting not only Lorenzo's liberality, but likewiſe his decency of manners.

The next charge brought againſt Leo in the *Encyclopædia* is, that he publiſhed general indulgences throughout Europe; and this is ſo expreſſed as to lead the ill-informed reader to ſuppoſe, either that no ſuch indulgences had ever been publiſhed by any of his predeceſſors, or that there was ſomething peculiarly ſcandalous in Leo's mode of publiſhing them. Both ſuppoſitions, however, are erroneous. The hiſtorian of the council of Trent, who certainly was not partial to the court of Rome, or to the diſpenſing power of the pope, has ſhewn, that the practice of raiſing money by the publication of indulgences, had prevailed ever ſince the year 1100; that many former popes had raiſed money in this manner for purpoſes much leſs laudable than thoſe which Leo had in his eye; and that the real cauſe of Luther's attack upon Leo's indulgences was, that they were preached through Saxony by the Dominican friars; whereas the preaching of former indulgences had been committed to the hermits of St Auguſtine, the order to which Luther himſelf belonged!

Leo is likewiſe accuſed in the *Encyclopædia* of being a profeſſed infidel, and of having called Chriſtianity "a fable very profitable for him and his predeceſſors." But of the truth of this accuſation there ſeems not to be the ſhadow of evidence. Leo had too much ſenſe to utter expreſſions of this kind, even had he been an unbeliever in his heart; for he could not poſſibly expect that his indulgences and pardons would be purchaſed, had he declared in ſuch ſtrong terms that they were of no value. Father Paul indeed ſays, that he was not a deep divine, or ſo pious as ſome of his predeceſſors; but he affirms, that he *adorned the papacy* with many admirable qualities; that he was learned, affable, liberal, *good;* that he delighted in healing differences, and that his equal had not, for many years, filled the chair of St Peter. Surely this is not the character of a profane infidel!

Leo has been charged with raiſing his own family to grandeur at the expence of juſtice; and of dealing treacherouſly, in order to effect this purpoſe, both with the emperor and with the French king. But the charge is either falſe or greatly exaggerated. He loſt no opportunity indeed of aggrandizing his relations, well knowing, that in order to ſecure to them any laſting benefit, it was neceſſary that they ſhould be powerful enough to defend themſelves, after his death, from the rapacious aims of ſucceeding pontiffs; but, in proſecuting this plan, he was ſo far from acting tyrannically or injuriouſly to others, that during his pontificate, the papal dominions enjoyed a degree of tranquillity ſuperior to any other Italian ſtate. During the conteſts that took place between the emperor and the French king, ſo far from acting treacherouſly, he diſtinguiſhed himſelf by his moderation, his vigilance, and his political addreſs; on which account he is juſtly celebrated by an eminent hiſtorian of our own *, as "the only prince of the age who obſerved the motions of the two contending monarchs with a prudent attention, or who diſcovered a proper ſolicitude for the public ſafety."

We truſt that no zealous Proteſtant will think we have employed our time ill, in vindicating the character of this ſplendid pontiff; for good learning, and, of courſe, true religion, are more indebted to Leo X. than to any other individual of the age in which he lived, his father Lorenzo alone excepted.

Leo Minor, the *Little Lion*, a conſtellation of the northern hemiſphere, and one of the new ones that were formed out of what were left by the ancients, under the name of *Stellæ Informes*, or unformed ſtars. See Astronomy, n° 406, *Encycl.*

LESLIE (Charles), was a man ſo eminent for his learning, his talents, and his piety, that a fuller account of him than that which is given in the *Encyclopædia* muſt be acceptable to our Chriſtian readers. He was the ſecond ſon of Dr John Leſlie biſhop of Clogher in Ireland, who was deſcended from an ancient family in the north of Scotland, and being an admirable ſcholar, roſe to the dignity of biſhop of Orkney in his own country, whence he was tranſlated, in 1633, to Raphoe in Ireland, and afterwards, in 1661, to the ſee of Clogher.

Our author was born in Ireland, but in what year we have not learned. A ludicrous ſtory goes indeed of his having been begotten in priſon, and of his father having ſaid that he hoped he would in conſequence become the greateſt ſcourge of the covenanters that Great Britain or Ireland had ever ſeen. This ſtory, with all its circumſtances as told to us, can hardly be true; but we think it could not have been fabricated, had not Charles Leſlie been born within a year of Cromwell's conqueſt of Ireland, when the good biſhop, having ſuſtained a ſiege in his caſtle of Raphoe againſt that arch rebel, was ſome time kept in cloſe confinement.

We are equally ignorant of the ſchool where he was educated as of the year of his birth; but we know that he had his academical education in Trinity College, Dublin, where he took the degree of maſter of arts. In the year 1671, he loſt his father, when he came over to England, and, entering himſelf in the temple, ſtudied law for ſome years, but afterwards relinquiſhed it for the ſtudy of divinity. In 1680, he was admitted into holy orders; and, in 1687, was made chancellor of Connor.

About this period he rendered himſelf particularly obnoxious to the Popiſh party in Ireland, by his zealous oppoſition to them, which was thus called forth. Roger Boyle, biſhop of Clogher, dying in 1687, Patrick Tyrrel was made titular Popiſh biſhop, and had the revenues of the ſee aſſigned him by king James. He ſet

* Dr Robertſon.

up a convent of friars in Monaghan: and, fixing his habitation there, held a public viſitation of his clergy with great ſolemnity; when, ſome ſubtle logicians attending him, he was ſo inſolent as to challenge the Proteſtant clergy to a public diſputation. Leſlie undertook the taſk, and performed it to the ſatisfaction of the Proteſtants; though it happened, as it generally does at ſuch conteſts, that both ſides claimed the victory. He afterwards held another public diſputation with two celebrated Popiſh divines, in the church of Tynan, in the dioceſe of Armagh, before a very numerous aſſembly of perſons of both religions; the iſſue of which was, that Mr John Stewart, a Popiſh gentleman, ſolemnly renounced the errors of the church of Rome.

As the Papiſts had got poſſeſſion of an Epiſcopal ſee, they engroſſed other offices too; and a Popiſh high-ſheriff was appointed for the county of Monaghan. This proceeding alarmed the gentlemen in that county; who, depending much on Leſlie's knowledge as a juſtice of peace, repaired to him, then confined, by the gout, to his houſe. He told them, that it would be as illegal in them to permit the ſheriff to act as it would be in him to attempt it. But they inſiſting that he ſhould appear himſelf on the bench at the next quarter-ſeſſions, and all promiſing to ſtand by him, he was carried thither with much difficulty and in great pain. When the ſheriff appeared, and was taking his place, he was aſked whether he was legally qualified; to which he anſwered pertly, "That he was of the king's own religion, and it was his majeſty's will that he ſhould be ſheriff." Leſlie replied, "That they were not inquiring into his majeſty's religion, but whether he (the pretended ſheriff) had qualified himſelf according to law, for acting as a proper officer; that the law was the king's will, and nothing elſe to be deemed ſuch; that his ſubjects had no other way of knowing his will, but as it is revealed to them in his laws: and it muſt always be thought to continue ſo, till the contrary is notifed to them in the ſame authentic manner." Upon this, the bench unanimouſly agreed to commit the pretended ſheriff, for his intruſion and arrogant contempt of the court. Leſlie alſo committed ſome officers of that tumultuous army which the Lord Tyrconnel raiſed for robbing the country.

In this ſpirited conduct Leſlie acted like a ſound divine and an upright magiſtrate; but though he thought himſelf authoriſed to reſiſt the illegal mandates of his ſovereign, like many other great and good men, he diſtinguiſhed between active and paſſive obedience, and felt not himſelf at liberty to transfer his allegiance from that ſovereign to another. Refuſing therefore to take the oaths to king William and queen Mary, he was deprived of all his preferments; and in 1689 he removed with his family to England, where he publiſhed the following works, beſides thoſe already noticed in the *Encyclopædia*: 1. Anſwer to Archbiſhop King's State of the Proteſtants in Ireland. 2. Caſſandra, concerning the new Aſſociations, &c. 1703, 4to. 3. Rehearſals; at firſt a weekly paper, publiſhed afterwards twice a-week in a half-ſheet, by way of dialogue on the affairs of the times; begun in 1704, and continued for ſix or ſeven years. 4. The Wolf ſtripped of his Shepherd's Clothing, in Anſwer to Moderation a Virtue, 1704, 4to. The pamphlet it anſwers was written by James Owen. 5. The Biſhop of Sarum's [Burnet's] proper Defence, from a Speech ſaid to be ſpoken by him againſt occaſional conformity, 1704, 4to. 6. The new Aſſociation of thoſe called Moderate Churchmen, &c. occaſioned by a pamphlet, intitled, The Danger of Prieſtcraft, 1705, 4to. 7. The new Aſſociation, part 2d, 1705, 4to. 8. The Principles of Diſſenters concerning Toleration and occaſional Conformity, 1705, 4to. 9. A Warning for the Church of England, 1706, 4to. Some have doubted whether theſe two pieces were his. 10. The good old Cauſe, or Lying in Truth; being a ſecond Defence of the Biſhop of Sarum from a ſecond Speech, &c. 1710. For this a warrant was iſſued out againſt Leſlie. 11. A Letter to the Biſhop of Sarum, in Anſwer to his Sermon after the Queen's Death, in Defence of the Revolution, 1715. 12. Salt for the Leech. 13. The Anatomy of a Jacobite. 14. Gallienus redivivus. 15. Delenda Carthago. 16 A Letter to Mr William Molyneux, on his Caſe of Ireland's being bound by the Engliſh Acts of Parliament. 17. A Letter to Julian Johnſon. 18. Several Tracts againſt Dr Higden and Mr Hoadly. 19 A Diſcourſe, ſhewing who they are that are now qualified to adminiſter Baptiſm. 20. The Hiſtory of Sin and Hereſy, &c. 1698, 8vo. 21. The Truth of Chriſtianity demonſtrated, in a Dialogue between a Chriſtian and a Deiſt, 1711, 8vo.—Againſt the Papiſts: 22. Of private Judgment and Authority in Matters of Faith. 23. The Caſe ſtated between the Church of Rome and the Church of England, &c. 1713. 24. The true notion of the Catholic Church, in Anſwer to the Biſhop of Meaux's Letter to Mr Nelſon, &c.

Beſides theſe, he publiſhed the four following tracts: 25. A Sermon preached in Cheſter, againſt Marriages in different Communions, 1702, 8vo. This ſermon occaſioned Mr Dodwell's diſcourſe upon the ſame ſubject. 26. A Diſſertation concerning the Uſe and Authority of Eccleſiaſtical Hiſtory. 27. The Caſe of the Regal and the Pontificate. 28. A Supplement, in Anſwer to a Book, intitled, The regal Supremacy in Eccleſiaſtical Affairs aſſerted, &c. Theſe two laſt pieces were occaſioned by the diſpute about the rights of convocation, between Wake, &c. on one ſide, and Atterbury and his friends, among whom was Leſlie, on the other.

It is ſaid by the authors of the Biographical Dictionary, that, in conſequence of a publication of his, intitled, "The hereditary right of the crown of England aſſerted," he was under the neceſſity of leaving the kingdom; and that he repaired to the Pretender at *Bar le duc*, where he was allowed to officiate, in a private chapel, after the rites of the church of England; and where he endeavoured, though in vain, to convert the Pretender to the Proteſtant religion.

That he repaired to *Bar le duc*, and endeavoured to convert to the church of England him whom he conſidered as the rightful ſovereign of England, is indeed true; but we have reaſon to believe that this was not in conſequence of his being obliged to leave the kingdom. There is, in the firſt place, ſome grounds to believe, that "The hereditary right of the crown of England aſſerted" was not written by him; and there is ſtill in exiſtence undoubted evidence, that, in conſequence of his great fame as a polemic, he was ſent to *Bar le duc* for the expreſs purpoſe of endeavouring to convert the ſon of James II. by ſome gentlemen of fortune in England, who wiſhed to ſee that prince on the throne of his anceſtors. The writer of this article had the honour, 16 or 17 years ago, to be known to the granddaughter of one of thoſe gentlemen—a lady of the ſtricteſt veracity; and from her he received many anecdotes of Leſlie and his aſſociates, which, as he did not then foreſee that he ſhould have the preſent occaſion for them, he has ſuffered to ſlip from his memory. That lady is ſtill alive, and we have reaſon to believe is in poſſeſſion of many letters by Leſlie, written in confidence to her grandfather, both from *Bar le duc* and from St Germains; and by the account which ſhe gave of theſe letters, Leſlie appears to have conſidered his prince as a weak and incorrigible bigot, though, in every thing but religion, an amiable and accompliſhed man. This may have been his genuine character; for we all know that it was the character of his father; but it is not of him that we are writing.

Mr Leſlie having remained abroad from the year 1709 till 1721, returned that year to England, reſolving, whatever the conſequences might be, to die in his own country. Some of his friends acquainting lord Sunderland with his purpoſes, implored his protection for the good old man, which his lordſhip readily and generouſly promiſed. Mr Leſlie had no ſooner arrived in London, than a member of the houſe of commons officiouſly waited on lord Sunderland with the news, but met with ſuch a reception from his lordſhip as the malice of his errand deſerved. Our author then went over to Ireland, where he died April 13. 1722. at his own houſe at Glaſlough in the county of Monaghan.

His character may be ſummed up in a few words. Conſummate learning, attended by the loweſt humility, the ſtricteſt piety without the leaſt tincture of moroſeneſs, a converſation to the laſt degree lively and ſpirited, yet to the laſt degree innocent, made him the delight of mankind, and leaves what Dr Hickes ſays of him unqueſtionable, that he made more converts to a ſound faith and holy life than any other man of our times.

A charge, however, has been lately brought againſt him of ſuch a nature, as, if well founded, muſt detract not only from his literary fame, but alſo from his integrity. "The ſhort and eaſy Method with the Deiſts" is unqueſtionably his moſt valuable, and apparently his moſt original work; yet this tract is publiſhed in French among the works of the Abbé St Real, who died in 1692; and therefore it has been ſaid, that unleſs it was publiſhed in Engliſh prior to that period, Charles Leſlie muſt be conſidered as a ſhameleſs plagiary.

The Engliſh work was certainly not publiſhed prior to the death of Abbé St Real; for the firſt edition bears date July 17th 1697; and yet many reaſons conſpire to convince us, that our countryman was no plagiary. There is indeed a ſtriking ſimilarity between the Engliſh and the French works; but this is no complete proof that the one was copied from the other. The article PHILOLOGY in the *Encyclypædia Britannica*, of which Dr Doig is the author, was publiſhed the very ſame week with Dr Vincent's diſſertation on the Greek verb. It was therefore impoſſible that either of theſe learned men, who were till then ſtrangers to each others names, could have ſtolen aught from the other; and yet Dr Vincent's derivation of the Greek verb bears as ſtriking a reſemblance to Dr Doig's as the Abbé St Real's work does to Charles Leſlie's. In the article MIRACLE (*Encycl.*), the credibility of the goſpel miracles is eſtabliſhed by an argument, which the author certainly borrowed from no man, and which the late principal Campbell conſidered as original; yet within half a year of the publication of that article, the credibility of the goſpel-miracles was treated in the very ſame manner by F. SAYERS, M. D. though there is in his diſſertation complete internal evidence that he had not ſeen the article in the *Encyclopædia*. Not many months ago, the author of this ſketch reviewed, in one of the journals, the work of a friend, which was at the ſame time reviewed in another journal, that at this moment he has never ſeen. Yet he has been told by a friend, who is much verſant in that kind of reading, and knows nothing of his concern with either review, that the book in queſtion muſt, in both journals, have been reviewed by the ſame hand; becauſe in both the ſame character is given of it in almoſt the very ſame words!

After theſe inſtances of apparent plagiariſm, which we know to be *only* apparent, has any man a right to ſay that Charles Leſlie and the Abbé St Real might not have have treated their ſubject in the way that they have done, without either borrowing from the other? The coincidence of arrangement and reaſoning in the two works is indeed very ſurpriſing; but it is by no means ſo ſurpriſing as the coincidence of etymological deductions which appears in the works of the Doctors Doig and Vincent. The divines reaſon from the acknowledged laws of human thought; the reaſonings of the grammarians, with all due deference to their ſuperior learning, we cannot help conſidering as ſometimes fanciful.

But this is not all that we have to urge on the ſubject. If there be plagiariſm in the caſe, and the identity of titles looks very like it, it is infinitely more probable that the editor of St Real's works ſtole from Leſlie, than that Leſlie ſtole from St Real, unleſs it can be proved that the works of the Abbé, and this work in particular, were publiſhed before the year 1697. At that period, the Engliſh language was very little read or underſtood on the continent; whilſt in Britain the French language was, by *ſcholars*, as generally underſtood as at preſent. Hence it is, that ſo many Frenchmen, and indeed foreigners of different nations, thought themſelves ſafe in pilfering ſcience from the Britiſh philoſophers *; whilſt there is not, that we know, one well authenticated inſtance of a Britiſh philoſopher appropriating to himſelf the diſcoveries of a foreigner. If, then, ſuch men as LEIBNITZ, John BERNOULLI, and DES CARTES, truſting to the improbability of detection, condeſcended to pilfer the diſcoveries of HOOKE, NEWTON, and HARRIOT, is it improbable that the editor of the works of St Real would claim to his friend a celebrated tract, of which he knew the real author to be obnoxious to the government of his own country, and therefore not likely to have powerful friends to maintain his right?

But farther, Burnet, biſhop of Sarum, was an excellent ſcholar, and well read, as every one knows, in the works of foreign divines. Is it conceivable, that this prelate, when ſmarting under the laſh of Leſlie, would have let ſlip ſo good an opportunity of covering with diſgrace his moſt formidable antagoniſt, had he known that antagoniſt to be guilty of plagiariſm from the writings of the Abbé St Real? Let it be granted, however,

---

* See *Quantity* (Encycl.), *Aſtronomy*, *Dynamics*, *Impulſion*, and *Harriot*, in this Suppl.

however, that Burnet was a ſtranger to theſe writings and to this plagiariſm; it can hardly be ſuppoſed that *Le Clarc* was a ſtranger to them likewiſe. Yet this author, when, for reaſons beſt known to himſelf, he choſe (1706) to depreciate the argument of *the ſhort method*, and to traduce its author as ignorant of ancient hiſtory, and as having brought forward his four marks for no other purpoſe than to put the deceitful traditions of Popery on the ſame footing with the moſt authentic doctrines of the goſpel, does not ſo much as inſinuate that he borrowed theſe marks from a Popiſh abbé, though ſuch a charge, could he have eſtabliſhed it, would have ſerved his purpoſe more than all his rude railings and invective. But there was no room for ſuch a charge. In the ſecond volume of the works of St Real, publiſhed in 1757, there is indeed a tract entitled *Methode Courte et Aiſée pour combattre les Deiſtes;* and there can be little doubt but that the publiſher wiſhed it to be conſidered as the work of his countryman. Unfortunately, however, for his deſign, a catalogue of the Abbé's works is given in the firſt volume; and in that catalogue the *Methode Courte et Aiſée* is not mentioned.

We have dwelt thus long on *The Short and Eaſy Method with the Deiſts*, becauſe it is one of the ableſt works that ever was written in proof of the Divine origin of the Jewiſh and Chriſtian Scriptures; a work of which the merit is acknowledged by Lord Bolingbroke, and which, as has been obſerved elſewhere (ſee THEOLOGY, nº 16. *Encycl.*) Dr Conyers Middleton confeſſes to be unanſwerable. If by men of ſcience we be thought to have ſpent our time well in vindicating the rights of our illuſtrious philoſophers Hooke and Newton, to diſcoveries which have been unjuſtly claimed by the philoſophers of Germany and France; we will not ſurely by the friends of Chriſtianity be thought to have employed our time ill in vindicating Leſlie's claim to this deciſive argument in ſupport of our holy religion.

LEVER, the firſt of the mechanical powers, for the properties of which ſee MECHANICS; and for a demonſtration of its fundamental property, ſee STEEL YARD, both in the *Encyclopædia*.

LICENSER of BOOKS (ſee LIBERTY *of the Preſs*, *Encycl*), has been an officer in almoſt every civilized nation, till the end of the laſt century that the office was aboliſhed in Great Britain. Profeſſor Beckmann, with his uſual induſtry *, has proved that ſuch an office was eſtabliſhed not only in the Roman Empire, but even in the republic, and in the free ſtates of ancient Greece. At Athens, the works of Protagoras were prohibited; and all the copies of them which could be collected were burnt by the public crier. At Rome, the writings of Numa, which had been found in his grave, were, by order of the ſenate, condemned to the fire, becauſe they were contrary to the religion which he had introduced. As the populace at Rome were, in times of public calamity, more addicted to ſuperſtition than ſeemed proper to the government, an order was iſſued, that all ſuperſtitious and aſtrological books ſhould be delivered into the hands of the prætor. This order was often repeated; and the emperor Auguſtus cauſed more than twenty thouſand of theſe books to be burnt at one time. Under the ſame emperor the ſatirical works of Labienus were condemned to the fire, which was the firſt inſtance of this nature; and it is related as ſomething ſingular, that, a few years after, the writings of the perſon who had been the cauſe of the order for that purpoſe ſhared the like fate, and were alſo publicly burnt. When Cremutius Cordus, in his hiſtory, called C. Caſſius the laſt of the Romans, the ſenate, in order to flatter Tiberius, cauſed the book to be burnt; but a number of copies were ſaved by being concealed. Antiochus Epiphanes cauſed the books of the Jews to be burnt; and in the firſt centuries of our æra the books of the Chriſtians were treated with equal ſeverity, of which Arnobius bitterly complains. We are told by Euſebius, that Diocleſian cauſed the ſacred Scriptures to be burnt. After the ſpreading of the Chriſtian religion the clergy exerciſed, againſt books that were either unfavourable or diſagreeable to them, the ſame ſeverity which they had cenſured in the heathens as fooliſh and prejudicial to their own cauſe.

Soon after the invention of printing, laws began to be made for ſubjecting books to examination; a regulation propoſed even by Plato; and which has been wiſhed for by many ſince. Our author gives a great deal of curious information on this important ſubject, which our limits do not permit us to repeat; but it is apparent from his work, that the liberty of the preſs is but a modern privilege; and that it has not been enjoyed completely in any country but this happy iſland.

LICHEN (ſee *Encycl.*), is a genus of plants, of which the moſt valuable ſpecies ſeems to be the LICHEN ROCELLA, or *Argol*. As that ſpecies has not been noticed in the article referred to, the following account of it from Profeſſor Beckmann will be acceptable to many of our readers:

It is found in abundance in ſome of the iſlands near the African coaſt, particularly in the Canaries, and in ſeveral of the iſlands in the Archipelago. It grows upright, partly in ſingle, partly in double ſtems, which are about two inches in height. When it is old, theſe ſtems are crowned with a button ſometimes round, and ſometimes of a flat form, which Tournefort, very properly, compares to the excreſcences on the arms of the ſepia. Its colour is ſometimes a light, and ſometimes a dark grey. Of this moſs, with lime, urine, and alkaline ſalts, is formed a dark red paſte, which in commerce has the ſame name, and which is much uſed in dyeing. That well-known ſubſtance called lacmus is alſo made of it.

Theophraſtus, Dioſcorides, and their tranſcriber Pliny, give the name of *Phycos thalaſſion*, or *pontion*, to this plant, which, notwithſtanding its name, is not a ſea weed but a moſs; as it grew on the rocks of different iſlands, and particularly on thoſe of Crete or Candia. It had, in their time, been long uſed for dyeing wool, and the colour it gave when freſh was ſo beautiful, that it excelled the ancient purple, which was not red, as many ſuppoſe, but violet. Pliny tells us, that with this moſs dyers gave the ground or firſt tint to thoſe cloths which they intended to dye with the coſtly purple. When it was firſt employed as a dye by the moderns, is not ſo certain, though the Profeſſor has proved, we think completely, that it muſt have been at leaſt as early as the beginning of the 14th century.

"Among the oldeſt and principal Florentine families (ſays he), is that known under the name of the

---

* *Hiſtory of Inventions*, vol 3.

Oricellarii or Rucellarii, Ruſcellai or Rucellai, ſeveral of whom have diſtinguiſhed themſelves as ſtateſmen and men of letters. This family are deſcended from a German nobleman, named Ferro or Frederigo, who lived in the beginning of the twelfth century. One of his deſcendants, in the year 1300, carried on a great trade in the Levant, by which he acquired conſiderable riches, and returning at length to Florence, with his fortune, firſt made known in Europe the art of dyeing with argol. It is ſaid, that a little before his return from the Levant, happening to make water on a rock covered with this moſs, he obſerved, that the plant, which was there called *reſpio*, or *reſpo*, and in Spain *orciglia*, acquired by the urine a purple, or, as others ſay, a red colour. He therefore tried ſeveral experiments; and when he had brought to perfection the art of dyeing wool with this plant, he made it known at Florence, where he alone practiſed it for a conſiderable time, to the great benefit of the ſtate. From this uſeful invention, the family received the name of Oricellarii, from which, at laſt, was formed Rucellai." The Profeſſor, however, does not believe that this Florentine diſcovered the dye by means of the above-mentioned accident, but that he learned the art in the Levant, and on his return taught it to his countrymen.

"Our dyers do not purchaſe raw argol, but a paſte made of it, which the French call *orſeille en pâte*. The preparation of it was for a long time kept a ſecret by the Florentines. The perſon who, as far as I know, made it firſt known was Roſetti; who, as he himſelf tells us, carried on the trade of dyer at Florence. Some information was afterwards publiſhed concerning it by Imperati * and Micheli the botaniſt †. In later times this art has been much practiſed in France, England, and Holland. Many druggiſts, inſtead of keeping this paſte in a moiſt ſtate with urine, as they ought, ſuffer it to dry, in order to ſave a little dirty work. It then has the appearance of a dark violet-coloured earth, with here and there ſome white ſpots in it.

"The Dutch (continues our author), who have found out better methods than other nations of manufacturing many commodities, ſo as to render them cheaper, and thereby to hurt the trade of their neighbours, are the inventors alſo of lacmus, a preparation of argol, called *orſeille en pierre*, which has greatly leſſened the uſe of that *en pâte*, as it is more eaſily tranſported and preſerved, and fitter for uſe; and as it is beſides, if not cheaper, at leaſt not dearer. This art conſiſts, undoubtedly, in mixing with that commodity ſome leſs valuable ſubſtance, which either improves or does not much impair its quality, and which, at the ſame time, increaſes its weight (A). Thus do they pound cinnabar and ſmalt finer than other nations, and yet ſell both theſe articles cheaper. Thus do they ſift cochineal, and ſell it cheaper than what is unſifted.

"It was for a long time believed, that the Dutch prepared their lacmus from thoſe linen rags which in the ſouth of France are dipped in the juice of the *croton tinctorium*; but at preſent, it is almoſt certainly known, that *orſeille en pâte* is the principal ingredient in *orſeille en pierre* that is in lacmus; and for this curious information we are indebted to Ferber. But whence ariſes the ſmell of the lacmus, which appears ſo like that of the Florentine iris?" Some of the latter may, perhaps, be mixed with it; for our author thinks, that he has obſerved in it ſmall indiſſoluble particles, which may have been bits of the roots. The addition of this ſubſtance can be of no uſe to improve the dye; but it may increaſe the weight, and give the lack more body; and perhaps it may be employed to render imperceptible ſome unpleaſant ſmell, for which purpoſe the roots of that plant are uſed on many other occaſions.

LIGHT, it has been obſerved in the article CHEMISTRY, n° 319. (*Suppl.*), conſiſts of rays differently flexible. This was eſtabliſhed by ſome well deviſed experiments made by Henry Brougham, Eſq; of which it may be proper to give an account here.

In the firſt experiment, he darkened his chamber in the uſual way, and let a beam of the ſun's light into it through the hole of a metal plate fixed in the ſhutter of the window, $\frac{1}{30}$th of an inch in diameter. At the hole within the room he placed a priſm of glaſs, of which the refracting angle was 45 degrees, and which was everywhere covered with black paper, except a ſmall part on each ſide; and through this part the light was refracted ſo as to form a diſtinct ſpectrum on a chart at ſix feet diſtance from the window. In the rays, at two feet from the priſm, he placed a black unpoliſhed pin, of which the diameter was $\frac{1}{10}$th of an inch, parallel to the chart, and in a vertical poſition. The ſhadow of the pin was found in the ſpectrum; and this ſhadow had a conſiderable penumbra, which was broadeſt and moſt diſtinct in the violet part, narroweſt and moſt confuſed in the red, and of an intermediate thickneſs and diſtinctneſs in the intermediate colours. The penumbra was bounded by curvilinear ſides, convex towards the axis to which they approached as to an aſymptote, ſo as to be neareſt to it in the place of the leaſt refrangible rays. By moving the priſm on its axis, and cauſing the colours to aſcend and deſcend on any bodies that were uſed inſtead of the pin, the red, wherever they fell, made the leaſt, and the violet the greateſt, ſhadow.

In the next experiment, a ſcreen was ſubſtituted in the place of the pin; and this ſcreen had a large hole, on which was a braſs plate, pierced with a ſmall hole $\frac{1}{32}$d of an inch in diameter. While an aſſiſtant moved the priſm ſlowly on its axis, the author obſerved the round image made by the different rays paſſing through the hole to the chart; that made by the red was greateſt, that of the violet leaſt, and that of each intermediate rays was of an intermediate ſize. When the ſharp blade of a knife was held at the back of the hole, "ſo as to produce the fringes mentioned by Grimaldo and Newton, theſe fringes in the red were broadeſt and moſt moved inwards to the ſhadow, and moſt dilated when the knife was moved over the hole; and the hole itſelf on the chart was more dilated during the motion when illuminated by the red than when illuminated by any other of the rays, and leaſt of all when illuminated by the violet."

From theſe two experiments, the author infers "that the rays of the ſun's light differ in degree of flexibility, and

(A) As dry lacmus is much cheaper than moiſt, it may be readily ſuppoſed that it is adulterated with ſand and other ſubſtances. *Valentini Hiſtoria ſimplicium.* Francf. ad Moen. 1716. fol. p. 152.

and that thoſe which are leaſt *refrangible* are *moſt inflexible*." From other experiments, he concludes, that the *moſt inflexible* rays are alſo *moſt deflexible*. In the ſequel of his paper, he aſcertains the proportion which the angle of *inflection* bears to that of *deflection* at equal incidences, and the proportion which the different *flexibilities* of the different rays bear to one another. We ſhall give an account of ſome other experiments made by him, and of the inferences drawn from them, under the word REFLEXITY, to which a reference has already been made.

LIMBERS, in artillery, a ſort of advanced train, joined to the carriage of a cannon on a march. It is compoſed of two ſhafts, wide enough to receive a horſe between them, called the *fillet horſe:* theſe ſhafts are joined by two bars of wood, and a bolt of iron at one end, and mounted on a pair of rather ſmall wheels. Upon the axle-tree riſes a ſtrong iron ſpike, which is put into a hole in the hinder part of the train of the gun-carriage, to draw it by. But when a gun is in action, the limbers are taken off, and run out behind it.

LIMIT OF A PLANET, has been ſometimes uſed for its greateſt heliocentric latitude.

LIMITED Problem, denotes a problem that has but one ſolution, or ſome determinate number of ſolutions: as to deſcribe a circle through three given points that do not lie in a right line, which is limited to one ſolution only; to divide a parallelogram into two equal parts by a line parallel to one ſide, which admits of two ſolutions, according as the line is parallel to the length or breadth of the parallelogram; or to divide a triangle in any ratio by a line parallel to one ſide, which is limited to three ſolutions, as the line may be parallel to any of the three ſides.

LOCAL PROBLEM, is one that is capable of an infinite number of different ſolutions; becauſe the point, which is to ſolve the problem, may be indifferently taken within a certain extent; as ſuppoſe any where in ſuch a line, within ſuch a plane figure, &c. which is called a *geometrical Locus*.

A local problem is *ſimple*, when the point ſought is in a right line; *plane*, when the point ſought is in the circumference of a circle; *ſolid*, when it is in the circumference of a conic ſection; or *ſurſolid*, when the point is in the perimeter of a line of a higher kind.

LOCI, the plural of

LOCUS, a line by which a local or indeterminate problem is ſolved; or a line of which any point may equally ſolve an indeterminate problem. See ALGEBRA, *Encycl.*

LOGISTIC CURVE, the ſame with *LOGARITHMIC Curve*, for which ſee *Encycl.*

LOGISTICS, or *LOGISTICAL Arithmetic*, a name ſometimes employed for the arithmetic of ſexageſimal fractions, uſed in aſtronomical computations.

The ſame term has been uſed for the rules of computations in algebra, and in other ſpecies of arithmetic: witneſs the logiſtics of Vieta and other writers.

Shakerly, in his *Tabulæ Britannicæ*, has a table of logarithms adapted to ſexageſimal fractions, and which he calls Logiſtical Logarithms; and the expeditious arithmetic, obtained by means of them, he calls Logiſtical Arithmetic.

LIBYAN LOTUS has been deſcribed (*Encycl.*) under the title RHAMNUS; but the following additional particulars from Mr Park will be acceptable to our botanical readers:

The lotus is very common in all the countries which our author viſited, and he had an opportunity to make a drawing of a branch in flower, of which an engraving is publiſhed in his travels, that with his permiſſion we have copied (ſee Plate XXX.). The lotus produces fruit which the negroes call *tomberongs*. Theſe are ſmall farinaceous berries, of a yellow colour and delicious taſte. They are much eſteemed by the natives, who convert them into a ſort of bread, by expoſing them for ſome days to the ſun, and afterwards pounding them gently in a wooden mortar, until the farinaceous part of the berry is ſeparated from the ſtone. This meal is then mixed with a little water, and formed into cakes; which, when dried in the ſun, reſemble in colour and flavour the ſweeteſt gingerbread. The ſtones are afterwards put into a veſſel of water, and ſhaken about ſo as to ſeparate the meal which may ſtill adhere to them: this communicates a ſweet and agreeable taſte to the water, and with the addition of a little pounded millet, forms a pleaſant gruel called *fondi*, which is the common breakfaſt in many parts of Ludamar, during the months of February and March. The fruit is collected by ſpreading a cloth upon the ground, and beating the branches with a ſtick. Our author thinks there can be little doubt of this being the lotus mentioned by Pliny, as the food of the Lybian Lotophagi. An army may very well have been fed with the bread made of the meal of the fruit, as is ſaid by Pliny to have been done in Lybia; and as the taſte of the bread is ſweet and agreeable, it is not likely that the ſoldiers would complain of it.

LOWANG, a Chineſe iſland of ſome extent in the neighbourhood of the CHUSAN-Iſles, which ſee in this *Supplement*. Some of the gentlemen belonging to the Britiſh embaſſy went aſhore on Lowang, which they deſcribed as naked both of trees and of cattle. They examined particularly a ſmall level plain recovered from the ſea, which was kept out by an embankment of earth, at leaſt thirty feet thick. The quantity of ground gained by it ſeemed ſcarcely to be worth the labour that it muſt have coſt. The plain was indeed cultivated with the utmoſt care, and laid out chiefly in rice-plats, ſupplied with water collected from the adjacent hills into little channels, through which it was conveyed to every part of thoſe plantations. It was manured, inſtead of the dung of animals, with matters more offenſive to the human ſenſes, and which are not very generally applied to the purpoſes of agriculture in England. Earthen veſſels were ſunk into the ground for the reception of ſuch manure; and for containing liquids of an analogous nature, in which the grain was ſteeped previouſly to its being ſown; an operation which is ſuppoſed to haſten the growth of the future plant, as well as to prevent any injury from inſects in its tender ſtate.

The party fell in with a peaſant who, though ſtruck with their appearance, was not ſo feared by it as to ſhun them. He was dreſſed in looſe garments of blue cotton, a ſtraw hat upon his head faſtened by a ſtring under his chin, and half boots upon his legs. He ſeemed to enter into the ſpirit of curioſity, naturally animating travellers, and readily led them towards an adjoining village.

village. Paſſing by a ſmall farm houſe, they were invited into it by the tenant, who, together with his ſon, obſerved them with aſtoniſhed eyes. The houſe was built of wood, the uprights of the natural form of the timber. No ceiling concealed the inſide of the roof, which was put together ſtrongly, and covered with the ſtraw of rice. The floor was of earth beaten hard, and the partitions between the rooms conſiſted of mats hanging from the beams. Two ſpinning wheels for cotton were ſeen in the outer room; but the ſeats for the ſpinners were empty. They had probably been filled by females, who retired on the approach of ſtrangers; while they remained, none of that ſex appeared. Round the houſe were planted cluſters of bamboo, and of that ſpecies of palm, of which each leaf reſembles the form of a fan; and, uſed as ſuch, becomes an article of merchandize.

LOXODROMIC Curve, or *Spiral*, is the ſame as the rhumb line, or path of a ſhip ſailing always on the ſame courſe in an oblique direction, or making always the ſame angle with every meridian. It is a ſpecies of logarithmic ſpiral, deſcribed on the ſurface of the ſphere, having the meridians for its radii.

LOXODROMICS, the art or method of oblique ſailing, by the loxodromic or rhumb line.

LUCIOLE, a name given in the *Annales de Chimie* to the Lampyris *Italica* (See Lampyris, *Encycl.*). According to Dr Carradori, the light of the luciole does not depend on the influence of any external cauſe, but merely on the will of thoſe inſects. While they fly about at freedom, their ſhining is very regular; but when they are once in our power, they ſhine very irregularly, or do not ſhine at all. When they are moleſted, they emit a frequent light, which appears to be a mark of their reſentment. When placed on their backs, they ſhine almoſt without interruption, making continual efforts to turn themſelves from that poſition. In the daytime it is neceſſary to torment them in order to make them ſhine; and thence it follows, that the day to them is the ſeaſon of repoſe. The luciole emit light at pleaſure from every point of their bellies, which proves that they can move all the parts of their viſcera independently of each other. They can alſo render their phoſphoreſcence more or leſs vivid, and continue it as long as they pleaſe.

A ſlight compreſſion deprives the luciole of their power of ceaſing to ſhine. The author is inclined to believe, that the movement by which they conceal their light is executed by drawing back their phoſphoric ſubſtance into a particular membrane or tunic. He ſuppoſes alſo, that the ſparkling conſiſts in a trembling or oſcillation of the phoſphoric maſs. He is of opinion, that there is no emanation of a phoſphoric ſubſtance, and that the whole phenomenon takes place in the interior part of the luminous viſcera. When the ſhining is at its greateſt degree of height, it is ſo ſtrong that a perſon may by it eaſily diſtinguiſh the hours on the ſmalleſt watch, and the letters of any type whatever.

The phoſphoric part of the luciole does not extend farther than to the extreme rings of the belly. It is there incloſed in a covering compoſed of two portions of membranes, one of which forms the upper, and the other the lower, part of the belly, and which are joined together. Behind this receptacle is placed the phoſphorus, which reſembles a paſte, having the ſmell of garlic, and very little taſte. The phoſphoric matter iſſues from a ſort of bag on the ſlighteſt preſſure; when ſqueezed out, this matter loſes its ſplendour in a few hours, and is converted into a white dry ſubſtance. A portion of the phoſphoric belly put into oil, ſhone only with a feeble light, and was ſoon extinguiſhed. In water, a like portion ſhone with the ſame vivacity as in the air, and for a much longer time. The author thence concludes, that the phoſphoreſcence of the luciole is not the effect of ſlow inflammation, nor of the fixation of azotic gas, as the oil in which they ſhine does not contain a ſingle air-bubble: beſides, the phoſphorus of theſe inſects ſhines in a barometrical vacuum. The obſervation made by Foſter, that the luciole diffuſed a more vivid light in oxygen gas than in atmoſpheric air, does not, according to Carradori, depend upon a combuſtion more animated by the inſpiration of this gas, but on the animals feeling themſelves, while in that gas, in a better condition. "Whence, then, ariſes (ſays the author) the phoſphoric light of the luciole? I am of opinion (adds he), that the light is peculiar and innate in theſe inſects, as ſeveral other productions are peculiar to other animals. As ſome animals have the faculty of accumulating the electric fluid, and of keeping it condenſed in particular organs, to diffuſe it afterwards at pleaſure, there may be other animals endowed with the faculty of keeping in a condenſed ſtate the fluid which conſtitutes light. It is poſſible, that by a peculiar organization they may have the power of extracting the light which enters into the compoſition of their food, and of tranſmitting it to the reſervoir deſtined for that purpoſe, which they have in their abdomen. It is not even impoſſible that they may have the power to extract from the atmoſpheric air the luminous fluid, as other animals have the power of extracting from the ſame air, by a chemical proceſs, the fluid of heat."

Carradori diſcovered, that the phoſphoreſcence of the luciole is a property independent of the life of theſe animals, and that it is chiefly owing to the ſoft ſtate of the phoſphoric ſubſtance. Its light is ſuſpended by drying, and it is again revived by ſoftening it in water; but only after a certain time of deſiccation. Reaumur, Beccaria, and Spallanzani, obſerved the ſame thing in regard to the *pholades* and the *meduſa*.

By plunging the luciole alternately into lukewarm and cold water, they ſhine with vivacity in the former, but their light becomes extinct in the latter; which, according to the author, depends on the alternate agreeable and diſagreeable ſenſation which they experience. In warm water their light diſappears gradually. Dr Carradori tried on the luciole and their phoſphorus the action of different ſaline and ſpirituous liquors, in which they exhibited the ſame appearances as other phoſphoric animals. Theſe laſt experiments prove that the phoſphoric matter of the luciole is only ſoluble in water.

LUDAMAR, a Mooriſh kingdom in the interior of Africa, of which the capital Benorm is placed by Major Rennel in 15° N. Lat. and 6° 50′ W. Long. It has for its northern boundary the great deſert (ſee Sahara in this *Supplement*), and is deſcribed by Mr Park as little better than a deſert itſelf. Our traveller was taken captive on the confines of this kingdom, and carried to the camp of the king, where he was ſubjected to

to the crueleſt indignities that the malice of bigotted Moors could invent. He was not ſuffered to travel beyond the camp; though he moved as it moved, and of courſe ſaw a conſiderable part of the country, and had an opportunity of obſerving the manners of the people. “The Moors of Ludamar ſubſiſt chiefly on the fleſh of their cattle; and are always in the extreme of either gluttony or abſtinence. In conſequence of the frequent and ſevere faſts which their religion enjoins, and the toilſome journeys which they ſometimes undertake acroſs the deſert, they are enabled to bear both hunger and thirſt with ſurpriſing fortitude; but whenever opportunities occur of ſatisfying their appetite, they generally devour more at one meal than would ſerve an European for three. They pay but little attention to agriculture; purchaſing their corn, cotton cloth, and other neceſſaries, from the Negroes, in exchange for ſalt, which they dig from the pits in the Great Deſert.

“The natural barrenneſs of the country is ſuch, that it furniſhes but few materials for manufacture. The Moors, however, contrive to weave a ſtrong cloth, with which they cover their tents; the thread is ſpun by their women from the hair of goats: and they prepare the hides of their cattle ſo as to furniſh ſaddles, bridles, pouches, and other articles of leather. They are likewiſe ſufficiently ſkilful to convert the native iron, which they procure from the Negroes, into ſpears and knives, and alſo into pots for boiling their food; but their ſabres and other weapons, as well as their fire-arms and ammunition, they purchaſe from the Europeans, in exchange for the Negro ſlaves which they obtain in their predatory excurſions. Their chief commerce of this kind is with the French traders on the Senegal river.”

The Moors of this country have ſingular ideas of feminine perfection. The gracefulneſs of figure and motion, and a countenance enlivened by expreſſion, are by no means eſſential points in their ſtandard; with them corpulence and beauty appear to be terms nearly ſynonymous. A woman, of even moderate pretenſions, muſt be one who cannot walk without a ſlave under each arm to ſupport her; and a perfect beauty is a load for a camel. In conſequence of this prevalent taſte for unwieldineſs of bulk, the Mooriſh ladies take great pains to acquire it early in life; and for this purpoſe many of the young girls are compelled by their mothers to devour an immenſe quantity of food, and drink a large bowl of camel's milk every morning. It is of no importance whether the girl has an appetite or not, the meat and the drink muſt be ſwallowed; and obedience is frequently enforced by blows. This ſingular practice, inſtead of producing indigeſtion and diſeaſe, ſoon covers the young lady with that degree of plumpneſs, which, in the eye of a Moor, is perfection itſelf.

“Although the wealth of the Moors conſiſts chiefly in their numerous herds of cattle; yet, as the paſtoral life does not afford full employment, the majority of the people are perfectly idle, and ſpend the day in trifling converſation about their horſes, or in laying ſchemes of depredation on the Negro villages.

“The uſual place of rendezvous for the indolent is the king's tent, where great liberty of ſpeech ſeems to be exerciſed by the company towards each other. While in ſpeaking of their chief, they expreſs but one opinion. In praiſe of their ſovereign, they are unanimous. Songs are compoſed in his honour, which the company frequently ſing in concert; but they are ſo loaded with groſs adulation, that no man but a Mooriſh deſpot could hear them without bluſhing. The king is diſtinguiſhed by the fineneſs of his dreſs, which is compoſed of blue cotton cloth brought from Tombuctoo, or white linen or muſlin from Morocco. He has likewiſe a larger tent than any other perſon, with a white cloth over it; but in his uſual intercourſe with his ſubjects, all diſtinctions of rank are frequently forgotten. He ſometimes eats out of the ſame bowl with his camel driver, and repoſes himſelf, during the heat of the day, upon the ſame bed.

“The military ſtrength of Ludamar conſiſts in cavalry. They are well mounted, and appear to be very expert in ſkirmiſhing and attacking by ſurpriſe. Every ſoldier furniſhes his own horſe, and finds his accoutrements, conſiſting of a large ſabre, a double barrelled gun, a ſmall red leather bag for holding his balls, and a powder horn flung over the ſhoulder. He has no pay, nor any remuneration but what ariſes from plunder. This body is not very numerous; for when Ali the king made war upon Bambara, our author was informed that his whole force did not exceed 2000 cavalry. They conſtitute, however, by what he could learn, but a very ſmall proportion of his Mooriſh ſubjects. The horſes are very beautiful, and ſo highly eſteemed, that the Negro princes will ſometimes give from twelve to fourteen ſlaves for one horſe.”

Cut off from all intercourſe with civilized nations, and boaſting an advantage over the Negroes, by poſſeſſing, though in a very limited degree, the knowledge of letters, the Moors of Ludamar are at once the vaineſt and proudeſt, and perhaps the moſt bigotted, ferocious, and intolerant of all the nations on the earth; combining in their character the blind ſuperſtition of the Negro with the ſavage cruelty and treachery of the Arab. It was with the utmoſt difficulty that our author made his eſcape from this inhoſpitable people.

LUPUS, the *Wolf*, a ſouthern conſtellation, joined to the Centaur, containing together 19 ſtars in Ptolomy's catalogue, but 24 in the Britannic catalogue.

LYNX, a conſtellation of the northern hemiſphere, compoſed by Hevelius out of the unformed ſtars. In his catalogue it conſiſts of 19 ſtars, but in the Britannic 44.

M.

MACHINERY.

THE denomination *Machine* is now vulgarly given to a great variety of ſubjects, which have very little analogy by which they can be claſſed with propriety under any one name. We ſay a travelling machine, a bathing machine, a copying machine, a threſhing machine, an electrical machine, &c. &c. The only circumſtance in which all theſe agree ſeem to be, that their conſtruction is more complex and artificial than the utenſils, tools, or inſtruments which offer themſelves to the firſt thoughts of uncultivated people. They are more artificial than the common cart, the bathing tub, or the flail. In the language of ancient Athens and Rome, the term was applied to every tool by which hard labour of any kind was performed; but in the language of modern Europe, it ſeems reſtricted either to ſuch tools or inſtruments as are employed for executing ſome philoſophical purpoſe, or of which the conſtruction employs the ſimple mechanical powers in a conſpicuous manner, in which their operation and energy engage the attention. An electrical machine, a centrifugal machine, are of the firſt claſs; a threſhing machine, a fire machine, are of the other claſs. It is nearly ſynonymous, in our language, with ENGINE; a term altogether modern, and in ſome meaſure honourable, being beſtowed only, or chiefly, on contrivances for executing work in which ingenuity and mechanical ſkill are manifeſt. Perhaps, indeed, the term *engine* is limited, by careful writers, to machines of conſiderable magnitude, or at leaſt of conſiderable art and contrivance. We ſay, with propriety, ſteam engine, fire-engine, plating-engine, boring-engine; and a dividing machine, a copying machine, &c. Either of theſe terms, *machine* or *engine*, are applied with impropriety to contrivances in which ſome piece of work is not executed on materials which are then ſaid to be manufactured. A travelling or bathing machine is ſurely a vulgariſm. A machine or engine is therefore a TOOL; but of complicated conſtruction, peculiarly fitted for expediting labour, or for performing it according to certain invariable principles: And we ſhould add, that the dependence of its efficacy on mechanical principles muſt be apparent, and even conſpicuous. The contrivance and erection of ſuch works conſtitute the profeſſion of the engineer; a profeſſion which ought by no means to be confounded with that of the mechanic, the artiſan, or manufacturer. It is one of the *artes liberales*; as deſerving of the title as medicine, ſurgery, architecture, painting, or ſculpture. Nay, whether we conſider the importance of it to this flouriſhing nation, or the ſcience that is neceſſary for giving eminence to the profeſſor, it is very doubtful whether it ſhould not take place of the three laſt named, and go *pari paſſu* with ſurgery and medicine. The inconſiderate reader, who peruſes *Cicero de Oratore* with ſatisfaction, is apt to ſmile at Vitruvius, who requires in his architect nearly the ſame accompliſhments which Cicero requires in his orator. He has not recollected, or perhaps did not know, that the profeſſion of an architect in the Auguſtan age was the moſt reſpectable of all thoſe which were not eſſentially connected with the management of ſtate affairs. It appears that the architects were all Greeks, or the pupils of Greeks, altogether different from the members of the *Collegium Murariorum*, the corporation of builders and maſons. The architecture of temples, ſtadiums, circuſes, amphitheatres, ſeems to have been monopoliſed, by ſtate authority, by a ſociety which had long ſubſiſted in Aſia, connected by certain myſterious bonds, both civil and religious. We find it in Syria; and we learn that it was brought thither from Perſia in very ancient times. From thence it ſpread into Ionia, where it became a very eminent and powerful aſſociation, under the particular protection of Bacchus, to whom the members had erected a magnificent temple at Teos, with a vaſt eſtabliſhment of prieſts and prieſteſſes, conſiſting of perſons of the firſt rank in the ſtate. They were the ſole builders of temples and ſtadiums throughout all Greece and the Leſſer Aſia; and the contractors for the machinery that was employed in the theatres, and in the great temples, for the celebration of the high myſteries of paganiſm. By the imperfect accounts which remain of the Eleuſinian and other myſteries, it appears, that this machinery muſt have been immenſe and wonderful, and muſt have required a great deal of mechanical ſkill. This indeed appears, in the moſt convincing manner, to any perſon who reflects on the magnificent ſtructures which they erected, which excite to this day the wonder of the world, not only on account of their magnificence and incomparable elegance, but alſo on account of the mechanical knowledge that ſeems indiſpenſably neceſſary for their erection. This will ever remain a myſtery. There are no traces of ſuch knowledge to be found in the writings of antiquity. Even Vitruvius, writing expreſsly on the ſubject, has given us nothing but what is in the loweſt degree of elementary knowledge.

This aſſociation of the Dyoniſiacs undoubtedly kept their mechanical ſcience a profound ſecret from the uninitiated, the profane. They were the engineers of antiquity, and Vitruvius was perhaps not one of the initiated. He ſpeaks of Myro and other Greek architects in terms of reſpect which border on veneration. Perhaps the modern aſſociation of free maſons is a remain of this antient fraternity, continued to our times by the company of builders, who erected the cathedrals and great conventual churches. No one who conſiders their works with ſcientific attention, can doubt of their being deeply verſed in the principles of mechanics, and even its more refined branches. They appear to have carried the art of vault-roofing almoſt to its acmé of perfection; far outſtripping their Grecian inſtructors in their knowledge of this moſt delicate branch of their art.

It were greatly to be wiſhed that ſome ſuch inſtitution did yet exiſt, where men might be induced by the moſt powerful motives to accompliſh themſelves in the knowledge neceſſary for attaining eminence in their profeſſion.

We have been informed (and we thought our authority good), that our gracious Sovereign has ſignified his intention of patroniſing an inſtitution of this kind. We heard, that it was propoſed to inſtitute degrees ſimilar to our univerſity degrees, and proceeding on ſimilar conditions of a regular education or ſtanding, which would enſure the *opportunities* of information, and alſo on an examination of the proficiency of the candidate. This examination, being conducted by perſons eminent in the profeſſion, perhaps ſtill exerciſing it, would probably be ſerious, becauſe the ſucceſsful candidate would immediately become a rival practitioner. Such an inſtitution would undoubtedly prevent many groſs impoſitions by unlettered mill-wrights and pump-makers, who now ſeldom appear under any name but that of engineer, although they are frequently ignorant even of the elements of mechanical ſcience, and are totally unacquainted with the higher mathematics; without which it is abſolutely impoſſible for them to contrive a machine well ſuited to the intended purpoſe, or to ſay with any tolerable preciſion what will be the performance of the engine they have erected. Yet theſe are queſtions ſuſceptible of accurate ſolution, becauſe they depend on the unalterable laws of matter and motion.

All who have a juſt view of the unſpeakable advantages which this highly favoured land poſſeſſes in the ſuperiority and activity of its manufactures, and who know how much of this ſuperiority ſhould be aſcribed to the great improvements which have been made in practical mechanics within theſe laſt thirty years, will join us in wiſhing ſucceſs to ſome ſuch inſtitution as that now mentioned.

We were naturally led to theſe reflections when we turned our thoughts to machinery in general, and obſerved what is done in this country by the native energy of its inhabitants, unaſſiſted by ſuch ſcientific inſtructions as they might have expected from the pupils of a Newton, their countryman, under the patronage of the beſt of Sovereigns, eminently knowing in theſe things, and ever ready to encourage thoſe ſciences and arts which have ſo highly contributed to the national proſperity. What might not be reaſonably expected from Britiſh activity, if thoſe among ourſelves who have knowledge and leiſure had been at the ſame pains with the members of the foreign academies to cultivate the Newtonian philoſophy, and particularly the more refined branches of mechanics, and to deduce from their ſpeculations maxims of conſtruction fitted to our ſituation as a great manufacturing nation? But ſuch knowledge is not attainable by thoſe who are acquainted only with the imperfect elements contained in the publications read by the bulk of our practitioners. Much to this purpoſe has been done on the continent by the moſt eminent mathematicians; but from want of individual energy, or perhaps of general ſecurity and protection, the patriotic labours of thoſe gentlemen have not done the ſervice to their country which might have been reaſonably expected. Indeed, their diſſertations have generally been ſo compoſed, that only the learned could ſee their value. They ſeem addreſſed only, or chiefly, to ſuch; but it is to thoſe authors that our countrymen generally have recourſe for information concerning every thing in their profeſſion that riſes above mere elementary knowledge. The books in our language which profeſs to be ſyſtems of mechanics rarely go beyond this: they contain only the principles of equilibrium. Theſe are abſolutely neceſſary for the knowledge of machines; but they are very far indeed from giving what may be called a practical knowledge of *working machinery*. This is never in a ſtate of equilibrium. The machine muſt move in order to work. There muſt be a ſuperiority of impelling power, beyond what is merely ſufficient for balancing the reſiſtance or contrary action of the work to be performed. The reader may turn to the article STATICS in the *Encyclopædia Britannica*, and he will there ſee ſome farther obſervations on this head. And in the article MECHANICS he will find a pretty ample detail of all the uſual doctrines, and a deſcription of a conſiderable variety of machines or engines, accompanied by ſuch obſervations as are neceſſary for tracing the propagation or tranſmiſſion of preſſure from that part of the machine to which the natural power is applied to the working part of the machine. Along with theſe two articles, it will be proper to read with peculiar attention the article ROTATION.

By far the greateſt number of our moſt ſerviceable engines conſiſt chiefly of parts which have a motion of rotation round fixed axes, and derive all their energy from levers virtually contained in them. And theſe acting parts are alſo material, requiring force to move them, over and above what is neceſſary for producing the acting force at the working part of the machine. The modifications which this circumſtance frequently makes of the whole motions of the machine, are indicated in the article ROTATION in an elementary way; and the propoſitions there inveſtigated will be found almoſt continually involved in the complete theory of the operation of a machine. Laſtly, it will be proper to conſider attentively the propoſitions contained in the article *STRENGTH of Materials*, that we may combine them with thoſe which relate wholly to the working of the machine; becauſe it is from this combination only that we diſcover the ſtrains which are excited at the various points of ſupport, and of communication, and in every member of the machine. We ſuppoſe all theſe things already underſtood.

1
The chief queſtion in mechanics.

Our object at preſent is to point out the principles which enable us to aſcertain what will be the preciſe motion of a machine of given conſtruction, when actuated by a natural power of known intenſity, applied to a given point of the machine, while it is employed to overcome a known reſiſtance acting at another point. To abbreviate language, we ſhall call that the IMPELLED POINT of the machine to which the preſſure of the moving power is immediately applied; and we may call that the WORKING POINT, where the reſiſtance ariſing from the work to be performed immediately acts.

To conſider this important ſubject, even in its chief varieties, requires much more room than can be allowed in an undertaking like ours, and therefore we muſt content ourſelves with a very limited view; but at the ſame time, ſuch a view as ſhall give ſufficient indication of the principles which ſhould direct the practical reader in every important caſe. We ſhall conſider thoſe machines

which

which perform their motions round fixed axes; theſe being by far the moſt numerous and important, becauſe they involve in their conſtruction and operations all the leading principles.

2 The proper meaſure of mechanical power exerted.

That we may proceed ſecurely, it is neceſſary to have a preciſe and adequate notion of moving force, as applied to machinery, and of its meaſures. We think this peculiarly neceſſary. Different notions have been entertained on this ſubject by Mr Leibnitz, Des Cartes, and other eminent mechanicians of the laſt century; and their ſucceſſors have not yet come to an agreement. Nay, ſome of the moſt eminent practitioners of the preſent times (for we muſt include Mr Smeaton in the number) have given meaſures of mechanical power in machinery which we think inaccurate, and tending to erroneous concluſions and maxims.

We take for the meaſure (as it is the effect) of exerted mechanical power the quantity of motion which it produces by its uniform exertion during ſome given time. We ſay *uniform exertion*, not becauſe this uniformity is neceſſary, but only becauſe, if any variation of the exertion has taken place, it muſt be known, in order to judge of the power. This would needleſsly complicate the calculations; but in whatever way the exertion may have varied, the whole accumulated exertion is ſtill accurately meaſured by the quantity of motion exiſting at the end of the exertion. The reader muſt perceive that this is the ſame thing that is expreſſed in the article Dynamics of this *Supplement*, n° 90. by the area of the figure whoſe abſciſſa or axis repreſents the time of exertion; and the ordinates are as the preſſures in the different inſtants of that time, the whole being multiplied by the number of particles (that is, by the quantity of matter), becauſe that figure repreſents the quantity of motion generated in one particle of matter only. All this is abundantly clear to perſons converſant in theſe diſquiſitions; but we wiſh to carry along with us the diſtinct conceptions of that uſeful claſs of readers whoſe profeſſion engages them in the conſtruction and employment of machines, and to whom ſuch diſcuſſions are not ſo familiar. We muſt endeavour therefore to juſtify our choice of this meaſure by appealing to familiar facts.

If a man, by preſſing uniformly on a maſs of matter for five ſeconds, generates in it the velocity of eight feet per ſecond, we obtain an exact notion of the proportion of this exertion to the mechanical exertion of gravity, when we ſay that the man's exerted force has been preciſely one-twentieth part of the action of gravity on it; for we know that the weight of that body (or, more properly, its heavineſs) would, in five ſeconds, have given it the velocity of 160 feet per ſecond, by acting on it during its fall. But let us attend more cloſely to what we mean by ſaying that the exerted force is one-twentieth of the exertion of gravity. The only notion we have of the exertion of gravity is what we call the weight of the body—the preſſure which we feel it make on our hand. To ſay that this is 20 pounds weight, does not explain it; becauſe this is only the action of gravity on another piece of matter. Both preſſures are the ſame. But if the body weighs 20 pounds, it will draw out the rod of a ſteelyard to the mark 20. The rod is ſo divided, that the 20th part of this preſſure will draw it out to 1. Now the fact is, that if the man preſſes on the maſs of 20 pounds weight with a ſpring ſteelyard during five ſeconds, and if during that time the rod of the ſteelyard was always at the mark 1, the body will have acquired the velocity of eight feet per ſecond. This is an acknowledged fact. Therefore we were right in ſaying, that the man's exertion is one-twentieth of the exertion of gravity. And ſince we believe the weight of bodies to be proportional to their quantity of matter, all matter being equally heavy, we may ſay, that the man's exertion was equal to the action of gravity on a quantity of matter whoſe weight is one pound. We expreſs it much more familiarly, by ſaying, that the man exerted on it the preſſure of one pound of matter, or the force of one pound.

In this manner, the motion communicated to a maſs of matter, by acting on it during ſome time, informs us with accuracy of the real mechanical force or preſſure which has been exerted. This is judged to be double when twice the velocity has been generated in the ſame maſs, or where the ſame velocity has been generated in twice the maſs; becauſe we know, that a double preſſure would have done either the one or the other.

But farther: We know that this preſſure is the exertion; we have no other notion of our own force; and our notion of gravity, of elaſticity, or any other natural force, is the ſame. We alſo know that the continuance of this exertion fatigues and exhauſts our ſtrength as completely as the moſt violent motion. A dead pull, as it is called, of a horſe, at a poſt fixed in the ground, is a uſual trial of his ſtrength. No man can hold out his arm horizontally for much more than a quarter of an hour; and the exertion of the laſt minutes gives the moſt diſtreſſing fatigue, and diſables the ſhoulder from action for a conſiderable time after. This is therefore an expenditure of mechanical power, in the ſtrict primitive ſenſe of the word. Of this expenditure we have an exact and adequate effect and meaſure in the quantity of motion produced; that is, in the product of the quantity of matter by the velocity generated in it by this exertion. And it muſt be particularly noticed, that this meaſure is applicable even to caſes where no motion is produced by the exertion; that is, if we know that the exertion which is juſt unable to ſtart a block of ſtone lying on a ſmooth ſtone pavement, but would ſtart it, if increaſed by the ſmalleſt addition; and if we know that this would generate in a ſecond 32 feet of velocity in 100 pounds of matter—we are certain that it was a preſſure equal to the weight of this 100 pounds. It is a good meaſure, though not immediate, and may be uſed without danger of miſtake when we have no other.

3 Mr Smeaton's meaſure

The celebrated engineer Mr Smeaton, in his excellent diſſertation on the power of water and wind to drive machinery, and alſo in two other diſſertations, all publiſhed in the Philoſophical Tranſactions, and afterwards in a little volume, has employed another meaſure, both of the expenditure of mechanical power, and of the mechanical effect produced. He ſays, that the weight of a body, multiplied by the height thro' which it deſcends, while driving a machine, is the only proper meaſure of the power expended; and that the weight, multiplied by the height through which it is uniformly raiſed, is the only proper meaſure of the effect produced. And he produces a large train of accurate experiments

riments to prove that a certain weight, deſcending through a certain ſpace, always produces the ſame effect, whether it has deſcended ſwiftly or ſlowly, employing little or much time.

Had this eminent engineer propoſed this as a popular meaſure, of eaſy comprehenſion and remembrance, and as well accommodated to the uſes of thoſe engaged in the conſtruction of machines, when reſtricted to a certain claſs of caſes, it might have anſwered very good purpoſes; but the author is at pains to recommend it to the philoſophers as a neceſſary correction of their theories, which he ſays tend to miſlead the artiſts. His own reaſonings terminate in the ſame concluſion with Mr Leibnitz's, namely, that the power of producing a mechanical effect, and the effect produced, are proportional to the ſquare of the velocity. The deference juſtly due to Mr Smeaton's authority, and the influence of his name among thoſe who are likely to make the moſt uſe of his inſtructions, render it neceſſary for us to examine this matter with ſome attention.

Mr Smeaton was led to the adoption of this meaſure by his profeſſional habits. Raiſing a weight to a height is, in one ſhape or another, the general taſk of the machines he was employed to erect; and we may add, the opportunities of expending the mechanical powers of nature which are in our command, are generally in this proportion. A certain daily ſupply of water, coming from a certain height, is our beſt opportunity, and may very properly be ſaid to be expended.

4
xamined,

This being the general caſe, the meaſure was obvious, and natural, and good. The power and effect were of the ſame kind, and *muſt* be meaſures of each other; at leaſt, in thoſe circumſtances in which they were ſet in oppoſition Yet even here Mr Smeaton was obliged to make a reſtriction of his meaſures: "The height thro' which a body *ſlowly and equably* deſcended, or to which it was raiſed." And why was this limitation neceſſary? "Becauſe in rapid or accelerated motions, the inertia of bodies occaſioned ſome variation *." But this is too vague language for philoſophical diſquiſition. Beſides, what is meant by this variation? What is the ſtandard from which the unreſtricted meaſure varies? This ſtandard, whatever it is, is the true meaſure, and it was needleſs to adopt any other. Now, the ſtandard from which Mr Smeaton eſtimates the deviation, is the very meaſure which we wiſh to employ, namely, the quantity of motion produced. Strictly ſpeaking, even this is not the immediate meaſure. The immediate meaſure is that faculty which we call preſſure. This is the intermedium perceivable in all productions of motion; and it is alſo the intermedium of mechanical effect, even when motion is not produced; as when the weight of a body bends a ſpring, or the elaſticity of a body ſupports another preſſure. How it operates in all or any of theſe caſes, we know not; but we know that all theſe meaſures of preſſure agree with each other. A double quantity of motion will bend a ſpring doubly ſtrong, will raiſe a double weight, will withſtand any double preſſure, &c. &c. In ſhort, preſſure is the immediate agent in every mechanical phenomenon. It penetrates bodies, overcoming their tenacity; it overcomes friction; it balances preſſure; it produces motion. Mr Smeaton's meaſure is only nearly true, in any caſe, and in all caſes it is far from being exact in the firſt inſtants of the motion, during its acceleration or retardation.

Page 7.

We have already noticed the complete expenditure of animal power by continued preſſure, even when motion is not produced: the only difficulty is to connect this in a meaſurable way with the power which the ſame exertion has of generating motion in a body.

When a man ſupports a weight for a ſingle inſtant, he certainly balances the preſſure or action of gravity on that body; and he continues this action as long as he continues to ſupport it: and we know that if this body were at the end of a horizontal arm turning round a vertical axis, the ſame effort which the man exerted in merely carrying the weight, if now exerted on the body, by puſhing it horizontally round the axis, will generate in it the ſame velocity which gravity would generate by its falling freely. On this authority therefore we ſay, that the whole accumulated action of a man, when he has juſt carried a body whoſe weight is 30 pounds for one minute, is equal to the whole exertion of gravity on it during that minute; and if employed, not to counteract gravity, but to generate motion, would generate, during that minute, the ſame motion that gravity would, that is, 60 × 32 feet velocity per ſecond, in a maſs of 30 pounds. There would be 30 pounds of matter moving with the velocity of 1920 feet per ſecond. We would expreſs this production or effect by 30 × 1920, or by 57600, as the meaſure of the man's exertion during the minute.

But, according to Mr Smeaton, there is no expenditure of power, nor any production of mechanical effect, in thus carrying 30 pounds for a minute; there is no product of a weight by a height through which it is equably raiſed; yet ſuch exertion will completely exhauſt a man's ſtrength if the body be heavy enough. Here then is a caſe to which Mr Smeaton's meaſure does not readily apply; and this caſe is important, including all the actions of animals at a dead pull.

But let us conſider more narrowly what a man really does when he performs what Mr Smeaton allows to be the production of a meaſurable mechanical effect. Suppoſe this weight of 30 pounds hanging by a cord which paſſes over a pulley, and that a man, taking this cord over his ſhoulder, turns his back to the pulley, and walks away from it. We know, that a man of ordinary force will walk along, raiſing this weight, at the rate of about 60 yards in a minute, or a yard every ſecond, and that he can continue to do this for eight or ten hours from day to day; and that this is all that he can do without fatigue. Here are 30 pounds raiſed uniformly 180 feet in a minute; and Mr Smeaton would expreſs this by 30 × 180, or 5400, and would call this the meaſure of the mechanical effect, and alſo of the expenditure of power. This is very different from our meaſure 57600.

5
And found to be inaccurate.

But this is not an accurate and complete account of the man's *action* on the weight, and of the whole effect produced. To be convinced of this, ſuppoſe that a man A has been thus employed, while another B, walking along ſide of him at the ſame rate, ſuddenly takes the rope out of his hand, frees him of the taſk, and *continues* to raiſe the weight without the ſmalleſt change on its velocity of aſcent. What is the action of B, and whether is it the ſame with that of A or not? It is acknowledged by all, that the exertion of B againſt the load is preciſely equal to 30 pounds. If he holds the rope by a ſpring ſteelyard, it will ſtand conſtantly at the mark 30. B exerts the ſame action on the load as when

when he ſimply ſupports it from falling back into the pit. It was moving with the velocity of three feet per ſecond when he took hold of the rope, and it would continue to move with that velocity if any thing could annihilate or counteract its gravity. If therefore there was no action when a perſon merely carried it, there is none at preſent when it is riſing 180 feet in a minute. The man does indeed work more than on that occaſion, but not againſt the load: his additional work is walking, the motion of his own body, as a thing previouſly neceſſary that he may continue to ſupport the load, that he may continue his mechanical effort as it follows him. It appears to yield to him: but it is not to *his* efforts that it yields; its weight completely balances thoſe efforts, and is balanced by them. It was to a *greater* effort of the man A that it yielded. It was then lying on the ground. He pulled at the cord, gradually perhaps increaſing his pull till it was juſt equal to its weight. When this obtains, the load no longer preſſes on the ground, but is completely carried by the rope. But it does not move by this effort of 30 pounds; but let him exert a force of 31 pounds, and continue this for three ſeconds. He will put it in motion; will accelerate that motion; and at the end of three ſeconds the load is riſing with the velocity of three feet per ſecond. The man feels that this is as much ſpeed as he can continue in his walk; he therefore ſlackens his pull, reducing his action to 30 pounds, and with this action he walks on. All this would be diſtinctly perceived by means of a ſteelyard. The rod would be pulled out beyond 30, till the load acquired the uniform velocity intended, and after this it would be obſerved to ſhrink back to 30.

More is done therefore than appears by Mr Smeaton's meaſure. Indeed, all that appears in it is the exertion neceſſary for *continuing* a motion already produced, but which would be immediately extinguiſhed by a contrary power, which muſt therefore be counteracted. This meaſure will not apply to numberleſs caſes of the employment of machines, where there is no ſuch oppoſing power, and where, notwithſtanding, mechanical power muſt be expended, even according to Mr Smeaton's meaſurement. Such are corn mills, boring mills, and many others.

How then comes it that Mr Smeaton's valuable experiments concur ſo exactly in ſhewing that the ſame quantity of water deſcending from the ſame height, always produces the ſame effect (as he meaſured it), whatever be the velocity? In the firſt place, all his experiments are caſes where the power expended and the work performed are of the ſame kind: A heavy body deſcends, and by its preponderancy raiſes another heavy body. But even this would not enſure the preciſe agreement obſerved in his experiments, if Mr Smeaton were not careful to exclude from his calculations all that motion where there is any acceleration, and all the expenditure of water during the acceleration, and to admit only thoſe motions that are ſenſibly uniform. In moderate velocities, the additional preſſure required for the firſt acceleration is but an inſignificant part of the whole; and to take theſe accelerated motions into the account, would have embarraſſed the calculations, and perhaps confuſed many of the readers. We ſee, in the inſtance now given, that the addition of one pound continued for three ſeconds only, was all that was neceſſary.

Mr Smeaton's meaſurement is therefore abundantly exact for practice; and being accommodated to the circumſtances moſt likely to engage the attention, is very proper for the inſtruction of the numerous practitioners in all manufacturing countries who are employed for ordinary erections: but it is improperly propoſed as an article eſſential to a juſt theory of mechanics, and therefore it was proper to notice it in this place. Beſides, there frequently occur moſt important caſes, in which the motion of a machine is, of neceſſity, deſultory, alternately accelerated, and retarded. We ſhould not derive all the advantages in our power from the firſt mover, if we did not attend particularly, and chiefly, to the *accelerating* forces. And in every caſe, the improvement, or the proper employment of the machine, is not attained, if we are not able to diſcriminate between the two parts of the mechanical exertion; one of them, by which the motion is produced and accelerated to a certain degree; and the other, by which that motion is continued. We muſt be able to appreciate what part of the effect belongs to each.—But it is now time to proceed to the important queſtion,

What will be the preciſe motion of a machine of given conſtruction, actuated by a power of known intenſity and manner of acting, and oppoſed by a known reſiſtance?

6
Things to be conſidered in a machine at work.

In the ſolution of this queſtion, much depends on the nature of both power and reſiſtance. In the ſtatical conſideration of machines, no attention is paid to any differences. The intenſity of the preſſures is all that it is neceſſary to regard, in order to ſtate the proportion of preſſure which will be exerted in the various parts of the machine. The preſſures at the impelled and working points, combined with the proportions of the machine, neceſſarily determine all the reſt. Preſſure being the ſole cauſe of all mechanical action among bodies, any preſſure may be ſubſtituted for another that is equal to it; and the preſſure which is moſt familiar, or of eaſieſt conſideration, may be uſed as the repreſentative of all others. This has occaſioned the mechanical writers to make uſe of the preſſure of gravity as the ſtandard of compariſon, and to repreſent all powers and reſiſtances by weights. However proper this may be in their hands, it has hurt the progreſs of the ſcience. It has rendered the uſual elementary treatiſes of mechanics very imperfect, by limiting the experiments and illuſtrations to ſuch as can be ſo repreſented with facility. This has limited them to the ſtate of equilibrium (in which condition a working machine is never found), becauſe illuſtrations by experiment out of this ſtate are neither obvious nor eaſy. It has alſo prevented the ſtudents of mechanics from accompliſhing themſelves with the mathematical knowledge required for a ſucceſsful proſecution of the ſtudy. The moſt elementary geometry is ſufficient for a thorough underſtanding of equilibrium, or the doctrines of ſtatics; but true mechanics, the knowledge of machines as inſtruments by which work is performed, requires more refined mathematics, and is inacceſſible without it.

Had not Newton or others improved mathematics by the invention of the infiniteſimal analyſis and calculus, we muſt have reſted contented with the diſcoveries (really great) of Galileo and Huyghens. But Newton,

ton, *ſuâ matheſi facem præferente*, opened a boundleſs field of inveſtigation, and has not only given a magnificent and brilliant ſpecimen of the diſcoveries to be made in it, but has alſo traced out the particular paths in which we are to find the ſolution of all queſtions of practical mechanics. This he has done by ſhewing another ſpecies of equilibrium, indicated, not by the ceſſation of all motion, but by the uniformity of motion; by the ceſſation of all acceleration or retardation. As the extinction of motion by the action of oppoſite forces is aſſumed by us as the indication of the perfect equality of thoſe forces; ſo the extinction of acceleration ſhould be received as the indication of ſomething equal and oppoſite to the force which was known to have cauſed the acceleration; and therefore as the indication of an equilibrium between oppoſite forces, or elſe of the ceſſation of all force.

7 Mechanical quilibrium. This new view of things was the ſource of all our diſtinct notions of mechanical forces, and gave us our only unexceptionable marks and meaſures of them. The 39th propoſition of the firſt book of Newton's Principles of Natural Philoſophy, and its corollaries, contain almoſt the whole doctrine of active mechanical nature, and are peculiarly applicable to our preſent purpoſe, becauſe they enable us to comprehend in this *mechanical equilibrium* (ſo different from the *ſtatical)* every circumſtance in which thoſe preſſures which are exerted by natural powers differ from each other, and vary in their action on the impelled and working points of a machine. Indeed, when we recollect that the operations of our machines are the ſame on board a ſhip as on ſhore, and that all our machines are moving with the ground on which they ſtand, we muſt acknowledge, that even ordinary ſtatics is only an imperfect view of an equilibrium among things which are in motion; and this ſhould have taught us that, even in thoſe caſes where nothing like equilibrium appears, an equilibrium may ſtill be uſefully traced.

8 Diſtinctions nuſt be nade in the ature of he powers pplied to vorking nachines. In the ſtatical conſideration of machines, the *quantity* of preſſure is all that we need attend to. But in the mechanical diſcuſſion of their *operations*, we muſt attend to their diſtinctions in kind: and it will by no means be ſufficient to repreſent them all by weights; for their diſtinction in kind is accompanied by great differences in their manner of acting on the machine. Some natural powers, in order to continue their action on the impelled point of the machine, muſt at the ſame time put into motion a quantity of matter external to the machine, in which theſe powers reſide; and this muſt be made to follow the impelled point in its motion, and not only follow, but continue to preſs it forward; or, this matter, thus continually put into motion, muſt be ſucceſſively applied to different points of the machine, which become impelled points in their turn. This is the caſe with a weight, with the action of a ſpring, the action of animals, the action of a ſtream of water or wind, and many other powers. A part of the natural mechanical powers muſt therefore be employed in producing this external motion. This is ſometimes a very conſiderable part of the whole natural power. In ſome caſes it is the whole of it. This obtains in the action of a deſcending weight, lying on the end of a lever and preſſing it down, or hanging by a chord attached to the machine.

There is alſo an important diſtinction in the manner in which this external motion is kept up. In a weight employed as the moving power, the actuating preſſure ſeems to reſide in the matter itſelf; and all that is neceſſary for continuing this preſſure is merely to continue the connection of it with the machine. But in the action of animals it may be very different: A man puſhing at a capſtan bar, muſt firſt of all walk as faſt as the bar moves round, and this requires the expenditure of his muſcular force. But this alone will not render his action an effective power: He muſt alſo *preſs forward* the capſtan bar with as much force as he has remaining over and above what he expends in walking at that rate. The proportion of theſe two expenditures may be very different in different circumſtances; and in the judicious ſelection of ſuch circumſtances as make the firſt of theſe as inconſiderable as poſſible, lies much of the ſkill and ſagacity of the engineer. In the common operation of thraſhing corn, much more than half of the man's power is expended in giving the neceſſary motion to his own body, and only the remainder is employed in urging forward the ſwiple with a momentum ſufficient for ſhaking off the ripe grains from the ſtalk. We had ſufficient proof of this, by taking off the ſwiple of the flail, and putting the ſame weight of lead on the end of the ſtaff, and then cauſing the hind to perform the uſual motions of thraſhing with all the rapidity that he could continue during the ordinary hours of work. We never could find a man who could make three motions in the ſame time that he could make two in the uſual manner, ſo as to continue this for half an hour. Hence we muſt conclude, that half (ſome will ſay two-thirds) of a thraſher's power is expended in merely moving his own body. Such modes of animal action will therefore be avoided by a judicious engineer; but to be avoided, their inconvenience muſt be underſtood. More of this will occur hereafter.—In other caſes, we are almoſt (never wholly) free from this unprofitable expenditure of power. Thus, in the ſteam engine, the operation requires that the external air follow the piſton down the cylinder, in order to continue its preſſure. But the force neceſſary for ſending in this rare fluid into the cylinder with the neceſſary velocity, is ſuch an inſignificant part of the whole force which is at our command, that it would be ridiculous affectation in any engineer to take it into account; and this is one great ground of preference to this natural power. The ſame thing may be ſaid of the action of a ſtrong and light ſpring, which is therefore another very eligible firſt mover for machinery. The ancient artilleriſts had diſcovered this, and employed it in their warlike engines.

We muſt alſo attend to the nature of the reſiſtance which the work to be performed oppoſes to the motion of our machine. Sometimes the work oppoſes, not a ſimple obſtruction, but a real reſiſtance or reaction, which, if applied alone to the machine, would cauſe it to move the contrary way. This always obtains in caſes where a heavy body is to be raiſed, where a ſpring is to be compreſſed, and in ſome other caſes. Very often, however, there is no ſuch contrary action. A flour mill, a ſaw mill, a boring mill, and many ſuch engines, exhibit no reaction of this kind. But although ſuch machines, when at reſt or not impelled by the firſt mover, ſuſtain no preſſure in the oppoſite direction, yet they will not acquire any motion whatever, unleſs they be impelled by a power of a certain determinate intenſity. Thus in a ſaw mill, a certain force muſt be impreſſed on the teeth of the ſaw, that the cohеſion of the fibres of the timber may be overcome. This requires that a certain force, determined by the proportions of the machine, be impreſſed on the impelled point. If this, and no more, be applied there, a force will be excited at the teeth of the ſaw, which will *balance* the cohеſion of the wood, but will not *overcome* it. The machine will continue at reſt, and no work will be performed. Any addition of force at the impelled point, will occaſion an addition to the force excited in the teeth of the ſaw. The cohеſion will be overcome, the machine will move, and work will be performed. It is only this *addition* to the impelling power that gives motion to the machine; the reſt being expended merely in balancing the cohеſion of the woody fibres. While therefore the machine is in motion, performing work, we muſt conſider it as actuated by a force impreſſed on the impelled point by the natural power, and by another acting at the working point, furniſhed by or derived from the reſiſtance of the work.

Again: It not unfrequently happens, that there is not even any ſuch reſiſtance or obſtruction excited at the working point of the machine; the whole reſiſtance (if we can with propriety give it that name) ariſes from the neceſſity of giving motion to a quantity of inert and inactive matter. This happens in urging round a heavy fly, as in the coining preſs, in the punching engine, in drawing a body along a horizontal plane without friction, and a few ſimilar caſes. Here the ſmalleſt force whatever, applied at the impelled point, will begin motion in the machine; and the *whole* force ſo applied is conſumed in this ſervice. Such caſes are rare, as the ultimate performance of a machine; but occaſionally, and for a farther purpoſe, they frequently occur; and it is neceſſary to conſider them, becauſe there are many of the moſt important applications of machinery where a very conſiderable part of the force is expended in this part of the general taſk.

Such are the chief circumſtances of diſtinction among the mechanical powers of nature which muſt be attended to, in order to know the motion and performance of a machine. Theſe never occur in the ſtatical conſideration of the machine, but here they are of chief importance.

9
The inertia of the machine itſelf muſt alſo be conſidered,

But farther: The action of the moving power is transferred to the working point through the parts of a machine, which are material, inert, and heavy. Or, to deſcribe it more accurately, before the neceſſary force can be excited at the working point of the machine, the various connecting forces muſt be exerted in the different parts of the machine; and in order that the working point may follow out the impreſſion already made, all the connecting parts or limbs of the machine muſt *be moved*, in different directions, and with different velocities. Force is neceſſary for thus changing the ſtate of all this matter, and frequently a very conſiderable force. Time muſt alſo elapſe before all this can be accompliſhed. This often conſumes, and really waſtes, a great part of the impelling power. Thus, in a crane worked by men walking in a wheel, it acquires motion by ſlow degrees; becauſe, in order to give ſufficient room for the action of the number of men or cattle that are neceſſary, a very capacious wheel muſt be employed, containing a great quantity of inert matter. All of this muſt be put in motion by a very moderate preponderance of the men. It accelerates ſlowly, and the load is raiſed. When it has attained the required height, all this matter, now in conſiderable motion, muſt be ſtopped. This cannot be done in an inſtant with a jolt, which would be very inconvenient, and even hurtful; it is therefore brought to reſt gradually. This alſo conſumes time; nay, the wheel muſt get a motion in the contrary direction, that the load may be lowered into the cart or lighter. This can only be accompliſhed by degrees. Then the tackle muſt be lowered down again for another load, which alſo muſt be done gradually. All this waſtes a great deal both of time and of force, and renders a walking wheel a very improper form for the firſt mover of a crane, or any machine whoſe uſe requires ſuch frequent changes of motion. The ſame thing obtains, although in a lower degree, in the ſteam engine, where the great beam and pump rods, ſometimes weighing very many tons, muſt be made to acquire a very briſk motion in oppoſite directions twice in every working ſtroke. It obtains, in a greater or a leſs degree, in all engines which have a reciprocating motion in any of their parts. Pump mills are of neceſſity ſubjected to this inconvenience. In the famous engine at Marly, about $\frac{19}{20}$ of the whole moving power of ſome of the water wheels is employed in giving a reciprocating motion to a ſet of rods and chains, which extend from the wheels to a ciſtern about three-fourths of a mile diſtant, where they work a ſet of pumps. This engine is, by ſuch injudicious conſtruction, a monument of magnificence, and the ſtruggle of ignorance with the unchangeable laws of Nature. In machines, all the parts of which continue the direction of their motions unchanged, the inertia of a great maſs of matter does no harm; but, on the contrary, contributes to the ſteadineſs of the motion, in ſpite of ſmall inequalities of power or reſiſtance, or unavoidable irregularities of force in the interior parts. But in all reciprocations, it is highly prejudicial to the performance; and therefore conſtructions which admit ſuch reciprocation without neceſſity, are avoided by all intelligent engineers. The mere copying artiſt, indeed, who derives all his knowledge from the common treatiſes of mechanics, will never ſuſpect ſuch imperfections, becauſe they do not occur in the ſtatical conſideration of machines.

10
And its friction.

Laſtly, no machine can move without a mutual rubbing of its parts, at all points of communication; ſuch as the teeth of wheelwork, the wipers and lifts, and the gudgeons of its different axes. In many machines, the ultimate taſk performed by the working point, is either friction, or very much reſembles it. This is the caſe in poliſhing mills, grinding mills, nay in boring mills, ſaw mills, and others. A knowledge of friction, in all its varieties, ſeems therefore abſolutely neceſſary, even for a moderate acquaintance with the principles of machinery. This is a very abſtruſe ſubject; and although a good deal of attention has been paid to it by ſome ingenious men, we do not think that a great deal has been added to our knowledge of it; nor do the experiments which have been made ſeem to us well calculated to lead us to a diſtinct knowledge of its nature and modifications. It has been conſidered chiefly with a view to diminiſh it as much as poſſible in the communicating parts

parts of machinery, and to obtain ſome general rules for aſcertaining the quantity of what unavoidably remains. Mr Amontons, of the Royal Academy of Sciences at Paris, gave us, about the beginning of this century, the chief information that we have on the ſubject. He diſcovered, that the obſtruction which it gave to motion was very nearly proportional to the force by which the rubbing ſurfaces are preſſed together. Thus he found, that a ſmooth oaken board, laid on another ſmooth board of the ſame wood, requires a force nearly equal to one third of what preſſes the ſurfaces together. Different ſubſtances required different proportions.

11 Meaſure of it by Amontons. He alſo found, that neither the extent of the rubbing ſurfaces, nor the velocity of the motion, made any conſiderable variation on the obſtruction to motion. Theſe were curious and unexpected reſults. Subſequent obſervations have made ſeveral corrections neceſſary in all theſe propoſitions. This ſubject will be more particularly conſidered in another place; but ſince the deviations from Mr Amontons's rule are not very conſiderable, at leaſt in the caſes which occur in this general conſideration of machines, we ſhall make uſe of it in the mean time. It gives us a very eaſy method of eſtimating the effect of friction on machines. It is a certain proportion of the mutual preſſure of the rubbing ſurfaces, and therefore muſt vary in the ſame proportion with this preſſure. Now, we learn from the principles of ſtatics, that whatever preſſures are exerted on the impelled and working point of the machine, all the preſſures on its different parts have the ſame conſtant proportion to theſe, and vary as theſe vary: Therefore the whole friction of the machine varies in the ſame proportion. But farther, ſince it is found that the friction does not ſenſibly change with the velocity, the force which is juſt ſufficient to overcome the friction, and put the loaded machine in motion, muſt be very nearly the ſame with the force expended in overcoming the friction while the machine is moving with any velocity whatever, and performing work. Therefore if we deduct from the force which juſt puts the loaded machine in motion that part of it which balances the reaction of the impelled point occaſioned by the reſiſtance of the work, or which balances the reſiſtance of the work, the remainder is the part of the impelling power which is employed in overcoming the friction. If indeed the actual reſiſting preſſure of the work varies with the velocity of the working point, all the preſſures, and all the frictions in the different communicating parts of the machine, vary in the ſame proportion. But the law of this variation of working reſiſtance being known, the friction is again aſcertained.

We can now ſtate the dynamical equilibrium of forces in the working machine in two ways. We may either conſider the efficient impelling power as diminiſhed by all that portion which is expended in overcoming the friction, and which only prepares the machine for performing work, or we may conſider the impelling power as entire, and the work as increaſed by the friction of the machine; that is, we may ſuppoſe the machine without friction, and that it is loaded with a quantity of additional reſiſtance acting at the working point. Either of theſe methods will give the ſame reſult, and each has its advantages. We took the laſt method in the ſlight view which we took of this ſubject in the *Encycl.* art. ROTATION, nº 64. and ſhall therefore uſe it here.

Suppoſing now this previous knowledge of all theſe variable circumſtances which affect the motion of machines of the rotative kind, ſo that, for any momentary poſition of it while performing work, we know what are the preciſe preſſures acting at the impelled and working points, and the conſtruction of the machine, on which depend the friction, and the momentum of its inertia (expreſſed in the article ROTATION by $\int p r^2$); we are now in a condition to determine its motion, or at leaſt its momentary acceleration, competent to that poſition. Therefore,

12 Compoſition of the formula expreſſing the performance of a machine. Let there be a rotative machine, ſo conſtructed, that while it is performing work, the velocity of its impelled point is to that of its working point as m to n. It is eaſy to demonſtrate, from the common principles of ſtatics, that if a ſimple wheel and axle be ſubſtituted for it, having the radius of the wheel to that of the axle in the ſame proportion of m to n, and having the ſame momentum of friction and inertia, and actuated by the ſame preſſures at the impelled and working points, then the velocities of theſe points will be preciſely the ſame as in the given machine.

Let p repreſent the intenſity (which may be meaſured by pounds weight) of the preſſure exerted in the moment at the impelled point; and r expreſs the preſſure exerted at the working point by the reſiſtance oppoſed by the work that is then performing. This may ariſe from the weight of a body to be raiſed, from the coheſion of timber to be ſawed, &c. Any of theſe reſiſtances may alſo be meaſured by pounds weight; becauſe we know, that a certain number of pounds hung on the ſaw of a ſaw mill, will juſt overcome this coheſion, or overcome it with any degree of ſuperiority. Therefore the impelling power p, and the reſiſtance r, however differing in kind, may be compared as mere preſſures.

Let x repreſent the quantity of inert matter which muſt be urged by the impelling power p, with the ſame velocity as the impelled point, in order that this preſſure p may really continue to be exerted on that point. Thus, if the impelling power is a quantity of water in the bucket of an overſhot wheel, acting by its weight, this weight cannot impel the wheel except by impelling the water. In this way, x may be conſidered as repreſenting the inertia of the impelling power, while p repreſents its preſſure on the machine. In like manner, let y repreſent the quantity of external inert matter which is really moved with the velocity of the working point in the execution of the taſk performed by the machine.

Whatever be the momentum of the inertia of the machine, we can always aſcertain what quantity of matter, attached to the impelled point, or the working point of the wheel and axle, will require the ſame force to give the wheel the ſame angular motion; that is, which ſhall have the ſame momentum of inertia. Let the quantity a, attached to the working point, give this momentum of inertia $a n^2$.

Laſtly, ſuppoſing that the wheel and axle have no friction, let f be ſuch a reſiſtance, that if applied to the working point, it ſhall give the ſame obſtruction as the friction of the machine, or require the ſame force at the impelled point to overcome it.

13 Angular motion of the machine.

Theſe things being thus eſtabliſhed, the angular velocity of the wheel and axle, that is, the number of turns, or the portion of a turn, which it will make in a given time, will be proportional to the fraction $\frac{pm - \overline{r+f}\,n}{xm^2 + \overline{a+y}\,n^2}$. (I.)—See ROTATION, n° 64, &c. *Encycl.*

Since the whole turns together, the velocities of the different points are as their diſtances from the axis, and may be expreſſed by multiplying the common angular velocity by theſe diſtances. Therefore the above formulæ, multiplied by *m* or *n*, will give the velocity of the impelled or of the working point. Therefore,

14 Velocity of the impelled point.

$$\text{Velocity of impelled point} = \frac{pm^2 - \overline{r+f}\,mn}{xm^2 + \overline{a+y}\,n^2}. \text{ (II.)}$$

15 Velocity of the working point.

$$\text{Velocity of working point} = \frac{pmn - \overline{r+f}\,n^2}{xm^2 + \overline{a+y}\,n^2}. \text{ (III.)}$$

In order to obtain a clear conception of theſe velocities, we muſt compare them with motions with which we are well acquainted. The propoſition being univerſally true, we may take a caſe where gravity is the ſole power and reſiſtance; where, for example, *p* and *r* are the weights of the water in the bucket of a wheel, and in the tub that is raiſed by it. In this caſe, $p = x$, and $r = y$. We may alſo, for greater ſimplicity, ſuppoſe the machine without inertia and friction. The velocity of *p* is now $\frac{pm^2 - rmn}{pm^2 + rn^2}$.

16 Abſolute meaſure of them.

Let *g* be the velocity which gravity generates in a ſecond. Then it will generate the velocity $g\dot{t}$ in the moment $\dot{t}$. Let $\dot{v}$ be the velocity generated during this moment in *p*, connected as it is with the wheel and axle, and with *r*. This connection produces a change of condition $= g\dot{t} - \dot{v}$. For, had it fallen freely, it would have acquired the velocity $g\dot{t}$, whereas it only acquires the velocity $\dot{v}$. In like manner, had *r* fallen freely, it would have acquired the velocity $g\dot{t}$. But, inſtead of this, it is raiſed with the velocity $\frac{n}{m}\dot{v}$. The change on it is therefore $= g\dot{t} + \frac{n}{m}\dot{v}$. Theſe changes of mechanical condition ariſe from their connection with the corporeal machine Their preſſures on it bring into action its connecting forces, and each of the two external forces is in immediate equilibrium with the force exerted by the other. The force excited at the impelled point, by *r* acting at the working point, may be called the momentum or energy of *r*. Theſe energies are preciſely competent to the production of the changes which they really produce, and muſt therefore be conceived as having the ſame proportions. They are therefore equal and oppoſite, by the general laws *obſerved* in all actions of tangible matter; that is, they are ſuch as balance each other. Thus, and only thus, the remaining motions are what we obſerve them to be.

$$\text{That is, } p \times \overline{g\dot{t} - \dot{v}} \times m = r \times \overline{gt + \frac{n}{m}\dot{v}} \times n$$

$$\text{Or } pmg\dot{t} - pm\dot{v} = rng\dot{t} + r\frac{n^2}{m}\dot{v}$$

$$\text{Or } pm^2g\dot{t} - pm^2\dot{v} = rmng\dot{t} + rn^2\dot{v}$$

$$\text{Or } \overline{pm^2 - rmn} \times g\dot{t} = \overline{pm^2 + rn^2} \times \dot{v}$$

That is, $pm^2 + rn^2 : pm^2 - rmn = g\dot{t} : \dot{v}$

That is, *the denominator of the fraction, expreſſing the velocity of the impelled point, is to the numerator as the velocity which a heavy body would acquire in the moment* $\dot{t}$, *by falling freely, is to the velocity which the impelled point acquires in that moment.* The ſame thing is true of the velocity of the working point.

This reaſoning ſuffers no change from the more complicated nature of the general propoſition. Here the impelling power is ſtill *p*, but the matter to be accelerated by it at the working point is $a + y$, while its reaction, diminiſhing the impelling power, is only *r*. We have only to conſider, in this caſe, the velocity with which $a + y$ would fall freely when impelled, not by $a + y$, but only by *r*. The reſult would be the ſame; $g\dot{t}$ would ſtill be to $\dot{v}$ as the denominator of the ſame fraction to its numerator.

Thus have we diſcovered the momentary acceleration of our machine. It is evident, that if the preſſures *p* and *r*, and the friction and inertia of the machine, and the external matter, continue the ſame, the acceleration will continue the ſame; the motion of rotation will be uniformly accelerated, and $pm^2 + \overline{a+y}\,n^2$ will be to $pm^2 - \overline{r+f}\,mn$ as the ſpace *s*, through which a heavy body would fall in any given time *t*, is to the ſpace through which the impelled point will really have moved in the ſame time. In like manner, the ſpace through which the working point moves in the ſame time is $= \frac{pmn - \overline{r+f}\,n^2}{pm^2 + \overline{a+y}\,n^2}s$.

Thus are the motions of the working machine determined. We may illuſtrate it by a very ſimple example. Suppoſe a weight *p* of five pounds, deſcending from a pulley, and dragging up another weight *r* of three pounds on the other ſide. *m* and *n* are equal, and each may be called 1. The formula becomes $\frac{p-r}{p+r}s$, or $\frac{5-3}{5+3}s$, or $\frac{2}{8}$, $= \frac{1}{4}s$. Therefore, in a ſecond, the weight *p* will deſcend $\frac{1}{4}$th of 16 feet, or 4 feet; and will acquire the velocity of 8 feet per ſecond.

17 Performance of the machine.

Having obtained a knowledge of the velocity of every point of the machine, we can eaſily aſcertain its performance. This depends on a combination of the quantity of reſiſtance that is overcome at the working point, and the velocity with which it is overcome. Thus, in raiſing water, it depends on the quantity (proportional to the weight) of water in the bucket or pump, and the velocity with which it is lifted up. This will be had by multiplying the third formula by *r*, or by $rg\dot{t}$, or by *r s*. Therefore we obtain this expreſſion,

$$\text{Work done} = \frac{pmrn - \overline{r+f}\,rn^2}{pm^2 + \overline{a+y}\,n^2}g\dot{t}. \text{ (IV.)}$$

Such is the general expreſſion of the momentary performance of the machine, including every circumſtance which can affect it. But a variation of thoſe circumſtances produces great changes in the reſults. Theſe muſt be diſtinctly noticed.

Cor. 1. If $pmrn$ be equal to $\overline{r+f}\,rn^2$, there will be no work done, becauſe the numerator of the fraction is annihilated. There is then no unbalanced force, and the

the natural power is only able to balance the preſſure propagated from the working point to the impelled point.

2. In like manner, if $n = o$, no work is done altho' the machine turns round. The working point has no motion. For the ſame reaſon, if m be infinitely great, although there is a great prevalence of impelling momentum, there will not be any ſenſible performance during a finite time. For the velocity which p can impreſs is a finite quantity, and the impelled point cannot move faſter than x would be moved by it if detached from the machine. Now when the infinitely remote impelled point is moved through any finite ſpace, the motion of the working point muſt be infinitely leſs, or nothing, and no work will be done.

Remark. We ſee that there are two values of n, viz. v, and $m \times \frac{p}{r}$, which give no performance. But in all other proportions of m and n ſome work is done. Therefore, as we gradually vary the proportion of m to n, we obtain a ſeries of values expreſſing the performance, which muſt gradually increaſe from nothing, and then decreaſe to nothing. There muſt therefore be ſome proportion of m to n, depending on the proportion of p to $\overline{r+f}$, and of x to $\overline{a+y}$, which will give the greateſt poſſible value of the performance. And, on the other hand, if the proportion of m to n be already determined by the conſtruction of the machine already erected, there muſt be ſome proportion of p to $\overline{r+f}$, and of x to $a+y$, by which the greateſt performance of the machine may be enſured. It is evident, that the determination of theſe two proportions is of the utmoſt importance to the improvement of machines. The well informed reader will pardon us for endeavouring to make this appear more forcibly to thoſe who are leſs inſtructed, by means of ſome very ſimple examples of the firſt principle.

Suppoſe that we have a ſtream of water affording three tons per minute, and that we want to drain a pit which receives one ton per minute, and that this is to be done by a wheel and axle? We wiſh to know the beſt proportion of their diameters m and n. Let m be taken $= 6$; and ſuppoſe,

1. That $n = 5$.

Then $\frac{p\,m\,r\,n - r^2 n^2}{p\,m^2 + r\,n^2} = \frac{3.6.1.5 - 1.25}{3.36 + 1.36}, = \frac{65}{133}, = 0,4887$

2. Let n be $= 6$. The formula is $= 0,5$.

3. Let $n = 7$. The formula is $= 0,49045$. Hence we find, that the performance is greater when n is 6, than when it is either 5 or 7.

As an example of the ſecond principle, ſuppoſe the machine a ſimple pulley, and let p be 10.

1. Let r be $= 3$. The formula is $\frac{10 \times 3 - 9}{10 + 3}, = \frac{21}{13}, = 1,6154$.

2. Let r be $= 4$. The formula is $= \frac{10 \times 4 - 16}{10 + 4}, = \frac{24}{14}, = 1,7143$.

3. Let r be $= 5$. The formula is $= \frac{10 \times 5 - 25}{10 + 5}, = \frac{25}{15}, = 1,6666$. Here it appears, that more work is done when r is 4 than when it is 5 or 3.

It muſt therefore be allowed to be one of the moſt important problems in practical mechanics to determine that conſtruction by which a given power ſhall overcome a given reſiſtance with the greateſt advantage, and the proportion of work which ſhould be given to a machine already conſtructed ſo as to gain a ſimilar end.

18 Proportion of the machine which gives the greateſt work.

I. The general determination of the firſt queſtion has but little difficulty. We muſt conſider n as the variable magnitude in the formula $\frac{p\,m\,r\,n - \overline{r+f}\,r\,n^2}{p\,m^2 + \overline{a+y}\,n^2}$, which expreſſes the work done; and find its value when the formula is a maximum. Taking this method, we ſhall find that the formula IV. is a maximum when n is

$$= m\,\frac{\sqrt{x^2(r+f)^2 + p^2 x(a+y)} - x(r+f)}{p(a+y)}.$$

This expreſſion of the performance, in its beſt ſtate, appears pretty complex; but it becomes much more ſimple in all the particular applications of it, as the circumſtances of the caſe occur in practice.

We have obtained a value of n expreſſed in parts of m If we ſubſtitute this for n in the third formula, we obtain the greateſt velocity with which the reſiſtance r, connected with the inertia y, can be overcome by the power p, connected with the inertia x, by the intervention of a machine, whoſe momentum of inertia and friction are $a\,n^2$ and $f\,n$. This is $= \frac{r+f}{2\,\overline{a+y}} \times \left(\sqrt{\frac{p^2\,\overline{a+y}}{\overline{r+f}^2\,x} + 1} - 1\right) g\,t$. This expreſſes the velocity of the working point in feet per ſecond, and therefore the actual performance of the machine.

But the proper proportion of m to n, aſcertained by this proceſs, varies exceedingly, according to the nature both of the impelling power, and of the work to be performed by the machine.

1. It frequently happens that the work exerts no contrary ſtrain on the machine, and conſiſts merely in impelling a body which reſiſts only by its inertia. This is the caſe in urging round a millſtone or a heavy fly; in urging a body along a horizontal plane, &c. In this caſe r does not enter into the formula, which now becomes $m \times \frac{\sqrt{x^2 f^2 + p^2 x(a+y)} - x\,f}{p(a+y)}$. If the friction be inſignificant we may take $n = m\sqrt{\frac{p^2 x(a+y)}{p^2(a+y)^2}} = m\sqrt{\frac{x}{a+y}}$. The velocity of the working point is nearly $= \frac{p}{2\sqrt{x\,\overline{a+y}}}$. In this caſe, it will be found that the velocity acquired at the end of a given time will be nearly in the proportion of the power applied to the machine.

2. On the other hand, and more frequently, the inertia of the external matter which muſt be moved in performing the work need not be regarded. Thus, in the grinding of grain, ſawing of timber, boring of cylinders, &c. the quantity of motion communicated to the flour, to the ſaw duſt, &c. is too inſignificant to be taken into the account. In this caſe, y vaniſhes from the formula, which becomes extremely ſimple when the friction and inertia of the machine are inconſiderable. We

ſhall not be far from the truth if we make m to n as $2r$ to p, or $n = m \times \frac{p}{2r+f}$. In this caſe, the velocity of the working point is $\frac{p^2}{4x(r+f)+\frac{ap^2}{4(r+f)}}$.

But it is rare that machines of this kind have a ſmall inertia. They are generally very ponderous and powerful; and the force which is neceſſary for generating even a very moderate motion in the unloaded machine (that is, unloaded with any work), bears a great proportion to the force neceſſary for overcoming the reſiſtance oppoſed by the work. The formula muſt therefore be uſed in all the terms, becauſe a is joined with y. It would have been ſimpler in this particular, had a been joined with x in the expreſſion of the angular velocity.

3. In ſome caſes we need not attend to the inertia of the power, as in the ſteam engine. In this caſe, if taken ſtrictly, n appears to have no value, becauſe x is a factor of every term of the numerator. But the formula gives this general indication, that the more inſignificant the inertia of the moving power is ſuppoſed, the larger ſhould m be in proportion to n; provided always, that the impelling power is not, by its nature, greatly diminiſhed, by giving ſo great a velocity to the impelled point. This circumſtance will be particularly conſidered afterwards.

4. If the inertia of the power and the reſiſtance be proportional to their preſſures, as when the impelling power is water lying in the buckets of an overſhot wheel, and the work is the raiſing of water, minerals, or other heavy body, acting *only* by its weight; then p and r may be ſubſtituted for x and y, and the formula expreſſing the value of n, when the performance is a maximum, becomes

$$n = m\frac{\sqrt{p^2\times\overline{r+f}^2+p^3\times\overline{a+r}}-p\times\overline{r+f}}{p\times\overline{a+r}}.$$

If, in this caſe, the inertia and friction of the machine may be diſregarded, as may often be done in pulleys, we have

$$n = m\sqrt{\frac{p}{r}+1}-1.$$

If we make m the unit of the radii, and r the unit of force, we have

$$n = \sqrt{p+1}-1, \text{ in parts of } m = 1.$$

Or, making $p = 1$, we have $n = \sqrt{\frac{1}{r}+1}-1$.

Theſe very ſimple expreſſions are of conſiderable uſe, even in caſes where the inertia of the machine is very conſiderable, provided that it have no reciprocating motions. A ſimple wheel and axle, or a train of good wheelwork, have very moderate friction. The general reſults, therefore, which even very unlettered readers can deduce from theſe ſimple formulæ, will give notions that are uſeful in the caſes which they cannot ſo thoroughly comprehend. Some ſervice of this kind may be derived from the following little table of the beſt proportions of m to n, correſponding to the proportions of the power furniſhed to the engineer, and the reſiſtance which muſt be overcome by it. The quantity r is always $= 10$, and $m = 1$.

p	n	p	n
1	0,0488	10	0,4142
2	0,0954	20	0,7321
3	0,1402	30	1,
4	0,1832	40	1,2362
5	0,2246	50	1,4495
6	0,2649	60	1,6457
7	0,3038	70	1,8284
8	0,3416	80	2,
9	0,3784	90	2,1623
10	0,4142	100	2,3166

This muſt ſuffice for a very general view of the firſt problem.

19 Beſt proportion of the power and work.

II. The next queſtion is not leſs momentous, namely, to determine for a machine of a given conſtruction that proportion of the reſiſtance at the working point to the impelling power which will enſure the greateſt performance of the machine; that is, the proportion of m to n being given, to find the beſt proportion of p to r.

This is a much more complicated problem than the other; for here we have to attend to the variations both of the preſſures p and r, and alſo of the external matters x and y, which are generally connected with them. It will not be ſufficient therefore to treat the queſtion by the uſual fluxionary proceſs for determining the maximum, in which r is conſidered as the only varying quantity. We muſt, in this curſory diſcuſſion, reſt ſatisfied with a comprehenſion of the circumſtances which moſt generally prevail in practice.

It muſt either happen, that when r changes, there is no change (that is, of moment) in the maſs of external matter which muſt be moved in performing the work, or that there is alſo a change in this circumſtance. If no change happens, the denominator of the fourth formula, expreſſing the performance, remains the ſame; and then the formula attains a maximum when the numerator $prmn - \overline{r+f}\,rn^2$ is a maximum. Alſo, we may include f without complicating the proceſs, by the conſideration, that f is always in nearly the ſame ratio to r; and therefore $r+f$ may be conſidered as a certain multiple of r, ſuch as br. We may therefore omit f in the fluxionary equations for obtaining the maximum, and then, in computing the performance, divide the whole by b. Thus if the whole friction be $\frac{1}{20}$th of the reſiſting preſſure r, we have $r+f = \frac{21}{20}$ of r, and $b = \frac{21}{20}$. Having aſcertained the beſt value for r, we put this in its place in the fourth formula, and take $\frac{20}{21}$ of this for the performance. This will never differ much from the truth.

This proceſs gives us $pmn = 2n^2r$, and $r = \frac{pmn}{2n^2}$, $= \frac{pm}{2n}$; and if we farther ſimplify the proceſs, by making $p = 1$, and $m = 1$, we have $r = \frac{1}{2n}$; a moſt ſimple expreſſion, directing us to make the reſiſtance one half of what would balance the impelling power by the intervention of the machine.

This will evidently apply to many very important caſes,

caſes, namely, to all thoſe in which the matter put in motion by the working point is but trifling.

But it alſo happens in many important caſes, that the change is at leaſt equally conſiderable in the inertia of the work. In this caſe it is very difficult to obtain a general ſolution. But we can hardly imagine ſuch a change, without ſuppoſing that the inertia of the work varies in the ſame proportion as the preſſure excited by it at the working point of the machine; for ſince r continues the ſame in kind, it can rarely change but by a proportional change of the matter with which it is connected. Yet ſome very important caſes occur where this does not happen. Such is a machine which forces water along a long main pipe. The reſiſtance to motion and the quantity of water do not follow nearly the ſame ratio. But in the caſes in which this ratio is obſerved, we may repreſent y by any multiple $b\,r$ of r, which the caſe in hand gives us; b being a number, integer, or fractional. In the farther treatment of this caſe, we think it more convenient to free r from all other combinations; and inſtead of ſuppoſing the force f (which we made equivalent with the friction of the machine) to be applied at the working point, we may apply it at the impelled point, making the effective power $q = p - f$. For the ſame reaſons, inſtead of making the momentum of the machine's inertia $= a\,n^2$, we may make it $a\,m^2$, and make $a + x = z$. Now, ſuppoſing q, or $p - f$, $= 1$, and alſo $m = 1$, our formula expreſſing the performance becomes $\frac{r\,n - r^2\,n^2}{z + b\,r\,n^2}$. This is a maximum when

$$r = \frac{\sqrt{z^2 + z\,b\,n} - z}{b\,n^2}.$$

Cor. 1. If the inertia of the work is always equal to its preſſure, as when the work conſiſts wholly in raiſing a weight, ſuch as drawing water, &c. then $b = 1$, and the formula for the maximum performance becomes

$$r = \frac{\sqrt{z\,n + z^2} - z}{n^2}.$$

2. If the inertia of the impelling power is alſo the ſame with its preſſure, and if we may neglect the inertia and friction of the machine, the formula becomes

$$r = \frac{\sqrt{n + 1} - 1}{n^2}.$$

Example. Let the machine be a common pulley, ſo that the radii m and n are equal, and therefore $n = 1$. Then, $r = \frac{\sqrt{1 + 1} - 1}{1}, = \sqrt{2} - 1, = 0{,}4142$, &c. more than $\frac{2}{5}$ths of what would balance it.

Here follows a ſeries of the beſt values of r, correſponding to different values of n. m and p are each $= 1$. The numbers in the laſt column have the ſame proportion to 1 which r has to the reſiſtance which will balance p.

$n = \frac{1}{4}$	$r =$ 1,8885	0,4724 to 1
$\frac{1}{3}$	1,3928	0,4639
$\frac{1}{2}$	0,8986	0,4493
1	0,4142	0,4142
2	0,1830	0,3660
3	0,1111	0,3333
4	0,0772	0,3088

From what has now been eſtabliſhed, we ſee with ſufficient evidence the importance of the higher mathematics to the ſcience of mechanics. If the velocities of the impelled and working points of an engine are not properly adjuſted to the preſſures, the inertia, and the friction of the machine, we do not derive all the advantages which we might from our ſituation. Hence alſo we learn the falſity of the maxim which has been received as well founded, that the augmentation of intenſity of any force, by applying it to the long arm of a lever, is always fully compenſated by a loſs of time; or, as it is uſually expreſſed, "what we gain by a machine in force we loſe in time." If the proportion of m to n is well choſen, we ſhall find that the work done, when it reſiſts by its inertia only, increaſes nearly in the proportion of the power employed; whereas when the inertia of the work is but a ſmall part of the reſiſtance, it increaſes nearly in the duplicate ratio of the power employed.

General but erroneous maxim.

It was remarked, in the ſetting out in the preſent problem, that the formulæ do not immediately expreſs the velocity of any point of the machine, but its momentary acceleration. But this is enough for our purpoſe; becauſe, when the momentary acceleration is a maximum, the velocity acquired, and the ſpace deſcribed, in any given time, is alſo a maximum. We alſo ſhewed how the real velocities, and the ſpaces deſcribed, may be aſcertained in known meaſures. We may ſay in general, that if g repreſent the preſſure of gravity on any maſs of matter w, then $\frac{g}{w}$ is to $\frac{p\,m\,n - \overline{r + f}\,n}{a\,m^2 + a + y\,n^2}$ as 16 feet to the ſpace deſcribed in a ſecond by the working point in a ſecond, or as 32 feet per ſecond is to the velocity acquired in that time.

20
Cauſes why machines do not continually accelerate.

A remark now remains to be made, which is of the greateſt conſequence, and gives an unexpected turn to the whole of the preceding doctrines. It appears, from all that has been ſaid, that the motion of a machine muſt be uniformly accelerated, and that any point will deſcribe ſpaces proportional to the ſquares of the times; for while the preſſures, friction, and momentum of inertia remain the ſame, the momentary acceleration muſt alſo be invariable. But this ſeems contrary to all experience. Such machines as are properly conſtructed, and work without jolts, are obſerved to quicken their pace for a few ſeconds after ſtarting; but all of them, in a very moderate time, acquire a motion that is ſenſibly uniform. Is our theory erroneous, or what are the circumſtances which remain to be conſidered, in order to make it agree with obſervation? The ſcience of machines is imperfect, till we have explained the cauſes of this deviation from the theory of uniform acceleration.

Theſe cauſes are various.

1. Increa of friction

1. In ſome caſes, every increaſe of velocity of the machine produces an increaſe of friction in all its communicating parts. By theſe means, the accelerating force, which is $p\,m - \overline{r + f\,n}$, or $\overline{p - f}\,m - r\,n$, is diminiſhed, and conſequently the acceleration is diminiſhed. But it ſeldom happens that friction takes away or employs the whole accelerating force. We are not yet well inſtructed in the nature of friction. Moſt of the kinds of friction which obtain in the communicating parts of machines, are ſuch as do not ſenſibly increaſe by an increaſe of velocity; ſome of them really diminiſh. Yet even the moſt accurately conſtructed machines, unloaded with work, attain a motion that is ſenſibly uniform. If we take off the pallets from a pendulum

dulum clock, and allow it to run down amain, it accelerates for a while, but in a very moderate time it acquires an uniform motion. So does a common kitchen jack. Theſe two machines ſeem to bid the faireſt of any for an uniformly accelerated motion; for their impelling power acts with the utmoſt uniformity. There is ſomething yet unexplained in the nature of friction, which takes away ſome of this acceleration.

2. Reſiſtance of air. But the chief cauſe of its ceſſation in theſe two inſtances, and others *of very rapid motion*, is the reſiſtance of the air. This ariſes from the motion which is communicated to the air diſplaced by the ſwift moving parts of the machine. At firſt it is very ſmall; but it increaſes nearly in the duplicate ratio of the velocity (ſee *Reſiſtance of Fluids*, Encycl.) Thus r increaſes continually; and, in a certain ſtate of motion, $\overline{r + f n}$ becomes equal to $p m$. Whenever this happens, the accelerating power is at an end. The acceleration alſo ceaſes; and the machine is in a ſtate of dynamical equilibrium; not at reſt, but moving uniformly, and performing work.

3. Increaſe of reſiſtance very imperfectly known. Still, however, this is not one of the general cauſes of the uniform motion attained by working engines. Rarely is the motion of their parts ſo rapid, as to occaſion any great reſiſtance from the air. But in the moſt frequent employments of machines, every increaſe of velocity is accompanied by an increaſe of reſiſtance from the work performed. This occurs at once to the imagination; and few perſons think of inquiring farther for a reaſon. But there is perhaps no part of mechanics that is more imperfectly underſtood, even in our preſent improved ſtate of mechanical ſcience. In many kinds of work, it is very difficult to ſtate what increaſe of labour is required in order to perform the work with twice or thrice the ſpeed. In grinding corn, for inſtance, we are almoſt entirely ignorant of this matter. It is very certain, that twice the force is not neceſſary for making the mill grind twice as faſt, nor even for making it grind twice as much grain equally well. It is not eaſy to bring this operation under mathematical treatment; but we have conſidered it with ſome attention, and we imagine that a very great improvement may ſtill be made in the conſtruction of griſt mills, founded on the law of variation of the reſiſtance to the operation of grinding, and a ſcientific adjuſtment of m to n, in conſequence of our knowledge of this law. We may make a ſimilar obſervation on many other kinds of work performed by machines. In none of thoſe works where the inertia of the work is inconſiderable, are we well acquainted with the real mechanical proceſs in performing it. This is the caſe in ſawing mills, boring mills, rolling mills, ſlitting mills, and many others, where the work conſiſts in overcoming the ſtrong coheſion of a ſmall quantity of matter. In ſawing timber (which is the moſt eaſily underſtood of all theſe operations), if the ſaw move with a double velocity, it is very difficult to ſay how much the actual reſiſting preſſure on the teeth of the ſaw is increaſed. Twice the number of fibres are neceſſarily torn aſunder during the ſame time, becauſe the ſame number are torn by one deſcent of the ſaw, and it makes that ſtroke in half the time. But it is very uncertain whether the reſiſtance is double on this account; becauſe if each fibre be ſuppoſed to have the ſame tenacity in both caſes, it reſiſts with this tenacity only for half the time. The parts of bodies reſiſt a ſimilar change of condition in different manners; and there is another difference in their reſiſtance of different changes—the reſiſtance of red hot iron under the roller may vary at a very different rate from that of its reſiſtance to the cutting tool. The reſiſtance of the ſpindles of a cotton mill, ariſing partly from friction, partly from the inertia of the heaped bobins, and partly from the reſiſtance of the air, is ſtill more complicated, and it may be difficult to learn its law. The only caſe in which we can judge with ſome preciſion is, when the inertia of matter, or a conſtant preſſure like that of gravity, conſtitutes the chief reſiſtance. Thus in a mill employed to raiſe water by a chain of buckets, the reſiſtance proceeds from the inertia only of the water. The buckets are moving with a certain velocity, and the loweſt of them takes hold of a quantity of water lying at reſt in the pit, and drags it into motion with its acquired velocity. The force required for generating this motion on the quieſcent water muſt be double or triple, when the velocity that muſt be given to it is ſo. This abſorbs the overplus of the impelling power, by which that power exceeds what is neceſſary for balancing the weight of the water contained in all the aſcending buckets. This is a certain determinate quantity which does not change; for in the ſame inſtant that a new bucket of water is forced into motion below, and its weight added to that of the aſcending buckets, an equal bucket is emptied of its water at top. The aſcending buckets require only to be balanced, and they then *continue* to aſcend, with any velocity already acquired. While the machine moves ſlow, the motion impreſſed on the new bucket of water is not ſufficient to abſorb all the overplus of impelling power. The quantity not abſorbed accelerates the machine, and the next bucket muſt produce more motion in the water which it takes up. This conſumes more of the overplus. This goes on till no overplus of power is left, and the machine accelerates no more. The complete performance of the machine now is, that "a certain quantity of water, formerly at reſt, is now moving with a certain velocity." Our engineers conſider it differently; "as a certain *weight* of water lifted up." But while the machine is thus moving uniformly, it is really not doing ſo much as before; that is, it is not exerting ſuch great preſſures as before the motion was rendered uniform: for at that time there was a preſſure at the working point equal to the weight of all the water in the aſcending buckets; and alſo an overplus of preſſure, by which the whole was accelerated. In the ſtate of uniform motion, the preſſure is no more than juſt balances the weight of the aſcending chain. We ſhall learn by and bye how the preſſures have been diminiſhing, although the mill has been accelerating; a thing that ſeems a paradox.

In this inſtance, then, we ſee clearly, why a machine muſt attain a uniform motion. A pumping machine gives us the ſame opportunity, but in a manner ſo different as to require explanation. The piſton may be ſuppoſed at the very ſurface of the pit water, and the impelling power may be leſs than will ſupport a column in the pipe as high as can be raiſed by the preſſure of the atmoſphere. Suppoſe the impelling power to be the water lying in the buckets of an overſhot wheel.

Let this water be laid into the buckets by a very ſmall ſtream. It will fill the buckets very ſlowly; and as this gives them a preponderance, the mill loſes its balance, the wheel begins to move, and the piſton to riſe, and the water to follow it. The water may be delivered on the wheel drop by drop; the piſton will riſe by inſenſible degrees, always ſtanding ſtill again as ſoon as the atmoſpheric preſſure on it juſt balances the water on the wheel. The water in the riſing pipe is always a balance to the preſſure of the atmoſphere on the ciſtern; therefore the preſſure of the atmoſphere on the piſton (which is the r in our formula) is equal to the weight of this water. Our pump-makers therefore (calling themſelves engineers) ſay, that the weight of water in the pipe balances the water on the wheel. It does not balance it, nor is it raiſed by the wheel, but by the atmoſphere; but it ſerves us at preſent for a meaſure of the power of the wheel. At laſt, all the buckets of the wheel are full, and the water is (for example) 25 feet high in the pipe. Now let the ſtream of water run its full quantity. It will only run over from bucket to bucket, and run off at the bottom of the wheel; but the mill will not move, and no work will be performed. (N. B. We are here excluding all impulſe or ſtroke on the buckets, and ſuppoſing the water to act only by its weight.) But now let all be emptied again, and let the water be delivered on the wheel in its full quantity at the firſt. The wheel will immediately acquire a preponderancy, which will *greatly* exceed the firſt ſmall preſſure of the atmoſphere on the piſton. It will therefore accelerate the piſton, overcoming the preſſure of the air with great velocity. The piſton riſes faſt; the water follows it, by the preſſure of the atmoſphere; and when it attains the former utmoſt height, it attains it with a conſiderable velocity. If allowed to run off there, it will *continue* to run off with that velocity; becauſe there is the ſame quantity of water preſſing round the wheel as before, and therefore enough to balance the preſſure of the atmoſphere on the piſton. The preſſure of the ſame atmoſphere on the water in the ciſtern, raiſed the water in the pipe with this velocity; therefore it will continue to do ſo, and the mill will deliver water by the pump with this velocity, although there is no more preſſure acting on it than before, when the water ran to waſte, doing no work whatever.

This mode of action is extremely different from the former example. The mill is not acting againſt the inertia y of the water to be moved, but againſt the preſſure r of the atmoſphere on the piſton. The preſſure of the ſame atmoſphere on the ciſtern is employed againſt the inertia of the water in the pipe; and the uſe of the mill is to *give occaſion*, by raiſing the piſton, to the exertion of this atmoſpherical preſſure, which is the real raiſer of the water. The maxim of conſtrnction, and the proper adjuſtment of m to n in this caſe, are different from the former; and we ſhould run the riſk of making an imperfect engine were we to confound them.

We muſt mention another caſe of a pumping mill, ſeemingly the ſame with this, but eſſentially different. Suppoſe the pipe of this pump to reach 30 feet below the ſurface of the pit water, and that the piſton is at the very bottom of it. Suppoſe alſo, that the wheel buckets, when filled with water, only enable it to *ſupport* 25 feet of water in the riſing pipe. Let the water be delivered into the wheel drop by drop. The wheel will gradually preponderate; the piſton will gradually riſe, lifting the water above it, ſuſtaining a preſſure of water which gradually increaſes. At laſt, the water in the pump is 25 feet higher than that in the ciſtern; the wheel is full and running to waſte; but no work is performed. Let all be emptied, and now let the water come to the wheel in its full ſtream, but without impulſe. The piſton will lift the water briſkly, bring it to 25 feet high with a conſiderable velocity, and the mill will now raiſe it with this velocity. In this example, the mill is the immediate agent in raiſing the water; but, in this caſe alſo, its ultimate office is not overcoming inertia, but overcoming preſſure. It was the overplus of power only that was employed in overcoming inertia, while accelerating the water in the riſing pipe, in order to give it the neceſſary velocity for a continued diſcharge.

These and ſimilar examples ſhew the great difference between the ſtatical and dynamical equilibrium of machines, and the neceſſity of a ſcientific attention by all who wiſh to improve practical mechanics. Without this, and even a pretty refined attention, we cannot ſee the connection between a copious ſupply of water to the bucket wheel and a plentiful diſcharge by the pump. We believe, that the greateſt part of thoſe employed in erecting machines conceive it as owing to the greater weight of water impelling the wheel with greater force; but we ſee that there is no difference in the preſſures on the mill at reſt, and the mill doing its work ſteadily and uniformly, with any velocity, however great. Without keeping the notions of that part of the impelling power which ſupports diſtinct from that of the part which accelerates, we ſhall never have a clear conception of the operation of machines, or of mechanical power in general. We cannot derive all the advantages of our natural powers, without knowing how our machine employs the preſſure excited by it at the working point; that is, without perceiving in what caſes it is oppoſed to inertia, and in what to the mechanical properties of tangible matter. This only can inform us at what rate the reſiſtance varies by a change of velocity; and when it happens that this augmentation, neceſſarily accompanied by an augmentation of all the frictions, and the reſiſtance of the air, is in equilibrio with the whole of the impelling power, and all acceleration is at an end. 21.

22
The chief cauſe is a real diminution of power.

Laſtly, another chief cauſe of the finally uniform motion of machines is, that, in moſt caſes, an increaſe of velocity produces a real diminution of impelling power. We hardly know any exception to this beſides the employment of *one* deſcending weight as a power or firſt mover. Moſt of the powers which we employ reſide in bodies external to the machine; and theſe bodies muſt be put in motion, and continued in that motion, in order to continue their preſſure on the impelled point. Frequently a great part of the power is employed in giving this neceſſary motion to the external matter, and the remainder only is employed in preſſing forward the machine. We mentioned a remarkable inſtance of this in the operation of thraſhing. Now, the power thus employed muſt increaſe in proportion to the motion required; that is, in proportion to the velocity of the impelled

pelled point; what remains, urging forward the machine, is therefore diminiſhed. The acceleration is therefore diminiſhed, and may ceaſe. At *laſt* the actual preſſure is ſo much diminiſhed, that it is no more than what is neceſſary for overcoming the increaſed reſiſtance of the work, the increaſed friction. The machine therefore accelerates no more, but moves uniformly.

This cauſe very general.

This cauſe of the diminution of power by an increaſe of velocity, obtains in all caſes where the ſtrength of animals, of ſprings, the force of fired gunpowder, &c. is exerted. In ſome caſes, the viſible effect is not very conſiderable; as in the employment of a ſtrong ſpring, the force of gunpowder, and a few others. In the action of animals, this defalcation of power is very great when the velocity is conſiderable. Nay, even in the action of gravity, although it acts as ſtrongly on a body in rapid motion as on one at reſt, yet when gravity is not the immediate agent, but acts by the intervention of a body in which it reſides, the neceſſity of previouſly moving this body frequently diminiſhes the acceleration which it would otherwiſe produce. Thus, in an overſhot wheel, if the water be delivered into the bucket with a velocity (eſtimated in the direction of the part of the wheel into which it is delivered) leſs than that of the rim of the wheel, it muſt retard the motion; for it muſt be immediately dragged into that motion; that is, part of the accelerating overplus, already acting on the wheel, muſt be employed in accelerating this new bucket of water, and this muſt leſſen the general acceleration of the machine. Hence we learn, that the water muſt be delivered on the wheel with a velocity that is at leaſt not leſs than that of the wheel's motion.

It obtains in all machines actuated by impulſion,

The caſe in which we ſee this diminution of power on machines moſt diſtinctly is, when water or wind, acting by impulſe alone, is our moving power. Since the mutual impulſes of bodies depend entirely on their relative motions (ſee IMPULSION, *Suppl.*), it follows, that when the velocity of the impelled point is augmented, the impulſion, or effective preſſure, muſt be diminiſhed. Nay, this velocity may be ſo increaſed, that there ſhall be no relative motion, and therefore no impulſion. If the floats of an underſhot wheel be moving with the velocity of the ſtream, they remain conjoined in their progreſs, but without any mutual action. Therefore, when an underſhot wheel is ſet into a running water, the firſt impulſions are ſtrong, and accelerate the wheel. This diminiſhes the next impulſion and acceleration: but the wheel is ſtill impelled and accelerated; leſs and leſs in every ſucceeding moment, as it moves faſter; by and bye, the acceleration becomes inſenſible, and the wheel appears to attain a motion which is perfectly uniform. This requires a very long time, or rather it is never attained, and we only cannot diſcern the very ſmall additions which are ſtill made to the velocity. All this happens generally after a very moderate time, by reaſon of various other obſtructions.

Or by the force of animals.

Animal action is ſubject to the ſame variation. We know, that there is a certain rate at which a horſe can run, exhauſting or employing his whole ſtrength. If he be made to drag any the ſmalleſt load after him, he muſt employ part of his force on it, and his ſpeed will be checked. The more he is loaded with a draught, the ſlower he will run, ſtill employing all his ſtrength. The draught may be increaſed till he is reduced to a trot, to a walk, nay, till he is unable to draw it. Now, juſt inverting this proceſs, we ſee, that there is a certain ſtrain which will ſufficiently tire the horſe without ſtirring from the ſpot, but which he could continue to exert for hours. This is greater than the load that he can juſt crawl along with, employing his ſtrength as much as would be prudent to continue from day to day. And, in like manner, every leſſer draught has a correſponding rate, at which the horſe, employing his whole working ſtrength, can continue to draw at during the working hours of a day. At ſetting out, he pulls harder, and accelerates it.* Following his pull, he walks faſter, and therefore pulls leſs (becauſe we are ſtill ſuppoſing him to employ his whole working ſtrength). At laſt he attains that ſpeed which occupies his whole ſtrength in merely continuing the pull. Other animals act in a ſimilar manner; and it becomes a general rule, that the preſſure actually exerted on the impelled point of a machine diminiſhes as its velocity increaſes.

23 We muſt diſtinguiſh between the power expended and the power employed.

From the concurrence of ſo many facts, we perceive that we muſt be careful to diſtinguiſh between the quantity of power expended, and the quantity that is uſefully employed, which muſt be meaſured ſolely by the preſſure exerted on the machine. When a weight of five pounds is employed to drag up a weight of three pounds by means of a thread over a pulley, it deſcends, with a motion uniformly accelerated, four feet in the firſt ſecond. Mr Smeaton would call this an expenditure of a mechanical power 20. The weight three pounds is raiſed four feet. Mr Smeaton would call this a mechanical effect 12. Therefore the effect produced is not adequate to the power expended. But the fact is, that the preſſure, ſtrain, or mechanical power really exerted in this experiment, is neither five nor three pounds; the five pound weight would have fallen 16 feet, but it falls only 4. A force has therefore acted on it ſufficient to make it deſcribe 12 feet in a ſecond, with a uniformly accelerated motion; for it has counteracted ſo much of its weight. The thread was ſtrained with a force equal to $3\frac{3}{4}$ pounds, or $\frac{3}{4}$ths of 5 pounds. In like manner, the three pound weight would have fallen 16 feet; but it was raiſed 4 feet. Here was a change preciſely equal to the other. A force of $3\frac{3}{4}$ pounds, acting on a maſs whoſe matter is only 3, will, in a ſecond, cauſe it to deſcribe 20 feet with a uniformly accelerated motion. Now, 5 × 12, and 3 × 20, give the ſame product 60. And thus we ſee, that the quantity of motion extinguiſhed or produced, and not the product of the weight and height, is the true unequivocal meaſure of mechanical power really expended, or the mechanical effect really produced; and that theſe two are always equal and oppoſite. At the ſame time, Mr Smeaton's theorem merits the attention of engineers; becauſe it generally meaſures the opportunities that we have for procuring the exertion of power. In ſome ſenſe Mr Smeaton may ſay, that the quantity of water multiplied by the height from which it deſcends in working our machines, is the meaſure of the power expended; becauſe we muſt raiſe this quantity to the dam again, in order to have the ſame uſe of it. It is expended, but not employed; for the water, at leaving the wheel, is ſtill able to do ſomething.

24 It requires but little conſideration to be ſenſible, that the

the preceding account of the ceſſation of accelerated motion in our principal machines, muſt introduce different maxims of conſtruction from thoſe which were expreſsly adapted to this acceleration; or rather, which proceeded on the erroneous ſuppoſition of the conſtancy of the impelling power and the reſiſtance. The examination of this point has brought into view the fundamental principle of working machines, namely, the perfect equilibrium which takes place between the impelling power and the ſimultaneous reſiſtance. It may be expreſſed thus:

irſt prin iple of working machines.

The force required for preſerving a machine in uniform motion, with any velocity whatever, is that which is neceſſary for balancing the reſiſtance then actually exerted on the working point of the machine. We ſaw this diſtinctly in the inſtance of the two weights acting againſt each other by the intervention of a thread over a fixed pulley. It is equally true of every caſe of acting machinery: for if the force at the impelled point be greater than what balances the reſiſtance acting at the ſame point, it muſt accelerate that point, and therefore accelerate the whole machine; and if the impelling force be leſs than this, the machine muſt immediately retard in its motion. When the machine has once acquired this degree of motion, every part of it will continue in its preſent ſtate of motion, if only the two external forces are in equilibrio, but not otherwiſe. But when the preſſure of the external power on the impelled point balances the reſiſtance oppoſed by that point, it is, in fact, maintaining the equilibrium with the external power acting at the working point; for this is the only way that external forces can be ſet in oppoſition to each other by the intervention of a body. The external forces are not in immediate equilibrio with each other, but each is in equilibrio with the force exerted by the point on which it acts This force excited by the point is a modification of the connecting forces of the body, all of which are brought into action by means of the actions of the external forces, and each is accompanied by a force preciſely equal and oppoſite to it. Now, the principles of ſtatics teach us the proportions of the external preſſures which are thus ſet in equilibrium by the intervention of a body; and therefore teach us what proportion of power and reſiſtance will keep a machine of a given conſtruction in a ſtate of uniform motion

This propoſition appears paradoxical, and contrary to common obſervation; for we find, that, in order to make a mill go faſter, we muſt either diminiſh the reſiſtance, or we muſt employ more men, or more water, or water moving with greater velocity, &c. But this ariſes from ſome of the cauſes already mentioned. Either the reſiſtance of the work is greater when the machine is made to move faſter, or the impulſion of the power is diminiſhed, or both theſe changes obtain. Friction and reſiſtance of air alſo come in for their ſhare, &c. The actual preſſure of a given quantity of the external power is diminiſhed, and therefore more of it muſt be employed. When a weight is *uniformly* raiſed by a machine, the preſſure exerted on it by the working point is preciſely equal to its weight, whatever be the velocity with which it riſes. But, even in this ſimpleſt caſe, more natural power muſt be expended in order to raiſe it faſter; becauſe either more natural power muſt be employed to accelerate the external matter which is to preſs forward the impelled point, or the relative motion of the preſſing matter will be diminiſhed.

It is well known, that, in the employment of the mechanic powers, whether in their ſtate of greateſt ſimplicity, or any how combined in a complicated machine, if the machine be put in motion, the velocities of the extreme points (which we have called the *impelled* and *working* points) are inverſely proportional to the forces which are in equilibrio when applied to theſe points in the direction of their motion. This is an inductive propoſition, and has been uſed as the foundation of ſyſtems of mechanics. It is unneceſſary to take up time in proving what is ſo familiarly known; conſequently, the products of the preſſures at theſe points by the velocities of the motions are equal; that is, the product of the preſſure actually exerted at the impelled point of a machine working uniformly, multiplied by the velocity of that point, is equal to the product of the reſiſtance actually exerted at the working point, multiplied by the velocity of that point, that is, by the velocity with which the reſiſtance is overcome,

$$p\,m = r\,n.$$

Now, the product of the reſiſtance, by the velocity with which it is overcome, is evidently the meaſure of the performance of the machine, or the work done. The product of the actual preſſure on the impelled point, by the velocity of that point, may be called the MOMENTUM OF IMPULSE.

Hence we deduce this propoſition:

25 Second principle. Momentum of impulſe and the performance of the machine are equal.

In all working machines which have acquired a uniform motion, the performance of the machine is equal to the momentum of impulſe (A).

(A) The truth of this propoſition has been long perceived in every particular inſtance that happened to engage the attention; but we do not recollect any mechanician before Mr Euler conſidering it as a general truth, expreſſing in a few words a mechanical law. This celebrated mathematician undertook, about the year 1735 or 1736, a general and ſyſtematic view of machines, in order to found a complete theory immediately conducive to the improvement of practical mechanics. In 1743 he publiſhed the firſt propoſitions of this uſeful theory in the 10th volume of the *Comment. Petropolitani*, containing the excellent dynamical theorems of which we have given the ſubſtance. In the 3d volume of the *Comment. Novi Petropol.* he proſecuted the ſubject a little farther; and in the 8th volume, he entered on what we are now engaged in, and formally announces this fundamental propoſition, calling theſe two products the *momentum of impulſe*, and the *momentum of effect*. It is much to be regretted, that this conſummate mathematician did not continue theſe uſeful labours; his ardent mind being carried away by more abſtruſe ſpeculations in all the moſt refined departments of mathematics and philoſophy. No man in Europe could have proſecuted the ſubject with more judgment and ſucceſs.—See alſo *Mem. Acad. Berlin*, 1747 and 1752.

This is a propoſition of the utmoſt importance in the ſcience of machines, and leads to the fundamental maxim of their conſtruction. Since the performance of a machine is equal to the momentum of impulſe, it increaſes and diminiſhes along with it, and is a maximum when the momentum of impuſe is a maximum; therefore, the fundamental maxim in the conſtruction of a machine is to faſhion it in ſuch a manner, that the momentum of impulſe ſhall be a maximum, or that the product of the preſſure actually exerted on the impelled point of the machine by the velocity with which it moves may be as great as poſſible. Then are we certain that the product of the reſiſtance, by the velocity of the working point, is as great as poſſible, provided that we take care that none of the impulſe be needleſsly waſted by the way by injudicious communications of motion, by friction, by unbalanced loads, and by reciprocal motions, which irrecoverably waſte the impelling power. This maxim holds good, whether the reſiſtance remains conſtantly the ſame, or varies by any law whatever.

26 Important deſiderata for practice. But much remains to be done for the improvement of mechanical ſcience before we can avail ourſelves of this maxim, and apply it with ſucceſs. The chief thing, and to this we ſhould give the moſt unremitting attention, is, to learn the changes which obtain in the actual preſſure exerted by thoſe natural powers which we can command; the changes of actual preſſure produced by a change of the velocity of the impelled point of the machine. Theſe depend on the ſpecific natures of thoſe powers, and are different in almoſt every different caſe. Nothing will more contribute to the improvement of practical mechanics than a ſeries of experiments, well contrived, and accurately made, for diſcovering thoſe laws of variation, in the caſes of thoſe powers which are moſt frequently employed. Such experiments, however, would be coſtly, beyond the abilities of an individual; therefore, it were greatly to be wiſhed that public aid were given to ſome perſons of ſkill in the ſcience to inſtitute a regular train of experiments of this kind. An experimental machine might be conſtructed, to be wrought either by men or by cattle. This ſhould be loaded with ſome kind of work which can be very accurately meaſured, and the load varied at pleaſure. When loaded to a certain degree, the men or cattle ſhould be made to work at the rate which they can continue from day to day. The number of turns made in an hour, multiplied by the load, will give the performance correſponding to the velocities; and thus will be diſcovered the moſt advantageous rate of motion. The ſame machine ſhould alſo be fitted for grinding, for ſawing, boring, &c. and ſimilar experiments will diſcover the relation between the velocities with which theſe operations are performed, and the reſiſtances which they exert. The laws of friction may be inveſtigated by the ſame machine. It ſhould alſo be fitted with a walking wheel, and the trial ſhould be made of the ſlope and the velocity of walking which gives the greateſt momentum of impulſe. It is not unreaſonable to expect great advantages from ſuch a train of experiments.

27 A ſubſtitute for them. Till this be done, we muſt content ourſelves with eſtabliſhing the above, in the moſt general terms, applicable to any caſe in which the law of the variation of force may hereafter be diſcovered.

There is a certain velocity of the impelled point of a machine which puts an end to the action of the moving power. Thus, if the floats of an underſhot wheel be moving with the velocity of the ſtream, no impulſe is made on them. If the arm of a gin or capſtan be moving with that velocity with which a horſe or a man can juſt move, ſo as to continue at that ſpeed from day to day, employing all his working ſtrength, but not fatiguing himſelf; in this ſtate of motion, the animal can exert no preſſure on the machine. This may be called the EXTINGUISHING VELOCITY, and we may expreſs it by the ſymbol e. Let f be that degree of force or preſſure which the animal can exert at a dead pull or thruſt, as it is called. We do not mean the utmoſt ſtrain of which the animal is capable, but that which it can continue unremittingly during the working hours of a day, fully employing, but not fatiguing itſelf. And let p be the preſſure which it actually exerts on the impelled point of a machine, moving with the velocity m. Let $e - m$ be called the RELATIVE VELOCITY, and let it be expreſſed by v. And let it be ſuppoſed, that it has been diſcovered, by any means whatever, that the actual preſſure varies in the proportion of v^q, or $\overline{e-m}^q$. This ſuppoſition gives us $e^q : v^q = f : p$, and $p = f \times \frac{v^q}{e^q}$. For the machine muſt be at reſt, in order that the agent may be able to exert the force f on its impelled point. But when the machine is at reſt, what we have named the relative velocity is e, the whole of the extinguiſhing velocity.

The momentum of impulſe is $p\,m$, that is $\frac{v^q}{e^q} f\,m$, or $f \times \frac{v^q}{e^q} \times \overline{e-v}$ (becauſe $m = e - v$). Therefore $f \times \frac{v^q}{e^q} \times \overline{e-v}$ muſt be made a maximum. But f and e^q are two quantities which ſuffer no change. Therefore the momentum of impulſe will be a maximum when $v^q \times \overline{e-v}$ is a maximum. Now $v^q \times \overline{e-v} = v^q e - v^q v, = v^q e - v^{q+1}$. The fluxion of this is $q e v^{q-1} \dot{v} - \overline{q+1}\, v^q \dot{v}$. This being ſuppoſed $= c$, we have the equation

$$q e v^{q-1} = \overline{q+1}\, v^q$$

$$\text{And } q e = \overline{q+1}\, v$$

$$\text{Therefore } v = \frac{q e}{q+1}$$

And m, which is $= e - v$, becomes $\frac{e}{q+1}$. Therefore we muſt order matters ſo, that the velocity of the impelled point of the machine may be $= \frac{e}{q+1}$. Now p is $= f \frac{v^q}{e^q}$, and therefore $= f \times \frac{q^q}{\overline{q+1}^q}$. And $p\,m$, $= f \frac{q^q}{\overline{q+1}^q} m, = f \frac{q^q}{\overline{q+1}^q} \times \frac{e}{q+1}, = f \times \frac{q^q e}{\overline{q+1}^{q+1}}, =$ the momentum of impulſe, and therefore $=$ the momentum of effect, or the performance of the machine, when in its beſt ſtate.

28 Example underſhot mills by Mr Parent. Thus may the maxim of conſtruction be ſaid to be brought to a ſtate of great ſimplicity, and of moſt eaſy recollection. A particular caſe of this maxim has been long known, having been pointed out by Mr Parent. Since the action of bodies depends on their relative velocity,

locity, the impulſe of fluids muſt be as the ſquare of the relative velocity. From which Mr Parent deduced, that the moſt advantageous velocity of the floats of an underſhot wheel is one-third of that of the ſtream. This maxim is evidently included in our general propoſition; for in this caſe, the index q of that function of the relative velocity v, which is proportional to the impulſe, is $= 2$. Therefore we have the maximum when $v = \frac{2e}{2+1}, = \frac{2}{3}e$, and $m = \frac{1}{3}e$. e, the extinguiſhing velocity, is evidently the velocity of the ſtream. Our propoſition alſo gives us the preciſe value of the performance. The impulſe of the ſtream on the float at reſt being ſuppoſed $= f$, its impulſe on the float moving with the velocity $\frac{2}{3}e$ muſt be $= \frac{4}{9}f$. This is the meaſure of the actual preſſure p. This being multiplied by m, or by $\frac{1}{3}e$, gives $\frac{4}{27}f$. Now f is conſidered as equal to the weight of a column of water, having the ſurface of the floatboard for its baſe, and the depth of the ſluice under the ſurface of the reſervoir (or, more accurately, the fall required for generating the velocity of the ſtream) for its height. Hence it has been concluded, that the utmoſt performance of an underſhot wheel is to raiſe $\frac{4}{27}$ of the water which impels it, to the height from which it falls. But this is not found very agreeable to obſervation. Friction, and many imperfections of execution in the delivery of the water, the direction of its impulſe, &c. may be expected to make a defalcation from this theoretical performance. But the actual performance, even of mills of acknowledged imperfection, conſiderably exceeds this, and ſometimes is found nearly double of this quantity. The truth is, that the particular fact from which Mr Parent firſt deduced this maxim (namely, the performance of what is called *Parent's* or *Dr Barker's mill*), is, perhaps of all that could have been ſelected, the leaſt calculated for being the foundation of a general rule, being of a nature ſo abſtruſe, that the firſt mathematicians of Europe are to this day doubtful whether they have a juſt conception of its principles. Mr Smeaton's experiments ſhew very diſtinctly, that the maximum of performance of an underſhot wheel correſponds to a velocity conſiderably greater than one-third of the ſtream, and approaches nearly to one-half; and he aſſigns ſome reaſons for this which ſeem well founded. But, independent of this, the performance of Mr Smeaton's model was much greater than what correſponds with the velocity by the above mentioned eſtimation of f. The theory of the impulſion of fluids is extremely imperfect; and Daniel Bernoulli ſhews, from very unqueſtionable principles, that the impulſe of a narrow vein of fluid on an extended ſurface is double of what was generally ſuppoſed; and his concluſions are abundantly confirmed by the experiments adduced by him.

ot accu- ate.

29 his ſub- itute is ſeful, even here it not alto- ether ex- t.

It is by no means pretended, that the maxim of conſtruction is reduced to the great ſimplicity enounced in the propoſition now under conſideration. We only ſuppoſed, that a caſe had been obſerved where the preſſure exerted by ſome natural agent did follow the proportions of v^q. This being admitted, the propoſition is ſtrictly true. But we do not know any ſuch caſe; yet is the propoſition of conſiderable uſe: for we can affirm, on the authority of our own obſervations, that the action both of men and of draught horſes does not deviate very far from the proportions of v^2. The obſervations were made on men and horſes tracking a lighter along a canal, and working ſeveral days together, without having any knowledge of the purpoſe of the obſervations. The force exerted was firſt meaſured by the curvature and weight of the track rope, and afterwards by a ſpring ſteelyard. This was multiplied by the number of yards per hour, and the product conſidered as the momentum. We found the action of men to be very nearly as $\overline{e - m}^2$. The action of horſes, loaded ſo as not to be able to trot, was nearly as $\overline{e - m}^{1,7}$.

The practitioner can eaſily avail himſelf of the maxim, although the function q ſhould never be reduced to any algebraic form. He has only to inſtitute a train of experiments on the natural agent, and ſelect that velocity which gives the higheſt product when multiplied by its correſponding preſſure.

30 Two methods of availing ourſelves of this maxim.

When this ſelection has been made, we have two ways of giving our working machines the maximum of effect, having once aſcertained the preſſure f which our natural power exerts on the impelled point of the machine when it is not allowed to move.

1. When the reſiſtance ariſing from the work, and from friction, is a given quantity; as when water is to be raiſed to a certain height by a piſton of given dimenſions.

Since the friction in all the communicating parts of the machine vary in the ſame proportion with the preſſure, and ſince theſe vary in the ſame proportion with the reſiſtance, the ſum of the reſiſtance and friction may be repreſented by $b\,r$, b being an abſtract number. Let n be the undetermined velocity of the working point; or let $m : n$ be the proportion of velocities at the impelled and working points. Then, becauſe the preſſures at theſe points balance each other, in the caſe of uniform motion, they are inverſely as the velocities at thoſe points. Therefore we muſt make $b\,r : p = m : n$, and $n = \frac{p\,m}{b\,r}, = \frac{\frac{q^q}{\overline{q+1}^q}f\,m}{b\,r}, = m\frac{q^q f}{\overline{q+1}^q b\,r}$, or $m : n = \overline{q+1}^q \times b\,r : q^q f$.

2. On the other hand, when $m : n$ is already given, by the conſtruction of the machine, but $b\,r$ is ſuſceptible of variation, we muſt load the machine with more and more work, till we have reduced the velocity of its impelled point to $\frac{e}{q+1}$.

In either caſe, the performance is expreſſed by what expreſſes $p\,m$, that is, by $f\,e \times \frac{q^q}{\overline{q+1}^{q+1}}$. But the uſeful performance, which is really the work done, will be had by dividing the value now obtained by the number b, which expreſſes the ſum of the reſiſtance overcome by the working point and the friction of the machine.

Recapitulation.

What has been now delivered contains, we imagine, the chief principles of the theory of machines, and points out the way in which we muſt proceed in applying them to every caſe. The reader, we hope, ſees clearly the imperfection of a conſideration

tion of machines which proceeds no farther than the ſtatement of the proportions of the ſimultaneous preſſures which are excited in all the parts of the machine by the application of the external forces, which we are accuſtomed to call the *power* and the *weight*. Unleſs we take alſo into conſideration, the immediate effect of mechanical force applied to body, and combine this with all the preſſures which ſtatical principles have enabled us to aſcertain, and by this combination be able to ſay what portion of unbalanced force there is acting at one and all of the preſſing points of the machine, and what will be the motion of *every part* of it in conſequence of this overplus, we have acquired no knowledge that can be of ſervice to us. We have been contemplating, not a working machine, but a ſort of balance. But, by reaſoning about theſe unbalanced forces in the ſame ſimple manner as about the fall of heavy bodies, we were able to diſcover the momentary accelerations of every part, and the ſenſible motion which it would acquire in any aſſigned time, if all the circumſtances remain the ſame. We found that the reſults, although deduced from unqueſtionable principles, were quite unlike the obſerved motions of moſt working machines. Proceeding ſtill on the ſame principles, we conſidered this deviation as the indication, and the preciſe meaſure, of ſomething which we had not yet attended to, but which the deviation brought into view, and enabled us to aſcertain with accuracy. Theſe are the changes which happen in the exertions of our actuating powers by the velocity with which we find it convenient to make them act. Thus we learn more of the nature of thoſe powers; and we found it neceſſary to diſtinguiſh carefully between the apparent magnitude of our actuating power and its real exertion in doing our work. This conſideration led us to a fundamental propoſition concerning all working machines when they have attained an uniform motion; namely, that the power and reſiſtance then really exerted on the machine preciſely balance each other, and that the machine is preciſely in the condition of a ſteelyard loaded with its balanced weights, and moved round its axis by ſome external force diſtinct from the power and the weight. We found that this force is the previous overplus of impelling power, before the machine had acquired the uniform motion; and on this occaſion we learned to eſtimate the effect produced, by the momentum (depending on the form of the machine) of the quantity of motion produced in the whole aſſemblage of power, reſiſtance, and machine.

31
Theory of machines ſtill intricate, eſpecially of ſuch as reciprocate.

The theory of machines ſeemed to be now brought back to that ſimplicity of equilibrium which we had ſaid was ſo imperfect a foundation for a theory; but in the availing ourſelves of the maxim founded on this general propoſition, we ſaw that the equilibrium is of a very different kind from a quieſcent equilibrium. It neceſſarily involves in it the knowledge of the momentary accelerations and their momenta; without which we ſhould not perceive that one ſtate of motion is more advantageous than another, becauſe all give us the ſame proportion of forces in equilibrio.

But this is not the only uſe of the previous knowledge of the momentary accelerations of machines; there are many caſes where the machine works in this very ſtate. Many machines accelerate throughout while performing their work; and their efficacy depends entirely on the final acceleration. Of this kind is the coining preſs, the great forge or tilt mill, and ſome other capital engines. The ſteam engine, and the common pump, are neceſſarily of this claſs, although their efficacy is not eſtimated by their final acceleration. A great number of engines have reciprocating motions in different ſubordinate parts. The theory of all ſuch engines requires for its perfection an accurate knowledge of the momentary accelerations; and we muſt uſe the formulæ contained in the firſt part of this article.

32
Working and returning ſtrokes.

Still, however, the application of this knowledge has many difficulties, which make a *good* theory of ſuch machines a much more intricate and complicated matter than we have yet led the reader to ſuppoſe. In moſt of theſe engines, the whole motion may be divided into two parts. One may be called the WORKING STROKE, and the other in which the working points are brought back to a ſituation which fits them for acting again, may be called the RETURNING STROKE. This return muſt be effected either by means of ſome immediate application of the actuating power, or by ſome other force, which is counteracted during the working ſtroke, and muſt be conſidered as making part of the reſiſtance. In the ſteam engine, it is generally done by a counterpoiſe on the outer end of the great working beam. This muſt be accounted a part of the reſiſtance, for it muſt be raiſed again; and the proportions of the machine for attaining the maximum muſt be computed accordingly. The quantity of this counterpoiſe muſt be adjuſted by other conſiderations. It muſt be ſuch, that the deſcent of the pump rods in the pit may *juſt employ the whole time* that is neceſſary for filling the cylinder with ſteam. If they deſcend more briſkly (which an unſkilful engineer likes to ſee), this muſt be done by means of a greater counterpoiſe, and this employs more power to raiſe it again. Deſaguliers deſcribes a very excellent machine for raiſing water in a bucket by a man's ſtepping into an oppoſite bucket, and deſcending by his preponderancy. When he comes to the bottom, he ſteps out, goes up a ſtair, and finds the bucket returned and ready to receive him again. This machine is extremely ſimple, and perhaps the beſt that can be contrived; and yet it is one of the moſt likely to be a very bad one. The bucket into which the man ſteps muſt be brought up to its place again by a preponderancy in the machine when unloaded. It may be returned ſooner or later. It ſhould arrive preciſely at the ſame time with the man. If ſooner, it is of no uſe, and waſtes power in raiſing a counterpoiſe which is needleſsly heavy; if later, time is loſt: Therefore, the perfection of this very ſimple machine requires the judicious combination of two maximums, each of which varies in a ratio compounded of two other ratios. Suppoſe the man to employ a minute to go up ſtairs 50 feet, which is very nearly what he can do from day to day as his only work, and ſuppoſe him to weigh 150 pounds, and that he acts by means of a ſimple pulley—the maximum for a lever of equal arms would require him to raiſe about 60 pounds of water. But when all the other circumſtances are calculated, it will be found that he muſt raiſe 138 pounds (neglecting the inertia of the machine). He ſhould raiſe 542 pounds 10 feet in a minute; and this is nearly the moſt exact valuation of a man's work.

There is the ſame neceſſity of attending to a variety of of circumſtances in all machines which reciprocate in the whole or any conſiderable part of their motion. The force employed for bringing the machine into another working poſition, muſt be regulated by the time neceſſary for obtaining a new ſupply of power; and then the proportion of *m* to *n* muſt be ſo adjuſted, that the work performed, divided by the *whole* time of the working and returning ſtrokes, may give the greateſt quotient. It is ſtill a difficult thing, therefore, to conſtruct a machine in the moſt perfect manner, or even to ſay what will be the performance of a machine already conſtructed; yet we ſee that every circumſtance is ſuſceptible of accurate computation.

With reſpect to machines which acquire a ſort of uniform motion in general, although ſubject to partial reciprocations, as in a pumping, ſtamping, forging engine, it is alſo difficult to aſſign the rate even of this general uniform motion. We may, however, ſay, that it will not be greater than if it were uniform throughout. Were it entirely free from friction, it would be exactly the ſame as if uniform; becauſe the accelerations during the advantageous ſituations of the impelling power would compenſate the retardations. But friction diminiſhes the accelerations, without diminiſhing the retardations.

We may conclude this article with ſome obſervations tending to the general improvement of machines.

33 Uniformity f motion hroughout of great dvantage.

Nothing contributes more to the perfection of a machine, eſpecially ſuch as is maſſive and ponderous, than great uniformity of motion. Every irregularity of motion waſtes ſome of the impelling power; and it is only the greateſt of the varying velocities which is equal to that which the machine would acquire if moving uniformly throughout; for while the motion accelerates, the impelling force is greater than what balances the reſiſtance then actually oppoſed to it, and the velocity is leſs than what the machine would acquire if moving uniformly: and when the machine attains its greateſt velocity, it attains it becauſe the power is then not acting againſt the whole reſiſtance. In both of theſe ſituations, therefore, the performance of the machine is leſs than if the power and reſiſtance were exactly balanced; in which caſe it would move uniformly.

34 How to at- in this.

Every attention ſhould therefore be given to this, and we ſhould endeavour to remove all cauſe of irregularity. The communications of motion ſhould be ſo contrived, that if the impelled point be moving uniformly, by the uniform preſſure of the power, the working point ſhall alſo be moving uniformly. Then we may generally be certain, that the maſſy parts of the machine will be moving uniformly. When this is not done through the whole machine, there are continual returns of ſtrains and jolts; the inertia of the different parts acting in oppoſite directions. Although the whole momenta may always balance each other, yet the general motion is hobbling, and the points of ſupport are ſtrained. A great engine ſo conſtructed, commonly cauſes the building to tremble; but when uniform motion pervades the whole machine, the inertia of each part tends to preſerve this uniformity, and all goes ſmoothly. It is alſo deſerving of remark, that when the communications are ſo contrived that the uniform motion of one part produces uniform motion on the next, the preſſures at the communicating points remain conſtant or invariable. Now the accompliſhing of this is always within the reach of mechanics.

35 Beſt forms for the teeth of wheels. Plate XXXIII. fig. 1.

One of the moſt uſual communications in machinery is by means of toothed wheels acting on each other. It is of importance to have the teeth ſo formed, that the preſſure by which one of them A urges the other B round its axis ſhall be conſtantly the ſame. It can eaſily be demonſtrated, that when this is the caſe, the uniform angular motion of the one will produce a uniform angular motion of the other; or, if the motions are thus uniform, the preſſures are invariable. This is accompliſhed on this principle, that the mutual actions of ſolid bodies on each other in the way of preſſure are perpendicular to the touching ſurfaces. Therefore let the tooth *a* preſs on the tooth *b* in the point C; and draw the line FCDE perpendicular to the touching ſurfaces in the point C. Draw AF, BE perpendicular to FE, and let FE cut the line AB in D. It is plain, from the common principles of mechanics, that if the line FE, drawn in the manner now deſcribed, always paſs through the ſame point D, whatever may be the ſituation of the acting teeth, the mutual action of the wheels will always be the ſame. It will be the ſame as if the arm AD acted on the arm BD. In the treatiſes on the conſtruction of mills, and other works of this kind, are many inſtructions for the formation of the teeth of wheels; and almoſt every noted millwright has his own noſtrums. Moſt of them are egregiouſly faulty in reſpect of mechanical principle. Indeed they are little elſe than inſtructions how to make the teeth clear each other without ſticking. Mr de la Hire firſt pointed out the above mentioned principle, and juſtly condemned the common practice of making the ſmall wheel or pinion in the form of a lantern (whence it alſo took its name), conſiſting of two round diſks, having a number of cylindrical ſpokes (fig. 2.) The ſlighteſt inſpection of this conſtruction ſhews, that, in the different ſituations of the working teeth, the line FCE continually changes its interſection with AB. If the wheel B be very ſmall in compariſon of the other, and if the teeth of A take deep hold of the cylindrical pins of B, the line of action EF is ſometimes ſo diſadvantageouſly placed, that the preſſure of the one wheel has ſcarcely any tendency at all to turn the other.

Epicycloids recommended by De la Hire.

Mr de la Hire, or Dr Hooke, was, we think, the firſt who inveſtigated the form of tooth which procured this conſtant action between the wheels; and in a very ingenious diſſertation, publiſhed among the Memoirs of the Academy of Sciences at Paris 1668, the former of theſe gentlemen ſhews, that this will be enſured by forming the teeth into epicycloids. Mr Camus of the ſame Academy has publiſhed an elaborate diſſertation on the ſame ſubject, in which he proſecutes the principle of Mr de la Hire, and applies it to all the variety of caſes which can occur in practice. There is no doubt as to the goodneſs of the principle; and it has another excellent property, "that the mutual action of the teeth is abſolutely without any friction." The one tooth only applies itſelf to the other, and rolls on it, but does not ſlide or rub in the ſmalleſt degree. This makes them laſt long, or rather does not allow them to wear in the leaſt. But the conſtruction is ſubject to a limitation which muſt not be neglected. The teeth muſt be ſo made, that the curved part of the tooth *b* is acted on by a flat part of the tooth *a* till it comes to the line AB in the courſe of its action; after which

which the curved part of *a* acts on a flat part of *b*; or the whole action of *a* on *b* is either completed, or only begins at the line AB, joining the centres of the wheels.

36 A better form.

Another form of the teeth ſecures the perfect uniformity of action without this limitation, which requires very nice execution. Let the teeth of each wheel be formed by evolving its circumference; that is, let the acting face GCH of the tooth *a* have the form of the curve traced by the extremity of the thread FC, unlapped from the circumference. In like manner, let the acting face of the tooth *b* be formed by unlapping a thread from its circumference. It is evident, that the line FCE, which is drawn perpendicularly to the touching ſurfaces in the point C, is juſt the direction or poſition of the evolving threads by which the two acting faces are formed. This line muſt therefore be the common tangent to the two circles or circumferences of the wheels, and will therefore always cut the line AB in the ſame point D. This form allows the teeth to act on each other through the whole extent of the line FCE, and therefore will admit of ſeveral teeth to be acting at the ſame time (twice the number that can be admitted in Mr de la Hire's method). This, by dividing the preſſure among ſeveral teeth, diminiſhes its quantity on any one of them, and therefore diminiſhes the dents or impreſſions which they unavoidably make on each other. It is not altogether free from ſliding and friction, but the whole of it can hardly be ſaid to be ſenſible. The whole ſlide of a tooth three inches long, belonging to a wheel of ten feet diameter, acting on a tooth of a wheel of two feet diameter, does not amount to $\frac{1}{60}$th of an inch, a quantity altogether inſignificant.

In the formation of the teeth of wheels, a ſmall deviation from theſe perfect forms is not perhaps of very great importance, except in caſes where a very large wheel drives a very ſmall one (a thing which a good engineer will always avoid). As the conſtruction, however, is exceedingly eaſy, it would he unpardonable to omit it. Well formed teeth, and a great number of them acting at once, make the communication of motion extremely ſmooth and uniform. The machine works without noiſe, and the teeth laſt a very long time without ſenſibly changing their ſhape. But there are caſes, ſuch as the pallets of clocks and watches, where the utmoſt accuracy of form is of the greateſt importance for the perfection of the work.

37 Maxim for the conſtruction of ſtampers, &c.

When heavy ſtampers are to be raiſed, in order to drop on the matters to be pounded, the wipers by which they are lifted ſhould be made of ſuch a form, that the ſtamper may be raiſed by a uniform preſſure, or with a motion almoſt perfectly uniform. If this is not attended to, and the wiper is only a pin ſticking out from the axis, the ſtamper is forced into motion at once. This occaſions violent jolts to the machine, and great ſtrains on its moving parts and their points of ſupport; whereas when they are gradually lifted, the inequality of deſultory motion is never felt at the impelled point of the machine. We have ſeen piſtons moved by means of a double rack on the piſton-rod. A half wheel takes hold of one rack, and raiſes it to the required height. The moment the half wheel has quitted that ſide of the rack, it lays hold of the other ſide, and forces the piſton down again. This is propoſed as a great improvement; correcting the unequable motion of the piſton moved in the common way by a crank. But it is far inferior to the crank motion. It occaſions ſuch abrupt changes of motion, that the machine is ſhaken by jolts. Indeed if the movement were accurately executed, the machine would be ſhaken to pieces, if the parts did not give way by bending and yielding. Accordingly, we have always obſerved that this motion ſoon failed, and was changed for one that was more ſmooth. A judicious engineer will avoid all ſuch ſudden changes of motion, eſpecially in any ponderous part of a machine.

When ſeveral ſtampers, piſtons, or other reciprocal movers, are to be raiſed and depreſſed, common ſenſe teaches us to diſtribute their times of action in a uniform manner, ſo that the machine may always be equally loaded with work. When this is done, and the obſervations in the preceding paragraph attended to, the machine may be made to move almoſt as ſmoothly as if there were no reciprocations in it. Nothing ſhews the ingenuity of the author more than the artful yet ſimple and effectual contrivances for obviating thoſe difficulties that unavoidably ariſe from the very nature of the work that muſt be performed by the machine, and of the power employed. The inventive genius and ſound judgment of Watt and Boulton are as perceptible to a ſkilled obſerver in theſe ſubordinate parts of ſome of their great engines, as in the original diſcovery on which their patent is founded. In ſome of thoſe engines the maſs of dead matter which muſt be put into motion, and this motion deſtroyed and again reſtored in every ſtroke, is enormous, amounting to above an hundred tons. The ingenious authors have even contrived to draw ſome advantages from it, by allowing a great want of equilibrium in certain poſitions; and this has been condemned as a blunder by engineers who did not ſee the uſe made of it.

38 The unavoidable i equalities of moving power mu be compe ſated by the conſtruction.

There is alſo great room for ingenuity and good choice in the management of the moving power, when it is ſuch as cannot immediately produce the kind of motion required for effecting the purpoſe. We mentioned the converſion of the continued rotation of an axis into the reciprocating motion of a piſton, and the improvement which was thought to have been made on the common and obvious contrivance of a crank, by ſubſtituting a double rack on the piſton-rod, and the inconvenience ariſing from the jolts occaſioned by this change. We have ſeen a great forge, where the engineer, in order to avoid the ſame inconvenience ariſing from the abrupt motion given to the great ſledge hammer of ſeven hundred weight, reſiſting with a five-fold momentum, formed the wipers into ſpirals, which communicated motion to the hammer almoſt without any jolt whatever; but the reſult was, that the hammer roſe no higher than it had been raiſed in contact with the wiper, and then fell on the iron bloom with very little effect. The cauſe of its inefficiency was not gueſſed at; but it was removed, and wipers of the common form were put in place of the ſpirals. In this operation, the rapid motion of the hammer is abſolutely neceſſary. It is not enough to *lift* it up; it muſt be *toſſed* up, ſo as to fly higher than the wiper lifts it, and to ſtrike with great force the ſtrong oaken ſpring which is placed in its way. It compreſſes this ſpring, and is reflected by it with a conſiderable velocity, ſo as to hit the iron as if it had fallen from a great height. Had it it been allowed to fly to that height, it would have fallen upon the iron with ſomewhat more force (becauſe no oaken ſpring is perfectly elaſtic); but this would have required more than twice the time.

38 Great inconveniences of a reciprocating power.

In employing a power which of neceſſity reciprocates, to drive machinery which requires a continuous motion (as in applying the ſteam engine to a cotton or a griſt mill), there alſo occur great difficulties. The neceſſity of reciprocation in the firſt mover waſtes much power; becauſe the inſtrument which communicates ſuch an enormous force muſt be extremely ſtrong, and be well ſupported. The impelling power is waſted in imparting, and afterwards deſtroying, a vaſt quantity of motion in the working beam. The ſkilful engineer will attend to this, and do his utmoſt to procure the neceſſary ſtrength of this firſt mover, without making it a vaſt load of inert matter. He will alſo remark, that all the ſtrains on it, and on its ſupports, are changing their directions in every ſtroke. This requires particular attention to the manner of ſupporting it. If we obſerve the ſteam engines which have been long erected, we ſee that they have uniformly ſhaken the building to pieces. This has been owing to the ignorance or inattention of the engineer in this particular. They are much more judiciouſly erected now, experience having taught the moſt ignorant that no building can withſtand their deſultory and oppoſite jolts, and that the great movements muſt be ſupported by a framework independent of the building of maſonry which contains it (B).

The engineer will alſo remark, that when a ſingle ſtroke ſteam engine is made to turn a mill, all the communications of motion change the direction of their preſſure twice every ſtroke. During the working ſtroke of the beam, one ſide of the teeth of the intervening wheels is preſſing the machinery forward; but during the returning ſtroke, the machinery, already in motion, is dragging the beam, and the wheels are acting with the other ſide of the teeth. This occaſions a rattling at every change, and makes it proper to faſhion both ſides of the teeth with the ſame care.

It will frequently conduce to the good performance of an engine, to make the action of the reſiſting work unequable, accommodated to the inequalities of the impelling power. This will produce a more uniform motion in machines in which the momentum of inertia is inconſiderable. There are ſome beautiful ſpecimens of this kind of adjuſtment in the mechaniſm of animal bodies.

39 Nature, operation, and uſe of Fly.

It is very cuſtomary to add what is called a Fly to machines. This is a heavy diſk or hoop, or other maſs of matter, *balanced on its axis*, and ſo connected with the machinery as to turn briſkly round with it. This may be done with the view of rendering the motion of the whole more regular, notwithſtanding unavoidable inequalities of the accelerating forces, or of the reſiſtances occaſioned by the work. It becomes a Regulator. Suppoſe the reſiſtance extremely unequal, and the impelling power perfectly conſtant; as when a bucket wheel is employed to work *one* pump. When the piſton has ended its working ſtroke, and while it is going down the barrel, the power of the wheel being ſcarcely oppoſed, it accelerates the whole machine, and the piſton arrives at the bottom of the barrel with a conſiderable velocity. But in the riſing again, the wheel is oppoſed by the column of water now preſſing on the piſton. This immediately retards the wheel; and when the piſton has reached the top of the barrel, all the acceleration is undone, and is to begin again. The motion of ſuch a machine is very hobbling: but the ſuperplus of accelerating force at the beginning of a returning ſtroke will not make ſuch a change in the motion of the machine if we connect the fly with it. For the accelerating momentum is a determinate quantity. Therefore, if the radius of the fly be great, this momentum will be attained by communicating a ſmall angular motion to the machine. The momentum of the fly is as the ſquare of its radius; therefore it reſiſts acceleration in this proportion; and although the overplus of power generates the ſame momentum of rotation in the whole machine as before, it makes but a ſmall addition to its velocity. If the diameter of the fly be doubled, the augmentation of rotation will be reduced to one-fourth. Thus, by giving a rapid motion to a ſmall quantity of matter, the great acceleration during the returning ſtroke of the piſton is prevented. This acceleration continues, however, during the whole of the returning ſtroke, and at the end of it the machine has acquired its greateſt velocity. Now the working ſtroke begins, and the overplus of power is at an end. The machine accelerates no more; but if the power is juſt in equilibrio with the reſiſtance, it keeps the velocity which it has acquired, and is ſtill more accelerated during the *next* returning ſtroke. But now, at the beginning of the ſubſequent working ſtroke, there is an overplus of reſiſtance, and a retardation begins, and continues during the whole riſe of the piſton; but it is inconſiderable in compariſon of what it would have been without the fly; for the fly, retaining its acquired momentum, drags forward the reſt of the machine, aiding the impelling power of the wheel. It does this by all the communications taking into each other in the oppoſite direction. The teeth of the intervening wheels are heard to drop from their former contact on one ſide, to a contact on the other. By conſidering this proceſs with attention, we eaſily perceive that, in a few ſtrokes, the overplus of power during the returning ſtroke comes to be ſo adjuſted to the deficiency during the working ſtroke, that the accelerations and retardations exactly deſtroy each other, and every ſucceeding ſtroke is made with the ſame velocity, and an equal number of ſtrokes is made in every ſucceeding minute. Thus the machine acquires a general uniformity with periodical inequalities. It is plain, that by ſufficiently enlarging either the diameter or the weight

---

(B) The gudgeons of a water-wheel ſhould never reſt on the wall of the building. It ſhakes it; and if ſet up ſoon after the building has been erected, it prevents the mortar from taking firm bond; perhaps by ſhattering the calcareous cryſtals as they form. When the engineer is obliged to reſt the gudgeons in this way, they ſhould be ſupported by a block of oak laid a little hollow. This ſoftens all tremors, like the ſprings of a wheel carriage. This practice would be very ſerviceable in many other parts of the conſtruction.

weight of the fly, the irregularity of the motion may be rendered as ſmall as we pleaſe. It is much better to enlarge the diameter. This preſerves the friction more moderate, and the pivot wears leſs. For theſe reaſons, a fly is in general a conſiderable improvement in machinery, by equaliſing many exertions that are naturally very irregular. Thus, a man working at a common windlaſs, exerts a very irregular preſſure on the winch. In one of his poſitions in each turn he can exert a force of near 70 pounds without fatigue, but in another he cannot exert above 25; nor muſt he be loaded with much above this in general. But if a large fly be connected properly with the windlaſs, he will act with equal eaſe and ſpeed againſt 30 pounds.

40
It is a powerful regulator.

This regulating power of the fly is without bounds, and may be uſed to render uniform a motion produced by the moſt deſultory and irregular power. It is thus that the moſt regular motion is given to mills that are driven by a ſingle ſtroke ſteam engine, where for two or even three ſeconds there is no force preſſing round the mill. The communication is made through a maſſive fly of very great diameter, whirling with great rapidity. As ſoon as the impulſe ceaſes, the fly, continuing its motion, urges round the whole machinery with almoſt unabated ſpeed. At this inſtant all the teeth, and all the joints, between the fly and the firſt mover, are heard to catch in the oppoſite direction.

If any permanent change ſhould happen in the impelling power, or in the reſiſtance, the fly makes no obſtacle to its producing its full effect on the machine; and it will be obſerved to accelerate or retard uniformly, till a new general ſpeed is acquired exactly correſponding with this new power and reſiſtance.

Many machines include in their conſtruction movements which are equivalent with this intentional regulator. A flour mill, for example, cannot be better regulated than by its milſtone; but in the Albion mills, a heavy fly was added with great propriety; for if the mills had been regulated by their milſtones only, then at every change of ſtroke in the ſteam engine, the whole train of communications between the beam, which is the firſt mover, and the regulating milſtone, which is the very laſt mover, would take in the oppoſite direction. Although each drop in the teeth and joints be but a trifle, the whole, added together, would make a conſiderable jolt. This is avoided by a regulator immediately adjoining to the beam. This continually preſſes the working machinery in one direction. So judiciouſly were the movements of that noble machine contrived, and ſo nicely were they executed, that not the leaſt noiſe was heard, nor the ſlighteſt tremor felt in the building.

Mr Valoué's beautiful pile engine employed at Weſtminſter Bridge is another remarkable inſtance of the regulating power of a fly*. When the ram is dropped, and its follower diſengaged immediately after it, the horſes would inſtantly tumble down, becauſe the load, againſt which they had been ſtraining hard, is at once taken off; but the gin is connected with a very large fly, which checks any remarkable acceleration, allowing the horſes to lean on it during the deſcent of the load; after which their draught recommences immediately. The ſpindles, cards, and bobbins, of a cotton mill, are alſo a ſort of flies. Indeed all bulky machines of the rotative kind tend to preſerve their motion with ſome degree of ſteadineſs, and their great momentum of inertia is as uſeful in this reſpect as it is prejudicial to the acceleration or any reciprocation when wanted.

41
A bad conſtruction of a fly.

There is another kind of regulating fly, conſiſting of wings whirled briſkly round till the reſiſtance of the air prevents any great acceleration. This is a very bad one for a *working* machine, for it produces its effect by *really waſting* a part of the moving power. Frequently it employs a very great and unknown part of it, and robs the proprietor of much work. It ſhould never be introduced into any machine employed in manufactures.

42
A conical pendulum is the moſt perfect regulator.

Some rare caſes occur where a very different regulator is required; where a certain determined velocity is found neceſſary. In this caſe the machine is furniſhed, at its extreme mover, with a conical pendulum, conſiſting of two heavy balls hanging by rods, which move in very nice and ſteady joints at the top of a vertical axis. It is well known, that when this axis turns round, with an angular velocity ſuited to the length of thoſe pendulums, the time of a revolution is determined. Thus, if the length of each pendulum be 39$\frac{1}{5}$ inches, the axis will make a revolution in two ſeconds very nearly. If we attempt to force it more ſwiftly round, the balls will recede a little from the axis, but it employs as long time for a revolution as before; and we cannot make it turn ſwifter, unleſs the impelling power be increaſed beyond all probability; in which caſe the pendulum will fly out from the centre till the rods are horizontal, after which every increaſe of power will accelerate the machine very ſenſibly. Watt and Boulton have applied this contrivance with great ingenuity to their ſteam engines, when they are employed for driving machinery for manufactures which have a very changeable reſiſtance, and where a certain ſpeed cannot be much departed from without great inconvenience. They have connected this receſs of the balls from the axis (which gives immediate indication of an increaſe of power or a diminution of reſiſtance) with the cock which admits the ſteam to the working cylinder. The balls flying out, cauſe the cock to cloſe a little, and diminiſh the ſupply of ſteam. The impelling power diminiſhes the next moment, and the balls again approach the axis, and the rotation goes on as before, although there may have occurred a very great exceſs or deficiency of power. The ſame contrivance may be employed to raiſe or lower the feeding ſluice of a water mill employed to drive machinery.

43
A fly ſom times col- lects pow

A fly is ſometimes employed for a very different purpoſe from that of a regulator of motion—it is employed as a *collector of power*. Suppoſe all reſiſtance removed from the working point of a machine furniſhed with a very large or heavy fly immediately connected with the working point. When a ſmall force is applied to the impelled point of this machine, motion will begin in the machine, and the fly begin to turn. Continue to preſs uniformly, and the machine will accelerate. This may be continued till the fly has acquired a very rapid motion. If at this moment a reſiſting body be applied to the working point, it will be acted on with very great force; for the fly has now accumulated in its circumference a very great momentum. If a body were expoſed immediately to the action of this circumference, it would be violently ſtruck. Much more will it be ſo, if the body be expoſed to the action of the working

---

* See Pile-*Engine*, Encycl.

working point, which perhaps makes one turn while the fly makes a hundred. It will exert a hundred times more force there (very nearly) than at its own circumference All the motion which has been accumulated on the fly during the whole progreſs of its acceleration is exerted in an inſtant at the working point, multiplied by the momentum depending on the proportion of the parts of the machine. It is thus that the coining preſs performs its office ; nay, it is thus that the blackſmith forges a bar of iron. Swinging the great ſledge hammer round his head, and urging it with force the whole way. this accumulated motion is at once extinguiſhed by impact on the iron. It is thus we drive a nail ; and it is thus that by accumulating a very moderate force exerted during four or five turns of a fly, the whole of it is exerted on a punch ſet on a thick plate of iron, ſuch as is employed for the boilers of ſteam engines. The plate is pierced as if it were a bit of cheeſe. This accumulating power of a fly has occaſioned many who think themſelves engineers to imagine, that a fly really adds power or mechanical force to an engine; and, not underſtanding on what its efficacy depends, they often place the fly in a ſituation where it only added a uſeleſs burden to the machine. It ſhould always be made to move with rapidity. If intended for a mere regulator, it ſhould be near the firſt mover. If it is intended to accumulate force in the working point, it ſhould not be far ſeparated from it. In a certain ſenſe, a fly may be ſaid to add power to a machine, becauſe by accumulating into the exertion of one moment the exertions of many, we can ſometimes overcome an obſtacle that we never could have balanced by the ſame machine unaided by the fly.

It is this accumulation of force which gives ſuch an appearance of power to ſome of our firſt movers. When a man is unfortunately catched by the teeth of a paltry country mill, he is cruſhed almoſt to mummy. The power of the ſtream is conceived to be prodigious; and yet we are certain, upon examination, that it amounts to the preſſure of no more than fifty or ſixty pounds. But it has been acting for ſome time; and there is a milſtone of a ton weight whirling twice round in a ſecond. This is the force that cruſhed the unfortunate man; and it required it all to do it, for the mill ſtopped. We ſaw a mill in the neighbourhood of Elbingroda in Hanover, where there was a contrivance which diſengaged the milſtone when any thing got entangled in the teeth of the wheels. It was tried in our ſight with a head of cabbage. It cruſhed it indeed, but not violently, and would by no means have broken a man's arm.

44
implicity
f conſtruc-
ion recom-
ended.

It is hardly neceſſary to recommend ſimplicity in the conſtruction of machines. This ſeems now ſufficiently underſtood. Multiplicity of motions and communications increaſes frictions ; increaſes the unavoidable loſſes by bending and yielding in every part ; expoſes to all the imperfections of workmanſhip ; and has a great chance of being indiſtinctly conceived, and therefore conſtructed without ſcience. We think the following conſtruction of a capſtan or crab a very good example of the advantages of ſimplicity. It is the invention of an untaught but very ingenious country tradeſman.

45
Example
of a very
ſimple and
powerful
capſtan.

Fig. 3. EAB is the barrel of the capſtan, ſtanding vertically in a proper frame, as uſual, and urged round by bars ſuch as EF. The upper part A of the barrel is 17 inches in diameter, and the lower B is 16. C is a ſtrong pulley 16 inches in diameter, having a hook D, which takes hold of a hawſer attached to the load. The rope ACB is wound round the barrel A, paſſes over the pulley C, and is then wound round the barrel B in the oppoſite direction. No farther deſcription is neceſſary, we think, to ſhew that, by heaving by the bar F, ſo as to wind more of the rope upon A, and unwind it from B, the pulley C muſt be brought nearer to the capſtan by about three inches for each turn of the capſtan ; and that this ſimple capſtan is equivalent to an ordinary capſtan of the ſame length of bar EF, and diameter of barrel B, combined with a 16 fold tackle of pulleys; or, in ſhort, that it is 16 times more powerful than the common capſtan ; free from the great loſs by friction and bending of ropes, which would abſorb a third of the power of a 16 fold tackle ; and that whereas all other engines become weaker as they multiply the power to a greater degree (unleſs they are proportionally more bulky), this engine becomes really ſtronger in itſelf. Suppoſe we wanted to have it twice as powerful as at preſent ; nothing is neceſſary but to cover the part B of the barrel with laths a quarter of an inch thick. In ſhort, the nearer the two barrels are to equality, the more powerful does it become. We give it to the public as an excellent capſtan, and as ſuggeſting thoughts which an intelligent engineer may employ with great effect. By this contrivance, and uſing an iron wire inſtead of a catgut, we converted a common eight day clock into one which goes for two months.

We intended to conclude this article with ſome obſervations on the chief claſſes of powers which are employed to drive machinery; ſuch as water, wind, atmoſpheric preſſure, gunpowder, and the force of men and other animals, giving ſome notion of their abſolute magnitudes, and the effect which may be expected from them. We ſhould then have mentioned what has been diſcovered as to their variation by a variation of velocity. And we intended to conclude with an account of what knowledge has been acquired concerning friction, and the loſs of power in machinery ariſing from this cauſe, and from the ſtiffneſs of ropes, and ſome other cauſes: But we have not yet been able to bring theſe matters into a connected form, which would ſuggeſt the methods and means of farther information thereon. We muſt endeavour to find another opportunity of communicating to the public what we may yet learn on thoſe ſubjects.

We have now eſtabliſhed the principles on which machines muſt be conſtructed, in order that they may produce the greateſt effect ; but it would be improper to diſmiſs the ſubject without ſtating to our readers Mr Bramah's new method of producing and applying a more conſiderable degree of power to all kinds of machinery requiring motion and force, than by any means at preſent practiſed for that purpoſe. This method, for which on the 31ſt of March 1796 he obtained a patent, conſiſts in the application of water or other denſe fluids to various engines, ſo as, in ſome inſtances, to cauſe them to act with immenſe force; in others, to communicate the motion and powers of one part of a machine to ſome other part of the ſame machine; and, laſtly, to communicate the motion and force of one machine to another, where their local ſituations preclude the application of all other methods of connection.

The firſt and moſt material part of this invention will be clearly underſtood by an inſpection of fig. 4. where "A is a cylinder of iron, or other materials, ſufficiently ſtrong, and bored perfectly ſmooth and cylindrical; into which is fitted the piſton B, which muſt be made perfectly water-tight, by leather or other materials, as uſed in pump making. The bottom of the cylinder muſt alſo be made ſufficiently ſtrong with the other part of the ſurface, to be capable of reſiſting the greateſt force or ſtrain that may at any time be required. In the bottom of the cylinder is inſerted the end of the tube C; the aperture of which communicates with the inſide of the cylinder, under the piſton B, where it is ſhut with the ſmall valve D, the ſame as the ſuction-pipe of a common pump. The other end of the tube C communicates with the ſmall forcing pump or injector E, by means of which water or other denſe fluids can be forced or injected into the cylinder A, under the piſton B. Now, ſuppoſe the diameter of the cylinder A to be 12 inches, and the diameter of the piſton of the ſmall pump or injector E only one quarter of an inch, the proportion between the two ſurfaces or ends of the ſaid piſtons will be as 1 to 2304; and ſuppoſing the intermediate ſpace between them to be filled with water or other denſe fluid capable of ſufficient reſiſtance, the force of one piſton will act on the other juſt in the above proportion, viz. as 1 is to 2304. Suppoſe the ſmall piſton in the injector to be forced down when in the act of pumping or injecting water into the cylinder A, with the power of 20 cwt. which could eaſily be done by the lever H; the piſton B would then be moved up with a force equal to 20 cwt. multiplied by 2304. Thus is conſtructed a hydro-mechanical engine, whereby a weight amounting to 2304 tons can be raiſed by a ſimple lever, through equal ſpace, in much leſs time than could be done by any apparatus conſtructed on the known principles of mechanics; and it may be proper to obſerve, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being uſefully extended beyond a certain degree; but in machines acted upon or conſtructed on this principle, every difficulty of this kind is obviated, and their power ſubject to no finite reſtraint. To prove this, it will be only neceſſary to remark, that the force of any machine acting upon this principle can be increaſed *ad infinitum*, either by extending the proportion between the diameter of the injector and the cylinder A, or by applying greater power to the lever H.

"Fig 5. repreſents the ſection of an engine, by which very wonderful effects may be produced inſtantaneouſly by means of compreſſed air. AA is a cylinder, with the piſton B fitting air-tight, in the ſame manner as deſcribed in fig. 4 C is a globular veſſel made of copper, iron, or other ſtrong materials, capable of reſiſting immenſe force, ſimilar to thoſe of air guns. D is a ſtrong tube of ſmall bore, in which is the ſtop-cock E. One of the ends of this tube communicates with the cylinder under the piſton B, and the other with the globe C. Now, ſuppoſe the cylinder A to be the ſame diameter as that in fig. 4. and the tube D equal to one quarter of an inch diameter, which is the ſame as the injector fig. 4.: then, ſuppoſe that air is injected into the globe C (by the common method), till it preſſes againſt the cock E with a force equal to 20 cwt. which can eaſily be done; the conſequence will be, that when the cock E is opened, the piſton B will be moved in the cylinder AA with a power or force equal to 2304 tons; and it is obvious, as in the caſe fig. 4. that any other unlimited degree of force may be acquired by machines or engines thus conſtructed.

"Fig. 6. is a ſection, merely to ſhew how the power and motion of one machine may, by means of fluids, be transferred or communicated to another, let their diſtance and local ſituation be what they may. A and B are two ſmall cylinders, ſmooth and cylindrical; in the inſide of each of which is a piſton, made water and air tight, as in figs 4. and 5. CC is a tube conveyed under ground, or otherwiſe, from the bottom of one cylinder to the other, to form a communication between them, notwithſtanding their diſtance be ever ſo great; this tube being filled with water or other fluid, until it touch the bottom of each piſton; then, by depreſſing the piſton A, the piſton B will be raiſed. The ſame effect will be produced *vice verſa*: thus bells may be rung, wheels turned, or other machinery put inviſibly in motion, by a power being applied to either.

"Fig. 7. is a ſection, ſhewing another inſtance of communicating the action and force of one machine to another; and how water may be raiſed out of wells of any depth, and at any diſtance from the place where the operating power is applied. A is a cylinder of any required dimenſions, in which is the working piſton B, as in the foregoing examples: into the bottom of this cylinder is inſerted the tube C, which may be of leſs bore than the cylinder A. This tube is continued, in any required direction, down to the pump cylinder D, ſuppoſed to be fixed in the deep well EE, and forms a junction therewith above the piſton F; which piſton has a rod G, working through the ſtuffing-box, as is uſual in a common pump. To this rod G is connected, over a pulley or otherwiſe, a weight H, ſufficient to overbalance the weight of the water in the tube C, and to raiſe the piſton F when the piſton B is lifted: thus, ſuppoſe the piſton B is drawn up by its rod, there will be a vacuum made in the pump cylinder D, below the piſton F; this vacuum will be filled with water through the ſuction pipe, by the preſſure of the atmoſphere, as in all pumps fixed in air. The return of the piſton B, by being preſſed downwards in the cylinder A, will make a ſtroke of the piſton in the pump cylinder D, which may be repeated in the uſual way by the motion of the piſton B, and the action of the water in the tube C. The rod G of the piſton F, and the weight H, are not neceſſary in wells of a depth where the atmoſphere will overbalance the water in the ſuction of the pump cylinder D, and that in the tube C. The ſmall tube and cock in the ciſtern I, are for the purpoſe of charging the tube C."

That theſe contrivances are ingenious, and may occaſionally prove uſeful, we are not inclined to controvert; but we muſt confeſs, that the advantages of them appear

appear not to us ſo great as to their author. Why they do not, we need not explain to any man who, with a ſufficient degree of mechanical and mathematical knowledge, has peruſed this article with attention. *Mr John Luccock*, however, of Marley, near Leeds, thinks ſo very differently from us on this ſubject, that, on Mr Bramah's principle, he propoſes to apply water or other denſe fluids, ſo as to make them ſupply the place of ſteam in what is commonly called the *ſteam engine*. He calls his engine the *paradoxical machine;* and he got a patent for it on the 28th of February 1799, though it differs in nothing from Mr Bramah's machine, repreſented by fig. 4. except that the tube C in the paradoxical machine is ſupplied with water, not by means of a forcing pump, but from a ciſtern elevated to ſuch a height as, that the water deſcending through the tube may produce its effect merely by its weight. Whether this variation, for it is no improvement, of Mr Bramah's machine intitled its author to a patent, it is not our buſineſs to inquire.

Macpherſon.

MACPHERSON (James, Eſq;), was born in the pariſh of Kinguſie, and county of Inverneſs, in the year 1738. His father was a farmer of no great affluence; and young Macpherſon received the earlier part of his education in one of the pariſh ſchools in the diſtrict called Badenoch. By an anonymous writer in the Edinburgh Magazine, he is ſaid to have been educated in the grammar ſchool of Inverneſs; and he may, for ought that we know to the contrary, have ſpent a year in that ſeminary; but we rather think that he went directly from a country ſchool to the univerſity of Aberdeen. At this our readers need not be ſurpriſed; for at the period to which we refer, ſome of the parochial ſchoolmaſters in Scotland, and more eſpecially in the Highlands, were men eminent for taſte and claſſical literature.

It was in the end of October or the 1ſt of November 1752, that James Macpherſon entered the King's College; where he diſplayed more genius than learning, entertaining the ſociety of which he was a member, and even diverting the younger part of it from their ſtudies, by his humorous and doggerel rhimes. About two years after his admiſſion into the univerſity, the King's College added two months to the length of its annual *ſeſſion* or *term;* which induced Macpherſon, with many other young men, to remove to the Mariſchal College, where the ſeſſion continued ſhort; and it is this circumſtance which leads us to ſuppoſe that his father was not opulent.

Soon after he left college, and perhaps before he left it, he was ſchoolmaſter of Ruthven, or Riven, of Badenoch; and we believe he afterwards delighted as little as his great antagoniſt Johnſon in the recollection of that period when he was compelled, by the narrowneſs of his fortune, to teach boys in an obſcure ſchool. It was during this period, we think in 1758, that he publiſhed *The Highlander*, an heroic poem in ſix cantos, 12mo. Of this work, as we have never ſeen it, we can ſay nothing. By the anonymous writer already quoted, it is mentioned as a "tiſſue of fuſtian and abſurdity;" whilſt others, and they too men of learning and character, have aſſured us, that it indicated conſiderable genius in ſo young an author.

Soon after this publication, Mr Macpherſon quitted his ſchool, and was received by Mr Graham of Balgowan into his family as tutor to his ſons; an employment of which he was not fond, and to which he was not long condemned. In the year 1760 he ſurpriſed the world by the publication of *Fragments of Ancient Poetry, collected in the Highlands of Scotland, and Tranſlated from the Gaelic or Erſe Language*, 8vo. Theſe fragments, which were declared to be genuine remains of ancient Scottiſh poetry, at their firſt appearance delighted every reader; and ſome very good judges, and amongſt the reſt Mr Gray, were extremely warm in their praiſes. Macpherſon had intended to bury them in a Scotch magazine, but was prevented from ſo injudicious a ſtep by the advice of a friend. He publiſhed them therefore in a pamphlet by themſelves, and thus laid the foundation of his future fortune.

As other ſpecimens were ſaid to be recoverable, a ſubſcription was ſet on foot by the Faculty of Advocates at Edinburgh, to enable our author to quit the family of Balgowan, perambulate the Highlands, and ſecure, if he could, the precious treaſure. He engaged in the undertaking, and was ſucceſsful; for all who poſſeſſed any of the long famed works, vied with each other in giving or ſending them to a man who had ſhewn himſelf ſo capable of doing them juſtice.

With his collection of poems, and fragments of poems, he went to London; and tagging them together in the form which he thought beſt, he publiſhed, in 1762, *Fingal, an Ancient Epic Poem, in ſix books*, together with ſeveral other poems, compoſed by Oſſian the ſon of Fingal, tranſlated from the Gaelic language, 4to. The ſubject of this epic poem is an invaſion of Ireland by Swaran king of Lochlin. Cuchullin, general of the Iriſh tribes during the minority of Cormac king of Ireland, upon intelligence of the invaſion aſſembled his forces near Tura, a caſtle on the coaſt of Ulſter. The poem opens with the landing of Swaran; councils are held, battles fought, and Cuchullin is at laſt totally defeated. In the mean time, Fingal, king of the Highlands of Scotland, whoſe aid had been ſolicited before the enemy landed, arrived, and expelled them from the country. This war, which continued but ſix days and as many nights, is, including the epiſodes, the ſtory of the Poem. The ſcene, the heath of Lena, near a mountain called Cromleach in Ulſter. This poem alſo was received with equal applauſe as the preceding Fragments.

The next year he produced *Temora*, an ancient epic poem, in eight books; together with ſeveral other poems compoſed by Oſſian ſon of Fingal, 4to, which, though well received, found the public ſomewhat leſs diſpoſed to beſtow the ſame meaſure of applauſe. Tho' theſe poems had been examined by Dr Blair and others, and their authenticity aſſerted, there were not wanting ſome of equal reputation for critical abilities, who either doubted or declared their diſbelief of the genuineneſs of them.

them. Into this queſtion it would be ſuperfluous to enter here particularly, as we have ſaid enough on it elſewhere. See OSSIAN, *Encycl.*

That any man ſhould ſuppoſe Macpherſon, after his tranſlation of Homer, the *author* of the poems which he aſcribes to Oſſian, appears to us very extraordinary; and it is little leſs extraordinary, that any one ſhould, for a moment, believe in the exiſtence of *manuſcripts* of theſe poems of *very high* antiquity. Part of them he undoubtedly received in manuſcript from Macdonald of Clanronald; but we can affirm, on the beſt authority, that the ſaid manuſcript was written at different times by the Macvurichs, hereditary bards to that family. He may likewiſe have received ſhort manuſcripts elſewhere; but every Highland gentleman of learning and of candour (and none elſe have a right to decide on this queſtion), declares, that by much the greater part of the poems had been preſerved in fragments and popular ſongs from a very remote age by oral tradition. To theſe fragments Macpherſon and his aſſociates (A) gave form; and it was by uniting together fragments of different ages, that he inadvertently furniſhed Gibbon and others with the opportunity of objecting, that the poems are ſometimes inconſiſtent with the truth of hiſtory. This, however, is no ſolid objection to their authenticity; for every Weſt Highlander ſixty years of age remembers to have heard, in his youth, great part of thoſe poems repeated by old men; and is confident that, many centuries ago, the names of *Fiune Mackuil* (Fingal), and of Oſſian's other heroes and heroines, were as familiar to a Highland ear, as the names of Agamemnon, Hector, Helen, &c. were to a Grecian ear at the time when the poems of Homer were reduced into their preſent form. For the ſubſtance of the poems, this is ſuch evidence as none will reject who does not prefer his own cobweb theories to the united teſtimony of a whole people.

With reſpect to authenticity, the poems of Oſſian have indeed been compared with the poems of Rowley; but the compariſon is abſurd. The poems of the Celtic bard were not found in an old cheſt, and preſented to a people who had never before heard either of them or of their author; they were the popular ſongs and traditions of ages collected together, and reduced into form, with additions occaſionally made by the tranſlator. It is ridiculous to aſk how theſe ſongs and ſtories could be ſo long preſerved among a rude and illiterate people; for it is only among ſuch a people, whoſe objects of purſuit are too few to occupy all their attention, that the exploits of their anceſtors can be handed down by tradition; and the moſt ſerious objection which we have ever met with to the tranſlator's account of the origin of the poems, ariſes from his having pretended that he received the greater part of them in old manuſcripts.

After the publication of Oſſian's poems, by which we have reaſon to believe that he gained twelve hundred pounds, Mr Macpherſon was called to an employment which withdrew him, for ſome time, both from the muſes and from his country. Captain Johnſtone was appointed governor of Penſacola, and Mr Macpherſon accompanied him as his ſecretary, being at the ſame time made ſurveyor-general of the Floridas. If our memory does not deceive us, ſome difference aroſe between the principal and his dependant, and they parted before their return to England. Having contributed his aid to the ſettlement of the civil government of that colony, he viſited ſeveral of the Weſt India iſlands, and ſome of the provinces of North America, and returned to England in the year 1766, where he retained for life his ſalary as ſurveyor, which we believe was L. 200 a-year.

He ſoon returned to his ſtudies, and in 1771 produced *An Introduction to the Hiſtory of Great Britain and Ireland*, 4to; a work which he ſays, "without any of the ordinary incitements to literary labour, he was induced to proceed in by the ſole motive of private amuſement." The ſubject of this performance, it might reaſonably be ſuppoſed, would not excite any violent controverſial acrimony; yet neither it nor its author could eſcape from ſeveral moſt groſs and bitter invectives, for ſome of which he perhaps gave too great occaſion.

His next performance produced him neither reputation nor profit. In 1773 he publiſhed, *The Iliad of Homer*, tranſlated in two volumes 4to; a work fraught with vanity and ſelf-conſequence, and which met with the moſt mortifying reception from the public. It was condemned by the critics, ridiculed by the wits, and neglected by the world. Some of his friends, and particularly Sir John Elliott, endeavoured to reſcue it from contempt, and force it into notice. Their ſucceſs was not equal to their efforts.

About this time ſeems to be the period of Mr Macpherſon's literary mortifications. In 1773 Dr Johnſon and Mr Boſwell made the tour to the Hebrides; and in the courſe of it, the former took ſome pains to examine into the proofs of the authenticity of Oſſian. The reſult of his inquiries he gave to the public in 1775, in his narrative of the tour; and his opinion was unfavourable. "I believe they (*i. e.* the poems, ſays he), never exiſted in any other form than that which we have ſeen. The editor or author never could ſhew the original; nor can it be ſhewn by any other. To revenge reaſonable incredulity by refuſing evidence, is a degree of inſolence with which the world is not yet acquainted; and ſtubborn audacity is the laſt refuge of guilt. It would be eaſy to ſhew it if he had it. But whence could it be had? It is too long to be remembered, and the language had formerly nothing written. He has doubtleſs inſerted names that circulate in popular ſtories, and may have tranſlated ſome wandering ballads, if any can be found; and the names and ſome of the images being recollected, make an inaccurate auditor imagine that he has formerly heard the whole."

Again, he ſays, "I have yet ſuppoſed no impoſture but in the publiſher; yet I am far from certainty, that ſome tranſlations have not been lately made, that

---

(A) We have been aſſured that he had aſſociates: and that for the deſcription of Cuchullin's chariot in particular he was indebted to Mr Macpherſon of *Stramazhie*; a man of native genius, and though not poſſeſſed of very extenſive erudition, well acquainted with Gaelic poetry.

may now be obtruded as parts of the original work.

"Credulity on the one part is a ſtrong temptation to deceit on the other, eſpecially to deceit of which no perſonal injury is the conſequence, and which flatters the author with his own ingenuity. The Scots have ſomething to plead for their eaſy reception of an improbable fiction: they are ſeduced by their fondneſs for their ſuppoſed anceſtors. Neither ought the Engliſh to be much influenced by Scotch authority; for of the paſt and preſent ſtate of the whole Erſe nation, the Lowlanders are at leaſt as ignorant as ourſelves. To be ignorant is painful; but it is dangerous to quiet our uneaſineſs by the deluſive opiate of haſty perſuaſion."

Theſe reaſonings, if reaſonings they can be called, might have been eaſily anſwered, had not Macpherſon pretended to the poſſeſſion of at leaſt one manuſcript which certainly never exiſted. He did not, however, attempt to anſwer them; but adopted a mode of proceeding which tended only to convince the world that Johnſon's opinion had ſome foundation, and that the editor of Oſſian had more imagination than ſound judgement. Prompted by his evil genius, he ſent a menacing letter to his illuſtrious antagoniſt, which produced the following brief but ſpirited reply:

"Mr James Macpherſon, No date.

"I received your fooliſh and impudent letter. Any violence that ſhall be offered to me, I will do my beſt to repel; and what I cannot do for myſelf, the law ſhall do for me; for I will not be hindered from expoſing what I think a cheat, by the menaces of a ruffian. What! Would you have me retract? I thought your work an impoſition: I think ſo ſtill; and, for my opinion, I have given reaſons, which I dare you to refute. Your abilities, ſince your *Homer*, are not ſo formidable; and what I hear of your morality, inclines me to believe rather what you ſhall prove than what you ſhall ſay."

Whether this letter ſhewed to Macpherſon the imprudence of his conduct, or that he had been made ſenſible of his folly by the interpoſition of friends, we know not; but certain it is, we hear no more afterwards of this ridiculous affair, except that our author is ſuppoſed to have aſſiſted Mr Macnicol in an anſwer to Dr Johnſon's Tour, printed in 1779. This ſuppoſition we are inclined to conſider as well-founded, becauſe we have been told by a gentleman of veracity, that Mr Macnicol affirms, that the ſcurrility of his book, which conſtitutes a great part of it, was inſerted, unknown to him, after the manuſcript was ſent for publication to London.

In 1775 Mr Macpherſon publiſhed *The Hiſtory of Great Britain from the Reſtoration to the Acceſſion of the Houſe of Hanover*, in two volumes 4to; a work in our opinion of great merit, though by one party it has been induſtriouſly, and, we are ſorry to add, too ſucceſsfully, decried. As an hiſtorian, our author could not indeed boaſt the attic elegance of a Robertſon, the ſplendour of a Gibbon, or the philoſophical profundity of a Hume; but his *ſtyle*, though it has ſometimes been the avowed, was not the real, cauſe of the coldneſs with which his hiſtory was received. The writer of this ſketch once ſaw a gentleman of rank, and of the Whig intereſt, turn over one of Macpherſon's volumes, and heard him ſay, upon ſhutting the book, "I cannot bear that work." He was aſked if he thought the narrative falſe? and he replied, "No! It is too true; but I cannot bear it, becauſe it gives me a bad opinion of thoſe great men to whom I have been accuſtomed to look back with reverence as to the ſaviours of my country."

That it has been abhorred by others on the ſame account, we have not a doubt; and yet language has no name too contemptuous for thoſe who will not follow truth whitherſoever ſhe may lead them; or who, on the abſurd pretence of having already made up their minds, will not ſtudy the evidence on both ſides of a diſputed queſtion in our national hiſtory. A man needs not ſurely diſapprove of the Revolution, or of the ſubſequent ſettlements, though he ſhould find complete proofs that Danby and Sunderland were crooked politicians, that Marlborough was ungrateful, or even that King William himſelf was not that upright and diſintereſted character which from their infancy they have been taught to believe. It is no uncommon thing for Divine Providence to accompliſh good ends by wicked inſtruments. Every Proteſtant ſurely conſiders the Reformation as one of the moſt bleſſed events that have taken place in the world ſince the firſt preaching of the goſpel of Chriſt; yet he would be a hardy champion who ſhould undertake to vindicate the motives which influenced the conduct of the firſt reformers—of Henry VIII. for inſtance, or even of Luther himſelf. And why may not the Revolution be conſidered as in the higheſt degree beneficial to the country, though the conduct of ſome of thoſe who brought it about ſhould be found to be ſuch as Macpherſon repreſents it?

That author certainly acted with great fairneſs; as together with the hiſtory he publiſhed the proofs upon which his facts were founded, in two quarto volumes, intitled, *Original Papers, containing the ſecret Hiſtory of Great Britain, from the Reſtoration to the Acceſſion of the Houſe of Hanover; to which are prefixed, Extracts from the Life of James II. as written by himſelf.* Theſe papers were chiefly collected by Mr Carte, but are not all of equal authority. They, however, clear up many obſcurities, and ſet the characters of many perſons in paſt times in a different light from that in which they have been uſually viewed. On this account we have no heſitation to ſay, that he who is capable of ſacrificing prejudice to truth, and wiſhes to underſtand the politics of the reigns of James, and William, and Anne, ſhould ſtudy with care the volumes of Macpherſon.

Soon after this period, the tide of fortune flowed very rapidly in Mr Macpherſon's favour, and his talents and induſtry were amply ſufficient to avail himſelf of every favourable circumſtance which aroſe. The reſiſtance of the Colonies called for the aid of a ready writer to combat the arguments of the Americans, and to give force to the reaſons which influenced the conduct of government, and he was ſelected for the purpoſe. Among other things (of which we ſhould be glad to receive a more particular account), he wrote a pamphlet, which was circulated with much induſtry, intitled, *The Rights of Great Britain aſſerted againſt the Claims of the Colonies; being an Anſwer to the Declaration of the General Congreſs*, 8vo, 1776, and of which many editions were publiſhed. He alſo was the author of *A ſhort Hiſtory of Oppoſition during the laſt Seſſion of*

Parliament, 8vo, 1779; a pamphlet which, on account of its merit, was by many aſcribed to Mr Gibbon

But a more lucrative employment was conferred on him about this time. He was appointed agent to the nabob of Arcot, and in that capacity exerted his talents in ſeveral appeals to the public in behalf of his client. Among others, he publiſhed, *Letters from Mahommed Ali Chan, Nabob of Arcot, to the Court of Directors; to which is annexed, a State of Facts relative to Tanjore, with an Appendix of Original Papers*, 4to, 1777; and he was ſuppoſed to be the author of *The Hiſtory and Management of the Eaſt India Company from its Origin in 1600 to the preſent Times*, vol. i. containing the affairs of the Carnatic, in which the rights of the nabob are explained, and the injuſtice of the Company proved, 4to, 1779.

In his capacity of agent to the nabob, it was probably thought requiſite that he ſhould have a ſeat in the Britiſh Parliament. He was accordingly in 1780 choſen member for Camelford; but we do not recollect that he ever attempted to ſpeak in the Houſe. He was alſo rechoſen in 1784 and 1790.

He had purchaſed, we think before the year 1790, an eſtate in the pariſh in which he was born; and changing its name from *Retz* to *Belville*, built on it a large and elegant manſion, commanding a very romantic and pictureſque view; and thither he retired, when his health began to fail, in expectation of receiving benefit from the change of air. He continued, however, to decline; and after lingering ſome time, died at his ſeat at Belville, in Inverneſs, on the 17th of February 1796.

He appears to have died in very opulent circumſtances; and by his will, dated June 1793, gave various annuities and legacies to ſeveral perſons to a great amount. He alſo bequeathed L. 1000 to John Mackenzie of Figtree Court, in the Temple, London, to defray the expence of printing and publiſhing Oſſian in the original. He directed L. 300 to be laid out in erecting a monument to his memory in ſome conſpicuous ſituation at Belville, and ordered that his body ſhould be carried from Scotland, and interred in the Abbey Church of Weſtminſter, the city in which he had paſſed the beſt part of his life. His remains were accordingly taken from the place where he died, and buried in the Poets Corner of Weſtminſter church.

MAGMA is properly the *refuſe* of any ſubſtance which has been ſubjected to preſſure; but, in chemiſtry, the term is ſometimes uſed to denote a mixture of two or more bodies, reduced to the conſiſtence of dough or paſte.

MAGNETISM,

IN natural philoſophy.—Our intention in the preſent article was principally to give a more diſtinct account of the theory of Mr Æpinus than is contained in the article MAGNETISM of the *Encyclopædia Britannica*, referring for proof and illuſtration to the many facts contained in that article: but, on more mature conſideration, we concluded, that this method would fret and confuſe the reader by continual references, and leave but a feeble impreſſion at laſt. We have therefore preferred the putting the whole into the form of a ſhort treatiſe on magnetiſm, ſimilar to our ſupplementary article of ELECTRICITY. This, we hope, will be more perſpicuous and ſatisfactory; ſtill leaving to the reader the full uſe of all the information contained in the article MAGNETISM of the Dictionary.

1
Reaſons why the ancients were ignorant of natural philoſophy.

The knowledge which the antient naturaliſts poſſeſſed of this ſubject was extremely imperfect, and affords, we think, the ſtrongeſt proof of their ignorance of the true method of philoſophiſing; for there can hardly be named any object of phyſical reſearch that is more curious in itſelf, or more likely to engage attention, than the apparent life and activity of a piece of rude unorganiſed matter. This had attracted notice in very early times; for Thales attributed the characteriſtic phenomenon, the attraction of a piece of iron, to the agency of a mind or ſoul reſiding in the magnet. Philoſophers, as they were called, ſeem to have been contented with this lazy notice of a ſlight ſuggeſtion, unbecoming an inquirer, and rather ſuch as might be expected from the moſt incurious peaſant. Even Ariſtotle, the moſt zealous and the moſt ſyſtematic ſtudent of Nature of whoſe labours we have any account, has collected no information that is of any importance. We know that the general imperfection of ancient phyſics has been aſcribed to the little importance that was attached to the knowledge of the material world by the philoſophers of Greece and Rome, who thought human nature, the active purſuits of men, and the ſcience of public affairs, the only objects deſerving their attention. Moſt of the great philoſophers of antiquity were alſo great actors on the ſtage of human life, and deſpiſed acquiſitions which did not tend to accompliſh them for this dignified employment: but they have not given this reaſon themſelves, though none was more likely to be uppermoſt in their mind. Socrates diſſuades from the ſtudy of material nature, not becauſe it was unworthy of the attention of his pupils, but becauſe it was too difficult, and that certainty was not attainable in it. Nothing can more diſtinctly prove their ignorance of what is really attainable in ſcience, namely, the knowledge of the *laws of nature*, and their ignorance of the only method of acquiring this knowledge, viz. obſervation and experiment. They had entertained the hopes of diſcovering the *cauſes* of things, and had formed their philoſophical language, and their mode of reſearch, in conformity with this hopeleſs project. Making little advances in the diſcovery of the cauſes of the phenomena of material nature, they deſerted this ſtudy for the ſtudy of the conduct of man; not becauſe the diſcovery of cauſes was more eaſy and frequent here, but becauſe the ſtudy itſelf was more immediately intereſting, and becauſe any thing like ſuperior knowledge in it puts the poſſeſſor in the deſirable ſituation of an adviſer, a man of ſuperior wiſdom; and as this ſtudy was cloſely connected with morals, becauſe the fear of God is truly the beginning of wiſdom, the character of the philoſopher acquired an eminence and dignity which was highly flattering to human vanity. Their procedure in the moral and intellectual ſciences is ſtrongly marked with the ſame ignorance of the true method of

philo-

philoſophiſing; for we rarely find them forming general propoſitions on copious inductions of facts in the conduct of men. They always proceed in the ſynthetic method, as if they were fully converſant in the firſt principles of human nature, and had nothing to do but to make the application, according to the eſtabliſhed forms of logic. While we admire, therefore, the ſagacity, the penetration, the candid obſervation, and the happy illuſtration, to be found in the works of the ancient moraliſts and writers on juriſprudence and politics, we cannot but lament that ſuch great men, frequently engaged in public affairs, and therefore having the fineſt opportunities for deducing general laws, have done ſo little in this way; and that their writings, however engaging and precious, cannot be conſidered as any thing more refined than the obſervations of judicious and worthy men, with all the diffuſeneſs and repetition of ordinary converſation. All this has ariſen from the want of a juſt notion of what is attainable in this department of ſcience, namely, the laws of intellectual and moral nature; and of the only poſſible method of attaining this knowledge, viz. obſervation and experiment, and the formation of general laws by the induction of particular facts.

2
Dr Gilbert vas the firſt xperimenal enquirer bout magetiſm.

We have been led into theſe reflections by the inattention of the ancients to the curious phenomena of magnetiſm; which muſt have occurred in conſiderable and entertaining variety to any perſon who had taken to the experimental method. And we have hazarded theſe free remarks, expecting the acquieſcence of our readers, becauſe the ſuperior knowledge which we, in theſe later days, have acquired of the magnetical phenomena, were the firſt fruits of the true method of philoſophiſing. This was pointed out to the learned world in 1590 by our celebrated countryman Chancellor Bacon, in his two great works, the *Novum Organum Scientiarum*, and *De Argumentis Scientiarum*. Dr Gilbert of Colcheſter, a philoſopher of eminence in many reſpects, but chiefly becauſe he had the ſame juſt views of philoſophy with his noble countryman, publiſhed about the ſame time his *Phyſiologia Nova, ſeu Tractatus de Magnete et Corporibus magneticis*. In the introduction, he recounts all the knowledge of the antients on the ſubject, and their ſupine inattention to what was ſo entirely in their hands; and the impoſſibility of ever adding to the ſtock of uſeful knowledge, ſo long as men imagined themſelves to be philoſophiſing while they were only repeating a few cant words, and the unmeaning phraſes of the Ariſtotelian ſchool. It is curious to remark the almoſt perfect ſameneſs of Dr Gilbert's ſentiments and language with thoſe of Lord Bacon. They both charge, in a peremptory manner, all thoſe who pretend to inform others, to give over their dialectic labours, which are nothing but ringing changes on a few trite truths, and many unfounded conjectures, and immediately to betake themſelves to experiment. He has purſued this method on the ſubject of magnetiſm with wonderful ardour, and with equal genius and ſucceſs; for Dr Gilbert was poſſeſſed both of great ingenuity, and a mind fitted for general views of things. The work contains a prodigious number and variety of obſervations and experiments, collected with ſagacity from the writings of others, and inſtituted by himſelf with conſiderable expence and labour. It would indeed be a miracle, if all Dr Gilbert's general inferences were juſt, or all his experiments accurate. It was untrodden ground. But, on the whole, this performance contains more real information than any writing of the age in which he lived, and is ſcarcely exceeded by any that has appeared ſince. We may hold it with juſtice as the firſt fruits of the Baconian or experimental philoſophy.

This work of Dr Gilbert's relates chiefly to the loadſtone, and what we call magnets, that is, pieces of ſteel which have acquired properties ſimilar to thoſe of the loadſtone. But he extends the term *magnetiſm*, and the epithet *magnetic*, to all bodies which are affected by loadſtones and magnets in a manner ſimilar to that in which they affect each other. In the courſe of his inveſtigation, indeed, he finds that theſe bodies are only ſuch as contain iron in ſome ſtate or other: and in proving this limitation he mentions a great variety of phenomena which have a conſiderable reſemblance to thoſe which he allows to be magnetical, namely, thoſe which he called *electrical*, becauſe they were produced in the ſame way that amber is made to attract and repel light bodies. He marks with care the diſtinctions between theſe and the characteriſtic phenomena of magnets. He ſeems to have known, that all bodies may be rendered electrical, while ferrugineous ſubſtances alone can be made magnetical.

3
His treatiſe contains many diſcoveries.

It is not ſaying too much of this work of Dr Gilbert's to affirm, that it contains almoſt every thing that we know about magnetiſm. His unwearied diligence in ſearching every writing on the ſubject, and in getting information from navigators, and his inceſſant occupation in experiments, have left very few facts unknown to him. We meet with many things in the writings of poſterior inquirers, ſome of them of high reputation, and of the preſent day, which are publiſhed and received as notable diſcoveries, but are contained in the rich collection of Dr Gilbert. We by no means aſcribe all this to mean plagiariſm, although we know traders in experimental knowledge who are not free from this charge. We aſcribe it to the general indolence of mankind, who do not like the trouble of conſulting originals, where things are mixed with others which they do not want, or treated in a way, and with a painful minuteneſs, which are no longer in faſhion. Dr Gilbert's book, although one of thoſe which does the higheſt honour to our country, is leſs known in Britain than on the continent. Indeed we know but of two Britiſh editions of it, which are both in Latin; and we have ſeen five editions publiſhed in Germany and Holland before 1628. We earneſtly recommend it to the peruſal of the curious reader. He will (beſides the ſound philoſophy) find more facts in it than in the two large folios of Scarella.

After this moſt deſerved eulogy on the parent of magnetical philoſophy, it is time to enter on the ſubject.

4
We can only claſs the phenomena.

In mechanical philoſophy, a phenomenon is not to be conſidered as explained, unleſs we can ſhew that it is the certain reſult of the laws of motion applied to matter. It is in this way that the general propoſitions in phyſical aſtronomy, in the theory of machines, in hydraulics, &c. are demonſtrated. But the phenomena called *magnetical* have not as yet obtained ſuch an explanation. We do not ſee their immediate cauſe, nor can we ſay with confidence that they are the effects of any

any particular kind of matter, acting on the bodies either by impulſion or preſſure.

All that can be done here is to claſs the phenomena in the moſt diſtinct manner, according to their generality. In this we obtain a two-fold advantage. We may take it for granted that the moſt general phenomenon is the neareſt allied to the general cauſe. But, farther, we obtain by this method a true theory of all the ſubordinate phenomena. For a juſt theory is only the pointing out the general fact of which the phenomenon under conſideration is a particular inſtance. Beginning therefore with the phenomenon which comprehends all the particular caſes, we explain thoſe caſes in ſhewing *in what manner* they are included in the general phenomenon, and thus we ſhall be able to predict what will be the reſult of putting the body under conſideration into any particular ſituation. And perhaps we may find, in them all, coincidences which will enable us to ſhew that they are all modifications of a fact ſtill more general. If we gain this point, we ſhall have eſtabliſhed a complete theory of them, having diſcovered the general fact in which they are all comprehended. Should we for ever remain ignorant of the cauſe of this general fact, we have nevertheleſs rendered this a complete branch of mechanical theory. Nay, we may perhaps diſcover ſuch circumſtances of reſemblance between this general fact and others, with which we are better acquainted, that we ſhall, with great probability at leaſt, be able to aſſign the cauſe of the general fact itſelf, by ſhewing the law of which it is a particular inſtance.

We ſhall attempt this method on the preſent occaſion.

5
First leading fact. Iron arranges itſelf in a particular poſition.

The leading facts in magnetiſm are the two following:

1. If any oblong piece of iron, ſuch as a bar, rod, or wire, be ſo fitted, that it can aſſume any direction, it will arrange itſelf in a certain determinate direction with reſpect to the axis of the earth. Thus, if, in any part of Britain, an iron or ſteel wire be thruſt through a piece of cork, as repreſented in fig. 1. ſo as that the whole may ſwim level in water, and if it be laid in the water nearly north-weſt and ſouth-eaſt, it will ſlowly change its poſition, and finally ſettle in a direction, making an angle of about 25 degrees with the meridian.

Plate XXXIV.

This experiment, which we owe to Dr Gilbert (ſee B. I. ch. 11.), is delicate, and requires attention to many circumſtances. The force with which the iron tends toward this final poſition is extremely weak, and will be balanced by very minute and otherwiſe inſenſible reſiſtances; but we have never found it fail when executed as here directed. An iron wire of the ſize of an ordinary quill, and about eight or ten inches long, is very fit for the purpoſe. It ſhould be thruſt through the cork at right angles to its axis; and ſo adjuſted, by repeated trials, as to ſwim level or parallel to the horizon. The experiment muſt alſo be made at a great diſtance from all iron; therefore in a baſon of ſome other metal or earthen ware. It may ſometimes require a very long while before the motion begin; and if the wire has been placed at right angles to the direction which we have mentioned as final, it will never change its poſition: therefore we have directed it to be laid in a direction not too remote, yet very ſenſibly different from the final direction.

But this is not the true poſition affected by the iron rod. If it be thruſt through a piece of wood or cork perfectly ſpherical, in ſuch a manner that it paſſes thro' its centre, and if the centre of gravity coincide with this centre, and the whole be of ſuch weight as to remain in any part of the water, without either aſcending or deſcending, then it will finally ſettle in a plane inclined to the meridian about 25°, and the north end will be depreſſed about 73° below the horizon.

All this is equivalent with ſaying, that if any oblong piece of iron or ſteel be very nicely poiſed on its centre of gravity, and at perfect liberty to turn round that centre in every direction, it will finally take the poſition now mentioned.

We have farther to obſerve with regard to this experiment, that it is indifferent which end of the rod be placed toward the north in the beginning of the experiment. That end will finally ſettle toward the north; and if the experiment be repeated with the ſame rod, but with the other end north, it will finally ſettle in this new attitude. It is, however, not always that we find pieces of iron thus perfectly indifferent. Very frequently one end affects the northerly poſition, and we cannot make the other end aſſume its place: the cauſes of this difference will be clearly ſeen by and bye.

6
Magnetical poſition.

The poſition thus affected by a rod of iron is called by Dr Gilbert the MAGNETICAL POSITION or DIRECTION. It is not the ſame, nor parallel, in all parts of the earth, as will be more particularly noticed afterwards.

7
Second fact. Iron attracts and repels iron.

2. The other leading fact is this: When a piece of iron, lying in the *magnetical* poſition, or nearly ſo, and at perfect liberty to move in every direction, is approached by another oblong piece of iron, held nearly in the ſame poſition, it is attracted by it; that is, the moveable piece of iron will gradually approach to the one that is preſented to it, and will at laſt come into contact with it, and may then be ſlowly drawn along by it.

This phenomenon, although not ſo delicate as the former, is ſtill very nice, becauſe the attraction is ſo weak that it is balanced by almoſt inſenſible obſtructions. But the experiment will ſcarcely fail if conducted as follows: Let a ſtrong iron wire be made to float on water by means of a piece of cork, in the manner already deſcribed, having one end under water. See fig. 1. B.

When it is nearly in the magnetical poſition, bring the end of a pretty big iron rod, ſuch as the point of a new poker, within a quarter of an inch of its ſouthern end (holding the poker in a poſition not very different from the magnetical poſition), and hold it there for ſome time, not exactly ſouthward from it, but a little to one ſide. The floating iron will be obſerved to turn towards it with an accelerated motion; will touch it, and may then be drawn by it through the water in any direction. We ſhall have the ſame reſult by approaching the northern extremity of the floating iron with the upper end of the poker.

The ſame phenomenon may be obſerved by ſuſpending the firſt piece of iron by its middle by a long and ſlender hair or thread. The ſuſpenſion muſt be long, otherwiſe the ſtiffneſs of the hair or thread may be ſufficient for balancing the very ſmall force with which the pieces of iron tend toward each other. The phenomenon

non may alſo be obſerved in a piece of iron which turns freely on a fine point, like the needle of the mariner's compaſs.

In this, as in the former experiment, the ends of the pieces of iron are obſerved, in general, to be indifferent; that is, either end of the one will attract either end of the other. It often happens, however, that the ends are not thus indifferent, and that the end of the moveable piece of iron, inſtead of approaching the other, will be obſerved to recede from it, and appear to avoid it. We ſhall ſoon learn the cauſe of this difference in the ſtates of iron.

8 This action mutual.

It is ſcarcely neceſſary to remark, that we muſt infer from theſe experiments, that the action is mutual between the two pieces of iron. Either of them may be the moveable piece which approaches the other, manifeſting the attraction of that other. This reciprocity of action will be abundantly verified and explained in its proper place.

9 Not peculiar to magnets or loadſtone;

Theſe two facts were long thought to be peculiar to loadſtones and artificial magnets, that is, pieces of iron which have acquired this property by certain treatment with loadſtones; but they were diſcovered by Dr Gilbert to be inherent in all iron in its metallic ſtate; and were thought by him to be neceſſary conſequences of a general principle in the conſtitution of this globe. Theſe phenomena are indeed much more conſpicuous in loadſtones and magnets; and it is therefore with ſuch that experiments are beſt made for learning their various modifications.

10 But, in iron, is indifferent, and momentary, and in loadſtones it is fixed and determinate.

But there is another circumſtance, beſides the degree of vivacity, in which the magnetiſm of common iron and ſteel remarkably differs from that of a loadſtone or magnet. When a loadſtone or magnet is ſo ſupported as to be at liberty to take any poſition, it arranges itſelf in the magnetical direction, and *one determined end* of it ſettles in the northern quarter; and if it be placed ſo that the other end is in that ſituation, it does not remain there, but gradually turns round, and, after a few oſcillations, the *ſame end* ultimately ſettles in the north. This is diſtinctly ſeen in the needle of the mariner's compaſs, which is juſt a ſmall magnet prepared in the ſame way with all other magnets. The ſeveral ends of loadſtones or magnets are thus permanently the north or the ſouth ends; whereas we ſaid that either end of a piece of common iron being turned to the northern quarter, it finally ſettles there

It is this circumſtance which has rendered magnetiſm ſo precious a diſcovery to mankind, by furniſhing us with the compaſs, an inſtrument by which we learn the different quarters of the horizon, and which thus tells the direction of a ſhip's courſe through the pathleſs ocean (ſee COMPASS and VARIATION, *Encycl.)*; and alſo ſhews us the directions of the veins and workings in the deepeſt mines. It was natural therefore to call thoſe the north and ſouth ends of the mariner's needle, or of a loadſtone or magnet. Dr Gilbert called them the POLES of the loadſtone or magnet. He had found it convenient for the propoſed train of his experiments to form his loadſtones into ſpheres, which he called TERRELLÆ, from their reſemblance to this globe; in which caſe the north and ſouth ends of his loadſtones were the poles of the terrellæ. He therefore gave the name *pole* to that part of any loadſtone or magnet which thus turned to the north or ſouth. The denomination was adopted by all ſubſequent writers, and now makes a term in the language of magnetiſm.

11 POLES.

Alſo, when we approach either end of a piece of iron A to either end of another B, theſe ends mutually attract; or if either end of a magnet A be brought near either end of a piece of common iron, they mutually attract each other. But if we bring that end of a magnet A which turns to the north near to the *ſimilar* end of another magnet B, theſe ends will not attract each other, but, on the contrary, will repel. If the two magnets are made to float on pieces of wood, and have their north poles fronting each other, the magnets will retire from each other; and in doing ſo, they generally turn round their axes, till the north pole of one front the ſouth pole of the other, and then they run together. This is a very notable diſtinction between the magnetiſm of magnets and that of common iron; and whenever we ſee a piece of iron ſhew this permanent diſtinction of its ends, we muſt conſider it as a magnet, and conclude that it has met with ſome peculiar treatment.

It is not, however, ſtrictly true, that the poles of loadſtones or magnets are ſo fixed in particular parts of their ſubſtance, nor that the poles of the ſame name ſo conſtantly repel each other; for if a ſmall or weak magnet A have its pole brought near the ſimilar pole of a large or ſtrong magnet B, they are often found to attract when almoſt touching, although at more conſiderable diſtances they repel each other. But this is not an exception to the general propoſition; for when the north pole of A is thus attracted by the north pole of B, it will be found, by other trials, to have all the qualities of a ſouth pole, while thus in the neighbourhood of the north pole of B.

12 Magnetic FORCE and POLARITY.

The magnetic properties and phenomena are conveniently diſtinguiſhed into thoſe of FORCE and of POLARITY. Thoſe of the firſt claſs only were known to the ancients, and even of them their knowledge was extremely ſcanty and imperfect. They may all be claſſed under the following general propoſitions.

13 Similar poles repel and diſſimilar poles attract, each other.

1. The ſimilar poles of two magnets repel each other with a force decreaſing as the diſtances increaſe.
2. The diſſimilar poles of two magnets attract each other with a force decreaſing as the diſtances increaſe.
3. Magnets arrange themſelves in a certain determinate poſition with reſpect to each other.

14 The law of attraction and repulſion is of difficult inveſtigation.

The firſt object of reſearch in our farther examination of theſe properties is the relation which is obſerved to obtain between the diſtances of the acting poles and their force of action. This has accordingly occupied much attention of the philoſophers, and numberleſs experiments have been made in order to aſcertain the law of variation, both of the attraction and the repulſion. A great number of theſe have been narrated in the article MAGNETISM of the *Encycl.* from which it appears that it has been a matter of great difficulty, and had not been aſcertained with certainty or preciſion when that article was publiſhed. It is obvious, from the nature of the thing, that the determination is very difficult, and the inveſtigation very complicated. We can only obſerve the ſimultaneous motion of the whole magnet; yet we know that there are four ſeparate actions coexiſting and contributing in different directions, and with different forces, to the ſenſible effect. The force which we meaſure, in any way whatever, is compounded

pounded of four different forces, which we cannot ſeparate and meaſure apart; for the north pole of A repels the north pole of B, and attracts its ſouth pole, while the ſouth pole of A exerts the oppoſite forces on the ſame poles of B. The attraction which we obſerve is the exceſs of two unequal attractions above two unequal repulſions. The ſame might be ſaid of an obſerved repulſion. Nay, the matter is incomparably more complicated than this; becauſe, for any thing that we know, *every* particle of A acts on *every* particle of B, and is acted on by it; and the intenſity of thoſe actions may be different at the ſame diſtances, and is certainly different when the diſtances are ſo. Thus there is a combination of an unknown number of actions, each of which is unknown individually, both in direction and intenſity. The preciſe determination is therefore, in all probability, impoſſible. By preciſe determination, we mean the law of mutual action between two magnetic particles, or that preciſe function of the diſtance which defines the intenſity of the force; ſo that meaſuring the diſtance of the acting particles on the axis of a curve, the ordinates of the curve may have the proportions of the attractions and repulſions.

It is almoſt needleſs to attempt any deduction of the law of variation from the numerous experiments which have been publiſhed by different philoſophers. An ample collection of them may be ſeen in Scarella's treatiſe. Mr Muſchenbroek has made a prodigious number; but all are ſo anomalous, and exhibit ſuch different laws of diminution by an increaſe of diſtance, that we may be certain that the experiments have been injudicious. Attention has not been paid to the proper objects. Magnets of moſt improper ſhapes have been employed, and of moſt diffuſe polarity. No notice has been taken of a circumſtance which, one ſhould think, ought to have occupied the chief attention; namely, the joint action of four poles, of which the experiment exhibits only the complex reſult. A very ſlight reflection might have made the enquirer perceive, that the attractions or repulſions are not the moſt proper phenomena for declaring the preciſe law of variation; becauſe what we obſerve is only the exceſs of a ſmall difference of attractions and repulſions above another ſmall difference. Mr Hawkſbee and Dr Brook Taylor employed a much better method, by obſerving the deviations from the meridian which a magnet occaſioned in a compaſs needle at different diſtances. This is occaſioned by the difference of the two ſums of the ſame forces; and this difference may be made a hundred times greater than the other. But they employed magnets of moſt improper ſhapes.

15
Judicious experiments by Mr Lambert.

We muſt except from this criticiſm the experiments of Mr Lambert, recorded in the Memoirs of the Academy of Berlin for 1756, publiſhed in 1758. This moſt ſagacious philoſopher (for he highly merits that name) placed a mariner's needle at various diſtances from a magnet, in the direction of its axis, and obſerved the declination from the magnetic meridian produced by the magnet, and the obliquity of the magnet to the axis of the needle. Thus, was the action of the magnet ſet in oppoſition and equilibrium with the natural polarity of the needle. But the difficulty was to diſcover in what proportion each of thoſe forces was changed by their obliquity of action on this little lever. No man excelled Mr Lambert in addreſs in deviſing methods of mathematical inveſtigation. He obſerved, that when the obliquity of the magnet to the axis of the needle was 30°, it cauſed it to decline 15°. When the obliquity was 75°, the diſtance being the ſame, it declined 30°. Call the obliquity *o*, and the declination *d*, and let *f* be that function of the angle which is proportionable to the action. Alſo let *p* be the natural polarity of the needle, and *m* the force of the magnet. It is evident that

$$p \times f,\ 15 = m \times f,\ 30$$

And $p : m = f,\ 30 : f,\ 15$; for the ſame reaſon

$$p : m = f,\ 75 : f,\ 30$$

Therefore $f.\ 15 : f\ 30 = f,\ 30 : f,\ 75°$.

But it is well known that

Sine 15 : Sine 30 = Sine 30 : Sine 75.

Hence Mr Lambert was led to conjecture, that the ſine was that function of the angle which was proportional to the action of magnetiſm on a lever. But one experiment was inſufficient for determining this point. He made a ſimilar compariſon of ſeveral other obliquities and declinations with the ſame diſtances of the magnet, and alſo with other diſtances; and he put it paſt all diſpute, that his conjecture was juſt.

Had Mr Lambert's experiments terminated here, it muſt be granted that he has made a notable diſcovery in the theory of the intimate nature of magnetiſm. It completely refutes all the theories which pretend to explain the action of a magnet by the impulſion of a ſtream of fluid, or by preſſure ariſing from the motion of ſuch a ſtream; for in this caſe the preſſure on the needle muſt have diminiſhed in the duplicate ratio of the ſine. The directive power with the angle 90 muſt be 4 times greater than with the angle 30°; whereas it was obſerved to be only twice as great. Magnetiſm does not act therefore by the impulſion or preſſure of a ſtream of fluid, but in the manner of a ſimple incitement, as we conceive attraction or repulſion to act.

Having aſcertained the effect of obliquity, Mr Lambert proceeded to examine the effect of diſtance; and, by a moſt ingenious analyſis of his obſervations, he diſcovered, that if we repreſent the force of the magnet by *f*, and the diſtance of the neareſt pole of the magnet from the centre of the needle by δ, and if a be a conſtant quantity, nearly equal to two-thirds of the length of the needle, we have *f* proportional to $\overline{\delta - a}^2$.

Mr Lambert found this hold with very great exactneſs with magnets ten times larger, and needles twice as ſhort. But he acknowledges, that it gives a very ſingular reſult, as if the action of a magnet were exerted from a centre beyond itſelf. He attributes this to its true cauſe, the ſtill great complication of the reſult, ariſing from the action of the remote pole of the magnet. He therefore takes another method of examination, which we ſhall underſtand by and bye, when we conſider the *directive* power of a magnet. We have mentioned this imperfect attempt chiefly on account of the unqueſtionable manner in which he has aſcertained the effect of obliquity, and the importance of this determination.

We have attempted this inveſtigation in a very ſimple manner. We got ſome magnets made, conſiſting of two balls connected by a ſlender rod. By a very particular mode of impregnation, we gave them a pretty good magne-

magnetiſm ; and the force of each pole ſeemed to reſide almoſt in the centre of the ball. This was our object in giving them this ſhape. It reduced the examination both of the attractive and of the directive power to a very eaſy computation. The reſult was, that the force of each pole varied in the inverſe duplicate ratio of the diſtance. The error of this hypotheſis in no caſe amounted to $\frac{1}{15}$th of the whole. In computing for the phenomena of the directive power, the irregularities and deviations from this ratio were much ſmaller.

The previous knowledge of this function would greatly expedite and facilitate our farther inveſtigation: but we muſt content ourſelves with a very imperfect approximation, and with arriving at the deſired determination by degrees, and by a very circuitous route.

lge of
is law.

It is a matter of experience, that when two magnets are taken, each of which is as nearly equal as poſſible in the ſtrength of both poles, then, if they are placed with their axes in one ſtraight line, and the north pole of one fronting the ſouth pole of the other, they attract each other with a force which diminiſhes as the diſtance increaſes ; and this variation of force is regular, that is, without any ſudden changes of intenſity, till it becomes inſenſible. No inſtance has occurred of its breaking ſuddenly off when of any ſenſible force, but it appears to diminiſh continually like gravity. No inſtance occurs in which attraction is changed into repulſion.

But it is, moreover, to be particularly remarked, that, having made this obſervation with the north pole of A fronting the ſouth pole of B, if the experiment be repeated with the ſouth pole of A fronting the north pole of B, the reſults will be preciſely the ſame. And, laſtly, it is a matter of unexcepted experience, that the ſenſible action of A on B, meaſured by the force which is neceſſary for preventing the farther approach of B, is preciſely equal to the action of B on A. This is the caſe, however unequal the force of the two magnets may be ; that is, although A may ſupport ten pounds of iron, and B only ten ounces.

Now, the ſimpleſt view we can take of this experiment is, by ſuppoſing the whole action of one end or pole of a magnet to be exerted at one point of it. This will give us four actions of A on B, accompanied by as many equal and oppoſite actions of B on A. It is plain that we may content ourſelves with the inveſtigation of one only of theſe ſets of actions.

What we obſerve is the exceſs of the attractions of the poles of A for the diſſimilar poles of B above the repulſions of the ſame poles of A for the ſimilar poles of B. At all diſtances there is ſuch an exceſs. The ſum of the attractions exceeds the ſum of the repulſions competent to every diſtance.

Now this will really happen, if we ſuppoſe that the poles of a magnet are of equal ſtrength, and that, however theſe different magnets differ in ſtrength, they have the ſame law of diminution by an increaſe of diſtance. The firſt circumſtance is a very poſſible thing, and the laſt is demonſtrated by the obſerved equality of action and reaction. Every thing will now appear very plain, by repreſenting (as we did in ELECTRICITY, *Suppl.* n° 44, &c.) the intenſities of attraction and repulſion by the ordinates of a curve, of which the abſciſſæ repreſent the diſtances of the acting poles.

Therefore let A and B (fig. 2.) repreſent the two magnets, placed with their four poles S, N, s, n, in a ſtraight line. In the ſtraight line Oq take Om, Op, On, Oq, reſpectively equal to Ns, Nn, Ss, Sn ; and let MPNQ be a curve line, having Oq for its axis and aſſymptote ; and let the curve, in every part, be convex towards its axis. Then draw the ordinates mM, pP, nN, qQ, to the curve. Theſe ordinates will repreſent the intenſities of the forces exerted between the poles of the magnets, in ſuch a manner as to fulfil all the conditions that are really obſerved : For mM repreſents the attraction of the north pole N of the magnet, A for the ſouth pole s of the magnet B ; pP repreſents the repulſion of N for n ; nN repreſents the repulſion of S for s ; and qQ repreſents the attraction of S for n. The diſtance between m and n, or between p and q, is equal to the length of the magnet A, and mp, or nq, is equal to that of B. Mm, Pp, and Nn, Qq, are pairs of equidiſtant ordinates. It ſurely requires only the inſpection of the figure to ſee that, in whatever ſituation along the axis we place thoſe pairs of equidiſtant ordinates, the ſum of Mm and Qq will always exceed the ſum of Pp and Nn ; that is, the ſum of the attractions will always exceed that of the repulſions. This will not be the caſe if the curve, whoſe ordinates are proportional to the forces, have a point Z of contrary flexure, as is repreſented by the dotted curve P′ZQ′. For this curve, having Oq for its aſſymptote (in order to correſpond with forces which diminiſh continually by an increaſe of diſtance, but do not abruptly ceaſe) muſt have its convexity turned toward this aſſymptote in the remote parts. But there will be an arch MPZ between Z and O, which is concave toward the aſſymptote. In which caſe, it is poſſible that Mm + Qq ſhall be leſs than Pp + Nn ; and then the repulſions will exceed the attractions ; which is contrary to the whole train of obſervation.

It may be thought, that if the repulſion exerted between two particles be always leſs than the attraction at the ſame diſtance, the phenomena will be accounted for, although the law of action be not repreſented by ſuch a curve as has been aſſumed. Undoubtedly they will, while the diſſimilar poles front each other. But the reſults of ſuch a ſuppoſition will not agree with the phenomena while the ſimilar poles front each other : For it is an uncontradicted fact, that when two fine hard magnets, whoſe poles are nearly or exactly of equal vigour, have their ſimilar poles fronting each other, the repulſions fall very little ſhort of the attractions at the ſame diſtances when their poſition is changed : When the diſtances are conſiderable, ſcarcely any difference can be obſerved in the beginning of the experiment. The differences, alſo, which are obſerved at ſmaller diſtances, are obſerved to augment by continuing the magnets in their places without changing their diſtances ; and therefore ſeem to ariſe from ſome change produced by each on the magnetiſm of the other. And, accordingly, if we invert one of the magnets, we ſhall find that the attractions have been diminiſhed as much as the repulſions. Now, the conſequences of magnetic repulſion, being always weaker than attraction, would be the reverſe of this. The differences would appear moſt remarkable in the greater diſtances, and magnets might be found which repel at ſmall diſtances, and attract at greater diſtances ; which is contrary to all obſervation.

From all this it follows, with ſufficient evidence for our

our preſent purpoſe, that the function of the diſtance which expreſſes the law of magnetic action muſt be repreſented by the ordinates of a curve of the hyperbolic kind, referred to its aſſymptote as an axis; and therefore always convex toward this axis. We think it alſo ſufficiently clear, that the conſequences which we have deduced from the ſimple ſuppoſition of four acting points, inſtead of the combined action of every particle, may be adopted with ſafety. For they would be juſt, if there were only thoſe four particles; they would be juſt with reſpect to another four particles—therefore they would be juſt when theſe are joined; and ſo on of any number. Therefore the curve, whoſe ordinates expreſs the mean action of each pole, as if exerted by its centre of effort, will have the ſame general form: It will be convex toward its aſſymptotic axis.

It will greatly aid our conceptions of the combined actions of the four magnetic poles, if we notice ſome of the primary properties of a curve of this kind, limited by no other condition.

17 Unqueſtionable inferences from the phenomena.

Draw the chords MQ, PN, MP, NQ. Biſect them in B, D, E, F, and join EF. Draw the ordinates E e F f, and BD b (cutting EF in C). Draw P u parallel to the axis, cutting E e in ϵ. Draw alſo Q i parallel to the axis, cutting F f in φ. Alſo draw FHL parallel to the axis, and P o t parallel to QN; and draw PL l, and P e x, cutting M m in l and x.

Let each ordinate be repreſented by the letter at its interſection with the axis. Thus, the ordinates M m and Q q may be repreſented by m and q, &c.

Becauſe MP is biſected in E, M t is double of E ϵ; M l is double of EL; M x is double of E e. Alſo, becauſe P t is parallel to QN, and P u to Q i, we have $t\,u = \mathrm{N}\,i$. From theſe premiſes, it is eaſy to perceive, that,

1. $\mathrm{B}\,b = \frac{m+q}{2}$.
2. $\mathrm{D}\,b = \frac{p+n}{2}$.
3. $\mathrm{BD} = \frac{\overline{m+q} - \overline{p+n}}{2}$.
4. $\mathrm{M}u = m - p$.
5. $u\,t = n - q$.
6. $\mathrm{M}\,t = \overline{m-p} - \overline{n-q}$.
7. $\mathrm{E}\,e = \frac{m+p}{2}$.
8. $\mathrm{F}\,f = \frac{n+q}{2}$.
9. $\mathrm{M}\,l = \overline{m+p} - \overline{n+q}$.
10. $\mathrm{EL} = \frac{\overline{m+p} - \overline{n+q}}{2}$.
11. $\mathrm{CD} = \frac{\overline{m+q} - \overline{p+n}}{4}$.
12. $\mathrm{CH} = \frac{\overline{m+p} - \overline{n+q}}{4}$.

Theſe combinations will ſuggeſt to the attentive reader the explanation of many modifications of the combined action of the four poles of two magnets. They are all comprehended in one propoſition, which it will be convenient to render familiar to the thought; namely, if two pairs of equidiſtant ordinates be taken, the ſum of the two extremes exceeds that of the intermediate ones. $m + q$ is greater than $p + n$. Alſo, the difference between the pair neareſt to O exceeds the difference between the remote pair.

Now, conceiving theſe ordinates to repreſent the mutual actions of the magnetic poles, we ſee that their tendency to or from each other, or their ſenſible attractions or repulſions, are expreſſed by $\overline{m+q} - \overline{n+p}$; that is, by the exceſs of the ſum of the actions of the neareſt and moſt remote poles above the ſum of the actions of the intermediate diſtant poles. It will alſo be frequently convenient to conſider this tendency as repreſented by $\overline{m-p} - \overline{n-q}$; that is, by the exceſs of the difference of the actions of the neareſt pole of A on the two poles of B, above the difference of the actions of its remote pole on the ſame poles of B.

Let us now conſider ſome of the chief modifications of theſe actions.

18 Explanation of the obſerved attraction of magnets,

1. Let the diſſimilar poles front each other. It is plain that $m + q$ repreſent attractions, and that $p + n$ repreſent repulſions. Alſo $m + q$ is greater than $p + n$. Therefore the magnets will attract each other. This attraction is alſo repreſented by $\overline{m-p} - \overline{n-q}$.

Now $\overline{m+q} - \overline{p+n}$ is evidently equal to M t, or to twice E o, or to twice BD, or to four times CD.

This action will be increaſed,

1. By increaſing the ſtrength of either of the magnets. The action of the magnets is the combined action of each acting particle of the one on each acting particle of the other; and it is mutual. Therefore all the ordinates will increaſe in the ratio of the ſtrength of each magnet, and their ſums and differences will increaſe in the ſame ratio.

2. By diminiſhing the diſtance between the magnets. For this brings all the ordinates nearer to O, while their diſtances mp, pn, nq, remain as before. In this caſe it is plain, that M u, the difference of M m and P p, will increaſe faſter than $t\,u$ or N i, the difference between N n and Q q. Therefore M t will increaſe; that is, the attraction will increaſe.

3. By increaſing the length of A, while the diſtance between them remains the ſame. For O m remaining the ſame, as alſo $m\,p$ and $n\,q$, while $n\,q$ is only removed farther from $m\,p$, it is plain M u remains the ſame, and that N i and $t\,u$ are diminiſhed; therefore M t muſt increaſe, or the attraction muſt increaſe.

4. By increaſing the length of B, the diſtance between them remaining the ſame. For this increaſes $m\,p$ and $n\,q$; and conſequently increaſes M u and $t\,u$. But M u increaſes more than $t\,u$; and therefore M t is increaſed, and the attraction or tendency is increaſed.

All theſe conſequences of our original ſuppoſition, that the magnetic action may be repreſented by the ordinates of a curve every where convex to an aſſymptotic axis, are ſtrictly conformable to obſervation.

19 And of their rep ſions.

If we place the magnets with their ſimilar poles fronting each other, it is evident that the ordinates which expreſſed attractions in the former caſe, will now expreſs repulſions; and that the forces with which the magnets now repel each other, are equal to thoſe with which they attracted when at the ſame diſtances. When the experiments are made with good loadſtones, or very fine magnets, tempered extremely hard, and having the energy of their poles ſenſibly reſiding in a ſmall ſpace very near the extremities, the reſults are alſo very near-

ly

ly conformable to this mathematical theory; but there is generally a weaker action. The magnets ſeldom repel as ſtrongly as they attract at the ſame diſtance; at leaſt when theſe diſtances are ſmall. If one or both of the magnets is ſoft, or if one of them be much more vigorous than the other, there are obſerved much greater deviations from this theory. The repulſions are *conſiderably* weaker than the attractions at the ſame diſtance, and the law of variation becomes extremely different. When placed at very conſiderable diſtances, they repel. As the magnet B is brought nearer to A, the repulſion increaſes, agreeably to the theory, but not ſo faſt. Bringing them ſtill nearer, the repulſion ceaſes to increaſe, then gradually diminiſhes, and frequently vaniſhes altogether, before the magnets are in contact; and when brought ſtill nearer, it is changed into attraction.

20
ming
eptions
iated.

But more careful obſervation ſhews, that this ano maly does not invalidate the theory. It is found that the vigour of the magnets is permanently changed by this proceſs. The magnets act on each other in ſuch a way as to weaken each other's magnetiſm. Nay, it frequently happens, that the weaker or the ſofter of the two has had its magnetiſm changed, and that the pole neareſt to the other has changed its nature. While they are lying in contact, or at ſuch a diſtance that they attract, although their ſimilar poles front each other, it is found that the pole of one of them is really changed; although it may ſometimes recover its former ſpecies again, but never ſo vigorouſly as when the other magnet is removed. In ſhort, it is obſerved, that the magnetiſm is diminiſhed in all experiments in which the magnets repel each other, and that it is improved in all experiments in which they attract.

We have hitherto ſuppoſed the magnets placed with their axes in one ſtraight line. If they are differently placed, we cannot aſcertain by this ſingle circumſtance of the law of magnetic action, whether they will attract or repel—we muſt know ſomewhat more of the variation of force by a change of diſtance.

21
RECTIVE
WER ex-
ined.

If the magnet B be not at liberty to approach toward A, or recede from it, but be ſo ſupported at its centre B that it can turn round it, it is very plain that it will retain the poſition in which it is drawn in the figure. For its ſouth pole *s* being more attracted by N than it is repelled by S, is, on the whole, attracted by the magnet A; and, by this attraction, it would vibrate like a pendulum that is ſupported at the centre B. In like manner, its north pole *n* is more repelled by N than it is attracted by S, and is, on the whole, repelled. The part B *n* would therefore alſo vibrate like a pendulum round B. Thus each half of it is urged into the very poſition which it now has; and if this poſition be deranged a little, the attraction of *s* B toward A, and the repulſion of *n* B from it, would impel it toward the poſition *s* B *n*.

This will be very evident, if we put the magnet B into the poſition $s'Bn'$, at right angles to the line AB. The pole s' and the pole n' are urged in oppoſite, and therefore conſpiring, directions with equal forces, very nearly at right angles to $n's'$, if the magnet B be ſmall. In any oblique poſition, the forces will be ſomewhat unequal, and account muſt be had of the obliquity of the action, in order to know the preciſe rotative momentum of the actions.

Dr Gilbert has given to this modification of the action of A on B, the name of VIS DISPONENS; which we may tranſlate by DIRECTIVE POWER or FORCE. Alſo, that modification of the tendency of B to or from A is called by him the VERTICITAS of B. We might call it the VERTICITY of B; but we think that the name POLARITY is ſufficiently expreſſive of the phenomenon; and as it has come into general uſe, we ſhall abide by it.

22
Its meaſure.

It is not ſo eaſy to give a general, and at the ſame time preciſe, meaſure of the directive power of A and polarity of B. The magnet B muſt be conſidered as a lever; and then the force tending to bring it into its ultimate poſition *n s* depends both on the diſtance of its poles from N and S, and alſo on the angle which the axis of B makes with the line AB. When the axis of B coincides with AB, the force acting on its poles, tending to *keep* them in that ſituation, is evidently $\overline{m+p}-\overline{n+q}$, and therefore may be repreſented by M *l* (in fig. 2.), or by twice EL. or by four times CH. If B has the poſition $n'Bs'$, perpendicular to AB, let the ordinates E*e* and F*f* cut the curve on I and K; and draw KL parallel to the axis (our figure cauſes this line almoſt to coincide with QL, and in all important caſes it will be nearly the ſame). In this caſe IL will expreſs one half of this force. Either of theſe eſtimations of this modification of the mutual action of the magnets, will be ſufficient for the objects we have in view.

23
How increaſed and diminiſhed.

The directive power of A, and the polarity of B, are increaſed,

1. By increaſing the ſtrength of one or both of the magnets. This is evident,

2. By diminiſhing the diſtance of the magnets. For this, by increaſing the ſum of M *m* and P *p* more than the ſum of N *n* and Q *q*, muſt increaſe EL or M *l*.

3. By increaſing the length of A. For this, by removing *n* and *q* farther from *m* and *p*, muſt depreſs the points L and *l*, and increaſe EL, or IL, or M *l*.

4. By diminiſhing the length of B, while the diſtance N *s* between the magnets remains the ſame. For this, by bringing *p* and *q* nearer to *m* and *n*, muſt increaſe M *m* + P *p* more than N *n* + Q *q*. Or, by bringing E *e* and F *f* nearer to M *m* and N *n*, it muſt increaſe EL and M *l*.

If the diſtance N *n* between the pole of A and the remote pole of B remain the ſame, the directive force of A, and polarity of B, are diminiſhed by diminiſhing the length of B, as is eaſily ſeen from what has been juſt now ſaid. It is alſo diminiſhed, but in a very ſmall degree, by diminiſhing the length of B, when the diſtance between the centres of A and B remain the ſame. For, in this caſe, the ordinates I *e* and K *f* retain their places; but the points *m* and *p* approach to *e*; and this brings the interſection E of the ordinate and chord nearer to I, and diminiſhes EL, becauſe the point L is not ſo much depreſſed by the approach of F to K as E is depreſſed.

24
Circumſtances affecting the proportion of the attractive and directive powers.

But in all caſes, the *ratio* of the directive power of A to its attractive force, or of the polarity of B to its tendency to A, is increaſed by diminiſhing the length of B. For it is plain, that by diminiſhing *m p* and *n q*, while I *e* and K *f* keep their places, the point *o* is raiſed, and the point L is depreſſed; and therefore the ratio of EL to E *o*, or of M *l* to M *t*, is increaſed. We even ſee that, by diminiſhing the length of B continually

and

and without end, the ratio of Ml to Mt may be made to exceed any ratio that can be aſſigned.

25
The polarity of a ſmall magnet may be great while the attraction is inſenſible.

Now, ſince diminiſhing the length of B increaſes the ratio of the directive power of A to its attractive power, while increaſing the length of A increaſes both, and alſo increaſes the ratio of EL to E o (as is very eaſily ſeen), and ſince this increaſe may be as great as we pleaſe, it neceſſarily follows, that if the ſame very ſmall magnet B be placed at ſuch diſtances from a large and ſtrong magnet A, and from a ſmaller and leſs vigorous one C, as to have equal polarities to both, its tendency to A will be leſs than its tendency to C. It may even be leſs in any ratio we pleaſe, by ſufficiently diminiſhing the length of B.

Dr Gilbert obſerved this; and he expreſſes his obſervation by ſaying, that the directive power extends to greater diſtances than the attracting power. We muſt juſt conclude, that the laſt becomes *inſenſible* at ſmaller diſtances than the firſt. This will be found a very important obſervation. It may be of uſe to keep in mind, that the directive power of a magnet A on another magnet B, is the difference of the *ſums* of the actions of each pole of A on both poles of B; and the attractive power of A for another magnet B, is the difference of the *differences* of theſe actions.

It may be alſo remarked juſt now, that the directive force of A always exceeds its attractive force by the quantity $2\ (p - q)$. For their difference may be expreſſed by tl, which is equal to twice o L. Now ϵe is equal to Pp, or to p; and ϵ L is equal to Pp — Ff, or to Pp — Qq — Fϵ, or to Pp — Qq — $o\epsilon$. Therefore $o\text{L} = \text{P}p - \text{Q}q$, and $tl = 2\ (\text{P}p - \text{Q}q), = 2\ (p - q)$.

By inſpecting this figure with attention, we obtain indications of many intereſting particulars. If the lengths of the magnets A and B are the ſame, the point n in the axis of the curve will coincide with p. As the length of A increaſes, the part nq is removed farther from the part mp. The line Pt becomes leſs inclined to the axis, and is ultimately parallel to it, when n is infinitely remote. At this time L falls on e; ſo that the ultimate ratio of the attraction to the polarity is that of Eϵ to Ee, when the magnet A is infinitely long. It is then the ratio of the difference of the actions of the neareſt pole of A on the two poles of B to the ſum of theſe actions. Hence it follows, that when A is very great and B very ſmall, the polarity of B is vaſtly greater than its tendency to A. It may have a great polarity when its tendency is inſenſible.

The ratio of the polarity to the attraction alſo increaſes by increaſing the diſtance of the magnets while their dimenſions continue the ſame. This will appear, by remarking that the chords MP and NQ muſt interſect in ſome point w; and that when the four points m, p, n, and q, move off from O, keeping the ſame diſtances from each other, Eo will diminiſh faſter than EL, and the ratio of EL to EO will continually increaſe.

Therefore when a ſmall magnet B is placed at ſuch a diſtance from a great magnet A, and from a ſmaller one C, as to have equal polarity to both, its tendency to C will exceed its tendency to A. For the polarities being equal, it muſt be farther from the great magnet; in which caſe the ratio of its polarity to its attraction is increaſed.

And this will alſo obtain if the magnets differ alſo in ſtrength. For, to have equal polarities, B muſt be ſtill farther from the great and powerful magnet.

For all theſe reaſons, a large and powerful magnet may exert a ſtrong directive power, while its attractive power is inſenſible.

26
Peculiarities of oblique poſitions of two magnets.

We have hitherto ſuppoſed the magnet B to be placed in the direction of the axis of A, and only at liberty to turn round its centre B. But let its centre be placed on the centre of A, as in fig. 3. it muſt evidently take a poſition which may be called ſubcontrary to that of A, the north pole of B turning toward the ſouth pole of A, and its ſouth pole turning toward the north pole of A.

The ſame thing muſt happen when the centre of B is placed in B, any where in the line AE perpendicular to NS. S attracts n with a force nb, while N repels n with a force no, ſomewhat ſmaller than nb. Theſe two compoſe the force nd. In like manner, the two forces se and sf, exerted by N and S on the pole s, compoſe the force sq. Now if the axis of the magnet B be parallel to NS, but the poles in a contrary poſition, and if each magnet be equally vigorous in both poles, the magnet B will retain this poſition; becauſe the forces nb and se are equal, as alſo the forces nc and sf. Theſe muſt compoſe two forces nd and sq, which are equal, and equally inclined to ns; and they will therefore be in equilibrio on this lever.

Let us now place the centre of the ſmall magnet in C, neither in the axis of the other, nor in the perpendicular AE. Let its north pole n point toward the centre of A. It cannot remain in this poſition; for N repels n with a force nc, while S attracts it with a force nb (ſmaller than nc, becauſe the diſtance is greater). Theſe two compoſe a force nd conſiderably different from the direction cn of its axis. In like manner, the ſouth pole s of the ſmall magnet is acted on by two forces se and sf, exerted by the two poles of A, which compoſe a force sq nearly equal and parallel to nd, but in a nearly oppoſite direction. It is plain that theſe forces muſt turn the ſmall magnet round its centre C, and that it cannot reſt but in a poſition nearly parallel to nd or sf. Its poſition is better repreſented by fig. 4. with its ſouth pole turned toward the north pole of the other magnet, and its north pole in the oppoſite direction.

What the preciſe poſition will be, depends on that function of the diſtance which is always proportional to the intenſity of the action; on the force of each of the poles of A, and on the length of the magnet B. Nay, even when we know this function, the problem is ſtill very intricate.

27
Means
acquirin
near me
ſure of t
law of a
tion.

There are methods by which we may approximate to the function with ſucceſs. If the magnet B be indefinitely ſmall, ſo that we may conſider the actions on its two poles as equal, the inveſtigation is greatly ſimplified. For, in this caſe, each pole of the ſmall magnet B (fig. 5.) may be conceived as coinciding with its centre. Then, drawing NB, SB, and taking Bb toward N, to repreſent the force with which N attracts the ſouth pole of B, and taking Bc, in SB produced, to repreſent the force with which S repels the ſame pole, the compound force acting on this pole is Bd, the diagonal of a parallelogram Bb, dc. In like manner, we muſt take Be, in Nb produced, and equal to Bb,

to

to repreſent the repulſion of N for the north pole of B, and B f equal to B c, to repreſent the attraction of S for this pole. The compound force will be B g, equal and oppoſite to B d. It follows evidently from this inveſtigation, that the ſmall magnet will not reſt in any poſition but dg. In this ſuppoſition, therefore, of extreme minuteneſs of the magnet B, one of the parallelograms is ſufficient. We may farther remark, that we have this approximation ſecure againſt any error ariſing from the ſuppoſition that all the action of each pole of B is exerted by one point. Although we ſuppoſe it diffuſed over a conſiderable portion of the magnet, ſtill the extreme minuteneſs of the whole makes the action, even on its extreme points, very nearly equal.

28
w of ac-
n inverſ-
ared—
AGNE-
CCURVE

Hence may be derived a conſtruction for aſcertaining the poſition of the needle, when the function m of the diſtance is given, or for diſcovering this function by obſervation of the poſition of the needle.

Let NS (fig. 5. n° 2.) meet the direction of the needle in K. Make BG = BN, and draw NF, GE, SH, perpendicular to BK. It is evident that B b is to B c, or $b\,d$, as the ſine of the angle HBS to the ſine of KBN. Therefore, becauſe BG and BN are equal, we have B b : B c = GE : NF.

Therefore GE : NF = BS^m : BN^m
But SH : GE = BS : BN
Therefore SH : NF = BS^{m+1} : BN^{m+1}
And SK : NK = BS^{m+1} : BN^{m+1}

If magnetic action be inverſely as the diſtance, we have SK : NK = BS^2 : BN^2, and B is in the circumference of a circle which paſſes through S and N, and has BK for a tangent, as is plain by elementary geometry. If the action be inverſely as the ſquare of the diſtance, we have SK : NK = BS^3 : BN^3, and B is in the circumference of a curve of more difficult inveſtigation. But, as in the circle, the ſum of the angles BSN and BNS is a conſtant angle; ſo, in this curve, the ſum of the coſines of thoſe angles is a conſtant quantity. This ſuggeſts a very ſimple conſtruction of the curve. Let it paſs through the point T of the line AT, drawn from the centre of the magnet, perpendicular to its axis. Deſcribe the ſemicircle SPQN, cutting ST and NT in P and Q. Then, in order to find the point where any line SB cuts the curve, let it cut the ſemicircle in p, and apply the line N q = SP + NQ — S p, and produce it till it meet the line SB in B, which is a point in the curve; for it is evident that S p and N q are the coſines of BSN and BNS. We hope to give, by the help of a learned friend, the complete conſtruction of curves for every value of m, in an Appendix to this article. It will form a new and curious claſs, arranged by the functions of the angles at N and S.

But, in the mean time, we have determined the poſition of an indefinitely ſmall needle, in reſpect of a magnet of which we may conceive the polar activity concentrated in two points; and we may, on the other hand, make uſe of the obſerved poſitions of ſuch a needle and magnet for diſcovering the value of m. For, ſince $\frac{SK}{NK} = \frac{SB^{m+1}}{NB^{m+1}}$, it is plain that $m = \frac{\text{Log. } SK : NK}{\text{Log. } SB : NB} - 1$. Thus, in an obſervation which the writer of this article made on a very ſmall needle, and a magnet having globular poles, and $8\frac{1}{8}$ inches between their centres, he found SB = $5\frac{1}{3}$, NB = $\frac{1}{3}$, SK = 11,49, and NK = 3,37. This gives m = 1,97, which differs from 2 only $\frac{1}{60}$th part. Finding it ſo very near the inverſe duplicate ratio of the diſtance, a circle VUZ was deſcribed, the circumference of which is the locus of SB : BN = 8 : 5,333. When the centre of the needle was placed anywhere in the circumference of this circle, it ſcarcely deviated from the point K, except when ſo far removed from the magnet that its natural polarity prevailed over the directive power of the magnet, or ſo near its middle that the action of the cylindrical part became very ſenſible.

It is plain that the length of the needle muſt occaſion ſome deviation from the magnetic direction, by deſtroying the perfect equality of action on its two poles. He therefore employed three needles of $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{4}$ of an inch in length; and by noticing the differences of direction, he inferred what would be the direction, if the forces on each pole were preciſely equal. He had the pleaſure of ſeeing that the deviation from the inverſe duplicate ratio of the diſtances was ſcarcely perceptible.

Mr Lambert's experiments on the directive power of the magnet, narrated in his ſecond diſſertation in the 22d volume of the Memoirs of the Academy of Berlin, are the moſt valuable of all that are on record; and the ingenious addreſs with which they are conducted, and the inferences are drawn, would have done credit to Newton himſelf. We earneſtly recommend the careful peruſal of that Eſſay, as the moſt inſtructive of any that we have read. The writer of this found himſelf obliged to repeat all his former experiments, mentioned above, in Mr Lambert's manner, and with his precaution of keeping the needle in its natural poſition; a circumſtance to which he had not ſufficiently attended before. The new reſults were ſtill more conformable to his conjecture as to the law of variation. Mr Lambert cloſes his diſſertation with an hypotheſis, "that the force of each tranſverſe element of a magnet is as its diſtance from the centre, and its action on a particle of another magnet is inverſely as the ſquare of the diſtance." On this ſuppoſition, he calculates the poſition of a very ſmall needle, and draws three of the curves to which it ſhould be the tangent. Theſe are very exactly coincident with ſome that he obſerved. We tried this with ſeveral magnetic bars, and found it very conformable to obſervation in ſome magnets; but deviating ſo far in the caſe of other magnets, that we are convinced that there is no rule for the force of each tranſverſe element of a magnet, and that the magnetiſm is differently diſpoſed in different magnets. It was chiefly this which induced us to form the magnets employed in this reſearch of two balls united by a ſlender rod. Lichtenberg, in his notes on Erxleben's Natural Philoſophy, ſays, that there is a MS. of the celebrated Tobias Mayer in the library of the Academy of Gottingen, in which he aſſumes the hypotheſis above-mentioned, and gives a conſtruction of the magnetic curves founded on it, making them a kind of catenaria. The interior curves do indeed reſemble the catenaria, but the exterior are totally unlike. But there is no occaſion for much argument to convince us, that the firſt part of this hypotheſis is not only gratuitous, but unwarranted by any general phenomena. We know that a magnetical bar may have its magnetiſm very differently diſpoſed; for it may have more than two poles, and the intermediate poles *cannot* have this diſpoſition of the magnetiſm.

netiſm. Such a diſpoſition is perhaps poſſible; but is by no means general, or even frequent. We are diſpoſed to think, that permanent magnetiſm muſt have its intenſity diminiſhing in the very extremity of the bar. The reader may gueſs at our reaſons from what is ſaid in ELECTRICITY, *Suppl.* n° 222.

29 Primary and secondary, or simple and compound curves.

The following very curious and inſtructive phenomenon was the firſt thing which greatly excited the curioſity of the writer of this article, and long puzzled him to explain it. Indeed it was his endeavours to explain it which gradually opened up to him the theory of the mutual action of magnets contained in theſe paragraphs, and firſt gave him occaſion to admire the ſagacity of Dr Gilbert, and to ſee the connecting principle of the vaſt variety of obſervations and experiments which that philoſopher had made It ſeems owing to the want of this connecting principle, that a book ſo rich in facts ſhould be ſo little read, and that ſo many of Dr Gilbert's obſervations have been publiſhed by others as new diſcoveries.

Amuſing himſelf in the ſummer 1758 with magnetic experiments, two large and ſtrong magnets A and B (fig. 6), were placed with their diſſimilar poles fronting each other, and about three inches apart. A ſmall needle, ſupported on a point, was placed between them at D, and it arranged itſelf in the ſame manner as the great magnets. Happening to ſet it off to a good diſtance on the table, as at F, he was ſurpriſed to ſee it immediately turn round on its pivot, and arrange itſelf nearly in the oppoſite direction. Bringing it back to D reſtored it to its former poſition. Carrying it gradually out along DF, perpendicular to NS, he obſerved it to become ſenſibly more feeble, vibrating more ſlowly; and when in a certain point E, it had no polarity whatever towards A and B, but retained any poſition that was given it. Carrying it farther out, it again acquired polarity to A and B, but in the oppoſite direction; for it now arranged itſelf in a poſition that was parallel to NS, but its north pole was next to N, and its ſouth pole to S.

This ſingular appearance naturally excited his attention. The line on which the magnets A and B were placed had been marked on the table, as alſo the line DF perpendicular to the former. The point E was now marked as an important one. The experiments were interrupted by a friend coming in, to whom ſuch things were no entertainment. Next day, wiſhing to repeat them to ſome friends, the magnets A and B were again laid on the line on which they had been placed the day before, and the needle was placed at E, expecting it to be neutral. But it was found to have a conſiderable verticity, turning its north pole toward the magnet B; and it required to be taken farther out, toward F, before it became neutral. While ſtanding there, ſomething chanced to joggle the magnets A and B, and they inſtantly ruſhed together. At the ſame inſtant, the little magnet or needle turned itſelf briſkly, and arranged itſelf, as it had done the day before, at F, quivering very briſkly, and thus ſhewing great verticity. This naturally ſurpriſed the beholders; and we now found that, by gradually withdrawing the magnets A and B from each other, the needle became weaker—then became neutral—and then turned round on its pivot, and took the contrary poſition. It was very amuſing to obſerve how the ſimply ſeparating the magnets A and B, or bringing them together, made the needle aſſume ſuch a variety of poſitions and degrees of vivacity in each.

The needle was now put in various ſituations, in reſpect to the two great magnets; namely, off at a ſide, and not in the perpendicular DF. In theſe ſituations, it took an inconceivable variety of poſitions, which could not be reduced to any rule; and in moſt of them, it required only a motion of one of the great magnets for an inch or two, to make the needle turn briſkly round on its pivot, and aſſume a poſition nearly oppoſite to what it had before.

But all this was very puzzling, and it was not till after ſeveral months, that the writer of this article, having conceived the notion of the magnetic curves, was in a condition to explain the phenomena. With this aſſiſtance, however, they are very clear, and very inſtructive

Nothing hinders us from ſuppoſing the magnets A and B perfectly equal in every reſpect. Let NHM, NEL, be two magnetic curves belonging to A; that is, ſuch that the needle arranges itſelf along the tangent of the curve. Then the magnet B has two curves SGK, SEI, perfectly equal, and ſimilar to the other two. Let the curves NHM and SGK interſect in C and F. Let the curves NEL and SEI touch each other in E.

The needle being placed at C, would arrange itſelf in the tangent of the curve KGS, by the action of B alone, having its north pole turned toward the ſouth pole S of B. But, by the action of A alone, it would be a tangent to the curve NHM, having its north pole turned away from N. Therefore, by the combined action of both magnets, it will take neither of theſe poſitions, but an intermediate one, nearly biſecting the angle formed by the two curves, having its north pole turned toward B.

But remove the needle to F. Then, by the action of the magnet A, it would be a tangent to the curve FM, having its north pole toward M. By the action of B, it would be a tangent to the curve KFG, having its north pole in the angle MFG, or turned toward A. By their joint action, it takes a poſition nearly biſecting the angle GFM, with its north pole toward A.

Let the needle be placed in E. Then, by the action of the magnet A, it would be a tangent to the curve NEL, with its north pole pointing to F. But, by the action of B, it will be a tangent to SEI, with its north pole pointing to D. Theſe actions being ſuppoſed equal and oppoſite, it will have no verticity, or will be neutral, and retain any poſition that is given to it.

The curve SEI interſects the curve NHM in P and Q. The ſame reaſoning ſhews, that when the needle is placed at P, it will arrange itſelf with its north pole on the angle SPH: but, when taken to Q, it will ſtand with its north pole in the angle EQM.

From theſe facts and reaſonings we muſt infer, that, for every diſtance of the magnets A and B, there will be a ſeries of curves, to which the indefinitely ſhort needle will always be a tangent. They will riſe from the adjoining poles on both ſides, croſſing diagonally the lozenges formed by the PRIMARY or SIMPLE curves, as in fig. 6. Theſe may be called COMPOUND or SECONDARY magnetic curves. Moreover, theſe ſecondary

condary curves will be of two kinds, according as they paſs through the firſt or ſecond interſections of the primary curves, and the needle will have oppoſite poſitions when placed on them. Theſe two ſets of curves will be ſeparated by a curve GEH, in the circumference of which the needle will be neutral. This curve paſſes through the points where the primary curves touch each other. We may call this the *line of neutrality* or inactivity.

We now ſee diſtinctly the effect of bringing the magnets A and B nearer together, or ſeparating them farther from each other. By bringing them nearer to each other, the point E, which is now a point of neutrality, may be found in the *ſecond* interſection (ſuch as F) of two magnetic curves, and the needle will take a ſubcontrary poſition. By drawing them farther from each other, E may be in the *firſt* interſection of two magnetic curves, and the needle will take a poſition ſimilar to that of C.

If the magnets A and B are not placed ſo as to form a ſtraight line with their four poles, but have their axes making an angle with each other, the contacts and interſections of their attending curves may be very different from thoſe now repreſented; and the poſitions of the needle will differ accordingly. But it is plain, from what has been ſaid, that if we knew the law of action, and conſequently the form of the primary curves, we ſhould always be able to ſay what will be the poſition of the needle. Indeed, the conſideration of the ſimple curves, although it was the mean of ſuggeſting to the writer of this article the explanation of thoſe more complicated phenomena, is by no means neceſſary for this purpoſe. Having the law of magnetic action, we muſt know each of the eight forces by which the needle is affected, both in reſpect of direction and intenſity; and are therefore able to aſcertain the ſingle force ariſing from their compoſition.

Secondary curves of repulſion.

When the ſimilar poles of A and B are oppoſed to each other, it is eaſy to ſee, that the poſition of the needle muſt be extremely different from what we have been deſcribing. When placed anywhere in the line DF, between two magnets, whoſe north poles front each other in N and S, its north pole will always point away from the middle point D. There will be no neutral point E. If the needle be placed at P or Q, its north pole will be within the angle EPH, or FQI. This poſition of the magnets gives another ſet of ſecondary curves, which alſo croſs the primary curves, paſſing diagonally through the lozenges formed by their interſection. But it is the other diagonal of each lozenge which is a chord to thoſe ſecondary curves. They will, therefore, have a form totally different from the former ſpecies.

30
Remarks on this inveſtigation.

The conſideration of this compounded magnetiſm is important in the ſcience, both for explaining complex phenomena, and for advancing our knowledge of the great deſideratum, the law of magnetic action. It ſerves this purpoſe remarkably. By employing a very ſmall needle, the points of neutrality aſcertain very nearly where the magnetic curves have a common tangent, and ſhews the poſition of this tangent. By placing the two magnets ſo as to form various angles with each other, we can, by means of theſe neutral points, know the poſition of the tangent in every point of the curve, and thus can aſcertain the form of the curve, and the law of action, with conſiderable accuracy. The writer of this article took this method; and the reſult confirmed him in the opinion, that it was in the inverſe duplicate ratio of the diſtances. The chief (perhaps the only) ground of error ſeemed to be the difficulty of procuring large magnets, having the action of each pole very much concentrated. Large magnets muſt be employed. He attempted to make ſuch, conſiſting of two ſpherical balls, joined by a ſlender rod. But he could not give a ſtrong magnetiſm to magnets of this form, and was forced to make uſe of common bars, the poles of which are conſiderably diffuſed. This diffuſion of the pole renders it very difficult to ſelect with propriety the points from which the diſtances are to be eſtimated, in the inveſtigation of the relation between the forces and diſtances.

He tried another method for aſcertaining this ſo much deſired law, which had alſo the ſame reſult. Having made a needle conſiſting of two balls joined by a ſlender rod, and having touched it with great care, ſo that the whole ſtrength of its poles ſeemed very little removed from the centres of the balls, he counted the number of horizontal vibrations which it made in a given time by the force of terreſtrial magnetiſm. He then placed it on the middle of a very fine and large magnet, placed with its poles in the magnetic meridian, the north pole pointing ſouth. In this ſituation he counted the vibrations made in a given time. He then raiſed it up above the centre of the large magnet, till the diſtance of its poles from thoſe of the great magnet were changed in a certain proportion. In this ſituation its vibrations were again counted. It was tried in the ſame way in a third ſituation, conſiderably more remote from the great magnet. Then, having made the proper reduction of the forces correſponding to the obliquity of their action, the force of the poles of the great magnet was computed from the number of vibrations. To ſtate here the circumſtances of the experiment, the neceſſary reductions, and the whole computations, would occupy ſeveral pages, and to an intelligent reader would anſwer little purpoſe. Mr Lambert's excellent diſſertation in the 22d vol. of the *Mem. de l'Acad. de Berlin*, will ſhew the prolixity and intricacy of this inveſtigation. Suffice it to ſay, that theſe experiments were the moſt conſiſtent with each other of any made by the writer of this article, with the view of aſcertaining the law of magnetic action; and it is chiefly from their reſult that he thinks himſelf authoriſed to ſay, with ſome confidence, that it is inverſely as the ſquare of the diſtance. Theſe experiments were firſt made in a rough way in 1769 and 1770. In 1775, obſerving that Mr Æpinus ſeemed to think the action inverſely as the diſtance (ſee his *Tentam. Theor. Electr. et Magn.* § 301. &c.), they were repeated with very great care; and to theſe were added another ſet of experiments, made with the ſame magnet and the ſame needle, placed not above the magnet, but at one ſide (but always in the line through the centre, perpendicular to the axis, ſo that the actions of the two poles might be equal). This diſpoſition evidently ſimplifies the proceſs exceedingly. The reſult of the whole was ſtill more ſatisfactory. This concluſion is alſo confirmed by the experiments of Mr Coulomb in the Memoirs of the Academy of Sciences at Paris for 1786 and 1787. It would ſeem therefore to be pretty well eſtabliſhed. Another method, which ſeems ſuſceptible of conſiderable accuracy, ſtill remains to be tried. It will be mentioned in due time.

Such then are the general laws obſerved in the mutual action of magnets. We think it ſcarcely neceſſary to enter into a farther detail of their conſequences, correſponding to the innumerable varieties of poſitions in which they may be placed with reſpect to each other. We are confident, that the ſenſible actions will always be found agreeable to the legitimate conſequences of the general propoſitions which we have eſtabliſhed in the preceding paragraphs. We proceed therefore to conſider ſome phyſical facts not yet taken notice of, which have great influence on the phenomena, and greatly aſſiſt us in our endeavours to underſtand ſomething of their remote cauſe.

31
Magnetiſm is temporary and periſhing.

Magnetiſm, in all its modifications of attraction, repulſion, and direction, is, in general, of a temporary or periſhing nature. The beſt loadſtones and magnets, unleſs kept with care, and with attention to certain circumſtances, are obſerved to diminiſh in their power. Natural loadſtones, and magnets made of ſteel, tempered as hard as poſſible, retain their virtue with greateſt obſtinacy, and ſeldom loſe it altogether, unleſs in ſituations which our knowledge of magnetiſm teaches us to be unfavourable to its durability. Magnets of tempered ſteel, ſuch as is uſed for watch-ſprings, are much ſooner weakened, part with a greater proportion of their force by ſimple keeping, and finally retain little or none. Soft ſteel and iron loſe their magnetiſm almoſt as ſoon as its producing cauſe is removed, and cannot be made to retain any ſenſible portion of it, unleſs their metallic ſtate ſuffer ſome change.

1. Hurt by improper poſition.

1. Nothing tends ſo much to impair the power of a magnet as the keeping it in an improper poſition. If its axis be placed in the magnetic direction, but in a contrary poſition, that is, with the north pole of it where the ſouth pole tends to ſettle, it will grow weaker from day to day; and unleſs it be a natural loadſtone, or be of hard tempered ſteel, it will, after no very long time, loſe its power altogether.

2. By heat; effects of thunder and electricity.

2. This diſſipation of a ſtrong magnetic power is greatly promoted by heat. Even the heat of boiling water affects it ſenſibly; and if it be made red hot, it is entirely deſtroyed. This laſt fact has long been known. Dr Gilbert tried it with many degrees of violent heat, and found the conſequences as now ſtated; but having no thermometers in that dawn of ſcience, he could not ſay any thing preciſe. He only obſerves, that it is deſtroyed by a heat not ſufficient to make it viſible in a dark room. Mr Canton found even boiling water to weaken it; but on cooling again the greateſt part was recovered.

3. By violent treatment.

3. What is more remarkable, magnetiſm is impaired by any rough uſage. Dr Gilbert found, that a magnet which he had impregnated very ſtrongly, was very much impaired by a ſingle fall on the floor; and it has been obſerved ſince his time, that falling on ſtones, or receiving any concuſſion which cauſes the magnet to ring or ſound, hurts it much more than beating it with any thing ſoft and yielding. Grinding a natural loadſtone with coarſe powders, to bring it into ſhape, weakens it much; and loadſtones ſhould therefore be reduced into a ſhape as little different from their natural form as poſſible; and this ſhould be done briſkly, cutting them with the thin diſks of the lapidary's wheel, cutting off only what is neceſſary for leaving their moſt active parts or poles as near their extremities as we can.

All theſe cauſes of the diminution of magnetiſm are more operative if the magnet be all the while in an improper poſition.

4. By other magnets.

4. Laſtly, magnetiſm is impaired and deſtroyed by placing the magnet near another magnet, with their ſimilar poles fronting each other. We have had occaſion to remark this already, when mentioning the experiments made with magnets in this poſition, for aſcertaining the general laws or variations of their repulſion. We there obſerved, that magnets ſo ſituated always weakened each other, and that a powerful magnet often changed the ſpecies of the neareſt pole of one leſs powerful. This change is recovered, in part at leaſt, when it has taken place in a loadſtone or a magnet of hard ſteel; but in ſpring tempered ſteel the change is generally permanent, and almoſt to the full extent of its condition while the magnets are together. It is to be remarked, that this change is gradual; and is expedited by any of the other cauſes, particularly by heat or by knocking.

32
Magnetiſm may be acquired,

On the other hand, magnetiſm is acquired by the ſame means, when ſome other circumſtances are attended to.

1. By magnetical poſition;

1. A bar of iron, which has long ſtood in the magnetic direction, or nearly ſo, will gradually acquire magnetiſm, and the ends will acquire the polarity correſponding to their ſituation. In this country, and the north of Europe, the old ſpindles of turret vanes, old bars of windows, &c. acquire a ſenſible magnetiſm; their lower extremity becoming a north pole, and the other end a ſouth pole. Gilbert ſays, that this was firſt obſerved in Mantua, in the vane ſpindle of the Auguſtine church—"*Vento flexa* (ſays he) *de prompta, et apothecario cuidam conceſſa, attrahebat ferrea ramenta, vi perquam inſigni.*" The upper bar of a hand rail to a ſtair on the north ſide of the higheſt part of the ſteeple of St Giles's church in Edinburgh is very magnetical; and the upper end of it, where it is lodged in the ſtone, is a vigorous ſouth pole. It is worth notice, that the parts of ſuch old bars acquire the ſtrongeſt magnetiſm when their metallic ſtate is changed by expoſure to the air, becoming foliated and friable. It would be worth while to try, whether the æthiops martialis, produced by ſteam in the experiments for decompoſing water, will acquire magnetiſm during its production. The pipe and the wires, which are converted into the ſhining æthiops, ſhould be placed in the magnetic direction.

2. By hammering;

2. If a bar of ſteel be long hammered while lying in the magnetic direction, it acquires a ſenſible magnetiſm (See Dr Gibert's plate, repreſenting a blackſmith hammering a bar of iron in the magnetic direction). The points of drills, eſpecially the great ones, which are urged by very great preſſure; and broaches, worked by a long lever, ſo as to cut the iron very faſt, acquire a ſtrong magnetiſm; and the lower end always becomes the north pole (*Phil. Tranſ.* xx. 417.) Even driving a hard ſteel punch into a piece of iron, gives it magnetiſm by a ſingle blow. In ſhort, any very violent ſqueeze given to a piece of tempered ſteel renders it magnetic, and its polarity correſponds with its poſition during the experiment. We can ſcarcely take up a cutting or boring tool in a ſmith's ſhop that is not magnetical. Even

ſoft ſteel and iron acquire permanent magnetiſm in this way. Iron alſo acquires it by twiſting and breaking. It is therefore difficult to procure pieces of iron or ſteel totally void of determinate and permanent magnetiſm; and this frequently mars the experiments mentioned in the firſt paragraphs of this article. The way therefore to enſure ſucceſs in theſe experiments is to deprive the rods of their accidental magnetiſm, by ſome of the methods mentioned a little ago. Let them be heated red hot, and allowed to cool while lying in a direction perpendicular to the magnetic direction (nearly E. N. E. and W. S. W. in this country).

By heat. 3. As heat is obſerved to deſtroy magnetiſm, ſo it may alſo be employed to induce it on ſubſtances that are ſuſceptible of magnetiſm. Dr Gilbert makes this obſervation in many parts of his work. He ſays, that the ores of iron which are in that particular metallic ſtate which he conſiders as moſt ſuſceptible of magnetiſm, will acquire it by long continuance in a red heat, if laid in the magnetic direction, and that their polarity is conformable to their poſition, that end of the maſs which is next the north becoming the north pole. He alſo made many experiments on iron and ſteel bars expoſed to ſtrong heats in the magnetical direction. Such experiments have been made ſince Gilbert's time in great number. Dr Hooke, in 1684, made experiments on rods of iron and ſteel one-fifth of an inch in diameter, and ſeven inches long. He found them to acquire permanent magnetiſm by expoſure to ſtrong heat in the magnetic direction, and if allowed to cool in that direction. But the magnetiſm thus acquired by ſteel rods was much ſtronger, and more permanent, if they were ſuddenly quenched with cold water, ſo as to temper them very hard. He found, that the end which was next to the north, or the lower end of a vertical bar, was always its permanent north pole. Even quenching the upper end, while the reſt was ſuffered to cool gradually, became a very ſenſible ſouth pole. No magnetiſm was acquired if this operation was performed on a rod lying at right angles to the magnetical direction.

In theſe trials the polarity was always eſtimated by the action on a mariner's needle, and the intenſity of the magnetiſm was eſtimated by the deviation cauſed in this needle from its natural poſition. Dr Gilbert made a very remarkable obſervation, which has ſince been repeated by Mr Cavallo, and publiſhed in the Philoſophical Tranſactions as a remarkable diſcovery. Dr Gilbert ſays, p. 69. "*Bacillum ferreum, valide ignitum appone verſorio excito; ſtat verſorium, nec ad tale ferrum convertitur: ſed ſtatim ut primum de candore aliquantulum remiſerit, confluit illico.*" In ſeveral other parts of his treatiſe he repeats the ſame thing with different circumſtances. It appears, therefore, that while iron is red hot, it is not ſuſceptible of magnetiſm, and that it is during the cooling in the magnetic direction that it acquires it. Gilbert endeavoured to mark the degree of heat moſt favourable for this purpoſe; but being unprovided with thermometers, he could not determine any thing with preciſion. He ſays, that the verſorium, or mariner's needle, was moſt deranged from its natural poſition a little while after the bar of iron ceaſed to ſhine in day-light, but was ſtill pretty bright in a dark room. But there are other experiments which we have made, and which will be mentioned by and bye; by which it appears, that although a bright red or a white heat makes iron unſuſceptible of magnetiſm while in that ſtate, it prediſpoſes it for becoming magnetical. When a bar of ſteel was made to acquire magnetiſm by tempering it in the magnetical direction, we found that the acquired magnetiſm was much ſtronger when the bar was made firſt of all very hot, even although allowed to come to its moſt magnetical ſtate before quenching, than if it had been heated only to that degree; nay, we always found it ſtronger when it was quenched when red hot. We offer no explanation at preſent; our ſole buſineſs juſt now being to ſtate facts, and to generalize them, in the hopes of finding ſome fact which ſhall contain all the others.

4. By juxtapoſition. 4. The moſt diſtinct acquiſitions and changes of magnetiſm are by juxtapoſition to other magnets and to iron. As the magnetiſm of a loadſtone or magnet is weakened by bringing its pole near the ſimilar pole of another magnet, it is improved by bringing it near the other pole; and it is always improved by bringing it near any piece of iron or ſoft ſteel.

But this action, and the mutual relation of magnets and common iron, being the moſt general, and the moſt curious and inſtructive of all the phenomena of magnetiſm, they merit a very particular conſideration.

Of the communication of Magnetiſm.

33 Communication of magnetiſm. THE whole may be comprehended in one propoſition, which may be ſaid to contain a complete theory of magnetiſm.

Fundamental propoſition.

Any piece of iron, when in the neighbourhood of a magnet, is a magnet, and its polarity is ſo diſpoſed that the magnet and it mutually attract each other.

The phenomena which reſult from this fundamental principle are infinitely various, and we muſt content ourſelves with deſcribing a ſimple caſe or two, which will ſufficiently enable the reader to explain every other.

34 Attractive power communicated. Take a large and ſtrong magnet NAS (fig. 7.), of which N is the north, and S the ſouth pole. Let it be properly ſupported in a horizontal poſition, with its poles free, and at a diſtance from iron or other bodies. Take any ſmall piece of common iron, not exceeding two or three inches in length, ſuch as a ſmall key. Take alſo another piece of iron, ſuch as another ſmaller key, or a bit of wire about the thickneſs of an ordinary quill.

1. Hold the key horizontally, near one of the poles, (as ſhewn at n° 1.), taking care not to touch the pole with it; and then bring the other piece of iron to the other end of the key (it is indifferent which pole is thus approached with the key, and which end of the key is held near the pole). The wire will hang by the key, and will continue to hang by it, when we gradually withdraw the key horizontally from the magnet, till, at a certain diſtance, the wire will drop from the key, becauſe the magnetiſm imparted from this diſtance is too weak. That this is the ſole reaſon of its dropping, will appear by taking a ſhorter, or rather a ſlenderer, bit of wire, and touch the remote end of the key with it: it will be ſupported, even though we remove the key ſtill farther from the magnet.

2. Hold the key *below* one of the poles, as at n° 2. or 3. and touch its remote end with the wire. It will be ſuſpended in like manner, till we remove the key too far from the magnet.

3. Hold

3. Hold the key *above* the poles, as at n° 4. or 5. and touch its adjacent end with the wire (taking care that the wire do not alſo touch the magnet). The wire will ſtill be ſupported by the key, till both are removed too far from the magnet.

Thus it appears, that in all theſe ſituations the key has ſhewn the characteriſtic phenomenon of magnetiſm, namely, attraction for iron. In the experiment with the key held above the pole, the wire is in the ſame ſituation in reſpect to magnetiſm as the key is when held below the pole; but the actions are mutual. As the key attracts the wire, ſo the wire attracts the key.

If the magnet be ſupported in a vertical poſition, as in fig. 8. the phenomena will be the ſame; and when the key is held directly above or directly below the pole, it will carry rather a heavier wire than in the horizontal poſition of the magnet and key.

Inſtead of approaching the magnet with the key and wire, we may bring the magnet toward them, and the phenomena will be ſtill more palpable. Thus, if the bit of wire be lying on the table, and we touch one end of it with the key, they will ſhew no connection whatever. While we hold the key very near one end of the wire, bring down the pole of a magnet toward the key, and we ſhall then ſee the end of the wire riſe up and ſtick to the key, which will now ſupport it. In like manner, if we lay a quantity of iron filings on the table, and touch them with the key, in the abſence of the magnet, we find the key totally inactive. But, on bringing the magnet anyhow near the key, it immediately attracts the iron filings, and gathers up a heap of them.

35 Alſo a directive power.

In the next place, this vicinity of a magnet to a piece of iron gives it a directive power. Let NAS (fig. 9.) be a magnet, and BC (n° 1.) a key held near the north pole, and in the direction of the axis. Bring a very ſmall mariner's needle, ſupported on a ſharp point, near the end C of the key which is fartheſt from N. We ſhall ſee this needle immediately turn its ſouth pole towards C, and its north pole away from C. This poſition of the needle is indicated at *c*, by marking its north pole with a dart, and its ſouth with a croſs. Thus it appears that the key has got a directive power like a magnet, and that the end C is performing the office of a north pole, attracting the ſouth pole of the needle, and repelling its north pole. It may indeed be ſaid, that the needle at *c* arranges itſelf in this manner by the directive power of the magnet; for it would take the ſame poſition although the key were away. But if we place the needle at *b*, it will arrange itſelf as there repreſented, ſhewing that it is influenced by the key, and not (wholly at leaſt) by the magnet. In like manner, if we place the needle at *a*, we ſhall ſee it turn its north pole toward B, notwithſtanding the action of the magnet on it. This action evidently tends to turn its north pole quite another way; but it is influenced by B, and B is performing the office of a ſouth pole.

In like manner, if we place the key as at n° 2. we ſhall obſerve the end B attract the ſouth pole of the needle placed at *a*, and the end C attract the north pole of a needle placed in *b*. In this ſituation of the key, we ſee that B performs the office of a north pole, and C performs the office of a ſouth pole.

Thus it appears that the key in both ſituations has become a magnet, poſſeſſed of both an attractive and a directive power. It has acquired two poles.

36 The attraction of iron is owing to the diſpoſition of its own temporary magnetiſm

Laſtly, the magnetiſm of the key is ſo diſpoſed, that the two magnets NAS and BC muſt mutually attract each other; for their diſſimilar poles front each other. Now, it is a matter of uniform and uncontradicted obſervation, that when a piece of iron is thus placed near a magnet, and the diſpoſition of its magnetiſm is thus examined by means of a mariner's needle, the diſpoſition is ſuch that two permanent magnets with their poles ſo diſpoſed muſt attract each other. The piece of iron, therefore, having the ſame magnetic relation to the magnet that a ſimilar and ſimilarly diſpoſed magnet has, muſt be affected in the ſame manner. We cannot, by any knowledge yet contained in this article, give any preciſe intimation in what way the polarity of the piece of iron will be diſpoſed. This depends on its ſhape as much as on its poſition. By deſcribing two or three examples, a notion is obviouſly enough ſuggeſted, which, although extremely gratuitous, and perhaps erroneous, is of ſervice, becauſe it has a general analogy with the obſerved appearances.

If one end of a ſlender rod or wire be held near the north pole of the magnet, while the rod is held in the direction of the axis (like the key in fig. 7. n° 1.), the near end becomes a ſouth, and the remote end a north pole. Keeping this ſouth pole in its place, and turning the rod in any direction from thence, as from a centre, the remote end is always a north pole. And, in general, the end of any oblong piece of iron which is neareſt to the pole of a magnet becomes a pole of the oppoſite name, while the remote end becomes a pole of the ſame name with that of the magnet.

If the iron rod be held perpendicularly to the axis, with its middle very near the north pole of the magnet, the two extremities of the iron become north poles, and the middle is a ſouth pole.

If the north pole of a magnet be held perpendicular to the centre of a round iron plate, and very near it, this plate will have a ſouth pole in its centre, and every part of its circumference will have the virtue of a north pole.

If the plate be ſhaped with points like a ſtar, each of theſe points will be a very diſtinct and vigorous north pole.

Something like this will be obſerved in a piece of iron of any irregular ſhape. The part immediately adjoining to the north pole of the magnet will have the virtue of a ſouth pole, and all the remote protuberances will be north poles.

The notion naturally ſuggeſted by theſe appearances is, that the virtue of a north pole ſeems to reſide in ſomething that is moveable, and that is protruded by the north pole of the magnet toward the remote parts of the iron; and is thus conſtipated in all the remote edges, points, and protuberances, much in the ſame manner as electricity is obſerved to be protruded to the remote parts and protuberances of a conducting body by the preſence of an overcharged body. This notion will greatly aſſiſt the imagination; and its conſequences very much reſemble what we obſerve.

As a farther mark of the complete communication of every magnetic power by mere vicinity to a magnet, we may here obſerve, that the wire D, of fig. 7. n° 2. and 3. will ſupport another wire, and this another; and ſo on, to a number depending on the ſtrength of the magnet. The key has therefore become a true magnet in every reſpect; for it induces complete magnetiſm on the appended wire. That this is not the ſame operation of the great magnet (at leaſt not wholly ſo), appears by examining the magnetiſm of D with the needle, which will be ſeen to be more influenced by D than by A. This fact has been long known. The ancients ſpeak of it: They obſerve, that a loadſtone cauſes an iron ring to carry another ring, and that a third; and ſo on, till the ſtring of rings appears like a chain.

37 ception plained. What has now been ſaid will explain a ſeeming exception to the univerſality of the propoſition. If the key be held in the ſituation and poſition repreſented by fig. 10. the bit of wire will not be attracted by it; and we may imagine that it has acquired no magnetiſm: But if we bring a mariner's needle, or a bit of wire, near to its remote end B, it will be ſtrongly attracted, and ſhew B to be a north pole. The needle held near to C will alſo ſhew C to be a ſouth pole. Alſo, if held near to D, it will ſhew D to be a north pole. Now the ends C, both of the key and of the wire, being ſouth poles, they cannot attract each other, but, on the contrary, they will repel; and therefore the wire will not adhere to the key. And if the key of fig. 17. nº 4. with the wire hanging to it, be gradually carried outward, beyond the north pole of the magnet, and then brought down till its lower end be level with the pole, the wire will drop off.

There is, however, one exception to the propoſition. If the key in fig. 7. with its appending wire D, be gradually carried from any of the ſituations 2, 3, 4, or 5, toward the middle of the magnet, the wire will drop off whenever it arrives very near the middle. If we ſuppoſe a plane to paſs through the magnetic centre A, perpendicular to the axis (which plane is very properly called the magnetic equatorial plane by Gilbert), a ſlender piece of iron, held anywhere in this plane, acquires no ſenſible magnetiſm. It gives no indication of any polarity, *and it is not attracted by the magnet.* It is well known, that the activity of a loadſtone or magnet reſides chiefly in two parts of it, which have been called its poles; and that thoſe are the beſt magnets or loadſtones in which this activity is leaſt diffuſed; and that a certain circumference of every loadſtone or magnet is wholly inactive. When a loadſtone or magnet of any ſhape is laid among iron filings, it collects them on two parts only of its ſurface; and between theſe there is a ſpace all round, to which no filings attach themſelves.

We preſume that the reader already explains this appearance to himſelf. Many things ſhew a contrariety of action of the two poles of a magnet. We have already obſerved, that the north pole of a ſtrong magnet will produce a ſtrong northern polarity in the remote end of a ſmall ſteel bar; and, if it be then applied near to that end in the oppoſite direction, it will deſtroy this polarity, and produce a ſouthern polarity. In whatever theſe actions may conſiſt, there is ſomething not only different but oppoſite. They do not blend their effects, as the yellow and blue making rays do in producing green. They oppoſe each other, like mechanical preſſures or impulſions. We have every mark of mechanical action; we have local motion, though unſeen, except in the gradual progreſſion of the magnetical faculties along the bar; but we have it diſtinctly in the ultimate effect, the approach or receſs of the magnets: and in theſe phenomena we ſee plainly, that the forces, in producing their effects, act in oppoſite directions. Whatever the internal inviſible motions may be, they are compoſed of motions whoſe equivalents are the ſame with the equivalents of the ultimate, external, ſenſible motions; therefore the internal motions are oppoſite and equal if the ſenſible motions are ſo, and converſely.

Adopting this principle, therefore, that the actions of the two poles are not only different but oppoſite, it follows, that if they are alſo equal and act ſimilarly, each muſt *prevent* the action of the other; and that there will be a mechanical equilibrium—it may even be called a magnetical equilibrium. Therefore if every part of a ſlender rod, or of a thin plate of iron, lie in the plane of the magnetic equator, the magnetic ſtate (in whatever it may conſiſt) cannot be produced in it. It will exhibit no magnetiſm; have no polar faculties; and we can ſee no reaſon why it ſhould be attracted by the magnet, or ſhould attract iron. We muſt not forget to obſerve in this place, that iron in a ſtate of incandeſcence acquires no magnetiſm by juxtapoſition. We have already remarked, that iron in this ſtate does not affect the magnet. If a bar of red hot iron be ſet near a mariner's needle, it does not affect it in the ſmalleſt degree till it almoſt ceaſes to appear red hot in day-light, as has been obſerved by Dr Gilbert. All actions that we know are accompanied by equal and oppoſite re-actions; and we ſhould expect, what really happens in the preſent caſe, namely, that red hot iron ſhould not be rendered magnetical and attractable.

38 Magnetiſm not impaired by communication. There is a very remarkable circumſtance which accompanies the whole of this communication of magnetiſm to a piece of iron. It does not impair the power of the magnet; but, on the contrary, improves it. This fact was obſerved, and particularly attended to, by Dr Gilbert. He remarks, that a magnet, in the hands of a judicious philoſopher, may be made to impart more magnetiſm than it poſſeſſes to each of ten thouſand bars of ſteel, and that it will be more vigorous than when the operations began. A magnet (ſays he) may be ſpoiled by injudicious treatment with other magnets, but never can touch a piece of common iron without being improved by it. He gives a more direct proof. Let a magnet carry as heavy a lump of iron as poſſible by its lower pole. Bring a great lump of iron cloſe to its upper pole, and it will now carry more. Let it be loaded with as much as it can carry while the lump of iron touches its upper pole. Remove this lump, and the load will inſtantly drop off. But the following experiment ſhews this truth in the moſt convincing manner:

Let NAS (fig. 11.) be a magnet, not very large, nor of extreme hardneſs. Let CD be a ſtrong iron wire, hanging perpendicularly from a hook by a ſhort thread or loop. The magnet, by its action on CD, renders D a north pole and C a ſouth pole, and the polarity of D's magnetiſm fits it for being attracted. Let it aſſume the poſition C *e*, and let this be very carefully marked. Now bring a great bar of iron *s* B *n* near to the other end of the magnet. We ſhall inſtantly perceive the wire C *e* approach to the ſouth pole of the magnet, taking a poſition C *f*. Withdraw the bar of iron, and C *f* will fall back into the poſition C *e*. As we bring the iron bar gradually nearer to the magnet,

the

the wire will deviate farther from the perpendicular, and when the bar B touches the magnet CD, will ſtart a great way forward. It is alſo farther to be obſerved, that the larger the bar of iron is, the more will CD deviate from the perpendicular.

Now this muſt be aſcribed to the action of the bar on the magnet. For if the magnet be removed, the bar alone will make no ſenſible change on the poſition of the wire. We know that the bar of iron becomes magnetical by the vicinity of the magnet. If we doubt this, we need only examine it by means of a piece of iron or a mariner's needle. This will ſhew us that *s* has become a ſouth, and *n* a north pole. Here then are two magnets with their diſſimilar poles fronting each other. In conformity with the whole train of magnetical phenomena, we muſt conclude that they attract each other, and muſt improve each other's magnetiſm.

39 Therefore nothing is transferred.

This is a moſt important circumſtance in the theory of magnetiſm. For it ſhews us, that, in rendering a piece of iron magnetic, there is no material communication. There is no indication of the transference of any ſubſtance reſiding in the magnet into the piece of iron; nor is there even any transference of a power or quality. Were this the caſe, or if the ſubſtance or quality which was in A be now transferred to B, it can no longer be in A; and therefore the phenomena reſulting from its preſence and agency muſt be diminiſhed. We muſt ſay that the magnet has excited powers inherent, but dormant, in the iron; or is, at leaſt, the occaſion of this excitement, by diſturbing, in ſome adequate manner, the primitive condition of the iron. We muſt alſo ſay, that the competency of the magnet and of the iron to produce the phenomena, is owing to the ſame circumſtances in both; becauſe we ſee nothing in the phenomena which authoriſes us to make any diſtinction between them. Whatever therefore cauſes one magnet to attract another, is alſo the reaſon why a piece of iron in the neighbourhood of a magnet attracts another piece of iron; and we muſt ſay that the cauſe of polarity, or the origin of the directive power, is the ſame in both. Now we underſtand perfectly the directive power of a magnet, as exerted on another magnet. We ſee that it ariſes from a combination and mechanical compoſition of attractions and repulſions. It muſt be the ſame in this magnetiſm now inherent in the iron. The piece of iron directs a mariner's needle, as a magnet would direct it; therefore, as there is ſomething in a piece of iron which *now* attracts ſomething in another piece of iron, ſo there is ſomething in the firſt which repels ſomething in the laſt.

40 Objections anſwered by a curious fact.

It may indeed be ſaid that it is not a piece of iron, but a mariner's needle, or magnet, that is thus directed by our iron magnetiſed by vicinity to a magnet. This objection is completely removed by the moſt curious of all the facts which occur in this manner of producing magnetiſm. Take a piece of common iron, faſhion it, and fit it up preciſely like a mariner's needle, and carefully avoid every treatment that can make it magnetical. Set it on its pivot, and bring it near the north pole of a magnet, placing the end, made like the ſouth pole of the needle, next to the north pole of the magnet. In ſhort, place it by hand exactly as a real mariner's needle would arrange itſelf. It will retain that poſition. Now carry it round the magnet, along the circumference of a magnetic curve, or in any regular and continuous route. This piece of iron will, in every ſituation, aſſume the very ſame poſition or attitude which the real magnetical needle would aſſume if in the ſame place, and it will oſcillate preciſely in the ſame way.

Here then it is plain, that there is no diſtinction of power between the magnetiſm of the iron and of the real needle. To complete the proof: Inſtead of approaching the magnet with this iron needle, bring it into the vicinity of a piece of iron, which is itſelf magnetical only by vicinity to a magnet, it will arrange itſelf juſt as the real needle would do, with the ſole difference, that it does not indicate the *kind* of polarity exiſting in the extremities of the iron, becauſe either end of it will be attracted by them. And this circumſtance leads us to the conſideration of the only diſtinction between the magnetiſm of a loadſtone or magnet and that of common iron.

41 Magnetiſm of iron is tranſitory and indifferent; but that of magnets is durable and determinate.

The magnetiſm of common iron is momentary, and therefore indifferent; whereas that of a magnet is permanent and determinate. When iron becomes magnetic in the way now mentioned, it remains ſo only while the magnet remains in its place; and when that is removed, the iron exhibits no ſigns of magnetiſm. Therefore when the north pole of a magnet has produced a ſouth pole in the neareſt end of an iron wire, and a north pole at its remote end, if we turn the magnet, and preſent its ſouth pole, the neareſt end of the wire inſtantly becomes a north pole, and the other a ſouth pole; and this change may be made as often, and as rapidly, as we pleaſe. This is the reaſon which made us direct the experimenter on the iron needle to begin his operation, by placing the end marked for a ſouth pole next to the north pole of the magnet. It becomes a real ſouth pole in an inſtant, and acts as ſuch during its peregrination round the magnet. But in any one of its ſituations, if we turn it half round with the finger, the end which formerly turned away from a pole of the magnet, will now turn as vigorouſly toward it. Therefore, in carrying the iron needle round the magnet, we directed the progreſs to be made in a continuous line, to avoid all chance of miſtaking the polarities.

42 MAGNETISM OF INDUCTION.

For all the reaſons now adduced, we think ourſelves obliged to ſay, that the magnetiſm produced on common iron by mere juxtapoſition to a magnet, is generated without any *communication* of ſubſtance or faculty. The power of producing magnetical phenomena is not *ſhared* between the magnet and the iron. We ſhall call it INDUCED MAGNETISM; MAGNETISM BY INDUCTION.

We have ſaid that induced magnetiſm of common iron is quite momentary. This muſt be underſtood with careful limitations. It is ſtrictly true only in the caſe of the fineſt and pureſt ſoft iron, free of all knots and hard veins, and therefore in its moſt metallic ſtate. Iron is rarely found in a ſtate ſo very pure and metallic; and even this iron will acquire permanent and determinate magnetiſm by induction, if it has been twiſted or hammered violently, although not in the magnetic direction; alſo the changes produced (we imagine) on the pureſt iron by the action of the atmoſphere make it ſuſceptible of fixed magnetiſm. But the magnetiſm thus inducible on good iron is ſcarcely ſenſible, and of no duration, unleſs it has lain in the neighbourhood of a magnet for a very long while.

What has now been ſaid of common iron, is alſo true of it when in the ſtate of ſoft ſteel.

But

43 empered el acires du ble magtiſm.

But any degree of temper that is given to ſteel makes a very important change in this reſpect. In the firſt place, it acquires magnetiſm more ſlowly by induction than an equal and ſimilar piece of common iron, and finally acquires leſs. Theſe differences are eaſily examined by the deviations which it cauſes in the mariner's needle from the magnetic meridian, and by its attraction.

When the inducing magnet is removed, ſome magnetiſm remains in the ſteel bar, which retains the polarity which it had in the neighbourhood of the magnet.

Steel tempered to the degree fit for watch ſprings acquires a ſtrong magnetiſm, which it exhibits immediately on the removal of the magnet. But it diſſipates very faſt; and, in a very few minutes, it is reduced to leſs than one-half of its intenſity while in contact with the magnet, and not two thirds of what it was immediately on removal from it. It continues to diſſipate for ſome days, though the bar be kept with care; but the diſſipation diminiſhes faſt, and it retains at leaſt one-third of its greateſt power for any length of time, unleſs careleſsly kept or injudiciouſly treated.

Steel tempered for ſtrong cutting tools, ſuch as chiſels, punches, and drills for metal, acquires magnetiſm ſtill more ſlowly by induction, and acquires leſs of it while in contact with the magnet; but it retains it more firmly, and finally retains a greater proportion of what it had acquired.

Steel made as hard as poſſible, is much longer in acquiring all the magnetiſm which ſimple juxtapoſition can give to it. It acquires leſs than the former; but it retains it with great firmneſs, and finally retains a much greater proportion.

Such ores of iron as are ſuſceptible of magnetiſm, are nearly like hard ſteel in theſe reſpects; that is, in the time neceſſary for their *greateſt* impregnation, and in the durability of the acquired magnetiſm. They differ exceedingly in reſpect to the degree of power which they can attain by mere juxtapoſition, and the varieties ſeem to depend on heterogeneous mixture. We muſt obſerve, that few ores of iron are ſuſceptible of magnetiſm in their natural ſtate. The ordinary ores, conſiſting of the metal in the ſtate of an oxyd, and combined with ſulphur, are not magnetizable while remaining in that ſtate. Moſt ores require roaſting, and a ſort of cementation, in contact with inflammable ſubſtances. This matter is not well underſtood; but it would ſeem that complete metallization is far from being the moſt favourable condition, and that a certain degree of oxydation, and perhaps ſome other compoſition, yet unknown, make the beſt loadſtones. But all this is extremely obſcure. The late Dr Gowin Knight made a compoſition which acquired a very ſtrong and permanent magnetiſm, but the ſecret died with him. Dr Gilbert ſpeaks of ſimilar compoſitions, in which ferrugineous clays were ingredients; but we know nothing of the ſtate of the metal in them, nor their mode of acquiring magnetiſm.

44 duction magnemis gra al and ogreſſive.

It is of peculiar importance to remark that the acquiſition of magnetiſm is gradual and progreſſive, and that the gradation is the more perceptible in proportion as the ſteel is of a harder temper. When a magnet is brought to one end of a bar of common iron, its remote extremity, unleſs exceedingly long, acquires its utmoſt magnetiſm immediately. But when the north pole of a magnet is applied to one end of a bar of hard ſteel, the part in contact immediately becomes a ſouth pole, and the far end is not yet affected. We obſerve a north pole formed at ſome diſtance from the contact, and beyond this a faint ſouth pole. Theſe gradually advance along the bar. The remote extremity becomes firſt a faint ſouth pole, and it is not till after a very long while (if ever) that it becomes a ſimple, vigorous, north pole. More frequently it remains a diffuſed and feeble north pole: nay, if the bar be very long, it often happens that we have a ſucceſſion of north and ſouth poles, which never make their way to the far end of the bar. This phenomenon was firſt obſerved (we think) by Dr Brook Taylor, who gives an account of his obſervations in the *Philoſophical Tranſactions*, n° 344.

45 Iron is attracted only becauſe it becomes magnetical.

From the account we have given of theſe phenomena of induced magnetiſm, it appears that the temporary magnetiſm is always ſo diſpoſed that the ſum of the mutual attractions of the diſſimilar poles exceeds the ſum of the repulſions between the ſimilar poles, and that therefore the two magnets tend to each other. This is evidently equivalent to ſaying, that a piece of unmagnetic iron is always attracted by a magnet. No exception has ever been obſerved to this fact; for Pliny's ſtory of a Theamedes, or loadſtone, which repels iron, is allowed by all to have been a fable.

We think ourſelves authoriſed to ſay that this attraction of the loadſtone for iron, or this tendency of iron to the loadſtone, is a ſecondary phenomenon, and is the *conſequence* of the proper diſpoſition of the induced magnetiſm. The proofs already given of the compound nature of this phenomenon, namely, that it ariſes from the exceſs of two attractions above two repulſions, need (we imagine) no addition. But the following conſiderations place the matter beyond doubt:

1. The magnetiſm of the two poles is evidently of an oppoſite nature; the one repelling what the other attracts. If the one attracts iron, therefore, the other ſhould repel it. But each pole, by inducing a magnetiſm oppoſite to its own, on the neareſt end of the iron, and the ſame with its own on the remote end, and its action diminiſhing with an increaſe of diſtance, there muſt always be an exceſs of attraction, and the iron muſt be attracted.

2. Each of the magnets A and B, in either of the poſitions repreſented in fig. 12. would alone attract the piece of common iron C. But when placed together, the ſouth pole of A tends to render the upper end of C a north pole; while the north pole of B tends to make it a ſouth pole. If their actions be nearly equal, the weight of C cannot be ſupported by the magnetiſm induced by any difference of action that may remain. While C is hanging by B alone, let A be gradually brought near; it gradually deſtroys the action of the north pole of B, ſo that C gradually loſes its magnetiſm and polarity, and its weight prevails.

3. In all thoſe caſes where the induction of magnetiſm is ſlow, the attraction is weak in proportion. This is particularly remarked by Dr Gilbert. If we take pieces of common iron, and of ſteel of different tempers, but all of the ſame ſize and form, we ſhall find that the iron is much more ſtrongly attracted than any of the reſt, and that the attraction for each of them is weaker in proportion as they are harder. This diverſity is ſo accurately obſerved, that when the piece is thoroughly

ſuſceptible of magnetiſm, we can tell, with conſiderable preciſion, what degree will be ultimately acquired and how much will be finally retained. Alſo, the attraction of the magnet for any of thoſe pieces of ſteel increaſes exactly in proportion as their acquired magnetiſm increaſes.

4. An ore of iron incapable of acquiring magnetiſm is not attracted by a magnet. But we know that, by cementation with charcoal duſt, they may be rendered ſuſceptible of magnetiſm. In this ſtate they are attracted. It is an univerſal fact, that any ſubſtance that is attracted by a magnet may be rendered magnetical, and that none elſe can. We have already obſerved that red hot iron is not attracted; nor does it acquire any directive power while in that ſtate. From all this we muſt conclude, that the previous induction of magnetiſm is the mean of the obſerved attraction of magnets for iron, and that this is not a primary fact in magnetiſm.

Theſe obſervations alſo complete the proof that magnetic attraction and repulſion are equal at the ſame diſtance, and follow the ſame law. Dr Gilbert ſeems to think, that the repulſion is always weaker than the attraction; and this is almoſt the only miſtake in conception into which that excellent philoſopher has fallen. But it only requires a fair compariſon of facts to convince a good logician, that ſince, *in every caſe*, and at every diſtance, either pole of a magnet attracts either end of a piece of common iron, it is impoſſible that one of theſe forces can exceed the other. It might be ſo, were it not that induced magnetiſm is durable in proper ſubſtances. And if we take magnets which have been made ſuch by induction, and preſent them to each other with their ſimilar poles fronting each other, they never fail to repel each other at conſiderable diſtances, and even at very ſmall diſtances for a few moments; and this is the caſe whichever poles are next each other. This cannot be on any other ſuppoſition. Caſes would occur of polarity without attraction, or of attraction without polarity. Such have never been ſeen, any more than the Theamedes, always repelling iron.

46 Phenomena of iron ſhreds and filings.

Let a great number of ſmall oblong pieces of iron be lying very near each other on the ſurface of quickſilver. Bring a ſtrong magnet into the midſt of them. It immediately renders them all magnetical by induction. The one neareſt the north pole of the magnet immediately turns one end toward it, and the other end away from it. The ſame effect is produced on the one that is juſt beyond this neareſt one. Thus the remote end of the firſt becomes a north pole, and the neareſt end of the ſecond becomes a ſouth pole. Theſe, being very near each other, muſt mutually attract. The ſame thing may be ſaid of a third, a fourth; and ſo on. And thus it appears, that not only is magnetiſm induced on them all, but alſo, that the magnetiſm of each is ſo diſpoſed, that both ends of it are in a ſtate of attraction for the ends of ſome of its neighbours; and that they will therefore arrange themſelves by coaleſcence in ſome particular manner. Should a parcel of them chance to be ſtanding with their centres in a magnetic curve, with their heads and points turned in any ways whatever, the moment that the magnet is brought among them, and ſet in the axis of that magnetic curve, the whole pieces of this row will inſtantly turn towards each other, and their ends will adhere together, if they are near enough; otherwiſe they will only point toward each other, forming a ſet of tangents to the magnetic curve, reaching from one pole of the magnet to the other.

Or, ſuppoſe a vaſt number of ſmall bits of iron, each ſhaped like a grain of barley, a little oblong. Let them be ſcattered over the ſurface of a table, ſo near each other as juſt to have room to turn round. Let a magnet be placed in the midſt of them. They will all have magnetiſm induced on them in an inſtant; and ſuch as are not already touching others, will turn round (becauſe they reſt on the table by one point only), and each will turn its ends to the ends of its neighbours; and thus they will arrange themſelves in curves, which will not differ greatly from true magnetic curves (becauſe each grain is very ſhort), iſſuing from one pole of the magnet, and terminating in the other.

Does not this ſuggeſt to the reflecting reader an explanation of that curious arrangement of iron filings round a magnet, which has ſo long entertained and puzzled both the philoſophers and the unlearned, and which has given riſe to the Carteſian and other theories of magnetiſm? The particles of iron filings are little rags of ſoft iron torn off by the file, and generally a little oblong. Theſe *muſt* have magnetiſm induced on them by a magnet, and, while falling through the air from the hand that ſtrews them about the magnet, they are at perfect liberty to arrange themſelves magnetically; and *muſt therefore ſo arrange themſelves*, forming on the table curves, which differ very little indeed from the true magnetic curves. Suppoſe them ſcattered about the table before the magnet is laid on it. If we pat the table a little, ſo as to throw it into tremors, this will allow the particles to dance, and turn round on their points of ſupport, till they coaleſce by their ends in the manner already deſcribed.

All this is the genuine and inevitable conſequence of what Dr Gilbert has taught us of induced magnetiſm. It muſt be ſo; and cannot be otherwiſe. This curious arrangement of iron filings round a magnet is therefore not a primary fact, and a foundation for a theory, but the reſult of principles much more general.

47 Remarks on the theories by impulſion.

Moſt of our readers know that this diſpoſition of iron filings has given riſe to the chief mechanical theories which have been propoſed by ingenious men for the explanation of all the phenomena of magnetiſm. An inviſible fluid has been ſuppoſed to circulate through the pores of a magnet, running along its axis, iſſuing from one pole, ſtreaming round the magnet, and entering again by the other pole. This is thought to be indicated by thoſe lines formed by the filings. The ſtream, running alſo through *them*, or around them, arranges them in the direction of its motion, juſt as we obſerve a ſtream of water arrange the flote graſs and weeds. It would require a volume to detail the different manners in which thoſe mechanicians attempt to account for the attraction, repulſion, and polarity of magnetic bodies, by the mechanical impulſion of this fluid. Let it ſuffice to ſay, that almoſt every ſtep of their theories is in contradiction to the acknowledged laws of impulſion. Nay, the whole attempt is againſt the firſt rule of all philoſophical diſcuſſion, never to admit for an explanation of phenomena the agency of any cauſe which we do not know to exiſt, and to operate in the very phenomenon. We know of no ſuch fluid; and we can demonſtrate, that the genuine effects of its impulſion would be totally unlike the phenomena of magnetiſm. But the proper refutation of theſe theories would fill volumes. Let it ſuffice (and to every logician it will abundantly ſuffice) to remark, that this phenomenon is but a ſecondary fact, depending on, and reſulting from, principles much more general, viz the induction of magnetiſm, and the attraction of diſſimilar, and repulſion of ſimilar, poles.

The above explanation of the curious diſpoſition of iron filings round a magnet, occurred to the writer of this article while ſtudying natural philoſophy, on ſeeing the Profeſſor exhibit Mr Henſhaw's beautiful experiment in proof of terreſtrial magnetiſm *. He at that time imagined himſelf the author, and promiſed himſelf ſome credit for the thought. But having ſeen the *Phyſiologia Nova de Magnete* by Dr Gilbert, he found that it had not eſcaped the notice of that ſagacious philoſopher; as will appear paſt diſpute from the following paſſage, as well as ſome others, leſs pointed, in that work: "Magnetica fruſta (that is, ſubſtances ſuſceptible of magnetiſm) bene et convenienter intra vires poſita, mutuo cohærent. Ferramenta, preſente magnete (etiamſi magnetem non attingant), concurrunt, ſolicité ſe mutuo quærunt, et amplexantur, et, conjuncta, quaſi ferruminantur. Scobs ferrea, vel in pulverem redacta, fiſtulis impoſita chartaceis—ſupra lapidem meridionaliter locata, vel propius tantum admota, in unum coaleſcet corpus; et ſubito tam multæ partes concreſcunt et combinantur; ferrumque aliud affectat conjuratorum turma et attrahit, ac ſi unum tantum et integrum eſſet ferri bacillum; dirigiturque ſupra lapidem in ſeptemtriones et meridiem. Sed cum longius a magnete removeantur (tanquam ſoluta rurſus) ſeparantur, et diffluunt ſingula corpuſcula." B. ii. c. 23.

See VA-
IATION,
ncycl.
.621.

Mr Æpinus alſo had taken the ſame view of the ſubject *. It is alſo very clearly conceived and expreſſed by the celebrated David Gregory, Savilian Profeſſor of aſtronomy in the Univerſity of Oxford, in a MS. volume of notes and commentaries, written by him in 1693, on Newton's *Principia*, and uſed by Newton in improving the ſecond edition. The M. S. is now in the library of the univerſity of Edinburgh. Gregory's words are as follow: "Mihi ſemper dubium viſum eſt num magnetica virtus mechanicé, *i. e.* per impulſum, producatur. Mirum eſt, effluvia, quæ ferrum agitare valent, bracteas aureas *interpoſitas* ne vel minimum a loco movere. Lucretii et Carteſii theoriam, de fugato intermedio aëre, refutat experimentum infra aquam inſtitutum. *Sulci in limatura ferri, magneti in plano cujuſvis meridiani circumpoſita, non fiunt ab effluviis ſecundum iſtos canales motis, ſed ex inde, quod ipſa ramenta, magnetice excitata, ſeſe ſecundum longitudinem et ſecundum polos diſponunt*. Ex altera vero parte exinde quod vis magnetica, interveniente flamma aut calore, interrumpatur, quod virga ferrea, vel diuturno ſitu perpendiculari, vel in eo ſitu frigeſcendo, virtutem magneticam a tellure acquirat, ut nos docet perſpicaciſſimus Gilbertus. Quod mallei ſuper incudem ictu forti ad alterum extremum, virtutem acquirat magneticam; quod ictu forti vel ſaltem fortiori ad alterum extremum poli permutantur, ut qui prius ſeptemtriones reſpiciebat nunc auſtrum reſpicit; quod ictu forti ad medium, virtutem illam prorſus amittat. Hæc inquam, et ſimilia, mechanicam ejus qualitates ortum arguunt. Hugenius, præter gravitatem, etiam magneticam, et electricam virtutem, aliaſque plures experimento novit vires naturales, ut mihi ipſi narravit hac eſtate anni 1693. Qualis ut hæc forſitan quod cymba papyracea, prope labra vaſis aquam, cui innatet, continentis, poſita, labrum viciniſſimum continuo, et cum impetu petat (A)." *Nat. MS. in Prop.* 23. ii. *Prin.*

* See § 306.

48 Filings are weakly attracted.

Not only the mere arrangement of the filings in curve lines follows of neceſſity from the properties of induced magnetiſm, but all the ſubordinate circumſtances of this phenomenon are included in the ſame explanation. By continuing to tap the table, and throw it into tremors, the filings are obſerved to approach gradually, but very ſlowly, to the poles of the magnet. Each particle is a very ſmall temporary magnet. The attractive power of the great magnet, $\overline{m-p}-\overline{n-q}$, is therefore extremely ſmall in proportion to its directive power, $\overline{m+p}-\overline{n+q}$. And we obſerve that the accumulation of the filings round the poles of the magnet is ſo much the ſlower as the filings are finer.

49 Curious fact.

If a paper be laid above the magnet, and the filings be ſprinkled on it, we obſerve them to conſtipate along its edges, while none remain immediately above its ſubſtance; they are all beyond, or on the outſide of its outline, and they are obſerved not to be lying flat on the paper, but to be ſtanding obliquely on one point. They move off from the paper immediately above the magnet, becauſe they repel each other. They ſtand obliquely from the edges, becauſe that is the direction of a magnetic meridian at its parting from the pole. If the magnet be at ſome diſtance below the paper, then tapping the paper will cauſe the filings to move away from the magnet laterally. This ſingular and unexpected appearance is owing to the combination of gravity with the magnetic action. A particle, ſuch as *n s* (fig. 13.), reſts on the paper by the point *n*, which is a temporary north pole (S being ſuppoſed the ſouth pole of the magnet). The particle takes a poſition *n s* nearer to the horizon than the poſition *n o*, which it would take if its centre of gravity *b* were ſupported. The poſition is ſuch, that its weight, acting vertically at *b*, is in equilibrio with the magnetic repulſion *s d*, exerted between S and *s*. When the paper is tapped, it is beaten down, or withdrawn from *n*, and the particle of iron is left for a moment in the air. It therefore turns quickly round *b*, in order to aſſume a poſition parallel to *n o*, and it meets the paper, as that riſes again after the ſtroke, in a point farther removed from the magnet, and again deſcends by its weight (turning round the newly ſupported point *n*), till it again takes a poſition parallel to *n s*, but farther off, as repreſented by the dotted line. Thus it travels gradually outwards from the magnet, appearing to be repelled, although it is really attracted by it. If the magnet be held above the paper, at a little diſtance, the filings, when we repeatedly pat the paper, gradually collect into a heap under it. This will appear very plainly to one who conſiders the ſituation of a particle in the manner now explained.

(A) Perhaps it may be proper to obſerve, that Dr Gregory expreſſes his differing in his opinion from Newton about magnetiſm. Newton, in this propoſition, thinks, that the law of magnetic action approaches to the inverſe triplicate ratio of the diſtances. Dr Gregory invalidates the argument uſed by Newton.

50 Filings arrange in magnetic curves.

The curve lines formed by very fine filings approach very nearly to the form of the primary curve which indicates the law of magnetic action in the way already explained. If the magnet be placed under water, and if filings be ſprinkled copiouſly on the ſurface of it from a gauze ſearce, held at ſome diſtance above it, the reſiſtance to their motion through the water gives them time to arrange themſelves magnetically before they reach the bottom, and the lines become more accurate. But they were ſo much deranged by any method that we could take for removing the water, and meaſuring them, that we were diſappointed in our expectations of obtaining a very near approximation to the law of action.

51 Alſo in ſecondary curves.

We took notice of ſome very ſingular phenomena of a compaſs needle in the neighbourhood of two magnets, and we obſerved that, in this caſe alſo, the needle was always a tangent to a curve of another kind, and which we called *ſecondary* and *compound magnetic curves*. Theſe are produced in the ſame way, by ſtrewing iron filings round the magnets. Many repreſentations have been given of theſe curves by different authors, particularly by Muſchenbrock, in his *Eſſais de Phyſique*; and by Fuſs in the *Comment. Petropolit.* Great uſe has been made of theſe arrangements of filings by two magnets in the theories of magnetiſm propoſed by thoſe who inſiſt on explaining all motion by impulſe. When the diſſimilar poles of two magnets A and B (fig. 14.) face each other, the curves formed by the filings conſiderably reſemble thoſe which ſurround a ſingle magnet, and give the whole ſomewhat of the appearance of a magnet with very diffuſed poles. The arranging fluid, which ſtreams from one pole of a magnet, is ſuppoſed to meet with no obſtruction to its entry into the adjoining pole of the other magnet, but, on the contrary, to be impelled into it; and therefore (ſay the propoſers) it circulates round both as one magnet, and by its vortex brings the magnets together; which phenomenon we call the attraction of the magnets. But when the ſimilar poles front each other; for example, the poles from which the arranging fluid iſſues, then the two ſtreams meet, obſtruct each other, accumulate, and, by this accumulation, cauſe the magnets to recede from each other; which we call the repulſion of the magnets. This is the only explanation of this kind that can make any pretenſions to probability, or indeed that can be conceived. For how the free circulation in the former caſe can bring the two magnets together, no perſon can form to himſelf any conception. We ſee nothing like this produced by any vortex that we are acquainted with. All ſuch vortices cauſe bodies to ſeparate. But even this explanation of magnetic repulſion is inadmiſſible. It will not apply to the repulſion of the receiving poles; and the phenomena of the filings are inconſiſtent with the notion of accumulation. The filings indeed accumulate, and they look not unlike two ſtreams which oppoſe each other, and deflect to the ſides (See fig. 15.): But, unfortunately, by tapping the paper gently, the filings do not move off from the magnets, but approach them much faſter than in any other experiment. The phenomenon receives a complete and palpable explanation from the principles we have eſtabliſhed. Both magnets concur in giving the ſame polarity to every particle of the filings. Thus, if the fronting poles are north poles, each particle has its neareſt end made a vigorous ſouth pole, and its remote end a north pole; and it is *therefore* ſtrongly attracted towards both magnets while it is arranged in the tangent to the ſecondary curve of that claſs, which croſſes the others nearly at right angles.

52 Magnets muſt affect each other.

Since it is found, that the magnetiſm, even of natural loadſtones and hard ſteel, and ſtill more thoſe of ſofter tempered ſteel, are continually tending to decay; and ſince we find that it may be induced by mere approach to a magnet; and ſince we know that magnets may oppoſe each other in producing it—it is reaſonable to ſuppoſe, that when a piece of iron has acquired a ſlight, though permanent magnetiſm, by the vicinity of a magnet, a magnet applied in the oppoſite direction will deſtroy it, and afterwards produce the oppoſite magnetiſm.

Accordingly, we may change the poles of ſoft magnets at pleaſure.

Farther; ſince we find that loadſtones and hard tempered ſteel bars are diſtinguiſhed from ſoft ones only by the *degree* of obſtinacy with which they retain their preſent condition, we ſhould alſo expect that hard magnets will even affect each other. It muſt therefore happen, that a powerful magnet applied to a weak one, ſo that their ſimilar poles are in contact, ſhall weaken, deſtroy, and even change the magnetiſm of the weaker. Dr Knight's famous magazine of magnets enabled him to change the poles of the greateſt and the ſtrongeſt natural loadſtone, or artificial magnet, that could be given him, in the ſpace of one minute.

53 Attractio muſt appear to ex ceed repu ſion.

We now ſee clearly the reaſon why magnetic repulſion is weaker than attraction at the ſame diſtance. When magnets are placed with their ſimilar poles fronting each other, in order to make trials of their repulſion, they really do weaken each other, and are not in the ſame magnetical condition as before. For ſimilar reaſons, we ſee how experiments with magnets attracting each other rather improve them, and make their attractive powers appear greater than they are. All theſe effects muſt be moſt remarkable in ſoft magnets, eſpecially when long.

54 The obſe ved law differs fr the true.

We alſo ſee, that the obſerved law of attraction and repulſion between two magnets muſt be different from the real law of magnetic action. For, in the experiments made on attraction at different diſtances, beginning with the greateſt diſtance, the magnetiſm is continually increaſing, and the attraction will appear to increaſe in a higher rate than the juſt one: the contrary may happen, if we begin with the ſmaller diſtances. The reſults of experiments on repulſion muſt be ſtill more erroneous; becauſe it is eaſier to diminiſh any accumulation which required an exertion to produce it, than to puſh it ſtill farther.

55 Magneti improve by inducing it c iron.

We have now a complete explanation of the remarkable fact, that the induction of magnetiſm does not weaken the magnet employed; but, on the contrary, improves it. The magnetiſm induced on the iron cauſes it to act on the magnet employed in the very ſame manner that a permanent magnet of the ſame ſhape, ſize, and ſtrength, would do. Nay, it will have even a greater effect; for as it improves the magnet, its own induced magnetiſm will improve; and will therefore ſtill farther improve the magnet.

56.

Hence it is, that, in whatever manner a magnet touches a piece of iron, it improves by it. It may be hurt by a magnet in an improper poſition; but it always puts common iron into a ſtate which increaſes its own magnetiſm.

magnetiſm. This has been known as long as magnetiſm itſelf; and the ancients conceived the notion, that the magnet ſomehow fed upon the iron (B).

We think that theſe obſervations authoriſe us to ſay, that in reducing a loadſtone into a convenient ſhape, as much as poſſible of the operation ſhould be performed by grinding them with emery, in cavities made in large blocks of *hammered* iron. The magnetiſm induced on the iron muſt be favourable to the conſervation of that in the loadſtone; which, we are perſuaded, is rapidly diſſipated by the tremors into which this very elaſtic ſubſtance is thrown by the grinding with coarſe powders in any mould but iron. We imagine, that the cutting off ſlices by the lapidaries wheel has the ſame bad effect.

57. Not only will a magnet lift a greater lump of iron by its north pole, when another lump is applied to its ſouth pole, but it will lift a greater piece of iron from an anvil than from a wooden table: for the magnet induces the properly diſpoſed polarity, not only in the iron which it lifts, but alſo in the anvil, or any piece of iron immediately beyond it. This is ſo diſpoſed as to increaſe the magnetiſm of the piece of iron between them; and therefore to increaſe their attraction. The magnetiſm induced on the anvil is alſo in part, and perhaps chiefly, induced by the intervening iron. Theſe experiments are extremely variable in their reſults.—Sometimes a ſmall magnet will pull an iron wire from a large and ſtrong one. Sometimes this will be done even by a piece of unmagnetic iron; and the reſults appear quite capricious. But they are accurately fixed, depending on the induced compound magnetiſm. Mr Æpinus has ſtated ſome of the more ſimple caſes, in which we can tell which magnet ſhall prevail. But the unfolding even of theſe caſes would take a great deal of room, and muſt be omitted here. Beſides, we are too imperfectly acquainted with the degree of magnetiſm induced on the various parts of an iron rod, and the degree of magnetiſm inherent in the various parts of the magnets, to be able to ſay, with certainty, even in thoſe ſimple caſes, on which ſide the ſuperiority of attraction will remain.

58
aking of
ificial
agnets.

We may now proceed to deduce from this theory (for ſo it may juſtly be called, ſince all is reduced to one fact) the proceſs for communicating magnetiſm to bodies fitted for receiving and retaining it; that is, the method of making artificial magnets. We ſhall not employ much time on this, becauſe the moſt approved methods have been delivered at length in the article Magnetism of the *Encyclopædia Britannica*; and therefore we ſhall juſt make ſuch obſervations on them as ſerve to confirm, or to perfect them by the theory. We acknowledge, that we do not know the internal proceſs by which magnetiſm is induced, nor even in what this magnetiſm conſiſts. All that we know is, that the bringing the pole of a magnet near to any magnetiſable matter, produces a magnetiſm of the kind oppoſite to that of the pole employed. We know that this is the caſe with both poles, and that it obtains at all the diſtances where magnetiſm is obſerved. We know that the action of one pole is contrary to that of the other; that is, it counteracts the other, prevents it from producing its effect, and deſtroys it when already produced: and we know, that the production of theſe effects reſembles in its reſult the protruſion of ſomething fluid through the pores of the body, conſtipating it in all remote parts; as if the virtue of a pole reſided in this moveable matter. This is nearly all that we know of it; and by theſe facts and notions we muſt judge of the propriety and effect of all the proceſſes for magnetiſing bodies.

The moſt ſimple method of magnetiſing a ſteel bar, is to apply the north pole of a magnet to that end which we wiſh to render a ſouth pole. Attention to the effects of this application is very inſtructive. Have in readineſs a very ſmall compaſs needle, turning on its pivot. It ſhould not exceed half an inch in length, and ſhould be as hard tempered as poſſible, and ſtrongly impregnated. Immediately after the application of the magnet, carry the needle along the ſide of the bar. If the bar be long, and very hard, we ſhall obſerve a ſouth polarity at the place of contact; a north polarity at a ſmall diſtance from it; beyond this a weak ſouth polarity; then a weak and diffuſed north polarity, &c.; toward the remote end the polarity will be found very uncertain. The ſame thing may be diſcovered by laying a ſtiff paper on the bar, and ſprinkling iron filings over it, and then gently tapping the paper, to make them arrange themſelves in curve lines; which will point out the various poles, and ſhew whether they are diffuſed or conſtipated. It is very amuſing and inſtructive to obſerve the progreſs of this impregnation. In a few minutes after the firſt application of the magnet, we ſhall perceive the ſtate of magnetiſm very ſenſibly changed. The north pole will be farther from the magnet, and will be more diſtinct; the ſouthern polarity will alſo be protruded, and may appear for a moment at the remote extremity. The change advances; but the progreſs is more ſlow, and at laſt is inſenſible. When the bar is not harder than the temper of a cutting tool, the proceſs is ſoon over; and if the bar is but ſix or eight inches long, the remote end ſhews the north polarity in a very few minutes. When the bar is very hard, the progreſs of impregnation is greatly expedited by ſtriking it ſo as to make it ſound. If it be ſuſpended by a ſtring in a vertical poſition, and the magnet applied to its lower end, the ſtriking it with a key will make it ring; and in this way make the progreſs of magnetization very quick: but it does not allow it to acquire all the magnetiſm that can be given it by a very ſtrong magnet.

But this is a bad way of impregnation. It is ſeldom that uniform magnetiſm, with only two poles, and thoſe of

---

(B) So Claudian.——“ Nam ferro nurunt vitam, ferrique vigore
Veſcitur, hoc dulces epulas, hoc pabula novit
Hinc proprias renovat vires, hinc fuſa per artus
Aſpera ſecretum ſervant alimenta vigorem
Hoc abſente perit, triſti morientia torpent
Membra fame, venaſque ſitis conſumit apertas.”

Pliny ſays, “ Sola hæc materia (ferrum) vires ab eo lapide, accipit retinetque longo tempore, aliud apprehendens ferrum, ut annulorum catena ſpectetur interdum, quod imperitum vulgus ferrum appellat vivum.

of equal ſtrength, can be given. Even when there are but two, the remote pole is generally diffuſed, and therefore feeble. It is much improved by employing two magnets, one at each end. And if the bar is not more than ſix or eight inches long, and good magnets are employed, the magnetiſm is abundantly regular. This, accordingly, is practiſed for the impregnation of dipping needles, which muſt not be touched, leſt we diſturb the centre of gravity of the needle. But in all caſes, this method is tedious, and does not give ſtrong magnetiſm.

The method which was uſually practiſed before we had obtained a pretty clear knowledge of magnetiſm, was to apply the pole of a magnet to one end of the bar, and paſs it along to the other end, preſſing moderately. This was repeated ſeveral times on both ſides of the bar, always beginning the ſtroke at the ſame end as at firſt, and, in bringing the magnet back to that end, keeping it at a diſtance from the bar. The effect of this operation was to leave the end at which we began the ſtroke poſſeſſed of the polarity of the pole employed.

A general notion of the proceſs may be given as follows, obſerving, however, that there occur very many great and capricious anomalies. When the north pole N (fig. 16.) of the magnet A is ſet on the end C of the bar CBD, a ſouth pole is produced at C, and a north pole at D, when the length of the bar is moderate. As the magnet advances ſlowly along the bar, the ſouthern polarity at C firſt increaſes, then diminiſhes, and vaniſhes entirely when N has arrived at a certain point *a*; after which, a northern polarity appears at C, and increaſes during the whole progreſs of the magnet. In the mean time, the northern polarity firſt produced at D increaſes till the magnet reaches a certain point *e*, then diminiſhes, vaniſhes when the magnet reaches a certain point *f*; after which, a ſouthern polarity appears at D, which increaſes till the magnet reaches D. Mr Brugmann, who firſt attended minutely to theſe particulars (for Gilbert ſpeaks of them pointedly), calls *a* and *f* *points of indifference*, and *e* the *culminating* point of the pole D, and *i* the culminating point of the pole C. Hardly can any general rule be given for the ſituation of theſe points, nor even for the order in which they ſtand; ſo great and capricious are the anomalies in an amazing ſeries of experiments narrated by Brugmann and by Van Swinden. Repeating the operation, and beginning at C, the northern polarity there is weakened (ſometimes deſtroyed), then reſtored, and continually increaſed during the reſt of the ſtroke. The ſouthern polarity at D is alſo firſt weakened, and ſometimes deſtroyed; then reſtored, and finally augmented. The points *i*, *a*, *e*, *f*, change their ſituations, and frequently their order.

Van Swinden has attempted to deduce ſome general laws from his immenſe liſt of experiments, avoiding every conſideration of a hypotheſis, or the leaſt conjecture by what means theſe faculties are excited. But though we have peruſed his inveſtigation with care and candor, we muſt acknowledge, that we have not derived any knowledge which can help us to predict the reſult of particular modes of treatment with any greater preciſion than is ſuggeſted by a ſort of common ſenſe, aided (or perhaps perverted) by a vague notion, that theſe energies reſide in ſomething, which avoids the pole of the ſame name, carrying along with it this diſtinctive energy or polarity. This conception tallies perfectly with theſe obſervations of Brugmann and Van Swinden; and admits of all the anomalies in the ſituation of Bergmann's indifferent and culminating points, if we only ſuppoſe that this motion is obſtructed by the particles of the body. We muſt leave this to the reflection of the reader, who will *gueſs* how, when the magnet is between C and *i*, this ſubſtance, avoiding the pole N of the magnet, eſcapes below it, and goes toward the farther end. As the magnet advances, it drives ſome of this back again, &c &c. This is gratuitous; but it aids the fancy, which, without ſome conception of this kind, has no object of ſteady contemplation. We have no thought when we ſpeak of the generating at C, or *a*, or *e*, a faculty of ſome kind, by the exertion of the ſame faculty in N. The conception is too abſtracted, and much too complex. We muſt content ourſelves with knowing, that N produces a ſouth pole immediately under it, and a north pole everywhere elſe, or endeavours to do ſo. It is unneceſſary to inſiſt longer on this method: Common ſenſe ſhews it to be a very injudicious one.

This method was greatly improved by beginning the friction at the centre. Apply the north pole at the centre or middle of the bar, and draw it over the end intended for the ſouth pole. Having done this ſeveral times to one end on both ſides, turn the magnet, applying its ſouth pole to the middle of the bar, and drawing it ſeveral times over the end intended for the north pole.

It was ſtill more improved by employing two magnets at once, placed as in fig. 17. on the middle B of the bar, and drawing them away from each other, over the ends of it, as ſhewn by the directing darts, and repeating this operation. It is plain that, as far as we underſtand any thing of this matter, this proceſs muſt be much preferable to either of the former two. The magnets A and E certainly concur in producing a properly diſpoſed magnetiſm on all that lies between them; and therefore on the whole bar at the end of each ſtroke. The end C muſt become a north, and D a ſouth pole. Still, however, as the ſtroke goes on to the point of indifference, each magnet tends to weaken the polarity of the parts ſituated beyond it.

This method continued to be practiſed till about the year 1750. Mr Canton, availing himſelf of the experiments of Mr Mitchell of Cambridge, publiſhed his method by the DOUBLE TOUCH as it is called. See *Monthly Review* for 1785.

59
Metho
double
touch.

We need not repeat what has been detailed in the *Encyclopædia*, MAGNETISM, p. 440, &c. and ſhall only make ſome obſervations on the peculiar advantages of this proceſs, as preſcribed by Mitchell, Canton, and improved by Mr Antheaume, in his memoir *ſur les Aimans artificiels* 1766, which was crowned by the Academy of Sciences. (See alſo diſſertations on the ſubject by *Le Maire and Du Hamel*, 1745).

There is an evident propriety in the arrangement invented by Mr Mitchell, repreſented in fig. 18. The magnetiſm induced on the two pieces of ſoft iron AD and BC is an excellent method for *ſecuring* every acceſſion of magnetiſm to either of the bars. A good deal depends on the proper ſize and length of theſe pieces; and our ignorance of the interior proceſs obliges us to have recourſe to experiment alone for aſcertaining this. Whatever circumſtances induce the ſtrongeſt magnetiſm on on thoſe pieces of iron, will cauſe them to produce the greateſt effect on the ſteel bars; and this will be indicated by a greater attraction. Therefore that diſtance will be the beſt which enables two bars AB and DC to lift the greateſt weight hung on the piece AD or BC. When we impregnated bars whoſe breadth was about one-tenth of their length, and their thickneſs about one-half of their breadth, we found, that if AD was about one fourth, or nearly one third, of AB, they carried more than if it was either much longer or much ſhorter. Mr Antheaume's addition of the two great bars of iron E and F makes a ſenſible improvement of the *beginning* of the impregnation, when very weak magnets are employed; but did not ſeem to us to be of any farther ſervice on the table. This is agreeable to any theory which can be eſtabliſhed by what we have ſaid hitherto.

The method of employing the magnets A and E (fig. 19), preſcribed by Mitchell and Canton, is extremely judicious. The meeting of the diſſimilar poles at top increaſes the magnetiſm of each. The two diſſimilar poles F and G, certainly tend to give a regular and proper magnetiſm to the part FG of the bar which lies between them; and this is the caſe on whatever part of the bar they are placed. But each pole tends to deſtroy the preſent magnetiſm of what lies between it and the pole of the bar on that ſide. But mark—they tend to produce the deſired magnetiſm on what lies between them with the *ſum* of their forces; while each tends to deſtroy the magnetiſm of the part without it by the *difference* only of their forces. Therefore, on the whole, as they are moved to and fro along the bar, and the foremoſt one even made to paſs over the end of it a little way, they always add to the magnetiſm already acquired. This conſideration ſeems to enjoin ſetting F and G extremely near each other; for this ſeems to increaſe the ſum, and to diminiſh the difference of their action. But it may be a queſtion, Whether we gain more by ſtrongly magnetiſing a very ſmall part during the very ſhort while that the magnets paſs over it, or by acting on more of the bar at once, and continuing a weaker action for a longer while on this larger portion. Mr Æpinus adds another conſideration depending on his notion of the internal proceſs; but we defer this to another opportunity. The ſafeſt direction ſeems to be, to place them at the diſtance which enables them to lift the greateſt weight. They are then undoubtedly acting with the greateſt effect.

Mr Antheaume directs to place the touching magnets as in fig. 20. for a reaſon to be mentioned afterwards. Mr Æpinus alſo recommends it for reaſons founded on his own hypotheſis. We muſt ſay, that, in our trials, we have found this method very ſenſibly ſuperior, eſpecially in the latter parts of the operation, when the reſiſtance to farther impregnation becomes nearly a balance for the accumulating power of the magnets; and we conſider this as no inconſiderable argument for the juſtice of Mr Æpinus's hypotheſis.

The great advantage of this method is the regularity of the magnetiſm which it produces. We never find more than two poles; and when the bars are hard, and of uniform texture, the polarity is very little diffuſed, and ſeemingly confined to a very ſmall ſpace at the very extremities of the bar. This is indeed a prodigious advantage in point of ſtrength. It is no leſs ſo in order to fit the magnets for experiments on the law of magnetic action; for the latitude which the diffuſed condition of the poles gives in the ſelection of the points from which the diſtances are to be computed, has hitherto hindered us from pronouncing on the law of magnetic action with the preciſion of which we think it fully ſuſceptible. This method alſo is the only one by which we have been able to impregnate two bars joined end to end, conſidering them as one bar. We have ſometimes (though very rarely) ſucceeded in this; ſo that when filings were ſtrewed over them, the appearance could not be diſtinguiſhed from a ſingle bar.—*N. B.* Yet even in this caſe, in one experiment with two bars of ſix inches long, treated as one, when it could not be diſtinguiſhed, either by the appearance of the filings, or by going round it very near with a compaſs needle, a very ſmall compaſs needle diſcovered a neutral point, and a reverſion of polarity ſimilar to fig. 14. at F, ſhewing that it was really acting as two bars. Perhaps it muſt always be ſo; and this queſtion is of conſiderable importance in the eſtabliſhment of any theory of the internal proceſs.

It deſerves remark, that, in order to ſucceed in this attempt, a very conſiderable preſſure is neceſſary. We were obliged to clean the ends of the bars very carefully, and to force the frame of bars and ſoft pieces of iron ſtrongly together by wedges, in the manner of a form of types. We thought that wetting the ends of the bars with pure water aided the experiment; and we are *very certain* that oil not only greatly obſtructed it, but even ſenſibly impeded the common proceſs. We had put a ſingle drop of oil on a pair of bars which we were touching in the common Cantonian method, that the magnets might be more eaſily drawn along them; but we were ſurpriſed at finding that we could not give a ſtrong impregnation. The oil undoubtedly prevents the cloſe contact. We found the fineſt gold leaf produce the ſame effect in a great degree; as alſo talc, of which a ſquare inch weighed $\frac{1}{24}$th of a grain. We do not infer any thing like obſtruction to the paſſage of ſomething material, but rather aſcribe it to mere diſtance; although we are of opinion, that in the impregnation of two contiguous bars, ſo that the magnetiſm (whatever it is) is diſpoſed *preciſely* as in one bar, there *is* a material transference. But we ſhall ſpeak of this in its due place.

It is not unworthy of remark, that we found bars to acquire more powerful magnetiſm when pretty well poliſhed than when rough. But we alſo found, that bars conſiderably rough acquired the firſt degrees of it much more expeditiouſly than thoſe which are ſmooth; although we never could bring them to that high degree of magnetiſm that the ſame bars acquired after they had been poliſhed. We think it probable that the tremors, occaſioned by the rough and harſh ſurfaces of the hard ſteel, are the cauſes of this phenomenon.

Some more obſervations on this method of the double touch will be made afterwards, when we conſider the hypotheſis of Mr Æpinus: and we conclude the preſent ſubject, by attempting to explain ſome puzzling appearances which frequently occur in making artificial magnets.

60
Difficulties explained.

A bar touched by a very ſtrong magnet has been ſaid by Muſchenbroek to be impaired by going over it with a weaker magnet. If it had been made as ſtrong as as poſſible, the weaker magnet, when paſſed over it in the way practiſed by Muſchenbroek, muſt *firſt* deſtroy part of this magnetiſm; and having done ſo, it is unable to raiſe it anew to the ſame degree of vigour.

Yet (ſays Muſchenbroek with ſurpriſe) a large bar of common iron has greatly improved the magnet. A very large piece of iron *muſt* do this (eſpecially if ſhaped like a horſeſhoe, and applied with both heels), if the bar be not already at its maximum.

It was thought wonderful, that, in the method of double touch, not only was the magnetiſm of the magnets employed not impaired, but, beginning with two magnets, whoſe power is almoſt inſenſible, and repeating the operations in the preciſe manner deſcribed by Mitchell or Canton, not only the bars intended to be made magnetical, but alſo the magnets employed, may be brought to their higheſt poſſible ſtate of magnetiſm. This is in evident conformity to the general facts of induced magnetiſm, and affords the ſtrongeſt proof that nothing is communicated in this operation, but that powers reſiding in the bars are excited, or brought into action. The manipulation merely *gives occaſion* to this action, as a ſpark of fire kindles a city.

61 Explanation of the beginning of Savery, Canton, and Antheaume's proceſs.

There ſtill remain ſome circumſtances of this method, as practiſed by Savery, Canton, and Antheaume, which are extremely curious and important.

Mr Savery had obſerved a ſmall bit of ſteel acquire very ſenſible magnetiſm by lying long in contact with the lower end of a great window bar. Telling this to a friend, he was, for the firſt time, informed, that this had been long obſerved, and that Dr Gilbert had made ſome curious inferences from it. Mr Savery wanted ſome magnets, and was at a diſtance from town. Reflecting, like a philoſopher, on what he had heard and obſerved, he ſaw here a ſource of magnetiſm which he could increaſe, in the manner commonly practiſed in making magnets. He placed the bar AB (fig. 21.) to be magnetiſed between two great bars of common iron C and D, placing all the three in the magnetical direction. He took another bar EF, and put two little pieces of iron, like the armour of a loadſtone, on its ends; and with thoſe ends he rubbed the bar AB, rubbing the upper half of it with the end F, and the lower with the end E. The reſult of this was a very briſk magnetiſm in a few minutes, which, by various well deviſed alternations, he brought to its higheſt degree. His numerous experiments publiſhed in the Philoſophical Tranſactions in 1746, contain much curious information, highly deſerving the attention of the philoſophers. Mr Canton, proceeding on the ſame principle, that bars of iron, which have been long in a vertical poſition, acquire an efficient magnetiſm, begins his operations by placing his ſteel bar on the head of a kitchen poker, and rubs it with the lower end of a pair of kitchen tongs. Mr Antheaume adheres more ſtrictly to the inferences from the principle of terreſtrial magnetiſm, and repeats preciſely the previous diſpoſition of things practiſed by Mr Savery, placing his little ſteel bar AB (fig. 22.) between two great bars C and D of common iron, and arranging the whole in the magnetic direction. Then, proceeding moſt judiciouſly on the ſame principle, he greatly improves the proceſs, by employing two bars EF and GH for the touch, holding them about an inch apart, inclined about 15° to the bar AB. It is plain, that the lower end of each of theſe five bars is a north pole, and the upper end a ſouth pole. Therefore the poles F and G concur in giving the proper magnetiſm to the portion FG of the ſteel bar which is between them; and by rubbing it with theſe poles up and down, overpaſſing each extremity about half an inch, he muſt ſoon give to the bar AB a regular magnetiſm; weak, perhaps, but to be afterwards increaſed in the Cantonian method, on a horizontal table. In this manner did Mr Antheaume make magnets of very great ſtrength in 1766. See his *Diſſertation* already quoted.

62 Gilbert's terreſtrial magnetiſ

Theſe obſervations naturally bring us to the Physiologia Nova de Magnete et corporibus Magneticis of Dr Gilbert; a diſcovery which the ſagacious Kepler claſſes among the greateſt in the annals of ſcience.

It could not be that a phenomenon ſo general, and ſo intereſting and important as the natural polarity of magnetic bodies, would be long known without exciting curioſity about its cauſe. Accordingly the philoſophers of the 16th century ſpeculated much about it, and entertained a variety of opinion, if that can be called an opinion which can hardly be ſaid to expreſs a thought. We have in *Marſigli Ficino* a ſhort notice of many of theſe opinions. Some maintained that the needle was directed by a certain point in the heavens, as if that were ſaying more than that it always pointed one way. Others, with more appearance of reaſoning, aſcribed the direction to vaſt magnetic rocks. But all this was without giving themſelves the trouble of trying to aſcertain what ſituation of ſuch rocks would produce the direction that is obſerved. Fracaſtori was, if we miſtake not, the firſt who thought this trouble at all neceſſary; and he obſerves very ſenſibly, that if thoſe rocks are ſuppoſed to be in any place yet viſited by navigators, and if they act as loadſtones do (a circumſtance which he ſays muſt be admitted, if we attempt to explain), the direction of the needle will be very different from what we know it to be. He therefore places them in the inacceſſible polar regions, but not in the very pole. Norman, the diſcoverer of the dip of the mariner's needle, or of the true magnetic direction, was naturally led by his diſcovery to conceive the directing cauſe as placed in the earth; becauſe the north point of the needle, in every part of Europe, points very far below the horizon. But although he calls the treatiſe in which he announces his diſcovery the *New Attractive*, he does not expreſs himſelf as ſuppoſing the needle to be attracted by any point within the earth, but only that it is always directed to that point.

It is to Dr Gilbert of Colcheſter that we owe the opinion now univerſally admitted, that magnetic polarity is a part of the conſtitution of this globe. Norman had, not long before, diſcovered, that if a ſteel needle be very exactly balanced on a horizontal axis, like the beam of a common balance, ſo that it would retain any poſition given it, and if it be then touched with a magnet, and placed on its axis in the magnetic meridian, it is no longer in equilibrio, but (at London) the north point of it will dip 72 or 73 degrees below the horizon. He did not, however, publiſh his diſcovery till he had obtained information how it ſtood in other parts of the world. The differences in the variation in different places naturally ſuggeſted the neceſſity of this to him. Being a maker of mariners compaſſes,

paſſes, and teacher of navigation in London, he had the faireſt opportunities that could be deſired, by furniſhing dipping needles to ſuch of the navigators, his ſcholars, as he knew moſt able to give him good information. And the accounts which he received made his diſcovery, when announced to the world, a very complete thing ; for the commanders of ſhips engaged in long voyages, and particularly to China, informed him that, in the vicinity of the equator, his dipping needles remained parallel to the horizon, but that in coming toward the north pole, the north end of the needle was depreſſed, and that the ſouth end dipped in like manner at the Cape of Good Hope, and in the Indian Ocean ; that the needle gradually approached the horizontal poſition as the ſhip approached the equator, but that in coming to the north of it at Batavia, the north point again dipped, and at Canton was ſeveral degrees below the horizon.

On theſe authorities, Norman boldly ſaid that, in the equatoreal regions, the needle was horizontal, and that either end dipped regularly as it approached either pole ; and that in the poles of the earth, the needle was perpendicular to the horizon. He therefore announced this as a diſcovery, not only ſingularly curious, but alſo of immenſe importance ; for by means of a dipping needle the latitude of a ſhip at ſea may be found without ſeeing the ſun or ſtars.

Dr Gilbert, comparing this poſition of the compaſs needle with the poſitions which he had obſerved ſmall needles aſſume in his numerous experiments in relation to a magnet, as we have deſcribed at great length, was naturally led to the notion of the earth's being a great loadſtone, or as containing one, and that this arranged the dipping, or, in general, the mariner's needle, in the ſame manner as he obſerved a great magnet arrange a ſmall needle poiſed on its pivot. He therefore compoſed his *Phyſiologia Nova de Magnete, et de Tellure magno Magnete;* in which he notices ſo many points of reſemblance to the directive power of a magnet, that the point ſeems no longer to admit of any doubt. Dr Gilbert's theory may be thus expreſſed :

All the phenomena of natural magnetiſm are analogous to what we ſhould obſerve, if the earth were a great magnet, having its poles near the poles of the earth's equator, the north pole not far from Baffin's Bay, and the ſouth pole nearly in the oppoſite part of the globe. A dipping needle, under the influence of this great magnet, muſt arrange itſelf in a plane which paſſes through the poles of the magnet, the poſition of which plane is indicated (at leaſt nearly) by the ordinary compaſs needle ; and it will be inclined to the horizon ſo much the more as we recede from the equator of the great magnet.

This opinion of Dr Gilbert was not leſs ingenious than important ; and if firmly eſtabliſhed, it furniſhes a complete theory of all the phenomena of magnetiſm. But obſervations were neither ſufficiently numerous in the time of Dr Gilbert, nor ſufficiently accurate, to enable that great genius to aſſign the poſition of this great magnet, nor the laws of its action. The theory was chiefly founded on the phenomena of the dipping needle ; phenomena which might have been unknown for ages, had the firſt notice of them fallen into any other hands than Norman's. They are not, like thoſe of variation, which might be made by any ſailor. They require for their exhibition a dipping needle, and the attention to circumſtances which can occur only to a mathematician. A dipping needle is to this day, notwithſtanding all our improvements in the arts, one of the moſt delicate and difficult taſks that an inſtrument maker can take in hand, and a good one cannot be had for leſs than twenty guineas. We are confident that ſuch as even Norman could make were far inferior to what are now made, and quite unfit for uſe at ſea while the ſhip is under ſail, although they may be tolerably exact for an obſervation of the dip in any port ; and we preſume that it was ſuch obſervations only that Norman confided in. Our readers will readily conceive the difficulty of poiſing a needle with ſuch a perfect coincidence of its centre of gravity and axis of motion, and perfect roundneſs of this axis, that it ſhall remain in any poſition that is given it. Add to this, that a grain of duſt, inviſible to the niceſt eye, getting under one ſide of this axis, may be ſufficient for making it aſſume another poſition. It muſt alſo be a difficult matter to preſerve this delicate thing, ſo as that no change can happen to it. Beſides, all this muſt be performed on a piece of tempered ſteel which we are certain has no magnetiſm. Where can this be got, or what can inſure us againſt magnetiſm? Nor is there leſs difficulty in making the obſervations without great riſk of error. If the needle, moveable only in a vertical plane, be not ſet in the plane of a magnetic meridian, it will always dip too much. At London, where the magnetic direction is inclined 73° to the horizon, if it be in a plane 20° from the magnetic meridian, it will ſtand almoſt perpendicular ; for it is eaſy to ſee, by the mechanical reſolution of forces, that it will take the poſition which brings it neareſt to the true magnetic direction. This, we think, is confirmed by ſeveral of Norman's and other old obſervations of dip. They are much greater than they have been ſince found in the ſame places.

63
Daniel Bernoulli's dipping needle.

Mr Daniel Bernoulli has given a very ingenious principle, by which we can make a dipping needle which will give a very accurate obſervation on ſhore ; and being ſo eaſily executed, it deſerves to be generally known. Let a dipping needle be made in the beſt manner that can be done by a workman of the place, and balanced with ſome care before impregnation, ſo that we may be certain that when touched it will take nearly the true dip. Touch it, and obſerve the dip. Deſtroy its magnetiſm, and then alter its balance in ſuch a manner that, without any magnetiſm, it will arrange itſelf in the inclination of the obſerved dip. Now touch it again, giving it the ſame poles as before. It is plain that it will now approach exceedingly near indeed to the true dip, becauſe its want of *perfect* equilibrium deranged it but a few degrees from the proper direction. If this ſecond obſervation of the dip ſhould differ ſeveral degrees from the firſt, by the inaccurate firſt formation of the needle, it will be proper to repeat the operation. Very rarely indeed will the third obſervation of the dip vary from the truth half a degree.

Mr Bernoulli makes this ſimple contrivance anſwer the purpoſe of an univerſal inſtrument in the following ingenious manner. A very light braſs graduated circle EFG (fig. 23.) is fixed to one ſide of the needle, concentric with its axis, and the whole is balanced as nicely as poſſible before impregnation. A very light index

CD is then fitted on the axis, ſo as to turn rather ſtiffly on it. This will deſtroy the equilibrium of the needle. If the needle has been made with perfect accuracy, and perfectly balanced, the addition of this index would cauſe it always to ſettle with the index perpendicular to the horizon, whatever degree of the circle it may chance to point at. But as this is ſcarcely to be expected, ſet the index at various degrees of the circle, and note what inclination the unmagnetic needle takes for each place of the index, and record them all in a table. Suppoſe, for example, that when the index is at 50, the needle inclines 46° from the horizon. If in any place we obſerve that the needle (rendered magnetic by lying between two ſtrong magnets), having the index at 50, inclines 46°, we may be certain that this is the dip at that place; for the needle is not deranged by the magnetiſm from the poſition which gravity alone would give it. As we generally know ſomething of the dip that is to be expected in any place, we muſt ſet the index accordingly. If the needle does not ſhew the expected dip, alter the poſition of the index, and again obſerve the dip. See whether this ſecond poſition of the index and this dip form a pair which is in the table. If they do, we have got the true dip. If not, we muſt try another poſition of the index. Noticing whether the agreement of this laſt pair be greater or leſs than that of the former pair, we learn whether to change the poſition of the index in the ſame direction as before, or in the oppoſite. The writer of this article has a dipping needle of this kind, made by a perſon totally unacquainted with the making of philoſophical inſtruments. It has been uſed at Leith, at Cronſtadt in Ruſſia, at Scarborough, and at New York, and the dip indicated by it did not in any ſingle trial differ $1\frac{1}{2}$ degrees from other trials, or from the dip obſerved by the fineſt inſtruments. He tried it himſelf in Leith Roads, in a rough ſea; and does not think it inferior, either in certainty or diſpatch, to a needle of the moſt elaborate conſtruction. It is worthy of its moſt ingenious author, and of the public notice, becauſe it can be made for a moderate expence, and therefore may be the means of multiplying the obſervations of the dip, which are of immenſe conſequence in the theory of magnetiſm, and for giving us an accurate knowledge of the magnetical conſtitution of this globe.

64
Opinions concerning the great magnet contained in this globe.

This knowledge is ſtill very imperfect, owing to the want of a very numerous collection of obſervations of the dip. They are of more importance than thoſe of the horizontal deviations from the meridian. All that we can ſay is, that the earth acts on the mariner's needle as a great loadſtone would do. But we do not think that the appearances reſemble the effects of what we would call a good loadſtone, having the regular magnetiſm of two vigorous poles. The dips of the needle in various parts of the earth ſeem to be ſuch as would reſult from the action of an extremely irregular loadſtone, having its poles exceedingly diffuſed. The increaſe of the dip, as we recede from thoſe places where the needle is horizontal, is too rapid to agree with the ſuppoſition of two poles of conſtipated magnetiſm, whether we ſuppoſe the magnetic action in the inverſe ſimple or duplicate ratio of the diſtances, unleſs the great terreſtrial magnet be of much ſmaller dimenſions than what ſome other appearances oblige us to ſuppoſe. If there be four poles, as Dr Halley imagined, it will be next to impoſſible to aſcertain the poſitions of the dipping needle. It will be a tangent to one of the ſecondary magnetic curves, and theſe will be of a very intricate ſpecies. We cannot but conſider the diſcovery of the magnetic conſtitution of this globe as a point of very great importance, both to the philoſopher and to ſociety. We have conſidered it with ſome care; but hitherto we have not been able to form a ſyſtematic view of the appearances which gives us any ſatisfaction. The well informed reader is ſenſible, that the attempt by means of the horizontal or variation needle is extremely tedious in its application, and is very unlikely to ſucceed; at the ſame time it muſt be well underſtood. The two diſſertations by Euler, in the 13th and 22d volumes of the Memoirs of the Royal Academy at Berlin, are moſt excellent performances, and give a true notion of the difficulty of the ſubject. Yet, even in theſe, a circumſtance is overlooked, which, for any thing we know to the contrary, may have a very great effect. If the magnetic axis be far removed from the axis of revolution, as far, for example, as Mr Churchman places it, the magnetic meridians will be (generally) much inclined to the horizon; and we ſhall err very far, if we ſuppoſe (as in Euler's calculus) that the dipping needle will arrange itſelf in the vertical plane, paſſing through the direction of the horizontal or variation needle; or if we imagine that the poles of the great magnet are in that plane. We even preſume to think that Mr Euler's aſſumption of the place of his fictitious poles (namely, where the needle is vertical), in order to obtain a manageable calculus, is erroneous The introduction of this circumſtance of inclination of the magnetic meridians to the horizon, complicates the calculation to ſuch a degree as to make it almoſt unmanageable, except in ſome ſelected ſituations. Fortunately, they are important ones for aſcertaining the places of the poles. But the inveſtigation by the poſitions of the dipping needle is incomparably more ſimple, and more likely to give us a knowledge of a multiplicity of poles. The conſideration of the magnetic curves (in the ſenſe uſed in the preſent article), teaches us that we are not to imagine the poles immediately under thoſe parts of the ſurface where the needle ſtands perpendicular to the horizon, nor the magnetic equator to be in thoſe places where the needle is horizontal; a notion commonly and plauſibly entertained. Unfortunately our moſt numerous obſervations of the dip are not in places where they are the moſt inſtructive. A ſeries ſhould be obtained, extending from New Zealand northward, acroſs the Pacific Ocean to Cape Fairweather on the weſt coaſt of North America, and continued through that part of the continent. Another ſeries ſhould extend from the Cape of Good Hope, up along the weſt coaſt of Africa to the tropic of Capricorn; from thence acroſs the interior of Africa (where it would be of great importance to mark the place of its horizontality) through Sicily, Italy, Dalmatia, the eaſt of Germany, the Gulph of Bothnia, Lapland, and the weſt point of Greenland. This would be nearly a plane paſſing through the probable ſituations of the poles. Another ſeries ſhould be made at right angles to this, forming a ſmall circle, croſſing the other near Cape Fairweather. This would paſs near Japan, through Borneo, and the weſt end of New Holland; alſo near Mexico, and a few degrees weſt of Eaſter Iſland. In this place, and at Borneo, the

See VARIATION, *Encycl.*

the inclination of the magnetic plane to the horizon would be conſiderable, but we cannot find this out. It may, however, be diſcovered in other points of this circle, where the dip is conſiderable. We have not room in this ſhort account to illuſtrate the advantages derived from theſe ſerieſes; but the reflecting reader will be very ſenſible of them, if he only ſuppoſes the great magnet to be accompanied by its magnetic curves, to which the needle is always a tangent. He will then ſee that the firſt ſeries from New Zealand to Cape Fairweather, and the ſecond from Cape Fairweather round the other ſide of the globe, being in one plane, and at very different diſtances from the magnetic axis, muſt contain very inſtructive poſitions of the needle. But we ſtill confeſs, that when we compare the dips already known with the variations, they appear ſo irreconcileable with the reſults of an uniform regular magnetiſm, that we deſpair of ſucceſs. Every thing ſeems to indicate a multiplicity of poles, or, what is ſtill more adverſe to all calculation, an irregular magnetiſm with very diffuſed polarity.

Much inſtruction may ſurely be expected from the obſervations of the Ruſſian academicians and their eleves, who are employed in ſurveying that vaſt empire; yet we do not meet with a ſingle obſervation of the dip of the needle in all the bygone publications of that academy, nor indeed are there many of the variation.

65 nd con- rning the uation of poles.

For want of ſuch information, philoſophers are extremely divided in their opinions of the ſituation of the magnetic poles of this globe. Profeſſor Kruſſt, in the 17th volume of the Peterſburgh Commentaries, places the north pole in lat. 70° N. and long. 23° W. from London; and the ſouth pole in lat. 50° S. and long. 92° E.

Wilcke of Stockholm, in his indication chart (*Swed. Mem.* tom. xxx p. 218.), places the north pole in N. Lat. 75°, near Baffin's Bay, in the longitude of California. The ſouth pole is in the Pacific Ocean, in lat. 70° S.

Churchman places the north pole in lat. 59° N and long. 135° W. a little way inland from Cape Fairweather; and the ſouth pole in lat. 59° S. Long. 165° E. due ſouth from New Zealand.

A planiſphere by the Academy of Sciences at Paris for 1786, places the magnetic equator ſo as to interſect the earth's equator in long. 75°, and 155° from Ferro Canary Iſland, with an inclination of 12 degrees nearly, making it a great circle very nearly. But we are not informed on what authority this is done; and it does not accord with many obſervations of the dip which we have collected from the voyages of ſeveral Britiſh navigators, and from ſome voyages between Stockholm and Canton. Mr Churchman has given a ſketch of a planiſphere with lines, which may be called parallels of the dip. Thoſe parts of each parallel that have been aſcertained by obſervation are marked by dots, ſo that we can judge of his authority for the whole conſtruction. It is but a ſketch, but gives more ſynoptical information than any thing yet publiſhed. The magnetic equator cuts the earth's equator in long. 15°, and 195° E. from Greenwich, in an angle of nearly 17 degrees. The circles of magnetic inclination are not parallel, being conſiderably nearer to each other on the ſhort meridian than on its oppoſite. This circumſtance, being founded on obſervation, is one of the ſtrongeſt arguments for the exiſtence of a magnet of tolerable regularity, as the cauſe of all the poſitions of the compaſs needle; for ſuch *muſt* be the poſitions of the circles of equal dip, if the axis of this magnet is far removed from the axis of rotation, and does not interſect it.

Now, if the ſituation of the poles be any thing near the average or medium of theſe determinations, and if we form all our notions by analogy, comparing the poſitions of the compaſs needle in relation to the great terreſtrial magnet, with the poſitions aſſumed by a ſmall needle in the neighbourhood of a magnet, we muſt conclude, that the magnetical conſtitution of this globe has little or no reference to its regular external form. The axis of the magnet is very far removed from that of the globe (at leaſt 1500 miles), and is not nearly parallel to it, nor in the ſame plane. It required the ſagacity and the ſkill of a Euler to ſubject ſuch anomalous magnetiſm to any rules of computation; and every perſon qualified to judge of the ſubject muſt allow his diſſertation in the 13th volume of the Berlin Memoirs to be a work of wonderful reſearch. It is a very agreeable thing to ſee ſuch a conformity between the lines which expreſs the regular magnetiſm of Euler's diſſertation, and the lines drawn by Dr Halley from obſervation, and which appeared to himſelf ſo capricious, that he deſpaired (notwithſtanding his conſummate ſkill in geometry) of their ever being reduced to a mathematical and preciſe ſyſtem. 66.

67 Confirmations of Dr Gilbert's phyſiology.

Without detracting from the merit of Dr Gilbert, we may preſume to ſay that his notion of the earth's being a great magnet was not, in his mind, more than a ſagacious conjecture, formed from a very general and even vague compariſon. Yet the compariſon was ſufficiently good to give him great confidence in his opinion that the action of this great magnet, in perfect conformity to what we obſerve in our experiments with magnets, is the ſource of all the magnetiſm that we obſerve. If there was nothing elſe in proof of the juſtneſs of his theory, it is abundantly proved by the beautiful experiment of Mr Henſhaw, mentioned in the article VARIATION, *Encycl.* p. 621. col. 2. An iron bar held nearly upright, attracts the ſouth end of a compaſs needle with its lower end; and if that end of the bar be kept in its place, and the bar turned round till it becomes the upper end, the ſouth point of the needle immediately turns away from it, and the north end is now attracted. This experiment may be perfectly imitated with artificial magnetiſm.

Having ſupported a large magnet SAN (fig. 24.), ſo that its ends are detached from ſurrounding bodies, place a ſmall needle B (poiſed on its pivot) about three inches below the north pole N of the magnet, and in ſuch a ſituation that its polarity to the magnet may be very weak. Take now a ſmall piece of common iron, and hold it in the poſition repreſented at C. Its lower end becomes a north pole, attracting the ſouth pole of the needle. Keeping this in its place, turn round the piece of iron into the poſition D; the ſouth pole of B will now avoid it, and the north pole will be attracted. We directed the needle to be ſo placed, that its polarity, in relation to the magnet, may be weak. If it be ſtrong, it may act on the end of C or D like a magnet, and counteract the magnetiſm induced on C or D by vicinity to A.

An

An anonymous writer in the Philoſophical Tranſactions, N° 177. Vol. XV. relates ſeveral obſervations made during a voyage to the Eaſt Indies, which are quite conformable to this. A few leagues northweſt from the iſland Aſcenſion, the ſouth point of the compaſs needle hardly ſhewed any tendency to or from the lower end of an iron bar. It ſeemed rather to avoid the upper end; it was not in the leaſt affected by the middle of the bar; but when the bar was laid horizontal, in the magnetic direction, its two ends affected the diſſimilar ends of the compaſs needle very ſtrongly; but when horizontal, and lying at right angles to the magnetic direction, its polarity was altogether indifferent.

As the other phenomena of induced artificial magnetiſm have the ſame reſemblance to the phenomena of natural magnetiſm, a bar which has remained long in the vicinity of a magnet acquires magnetiſm (permanent) in the ſame way, and modified by the ſame circumſtances, as in natural magnetiſm. Hammering a bit of common iron in the immediate vicinity of a magnet, gives it very good magnetiſm. Expoſing a red hot bar to cool in the neighbourhood of a magnet has the ſame effect. Alſo quenching it ſuddenly has the ſame effect. Quenching a ſmall red hot ſteel bar between two magnets, was found by us to communicate a much ſtronger magnetiſm than we could give it by any other method. Its form indeed was very unfavourable for the ordinary method of touching; for it conſiſted of two little ſpheres connected by a ſlender rod, and could ſcarcely be impregnated in any other way than by placing it for a very long while between magnets. In all theſe experiments, the polarity acquired is preciſely ſimilar to that acquired by the ſame treatment in relation to this ſuppoſed great terreſtrial magnet. In ſhort, in whatever manner we purſue this analogy in our experiments, we find the reſemblance moſt perfect in the phenomena.

We cannot but think, therefore, that this new phyſiology of the magnet by Dr Gilbert is well eſtabliſhed; and we think ourſelves authoriſed to aſſume it as a propoſition fully demonſtrated, that the earth is a great magnet, or contains a great magnet, the agency of which produces the direction of the magnetic needle, and all the magnetiſm which iron acquires by long continuance in a proper poſition. It is this which made us ſay, in the beginning of this article, that attraction and polarity were not confined to magnets, but were properties belonging to all iron in its metallic ſtate. We now ſee the reaſon why any piece of iron brought very near to another piece will attract it—both become magnetical, in conſequence of the agency of the great magnet; and their magnetiſm is ſo diſpoſed, that their mutual attractions exceed their repulſions. Alſo, why an iron rod, placed nearly in the magnetical direction, will finally arrange itſelf in that direction. Alſo, why the terreſtrial polarity of common iron is indifferent, and either end of the rod will ſettle in the north, if it have nearly that poſition at firſt. The magnetiſm induced by mere momentary poſition is ſo feeble as to yield to any artificial magnetiſm. As a moment was ſufficient for imparting it, a moment ſuffices for deſtroying it; and another moment will impart the oppoſite magnetiſm. But artificial magnetiſm requires more force for its production, and ſome of it remains when the producing cauſe is removed, and it does not yield at once to the contrary magnetiſm. That there is no farther difference appears from this, that long continued poſition gives determined and permanent magnetiſm, and that it is deſtroyed by an equally long continuance in the contrary poſition. It ſeems to be very generally true, that a magnet will carry more by its north than by its ſouth pole. It ſhould be ſo in this part of the world, becauſe the terreſtrial magnetiſm induced on the iron conſpires with the magnetiſm induced by the north pole of a magnet, but counteracts the magnetiſm induced by the ſouth pole.

The propriety of Mr Savery's, Mr Canton's, and Mr Antheaume's proceſſes for beginning the impregnation of hard ſteel bars is now plain, and the ſuperior effect of the two great bars of common iron in the propoſed method of Mr Antheaume. We cannot but take this opportunity of paying the proper tribute of praiſe to the ingenuity of Mr Savery. Every circumſtance of his proceſs was ſelected in conſequence of an accurate conception of magnetiſm, and the combination of this ſcience with Dr Gilbert's theory. His proceſs is the ſame with Antheaume's in every reſpect, except the circumſtance of the double touch borrowed from Mitchell and Canton. Theſe obſervations do not detract from the diſcernment of Mitchell and Canton, who ſaw in thoſe experiments what had eſcaped the attention of hundreds of readers.

68 Seeming objection deduced from the want of ſenſible a traction.

But there occurs an objection to this theory of Dr Gilbert, which was urged againſt it with great force. We obſerve no tendency in the magnet or compaſs needle toward this ſuppoſed magnet. An iron or ſteel bar is not found to increaſe its tendency downwards, that is, is not ſenſibly heavier, when its ſouth pole is uppermoſt in this part of the world. A needle ſet afloat on a piece of cork arranges itſelf quickly in the proper direction; but if continued ever ſo long afloat, it has never been obſerved to approach the north ſide of the veſſel. This is quite unlike what we obſerve in the mutual actions of magnets, or the action of magnets on iron. This objection appears to have given Dr Gilbert ſome concern; and he mentions many experiments which have been tried on purpoſe to diſcover ſome magnetical tendency. He gets rid of it as well as he can, by ſaying, that the directive power of a magnet extends much farther than its attractive power. He confirms this by ſeveral experiments. But Dr Gilbert had not ſtudied the ſimultaneous actions of the four poles, nor explained, by the principles of compound motion, how theſe produced all the poſſible poſitions of the needle. Indeed, the compoſition of mechanical forces was by no means familiar with philoſophers at the end of the 16th century. We ſee it now very diſtinctly. The polarity of the needle, or the force with which it turns itſelf into the magnetical poſition, depends on the difference between the *ſums* of the actions of each pole of the magnet on both the poles of the needle; whereas its tendency towards the magnet depends on the difference of the *differences* of thoſe actions (ſee n° 22, 25.) The firſt may thus be very great when the other is almoſt inſenſible. We ſee, that coarſe iron filings heap about the magnet very faſt, and that very fine filings approach it very ſlowly. Now, the largeſt magnet that we can employ, when compared with the great magnet in the earth, is but as a particle of the fineſt filings that can be conceived. This ſurely diminiſhes exceedingly, if it does not entirely annihilate the objection: but as we have heard it urged by many as an improbable thing, that a long magnet, kept afloat for many months (which has been done) ſhall not ſhew the *ſmalleſt* tendency towards the pole of the terreſtrial magnet, we think it deſerves to be conſidered with accuracy, and the queſtion decided in a way which will admit of no doubt.

69
s com-
ely an-
red.

Let the very ſmall magnet C (fig. 25.) be placed near a great magnet A, and then near a ſmaller magnet B, in ſuch a manner that its polarity to both ſhall be the ſame; and then let us determine the proportion between the attractions of A and B for the ſmall magnet C.

This will evidently depend on the law of magnetic action. For greater ſimplicity of inveſtigation, we ſhall content ourſelves with ſuppoſing the action to be inverſely as the diſtance.

Let AN, $= $AS, $= a$; BN $= b$; C$n = c$, AC $= d$, BC $= \delta$; and let the abſolute force of A be to that of B at the ſame diſtance as m to 1.

The magnetic action being ſuppoſed proportional to $\frac{1}{d}$, we have,

1. Action of AN on C$s = \frac{m}{d-a-c}$.

2. ——— AN on C$n = -\frac{m}{d-a+c}$.

3. ——— AS on C$s = -\frac{m}{d+a-c}$.

4. ——— AS on C$n = \frac{m}{d+a+c}$.

5. The whole action $= \frac{8macd}{\overline{d^2-\overline{a+c}^2}\vert^2 \times \overline{d^2-\overline{a-c}^2}\vert^2}$.

6. If c be very ſmall in compariſon with a or b, the whole action of A is very nearly $= \frac{8macd}{\overline{d^2-a^2}^2}$.

7. And the tendency of C to B is, in like manner, $= \frac{8bc\delta}{\overline{\delta^2-b^2}^2}$.

The directive powers of A and B are at their maximum ſtate when C is placed with its axis at right angles to the lines AC or BC. In which caſe we have,

8. The directive power of A $= \frac{4ma}{d^2-a^2}$.

9. The directive power of B $= \frac{4b}{\delta^2-b^2}$.

When theſe directive powers are made equal, by placing C at the proper diſtances from A and B, we have,

10. $4ma : 4b$, or $ma : b = d^2 - a^2 : \delta^2 - b^2$
And $ma\delta^2 - mab^2 = bd^2 - ba^2$
$ma\delta^2 = b(d^2 - a^2) + mab^2$.

11. $\delta^2 = \frac{b}{ma}(d^2 - a^2) + b^2$.

12. $\delta = \sqrt{\frac{b}{ma}(d^2 - a^2) + b^2}$.

Let the attractions of A and B for the very ſmall magnet C, when its polarity to both is the ſame, be expreſſed by the ſymbols α and β. We have $\alpha : \beta = \frac{8macd}{(d^2-a^2)^2} : \frac{8bc\delta}{(\delta^2-b^2)^2}$, which, by n° 10. is $= \frac{8(d^2-a^2)cd}{(d^2-a^2)^2} : \frac{8(\delta^2-b^2)c\delta.}{(\delta^2-b^2)^2} = \frac{d}{d^2-a^2} : \frac{\delta}{\delta^2-b^2}$, $= bd : ma\delta$; that is,

13. Attr^n of A : attr^n of B $= bd : ma\delta$.

As an example of this compariſon, let us ſuppoſe the great terreſtrial magnet to be a thouſand times larger and ſtronger than the magnet whoſe attraction we are comparing with that of terreſtrial magnetiſm. Let us alſo ſuppoſe the diſtance from the pole of the great magnet to be ſmall, ſo that its attraction may be conſiderable. Let us make $d = 1200$, a being $= 1000$, and $b = 1$. Theſe are all very reaſonable ſuppoſitions. Subſtituting theſe values in the formula, we have attr^n of A : attr^n of B $= 1 : 1000$ very nearly; and therefore when the needle, when placed near a magnet, vibrates by its polarity as faſt as it does by natural magnetiſm, its tendency toward that magnet muſt be altogether inſenſible; for the diſproportion is incomparably greater than that of 1 to 1000, in the largeſt magnets with which we can make experiments. Obſerve alſo, that we have taken the caſe where the attractions are the ſtrongeſt, viz. when the magnet C is placed in the axis of A or B. In the oblique poſitions, tangents to the magnetic curves, the attractions are ſmaller, almoſt in any ratio.

We took the inverſe ratio of the diſtances for the law of action, only becauſe the analyſis was very ſimple. It is very evident, that the diſproportion will be ſtill more remarkable if the action be inverſely as the ſquare of the diſtance.

The objection therefore to the origin of the polarity of the compaſs needle, and of all other magnets, namely, the action of a great magnet contained in the earth, appears plainly to be of no force. We rather think that the want of all ſenſible attraction, where there is a briſk polarity, is a proof of the juſtneſs of the conjecture; for if the compaſs needle were arranged by the action of magnetic rocks, or even extenſive ſtrata, near the ſurface of the earth, the attractions would bear a greater proportion to the polarities. We have even obſerved this. A conſiderable maſs of magnetic ſtratum was found to derange the needle of a ſurveyor's theodolite at a conſiderable diſtance all around (about 140 yards). The writer placed the needle on a thin lath, which juſt floated it on water in a large wooden diſh, and ſet it in a place where it was drawn about 15 degrees from the magnetic meridian. It was left in that ſituation a whole night, well defended from the wind by a board laid on the diſh. Next morning it was found applied to that ſide of the diſh which was neareſt to the diſturbing rocks. It had moved about ſix inches. This was repeated three times, and each time it moved in the ſame direction (nearly), which differed conſiderably from the direction of the needle itſelf.

It is now plain that we may, with confidence, aſſume Dr Gilbert's theory of terreſtrial magnetiſm as ſufficiently eſtabliſhed. And, ſince we muſt certainly call that the north pole of the great magnet which is ſituated in the northern parts of the earth, and ſince thoſe poles of magnets which attract each other have oppoſite polarities, we muſt ſay, that what we call the north pole of a mariner's needle, or of any other magnet, has the ſouthern polarity.

We may now venture to go farther with Dr Gilbert, and

70 The great magnet is the ſource of all natural magnetiſm.

and to ſay that *all* the magnetiſm which we obſerve, whether in nature or art, is either the immediate or the remote effect of the action of the great magnet. As ſoft bars ſoon acquire a tranſient magnetiſm; as hard bars, after long expoſure, acquire a ſenſible and permanent magnetiſm—we muſt infer, that ores of iron, which are in a ſtate fit for impregnation, muſt acquire a ſenſible and permanent magnetiſm, by continuing, for a ſeries of ages, in the bowels of the earth. And thus the magnetiſm of loadſtones, which, till the diſcovery of the natural magnetiſm acquired by poſition, were the ſources of all our magnetical phenomena, is now proved to be a neceſſary conſequence of the exiſtence and agency of a great magnet contained in the bowels of the earth.

71 Loadſtones in the mine may have their poles in any poſition.

It ſeems to reſult from this theory, that, in theſe northern parts of the world, that part of every natural loadſtone that is at the extremity of the line drawn through the ſtone in the magnetic direction ſhould be its pole; and that the loadſtone, when properly poiſed, ſhould of itſelf aſſume the very poſition which it had in the mine. Dr Gilbert complains of the inattention of miners *(rude hominum genus, lucro potius quam phyſicæ conſulentes)* to this important circumſtance. Once, however, he had the good fortune to be advertiſed of a great magnetic maſs lying in its matrix. He repaired quickly to the mine, examined it, and marked its points which were in the extremities of the magnetic line. When it was detached from its matrix, he had the pleaſure of finding its poles in the very places he expected. The loadſtone was of conſiderable ſize, weighing about 20 pounds.—Mr Wilcke gives in the Swediſh Commentaries ſeveral inſtances of the ſame kind.

But ſhould this always be the caſe? By no means. There are many circumſtances which may give the magnetiſm of a loadſtone a very different direction. We have fonnd, that ſimple juxtapoſition to a magnet will ſometimes give a ſucceſſion of poles to a long bar of hard ſteel. The ſame thing may happen to an extenſive vein of magnetiſable matter. The loadſtone taken out of this vein may have been placed like that of a ſoft bar placed in the magnetic line, if lying in one part of the vein; if taken from another part of it, its polarity may be the very reverſe; and in another part it may have no magnetiſm, although completely fitted for acquiring it. It may have its poles placed in a direction different from all theſe, in conſequence of the vicinity of a greater loadſtone. As loadſtones poſſeſſed of vigorous magnetiſm are always found only in ſmall pieces, and in pieces of various ſizes and force, we muſt expect every poſition of their poles. The only thing that we can expect by theory is, that adjoining loadſtones will have their friendly poles turned toward each other, and a general prevalence of or tendency to a polarity ſymmetrical with that of the earth. The reader will find ſome more obſervations to this purpoſe in the article VARIATION, *Encycl.* p. 623. as alſo in Gilbert's treatiſe, B. III. c. 2. p. 121.

Nor ſhould all ſtrata or maſſes of iron ore be magnetical. We know that none are ſuſceptible of induced magnetiſm, but ſuch as are, to a certain degree, in the metallic ſtate. Such ores are not abundant. Nay, even all of ſuch ſtrata do not neceſſarily acquire magnetiſm by the action of the great magnet. If their principal dimenſions lie nearly perpendicular to the magnetic direction, they will not acquire any ſenſible quantity. A ſtratum in this country, riſing about 17 degrees to the N. N. W. will ſcarcely acquire magnetiſm. It may alſo happen, that the influence of the great magnet is counteracted by that of ſome extenſive ſtratum inacceſſible to man, by reaſon of its great depth.

72 Probable cauſe of their great natural vigour.

Thus we ſee, that all the appearances of the original magnetiſm of loadſtones are perfectly conſiſtent with the notion that they are effects of one general coſmical cauſe, the action of the great magnet contained in the earth, and that there is no occaſion to ſuppoſe this great magnet to differ, in its conſtitution or manner of action, from the ſmall maſſes of ſimilar matter called loadſtone. The only difficulty that preſents itſelf is the great ſuperiority of magnetic force obſervable in ſome loadſtones over other maſſes of ores circumjacent, which are not diſtinguiſhable by us by any other circumſtance. We acknowledge ourſelves unable to ſolve this difficulty; for the magnetiſm of ſuch pieces is ſometimes incomparably ſtronger than what a bar of iron acquires by poſition; yet this bar is much more ſuſceptible than the ores which are fit for becoming loadſtones. Perhaps there is ſome chemical change which obtains gradually in certain maſſes, which aids the impregnation, in the ſame way that we know that being red hot deſtroys all magnetiſm, whether in a metal bar or in an ore. This ſeems to be confirmed by what we ſee in ſome old iron ſtanchions, which acquire the ſtrongeſt magnetiſm in thoſe parts of their ſubſtance which are combining themſelves with ingredients floating in the atmoſphere. That part which is caſed in the ſtone, and exfoliates and ſplits with ruſt, being converted into ſomething like what is called finery cinder, becomes highly and permanently magnetic. Such peculiarities as theſe, operating for ages, may allow a degree of magnetical impregnation (in whatever this may conſiſt) to take place, to which we can ſee no reſemblance in our experiments. It would be worth while to place iron wires in a tube in the magnetic direction, which could be kept of a proper red heat, while it is converted into æthiops by ſteam. It is not unlikely that it wonld acquire a ſenſible and permanent magnetiſm in this way. It may be, that the little atoms, as they arrange themſelves in a ſort of cryſtalline or ſymmetrical form, may alſo arrange ſo as to favour magnetiſm. Were this tried in the vicinity of a ſtrong magnet, the effect might be more remarkable and preciſe. Perhaps, too, while iron is precipitated in a metallic form from its ſolutions by another metal, ſomething of the ſame kind may happen. We know, that proper ores of iron, expoſed to cementation in a low red heat, in the magnetic direction, become magnetic.

73 Natural cauſes of the chan of the m netic dir tion.

Notice has been taken in the *Encycl.* art. VARIATION, of the attempts of ingenious men to explain the change which is obſerved in all parts of the globe, on the direction of the mariner's needle, the gradual change of the variation. The hypotheſis of Dr Halley, that the globe which we inhabit is hollow, and incloſes a magnetic nucleus, moving round another axis, is not inconſiſtent with any natural law, if he did not ſuppoſe the interval filled up with ſome fluid. The action of the nucleus and ſhell on the intervening fluid would gradually bring the two to one common motion of rotation, as may be inferred from the reaſonings employed by Newton in his remarks on the Carteſian vortices.

Leaving

Leaving out this circumſtance, there is only another cauſe which can affect, and muſt affect, the rotation of both; namely, the mutual action of the magnetic nucleus, and the maſſes of magnetic matter in the ſhell. If the axis of rotation of this nucleus be different from the line joining its magnetic poles, theſe poles will have a motion relative to the ſhell; and this motion may eaſily be conceived ſuch as will produce the changes of magnetic direction which we obſerve. It may even produce a motion of the northern magnetic pole in one direction, and of the ſouthern pole in the oppoſite direction, and this with the appearance of different periods of rotation, as ſuppoſed by Mr Churchman. We may here obſerve, by the way, that the change of magnetic direction in this country is not nearly ſo great as is commonly imagined. The horizontal needle has ſhifted its poſition about 35° at London ſince 1585; but the point of the dipping needle has not changed 10°. We may alſo obſerve, that when the pole of the central magnet changes its place, the magnetiſm of an extenſive ſtratum, influenced by it, may ſo alter its diſpoſition, as to change the poſition of the compaſs needle in the oppoſite direction to that of the change which the central magnet alone would induce on it.

But as motions have not yet been aſſigned to this nucleus, which quadrate with the obſerved poſitions of the needle, and as the very exiſtence of it is hypothetical, it may not be amiſs to examine, whether ſuch a change of variation may not be explained by what we know of the laws of magnetiſm, and of the internal conſtitution of this earth?

1. It is pretty certain, that the veins in which loadſtones are found are not parts of the great magnet. This appears from their having two poles while in the mine, and alſo from the very ſmall depth to which man has been able to penetrate. When we compare the poſitions of the dipping needle with thoſe of a ſmall needle near a magnet, we muſt infer, that the poles are very far below the ſurface.

Yet we know, that there are magnetiſable ſtrata of very great extent occupying a very conſiderable portion of the external covering. Though their bulk and abſolute power may be ſmall, when compared with thoſe of the great magnet, yet their greater vicinity to the needles on which obſervations are made, may give them a very ſenſible influence. In this way may a great deal of the obſerved irregularities of the poſitions of the needle be accounted for. In the Lagoon at Teneriffe, *Feuillée* obſerved the variation 13° 30′ weſt in 1724, while at the head of the iſland it was only 5°. The dip at the Lagoon was 63° 30′, greatly ſurpaſſing what was obſerved in the neighbourhood. Muller found, in the mountains of Bohemia, great and deſultory differences of declination, amounting ſometimes to 50°. At Mantua, the variation in 1758 was 12°; while at Bononia and Brixia it was nearly 18°. Great irregularities were obſerved by Goëte in the Gulph of Finland, eſpecially near the iſland of Suſſari, among ſome rocks: on one of theſe, the needle ſhewed no polarity. Captain Cook and Captain Phipps obſerved differences of 10°, extending to a conſiderable diſtance, on the weſt coaſts of North America. In the neighbourhood of the iſland Elba in the Mediterranean, the poſition of the needle is greatly affected by the iron ſtrata, in which that iſland ſo much abounds. In this country, there are alſo obſerved ſmall deviations, which extend over conſiderable tracts of country, indicating a great extent of ſtrata that are weakly magnetic. Since ſuch ſtrata receive their magnetiſm by induction, in a manner ſimilar to a bar of hard ſteel, and ſince we know that this receives it gradually, it may very probably happen, that a long ſeries of years may elapſe before the magnetiſm attains its ultimate diſpoſition.

Here, then, is a neceſſary change of the magnetic direction; and although it may be very different in different places, according to the diſpoſition and the power of thoſe ſtrata, there muſt be a general vergency of it one way.

2. It is well known that all metals, and particularly iron, are in a progreſs of continual production and demetallization. The veins of metals, and more particularly thoſe of iron, are evidently of poſterior date to that of the rocks in which they are lodged. Chemiſtry teaches us, by the very nature of the ſubſtances which compoſe them, that they are in a ſtate of continual change. This is another cauſe of change in the magnetic direction. Nay, we know that ſome of them have ſuddenly changed their ſituation by earthquakes and volcanoes. Some of the ſtreams of lava from Veſuvius and Ætna abound in iron. This has greatly changed its ſituation; and if the ſtrata from which it proceeded were magnetical, the needle in its neighbourhood muſt be affected. Nay, ſubterranean heat alone will effect a change, by changing the magnetiſm of the ſtrata. Mr Lievog, royal aſtronomer at Beſſeſtedt in Iceland, writes, that the great eruption from Hecla in 1783, changed the direction of the needle nine degrees in the immediate neighbourhood. This change was produced at a mile's diſtance from the frozen lava; and it diminiſhed to two degrees at the diſtance of 2½ miles. He could not approach any nearer, on account of the heat ſtill remaining in the lava, after an interval of 14 months.

All theſe cauſes of change in the direction of the mariner's needle muſt be partial and irregular. But there is another cauſe, which is coſmical and univerſal. Dr Halley's ſuppoſition of four poles, or, at leaſt, the ſuppoſition of irregular and diffuſed poles, ſeems the only thing that will agree with the obſervations of declination. We know that all magnetiſm of this kind (that is, diſpoſed in this manner) has a natural tendency to change. The two northern poles may have the ſame or oppoſite polarities. If they are the ſame, their action on each other tends to diminiſh the general magnetiſm, and to cauſe the centre of effort to approach the centre of the magnet. If they have oppoſite polarities, the contrary effect will be produced. The general magnetiſm of each will increaſe, and the pole (or its centre of effort) will approach to the ſurface. In either of theſe caſes, the compound magnetiſm of the whole may change exceedingly, by a change by no means conſiderable in the magnetiſm of each pair of poles. It is difficult to ſubject this to calculation; but the reader may have very convincing proof of it, by taking a ſtrong and a weaker magnet of the ſame length, and one of them, at leaſt, of ſteel not harder than ſpring temper. Lay them acroſs each other like an acute letter X; and then place a compaſs needle, ſo that its plane of rotation may be perpendicular to the plane of the X. Note exactly the poſition in which the needle ſettles. In a few minutes after, it will be found to change conſiderably, although no remarkable change has yet happened to the magnets themſelves.

---

74 Speculations about the origin of magnetiſm. Hypotheſis of Æpinus.

We flatter ourſelves, that our readers will grant that the preceding pages contain what may juſtly be called a theory of magnetiſm, in as much as we have been able to include every phenomenon in one general fact, the induction of magnetiſm; and have given ſuch a deſcription of that fact and its modifications, that we can accurately predict what will be the appearances of magnets and iron put into any deſired ſituation with reſpect to each other. If our notions of philoſophical diſquiſition (delivered in art. Philosophy, *Encycl. Brit.*) be juſt, we have explained the ſubordinate phenomena, or have given a theory of magnetiſm.

But it is not eaſy to ſatisfy human curioſity. Men have even inveſtigated, or ſought for cauſes of the perſeverance of matter in its preſent condition. We have not been contented with Newton's theory of the celeſtial motions, and have ſought for the cauſe of that mutual tendency which he called gravitation, and of which all the motions are particular inſtances.

Philoſophers have been no leſs inquiſitive after what may be the cauſe of that mutual attraction of the diſſimilar poles, and the repulſion of the ſimilar poles, and that faculty of mutual impregnation, or excitement, which ſo remarkably diſtinguiſh iron, in its various ſtates, from all other ſubſtances. The action of bodies on each other at a diſtance, has appeared to them an abſurdity, and all have had recourſe to ſome material intermedium. The phenomenon of the arrangement of iron filings is extremely curious, and naturally engages the attention. It is hardly poſſible to look at it without the thought ariſing in the mind of a ſtream iſſuing from one pole of the magnet, moving round it, entering by the other pole, and again iſſuing from the former outlet. Accordingly, this notion has been entertained from the earlieſt times, and different ſpeculatiſts have had different ways of conceiving how this ſtream operated the effects which we obſerve.

The ſimpleſt and moſt obvious was juſt to make it act like any other ſtream of fluid matter, by impulſion. Impulſion is the thing aimed at by all the ſpeculatiſts. They have a notion, that we conceive this way of communicating motion with intuitive clearneſs, and that a thing is fully explained when it can be ſhewn that it is a caſe of impulſion. We have conſidered the authority of theſe explanations in the article Impulsion of this *Supplement*, and need not repeat our reaſons for refuſing it any pre-eminence. But even when we have ſhewn the phenomena to be caſes of impulſion by ſuch a ſtream, the greateſt difficulty, the moſt curious and the moſt embarraſſing, is to aſcertain the ſources of this impulſive motion of the fluid—How, and from what cauſe does it begin? What forces bend it in curves round the magnet? Thoſe philoſophers, whoſe principle obliges them to explain gravitation alſo by impulſe, muſt have another ſtream to impel this into its curves. Acting by impulſion, this magnetic ſtream muſt loſe a quantity of motion equal to what it communicates. What is to reſtore this? What directs it in a particular courſe thro' the magnet? And what is it that can totally alter that courſe—in a moment—in all the phenomena of induced magnetiſm? How does it impel? Lucretius, either of himſelf, or ſpeaking after the Greek philoſophers, makes it impel, not the iron, but the ſurrounding air, ſweeping it out of the way; and thus giving occaſion for the ſurrounding air to ruſh around the magnet, and to hurry the bits of iron toward it. There is, perhaps, more ingenious refinement in this thought than in any of the impulſive theories adopted ſince his day by Des Cartes, Euler, and other great philoſophers: But it is ſagaciouſly remarked by D. Gregory, in his MS. notes on Newton, that this theory of Lucretius falls to the ground; becauſe the experiments ſucceed juſt as well under water as in the air. As to the explanations, or deſcriptions, of the canals and their dock gates, opening in one direction, and ſhutting in the other, conſtructions that are changed in an inſtant in a bar of iron, by changing the poſition of the magnet, we only wonder that men, who have a reputation to loſe, ſhould ever hazard ſuch crude and unmechanical dreams before the public eye. The mind of man cannot conceive the poſſibility of their formation; and if they are really formed, the effects ſhould be the very oppoſite of thoſe that are obſerved: the ſtream ſhould move thoſe bodies leaſt which afford ready channels for its paſſage. If a rag of iron filings be arranged by the impulſion of ſuch a ſtream, it ſhould be carried along by it; and if it is *impelled toward* one end of the magnet, it ſhould be impelled *from* the other end. Since we now know, that each particle of filings is a momentary magnet, we muſt allow a ſimilar ſtream whirling round each. Is that an explanation which exceeds all power of conception?

But has it ever been ſhewn, that there is any impulſion at all in theſe phenomena? Where is the impelling ſubſtance? The only argument ever offered for its exiſtence is, that we are reſolved that the phenomena of magnetiſm ſhall be produced by impulſion, and the arrangement of iron filings looks ſomewhat like a ſtream. But enough of this. We truſt that we have ſhewn the way in which this arrangement obtains in the cleareſt manner. Every particle becomes magnetic by induction. This is a fact, which ſets all reaſoning at defiance. The polarity of each rag is ſo diſpoſed, that their adjoining ends turn to each other. This is another uncontrovertible fact. And theſe two facts explain the whole. The arrangement of iron filings, therefore, is a ſecondary fact, depending on principles more general; and therefore cannot, conſiſtently with juſt logic, be aſſumed as the foundation of a theory.

Had magnetiſm exhibited no phenomena beſides the attraction and repulſion of magnets, it is likely that we ſhould not have proceeded very far in our theories, and would have contented ourſelves with reducing theſe phenomena to their moſt general laws. But the communication of magnetiſm ſeems a great myſtery. The ſimple approach of a magnet communicates theſe powers to a piece of iron; and this without any diminution of its own powers. On the contrary, beginning with magnets which have hardly any ſenſible power, we can, by a proper alternation of the manipulations, communicate the ſtrongeſt magnetiſm to as many hard ſteel bars as we pleaſe; and the original magnets ſhall be brought to their higheſt degree of magnetiſm. We have no notion of powers or faculties, but as qualities of ſome ſubſtances in which they are inherent. Yet here is no appearance of ſomething abſtracted from one body, and communicated to, or ſhared with another. The proceſs is like kindling a great fire by a ſimple ſpark; here is no communication, but only *occaſion* given to the exertion of powers inherent in the combuſtible matter. It appears probable, that the caſe is the ſame in magnetiſm; and that all that is performed in making a magnet is the excitement of powers already in the ſteel, or the giving occaſion for their exertion; as burning the thread which ties together the two ends of a bow, allows it to unbend. This notion did not eſcape the ſagacity of Dr Gilbert; and he is at much pains to ſhew, that the *coitio magnetica* is a quality inherent in all magnetical bodies, and only requires the proper circumſtance for its exertion. He is not very fortunate in his attempts to explain *how* it is developed by the vicinity of a magnet, and how this faculty, or actual exertion of this power, becomes permanent in one body, while in another it requires the conſtant preſence of the magnet.

74 Magnetical hypotheſis of Æpinus.

It is to Mr Æpinus, of the Imperial Academy of St Peterſburgh, that we are indebted for the firſt really philoſophical attempt to explain all theſe myſteries. We mentioned, in the article ELECTRICITY, *Suppl.* the circumſtance which ſuggeſted the firſt hint of this theory to Æpinus, *viz.* the reſemblance between the attractions and repulſions of the tourmaline and of a magnet. A material cauſe of the electric phenomena had long been thought familiar to the philoſophers. They had attributed them to a fluid which they called an electric fluid, and which they conceived to be ſhared among bodies in different proportions, and to be transferable from one to another. Dr Franklin's theory of the Leyden phial, which led him to think that the faculty of producing the electrical phenomena depended on the deficiency as well as the redundancy of this fluid, combined with the phenomena of induced electricity, ſuggeſted to Æpinus a very perſpicuous method of ſtating the analogy of the tourmaline and the magnet; which he publiſhed in 1758 in a paper read to the academy.

Reflecting more deeply on theſe things, Mr Æpinus came by degrees to perceive the perfect ſimilarity between all the phenomena of electricity by poſition and thoſe of magnetiſm; and this led him to account for them in the ſame manner. As the phenomena of the Leyden phial, explained in Franklin's manner, ſhews that a body may appear electrical all over, by having leſs than its natural quantity of the electric fluid, as well as by having more, it ſeemed to follow, that it may alſo be ſo in reſpect to different parts of the ſame body; and therefore a body may become electrified in oppoſite ways at its two extremities, merely by abſtracting the fluid from one end, and condenſing it in the other; and thus may be explained the phenomena of induced electricity, where nothing appears to have been communicated from one body to the other. If this be the caſe, the two ends of a body rendered electric by induction ſhould exhibit the ſame diſtinctions of phenomena that are exhibited by bodies wholly redundant and wholly deficient. The redundant ends ſhould repel each other; ſo ſhould the deficient ends; and a redundant part ſhould attract a deficient. All theſe reſults of the conjecture tally exactly with obſervation, and give a high degree of probability to the conjecture. The ſimilarity of theſe phenomena to the attractions of the diſſimilar poles of a magnet, and the repulſions of the ſimilar poles, is ſo ſtriking, that the ſame mode of explanation forces itſelf on the mind, and led Mr Æpinus to think, that the faculty of producing the magnetical phenomena belonged to a magnetical fluid, reſiding in all bodies ſuſceptible of magnetiſm; and that the exertion of this faculty require nothing but the abſtraction of the fluid from one end of the magnetic bar, and its conſtipation in the other. And this conjecture was confirmed by obſerving, that in the induction of magnetiſm on a piece of iron, the power of the magnet is not diminiſhed.

All theſe circumſtances led Mr Æpinus to frame the following hypotheſis:

1. There exiſts a ſubſtance in all magnetic bodies, which may be called the magnetic fluid; the particles of which repel each other with a force decreaſing as the diſtance increaſes.

2. The particles of magnetic fluid attract, and are attracted by the particles of iron, with a force that varies according to the ſame law.

3. The particles of iron repel each other according to the ſame law.

4. The magnetic fluid moves, without any conſiderable obſtruction, through the pores of iron and ſoft ſteel; but is more and more obſtructed in its motion as the ſteel is tempered harder; and in hard tempered ſteel, and in the ores of iron, it is moved with the greateſt difficulty.

In conſequence of this ſuppoſed attraction for iron, the fluid may be contained in it in a certain determinate quantity. This quantity will be ſuch, that the accumulated attraction of a particle for all the iron balances, or is equal to, the repulſion of all the fluid which the iron contains. The quantity of fluid competent to a particle of iron is ſuppoſed to be ſuch, that the repulſion exerted between it and the fluid competent to another particle of iron is alſo equal to its attraction for that particle of iron: And therefore the attraction between the fluid in an iron bar A for the iron of another bar B, is juſt equal to its repulſion for the fluid in B; it is alſo equal to the repulſion of the iron in A for the iron in B. This quantity of fluid reſiding in the iron may be called its NATURAL QUANTITY.

In conſequence of the mobility through the pores of the iron, the magnetic fluid may be abſtracted from one end of a bar, and condenſed in the other, by the agency of a proper external force. But this is a violent ſtate. The mutual repulſion of the particles of condenſed fluid, and the attraction of the iron which it has quitted, tend to produce a more uniform diſtribution. If we reflect on the law of action, we ſhall clearly perceive, that ſomewhat of this tendency muſt obtain in every ſtate of condenſation and rarefaction, and that there can be a perfect equilibrium only when the fluid is diffuſed with perfect uniformity. This, therefore, may be called the NATURAL STATE of the iron.

If the reſiſtance oppoſed by the iron to the motion of the magnetic fluid be like that of perfect fluids to the motion of ſolid bodies, ariſing entirely from the communication of motion, there is no tendency to uniform diffuſion ſo weak as not to overcome ſuch reſiſtance, and finally to produce this uniform diſtribution. But (as is more probable) if the obſtruction reſembles that of a clammy fluid, or of a ſoft plaſtic body like clay, ſome of the accumulation, produced by the agency of an external force, may remain when the force is removed; the diffuſion will ceaſe whenever the equaliſing force is juſt in equilibrio with the obſtruction.

All the preceding circumſtances of the hypotheſis are

are ſo perfectly analogous to the hypotheſis of Mr Æpinus for explaining the electrical phenomena, which is given in detail in the article Electricity of this *Supplement*, that it would be ſuperfluous to enter into a minute diſcuſſion of their immediate reſults. We therefore beg the reader to peruſe that part of the article Electricity where the elements of Æpinus's hypotheſis are delivered, and the phenomena of induced electricity explained (*viz.* from nº 11. to 60. incluſive), and to ſuppoſe the diſcourſe to relate to the *magnetical* fluid. Let N, S, *n*, *s*, be conſidered as the overcharged and undercharged parts of a magnetical body, or the poles of a magnet, and of iron rendered magnetical by induction. We ſhall confine our obſervations in this place to thoſe circumſtances in which the mechanical phenomena of magnetiſm are limited by the circumſtance, that magnets always contain their natural quantity of fluid; ſo that their action on iron, and on each other, depends entirely on its unequable diſtribution; as is the caſe with induced electricity.

75
Magnetiſm how induced on iron by juxtapoſition.

Let the magnet NAS (fig. 26.), having its north pole NA overcharged, be ſet near to the bar *n* B *s* of common iron, and let their axes form one ſtraight line. Then (as in the caſe of electrics) the overcharged pole NA acts on the bar B only by means of the redundant fluid which it contains. For that portion of its fluid, which is juſt ſufficient for ſaturating the iron, will repel the fluid in B, juſt as much as the iron in NA attracts it; and therefore the fluid in B ſuſtains no change from this portion of the fluid in NA. In like manner, the pole SA acts on B only in conſequence of the iron in SA, which is not ſaturated or attended by its equivalent fluid.

If the fluid in B is immoveable, even the redundant fluid in NA, and redundant iron in SA, will produce no *ſenſible* effect on it: For every particle of iron in B is accompanied by as much fluid as will balance, by its repulſions and attractions, the attractions and repulſions of the equidiſtant particle of iron. But as the magnetical fluid in B is ſuppoſed to be eaſily moveable, it will be repelled by the redundant fluid in AN toward the remote extremity *n*, till the reſiſtance that it meets with, joined to its own tendency to uniform diffuſion, juſt balances the repulſion of AN. This tendency to uniform diffuſion obtains as ſoon as any fluid quits its place; as has been ſufficiently explained in the Supplementary article Electricity, nº 16. 17. &c.

But, at the ſame time, the redundant iron in AS attracts the fluid in B, and would abſtract it from B *n*, and condenſe it into B *s*. This attraction oppoſes the repulſion now mentioned. But, becauſe AS is more remote from every point of B than AN is from the ſame point, the repulſions of the redundant fluid in AN will prevail; and, on the whole, fluid will be propelled toward *n*, and will be rarefied on the part B *s*. But as to what will be the law of diſtribution, both in the redundant and deficient parts of B, it is plain that nothing can be ſaid with preciſion. This muſt depend on the diſtribution of the fluid in the magnet NAS. The more diffuſed that we ſuppoſe the redundant fluid and matter in the magnet, the farther removed will the centres of effort of its poles be from their extremities; the ſmaller will be the action of AN and AS, the ſmaller will be their difference of action; and therefore the ſmaller will be the condenſation in B *n*, and the rarefaction in B *s*. Hence we learn, in the outſet of this attempt to explanation, that the action of a magnet will be ſo much the greater as its poles are more concentrated. This is agreeable to obſervation, and gives ſome credit to the hypotheſis. We can juſt ſee, in a very general manner, that the fluid will be rarer than its natural ſtate in *s*, and denſer in *n*; and that the change of denſity is gradual, and that the denſity may be repreſented by the ordinates of ſome line *c b d* (fig. 27.), while the natural denſity is repreſented by the ordinates to the line C *b* D, parallel to *s n*. There will be ſome point B of the iron bar, where the fluid will be of its natural denſity, and the ordinate B *b* will meet the line *c b d* in the point of its interſection with CD.

All this action is internal and imperceptible. Let us inquire what will be the *ſenſible* external action. There is a ſuperiority of attraction towards the magnet: For ſince the magnetic action is ſuppoſed to diminiſh continually by an increaſe of diſtance, the curve, whoſe ordinates repreſent the forces, has its convexity toward the axis. Alſo, the force of the poles AN, AS are equal at equal diſtances: For, by the hypotheſis, the attraction and repulſion of an individual particle are equal at equal diſtances; and the condenſation in AN is equal to the deficiency in AS, by the ſame hypotheſis; becauſe NAS ſtill contains its natural quantity of fluid. Therefore the action of both poles may be expreſſed by the ordinates of the ſame curve, and they will differ only by reaſon of their diſtances. We may therefore expreſs the actions by the four ordinates Mm, Pp, Nn, Qq, of fig. 2.; of which the property (deduced from the ſingle circumſtance of its being convex toward the axis) is, that $Mm + Qq$ is greater than $Pp + Nn$. There is therefore a ſurplus of attraction. It is only this ſurplus that is perceived. The fluid, moveable in B, but retained by it ſo as not to be allowed to eſcape, is preſſed towards its remote end *n* by the exceſs $Pp - Qq$ of the repulſion of the redundant fluid in AN, above the attraction of the redundant iron in AS. This exceſs on every particle of the fluid is tranſmitted, by the common laws of hydroſtatics, to the ſtratum immediately incumbent on the extremity *n*, and B is thus preſſed away from A. But every particle of the ſolid matter in B is attracted towards A by the exceſs $Mm - Nn$ of the attraction of the redundant fluid in AN above the repulſion of the redundant iron in AS: and this exceſs is greater than the other; for $m + q$ is greater than $p + n$.

The piece of common iron *n* B *s* is therefore attracted, *in conſequence* of the fluid in it having been propelled towards its remote extremity, and diſtributed in a manner ſomewhat reſembling its diſtribution in NAS. Now, in this hypotheſis, magnetiſm is held to depend entirely on the diſtribution of the fluid. B has therefore become a magnet, has magnetiſm induced on it, and, only in conſequence of this induction, is attracted by A.

Had we ſuppoſed the deficient, or ſouth pole of A, to have been neareſt to B, the redundant matter in AN would have attracted the moveable fluid in B more than the remoter redundant fluid in AS repels it; and, on this account, the magnetic fluid would have been conſtipated in B *s*, and rarefied in B *n*. It would, in this caſe alſo, have been diſtributed in a manner ſimilar to its ſituation in the magnet. And B would therefore have been a momentary magnet, having its redundant pole fronting the deficient or diſſimilar pole of A. It is plain, that there would be the ſame ſurplus of attraction in this as in the former inſtance, and B would (on the whole) be attracted in conſequence, and only in conſequence, of having had a properly diſpoſed magnetiſm induced on it by juxtapoſition. The ſenſible attraction, in this caſe, is a *conſequence* of the diſtribution now deſcribed; becauſe, ſince the fluid conſtipated in the end next to A cannot quit B, the tendency of this fluid toward A muſt preſs the ſolid matter of B in this direction (by hydroſtatical laws) more than this ſolid matter is repelled in the oppoſite direction.

Thus it appears, that the hypotheſis tallies preciſely with the induction of magnetiſm. We do not call this an explanation of the phenomenon; for the fact is, that it is the hypotheſis that is explained by the phenomenon: That is, if any perſon be told that induced magnetiſm is produced by the action of a fluid, in conſequence of its ſituation being changed, he will find, that in order to agree with the attraction of diſſimilar, and the repulſion of ſimilar poles, he muſt accommodate the fluid to the phenomena, by giving it the properties aſſigned to it by Æpinus.

76 Conformity of the hypotheſis with a vaſt variety of phenomena.

But the agreement with this ſimpleſt poſſible caſe of the moſt ſimple example of induced magnetiſm, is not enough to make us adopt the hypotheſis as adequate to the explanation of all the magnetic phenomena. We muſt confront the hypotheſis with a variety of obſervations, to ſee whether the coincidence will be without exception.

When the key CB, in fig. 8. is brought below the conſtipated north pole N of the magnet SAN, its own moveable fluid is propelled from C towards B, and is diſpoſed in CB nearly after the ſame manner as in SAN. Therefore the redundant fluid in the lower end of the key repels the moveable fluid in the wire BD more than the redundant matter in the upper end C attracts it; and thus the fluid is rarefied in the upper end of the wire BD, and condenſed in its lower end D. CB and BD therefore are two temporary magnets, having their diſſimilar poles in contact, or neareſt to each other. This is all that is required for their attraction. This effect is promoted by the action of N on the wire BD, alſo propelling the fluid toward D; and thus increaſing the mutual attraction of CB and BD. In like manner, when the key CB is held above the magnet, the moveable fluid in it is more attracted by the redundant matter in SA than it is repelled by the more remote redundant fluid in AN. The ſame thing happens to the fluid in the wire BD. Therefore CB and BD muſt attract each other; and the key will carry the wire, although the magnet is below it, and alſo attracts it. This ſingularity proceeds from the almoſt perfect mobility of the fluid in the two pieces of common iron, which renders their poles extremely conſtipated; whereas the hardneſs required for the fixed magnetiſm of the magnet prevents this complete conſtipation and rarefaction. This can be ſtrictly demonſtrated in the caſe of ſlender rods of iron; but we can ſhew, and experience confirms it, that in other caſes, depending on the ſhape and the temper of the pieces, the wire will not adhere to the key, but to the magnet.

In the various ſituations and poſitions of the key and wire repreſented in fig. 7. the actions of ſome of the poles on the moveable fluid in the iron are oblique in regard to the length of the pieces; but, ſince the moveable matter is ſuppoſed to be a fluid, it will ſtill be propelled along the pieces, notwithſtanding their obliquity, in the ſame manner as gravity makes water occupy the lower end of a pipe lying obliquely. If indeed the magnetic fluid could eſcape from the iron without any obſtruction by the propulſion of the magnet, it could produce no attraction, or ſenſible motion, any more than light does in a tranſparent body. What is demonſtrated of the electric fluid in the Supplemental article Electricity, n° 133. is equally true here. Why the fluid does not eſcape when it is ſo perfectly moveable, is a queſtion of another kind, and will be conſidered afterwards; at preſent, the *hypotheſis* is, that it does not eſcape.

If the key and wire have the poſition fig. 10. n° 1. the fluid is expelled from the parts in contact, and is condenſed in the remote ends. So far from attracting each other, the key and wire muſt repel. They are temporary magnets, having their ſimilar poles fronting each other. They muſt repel each other, if preſented in a ſimilar manner to the ſouth pole of the magnet.

If they be preſented as in n° 2. fig. 10. where the actions of both poles of the magnet are equal, the ſtate of the fluid in them will not be affected. The redundant pole of the magnet repels the moveable fluid in both the key and the wire toward the upper ends; but the deficient pole acts equally on it in the oppoſite direction. It therefore remains uniformly diſtributed through their ſubſtance; and therefore they can exhibit no appearance of magnetiſm.

But if the key and wire be preſented to the *ſame* part of the magnet, but in another poſition, as ſhewn in fig. 8. n° 3. the fluid of the key will be abſtracted from C, and condenſed in B, by the joint action of both poles of the magnet. The ſame thing will happen in the wire BD. Here, therefore, we have two magnets with their diſſimilar poles touching. They will attract each other ſtrongly; and if carried gradually toward the upper or lower end of the magnet, they will ſeparate before the point B arrives abreaſt of N or S. For ſimilar reaſons, the pieces of iron preſented to the middle of the magnet, as in fig. 10 will have one ſide a weak north pole, and the other ſide a weak ſouth pole; but this will not be conſpicuous, unleſs the pieces be broad.

This experiment ſhews, in a very perſpicuous manner, the competency of the hypotheſis to the explanation of the phenomena. When the fluid is not moved, magnetiſm is not induced, even on the moſt ſuſceptible ſubſtance.

When a piece of iron A (fig. 10.), nearly as large as the magnet can carry, hangs at either pole, a large piece of iron B, brought near to the pole on the other ſide, ſhould cauſe it immediately to fall If S be the deficient pole, it cauſes the fluid in A to aſcend to the top, and A is attracted: but, for the ſame reaſon, it cauſes the fluid in B to accumulate in its lower end. This redundant fluid muſt evidently counteract the redundant matter in S, in the induction of the magnetic ſtate on A. Being more remote from A than S is, it cannot wholly prevent the accumulation in the upper end of A; but it renders it ſo trifling, that the remaining attraction thence ariſing cannot ſupport the weight of A. This is a very inſtructive experiment.

But if, on the contrary, we bring a large piece of iron C below the heavy key A, this piece C will have its fluid accumulated in its upper end, both by the action of A on it, and by the action of the magnet. The attraction of the magnet for A ſhould therefore be augmented; and a magnet ſhould carry a heavier lump of iron when a great lump is beyond it. And it is clear (we think), for ſimilar reaſons, that the magnetiſm of the magnet itſelf in fig. 11. ſhould be increaſed by bringing a great lump of iron near its oppoſite pole: for the magnet differs from common iron only in the *degree* of the mobility of its fluid.

When a compaſs needle is placed oppoſite to the redundant pole N of a magnet AN (fig. 28.), it arranges itſelf magnetically. If a piece of common iron be now preſented laterally to the near point of the needle, the redundant matter in the adjoining parts of the needle and the iron ſhould make them repel; but if preſented to the remote end, the redundant matter in the iron ſhould attract the redundant fluid in that end of the needle, and that end ſhould turn toward the iron.

A parcel of ſlender iron wires, carried by the pole of a magnet, as in fig. 29. ſhould avoid each other. If N be the redundant pole, the fluid in each wire will be driven to the remote end, where it muſt repel the ſimilarly ſituated fluid of its neighbour. The ſame external appearance muſt be exhibited by pieces of wire hanging at the deficient pole of the magnet.

The redundant pole of a magnet A (fig. 30.) being held vertically above the centre of two pieces of common iron, moveable round a ſlender pin, renders the middle of each deficient, and their extremities redundant; therefore they ſhould repel each other, and ſpread out. The ſame effect ſhould be produced by the under charged pole of A.

The redundant pole of a magnet A being applied to one branch of the piece of forked iron NCS (fig. 31.), ſhould drive the fluid into its remote parts C, and then the branch NC ſhould be able to induce the magnetic ſtate on a bit of iron D. But if the deficient pole S of another magnet B be applied to the other branch, theſe two actions ſhould counteract each other at C, and the iron ſhould remain indifferent, and fall.—Yet the magnet B alone would equally cauſe C to carry the piece of iron.

It is ſurely unneceſſary to demonſtrate, that the conſequence of this hypotheſis muſt be, that when a magnet puts any piece of iron into the magnetic ſtate, its own magnetiſm is improved. For the induced magnetiſm of the iron is always ſo diſpoſed as to give the fluid in the magnet a greater conſtipation where already condenſed, and to abſtract more fluid from the parts already deficient. If magnetiſm be produced by ſuch a fluid, a magnet muſt always improve by lying any how among pieces of iron.

But the caſe may be very different when magnets are kept in each others neighbourhood. When the overcharged poles of two magnets are placed fronting each other, the redundant fluid in each repels that in the other more than it attracts the remoter redundant iron. The magnets muſt therefore repel each other. Moreover, in rendering them magnetical, the repulſion of redundant fluid, or the attraction of redundant matter of ſome other magnet, had been employed; and when the magnet was removed, ſome of the conſtipated fluid overcame the obſtruction to its uniform diffuſion, and eſcaped into the deficient pole; what remains is withheld by the obſtruction, and the reſtoring forces are juſt in equilibrio with this obſtruction. If we now add to them the repulſion of redundant fluid, directed toward the deficient pole, ſome more of the conſtipated fluid muſt be driven that way, and the magnet muſt be weakened. Nay, it may be deſtroyed, and even reverſed, if one of the magnets be very powerful, and have its own magnetiſm very fixed; that is, if its fluid be very redundant, and meet with very great obſtruction to its motion. Hence it alſo ſhould follow, that the repulſion obſerved between two magnets ſhould be weaker at the ſame diſtance than their attraction, and ſhould follow a different law. For, in the courſe of the experiments, the ſituation of the fluid in the magnets is continually changing, and approaching to a ſtate of uniform diffuſion.

77
Explanation of the directive power, and of polarity.

Let us now examine into the ſenſible effect of this fluid on a magnet which cannot move from its place, but can turn on its centre like a compaſs needle. This ſcarcely requires any diſcuſſion. We ſhould only be repeating, with regard to the redundant fluid and redundant matter, what we formerly ſaid in regard of north pole and ſouth pole; the little magnet muſt arrange itſelf nearly in the tangent of a magnetic curve. But it requires a more minute inveſtigation to determine what the ſenſible phenomenon ſhould be when the fluid of the little magnet is perfectly moveable.

Suppoſe therefore a particle C (fig. 32.) of magnetic fluid, at perfect liberty to move in every direction, and acted on by the redundant and deficient poles of a magnet NAS. The redundant iron in S attracts C in the direction and with the force CF, while the redundant fluid in N repels it in the direction and with the force CD. By their joint action it muſt be urged in the direction and with the force CE, the diagonal of the parallelogram CDEF, which muſt be accurately a tangent to a magnetic curve. If this particle of fluid belong to the piece of iron *n* C *s*, which lies in that very direction, it will unqueſtionably be puſhed towards the extremity *n*. The ſame muſt happen to other particles. Hence it appears that a piece of common iron in this ſituation and poſition muſt become a magnet, and muſt retain this poſition; only the mechanical energy of the lever may change the equilibrium of the magnetic forces a little; becauſe when the piece of iron *n* C *s* has any ſenſible magnitude, the action on its different points will be a little unequal, and may compoſe diagonals which divide a little from the tangent.

Should the iron needle chance not to have the exact poſition, but not deviate very far from it, it is alſo clear that the fluid, not being able to eſcape, will preſs on the ſide toward which it is impelled; and thus will cauſe the needle to turn on its pivot, and finally arrange itſelf in magnetical and mechanical equilibrium, deviating ſo much the leſs from a tangent to a magnetic curve as the piece of iron is ſmaller. Any piece of common iron, held in the neighbourhood of a magnet, will become more overcharged at one end and undercharged at the other, in proportion as the poſition of its length comes nearer to the tangent of a magnetic curve. A ſlender wire held perpendicular to this poſition, that

is,

is, perpendicular to the curve, ſhould not acquire any ſenſible magnetiſm, either attractive or directive.

78 E lana- ti of the c es fo ed by ir filings.

We ſurely need not now employ many words to ſhew that a parcel of iron filings, ſtrewed round a magnet, ſhould arrange themſelves in the primary magnetic curves, or that when ſtrewed round two magnets they ſhould form the ſecondary or compoſite curves.

79 E ana- ti of tr ſitory a of per- m ent m netiſm, a of in- d rent a deter- m ate n netiſm.

Let us now enquire more particularly into the modifications of this accumulation of magnetic fluid which may reſult from the nature of the piece of iron, as it is put into the magnetic ſtate. The propelling force of A acts againſt the mutual repulſion of the particles of fluid in B, and alſo againſt the obſtruction to its motion through the pores of B. The greater this obſtruction, the ſmaller will be the accumulation which ſuffices, in conjunction with the obſtruction and the attraction of the deſerted iron, to balance the propulſive force of the redundant fluid in the overcharged pole of A. This circumſtance therefore muſt limit the accumulation that can be produced in a given time. Therefore the magnetiſm produced on ſoft ſteel or iron ſhould be greater than that produced in hard ſteel at the ſame diſtance. Hence the great advantage of ſoft poles, or of armour, or of capping, to a loadſtone, or to a bundle of hard bars. The beſt form and dimenſions of this armour is certainly determinable by mathematical principles, if we knew the law of magnetical action, and the diſpoſition of the magnetiſm in our loadſtone; but theſe are too imperfectly known in all caſes for us to pretend to give any exact rules. We muſt decide experimentally by making the caps large at firſt, and reducing them till we find the loadſtone carry leſs; then make them a ſmall matter larger. The chief things to be minded are the purity, the uniformity, and the ſoftneſs of the iron, and the cloſeſt poſſible contact.

If the obſtruction reſemble that to motion through a clammy fluid, the final accumulation in hard ſteel may be nearly equal to that in iron, but will require much longer time. Alſo, becauſe ſuch obſtruction to the motion of the fluid will nearly balance the propelling force in parts that are far removed from the magnet, the accumulation will begin thereabouts, while the bar beyond is not yet affected. A redundant pole will be formed in that place. This will operate on what is *immediately* beyond it, driving the fluid farther on, and occaſioning another accumulation at a ſmall diſtance. This may produce a ſimilar effect in a ſtill ſmaller degree farther on. Thus the ſteel bar will have the fluid alternately condenſed and rarefied, and contain alternate north and ſouth poles. This ſtate of diſtribution will not be permanent; fluid will be gradually changing its place; theſe poles will gradually advance along the bar, the remoter poles becoming gradually more diffuſe and faint; and it will not be till after a very long time that a regular magnetiſm with two poles will be produced. To ſtate mathematically the procedure of this mechaniſm would require many pages. Yet it may be done in ſome ſimple caſes, as Newton has ſtated the proceſs of aerial undulation. But we cannot enter upon the taſk in this limited diſſertation. What is ſaid in the Supplementary article ELECTRICITY (n° 217, 218.) on the diſtribution of the electric fluid in an imperfect inſulator, will aſſiſt the reader to form a notion of the ſtate of magnetiſm during its induction. That ſuch alternations proceed from ſuch mechaniſm, we have ſufficient proof in the inſtances mentioned in the former part of this article. The wave, or curl, produced on the ſurface of a clammy fluid, is a phenomenon of the ſame kind, and owing to ſimilar cauſes.

When the magnet which has produced all theſe changes is removed, it is evident that a part of this accumulation will be undone again. The repulſion of the condenſed fluid, and the attraction of the deſerted iron, will bring back ſome of the fluid. But it is very evident, that a part of the accumulation will remain, by reaſon of the obſtruction to its motion in returning; and this remainder muſt be ſo much the greater as the obſtruction to the change of ſituation is greater. In ſhort, we cannot doubt but that the magnetiſm which remains will be greater in hard than in ſpring tempered ſteel.

80 Rationale of the proceſs for making magnets.

Thus have we traced the hypotheſis in a great variety of circumſtances and ſituations, and pointed out what ſhould be the external appearance in each. We did not, in each inſtance, mention the perfect coincidence of theſe conſequences with what is really obſerved, but left it to the recollection of the reader. The coincidence is indeed ſo complete, that it ſeems hardly poſſible to refuſe granting that nature operates in this or ſome very ſimilar manner. We get ſome confidence in the conjecture, and may even proceed to explain complicated phenomena by this hypothetical theory. We might proceed to ſhew, that the effects of all the methods practiſed by the artiſts in making artificial magnets are eaſy conſequences of the hypotheſis: but this is hardly neceſſary. We ſhall juſt mention ſome facts in thoſe proceſſes which have puzzled the naturaliſts.

1. A ſtrong magnet is known to communicate the greateſt magnetiſm to a bar of hard ſteel; but Muſchenbroek frequently found, that a weak magnet would communicate more to a ſoft than to a hard bar.

Explanation. When the magnet is ſtrong enough to impregnate both as highly as they are capable of, the hard bar muſt be the ſtrongeſt; but if it can ſaturate neither, the ſpring-tempered bar muſt be leſt the moſt magnetical.

2. A ſtrong magnet has ſometimes communicated no higher magnetiſm than a weaker one; both have been able to ſaturate the bar.

3. A weak magnet has often impaired a ſtrong one by ſimply paſſing along it two or three times; but a piece of iron always improves a magnet by the ſame treatment.

Explanation. When the north pole of a weak but hard magnet is ſet on the north pole of a ſtrong one, it muſt certainly repel part of the fluid towards the other end, and thus it muſt weaken the magnet. When it is carried forward, it cannot repel this back again, becauſe it is not of itſelf ſuppoſed capable of making the magnet ſo ſtrong. But the end of a piece of iron, always acquiring a magnetiſm oppoſite to that of the part which it touches, muſt increaſe the accumulation of fluid where it is already condenſed, and muſt expel more from thoſe parts which are already deficient.

4. All the parts of the proceſs of the double touch, as practiſed by Meſſis Mitchell and Canton, are eaſily explained by this hypotheſis. A particle of fluid *p* (fig. 33.), ſituated in the middle between the two magnets, is repelled in the direction *pe* by the redundant pole of the magnet AN, whoſe centre of effort is ſuppoſed to be

be at C. It is attracted with an equal force in the direction *p d* toward the centre of effort of the deficient pole of AS. By theſe combined actions it is impelled in the direction *p f*. Now it is plain that, although by increaſing the diſtance between N and S, the forces with which theſe poles act on *p* are diminiſhed, yet the compound force *p f* may increaſe by the diminution of the angle *d p e*. If the action is as $\frac{1}{x^2}$, *p f* will be greateſt when $\frac{\text{Coſ. } d p f}{d p^2}$ is a maximum, or (nearly) when Sin.^{2} *d p f* × Coſ. *d p f* is a maximum: but this depends on the place of the centre of effort. We can, however, gather from this obſervation, that the nearer we ſuppoſe the centres of effort of the poles N and S to the extremities of the magnets, the nearer muſt they be placed to each other. But we muſt alſo attend to another circumſtance; that by bringing the poles nearer together, although we produce a greater action on the intervening fluid, this action is exerted on a ſmaller quantity of it, and therefore a leſs effect may be produced. This makes a wider poſition preferable; but we have too imperfect a knowledge of the circumſtances to be able to determine this with accuracy. The unfavourable action on the fluid beyond the magnets muſt alſo be conſidered. Yet all this may be aſcertained with preciſion in ſome very ſimple inſtances, and the determination might be of ſervice, if we had not a better method, independent of all hypotheſes or theory; namely, to place the magnets at the diſtance where they are *obſerved* to lift the heavieſt bar of iron; then we are certain that their action is moſt favourable, all circumſtances being combined.

We alſo ſee a ſufficient reaſon for preferring the poſition of the magnets employed by Mr Antheaume (and before him by Mr Servington Savery), in his proceſs for making artificial magnets. The form of the parallelogram *d p e f* is then much more favourable, the diagonal *p f* being much longer.

We alſo ſee, in general, that, by the method of double touch, a much greater accumulation of fluid may be produced than by any other known proceſs.

And, laſtly, ſince no appearances indicate any difference between natural and artificial magnetiſm, this hypotheſis is equally applicable to the explanation of the phenomena of natural magnetiſm; ſuch as the poſition of the horizontal, and of the dipping needle, and the impregnation of natural loadſtones.

Having ſuch a body of evidence for the aptitude of this hypotheſis for the explanation of phenomena, it will ſurely be agreeable to meet with any circumſtances which render the hypotheſis itſelf more probable. Theſe are not wanting: although it muſt be acknowledged that nothing has yet appeared, beſides the phenomena of magnetiſm, to give us any indication of the exiſtence of ſuch a fluid; but there are many particulars in their appearance which greatly reſemble the mechanical properties of a fluid.

81
Probability of the exiſtence of a magnetical fluid.

Heating a rod of iron, and allowing it to cool in a poſition perpendicular to the magnetic direction, deſtroys its magnetiſm. Iron is expanded by heat. If the particles of the magnetic fluid are retained between thoſe of the iron, notwithſtanding the forces which tend to diffuſe them uniformly, they may thus eſcape from between the ferrugineous particles which with-held them. For ſimilar reaſons, magnetiſm ſhould be acquired by heating a bar and letting it cool in the magnetic direction. But, beſides this evident mechanical *opportunity* of motion, the union of fire (or whatever name the neologiſts may chooſe to give to the cauſe of expanſion and of heat) with the particles of iron may totally change the action of thoſe particles on the particles of fluid in immediate contact with them; nay, it may even change the ſenſible law of action between magnet and magnet. Of this no one can doubt who underſtands the application of mathematical ſcience to corpuſcular attraction (See Boscovich, *Suppl.*) A change may be produced in the action between magnets without any remarkable change happening in the actions within the magnet, and it may be juſt the reverſe. The union of fire with the magnetic fluid may increaſe the mutual repulſion of its parts, as it does in all aerial fluids or gaſes. This alone would produce a diſſipation of ſome magnetiſm. It may increaſe the attraction (at inſenſible diſtances) between the fluid and the iron, as it does in numberleſs caſes in chemiſtry.

82
Farther grounds of belief.

It is well known that violently knocking or hammering a magnet weakens its force, and that hammering a piece of iron in the magnetic direction will give it ſome magnetiſm. By this treatment the parts of the iron are put into a tremulous motion, alternately approaching and receding from each other. In the inſtants of their receſs, the pent-up particles of the fluid may make their eſcape. A quantity of ſmall ſhot may be uniformly mixed with a quantity of wheat, and will remain ſo for ever, if nothing diſturb the veſſel; but continue to tap it ſmartly with a ſtick for a long time, and the grains of ſmall ſhot will eſcape from their confinements, and will all go to the bottom. We may conceive the particles of magnetic fluid to be affected in the ſame way. The ſame effect is produced by grinding or filing magnets and loadſtones. The latter are frequently made worthleſs by grinding them into the proper ſhape. This ſhould be avoided as much as poſſible, and it ſhould always be done in moulds made of ſoft iron and very maſſive; but this will not always prevent the diſſipation of *ſtrong* magnetiſm. As a farther reaſon for aſſigning this cauſe for the diſſipation in ſuch caſes, it muſt be obſerved (Muſchenbroek takes notice of it), that a magnet or loadſtone may be ground at its neutral point without much damage. But we had the following moſt diſtinct example of the proceſs. A very fine artificial magnet was ſuſpended by a thread, with its ſouth pole down. A perſon was employed to knock it inceſſantly with a piece of pebble, in ſuch a manner as to make it ring very clearly, being extremely hard and elaſtic. Its magnetiſm was examined from time to time with a very ſmall compaſs needle. In three quarters of an hour, its magnetiſm was not only deſtroyed, but the lower end ſhewed ſigns of a north pole. The ſame magnet was again touched, and made as ſtrong as before, and was then wound about very tight with wetted whipcord, leaving a ſmall part bare in the middle. It was again knocked with the pebble, but could no longer ring. At the end of three quarters of an hour its magnetiſm was ſtill vigorous, and was not near gone after two hours and a quarter. We diſcharged a Leyden jar (coated with gold leaf) in the ſame way. It ſtood on the top of an axis; and while this was turned round, the edge was rubbed with a very dry cork filled

with

with roſin, and faſtened to the end of a glaſs rod. This made the jar ſound like the glaſs of a harmonica. One of them was ſplit in this operation.

A ſmall bar of ſteel was heated red hot and tempered hard between two ſtrong magnets lying in ſhallow boxes filled with water, and was more ſtrongly impregnated in this way than in any other that we could think of for a bar of that ſhape. It has not yet been aſcertained in what temperature it is moſt ſuſceptible of magnetiſm, but it was conſiderably hotter than to be juſt viſible in a dark place. It is no objection to our way of conceiving magnetiſm, that the fluid is immoveable or inactive when the iron is red hot. Either of theſe, or both of them, may reſult from the union with the cauſe of heat. Even a particular degree of expanſion may ſo change the law of action as to make it *immoveable*; or the union with caloric may render it *inactive* at all ſenſible diſtances. We cannot but think, that ſome very inſtructive facts might be obtained by experiments made on iron in the moment of its production, and changes in various chemical proceſſes. All magnetiſm is gone when it is united with ſulphur and arſenic in the greateſt number of ores; and when it is in the ſtate of an ochre, ruſt, æthiops, or ſolution in acids; and when united with aſtringent ſubſtances, ſuch as galls. When, and in what ſtate, does it become magnetic? And whence comes the fluid of Æpinus? It were worth while to try, whether magnets have any influence in the formation or cryſtallization of the martial ſalts; and what will be their effect on iron when precipitated from its ſolutions by another metal, &c. &c.

83
hy mag-
s have
ays
re than
pole.

There remains one remarkable fact to be taken notice of, which, in one point of view, is a confirmation of the hypotheſis, but in another preſents conſiderable difficulties. It is well known, that no magnet has ever been ſeen which has but one pole; that is, on the hypotheſis of Æpinus, which is wholly redundant, or wholly deficient. If all magnetiſm be either the immediate or the remote effect of the great magnet contained in the earth, and if it be produced by induction, without any communication of ſubſtance, but only by changing the diſpoſition of the fluid already in the iron, we never ſhould ſee a magnet with only one pole. It muſt be owned, that we never can make ſuch a magnet by any of the proceſſes hitherto deſcribed; but the exiſtence of ſuch does not ſeem impoſſible. Suppoſing a magnet, of the moſt regular magnetiſm, having only two poles; and that we cut it through at the neutral point, or that we cut or break off any part of it—the fact is, (for the experiment has been tried ever ſince men began to ſpeculate about magnetiſm), that each part becomes an ordinary magnet, with two poles, one of which is of the ſame kind as before the ſeparation. The queſtion now is, What ſhould happen according to the theory maintained by Æpinus?—*Tentam. Theor. Elect. et Magnetiſmi*, p. 104, &c.

Let NAS (fig. 34.) be a magnet, of which N is the overcharged pole. Let the ordinates of the curve DAE expreſs the difference between the natural denſity of the fluid, in a ſtate of uniform diffuſion, and its denſity as it is really diſpoſed in the magnet. The area pnND will there expreſs the quantity of redundant fluid in the part nN, and the area qESm expreſſes the fluid wanting in the part Sm. The interſection A marks that part of the magnet where the fluid is of its natural denſity. Suppoſe the part Nn to be ſeparated from the reſt, containing the redundant fluid NDpn. The tendency of this fluid to eſcape from the iron with which it is connected will be greater (Mr Æpinus thinks) than before; becauſe its tendency to quit the magnet formerly was repreſſed by the attractions of the redundant matter contained in AS. This is certainly true of the extremity N; nay, perhaps of all the old external ſurface. Fluid will therefore eſcape. Suppoſe that ſo much has quitted the iron that the point n has the fluid of its natural denſity, as is repreſented in n° 3. there is ſtill a force operating at n, tending to eſcape, ariſing from the repulſion of all the redundant fluid nDN. If this be ſufficient for overcoming the obſtruction, it will really eſcape, and the iron will be left in the ſtate repreſented by n° 4. with an overcharged part fN, and an undercharged part fn.

In like manner, the tendency of the magnetic fluid ſurrounding the magnet to enter into its deficient pole, will be greater when it is ſeparated from the other, not being checked by the repulſion of the redundant fluid in that other.

Mr Æpinus relates ſome experiments which he made on this ſubject. The general reſult of them was, that the moment the parts were ſeparated, each had two poles, and that the neutral point of each magnet was much nearer to the place of their former union than to their other ends. In a quarter of an hour afterward, the neutral points had advanced nearer to their middle, and continued to do ſo, by very ſmall ſteps, for ſome hours, and ſometimes days, and finally were ſtationary in their middles.

84
Defects of this reaſoning.

We acknowledge, that this reaſoning does not altogether ſatisfy us, and that the gradual progreſs of the neutral point toward the middle of each piece, although agreeable to what ſhould reſult from an eſcape of fluid, is not a proof of it. We know already, that the induction of magnetiſm is a progreſſive thing; and we ſhould have expected this change of the ſituation of the neutral point, whatever be the nature of magnetiſm. There is ſomething ſimilar to this, and perhaps equally puzzling, in the immediate recovery of magnetiſm which has been weakened by heat; it is partly recovered on cooling.

But our chief difficulty is this: At the point A (fig. 34.) every thing is in equilibrium before the fracture. The particle A is repelled by the redundant fluid in AN, and attracted by the redundant matter in AS; yet it does not move, for the magnetiſm is ſuppoſed to have permanency. Therefore the obſtruction at A cannot be overcome by the united repulſion of AN and attraction of AS. Nor can the obſtruction at N be overcome by the difference of theſe two forces. Now ſuppoſe AS annihilated. The change made on the ſtate of things at A is ſurely greater than that at N, becauſe the force abſtracted is greater, the diſtance being leſs. It does not clearly appear, therefore, that the removal of AS ſhould occaſion an efflux at N. This, however, is not impoſſible; becauſe the fluid may be ſo diſpoſed, by great conſtipation near N, and no great exceſs of denſity near A, that a ſmaller change at N may produce an efflux there. But ſurely the tendency to eſcape at A muſt now be diminiſhed, inſtead of being greater after the fracture. And if any eſcape from N, this will ſtill more diminiſh that tendency to eſcape from

from A. It does not therefore appear a clear conſequence of the general theory, that the conſtipated fluid ſhould eſcape; and more particularly, that A ſhould become deficient. And with reſpect to the entry of fluid into the other fragment, and its becoming overcharged at *m*, the reaſoning ſeems ſtill leſs convincing. The ſteps of the phyſical proceſs in the two parts of the original magnet are by no means convertible or counterparts of each other. There is nothing in the part AS to reſemble the force of repulſion really exerting itſelf in the correſponding point of AN. There would be, if there were a particle of fluid in that place; but there is not. The tendency therefore of external fluid to enter there, does not reſemble the tendency of the internal fluid to expand and diſſipate. It is true, indeed, the diſcourſe ſhould be confined to points of the ſurface. But the internal motion muſt alſo be conſidered; and the great objection always remains, namely, that the obſtruction at A (n° 1.) or at *n* (n° 3.) is ſufficient to prevent the paſſage of a particle of fluid from the pole AN into the pole AS, when urged by the repulſion of the fluid in the one and the attraction of the iron in the other; and yet will not prevent the eſcape of a particle when one of thoſe cauſes of motion is removed. Add to this, that the whole hypotheſis aſſumes as a principle, that the reſiſtance to eſcape from any point is greater than the obſtruction to motion through the pores. This is readily granted; for however great we ſuppoſe the attraction, in the limits of phyſical contact, it will be no obſtruction to motion through the pores, becauſe the particle is equally affected by the oppoſite ſides of the pores; whereas, in quitting the body altogether, there is nothing beyond the body to counteract the attraction by which it is retained.

There ſeems ſomething wanting to accommodate this beautiful hypotheſis of Mr Æpinus to this remarkable phenomenon; and the coincidence is otherwiſe ſo complete, that we are almoſt obliged to conclude that it is merely a deficiency, ariſing from our not having a ſufficient knowledge of the law of magnetic action. This is quite ſufficient: For it may be ſtrictly demonſtrated, that if the magnetic action decreaſes in higher ratio than that of the ſquares of the diſtances, the permanency of the fluid in any particular diſpoſition has ſcarcely any dependence on the particles at any ſenſible diſtance, and is affected only by the *variations* of its denſity (See ELECTRICITY, *Suppl.* n° 217. for a caſe ſomewhat ſimilar). Therefore, if the fluid be ſo diſpoſed, that its denſity may be repreſented by the ordinates of ſuch a curve as is drawn in fig. 34. having its two extremities concave toward the axis, and a point of contrary flexure at A, the tendency to eſcape at A will be the greateſt poſſible; and when the magnet is broken at A (n° 1.), or when the fluid has taken the arrangement repreſented by n° 3. it *cannot* ſtop there, and *muſt* become deficient in that part. Now, it muſt be acknowledged, that we are not abſolutely certain that the magnetic action is in the preciſe inverſe duplicate ratio of the diſtance. All that we are certain of is, that it is much nearer to it than to either the inverſe ſimple or inverſe triplicate ratio. We own ourſelves rather diſpoſed to aſcribe the preſent difficulty to our ignorance of ſome circumſtance, purely mathematical, overlooked, or miſtaken, than to think a conjecture unfounded, which tallies ſo accurately with ſuch a variety of phenomena.

We may here obſerve, that we are not altogether ſatisfied with Æpinus's form of the experiment. He did not break a magnet; he ſet two ſteel bars end to end, and touched them as one bar, making the magnetiſm perfectly regular; he then ſeparated them, and found that each had two poles. But was he certain that, when joined, they made but one magnet? We have ſometimes ſucceeded in doing this, as we thought, by the curves of iron filings; but on putting the needle with which we were examining their polarity into proper ſituations, we ſometimes found it in the ſecond interſection of the ſecondary curves, ſhewing that the bars were really two magnets, and not one.

On the other hand, when a piece is broken off from a magnet, the ſuccuſſion and elaſtic tremor into which the parts are thrown, and even the bending previous to the fracture, may give opportunity to a diſſipation, which could not otherwiſe happen. The parts ſhould be ſeparated by corroſion in an acid, and the gradual change of magnetiſm ſhould be carefully noted. The writer of this article has made ſome experiments of this nature, the reſults of which preſent ſome curious obſervations: but they are not yet brought to a concluſion that is fit to be laid before the public.

85 Hypotheſis of Prevôt. Mr Prevôt of Geneva, in a diſſertation on the origin of magnetic forces, endeavours to give a theory which obviates the only difficulty in that of Æpinus; but it is incomparably more complex, employing two fluids, which by their union compoſe a third, which he calls combined fluid. There is much ingenuity, and even mathematical addreſs, in adjuſting the relative properties of thoſe fluids. But ſome of them are palpably incompatible; *ex. gr.* the particles of each attract each other, but thoſe of the other kind moſt ſtrongly; yet they are both elaſtic like air. This is ſurely inconceivable.—Granting this, however, he ſuits his different attractions, ſo that a ſtrong elective attraction of the combined fluid for iron decompoſes part of the fluid in the iron, and each of its ingredients occupies oppoſite ends of the bar: then will the bars approach or recede, according as the near ends contain a different or the ſame ingredient. All this is operated without repulſion.

But the whole of this is mere accommodation, like Æpinus's, but ſo much more complex, that it requires very intenſe contemplation to follow the author through the conſequences. Add to this, that his attractions are operated by another fluid, infinitely more ſubtle than either of thoſe already mentioned, every particle of theſe being, as it were, a world in compariſon of thoſe of the other. In ſhort, he adopts all the extravagant ſuppoſitions of Le Sage of Geneva, and every thing is ultimately impulſion. Nor is the contrivance for obviating the difficulty (ſo often mentioned) at all clear and convincing; and it is equally gratuitous with the reſt. We cannot think this hypotheſis at all intitled to the name of *explanation*.

86 Remarks on hypotheſes. This muſt ſerve for an account of the hypotheſis of Æpinus. The philoſophical reader will ſee, that however exactly it may tally with every phenomenon, it cannot be called an explanation of the phenomena; becauſe it is the phenomena which explain the hypotheſis, or give us the characters of the magnetic fluid, if ſuch

ſuch fluid exiſts. But we are not obliged to admit this exiſtence, as we admit that to be the true decyphering of a letter which makes ſenſe of it. In that caſe we know both parts of the ſubject—the characters and the ſounds; but are ignorant which correſponds to which. Did we ſee a fluid abſtracted from one part of a bar and conſtipated in another, and perceive the abſtraction and conſtipation always accompanied by the obſerved attractions and repulſions, the rules of philoſophical diſcuſſion, nay, the conſtitution of our own mind, would oblige us to aſſign the one as the cauſe or occaſion of the other. But this important circumſtance is wanting in the preſent caſe. We think, however, that it merits a cloſe attention; and we entertain great hopes of its being one day completed, by including this ſingle exception.

At the ſame time, it muſt be owned, that it gives no extenſion of knowledge; for it can have no greater extenſion than the phenomena on which it is founded, and cannot, without riſk of error, be applied to an untried caſe, of a kind diſſimilar in its nature to the phenomena on which it is founded. We doubt not but that its ingenious author would have ſaid, that a bit broken off from the north pole of a magnet would be wholly a north pole, if he had not known that the fact was otherwiſe.

But this hypotheſis greatly aids the imagination in conceiving the proceſs of the magnetical phenomena. The more we ſtudy them, the more do they appear to reſemble the protruſion of a fluid through the parts of an obſtructing body. It proceeds gradually. It may be, as it were, overdone, and regorges when the propelling cauſe is removed. The motion is aided by what we know to aid other obſtructed motions. As a fluid would be conſtipated in all protuberances, ſo the faculty of producing the phenomena is greater in all ſuch ſituations, &c. &c. This, joined to the impoſſibility of ſpeaking, with clearneſs of conception, of the propagation of powers without the protruſion of ſomething in which they inhere, gives it a hold of the imagination which is not eaſily ſhaken off.

To ſay that nothing is explained when the attraction of the fluid is not explained, and that this is the main queſtion, gives us little concern. We offer no explanation of this attraction, more than of the attraction of gravity. There is nothing contrary to the laws of human intellect, nothing inconſiſtent with the rules of reaſoning, in ſaying, that things are ſo conſtituted, that when two particles are together, they ſeparate, although we are ignorant of the immediate cauſe of their ſeparation. Thoſe who think that all motion is performed by impulſion, and who explain magnetiſm by a ſtream of fluid circulating round the magnet, muſt have another fluid to impel this fluid into its curvilineal path; for they inſiſt, that the planets are ſo impelled. Then they muſt have a third fluid to deflect the vertical motions of the ſecond, and ſo on without end. This is evident, and it is abſurd. But we have ſaid enough in the article Impulsion, *Suppl.* to ſhew that all *hypotheſes* framed on purpoſe to explain action *e diſtanti* by impulſion are illogical; becauſe impulſion requires explanation as much as the other, and neither the one nor the other will ever be reſolved into any thing but the fiat of the Allwiſe Author of the univerſe.

87 The preceding theory is not a hypotheſis.

We conclude with deſiring the reader to remark, that the explanation which we have given of the magnetical phenomena is independent of the hypotheſis of Æpinus, or any hypotheſis whatever. We have narrated a variety of very diſtinguiſhable facts, and have marked their diſtinctions. We have been able to reduce them to general claſſes; and even to groupe thoſe claſſes into others ſtill more general; and at laſt, to point out one which is diſcoverable in them all. This is giving a philoſophical theory, in the ſtricteſt ſenſe of the word; becauſe we ſhew, in every caſe, the modification of the general fact which allots it this or that particular place in the claſſification. Thus we have ſhewn that the polarity or directive power of magnets is only a modification of the general fact of attraction and repulſion. Dr Gilbert's theory of *terreſtrial* magnetiſm is indeed a hypotheſis, and we enounced it as ſuch. It only claims probability, and we apprehend that a very high degree of credit will be given to it.

We hope that many of our readers will have their curioſity excited by the account we have given of Æpinus's theory. To ſuch we earneſtly recommend the ſerious peruſal of his book *Tentamen Theoriæ Electricitatis et Magnetiſmi, Auct. F. Æpino, Petropoli*, 1759. Van Swinden has included a very good abſtract of it in his 2d volume *Sur l'Electricité*, written by Profeſſor Steiglehner of Ratiſbon or Ingolſtadt. The mathematical part is greatly ſimplified, and the whole is preſented in a very clear and accurate manner. Mr Van Swinden is a profeſſed foe to all hypotheſes; but he is not moderate, and we wiſh that we could ſay that he is candid. He attacks every thing; and takes the opportunity of every analogy pointed out by Æpinus between magnetiſm and electricity to repeat the firſt ſentence of his diſſertation, namely, that magnetiſm and electricity are not the ſame; a thing that Æpinus alſo maintains. But he even charges Æpinus with a miſtake in his fundamental equations, which invalidates his whole theory. He ſays that Æpinus has omitted one of the acting forces aſſumed in his hypotheſis. This is a moſt groundleſs charge; and we own that we cannot conceive how Van Swinden could fall into ſuch a miſtake. We are unwilling to call it intentional, for the mere purpoſe of raiſing a man of ſtraw to knock him down again. Abbé Haüy of the French Academy has alſo publiſhed an abridgment of Æpinus's theory, with many excellent remarks, tending to clear the theory of the only defect that has been found in it. This work was much approved of, and recommended by the Academy. We have not had the good fortune to ſee a copy of it.

88 Analogy of magnetiſm and electricity.

The reader cannot but have remarked the cloſe analogy between the magnetical phenomena and thoſe of induced electricity; indeed, all the phenomena of attraction and repulſion are the ſame in both. The mechanical compoſition of thoſe actions produces a directive power and a polarity, in electrical as well as in magnetical bodies. We can make an electrical needle which will arrange itſelf, with reſpect to the overcharged and undercharged ends of a body electrified by mere poſition, juſt as a compaſs needle is arranged by a magnet. We can touch a ſtick of ſealing wax in the manner of the double touch, ſo as to give it poles of conſiderable force and durability. As a red hot ſteel bar acquires permanent poles by quenching it near a magnet, ſo melted wax acquires them by freezing in the neighbourhood of a poſitive and negative electric. Some have inferred a ſameneſs of origin of theſe two ſpecies of powers from thoſe various circumſtances of reſemblance; but the original cauſes ſeem to be diſtinct on many accounts. Electricity is common to all bodies. The cauſe of magnetiſm can operate only on iron. Although lightning or an electrical ſhock gives polarity to a needle, we need not infer the identity of the cauſe, becauſe the polarity which it gives is always the ſame with that given by great heat; and there is always intenſe heat in this operation. The phenomenon which looks the moſt like an indication of identity of the origin of electricity and magnetiſm is the direction of the rays of the aurora borealis—they converge to the ſame point of the heavens to which the elevated pole of the dipping needle directs itſelf. But this is by no means a ſufficient foundation for eſtabliſhing a ſameneſs. Electricity and magnetiſm may, however, be related by means of ſome powers hitherto unknown. But we are decidedly of opinion, that the electric and magnetic fluid are totally different, although their mechanical actions are ſo like that there is hardly a phenomenon in the one which has not an exact counterpart in the other. But we ſee them both operating, with all their marks of diſtinction, in the ſame body; for iron and loadſtones may be electrified, like any other body, and their magnetiſm ſuffers no change or modification. We can ſet theſe two forces in oppoſition or compoſition, juſt as we can oppoſe or compound gravity with either. While the iron filings are arranging themſelves round a magnet, the mechanical action of electricity may be employed either to promote or hinder the arrangement. They are therefore diſtinct powers, inherent in different ſubjects.

89
They are not, however, effects of the ſame cauſe.

But there are abundance of other phenomena which ſhew this diverſity. There is nothing in magnetiſm like a body overcharged or undercharged *in toto*. There is nothing which indicates the preſence of the fluid to the other ſenſes—nothing like the ſpark, the ſnap, the viſible diſſipation; becauſe the magnetic fluid enters into no union with air, or any thing but iron. There is nothing reſembling that inconceivably rapid motion which we ſee in electricity; the quickeſt motion of magnetiſm ſeems inferior (even beyond compariſon) with the ſloweſt motion along any electric conductor. Therefore there is no poſſibility of diſcharging a magnet as we diſcharge a coated plate. Indeed, the reſemblance between a magnet and a coated plate of glaſs is exceedingly ſlight. The only reſemblance is between the magnet and an inconceivably thin ſtratum of the glaſs, which ſtratum is poſitive in one ſide and negative in the other. The only perfect reſemblance is between the induced magnetiſm of common iron, and the induced electricity of a conductor.

The following ſeem the moſt inſtructive diſſertations on magnetiſm, either as valuable collections of obſervations, or as judicious reaſonings from them, or as the ſpeculations of eminent or ingenious men concerning the nature of magnetiſm.

Beſides theſe original works, we have ſeveral diſſertations on magnetical vortices by Des Cartes, Bernoulli, Euler, Du Tour, &c. publiſhed in the collections of the works of thoſe authors, and many diſſertations in the memoirs of different academies; and there are many popular treatiſes by the traders in experimental philoſophy in London and Paris. Dr Gown Knight, the perſon in Europe who was moſt eminently ſkilled in the knowledge of the phenomena, alſo publiſhed a diſſertation intitled, *An attempt to explain the Phenomena of Nature by two principles, Attraction and Repulſion*, Lond. 1748, 4to, in which he has included a theory of magnetiſm. It is a very curious work, and ſhould be ſtudied by all thoſe who have recourſe without ſcruple to the agency of inviſible fluids, when they are tired of patient thinking. They would there ſee what thought and combination are neceſſary before an inviſible fluid can be really fitted for performing any office we chooſe to aſſign it. And they will get real inſtruction as to what ſervices we may expect of ſuch agents, and from what taſks they muſt be excluded. The Doctor's theory of magnetiſm is very unlike the reſt of the performance; for he does not avail himſelf of the vaſt apparatus of propoſitions which he had eſtabliſhed, and adopts without any nice adjuſtment the moſt common notions of an impulſive vortex. Both the production and maintenance of this vortex, and its mode of operation, are irreconcileable with the acknowledged laws of impulſion.

Si quid noviſti rectius iſtis, candidus imperti—ſi non—his utere mecum.

APPENDIX.

Inveſtigation of the magnetic curve.

We have been favoured with the following inveſtigation of the curves, to which a needle of indefinite minuteneſs will be a tangent, by Mr Playfair, Profeſſor of Mathematics in the Univerſity of Edinburgh.

Two magnetical poles being given in poſition, the force of each of which is ſuppoſed to be as the *m*th power of the diſtance from it reciprocally, it is required to find a curve, in any point of which a needle (indefinitely ſhort) being placed, its direction, when at reſt, may be a tangent to the curve?

1. Let A and B (fig. 35.) be the poles of a magnet, C any point in the curve required; then we may ſuppoſe the one of theſe poles to act on the needle only by repulſion, and the other only by attraction, and the direction of the needle, when at reſt, will be the diagonal of a parallelogram, the ſides of which repreſent theſe forces. Therefore, having joined AC and BC, let AD be drawn parallel to BC, and make $\frac{1}{AC^m} : \frac{1}{BC^m} :: AC : AD$; join CD, then CDF will touch the curve in C.

2. Hence an expreſſion for AF may be obtained. For, by the conſtruction, $AD = \frac{AC^{m+1}}{BC^m}$, and ſince BC : AD : : BF : FA, and BC − AD : AD : : AB : AF, we have $AF = \frac{AB \times AC^{m+1}}{BC^{m+1} - AC^{m+1}}$.

3. A fluxionary expreſſion for AF may alſo be found in terms of the angles CAB, ABC. In CF take the indefinitely ſmall part CH, draw AH, BH, and from C draw CL perpendicular to AH and CK to BH. Draw alſo BC and AM at right angles to FH. Let the angles CAB = φ, and CBA = ψ; then CAH = $\dot{\varphi}$, and CBH = $-\dot{\psi}$; alſo CL = AC × $\dot{\varphi}$, and CK = − BC × $\dot{\psi}$. Now HC : CL : : AC : AM = $\frac{AC^2 \times \dot{\varphi}}{HC}$; and for the ſame reaſon BC = $-\frac{BC^2 \times \dot{\psi}}{HC}$. Therefore ſince AF : FB : : AM : BC, AF : FB : : $\frac{AC^2 \times \dot{\varphi}}{HC} : -\frac{BC^2 \times \dot{\psi}}{HC}$, and AF : AB : : $\text{ſin.}\,\dot{\psi}^2\dot{\varphi} : -\text{ſin.}\,\psi^2\dot{\varphi} - \text{ſin.}\,\varphi^2\dot{\psi}$; wherefore if AB = *a*, AF = $\frac{-a\dot{\varphi}\,\text{ſin.}\,\psi^2}{\dot{\psi}\,\text{ſin.}\,\varphi^2 + \dot{\varphi}\,\text{ſin.}\,\psi^2}$.

4. If this value of AF be put equal to that already found, a fluxionary equation will be obtained, by the integration of which the curve may be conſtructed. Becauſe $AF = \frac{AB \times AC^{m+1}}{Be^{m+1} - Ae^{m+1}}$; and ſince $AC = \frac{a\,\text{ſin.}\,\psi}{\text{ſin.}\,(\varphi + \psi)}$, and $BC = \frac{a\,\text{ſin.}\,\varphi}{\text{ſin.}\,(\varphi + \psi)}$, we have by ſubſtitution $AF = \frac{a\,\text{ſin.}\,\psi^{m+1}}{\text{ſin.}\,\varphi^{m+1} - \text{ſin.}\,\psi^{m+1}} = -\frac{a\dot{\varphi}\,\text{ſin.}\,\psi^2}{\dot{\psi}\,\text{ſin.}\,\varphi^2 + \dot{\varphi}\,\text{ſin.}\,\psi^2}$. Hence, $\text{ſin.}\,\varphi^2 \times \dot{\psi}\,\text{ſin.}\,\psi^{m+1} + \dot{\varphi}\,\text{ſin}\,\psi^{m+3} = -\text{ſin.}\,\psi^2 \times \dot{\varphi}\,\text{ſin.}\,\varphi^{m+1} + \dot{\varphi}\,\text{ſin.}\,\psi^{m+3}$, and therefore $\dot{\psi}\,\text{ſin.}\,\psi^{m-1} = -\dot{\varphi}\,\text{ſin.}\,\varphi^{m-1}$; and alſo, $\int \dot{\psi}\,\text{ſin.}\,\psi^{m-1} + \int \dot{\varphi}\,\text{ſin.}\,\varphi\, m^{-1} = C$.

5. Theſe fluents are eaſily found when *m* is any whole poſitive number.

If $m = 1$, we have $\dot{\psi} + \dot{\varphi} = 0$.
$m = 2$, $\dot{\psi}\,\text{ſin.}\,\psi + \dot{\varphi}\,\text{ſin.}\,\varphi = 0$.
$m = 3$, $\dot{\psi}\,\text{ſin.}\,\psi^2 + \dot{\varphi}\,\text{ſin.}\,\varphi^2 = 0$.
$m = 4$, $\dot{\psi}\,\text{ſin.}\,\psi^3 + \dot{\varphi}\,\text{ſin.}\,\varphi^3 = 0$, &c.
Therefore, &c.
Alſo if $m = 1$, $\varphi + \psi = C$.
$m = 2$, $\text{coſ.}\,\varphi + \text{coſ.}\,\psi = C$.
$m = 3$, $-\text{ſin.}\,2\varphi + 2\varphi - \text{ſin.}\,2\psi + 2\psi = C$.
$m = 4$, $\text{coſ.}\,3\varphi - 9\,\text{coſ.}\,\varphi + \text{coſ.}\,3\psi - 9\,\text{coſ.}\,\psi = C$, &c. &c.

The firſt of the above equations belongs to a ſegment of a circle deſcribed upon AB, which therefore would be the curve required if the magnetical force were inverſely as the diſtances.

If the magnetical force be inverſely as the ſquare of the diſtance, that is, if $m = 2$, coſ. φ + coſ. ψ is equal to a conſtant quantity. Hence if, beſide the points A and B, any other point be given in the curve, the whole may be deſcribed. For inſtance, let the point E (fig. 36.) be given in the curve, and in the line DE which biſects AB at right angles. Deſcribe from the centre A a circle through E, viz. QER; then AD being the coſine of DAE to the radius AE, the ſum of the coſines of $\varphi \times \psi$ will be everywhere (to the ſame radius) = 2 AD = AB. Therefore to find E, the point in which any other line AN, making a given angle with AB, meets the curve, draw from N, the point in which it meets the circumference of the circle QER, NO, perpendicular to AB, ſo that AO may be the coſine of NAO, and from O toward A take OP = AB, then AP will be the coſine of the angle ABE; ſo to find BE′, draw PQ perpendicular to AP, meeting the circle in Q; join AQ, and draw BE′ parallel to AQ, meeting AE′ in E′, the point E′ is in the curve. In this way the other points of the curve may be found.

The curve will paſs through B, and will cut AB at an angle of which the coſine = RB. If then E be ſuch, that AE = AB, the curve will cut AB at right angles. If E″ be more remote from A, the curve will make with AB an obtuſe angle toward D; in other caſes it will make with it an acute angle.

A conſtruction ſomewhat more expeditious may be had by deſcribing the ſemicircle AFB, cutting AE in F, and AE′ in N, and deſcribing a circle round A, with the diſtance AL = 2AF, cutting AE′ in *b*. If AG be applied in the ſemicircle AFB = N*b*, AG muſt cut AN in a point E of the curve, becauſe AN + BG = 2AF, and AN and GB are coſines of the angles at A and B.

As the lines AN and BG may be applied either above or below AB, there is another ſituation of their interſection E′. Thus A*n* being applied above, and B*g* below, the interſection is in *e*′. The curve has a branch extending below A; and if D*e* be made = DE, and B*e* be drawn, it will be an aſſymptote to this branch. There is a ſimilar branch below B. But theſe portions of the curve evidently ſuppoſe an oppoſite direction of one of the two magnetic forces, and therefore have no connection with the poſition of the needle.

Addition to nº 65.

WE omitted the inſerting in its proper place, nº 65. a hypotheſis of the celebrated aſtronomer Tobias Mayer of Gottingen, by which the direction of the mariner's needle in all parts of the earth may be determined. He ſuppoſes that the earth contains a very powerful magnet of inconſiderable dimenſions, which arranges the needle according to the known laws of magnetiſm. The centre of this magnet was diſtant from the centre of the earth about 480 Engliſh miles in 1756, and a line joining theſe centres interſected the earth's ſurface in a point ſituated in 17° N. Lat. and 183° E. Long. from London. The axis of the magnet is perpendicular to this line, and the plane in which it lies is inclined about 11° to the plane of the meridian, the north end of the axis lying on the eaſt ſide of that meridian.

From theſe data, it will be found that the axis of this magnet cuts the ſurface of the earth about the middle of the eaſtern ſhore of Baffin's Bay, and in another point about 800 miles S.S.W. of the ſouthern point of New Zealand. Profeſſor Lichtenberg of Gottingen, who gives this extract from the manuſcript, ſays, that the hypotheſis is accompanied by a conſiderable liſt of variations and dips calculated by it, and compared with obſervations, and that the agreement is very remarkable. He gives indeed a dozen inſtances in very different regions of the earth. But we ſuſpect that there is ſome error or defect in the data given by him, becauſe the annual changes, which he alſo gives, are ſuch as are inconſiſtent with the data, and even with each other. He ſays, that the diſtance from the centre increaſes about four miles annually, and that *thence* ariſes an annual diminution of 8 minutes in the latitude and 14 in the longitude of that point where the ſtraight line joining the centres meets the ſurface. It can have no ſuch conſequence He ſays alſo, that the above mentioned inclination of the planes increaſes 8 minutes annually. The compound force of the magnet is ſaid to be as the ſquare root of the diſtance inverſely. We are at a loſs to underſtand the meaning of this circumſtance; becauſe Mayer's hypotheſis concerning the law of magnetic action is exceedingly different, as related by Mr Lichtenberg from the ſame manuſcript. But it was our duty to communicate this notice, though imperfect, of the ſpeculations of this celebrated mathematician. See *Exliben's Elem. of Nat. Phil.* publiſhed by Lichtenberg 1784, p. 645.

Addition to n° 64.

Addition to n° 64.

Let HZOF (fig. 37.) be the plane of a magnetic meridian, H n' O the plane of the horizon, and NS the poſition of the magnetic needle in any place, when it is at liberty to ſettle in the true magnetic direction. The angle HON is the inclination or dip of the needle. Let Z n F be a vertical circle, in which a well conſtructed dipping needle can freely play up and down. This needle cannot place itſelf in the magnetic direction, becauſe it can only move in a vertical plane. Its north point is impelled in the direction $n\,o$, and its ſouth point in the direction $s\,p$, both of which are parallel to NS. By the laws of mechanical equilibrium, it cannot reſt, except in ſuch a poſition that the forces $n\,o$ and $s\,p$ are in a plane perpendicular to the plane Z n F. In any other poſition, there would be a force impelling the needle toward that ſide on which $n\,o$ makes an acute angle with the tangent $r\,n\,t$ of the vertical circle. Therefore the ſpherical triangle N n F is right angled in n, and Coſ. NF n : R = Tan. n F : Tan. NF, = Tan. HN : Tan. $n'\,n$. Therefore

$$\text{Tan. } n'n = \frac{\text{Tan. HN}}{\text{Coſ. H}\,n'}, = \text{Tan. HN} \times \text{Sec. H}\,n'.$$

Therefore, in any place, the real inclination of the magnetical direction to the horizon is different from what is pointed out by a dipping needle when it is in a plane which declines from the magnetic meridian; and the tangent of the obſerved dip of the needle exceeds that of the inclination of the magnetic direction in the proportion of radius to the coſine of the deviation HC n', or the proportion of the ſecant of this angle to the radius. If therefore the dipping needle play in a magnetic eaſt and weſt circle, it will ſtand perpendicular to the horizon.

Maleſherbes.

MALESHERBES (Chriſtian William de Lamoignon) was born December the 6th 1721. At the age of 24 he became a counſellor of Parliament, and ſix years afterwards chief preſident of the *cour des aides*. He remained in that important ſituation during a period of 25 years, and diſplayed on many occaſions proofs of firmneſs, eloquence, and wiſdom.

When the prince of Condé was ſent by the king in 1768 to ſilence the magiſtrates who oppoſed the taxes, Maleſherbes replied to him, "Truth. Sir, muſt indeed be formidable, ſince ſo many efforts are made to prevent its approach to the throne." About the ſame time that he became preſident of the *cour des aides*, he was appointed by his father, then chancellor of France, ſuperintendant of the preſs; an office of the greateſt importance, of which the principles which Maleſherbes had imbibed from D'Alembert rendered him very ill qualified to diſcharge the duties. He was what the French called a *philoſopher*; a term with them of the ſame import with a naturaliſt, who openly denies revealed religion, and has no adequate notions of the moral attributes of God. The conſequence was, that when the authors of impious and immoral books were brought before him in his official capacity to undergo examination, he appeared to them as adviſing, aſſiſting, and protecting them, againſt that very power which was veſted in himſelf; and they were commonly diſmiſſed with this ſenſeleſs obſervation, that all books of whatever tendency ſhould be conſidered merely as *objects of commerce*. Had it not been for the protecting influence of Maleſherbes, the *Encyclopedie*, of which the publication was frequently ſuſpended (ſee Diderot in this *Supplement*), would probably have been altogether ſuppreſſed; and the works of Rouſſeau and Raynal, which ſo powerfully contributed to that revolution in which he was overwhelmed, would certainly not have ſpread ſo rapidly over the kingdom of France. It was he, ſaid D'Alembert, who *broke the ſhackles of literature*.

In vain will it be replied, that he left the ſame liberty to the religious as to the impious writers; for that was not always ſtrictly true. The Abbé Barruel has brought the teſtimony of D'Alembert himſelf to prove, that it was much againſt his will that Maleſherbes ſuffered works refuting the ſophiſters to appear; and, as he very properly obſerves, what a miniſter allows with reluctance, he finds abundant means of preventing.

In 1775 he reſigned the office of chief preſident of the *cour des aides*, and was appointed miniſter and ſecretary of ſtate in the place of La Vrillière. Thus placed in the centre of a frivolous yet brilliant court, Maleſherbes did not in the leaſt deviate from his former ſimplicity of life and manners; but, in lieu of complying with the eſtabliſhed etiquette which required magiſtrates, when they became miniſters of ſtate, to exchange their ſable habit and head-dreſs for a coloured ſuit, bag-wig, and ſword, he retained his black coat and magiſterial *peruke!* This is recorded by a panegyriſt to his honour; but we perceive not the honour

which

which it reflects on him. It ſurely requires no great powers of abſtraction to diſcover, that a coloured coat, bag-wig, and ſword, are not in themſelves more frivolous or contrary to nature, than a black coat and enormous peruke; and if the manners of a country have appropriated theſe different dreſſes to different ſtations in life, the individual muſt be actuated by a very abſurd kind of pride, who ſets up his own caprice againſt the public opinion.

As, when inveſted with the power to reſtrain within juſt limits the freedom of the preſs, it was his chief aim to encourage and extend that freedom; ſo, when raiſed to an office which gave him the unlimited power of iſſuing *lettres de cachet*, it was their total ſuppreſſion that became the earlieſt object of his *moſt ardent* zeal. Till that time *lettres de cachet*, being conſidered as a part of the general police, as well as of the royal prerogative, were iſſued not only at the will of the miniſter, but even at the pleaſure of a common clerk, or perſons ſtill more inſignificant. Maleſherbes began by relinquiſhing himſelf this abſurd and iniquitous privilege. He delegated the right to a kind of tribunal, compoſed of the moſt upright magiſtrates, whoſe opinion was to be unanimous, and founded upon open and well eſtabliſhed facts. He had but one more object to attain, and that was to ſubſtitute a legal tribunal in the place of that which he had eſtabliſhed; and this object he was upon the point of accompliſhing, when the intrigues of the court procured the diſmiſſion of Turgot; and Maleſherbes, in conſequence, reſigned on the 12th of May 1776. For this part of his conduct he is intitled to praiſe, which we feel not ourſelves inclined to withhold from his memory. Even M. Barruel admits, that he had many moral virtues, and that he diſplayed real benevolence when alleviating the rigours of impriſonment, and remedying the abuſe of *lettres de cachet*; but France, ſays he, ſhall nevertheleſs demand of him her temples that have been deſtroyed; for it was he who, above all other miniſters, abuſed his authority to eſtabliſh in that kingdom the reign of impiety.

After this epoch he undertook ſeveral journeys into different parts of France, Holland, and Switzerland, where he collected with zeal and taſte objects of every kind intereſting to arts and ſciences. As he travelled with the ſimplicity and economy of a man of letters, who had emerged from obſcurity for the purpoſe of making obſervations and acquiring knowledge, he by that means was enabled to reſerve his fortune for important occaſions, in which it might procure him information on intereſting ſubjects. He travelled ſlowly, and frequently on foot, that his obſervations might be the more minute; and employed part of his time in ſuitably arranging them. Theſe obſervations formed a valuable collection of intereſting matter relative to the arts and ſciences, but which has been almoſt totally deſtroyed by the fury of revolutioniſts, who have done as much prejudice to the intereſts of ſcience as of humanity.

Returning from his travels, Maleſherbes for ſeveral years enjoyed a philoſophic leiſure, which he well knew how to direct to uſeful and important objects. The two treatiſes which he compoſed in the years 1785 and 1786 on the civil ſtate of the proteſtants in France are well known. The law which he propoſed in theſe, was only preparatory to a more extenſive reform; and theſe treatiſes were to have been followed up by another work, the plan of which he had already laid down, when affairs growing too difficult to be managed by thoſe who held the reins of government, they were compelled to call him to their councils. They did not, however, aſſign him the direction of any department, and introduced him merely (as ſubſequent events have ſhewn) to cover their tranſactions under a popular name, and paſs them on the world as acts in which he had taken part. Maleſherbes accepted their overtures merely to ſatisfy the deſire he felt to reveal ſome uſeful truths; but it was not for that purpoſe that they had invited him to their councils. Thoſe who preſided at them took umbrage at his firſt efforts to call their attention to the voice of truth and wiſdom; and ſucceeded ſo well in their oppoſition, that he was reduced to the neceſſity of delivering in writing the counſel which he wiſhed to offer. Such was the origin of two treatiſes relative to the calamities of France, and the means of repairing them. He tranſmitted theſe treatiſes to the king, who never read them; nor was he ever able to obtain a private audience although a miniſter of ſtate.

Such is the account of his laſt conduct in office which is given by his friends; and as we have not read his treatiſes on the calamities of France, we have no right to controvert it. From his known principles, however, we are intitled to conclude, that his plans of reformation were ſimilar to thoſe of Neckar, the offſpring rather of a head teeming with viſionary theories, than of the enlightened mind of a practical ſtateſman, or the corrupt heart of a Jacobin conſpirator.

Perceiving the inutility of his endeavours, diſguſted with what he thought the repeated errors of the government, and deprived of every means of expoſing them, or preventing their fatal effects; after frequent ſolicitations, he at length obtained leave to retire. He repaired to his eſtate at Maleſherbes, and from that moment entirely devoted his time to thoſe occupations that had ever formed the chief pleaſure of his life. He paſſed the evenings and a great part of the night in reading and ſtudy.

In this tranquil ſtate he was paſſing the evening of his days amidſt his woods and fields, when the horrors of the Revolution brought him again to Paris. During the whole of its progreſs, he had his eyes conſtantly fixed on his unhappy ſovereign, and, ſubduing his natural fondneſs of retirement, went regularly to court every Sunday, to give him proofs of his reſpect and attachment. He impoſed it as a duty on himſelf to give the miniſters regular information of the deſigns of the regicide faction *; and when it was determined to bring the king to trial, he voluntarily offered to be the defender of his maſter, in his memorable letter of the 11th of December 1792, that eternal monument of his loyalty and affection. His offer was accepted; and he pleaded the cauſe of the monarch with a ſtrength of argument that nothing could have reſiſted but the bloodthirſty minds of a den of Jacobins. "What Frenchman (ſays a valuable writer), what virtuous man, of any country, can ever forget that affecting ſcene, when the reſpectable old man, penetrating, for the firſt time, into the priſon of the Temple, melted into tears, on finding himſelf preſſed in the arms of his king; and that ſtill more affecting ſcene, when, entruſted with the moſt agonizing commiſſion that a ſubject could poſſibly have to his ſovereign, he threw himſelf at the feet of the innocent victim, while, ſuffocated with his ſobs, his voice,

Maleſherbes.

ſtill re-animated by the courage of the virtuous Louis, was inadequate to announce the fatal ſentence of death*.

Having diſcharged this painful and hazardous duty he once more returned to his country reſidence, and reſumed his tranquil courſe of life. But this tranquillity was of ſhort duration. About a twelvemonth afterwards, in the month of December 1793, three worthy members of the Revolutionary Committee of Paris came to reſide with him, his ſon-in-law, and his daughter, and apprehended the two latter as criminals. Left alone with his grandchildren, Maleſherbes endeavoured to conſole the reſt of his unfortunate family with the hopes which he himſelf was far from entertaining, when, the next day, the new formed guards arrived to apprehend him, and the whole of his family, even the youngeſt infants. This circumſtance ſpread a general conſternation throughout the whole department; for there was hardly a man in France, a few ex-jeſuits excepted, who did not revere the mild virtues of the laſt friend of the unfortunate king.

In this calamity Maleſherbes preſerved the undiſturbed equanimity of virtue. His affability and good humour never forſook him, and his converſation was as uſual; ſo that to have beheld him (without noticing his wretched guards), it ſeemed that he was travelling for his pleaſure with his neighbours and friends. He was conducted the ſame night to the priſon of the Madelonette with his grandſon Louis Lepelletier, at the ſame time that his other grandchildren were ſeparated into different priſons. This ſeparation proving extremely afflicting to him, he earneſtly ſolicited againſt it; and at length, on his repeated entreaties, they all met together once more at Port-Libre. They remained there but a ſhort period. The ſon-in-law of Maleſherbes, the virtuous Lepelletier Raſambo, the firſt of them who was arreſted, was ordered into another priſon, and ſacrificed a few days after. Maleſherbes himſelf, his daughter, his grand-daughter, and her huſband, were ſoon after all brought to the guillotine. They approached it with fortitude and ſerenity. It was then that his daughter addreſſed theſe pathetic words to Mademoiſelle Sombreuil, who had ſaved the life of her own father on the 2d of September: "You have had the exalted honour to preſerve *your* father—I have, at leaſt, the conſolation to die with *mine*."

Maleſherbes, ſtill the ſame, even to his laſt moments exhibited to his relations an example of fortitude. He converſed with the perſons that were near him without beſtowing the leaſt attention on the brutalities of the wretches who tied his hands. As he was leaving the priſon to aſcend the fatal cart, he ſtumbled againſt a ſtone, and made a falſe ſtep. "See (ſaid he ſmiling), how bad an omen! A Roman in my ſituation would have been ſent back again." He paſſed through Paris, aſcended the ſcaffold, and ſubmitted to death with the ſame unſhaken courage. He died at the age of 72 years, 4 months, and 15 days. He had only two daughters, and the ſon of one of them alone remains to ſucceed. From this account of Maleſherbes's behaviour at his laſt moments, we are inclined to believe that his intentions were better than ſome parts of his practical conduct; and we know, that having diſpelled the vain illuſions of philoſophiſm, he acknowledged his paſt errors; exclaiming, in the accents of grief, "That falſe philoſophy (to which I confeſs I was myſelf a dupe) has plunged us into the gulph of deſtruction, and, by an inconceivable magic, has faſcinated the eyes of the nation, and made us ſacrifice reality to a mere phantom. For the ſimple words *political liberty*, France has loſt that *ſocial freedom* which ſhe poſſeſſed in every reſpect, in a higher degree, than any other nation! How truly great did the king appear in his laſt moments! All their efforts to degrade him were vain; his unſhaken virtue triumphed over their wickedneſs. It is true, then, that religion alone transfuſes ſufficient courage into the mind of man, to enable him to ſupport, with ſo much dignity, ſuch dreadful trials †.

Malguzzary, Malphaghino.

MALGUZZARY, in the language of Bengal, *payment* of revenue; the *revenue* itſelf.

MALPHAGHINO (John), otherwiſe called John de Ravenna, from the place of his birth, was born in the year 1352, of a family diſtinguiſhed neither by riches nor nobility. His father, however, committed him to the care of Donatus the grammarian, an intimate friend of Petrarch, who at that time taught the Latin tongue with great applauſe at Venice. Donatus thought he diſcovered ſuch happy diſpoſitions in young Malphaghino, that he recommended him to Petrarch, not only as an excellent aſſiſtant to facilitate his labours, by reading or tranſcribing for him, but as a youth of the moſt promiſing talents, and worthy of being formed under the inſpection of the greateſt man of the fourteenth century.

It appears from ſome of Petrarch's letters, for it is from theſe chiefly we can obtain information reſpecting John de Ravenna, that he fully anſwered the expectations formed of him; and that he even gained the favour and affection of his patron ſo much, that he loved him and treated him as if he had been his own ſon. In a letter to John de Certaldo (A), Petrarch highly extols him, not only for his genius and talents, but alſo for his prudent and virtuous conduct. "He poſſeſſes (ſays he) what is very rare in our times, a great turn for poetry, and a noble deſire to become acquainted with every uſeful and ornamental part of knowledge. He is favoured by the Muſes, and already attempts verſes of his own; from which one can foretel, that, if his life be ſpared, and if he goes on as hitherto, ſomething great may be expected from him."

Not long, however, after this panegyric was written, young Malphaghino conceived an inſuperable deſire to ſee the world; and, notwithſtanding all Petrarch's remonſtrances, perſiſted in his reſolution of quitting him. Petrarch's paternal care and regard for his pupil appear, on this occaſion, in the moſt favourable light, as may be ſeen in his letters to Donatus; and his whole behaviour, though the young man inſiſted on leaving him, without aſſigning a ſufficient reaſon for his precipitate and ungrateful conduct, does as much honour to his head as to his heart.

The precipitation with which John de Ravenna carried his plan into execution was not likely to make it anſwer his expectations. He departed without taking with him letters of recommendation which Petrarch offered him to his friends. He, however, purſued his journey over the Appenines, amidſt continual rain, giving out that he had been diſmiſſed by Petrarch; but, though he experienced from many a compaſſion to which he was not entitled by his conduct, he now began to awaken from his dream. He proceeded therefore to Piſa,

Piſa, in order to procure a veſſel to carry him back towards Pavia: but being diſappointed, while his money waſted as much as his patience decreaſed, he ſuddenly reſolved to travel back acroſs the Appenines. When he deſcended into the Ligurian plains, he attempted to wade through a river in the diſtrict of Parma, which was much ſwelled by the rains; and being carried by the force of the ſtream into a whirlpool, he would have loſt his life, had he not been ſaved by ſome people who were accidentally paſſing that way. After eſcaping this danger, he arrived, pennyleſs and famiſhed, at the houſe of his former patron, who happened then not to be at home; but he was received and kindly entertained by his ſervants till their maſter returned.

Petrarch, by his intreaties and paternal admonitions, retained the young man at his houſe for about a year, and prevented him from engaging in any more romantic adventures; but, at the end of that period, his deſire for rambling again returned; and as Petrarch found that all attempts to check him would be fruitleſs, he gave him letters of recommendation to two of his friends, Hugo de St Severino and Franciſcus Brunus, at Rome. To the former of theſe, Petrarch ſays, "This youth of rare talents, but ſtill a youth, after propoſing to himſelf various plans, has at length embraced the nobleſt; and as he once travelled, he is now deſirous of doing ſo again, in order to gratify his thirſt of knowledge. He has, in particular, a ſtrong inclination for the Greek language; and entertains a wiſh which Cato firſt conceived in his old age. This wiſh I have endeavoured for ſome years to ſubdue; ſometimes by intreaties, at other times by admonition; ſometimes by repreſenting how much he is ſtill deficient in the Roman language; and ſometimes by laying before him the difficulties which muſt attend him in his journey, eſpecially as he once before left me, and by want was obliged to return. As long as that unfortunate excurſion was freſh in his memory he remained quiet, and gave me hopes that his reſtleſs ſpirit could be overcome and reſtrained. But now, ſince the remembrance of his misfortunes is almoſt obliterated, he again ſighs after the world; and can be retained neither by force nor perſuaſion. Excited by a deſire which betrays more ardour than prudence, he is reſolved to leave his country, friends, and relations, his aged father, and me whom he loved as a father, and whoſe company he preferred to a reſidence at home, and to haſten to you whom he knows only by name. This precipitation even has an appearance of prudence. The young man firſt wiſhed to viſit Conſtantinople; but when I told him that Greece, at preſent, is as poor as it was formerly rich in learning, he gave credit to my aſſertion, and at any rate altered his plan; which he could not carry into execution. He is now deſirous of traverſing Calabria, and the whole coaſt of Italy, diſtinguiſhed formerly by the name of Magna Græcia, becauſe I once told him that there were in that quarter ſeveral men well ſkilled in the Greek language, particularly a monk, Barlaam, and one Leo, or Leontius, with whom I was intimately acquainted, and of whom the firſt had been ſome time my ſcholar. In conſequence of this propoſal, he begged me to give him a recommendatory letter to you, as you have conſiderable influence in that part of the country. This requeſt I granted, in hopes that the young man, by his genius and talents, will afford you ſatisfaction equal to the ſervice which you may render to him." In his letter to Brunus, Petrarch expreſſes himſelf as follows: "He is a young man who wiſhes to ſee the world as I formerly did; but I never reflect on it without horror. He is deſirous of ſeeing Rome; and this deſire I cannot condemn, as I myſelf have ſo often viſited that city, and could ſtill reviſit it with pleaſure. I ſuſpect, however, that he will venture on a more extenſive ocean, and that he imagines to find a fortune where he will, perhaps, meet with a ſhipwreck. At any rate, he is deſirous, he ſays, of putting his fortune to a trial. I wiſh it may be favourable; ſhould it be adverſe, he is ſtill at liberty to return to my peaceful, though ſmall, haven; for I hang out a light, during the day as well as the night, to guide thoſe who quit me through youthful folly, and to enable them to find their way back. The ardour by which he is impelled muſt not be aſcribed ſo much to him as to his age, and is in itſelf commendable. If I am not much deceived, the young man loves me and virtue in general. He is unſteady, but modeſt; and deſerves that all good men ſhould contribute to his proſperity as far as they can."

From the letters of Petrarch, there is reaſon to believe, that John de Ravenna lived with him only about three years in all; and that he had not attained to the full age of manhood when he left him. It appears alſo, for this circumſtance is very obſcure, that after he quitted him, he wandered about a conſiderable time before he was ſo fortunate as to meet with a protector and patron, at whoſe houſe, as he wrote to Petrarch, he at laſt found a permanent aſylum. How long he remained with his patron, whom ſome believe to have been Cardinal Philip, and what happened to him till the death of Petrarch in 1374, and for ſome years after, is unknown. The literary monuments of the fourteenth and fifteenth centuries ſay nothing farther of him till his appearance at Padua; where, according to the teſtimony of Sicco (B), one of the moſt celebrated of his ſcholars, he not only taught the Roman Eloquence, but alſo the ſcience of moral philoſophy, with ſuch ſucceſs and applauſe, and improved his ſcholars ſo much by his life and example, that, according to univerſal opinion, he far excelled all the profeſſors of thoſe ſciences who had ever before appeared. That he was here of conſiderable ſervice in reviving the ſtudy of the Latin language, and of the works of the ancient Romans, was acknowledged by all his ſcholars, and is confirmed by the following teſtimony of Blondus (C).

"About the ſame period, Ravenna produced that learned

(B) Adoleſcens tum ego poetas, et inſtituta Tullii audiebam. Legebat tunc hac in civitate Padua, literarum nutrice, *Johannes Ravennas* vir et ſanctimonia morum, et ſtudio iſto excellens, atque ſi poteſt ſine invidia, dici ceteris, qui magiſtri artis hujus in terra Italia uſquam degerent et doctiſſimi haberentur, quantum recordari videor, omnium judicio præferendus. Hoc namque a præceptore non eloquentia modo, quam ex ordine legerit ſed mores etiam, ac quædam bene honeſteque vivendi ratio cum doctrina tum exemplis diſcebatur.—*Sicco Polentonus*, Ap. Mehus, l. c. p. 139.

(C) Blondi Flavii Forlivienſis Italia illuſtrata. Bas. 1559. fol. p. 346.

learned grammarian and rhetorician Johannes, of whom Leonardus Aretinus uſed to ſay, that he firſt introduced into Italy, after a long period of barbariſm, the ſtudy of the Latin language and eloquence, now ſo flouriſhing; a circumſtance which deſerves to be enlarged on in the preſent work. Thoſe well acquainted with Roman literature know, that after the periods of Ambroſe, Jerom, and Auguſtine, there were none, or very few, who wrote with any elegance, unleſs we add to theſe good writers, St Gregory, the venerable Bede, and St Bernard. Francis Petrarcha was the firſt who, with much genius, and ſtill greater care, recalled from the duſt the true art of poetry and of eloquence. He did not attain to the flowers of Ciceronian eloquence, with which many are adorned in the preſent century; but this was owing rather to a want of books than of talents. Though he boaſted of having found at Vercelli Cicero's letters to Lentulus, he was unacquainted with the books of that great Roman *De Oratore*, Quintilian's Inſtitutes, the *Orator*, the *Brutus*, and other writings of Cicero. John de Ravenna was known to Petrarch both in his youth and in his old age. He was not more converſant with the ancients than Petrarch; and, as far as I know, left no works behind him. By his excellent genius, however, and, as Leonardus Aretinus ſays, by the particular diſpenſation of God, he was the preceptor of this Leonardus, of Petrus Paulus Vergerius, of Annebonus de Padua, of Robert Roſſi, of James Angeli of Florence, of Poggius and Guarino of Verona, of Victorinus, Sicco, and other men of leſs note, whom he incited to the ſtudy of better knowledge, and to imitate Cicero, if he could not form them or inſtruct them completely.

"About the ſame time, Manuel Chryſoloras, a man as virtuous as learned, came from Conſtantinople to Italy, and inſtructed in the Greek language, partly at Venice and partly at Florence and Rome, all the before mentioned ſcholars of John de Ravenna. After he had continued this inſtruction for ſome years, thoſe unacquainted with the Greek language, and the ancient Greek writers, were conſidered in Italy as more ignorant than thoſe unacquainted with the Latin. A great many young men and youths were inflamed with an enthuſiaſtic deſire for the works of the ancient Greeks and Romans. At the time of the council of Conſtance, in the beginning of the fifteenth century, many of my countrymen endeavoured, by ſearching the neighbouring cities and convents, to diſcover ſome of the Roman manuſcripts which had been loſt. Poggius firſt diſcovered a complete copy of Quintilian, which was ſoon followed by the letters of Cicero to Atticus. As our youth applied to the ſtudy of theſe works with the utmoſt diligence, that celebrated grammarian and rhetorician Caſparinus de Bergamo, opened a ſchool at Venice, ſuperior to the former, and in which young perſons were encouraged to ſtudy the ancient languages and writers. About the ſame time flouriſhed Petrus Paulus Vergerus, Leonerdus Aretinus, Robert Roſſi, James Angeli, Poggius, and Nicolaus de Medici, whom Aretin had long inſtructed. Guarinus alſo had begun to inſtruct many at Venice, and Victorinus at Mantua, when Philip III. Duke of Milan, recalled Caſparinus as his ſubject, from Venice to Padua and Milan. The increaſing ſtudy of ancient literature was much promoted by Gerard Landriano biſhop of Lodi, diſcovering under ſome ruins an old copy of Cicero, written in characters ſcarcely legible, which, among other rhetorical writings of that great Roman, contained the whole books *De Oratore*, with his *Brutus* and *Orator*. This ſaved Caſparinus the trouble of ſupplying the books of Cicero *De Oratore*, as he had attempted to ſupply the works of Quintilian. As no one was found in all Milan who could read this old manuſcript of Cicero, an ingenious young man of Verona, named Caſmus, was ſo fortunate as firſt to tranſcribe the books *De Oratore*, and to fill all Italy with copies of a work which was univerſally ſought for with the utmoſt avidity. I myſelf, in my youth, when I went to Milan on the buſineſs of my native city, tranſcribed, with as much ardour as ſpeed, the *Brutus* of Cicero, and ſent copies of my tranſcription to Guarinus at Verona, and to Leonard Juſtiniani at Venice; by which means this work was ſoon diſperſed all over Italy. By theſe new works eloquence acquired new fire; and hence it happens, that in our age people ſpeak and write better than in the time of Petrarch. The ſtudy of the Greek language, beſides the abundance of new and uſeful knowledge which it diſcloſed, was attended with this great advantage, that many attempted to tranſlate Greek works into Latin, and thereby improved their ſtyle much more than they could have done without that practice. After this period, ſchools for teaching the ancient languages increaſed in Italy, and flouriſhed more and more. Moſt cities had ſchools of this kind; and it gives one pleaſure to obſerve, that the ſcholars excelled their maſters, not only when they left them, but even while they were under their tuition. Of the ſcholars of John de Ravenna, two of the oldeſt, Guarinus and Victorinus, the former at Venice, and the latter at Mantua, Verona, Florence, and Ferrara, inſtructed an immenſe number of pupils; and among theſe, the Princes of Ferrara and Mantua. George of Trebiſonde, when he lectured at Rome, had for his auditors, beſides Italians, many French, Spaniards, and Germans, among whom ſometimes there were men of rank and eminence. Franciſcus Philelphus, who had been taught at Conſtantinople by Chryſoloras himſelf, inſtructed a great many young men and youths in the Greek and Latin languages at Venice, Florence, Siena, Bologna, and, laſt of all, at Milan." In the above quotation, the ſhare which John de Ravenna had in reviving and diffuſing a knowledge, not only of the Roman, but alſo of the Grecian literature, is ſo clearly repreſented, that no farther teſtimony is neceſſary to eſtabliſh his claim to celebrity.

After John de Ravenna had taught at Padua, he removed for the like purpoſe to Florence; where, as appears, he inſtructed young people for ſome time, without being expreſsly invited by the government, and without being publicly paid for his labours. In the beginning of his reſidence at Florence, he ſeems to have been recommended by Colucius to the learned Charles de Malateſta. "There lives here at preſent (ſays Colucius, in one of his letters) a teacher of great merit, John de Ravenna.—He is (continues he) of mature age; irreproachable in his manners, and ſo diſpoſed in general, that if you receive him, as I hope and wiſh, among the number of your intimate friends, you will find him an agreeable and incomparable aſſiſtant to you in your labours and ſtudies. What can be more deſirable to you than to poſſeſs a man who will lucubrate and labour for you? and who, in a ſhort time, can communicate to you what you could not obtain by your own exertions without great difficulty. I do not know whether you will find his like in all Italy ; and I therefore wiſh, that, if you confide in my judgment, you will receive John de Ravenna in the room of your late learned friend James de Alegretti." It is not known whether John de Ravenna went to reſide with Malateſta or not. It is, however, certain, that the former, in 1397 (the ſame year in which Manuel Chryſoloras came to Florence), was invited thither by the magiſtrates of that city, with the promiſe of an annual ſalary, to inſtruct young people in the Roman language and eloquence ; that John de Ravenna, at the period when he entered into this honourable engagement, was 45 years of age ; and that the ſcholars of John de Ravenna were, at the ſame time, ſcholars of Chryſoloras. Saluratus Colucius, in all probability, was the cauſe of this invitation, as he was acquainted with the ſervices of John de Ravenna, and knew how to appreciate them. "We know (ſays he, in one of his letters to John de Ravenna), and all who reſpect you know alſo, that none of the moderns, or even ancients, approached ſo near to Cicero as you ; and that to the moſt wonderful beauty and powers of ſpeech, you join the deepeſt knowledge." John de Ravenna, like Chryſoloras, and moſt of the teachers of the Greek and Roman languages in the beginning of the fifteen century, was, no doubt, engaged at firſt only for a few years ; when theſe were elapſed, the engagement was renewed, perhaps for the laſt time, in 1412, and he was bound, beſides teaching the Roman eloquence, to read publicly, and explain in the cathedral, on feſtivals, the poems of Dante. John de Ravenna did not long ſurvive the above renewal of his engagement ; for an anonymous writer, who, in 1420, finiſhed *A Guide to Letter-writing, according to the Principles of John de Ravenna*," ſpeaks of his preceptor as of a man not then in exiſtence.

MALT. See Brewing (*Encycl.*), where a full account is given of Sir Robert Murray's method of malt-making, together with ſome valuable obſervations on malt by Mr Richardſon of Hull. In a late edition of this latter gentleman's *Theoretic Hints on Brewing*, we are told, that Mr Edward Rigby of Norwich is of opinion, that the mere exſiccation of corn is not the only object obtainable by drying it on the kiln, but that ſome portion of the ſaccharum of malt is the effect of that proceſs. "The operation of kiln drying the malt (ſays Mr Rigby) is as follows:—The grain is ſpread thick upon a floor made of flat bricks (*tiles*), or iron plates, which are full of perforations ; immediately under this floor is the oven or furnace, in which is a large fire made of *coaks*, cinders, or, in ſome places, billet wood ; a current of air, at the mouth of the furnace, keeps up the combuſtion of the coaks, and the air which is phlogiſticated by their burning, and which, in a common fire place, riſes up the chimney, paſſes, in this inſtance, through the apertures in the floor, and penetrates the whole ſtratum of malt before it can paſs into the external air. Under theſe circumſtances, it is evident, that the interſtices of the malt muſt be filled with phlogiſtic air ; and as the grain uſually remains in this ſituation about two days, it is obvious, that if it have the power of abſorbing phlogiſton, it certainly muſt do it when ſo long in contact with it. And that the malt does really imbibe ſome of this principle, is not only probable on the general ground of the truth of the preceding theory, but, I believe, it will be found, that the phlogiſticated air which riſes from the burning ſubſtances underneath, is corrected in paſſing through the malt ; for without its being meliorated by this or ſome other cauſe, it is evident that the air in the kiln-chamber, more eſpecially the lower ſtrata of it, muſt be noxious, and probably even ſo much ſo as to be unfit for reſpiration and combuſtion. But ſo far from this being the caſe, I am informed, that workmen will lie and ſleep many hours on the malt in this ſituation without ſuffering any inconvenience. And after mentioning this, it is ſcarcely neceſſary to add, that I find alſo, by experiment, that a candle will burn perfectly well in the air which is immediately on the ſurface of the malt.

"Were heat alone ſufficient for the purpoſe of completing the operation of malting, it certainly might be applied in a much more cheap way than is at preſent done ; for the floor on which the grain is laid might, unqueſtionably, be heated equally without there being perforations in it, as with them. In which caſe, one kind of fuel would be as good as another ; and, conſequently, the preſent expence of previouſly burning the coals, to convert them into coaks or cinders, might be ſaved.

"But, admitting that the application of phlogiſton to the malt, as well as heat, is requiſite in this operation, the neceſſity of theſe perforations becomes evident, and alſo the propriety of previouſly burning the coals in ſuch a way, that all the water, and thoſe other heterogeneous particles which compoſe ſmoke and ſoot, may be diſſipated ; for theſe, merely as ſuch, would obviouſly contribute little to the phlogiſtication of the malt, and would evidently impart ſome offenſive flavour, if not ſome obnoxious quality to it.

"Reaſoning from the above premiſes (Mr Rigby concludes), it would ſeem, that as all the farinaceous parts of the barley are ſeldom diſſolved in brewing, and the grains which are left have uſually the diſpoſition to become ſour, thereby manifeſting ſome of the acid principle to be ſtill exiſting in them, it is not improbable but ſome further ſaccharine matter might be obtained from the grain by another expoſure to phlogiſticated air, or, in other words, by being once more laid on the kiln."

This is indeed ſo far from being improbable, that we think it muſt infallibly be the caſe. Sugar, it is well known, conſiſts of oxygen, hydrogen, and carbon (ſee Chemistry in this *Supplement*, n° 466.) ; but from the diſpoſition of the grains to become ſour, it is plain, that after the proceſs of brewing they ſtill retain much oxygen ; and the azotic gas, which is here called phlogiſticated air, there is every reaſon to believe contains both hydrogen and carbon. Theſe, therefore, uniting with the oxygen of the grains, muſt make an addition to the ſaccharine matter. This has, indeed, been found to be the fact by Mr Richardſon, who, in conſequence of Mr Rigby's ſuggeſtion, was induced to brew a ſmall brewing of malt, of ten quarters only, and ſtopping the proceſs when, according to his general practice, one extract was ſtill due, he ordered the grains to be laid upon one of his malt-kilns, and cinders to be applied the ſame as for drying of malt. This was continued for two days and a half, when the grains, being perfectly dried, were put into ſacks, and, when cold, returned again into the maſh-tun. The event, in ſome meaſure, juſtified Mr

Mammalukes.

Rigby's expectation ; for the produce of fermentable matter was conſiderably more than he had reaſon to conclude would have been the caſe, had the extract been made in immediate ſucceſſion, as it would have been in the ordinary courſe of his practice. He attempts, indeed, to account for it in a way very different from ours ; but though we have the higheſt confidence in Mr Richardſon as an experienced brewer, we muſt ſometimes beg leave to think for ourſelves as chemiſts. Like a man of ſenſe, however, and a man of ſcience, he ſays, " I am ſo well ſatisfied with the event of this experiment, that I ſhall probably be inclined, on ſome future occaſion, to repeat it, in various ſtages of the proceſs. The fine lively froth on the ſurface of the wort, in the underback, added to its tranſparency and good flavour, are circumſtances which induce me to thank Mr Rigby for the hint, which, it is not improbable, may be applied to ſome uſeful purpoſe, in certain ſituations which ſometimes occur in the brewing trade."

MAMMALUKES, Mamalucs, *Mamaloucs*, or *Mamluks*, were a dynaſty that reigned for a conſiderable time in Egypt, and of which ſome account has been given in that article (*Encycl.*). A fuller account of them muſt, however, be acceptable to our readers, as, ſince the expedition of Buonaparte, they have attracted the attention of all Europe.

Antijacobin Review, nº 12. and *Brown's Travels.*

They were firſt introduced into Egypt, as we have already obſerved, by Saladine, who, when he had it in contemplation to beſiege Jeruſalem, very naturally endeavoured to collect the moſt forcible means to accompliſh ſo deſirable an end ; and, in conſequence, obſerving that the ancient inhabitants of Egypt were, from their effeminate mode of education, and the quiet and tranquil habits of their lives, much fitter for thoſe occupations in which they delighted, namely, the arts, merchandize, and mechanics, than military tactics and military toil, he reſolved, as little as poſſible, to employ or depend upon them.

This reſolution ſtimulating him to procure a hardier race of ſoldiers, he therefore commiſſioned agents to treat with the Circaſſians, by the Lake of Mæotis, near Tawrica Cherſoneſas, whence, about the year 1176, they purchaſed more than a thouſand ſlaves. Men inured to hardſhip, nurtured in the lap of toil and danger, and bred from their infancy to war, which was to them rather an inſtinct than a ſcience, as the continual incurſions of the Tartars rendered ſelf-defence, in their ſituation, abſolutely neceſſary.

Theſe ſlaves Saladine trained to military diſcipline, and, at the ſame time that he made them renounce Chriſtianity, had them inſtructed in the Mahometan religion ; and although he prohibited them from marrying, he allowed them an unbounded licence with reſpect to deſultory gallantry. What progreſs they made in the doctrines of the Alcoran, whether the tenets of that ſacred volume effectually eradicated all their firſt principles, is uncertain ; but it is certain, that in time they became excellent ſoldiers, and that the military glory of Saladine, which was feebly ſupported by the native Egyptians, expanded in the hands of the Mameloucs, who extended their conqueſts on every ſide, until, pervading the Holy Land, they entered in the plain of Aſkelon.

Theſe Mameloucs, who were continually adding to their numbers, in proceſs of time became naturalized to the country ; and, as it has been obſerved, they excelled the Egyptians in ſtrength of body, in military diſcipline, in their ſkill in horſemanſhip, and in courage ; ſo they, by the liberality of their generals, and the plunder of cities and provinces, alſo excelled them in wealth. In fact, their mode of education fitted them for the moſt dangerous and adventurous enterpriſes, and, from being the ſlaves, enabled them in time to become the maſters of even the Turks, by whom they had originally been purchaſed.

After the death of Saladine, who left the kingdom to his brother, they roſe to ſtill greater importance than they had acquired during his reign, and continued, if not abſolutely to govern, yet, like the Roman ſoldiers in the time of Pertinax, Alexander, and Valerian, to awe the monarch.

This influence continued through the reigns of five ſucceſſive Caliphs, until that of Melachſala, the laſt of the poſterity of Saladine, who being at war with the Arriſtians, and, at the ſame time, wiſhing to repreſs the enormous power of the Mameloucs, purchaſed ſlaves from all the ſurrounding countries, whom, in imitation of his anceſtor, he armed and appointed to defend his dominions. The event of this meaſure was exactly what might have been expected. Melachſala was, in conſequence of a conſpiracy betwixt his new and his old ſoldiers, ſlain; and Turquemenus, the leader of this mutiny and rebellion, hailed by the title of Great Sultan of Egypt. With him began the government of the Mameloucs, about the year 1250; which had the next year gathered ſuch ſtrength, that it was thought neceſſary, in order to repreſs thoſe exuberances to which new formed governments are liable, and bring it nearer to a ſyſtem, to cauſe the following articles, in the form of a charter, to be ſubſcribed to by their principal leaders, as an act of the whole people :—" 1ſt, That the Sultan ſhould be choſen from the body of Mameloucs; 2dly, That none ſhould be admitted into the order that were by birth either Jews or Turks, but only Chriſtian captives ; 3dly, That the native Egyptians ſhould not be permitted to uſe, or have, any weapons, except the inſtruments of agriculture."

Turquemenus, as is frequently the practice with thoſe that experience a ſudden elevation, endeavoured to kick down the ladder by which he had been raiſed ; or, in other words, his carriage was ſo haughty and diſdainful to his former companions, that he was by them, or rather by one of them named Clotho, ſuddenly ſlain ; for which the murderer was rewarded with his ſceptre. After him ſucceeded a long race of princes, many of whom were as eminent for their talents as for their valour ; among whom, the name of Caitbeius has been tranſmitted to us as that of the greateſt ſtateſman and general of his age ; but, as every one who conſiders the *materials* of which the government was compoſed, muſt rather wonder that it exiſted ſo long, than that it ſhould, through almoſt the whole courſe of its operation, be expoſed to all the various evils and diſtreſſes ariſing from a long train of ſedition and tumults, ſo he muſt lament that it ſhould expire in the reign of one of their wiſeſt and beſt monarchs : yet it is ſome conſolation to reflect, that Campſon, the laſt Sultan of the Mameloucs, was not *murdered by his own ſubjects*, but having for many years governed the kingdoms of Egypt, Judea, and Syria, in a manner that has excited the praiſe

of

of the hiſtoric pen, he, oppreſſed with age and diſeaſe, and encumbered with his armour, ſunk upon the field of battle, and, with his laſt breath, yielded the victory to the fortunate Selim.

With this monarch, who expired January 20, 1516, ended the government of the Mameloucs, after it had continued 276 years; for although an attempt was made by Tomumby to get himſelf declared Sultan, in which attempt he actually ſucceeded ſo far as to be inveſted with the title, yet he was ſoon after defeated by the victorious Selim. He was then forſaken by his troops, taken and executed; while the Mameloucs, broken and diſperſed, it was the policy of Selim to rally, and, by offers too tempting to be by them refuſed, engage in his ſervice. The uſe of theſe ſoldiers ſoon became ſufficiently apparent to the Turkiſh Emperors, to ſtimulate them to augment their number, enlarge their ſphere of action, and combine them cloſer to the ſtate, by the allowance of ſtill greater privileges and advantages than they had before enjoyed.

The Beys were ordained to be choſen from among them; and the Paſha, or chief governor for the Porte, was to ſhare his power with thoſe Beys, and even to continue in office no longer than ſhould be agreeable to their collective will. At firſt the power of the Paſha was very extenſive; but, by the intrigues and ambition of the Beys, it has been reduced almoſt to a cypher. It was rather of a civil than military nature. He was always preſident of the Divan, which was held in the caſtle where he reſided. But that council now commonly meets in the palace of one of the chief Beys, except when a firman or mandate is received from Conſtantinople, when the Beys are ſummoned to the caſtle, to hear the commands of the Porte. The few who attend, as ſoon as the reading is finiſhed, anſwer, as is uſual, "*Eſmana wa taana*," "We have heard, and we obey." On leaving the caſtle, their general voice is "*Eſmana wa awſina*," We have heard, and ſhall diſobey."

In the year 1791, Salah Aga, a ſlave of Murad Bey, was deputed from the government of Egypt to negociate their peace with the Porte. He carried preſents of horſes, rich ſtuffs, &c. A ſpontaneous tribute, which the Porte was in no condition to enforce, implied obligation on the part of the latter. He was well received, and afterwards was appointed *Waquil es Sultan*, agent or attorney to the Sultan in Cairo. It is probable, this office was given him to incline him to ſecond the efforts of the Court in diſuniting the Beys; but it was ineffectual. Theſe had formerly experienced the evils of diviſion, and now were united by common intereſt, grown rich, and well provided with ſlaves; ſo that no tribute has ſince that time found its way to Conſtantinople.

The Mameloucs remain, as they have ever been, military ſlaves, imported from Georgia, Circaſſia, and Mingrelia. A few have been priſoners, taken from the Auſtrians and Ruſſians, who have exchanged their religion for an eſtabliſhment. The Beys give general orders to their agents at Conſtantinople, to purchaſe a certain number every year; and many are brought to Egypt by private merchants on ſpeculation. When the ſupply proves inſufficient, or many have been expended, black ſlaves from the interior of Africa are ſubſtituted, and, if found docile, are armed and accoutred like the reſt.

Particular attention is paid to the education of theſe favoured ſlaves. They are inſtructed in every exerciſe of agility or ſtrength, and are, in general, diſtinguiſhed by the grace and beauty of their perſons. The gratitude of the diſciples is equal to the favour of their maſters, whom they never quit in the hour of danger. If they have a diſpoſition for learning, they are taught the uſe of letters, and ſome of them are excellent ſcribes; but the greater part neither can read nor write. A ſtriking example of which deficiency is obſervable in Murad Bey himſelf.

The inferior Mameloucs conſtantly appear in the military dreſs, and are commonly armed with a pair of piſtols, a ſabre, and a dagger. They wear a peculiar cap of a greeniſh hue, around which is wreathed a turban. The reſt of their dreſs reſembles that of other Mohamedan citizens, and is reſtricted to no particular colour; but another ſingularity is, their large drawers of thick Venetian cloth, of a crimſon colour, to which are attached their ſlippers of red leather. On horſeback they add to their arms a pair of large horſe piſtols, and the dubbus or battle axe. In battle, many of them wear an open helmet, and the ancient ring armour of interwoven links of ſteel, worn under part of their dreſs, and thus concealed. Theſe are dear; ſometimes coſting 500 piaſtres, or about L. 40. Some of them are made at Conſtantinople, others in Perſia. Their horſes are of the fineſt Arabian breed, and are often purchaſed at three or four purſes, L. 150 to L. 200 ſterling.

They have no pay, as they eat at a table in the houſe of their maſter the Bey, Caſhef, or other officer. Any military officer may purchaſe a ſlave, who becomes, *ipſo facto*, a Mamelouc. The name, from *malek*, to poſſeſs, implies merely a perſon who is the property of another. After a proper education, the candidate thus conſtituted a Mamelouc, receives a preſent of a horſe and arms from his maſter, together with a ſuit of clothes; which is renewed every year in the month Ramadan. The generoſity of their maſters, and rewards or extortions from others, afford them ſupplies of money, either for avarice or debauchery. Some of them, admitted to peculiar favour by the Beys, as chaſnadars, or purſe-bearers, &c. acquire great wealth. They are rather gay and thoughtleſs than inſolent, fond of ſhow, and unprincipled in their means of acquiring it. They ſeldom marry till they acquire ſome office.

Though born of Chriſtian parents, they ſeem highly ſatisfied with their condition, which they have been known to refuſe to exchange for freedom. The majority are regarded by the Arabs as little ſtrict in the principles or duties of Mohamediſm. It is worthy of remark, that though the Mameloucs, in general, be ſtrong and perſonable men, yet the few who marry very ſeldom have children. As the ſon, even of a Bey, is not honoured with any particular conſideration, the women, perhaps, procure abortions. Of eighteen Beys, with whoſe hiſtory Mr Browne was well acquainted, two only had any children living.

Hardy, capable of every fatigue, of undaunted courage, and eminent ſkill in horſemanſhip and the uſe of the ſabre, the Mameloucs may be regarded as by far the beſt troops in the Eaſt. But in a regular battle, conducted by manœuvres, and large or rapid movements, they are equally inferior to European troops.

Being diſtinguiſhed by favouritiſm or merit, the Mameloue becomes a Caſhef, and in time a Bey. The chief cauſe of preference ariſes from political adherence to ſome powerful leader.

The government of Cairo, and Egypt, in general, is veſted in 24 Beys; each of whom is nominally choſen by the remaining 23, but, in fact, appointed by one of the moſt powerful. The Yenk-tchery, Aga, and ſeveral other officers, are enumerated among the 24 Beys.

Beſides being governors of certain diſtricts of Egypt, ſeveral of the Beys receive other dignities from the Porte: Such are the Shech el Bellad or governor of the city; the Defterdar, or accountant-general; the Emir el Hadj, or leader of the ſacred caravan; and the Emir es Said, or governor of the Upper Egypt. Theſe two laſt offices are annual. Theſe officers have alſo revenues allotted them by the Porte, ill defined, and liable to much abuſe.

Of the other Beys, each appoints all officers and governors within his diſtrict, putting into it ſome ſlave of his own, who is compelled to render an account of the receipts, of which a great part paſſes to ſupport the grandeur of his maſter. An opulent Bey may have from 600 to 1000 purſes annually; the revenue of Murad Bey more than doubles that ſum. The inferior Beys may have 300 purſes, or L. 15,000.

Every Bey ſits in judgment on caſes of equity. Theſe perſonages are very obſervant of their reſpective juriſdictions; and no Bey will impriſon a man liberated by another. Though ſometimes too impetuous, they nevertheleſs diſplay great acuteneſs and knowledge of characters. This government, at leaſt, poſſeſſes every advantage of publicity, as every Bey is a magiſtrate.

MAN, has been conſidered in a great number of particulars under the title Man (*Encycl.*); but a reference was made from that article to the article *Varieties of the Human Species*, which was, after all, omitted entirely.

Perhaps enough has been ſaid on the varieties of the human ſpecies in the articles Complexion and Negro (*Encycl.*); but as infidel ignorance is perpetually pretending, that the diminutive Icelander, the ugly Eſquimaux, the woolly-headed Negro, and the copper-coloured American, could not have deſcended from one original pair, either of European complexion or of Hindoo ſymmetry—it may not be improper, in this place, to ſhew the weakneſs of this popular objection to the Moſaic hiſtory of the origin of man. This has been done in ſo ſatisfactory a manner by Profeſſor Blumenbach, that we have nothing to do but lay his obſervations before our readers, convinced, as we are, that they are intelligible to every capacity, and that they will carry conviction to all who are not the ſlaves of prejudice.

Phil. Mag. vol. iii. p. 284. "Some late writers on natural hiſtory (ſays the Profeſſor) ſeem doubtful whether the numerous diſtinct races of men ought to be conſidered as mere varieties, which have ariſen from degeneration, or as ſo many ſpecies altogether different. The cauſe of this ſeems chiefly to be, that they took too narrow a view in their reſearches; ſelected, perhaps, two races the moſt different from each other poſſible, and, overlooking the intermediate races that formed the connecting links between them, compared theſe two together; or, they fixed their attention too much on man, without examining other ſpecies of animals, and comparing their varieties and degeneration with thoſe of the human ſpecies. The firſt fault is, when one, for example, places together a Senegal negro and an European Adonis, and at the ſame time forgets that there is not one of the bodily differences of theſe two beings, whether hair, colour, features, &c. which does not gradually run into the ſame thing of the other, by ſuch a variety of ſhades, that no phyſiologiſt or naturaliſt is able to eſtabliſh a certain boundary between theſe gradations, and conſequently between the extremes themſelves.

"The ſecond fault is, when people reaſon as if man were the only organiſed being in nature, and conſider the varieties in his ſpecies to be ſtrange and problematical, without reflecting that all theſe varieties are not more ſtriking or more uncommon than thoſe with which ſo many thouſands of other ſpecies of organiſed beings degenerate, as it were, before our eyes."

As what we have ſaid under the articles Complexion and Negro may be ſufficient to warn mankind againſt the firſt error, and at the ſame time to refute it, we haſten to refute the ſecond by our author's compariſon between the human race and that of ſwine.

"More reaſons (ſays he) than one have induced me to make choice of ſwine for this compariſon; but, in particular, becauſe they have a great ſimilarity, in many reſpects, to man: not, however, in the form of their entrails, as people formerly believed, and therefore ſtudied the anatomy of the human body purpoſely in ſwine; ſo that, even in the laſt century, a celebrated diſpute, which aroſe between the phyſicians of Heidelberg and thoſe of Durlach, reſpecting the poſition of the heart in man, was determined, in conſequence of orders from government, by inſpecting a ſow, to the great triumph of the party which really was in the wrong. Nor is it becauſe in the time of Galen, according to repeated aſſertions, human fleſh was ſaid to have a taſte perfectly ſimilar to that of ſwine; nor becauſe the fat, and the tanned hides of both, are very like to each other; but becauſe both, in regard to the economy of their bodily ſtructure, taken on the whole, ſhew unexpectedly, on the firſt view, as well as on cloſer examination, a very ſtriking ſimilitude.

"Both, for example, are domeſtic animals; both *omnivora;* both are diſperſed throughout all the four quarters of the world; and both conſequently are expoſed, in numerous ways, to the principal cauſes of degeneration ariſing from climate, mode of life, nouriſhment, &c.; both, for the ſame reaſon, are ſubject to many diſeaſes, and, what is particularly worthy of remark, to diſeaſes rarely found among other animals than men and ſwine, ſuch as the ſtone in the bladder; or to diſeaſes excluſively peculiar to theſe two, ſuch as the worms found in meaſled ſwine.

"Another reaſon (continues he) why I have made choice of ſwine for the preſent compariſon is, becauſe the degeneration and deſcent from the original race are far more certain in theſe animals, and can be better traced, than in the varieties of other domeſtic animals. For no naturaliſt, I believe, has carried his ſcepticiſm ſo far as to doubt the deſcent of the domeſtic ſwine from the wild boar; which is ſo much the more evident, as it is well known that wild pigs, when caught, may be eaſily rendered as tame and familiar as domeſtic ſwine: and the contrary alſo is the caſe; for if the latter by any accident get into the woods, they as readily become wild again; ſo that there are inſtances of ſuch animals being ſhot for wild ſwine; and it has not been till they were opened, and found caſtrated, that people were led to a diſcovery of their origin, and how, and at what time, they ran away. It is well aſcertained, that, before the diſcovery of America by the Spaniards, ſwine were unknown in that quarter of the world, and that they were afterwards carried thither from Europe. All the varieties, therefore, through which this animal has ſince degenerated, belong, with the original European race, to one and the ſame ſpecies; and ſince no bodily difference is found in the human race, as will preſently appear, either in regard to ſtature, colour, the form of the cranium, &c. which is not obſerved in the ſame proportion among the ſwine race, while no one, on that account, ever doubts that all theſe different kinds are merely varieties that have ariſen from degeneration through the influence of climate, &c. this compariſon, it is to be hoped, will ſilence thoſe ſceptics who have thought proper, on account of theſe varieties in the human race, to admit more than one ſpecies.

"With regard to ſtature, the Patagonians, as is well known, have afforded the greateſt employment to anthropologiſts. The romantic tales, however, of the old travellers, who give to theſe inhabitants of the ſouthern extremity of America a ſtature of ten feet and more, are ſcarcely worth notice; and even the more modeſt relations of later Engliſh navigators, who make their height from ſix to ſeven feet, have been doubted by other travellers, who, on the ſame coaſt, ſought for ſuch children of Enoch in vain. But we ſhall admit every thing ſaid of the extraordinary ſize of theſe Patagonians by Byron, Wallis, and Carteret; the firſt of whom aſſigns to their chief, and ſeveral of his attendants, a height of not leſs than ſeven feet, as far as could be determined by the eye; the ſecond, who aſſerts that he actually meaſured them, gives to the greater part of them from 5 feet 10 inches to 6 feet; to ſome 6 feet 5 inches, and 6 feet 6; but to the talleſt, 6 feet 7 inches: and this account is confirmed by the laſt-mentioned of the above circumnavigators. Now, allowing this to be the caſe, it is not near ſuch an exceſs of ſtature as that obſerved in many parts of America among the ſwine, originally carried thither from Europe; and of theſe I ſhall mention in particular thoſe of Cuba, which are more than double the ſize of the original ſtock in Europe.

"The natives of Guinea, Madagaſcar, New Holland, New Guinea, &c. are black; many American tribes are reddiſh brown, and the Europeans are white. An equal difference is obſerved among ſwine in different countries. In Piedmont, for example, they are black. When I paſſed (ſays our author) through that country, during the great fair for ſwine at Salenge, I did not ſee a ſingle one of any other colour. In Bavaria, they are reddiſh brown; in Normandy, they are all white.

"Human hair is, indeed, ſomewhat different from ſwine's briſtles; yet, in the preſent point of view, they may be compared with each other. Fair hair is ſoft, and of a ſilky texture; black hair is coarſer, and among ſeveral tribes, ſuch as the Abyſſinians, Negroes, and the inhabitants of New Holland, it is woolly, and moſt ſo among the Hottentots. In the like manner, among the white ſwine in Normandy, as I was aſſured by an incomparable obſerver, Sulzer of Ronneburg, the hair on the whole body is longer and ſofter than among other ſwine; and even the briſtles on the back are very little different, but lie flat, and are only longer than the hair on the other parts of the body. They cannot, therefore, be employed by the bruſh makers. The difference between the hair of the wild boar and the domeſtic ſwine, particularly in regard to the ſofter part between the ſtrong briſtles, is, as is well known, ſtill greater.

"The whole difference between the cranium of a Negro and that of an European, is not in the leaſt degree greater than that equally ſtriking difference which exiſts between the cranium of the wild boar and that of the domeſtic ſwine. Thoſe who have not obſerved this in the animals themſelves, need only to caſt their eye on the figure which Daubenton has given of both.

"I ſhall paſs over (ſays our author) leſs national varieties which may be found among ſwine as well as among men, and only mention, that I have been aſſured by Mr Sulzer, that the peculiarity of having the bone of the leg remarkably long, as is the caſe among the Hindoos, has been remarked with regard to the ſwine in Normandy. 'They ſtand very long on their hind legs (ſays he, in one of his letters); their back, therefore, is higheſt at the rump, forming a kind of inclined plane; and the head proceeds in the ſame direction, ſo that the ſnout is not far from the ground.' I ſhall here add, that the ſwine, in ſome countries, have degenerated into races which in ſingularity far exceed every thing that has been found ſtrange in bodily variety among the human race. Swine with ſolid hoofs were known to the ancients, and large herds of them are found in Hungary, Sweden, &c. In the like manner, the European Swine, firſt carried by the Spaniards, in 1509, to the iſland of Cuba, at that time celebrated for its pearl fiſhery, degenerated into a monſtrous race, with hoofs which were half a ſpan in length."

From theſe facts, our author concludes, that it is abſurd to allow the vaſt variety of ſwine to have deſcended from one original pair, and to contend that the varieties of men are ſo many diſtinct ſpecies.

MANDING, a large ſtate in the interior of Africa, of which the only ſatisfactory account that we have is by Mr Park, who, for ſeveral months, was hoſpitably entertained in Kamalia, one of its towns, ſituated in 12° 40′ N. Lat. and 6° 40′ W. Long. The government of Manding appeared to our author to be a ſort of republic, or rather an oligarchy. Every town is indeed governed by a chief magiſtrate called Manſa, which uſually ſignifies king; but the chief power of the ſtate, in the laſt reſort, is lodged in the aſſembly of theſe manſas (A). The caſe, however, is different in other countries, which are occupied by people who have emigrated from Manding; for in all the Mandingo ſtates

---

(A) Mr Park, for the moſt part, writes with remarkable perſpicuity; but we are not ſure that here we have not miſtaken his meaning. He ſays, that the chief power of the ſtate is lodged in the aſſembly of that *whole body*; but we think, that by the whole body muſt be meant the body of *Manſas*, otherwiſe the government could not be called an oligarchy.

near the Gambia, the government is monarchical, tho' the power of the ſovereign is by no means unlimited.

As Mr Park's route was confined to a tract of country, bounded nearly by the 12th and 15th parallels of latitude, the climate throughout the whole was nearly the ſame as that of Manding, and extremely hot: Yet, where the country aſcended into hills, he found it comparatively cool and pleaſant; though none of the diſtricts which he traverſed could be called mountainous. About the middle of June, the hot and ſultry atmoſphere is agitated by violent guſts of wind (called *tornadoes*), accompanied with thunder and rain. Theſe uſher in what is denominated *the rainy ſeaſon;* which continues until the month of November. During this time, the diurnal rains are very heavy; and the prevailing winds are from the ſouth-weſt. The termination of the rainy ſeaſon is likewiſe attended with violent tornadoes; after which the wind ſhifts to the north-eaſt, and continues to blow from that quarter during the reſt of the year.

When the wind ſets in from the north-eaſt, it produces a wonderful change in the face of the country. The graſs ſoon becomes dry and withered; the rivers ſubſide very rapidly, and many of the trees ſhed their leaves. About this period is commonly felt the *harmattan*, a dry and parching wind, blowing from the north eaſt, and accompanied by a thick ſmoky haze; through which the ſun appears of a dull red colour. This wind, in paſſing over the great deſert of Sahara, acquires a very ſtrong attraction for humidity, and parches up every thing expoſed to its current. It is, however, reckoned very ſalutary, particularly to Europeans, who generally recover their health during its continuance. The truth of this our author experienced both at Kamalia and Piſania, when he had been brought to the very brink of the grave by ſickneſs.

Whenever the graſs is ſufficiently dry, the negroes ſet it on fire; but in Ludamar, and other Mooriſh countries, this practice is not allowed; for it is upon the withered ſtubble that the Moors feed their cattle until the return of the rains. The burning of the graſs in Manding exhibits a ſcene of terrific grandeur. "In the middle of the night (ſays Mr Park), I could ſee the plains and mountains, as far as my eye could reach, variegated with lines of fire; and the light reflected on the ſky, made the heavens appear in a blaze. In the day time, pillars of ſmoke were ſeen in every direction; while the birds of prey were obſerved hovering round the conflagration, and pouncing down upon the ſnakes, lizards, and other reptiles, which attempted to eſcape from the flames." This annual burning is ſoon followed by a freſh and ſweet verdure, and the country is thereby rendered more healthful and pleaſant.

Though many ſpecies of the edible roots, which grow in the Weſt India iſlands, are found in Africa, yet our traveller never ſaw, in any part of his journey, either the ſugar cane, the coffee, or the cocoa tree; nor could he learn, on inquiry, that they were known to the natives. The pine-apple, and the thouſand other delicious fruits which the induſtry of civilized man (improving the bounties of nature), has brought to ſo great perfection in the tropical climates of America, are here equally unknown. He obſerved, indeed, a few orange and banana trees, near the mouth of the Gambia; but whether they were indigenous, or were formerly planted there by ſome of the white traders, he could not poſitively learn.

Concerning property in the ſoil, it appeared to Mr Park, that the lands in native woods were conſidered as belonging to the king, or (where the government was not monarchical) to the ſtate. When any individual of free condition had the means of cultivating more land than he actually poſſeſſed, he applied to the chief man of the diſtrict, who allowed him an extenſion of territory, on condition of forfeiture if the lands were not brought into cultivation by a given period. The condition being fulfilled, the ſoil became veſted in the poſſeſſor; and, for aught that appeared, deſcended to his heirs.

The Mandingoes are a very gentle race of people; cheerful in their diſpoſitions, inquiſitive, credulous, ſimple, and fond of flattery. The men are commonly above the middle ſize, well ſhaped, ſtrong, and capable of enduring great labour; the women are good natured, ſprightly, and agreeable. The dreſs of both ſexes is compoſed of cotton cloth of their own manufacture; that of the men is a looſe frock, not unlike a ſurplice, with drawers which reach half way down the leg; and they wear ſandals on their feet, and white cotton caps on their heads. The womens dreſs conſiſts of two pieces of cloth, each of which is about ſix feet long and three broad; one of theſe they wrap round the waiſt, which, hanging down to the ancles, anſwers the purpoſe of a petticoat; the other is thrown negligently over the boſom and ſhoulders. Both men and women among the Mandingoes ſeem to have an invincible propenſity to commit depredations on the property of unprotected ſtrangers; whilſt ſuch is the good nature of thoſe poor heathens, that they will readily ſympathiſe in the ſufferings, relieve the diſtreſſes, and contribute to the perſonal ſafety, of the very ſtrangers whom they are bent upon plundering.

Among the Mandingoes, the parental and filial affection is remarkably ſtrong between the mother and her child; but not ſo between the father and his children. This, as Mr Park obſerves, is eaſily accounted for. The ſyſtem of polygamy, while it weakens the father's attachment, by dividing it among the children of different wives, concentrates all the mother's jealous tenderneſs to one point, the protection of her own offſpring. He perceived, with great ſatisfaction too, that the maternal ſolicitude extended, not only to the growth and ſecurity of the perſon, but alſo, in a certain degree, to the improvement of the mind of the infant; for one of the firſt leſſons, in which the Mandingo women inſtruct their children, is *the practice of truth.*

The Mandingo women ſuckle their children until they are able to walk of themſelves. Three years nurſing is not uncommon; and during this period, the huſband devotes his whole attention to his other wives. To this practice it is owing, that the family of each wife is ſeldom very numerous. Few women have more than five or ſix children. As ſoon as an infant is able to walk, it is permitted to run about with great freedom. The mother is not over ſolicitous to preſerve it from ſlight falls, and other trifling accidents. A little practice ſoon enables a child to take care of itſelf, and experience acts the part of a nurſe. As they advance in life, the girls are taught to ſpin cotton, and to beat corn, and are inſtructed in other domeſtic duties; and the

the boys are employed in the labours of the field. Both ſexes, whether Buſhreens or Kafirs, on attaining the age of puberty, are circumciſed. This painful operation is not conſidered by the Kafirs ſo much in the light of a religious ceremony, as a matter of convenience and utility. They have, indeed, a ſuperſtitious notion, that it contributes to render the marriage ſtate prolific.

When a young man takes a fancy to a young girl, and wiſhes to marry her, it is by no means conſidered as neceſſary that he ſhould make an overture to the girl herſelf. The firſt object is to agree with the parents, concerning the recompence to be given them for the loſs of the company and ſervices of their daughter. The value of two ſlaves is a common price, unleſs the girl is thought very handſome; in which caſe, the parents will raiſe their demand very conſiderably. If the lover is rich enough, and willing to give the ſum demanded, he then communicates his wiſhes to the damſel: but her conſent is by no means neceſſary to the match; for if the parents agree to it, and eat a few *kolla nuts*, which are preſented by the ſuitor as an earneſt of the bargain, the young lady muſt either have the man of their choice, or continue unmarried, for ſhe cannot afterwards be given to another. If the parents ſhould attempt it, the lover is then authoriſed, by the laws of the country, to ſeize upon the girl as his ſlave. At the celebration of a marriage, no religious ceremony ſeems to be practiſed. A ſelect number of people are indeed invited to the wedding, and feaſted; but conſummation conſtitutes the marriage; for towards the morning, the new married couple are always diſturbed by the women, who aſſemble to inſpect the nuptial ſheet (according to the manners of the ancient Hebrews, as recorded in Scripture), and dance round it. This ceremony is thought indiſpenſably neceſſary; nor is the marriage conſidered as valid without it.

The Mandingoes, and indeed all the negro ſtates, whether Mahomedan or Pagan, allow a plurality of wives. The conſequence is, that the wives frequently quarrel among themſelves. When this happens, the huſband decides between them; and ſometimes finds it neceſſary to adminiſter a little corporal chaſtiſement before tranquillity can be reſtored. But if any one of the ladies complains to the chief of the town, that her huſband has unjuſtly puniſhed her, and ſhewn an undue partiality to ſome other of his wives, the affair is brought to a public trial. In theſe *palavers*, however, which are conducted chiefly by married men, our author was informed, that the complaint of the wife is not always conſidered in a very ſerious light; and the complainant herſelf is ſometimes convicted of ſtrife and contention, and left without remedy. If ſhe murmurs at the deciſion of the court, the magic rod of *Mumbo Jumbo* ſoon puts an end to the buſineſs. See MUMBO JUMBO in this *Suppl.*

A child, among them, is named when it is ſeven or eight days old. The ceremony commences by ſhaving the infant's head; and a diſh called *dega*, made of pounded corn and ſour milk, is prepared for the gueſts. If the parents are rich, a ſheep or a goat is commonly added. This feaſt is called *ding koon lee*, "the child's head ſhaving." During Mr Park's ſtay at Kamalia, he was preſent at four different feaſts of this kind, and the ceremony was the ſame in each, whether the child belonged to a Buſhreen or a Kafir. The ſchoolmaſter, who officiated as prieſt on thoſe occaſions, and who is neceſſarily a Buſhreen, firſt ſaid a long prayer over the *dega*; during which, every perſon preſent took hold of the brim of the calabaſh with his right hand. After this, the ſchoolmaſter took the child in his arms, and ſaid a ſecond prayer; in which he repeatedly ſolicited the bleſſing of God upon the child, and upon all the company. When this prayer was ended, he whiſpered a few ſentences in the child's ear, and ſpit three times in its face; after which he pronounced its name aloud, and returned the infant to the mother. This part of the ceremony being ended, the father of the child divided the *dega* into a number of balls, one of which he diſtributed to every perſon preſent. And inquiry was then made, if any perſon in the town was dangerouſly ſick; it being uſual, in ſuch caſes, to ſend the party a large portion of the *dega*, which is thought to poſſeſs great medical virtues.

The Mandingoes have no artificial method of dividing time. They calculate the years by the number of *rainy ſeaſons*. They portion the year into *moons*, and reckon the days by ſo many *ſuns*. The day they divide into morning, mid-day, and evening; and further ſubdivide it, when neceſſary, by pointing to the ſun's place in the heavens. Our author frequently inquired of ſome of them, what became of the ſun during the night, and whether we ſhould ſee the ſame ſun, or a different one, in the morning? But that ſubject appeared to them as placed beyond the reach of human inveſtigation; they had never indulged a conjecture, nor formed any hypotheſis, about the matter. The moon, by varying her form, has more attracted their attention. On the firſt appearance of the new moon, which they look upon to be newly created, the Pagan natives, as well as Mahomedans, ſay a ſhort prayer; and this ſeems to be the only viſible adoration which the Kafirs offer up to the Supreme Being. This prayer is pronounced in a whiſper; the party holding up his hands before his face: its purport is to return thanks to God for his kindneſs through the exiſtence of the paſt moon, and to ſolicit a continuation of his favour during that of the new one. At the concluſion, they ſpit upon their hands, and rub them over their faces. Great attention is paid to the changes of this luminary in its monthly courſe; and it is thought very unlucky to begin a journey, or any other work of conſequence, in the laſt quarter. An eclipſe, whether of the ſun or moon, is ſuppoſed to be effected by witchcraft. The ſtars are very little regarded; and the whole ſtudy of aſtronomy appears to them as a uſeleſs purſuit, and attended to by ſuch perſons only as deal in magic.

Their notions of geography are equally puerile. They imagine that the world is an extended plain, the termination of which no eye has diſcovered; it being, they ſay, overhung with clouds and darkneſs. They deſcribe the ſea as a large river of ſalt water, on the farther ſhore of which is ſituated a country called *Tobaubo doo*; "the land of the white people." At a diſtance from Tobaubo doo, they deſcribe another country, which they allege is inhabited by cannibals of gigantic ſize, called *Koomi*.

Mr Park ſays he has converſed with all ranks and conditions of negroes on the ſubject of their faith, and that he can pronounce, without the ſmalleſt ſhadow of doubt, that the belief of one God, and of a future ſtate of reward and puniſhment, is entire and univerſal among them.

them. It is remarkable, however, that, except on the appearance of a new moon, as before related, the Pagan natives do not think it neceſſary to offer up prayers and ſupplications to the Almighty. They repreſent the Deity, indeed, as the creator and preſerver of all things; but in general they conſider him as a Being ſo remote, and of ſo exalted a nature, that it is idle to imagine the feeble ſupplications of wretched mortals can reverſe the decrees, and change the purpoſes, of unerring wiſdom. The concerns of this world, they believe, are committed by the Almighty to the ſuperintendance and direction of ſubordinate ſpirits, over whom they ſuppoſe that certain magical ceremonies have great influence. A white fowl, ſuſpended to the branch of a particular tree, a ſnake's head, or a few handfuls of fruit, are offerings which ignorance and ſuperſtition frequently preſent, to deprecate the wrath, or to conciliate the favour, of theſe tutelary agents.

The Mandingoes ſeldom attain extreme old age. At forty, moſt of them become grey haired, and covered with wrinkles; and but few of them ſurvive the age of fifty-five, or ſixty. Yet their diſeaſes appeared but few; fevers and fluxes being the moſt common, and the moſt fatal. For theſe they generally apply *ſaphies*, i. e. charms, to different parts of the body; though ſometimes, on the firſt attack of a fever, the patient is, with great ſucceſs, placed in a ſort of vapour bath. The other diſeaſes which prevail among the negroes, are the *yaws*, the *elephantiaſis*, and a *leproſy* of the very worſt kind, together with the *Guinea worm*, which they attribute to bad water.

When a perſon of conſequence dies, the relations and neighbours meet together, and manifeſt their ſorrow by loud and diſmal howlings. A bullock or goat is killed for ſuch perſons as come to aſſiſt at the funeral; which generally takes place in the evening of the ſame day on which the party died. The negroes have no appropriate burial places, and frequently dig the grave in the floor of the deceaſed's hut, or in the ſhade of a favourite tree. The body is dreſſed in white cotton, and wrapped up in a mat. It is carried to the grave, in the duſk of the evening, by the relations. If the grave is without the walls of the town, a number of prickly buſhes are laid upon it, to prevent the wolves from digging up the body; but our author never obſerved that any ſtone was placed over the grave as a monument or memorial.

With reſpect to employment, the men cultivate the ground, or catch fiſh in large rivers; while the women manufacture cotton cloth. It is only the ſpinning and the dyeing, however, that are performed by the women; for the web, which is ſeldom more than four inches broad, is wove by the men in a loom made exactly upon the ſame principle as that of Europe. As the arts of weaving, dyeing, ſewing, &c. may eaſily be acquired, thoſe who exerciſe them are not conſidered in Africa as following any particular profeſſion; for almoſt every ſlave can weave, and every boy can ſew. The only artiſts which are diſtinctly acknowledged as ſuch by the negroes, and who value themſelves on exerciſing appropriate and peculiar trades, are the manufacturers of leather and of iron. The firſt of theſe are called *Karrankea* (or as the word is ſometimes pronounced *Gaungay*). They are to be found in almoſt every town, and they frequently travel through the country in the exerciſe of their calling. They tan and dreſs leather with very great expedition, by ſteeping the hide firſt in a mixture of wood aſhes and water, until it parts with the hair; and afterwards by uſing the pounded leaves of a tree, called *goo*, as an aſtringent.

The manufacturers in iron are not ſo numerous as the *Karrankeas*; but they appear to have ſtudied their buſineſs with equal diligence. The negroes on the coaſt being cheaply ſupplied with iron from the European traders, never attempt the manufacturing of this article themſelves; but in the inland parts, the natives ſmelt this uſeful metal in ſuch quantities, as not only to ſupply themſelves from it with all neceſſary weapons and inſtruments, but even to make it an article of commerce with ſome of the neighbouring ſtates. During our author's ſtay at Kamalia, there was a ſmelting furnace at a ſhort diſtance from the hut where he lodged, and the owner and his workmen made no ſecret about the manner of conducting the operation; and readily allowed him to examine the furnace, and aſſiſt them in breaking the iron-ſtone. The proceſs it is needleſs to deſcribe; though it be proper to obſerve, that the maſs of metal obtained by it was rather ſteel than iron. Moſt of the African blackſmiths are acquainted alſo with the method of ſmelting gold, in which proceſs they uſe an alkaline ſalt, obtained from a ley of burnt corn-ſtalks evaporated to dryneſs. They likewiſe draw the gold into wire, and form it into a variety of ornaments, ſome of which are executed with a great deal of taſte and ingenuity.

The reader will obſerve, that in the extracts which we have made from Mr Park's intereſting travels, the terms African and Negro are frequently uſed as if all Africans and Negroes were Mandingoes. The reaſon is, that the Mandingoes were not only the moſt numerous tribe which he viſited, but were alſo ſpread over all that tract of country which he traverſed.

MANIANA, a ſmall negro kingdom lying between 12° and 14° North Lat. and between the meridian of Greenwich and 1° and 30′ Weſt Long. Its inhabitants, as Mr Park was informed by a variety of people in many different kingdoms, are remarkable for cruelty and ferocity; carrying their reſentment to their enemies ſo far as never to give quarter, and even indulging themſelves with banquets of human fleſh. Hence the inhabitants of Bambarra, who carried on with them a long and bloody war, and muſt of courſe be well aſcertained of the fact, call them *Ma dummulo*, which ſignifies meneaters.

MANURE is ſo eſſential to agriculture, that the want of it, or an improper manner of uſing it, is the principal cauſe of the ſterility of a country. We have therefore treated of manures and their action at ſome length in the article AGRICULTURE in the *Encyclopædia*; but as the theoretical part of that diſquiſition reſts in a great meaſure on the doctrine of phlogiſton, which is now exploded, it may not be improper to reſume the ſubject here. Experience however being, after all, the only guide which the farmer can ſafely and confidently follow, inſtead of amuſing our readers with theories of our own, we ſhall lay before them the obſervations of a man who ſeems to have united theory with practice.

"The uſe of manures (ſays M. Parmentier*) has been known in all ages, but we are yet far from having any clear and preciſe ideas of the nature of the juices which

---

* *Memoi of the R Society of griculture Paris.*

which are deſtined for the nouriſhment of vegetables, and of the manner in which they are tranſmitted to their organs. The writers on agriculture, who have endeavoured to explain theſe matters, perceiving ſalts in moſt plants, were perſuaded that theſe ſalts, by the help of water and heat, paſſed, in a ſaline form, through the vegetable filter. Theſe firſt philoſophers did not heſitate to conſider every thing that has been done by the induſtry of man, to improve the nature of land, and its productions, as merely forming reſervoirs of theſe ſalts, which they conſidered as the principle of fertility. This opinion was ſo well eſtabliſhed among the improvers of land, that, to this day, many of them have no object in view, in their operations, but to diſengage ſalts; and, when they attempt to explain certain phenomena which take place in their fields or orchards, they talk confidently about the *nitre of the air*, *of rain*, *of ſnow*, *of dew*, *and fogs*; of the *ſalts of the earth*, *of dung*, *of marle*, *of lime*, *of chalk*, &c. and make uſe of thoſe vague terms, *oil*, *ſulphur*, *ſpirit*, &c. which ought henceforward to be baniſhed from our elementary books on agriculture.

" Among the authors who have attacked, and combated with moſt ſucceſs, the opinion that the fruitfulneſs of ſoils, and the aliment of vegetables, reſide in ſaline ſubſtances, muſt be reckoned Eller and Wallerius. Theſe philoſophers examined, by every means which chymiſtry at that time could furniſh, the various kinds of earth proper for cultivation, and alſo thoſe ſubſtances which have always been conſidered as the moſt powerful manures, without being able to obtain, from any of them, any thing more than mere atoms of ſalt.

" Animated with the ſame zeal, and taking advantage of the inſtructions found in their writings, I thought it neceſſary to determine, by experience, whether, as has been aſſerted, there really exiſt neutral ſalts in earths; and alſo, whether thoſe earths are more fertile in proportion to the quantity of ſuch ſalts they contain. With this view, I lixiviated, by means of diſtilled water, many ſpecies of cultivated earths, taken in various ſtates, from freſh earth to that which had been impoveriſhed by the growth of ſeveral crops; I alſo tried dung, reduced more or leſs into the ſtate of mould; and likewiſe the moſt active manures, ſuch as the offal of animal ſubſtances rotted by putrefaction; but in none of theſe, however carefully analyzed, were found any ſalts in a free ſtate. They contain indeed the materials proper for forming ſalts, but if they contain any ready formed, it is merely by accident.

" The reſearches of Kraft, and thoſe of Alſton, were not attended with different reſults. Having ſown ſome oats in aſhes, not lixiviated, and in ſand ſtrongly impregnated with potaſh and with ſaltpetre, and having found that the oats did not grow, they concluded that neutral ſalts, and alkalies, not only retarded the growth of vegetables, but that they abſolutely prevented it. It is well known that in Egypt there are diſtricts where the earth is entirely covered with ſea-ſalt, and theſe diſtricts are quite barren. It is probably owing to this property of ſea-ſalt, that the Romans were accuſtomed to ſcatter large quantities of it over fields where any great crime had been committed, and of which they wiſhed to perpetuate the remembrance, by rendering the part barren for a certain time.

" The idea that ſalts had great influence in vegetation, ought to have been greatly weakened by the following ſimple reflection. Suppoſing that ſalts exiſted in garden mould, they would be very ſoon diſſolved by the rain, and carried away, towards the lower ſtrata of the earth, to a depth to which the longeſt roots would not reach. Indeed the famous experiment of Vanhelmont would have been ſufficient to have deſtroyed the above opinion, if it did not generally happen that we are no ſooner ſet free from one error than we fall into another not leſs extraordinary. The ſurpriſing effects of vegetation brought about by the overflowing of water, and in the neighbourhood of ſalt marſhes, and the infinite number of inhaling capillary tubes obſerved upon the ſurface of vegetables, led to an opinion that the air and water, abſorbed by the roots and leaves of plants, were only vehicles loaded with ſaline matter, analogous to the vegetables nouriſhed by them.

" To the experiment of Vanhelmont, which was repeated by many accurate obſervers, ſucceeded thoſe of modern philoſophers; from which it clearly appeared, that plants could grow, and produce fruit, in the air of the atmoſphere, and in diſtilled water, alſo in pure ſand, in powdered glaſs, in wet moſs or ſponge, in the cavity of fleſhy roots, &c. and that plants which had nothing but the above-mentioned fluids for their nouriſhment, gave, when ſubmitted to chymical analyſis, the ſame products as thoſe which had undergone their proceſs of vegetation in a ſoil perfectly well manured. It was alſo obſerved, that the moſt barren ſoils were rendered fertile when they were properly ſupplied with water by canals; and the efficacy of irrigation was repeatedly evinced in different ways: from theſe obſervations was formed the following ſyſtem, that water riſes in plants in the form of vapour, as in diſtillation; that air introduces itſelf into their pores; and that, if ſalts contribute to the fruitfulneſs of ſoils, it is only in conſequence of their containing the two fluids above mentioned in great abundance."

Our author, after making many experiments upon various ſoils and ſalts, and after attending minutely to the proceſs of vegetation, thinks himſelf warranted to maintain, " that ſaline ſubſtances have no ſenſible effects in promoting vegetation, except inaſmuch as they are of a deliqueſcent nature, have an earthy baſis eaſily decompoſed, and are uſed only in ſmall quantity. In thoſe circumſtances they have the power of attracting, from the immenſe reſervoir of the atmoſphere, the vapours which circulate in it; theſe vapours they retain, along with the moiſture that is produced from rain, ſnow, dew, fog, &c. which moiſture they prevent from running together in a maſs, or from being loſt, either by exhaling into the air of the atmoſphere, or by filtering itſelf through the inferior ſtrata of the earth, and thereby leaving the roots of vegetables dry; they diſtribute that moiſture uniformly, and tranſmit it, in a ſtate of great diviſion, to the orifices of the tubes deſtined to carry it into the texture of the plant, where it is afterwards to undergo the laws of aſſimilation. As every kind of vegetable manure poſſeſſes a viſcous kind of moiſture, it thereby partakes of the property of deliqueſcent ſalts. In ſhort, the preparation of land for vegetation has no other object in view but to divide the earthy particles, to ſoften them, and to give them a form capable of producing the above mentioned effects. It is ſufficient, therefore, that water, by its mixture

Manure.

with the earth and the manure, be divided, and ſpread out ſo as to be applied only by its ſurface, and that it keep the root of the plant always wet, without drowning it, in order to become the eſſential principle of vegetation. But as plants which grow in the ſhade, even in the beſt ſoil, are weakly, and as the greater part of thoſe which are made to grow in a place that is perfectly dark neither give fruit nor flowers, it cannot be denied that the influence of the ſun is of great importance in vegetable economy."

Such was the opinion which our author gave of the manner in which ſalts act in vegetation, at a time when it was not known that air and water (which had been ſo long conſidered as elements), far from being ſimple ſubſtances, are capable of being decompoſed by a great variety of operations both of nature and art; and nothing was wanting to complete his theory, but to know that air and water act their part in vegetation only in a ſtate of decompoſition; and that if earth well manured is a better matrix than water itſelf, it is becauſe ſuch earth has the power of converting the water into gaſes which are eaſily abſorbed, and which, while their abſorption takes place, communicate to the plants a motion and heat which they received when taking the form of gas, and which they loſe when they enter again into combination; whence it is natural to conclude, that this motion and this heat muſt neceſſarily develope themſelves in ſeeds, and maintain the vital action in plants.

What is a vegetable, conſidered chemically, according to the preſent ſtate of our knowledge? It is, ſay the chemiſts, a compound of hydrogen, oxygen, and carbon, the proportions of which vary according to the agents which have concurred to its developement, and according to the matrix which received and aſſimilated them, in order to create thoſe combinations which are varied to infinity, by their forms and properties, and known by the generic terms of ſalt, oil, and mucilage. It appears, therefore, needleſs to ſeek theſe combinations in the different ſubſtances which are uſed for manure, when we wiſh to determine the nature of them, and explain their manner of acting in vegetation; becauſe, ſuppoſing it true that theſe ſalts, theſe oils, or theſe mucilages, exiſt in their combined ſtate, nothing but their conſtituent elements, namely, hydrogen, oxygen, and carbon, can poſſibly have any action.

The ſuperiority of animal ſubſtances, as manures, and the remarkable luxuriance of thoſe plants which are watered with putrid water, prove inconteſtibly, that the putrid ſtate is favourable to vegetation, and that every ſubſtance which is liable to enter, to a certain degree, into that ſtate, contributes very powerfully thereto. The moſt aerated waters are, in this caſe, the moſt beneficial. It is obſerved that rain, particularly in ſtormy weather, quickens vegetation ſo much, that the gardeners in the neighbourhood of Paris are often obiged to drench their plants with water taken from their wells, which, in conſequence of its rawneſs, or its want of air, retards the vegetation of the plants; either becauſe it precipitates the meteoriſed or electrified water, or becauſe, by being mixed with the other water, it diminiſhes its fertilizing quality; whereas, in ſummer, this ſame well-water, by being expoſed to the ſun for ſome days, acquires a ſmell like that of ſtale eggs, loſes its rawneſs, and becomes very fit for accelerating vegetation. An atom of vegetable or animal matter is, at that time, ſufficient to bring about more quickly this ſtate of putrefaction; while theſe ſame ſubſtances, by being employed in certain proportions, far from acting as a leaven on the liquids which hold them in ſolution, preſerve thoſe liquids, or at leaſt make them more ſlow to change.

Salts and dung, therefore, are not merely decompoſed by the power of vegetation; by furniſhing the reſults of their decompoſition, they alſo act in the manner of leavens, the action of which is ſcarcely perceptible in cold or dry weather; but when they are heated by the ſun, and ſufficiently penetrated with moiſture, they very ſoon enter into a ſort of fermentation, ſuffering the various gaſes with which they are provided to eſcape. Thus manures may be conſidered as decompoſing inſtruments, provided by nature, and prepared by art, to act upon water ſo as to bring it to a proper ſtate of attenuation. The ſubſtances which enter into the compoſition of plants are, therefore, nothing but products of the decompoſition of air and water, and combinations of the conſtituent principles of theſe two fluids, determined by the power which preſides in the ſeed, and which thence has paſſed into the plant.

It is now eaſy to account for the effects of charcoal-powder, ſtraw, &c which are made uſe of to cover ground during long droughts with undoubted benefit: they are mechanical means of preventing the diſſipation of moiſture, and of determining it to take the form of thoſe gaſeous fluids which have ſuch powerful effect in vegetation. As water is compoſed of hydrogen and oxygen, it is not ſurpriſing that, when aſſiſted by the influence of the ſun, and that of electricity, it is capable of forming, almoſt by itſelf, the ſolids and fluids of vegetables; taking from the atmoſphere the carbon it ſtands in need of, to give them their moſt eſſential characters. We ſay their moſt eſſential characters; for thoſe terreſtrial plants which have grown in air and water do not abound in principles, and their offſpring, when they have any, is by no means vigorous. We ſee alſo, that plants which are naturally of an aquatic nature, have in general but little ſmell, becauſe the medium in which they live and grow furniſhes only a ſmall quantity of carbon, in proportion to the hydrogen and oxygen, which are the conſtituent principles of water. This is the reaſon why, in cold and wet years, flowers are leſs odoriferous, fruit leſs full of flavour, and more difficult to be preſerved. The germ of their reproduction is weak; and they are, if the expreſſion may be uſed, in a ſort of dropſy; that is to ſay, they are loaded with the principles which conſtitute water, and even with water itſelf.

Theſe obſervations, to which more might be added, may ſerve to explain why vegetation is ſlow and weak in a ſoil which is too much charged with ſaline matter, while it is rendered quick and vigorous by a ſmall quantity of this ſame matter; and why earth, which is perfectly lixiviated, and watered, from time to time, with diſtilled water only, is capable of giving to bitter plants their bitterneſs, to ſweet ones their ſweetneſs, to acid ones their acidity, to aromatic ones their ſpicineſs, and to poiſonous ones their deleterious qualities; in ſhort, why the inherent characters of plants are more ſtrongly marked, in proportion as the ſoil in which they grow is furniſhed with natural or mechanical means to produce a quantity of gas neceſſary to the formation of the ſubſtances on which thoſe characters depend.

If a nitrous or marine plant can, even when growing in a ſoil deſtitute of nitre or ſea-ſalt, occaſion the production of theſe ſalts, it muſt be allowed that ſuch plants would vegetate more ſtrongly, and contain more of ſuch ſalts, if they grew in ſoils more abounding in materials proper to form them. Thus, the different ſpecies of ſamphire, glaſſwort, ſea wrack, &c. flouriſh on the borders of the ſea, ſuch ſoils being ſtrongly impregnated with the fluids neceſſary to form the muriatic gas and ſea ſalt which enter into the compoſition of thoſe plants; while the ſun flower, pellitory, &c. ſucceed beſt in earth which is mixed with the ruins of old buildings, in which the materials for the production of nitrous gas, and even of nitre itſelf, are very abundant. In ſhort, the organization of theſe plants is a real elaboratory for forming the forementioned ſalts.

Thoſe plants which, for their vegetation, require the moſt aſſiſtance from the ſoil and manure, are very apt to contract a diſagreeable taſte, if either the ſoil or manure are capable of ſupplying the principles from which it is acquired. The claſs *tetradynamia*, particularly all ſorts of cabbages (which contain ſulphur ready formed), contract a bad taſte in a ſoil compoſed of mud and dung, becauſe theſe ſubſtances, as they are decompoſed, furniſh a great quantity of hepatic gas, or of ſulphuriſed hydrogen gas; yet plants of another claſs may grow in the ſame ſoil, cloſe by the cabbages, without partaking even in the ſmalleſt degree of the bad taſte of the latter. The plants laſt mentioned, when growing in hepatic gas, retain only ſo much of it as is ſufficient for the production of the ſubſtances of which they are formed; the overplus, which could not be aſſimilated, is thrown out by the excretory veſſels, after undergoing thoſe modifications which the digeſtive juices and organization of the plant, and the ſtate of the atmoſphere, have produced.

Thus we ſee that thoſe plants which abound moſt in oily, ſaline, and mucilaginous principles, are generally ſuch as require a ſoil well manured. Tobacco, for inſtance, gives forty pounds of alkaline ſalt or potaſh from every hundred weight of aſhes: this plant may, by being buried in the ground, be converted into a very powerful manure; while other plants, which thrive in a middling ſoil, and appear as vigorous, are, in general, ſuch as have not ſo great a quantity of principles in their compoſition, and when thrown on the dunghill, and left to rot, furniſh very little manure. From ſuch obſervations, it may perhaps not be impoſſible hereafter to judge, by the analyſis of a plant, not only whether it requires a large or a ſmall quantity of manure, but likewiſe what kinds of ſoil and manure are moſt fit to promote its vegetation: wild plants alſo may ſerve to ſhew the nature of the ſoil which they ſeem moſt to flouriſh in.

Beſides the phyſical action of manures, they have a very evident mechanical action. When mixed with earth, in a certain proportion, they not only render it more permeable to water, but the roots of plants can, with greater eaſe, acquire their proper ſize and form in it: in other caſes, manures tend to unite that earth which is too looſe, and, by rendering it more tenacious, they prevent the water from being loſt, and the roots from becoming dry. Thoſe manures which are called *warm* are ſuited to cold lands, not only becauſe they render them leſs compact, but alſo becauſe they take off a part of that moiſture which ſuch lands always have in too great quantity. Cold manures, on the other hand, by their viſcid quality, give tenacity to dry and hot ſoils, attracting and retaining, for a longer time, the moiſture which comes in their way. The nature of the ſoil muſt therefore determine what kind of manure it ſtands in need of, and alſo whether cultivating it by means of oxen or by horſes is preferable; for the manures produced from theſe two animals have thoſe oppoſite qualities which we have above deſcribed. By ſuch obſervations, we ſhall perhaps be able to reſolve a queſtion, reſpecting which the ſentiments of cultivators in many parts of the kingdom are much divided.

It cannot, however, be denied, that the earth is able of itſelf to ſerve as a baſis and ſupport to plants, and that it has an action more or leſs evident upon air, upon water, and upon dung. There is a well-known method of diſtinguiſhing clay from other earths; by merely breathing upon it, a ſmell is immediately perceived, ſufficiently ſtrong to ſhew that a decompoſition and freſh combination have taken place. In ſummer, after a drought of ſome days continuance, there always ariſes in the fields a particular ſmell during a ſhower of rain; and there is no kind of vegetable manure which, when mixed with earth, does not ſend forth a ſmell. This proves, that the nature of the ſoil muſt have an influence, not only upon air and upon water, but alſo upon the effect of manures; and that before we ſpeak of their power, we ſhould always ſpecify what kind of earth they were applied to; becauſe when manures and earth are mixed together, there enſues an action and reaction more or leſs favourable to vegetation.

Having examined to what degree air and water enter, in ſubſtance, into the veſſels of plants, and having ſhewn that the principal action of earth, of ſalts, and of manures, conſiſts in preparing, elaborating, and decompoſing theſe two fluids, and in giving to the products of their decompoſition the forms they require, to accompliſh the purpoſe of nature in vegetation, our author makes ſome obſervations upon the particular effects of certain ſubſtances uſed for improving land, ſuch as marl, lime, chalk, and wood aſhes; which are uſually applied either to an exhauſted ſoil, in order to reſtore it, or to a drooping plant, with a view to give it ſtrength. Of the efficacy of theſe ſubſtances no one doubts, but it does not appear that we are equally agreed reſpecting their manner of acting.

Marl (a manure whoſe effects are well known, and which is found to be of the greateſt benefit in thoſe diſtricts where it can be procured in ſufficient quantity) is capable of acting in the ſame manner as the moſt fertile ſoil, when the principles of which it is compoſed, namely, clay, ſand, calcareous earth, and magneſian earth, are juſtly proportioned to each other. But it is ſometimes compact and tenacious, becauſe it contains a ſuperabundant portion of clay, and at other times porous and friable, becauſe it contains too much ſand, and therefore is not in general fit for vegetation by itſelf. Theſe conſiderations ought always to be our guide when we mean to employ marl as a manure.

It has been ſuppoſed that *to marl* was a ſort of technical expreſſion, intended to denote the bringing together or dividing the earthy particles by means of clay or ſand. It appears to our author, that neither of the above operations can properly be called *marling;* becauſe, in either caſe, all we do is, to put the ſoil into a ſituation to receive and to profit by the influence of the atmoſphere, and that of the manures made uſe of. The peculiar principle of marl is, that part of it which, like lime, acts very powerfully upon the different aeriform fluids, is eaſily reduced to powder, efferveſces with acids, and ſends forth a quantity of air-bubbles when water is poured upon it. Now this matter, which in a particular manner does the office of manure, reſides neither in clay nor in ſand. Upon the proportion of it depends the duration of the fertility it produces; conſequently it is of importance, when we make uſe of marl, to know which of its conſtituent parts it contains in the greateſt proportion, otherwiſe in ſome caſes we ſhould only add one common kind of earth to another. Hence our author infers, that for a chalky ſoil clay is the proper manure, and that in ſuch a ſoil a clay bottom is of more value than a gold mine.

“ Wood-aſhes, as a manure, may be, in ſome reſpects, compared to marl; at leaſt they contain the ſame earths as thoſe which generally enter into the compoſition of marl, but they contain a greater quantity of ſaline ſubſtances, proceeding from the vegetables of which they are the reſidue, and from the proceſs made uſe of in their combuſtion; a proceſs which increaſes their activity, and ſhould render us careful in what manner and for what purpoſes we employ them. Wood aſhes, when ſcattered over fields, at proper times and in proper quantities, deſtroy weeds, and encourage the vegetation of good plants. But do the aſhes produce this effect by a ſort of corroſive power? I cannot (ſays our author) think it; for in that caſe all kinds of plants would indiſcriminately be acted upon by them, and to a certain degree deſtroyed.

“ Beſides, the aſhes of freſh wood are ſeldom employed until they have been lixiviated, in which ſtate they are deprived of their cauſtic principle; thoſe aſhes which are moſt commonly made uſe of for manure are produced either from wood that has been floated in water, or from turf, or from pit-coal, and contain little or no alkaline ſalt.

“ It appears much more probable that aſhes, when laid upon ground, deſtroy the weeds by a well-known effect, namely, by ſeizing with eagerneſs that moiſture which ſerved to produce thoſe weeds, and which in a ſuperabundant quantity is neceſſary to their exiſtence and ſupport. Whereas thoſe plants which have a firmer texture and a longer root, which are rendered ſtrong by age and by having withſtood the rigour of winter, and which are in fact the plants of which the fields are compoſed, do not ſuffer any damage from the application of the aſhes; but, on the contrary, by being freed from the ſuperfluous weeds which ſtifled them, and robbed them of a part of their ſuſtenance, they receive a quantity of nouriſhment proportioned to their wants. The ſtate of relaxation and languor to which they were reduced by a ſuperabundance of water, leaves them, the ſoil gets its proper conſiſtence, and the graſs, corn, &c. acquiring the ſtrength and vigour which is natural to them, ſoon overcome the moſs, ruſhes, and other weeds; thus a good crop, of whatever the field conſiſts of, is produced. It is in the above manner that wood aſhes act, whenever in the ſpring it is neceſſary to apply them to meadows, corn fields, &c. the plants of which are ſtifled and weakened by a luxuriant vegetation of weeds, the uſual conſequence of mild and wet winters.

“ When wood aſhes produce an effect different from what is above deſcribed, it is either becauſe they happen to contain too much alkaline ſalt, or that they are laid on the ground in too great quantity, or that the fields to which they are applied were not ſufficiently wet to reſtrain their action; for when they are ſcattered upon cold ſoils, and buried by the plough before the time of ſowing, they are, like lime, of great ſervice. The laſt-mentioned ſubſtance is very efficacious in other circumſtances; and there is a well-known method of uſing it, practiſed by the Germans, as follows: A heap of lime is formed by the ſide of a heap of poor earth, and water is poured upon the lime; the earth is then thrown over it, and becomes impregnated with the vapours which eſcape from the lime while it is ſlaked. The earth, after being thus aerated, may be ſeparated; and although no lime remains mixed with it, is, by the operation juſt deſcribed, rendered capable of giving a luxuriant vegetation to whatever plants may be put into it.

“ It is poſſible, therefore, to aerate earth as well as fluids; for this purpoſe, by mixing it with certain ſubſtances, during their decompoſition, we muſt attach to it the principles of which thoſe ſubſtances are compoſed; from which there reſults a matter ſo loaded with gas, as to form a more compound ſubſtance, and one which has acquired new properties. The Arabians, for example, who take great pains to improve their land, are accuſtomed to make large pits, which they fill with animals which happen to die: theſe pits they afterwards cover with calcareous or clayey earth; and after ſome time theſe earths, which of themſelves are ſterile, acquire the properties of the richeſt manures.

“ The foregoing obſervations may at leaſt be conſidered as proving, that thoſe ſubſtances which, when employed freſh and in too great quantity, are moſt prejudicial to vegetation, have, on the contrary, an advantageous effect, when they are previouſly made to undergo a fermentation; or when they are mixed with earth or water, in a proportion adapted to the end propoſed. The graſs of fields in which cattle or poultry go to feed, after the firſt or ſecond crop of hay, appears to be dried by the urine and dung of thoſe animals; as if fire had been applied to it; whereas theſe ſame excrementitious ſubſtances, when combined with earth, or diluted with water, are capable, without any other preparation, of performing the office of good manure.

“ But if animal ſecretions, when applied in ſubſtance to plants, were capable of acting upon them, as is affirmed, in ſuch a way as to corrode or burn them, how could ſeed which has been ſwallowed, and eſcaped the action of the digeſtive powers, be prolific when thrown out by the animal, after having remained ſo long in its dung? yet we often ſee oats, ſo circumſtanced, grow and produce ſeed. Is it not more conſiſtent with experience and obſervation to ſuppoſe, that theſe excrementitious ſubſtances, being ſtill endowed with animal heat, and with an organic motion, diffuſe round plants in vegetation a deleterious principle or inflammable gas, which deſtroys them; for ſoon after their application, the foliage of the plant grows yellow, dries up, and the plant withers, unleſs there happens a ſhower of rain which

which revives it. When theſe ſubſtances are diluted, by being mixed with water and earth, they loſe that principle which is ſo deſtructive to vegetable life, and an incipient fermentation augments their power as a manure, ſo that they may be immediately made uſe of without any apprehenſion of injury from their effects.

" It appears, therefore, that any operation upon excrementitious ſubſtances, by which they are dried and reduced to powder, cannot be practiſed without depriving thoſe ſubſtances of a great part of ſuch of their principles as are eaſily evaporated, and upon which their fluidity depends; theſe principles, when diluted with water, and confined by being mixed with earth, are capable of increaſing the produce of the ſoil. Such is the way in which the huſbandmen in Flanders make uſe of this kind of manure, in the cultivation of a kind of rape or cole ſeed, which is to them a very important branch of agricultural induſtry and commerce; and they never obſerve that the ſap carries up any of thoſe principles which give ſuch manure its offenſive ſmell; nor do they obſerve, that the fodder produced from fields ſo manured, whether eaten freſh or dry, is diſagreeable to their cattle. The excrements of all animals would be injurious to plants, if applied too freſh, or in too great quantity; and a gardener could not commit a greater fault, than to put more than a certain quantity of them into the water he means to make uſe of to water his young plants; in ſhort, this kind of manure is to be uſed in a very ſparing manner; and he that is too prodigal of it will find, to his coſt, that exceſs, even of that which is otherwiſe beneficial, becomes an evil.

" It muſt certainly be allowed, that excrementitious ſubſtances are a very advantageous manure for cold ſoils, and ſuited to moſt vegetable productions; a long experience of their effects over a large tract of country, and the acknowledged intelligence of the Flemiſh farmers, ought to be conſidered as ſufficient to overcome the prejudice that has been raiſed againſt this ſort of manure. Suppoſing that the bad effects which have been attributed to it, when uſed in the ſtate in which it is taken out of privies, &c. are not the offspring of a prejudiced imagination, they may have ariſen from its having been made uſe of at an improper time, or in too great quantity; or from its having been applied to a ſoil and for the cultivation of plants to which it was not adapted; for we know that the exceſs of any kind of manure changes the ſmell and taſte of plants, and the ſame effect is produced by watering them too frequently. Striking examples of this change are ſeen in the ſtrawberry and in the violet, when ſuch as have grown in the woods are compared to thoſe produced from ſome of our over-manured gardens; alſo in the lettuce, and ſome other plants, when thoſe raiſed for ſale by the gardeners about Paris are compared to thoſe of ſome particular kitchen gardens. In the markets of ſome cities, the carrots, turnips, and potatoes of the fields, are preferred to the ſame kind of roots cultivated by the gardeners (A); for though the laſt are of a larger ſize, they have not ſo good a flavour. Some vegetables, therefore, are like certain wild ſpecies of the animal kingdom; they reſiſt every kind of culture, as thoſe animals reſiſt every effort to tame them.

" Although experience has taught the Flemiſh farmers, that excrementitious ſubſtances are more active in their natural ſtate than when dried, yet it cannot be denied that drying them, and reducing them into powder, is ſometimes very advantageous, becauſe in that ſtate they are much leſs offenſive, are eaſily tranſported to any diſtance, and may be uſed when moſt convenient or moſt proper. In many cities the inhabitants pay to have their privies emptied: in other places, thoſe who empty them pay for their contents; and it would aſtoniſh any one to be told how great a revenue is produced in the city of Liſle in Flanders by the ſale of this kind of manure. I am, however (ſays our author), far from thinking that it is right, in all caſes, to employ it in the above mentioned ſtate of concentration; it would be better, in my opinion, to follow the example of the Flemiſh farmers, who uſe it the firſt year for the cultivation of plants for oil, or for hemp or flax; and the ſecond year for the beſt kinds of grain: thus obtaining two crops, inſtead of one, without any farther preparation of the land. What is ſaid above may be applied alſo to the manures produced from the dung of cattle, poultry, &c. (particularly to pigeons dung, the moſt powerful manure of its kind), all which, by being dried and powdered before they are uſed, loſe a great portion of their activity. From theſe obſervations another fact may be deduced, namely, that manure ſhould not be taken from the place where it has been thrown together until the ſeaſon of the year and the ſtate of the land are ſuch that it may be put into the ground as ſoon as it is brought to it. In ſome diſtricts a very injurious cuſtom prevails of carrying the manure into the fields, and leaving it there formed into ſmall heaps, expoſed for ſome days to the elements; during which time, either the ſun and wind dry up its natural moiſture, leaving a maſs which is much leſs active; or the rain diſſolves and carries away the extractive part impregnated with the ſalt. This kind of brine, which is the moſt powerful part of the manure, penetrates the earth to a conſiderable depth, and ſhews (by the thick tufts which ariſe in thoſe places, and which produce more ſtraw than grain) that manure ought to be put into the ground as ſoon as it is brought to it, becauſe it then poſſeſſes its full force and effect, and conſequently would be then uſed to the greateſt advantage.

" We have always at hand the means of compoſing, from a great variety of vegetable and animal ſubſtances, ſuch manures as, when brought into a proper ſtate, and mixed with land, contribute to its fertility. Chemiſtry alſo offers to us a number of ſubſtances, which, although when uſed ſeparately they tend to diminiſh the fertiliſing quality of the earth, are yet capable, by being combined, of forming excellent manures; ſuch, for inſtance, is that ſaponaceous combination which is produced from a mixture of potaſh, oil, and earth. What an advantage it would be, if, inſtead of being ſparing of manure, the inhabitants of the country would endeavour to increaſe the number of theſe reſources, and to render them more beneficial, by employing them in a

more

(A) We believe they are univerſally preferable.

Manure, Maouana.

more effectual manner. How many years had paſſed before it was known that the refuſe of apples and pears, after they are preſſed (and which uſed to be thrown away as uſeleſs), is capable of forming as valuable a manure, in cyder and perry countries, as the refuſe of grapes does in wine countries."

From what has been obſerved, our author concludes, that manures act, in many circumſtances, like medicines, and conſequently that the ſame ſort of manure cannot be adapted to every ſituation, and every kind of ſoil; we muſt therefore take care to make proper diſtinctions between them. Whoever ſhall pretend that any particular kind of manure may be uſed, with equal benefit, in graſs land, corn-fields, vineyards, orchards, kitchen gardens, &c. ought to be claſſed amongſt thoſe quacks who undertake to cure all perſons with the ſame remedy, without any regard to their age, conſtitution, &c. It is probably from not having paid ſufficient attention to the forementioned diſtinctions, that ſome authors have found fault with particular manures, while others have ſpoken too highly in their favour. He thinks, however, and we agree with him, that we are ſtill in want of a courſe of comparative experiments upon the various kinds of manures, conſidered according to their influence with reſpect to different ſoils, ſituations, and productions. If this part of rural economy were better underſtood, we ſhould perhaps ſee many places in a ſtate of cultivation, which, on account of the bad quality of their ſoil, have hitherto reſiſted all our endeavours to render them fertile.

Perhaps it would not be proper to diſmiſs this ſubject without noticing Mr Middleton's obſervations on various kinds of manure, which were publiſhed in the Tranſactions of the Society of Arts for the year 1799. This gentleman agrees with Mr Parmentier in recommending the *excrementitious matter of privies* as the moſt powerful of all manures on ſome kinds of ſoil; but he differs from him, and we believe from moſt writers on agriculture, when he affirms, that *wood aſhes*, when ſpread on the graſs in February or March, are of very little ſervice, and that the aſhes of *coal* and even of *peat* are of none upon any kind of land. He likewiſe affirms *ſoot* to be of very little value as a manure, *ſoapmakers waſte* to be of none, or rather to be hurtful; and he ſeems to conſider *malt-duſt*, including the duſt from the malt-kilns, to be, after the ſoil of privies, one of the moſt powerful manures. He affirms, from his own experience, that, with reſpect to fertiliſing power, the ſoil of privies, compared with farm-yard dung, is in the proportion of five to one.

MAOUANA, one of that cluſter of iſlands in the South Sea which were diſcovered by M. Bougainville, and by him named Navigator's Iſlands. It was viſited by La Perouſe in 1787, who deſcribes it as exceedingly rich in every animal and vegetable production neceſſary to the ſuſtenance of man. The two frigates which he commanded had no ſooner approached the ſhore, than he diſcovered at the bottom of each creek a number of villages, from whence came innumerable canoes, laden with hogs, cocoa nuts, and other fruits, which were purchaſed for glaſs ware. This was in the evening; and next morning the commerce was renewed in the moſt friendly manner. As early as the dawn of day, the iſlanders had ſurrounded the two frigates with 200 canoes full of different kinds of proviſion, which they would exchange only for beads—in their eſtimation diamonds of the firſt water. Axes, cloth, and all other articles of commerce, they diſdained. Abounding in real bleſſings, they were deſirous of obtaining ſuperfluities alone.

Maouana.

Two boats, filled with empty caſks, were ſent aſhore for freſh water; and Perouſe himſelf accompanied them in his pinnace. A line of ſoldiers was poſted between the beach and the Indians, who amounted to about 200, including a great many women and children. The French commander prevailed upon them all to ſit down under cocoa trees, that were not more than eight toiſes diſtant from the ſhips boats. Each of them had by him fowls, hogs, parrots, pigeons, or fruit, and all wiſhed to ſell them at once, which occaſioned ſome confuſion.

The women, ſome of whom were very pretty, offered their favours, as well as their fowls and fruit, to all thoſe who had beads to give them; and ſoon tried to paſs through the line of ſoldiers, who oppoſed but a feeble reſiſtance to their attempts. Europeans who have made a voyage round the world, eſpecially Frenchmen, have no arms to ward off ſimilar attacks. Accordingly the fair ſavages found little difficulty in breaking the ranks; the men then approached; and the confuſion was growing general; when Indians, who ſeemed to be chiefs, made their appearance with ſticks in their hands, and reſtored order, every one returning to his poſt, and the traffic beginning anew, to the great ſatiſfaction of both buyers and ſellers.

While all this was paſſing with the greateſt tranquillity, and the caſks were filling with water, Perouſe thought he might venture to the diſtance of 200 yards to viſit a charming village, ſituated in the midſt of a wood, or rather of an orchard, all the trees of which were loaded with fruit. The houſes were placed upon the circumference of a circle, of about 150 toiſes in diameter, the interior forming a vaſt open ſpace, covered with the moſt beautiful verdure, and ſhaded by trees, which kept the air delightfully cool. Women, children, and old men, accompanied him, and invited him into their houſes. They ſpread the fineſt and freſheſt mats upon a floor formed of little choſen pebbles, and raiſed about two feet above the ground, in order to guard againſt humidity. He went into the handſomeſt of theſe huts, which probably belonged to a chief; and great was his ſurpriſe to ſee a large cabin of lattice-work, as well executed as any of thoſe in the environs of Paris. The beſt architect could not have given a more elegant curve to the extremities of the ellipſis that terminated the building; while a row of pillars, at five feet diſtance from each other, formed a complete colonnade round the whole. The pillars were made of trunks of trees very neatly wrought, and between them were fine mats laid over one another with great art, like the ſcales of a fiſh, and drawing up and down with cords, like our Venetian blinds. The reſt of the houſe was covered with leaves of the cocoa palm.

This charming country combines the advantages of a ſoil fruitful without culture, and of a climate which renders clothing unneceſſary. The trees that produce the bread-fruit, the cocoa-nut, the banana, the guava, and the orange, hold out to theſe fortunate people an abundance of wholeſome food; while the fowls, hogs, and dogs, which live upon the ſurplus of theſe fruits, afford them an agreeable variety of viands. What cold imagination could ſeparate the idea of happineſs from ſo

Maouana, Maſon.

ſo enchanting a place! But Maouana is not the abode of innocence. No arms were indeed perceived; but the bodies of the Indians, covered over with ſcars, proved that they were often at war, or elſe quarrelling among themſelves; while their features announced a ferocity that was not perceptible in the countenances of the women. Nature had, no doubt, ſtamped this character on their faces, by way of ſhewing, that the half ſavage, living in a ſtate of anarchy, is a more miſchievous being than the moſt ferocious of the brute creation.

Of their ferocity and their treachery, Perouſe had too ſoon the moſt complete evidence. M. de Langle, the ſecond in command, went aſhore for freſh water, accompanied by ſixty Frenchmen, officers, ſailors, and ſoldiers. They were received with an air of good humour by crowds of people waiting on the beach with immenſe quantities of fruit and hogs; but this calm was of ſhort duration. The Indians picked a quarrel with them, pelted them with ſtones, thrown with great dexterity and with equal force; and it was with difficulty that, of the ſixty-one, forty-nine reached the ſhips, many of whom were ſeverely wounded. Among the killed were De Langle, and Lamanon the naturaliſt (See LAMANON in this *Suppl.*). Perouſe deſcribes the men of Maouana as of gigantic ſtature, and of great muſcular ſtrength. See *NAVIGATORS Iſlands* in this *Suppl.*

MASON (the Rev. William) was a man of ſuch eminence both as a poet and as a ſcholar, that a more particular account of his life and of his ſtudies ſhould be publiſhed than our ſcanty materials enable us to give. He was born at Hull, where his father poſſeſſed the vicarage of St Trinity; but where he received his ſchool education we have not been able to learn. At the proper time he was admitted into St John's College, Cambridge; where he took the degrees of B. A. and M. A. and in 1747, he obtained a fellowſhip in Pembroke Hall. It was there that he contracted an intimate friendſhip with Gray the poet, and with Mr Hurd, now Biſhop of Worceſter. When the former of theſe gentlemen died, Mr Maſon took upon himſelf the office of editor of his works and guardian of his fame; and upon the promotion of the latter to the ſee of Litchfield and Coventry, he expreſſed his ſatisfaction in ſome beautiful verſes, which we read at the time, but do not recollect where.

In 1754 he entered into holy orders, and was patronized by the then Earl of Holderneſs, who obtained for him the appointment of chaplain to the king, and preſented him with the valuable rectory of Aſton in Yorkſhire. He was ſome time afterwards made precentor of York Cathedral, when he publiſhed a ſmall volume of church muſic, which has alternately met with oppoſition and applauſe. In our opinion ſome of his anthems are unrivalled.

It was natural for the precentor of a cathedral church, who was likewiſe a poet, to turn his attention to ſacred muſic; and Maſon had been a poet from his early years. His *Elfrida* and *Caractacus*, two tragedies on the Grecian model, were both publiſhed before the year 1757. Theſe two dramas, in the opinion of Dr Hurd, do honour to modern poetry, and are, according to him, a ſufficient proof of the propriety of reviving the chorus on the Britiſh ſtage. In this ſentiment few critics, we believe, will agree with his Lordſhip; but the tragedies have certainly great merit, and

Maſon.

tranſcend perhaps every poem of the ſame caſt in our own or any other modern tongue. In the firſt, the language is elegant and ſweet; in the latter, it is daring and ſublime. The author himſelf always conſidered the former as the moſt perfect; and Johnſon, whoſe critical judgment will not be raſhly queſtioned, ſeems to have been of the ſame opinion. Johnſon's partiality to Oxford, as is well known, made him embrace every opportunity of turning into ridicule Cambridge men and Cambridge poems; but while he boaſted of having ſpent hours in burleſquing Caractacus for the amuſement of his Oxford friends, he confeſſed that Elfrida was too beautiful to be hurt by ridicule. The voice of the public, however, ſeems to give the preference to the latter, and to conſider it as ſtanding, like Dryden's celebrated ode, without a rival. In both are ſentiments and expreſſions which would do honour to the genius of Shakeſpeare; and Caractacus, in the Greek verſion of Mr Glaſs, would not have diſgraced an Athenian theatre.

Beſides his two tragedies, Mr Maſon publiſhed many other poems. His Engliſh Garden is univerſally read and admired, being unqueſtionably the fineſt poem of the kind that has appeared ſince the days of Thomſon; though ſome have affected to conſider it as treating the ſubject rather with profeſſional ſkill than with poetical genius. That there are in it a few proſaic expreſſions we ſhall not controvert; for ſuch ſeem inſeparable from didactic poetry; but, taken as a whole, where ſhall we find its equal? His elegies, particularly that on the death of his wife, and that on the demiſe of Lady Coventry, have been generally read and extolled, though not more than they deſerve, as ſuperior in claſſic elegance to any thing of the kind in the Engliſh tongue, and expreſſing a manlineſs and tenderneſs of the pathetic, rarely found in the moſt poliſhed elegies of Roman writers. The ſplendor of genius, and accuracy of judgement, conſpicuous in his dramas, are equally diſplayed in his character as a lyric writer. His quarry was bold and impetuous, and he never ſwept the ground with an ignominious flight. In his Sappho and Phaon he has happily imitated the ſtyle of Dryden and Metaſtaſio; and at his death he was employed on a poem in which he propoſed to meaſure his ſtrength with Dryden.

We have reaſon to believe that this ingenious man was not only a poet and a muſical performer, but the inventor of the faſhionable inſtrument the Piano Forte. We cannot indeed at preſent bring evidence of this fact; but we have inſtituted ſuch inquiries as, we hope, ſhall enable us to aſcertain the truth under the article *PIANO Forte*.

Poetry and muſic, and the duties of his office, might be ſuppoſed to have employed all his time; but, unfortunately, he caught the alarm which in 1769 was ſpread over the nation by the expulſion of Mr Wilkes from the Houſe of Commons, and immediately inrolled himſelf among the ſupporters of the *Bill of Rights*. The deciſion of the Houſe, which pronounced Mr Lutteral duly elected in oppoſition to Mr Wilkes, he conſidered as a groſs violation of the rights of the people; and though he ſurely did not approve of the conduct of the exiled member, he joined with other freeholders in Yorkſhire in a petition to the king that he would diſſolve the parliament.

Being now leagued with the oppoſition, he joined in ſome violent clamours for a parliamentary reform. In the

the year 1779, when the city of London, and ſome other commercial towns, agreed to preſent their petitions to parliament for a more economical expenditure of the public money, and a more equal repreſentation of the people, Mr Maſon came forward, and took an active part in promoting theſe deſigns, as one who was convinced of their importance and neceſſity. When the county of York aſſembled, on the 30th of December 1779, and reſolved unanimouſly, "that a committee of correſpondence ſhould be appointed, for the effectually promoting the object of the petition then agreed to, and alſo to prepare a plan of *aſſociation* to ſupport that laudable reform, and ſuch other meaſures as may conduce to reſtore the *freedom of parliament*," he was choſen upon the committee, and was conſulted with, or aſſiſted in drawing up thoſe various high-ſpirited reſolutions and addreſſes to the public, for which the Yorkſhire committee was ſo celebrated; and which was afterwards generally adopted by the other aſſociated bodies of reformers. This part of his conduct is ſurely entitled to no praiſe. Thinking as we do of the parliamentary reformers, we cannot but regret that a man of Mr Maſon's talents and virtues ſhould have embarked in their dangerous purſuits; and though we perceived leſs hazard in thoſe purſuits than we do, we ſhould ſtill conſider them as unſuitable to the character of a clergyman. Our author, however, was of a different opinion. In reply to a cenſure paſſed by a dignified clergyman on the political conduct of himſelf and ſome of his reverend brethren, he publiſhed, without his name indeed, a ſpirited defence of their proceedings and deſigns in ſome of the country papers. The York committee, too, at its next meeting, reſolved, "that a Proteſtant, by entering into holy orders, does not abandon his civil rights;" they alſo reſolved, "that the thanks of the committee be given to thoſe reverend gentlemen who, thus preferring the public good to their own private emoluments, have ſtood forth the firm friends to the true intereſts of their country."

Mr Maſon, however, ſhowed, by his ſubſequent conduct, that however earneſtly he might wiſh for what he doubtleſs conſidered as an expedient reform in the commons-houſe of Parliament, he was firmly attached to the Britiſh conſtitution. He was indeed a whig; but he was a whig of the old ſchool. In the beginning of 1794, when the reformers had betrayed the principles of French democrates, he deſerted them, and ranged himſelf under the banners of the ſervants of the crown; and for this conduct, which was certainly conſiſtent, he has been plentifully traduced by our Jacobin journaliſts as an alarmiſt, who not only deſerted his old friends, but aſcribed to them a certain degree of guilt and political depravity.

The death of this great and good man, which happened in April 1797, was occaſioned neither by age nor by inveterate diſeaſe. As he was ſtepping into his chariot, his foot ſlipped, and his ſhin grazed againſt the ſtep. This accident had taken place ſeveral days before he paid the proper attention to it; and on April the 3d a mortification enſued, which, in the ſpace of forty-eight hours, put a period to his life.

That he was a ſcholar and a poet of high eminence is univerſally acknowledged; and we are aſſured, that his poſthumous works, when publiſhed, will not detract from his living fame. In private life, though he affected perhaps too much the faſtidious manners of Mr Gray, whoſe genius he eſtimated with a degree of enthuſiaſm amounting almoſt to idolatry, his character was diſtinguiſhed by philanthropy and the moſt fervid friendſhips; and he may be conſidered as a man who merits to be ranked with the ableſt ſupporters of Britiſh liberty and Britiſh morals.

FREE MASONRY, is a ſubject which, after the copious detail given in the *Encyclopædia* of its lodges, and wardens, and grand maſters, we ſhould not have reſumed in this place, but to warn our countrymen againſt the pernicious ſuperſtructures which have been raiſed by the French and Germans on the ſimple ſyſtem of Britiſh maſonry.

Much falſehood is current reſpecting the origin and antiquity of the maſonic aſſociations. That the Dionyſiacs of Aſia Minor were a ſociety of architects and engineers, who had the excluſive privilege of building temples, ſtadia, and theatres, under the myſterious tutelage of Bacchus, ſeems to be unqueſtionable. "We are alſo certain, that there was a ſimilar trading aſſociation during the dark ages in Chriſtian Europe, which monopolized the building of great churches and caſtles, and enjoyed many privileges under the patronage of the various ſovereigns. Circumſtances (ſays Dr Robiſon), which it would be tedious to enumerate and diſcuſs, continued this aſſociation longer in Britain than on the continent;" but there is no good evidence, that, anterior to the year 1648, any man ſought admiſſion into it, who was not either a builder by profeſſion, or at leaſt ſkilled in the ſcience of architecture. At that period, indeed, Mr Aſhmole, the famous antiquary (ſee ASHMOLE, *Encycl.*), was admitted into a lodge at Warrington, together with his father-in-law Colonel Mainwaring; and theſe are the firſt diſtinct and unequivocal inſtances that we have in Britain of men unconnected with the operative maſons being received into their myſterious fraternity. The ſecrecy, however, of the lodges, made them fit places for the meetings of the royaliſts; and accordingly many royaliſts became free maſons. "Nay, the ritual of the maſter's degree ſeems to have been formed, or perhaps twiſted from its original inſtitution, ſo as to give an opportunity of ſounding the political principles of the candidate, and of the whole brethren preſent. For it bears ſo eaſy an adaptation to the death of the king, to the overturning of the venerable conſtitution of the Engliſh government of three orders by a mean democracy, and its re-eſtabliſhment by the efforts of the loyaliſts, that this would ſtart into every perſon's mind during the ceremonial, and could hardly fail to ſhew, by the countenances and behaviour of the brethren, how they were affected."

This ſuppoſition receives much countenance from the well known fact, that "Charles II. was made a maſon, and frequented the lodges. It is not unlikely, that beſides the amuſement of a vacant hour, which was always agreeable to him, he had pleaſure in meeting with his loyal friends, and in the occupations of the lodge, which recalled to his mind their attachment and ſervices. His brother and ſucceſſor James II. was of a more ſerious and manly caſt of mind, and had little pleaſure in the frivolous ceremonies of maſonry. He did not frequent the lodges. But, by this time, they were the reſort of many perſons who were not of the profeſſion, or members of the trading corporation. This circumſtance,

ſtance, in all probability, produced the denominations of *free* and *accepted* maſons. A perſon who has the privilege of working at any incorporated trade, is ſaid to be a *freeman* of that trade. Others were *accepted* as brethren, and admitted to a kind of honorary freedom; as is the caſe in many other trades and incorporations, without having (as far as we can learn for certain) a legal title to earn a livelihood by the exerciſe of it."

It was not till ſome years after this period that the lodges made open profeſſion of the cultivation of general benevolence, and that the grand aim of the fraternity was to enforce the exerciſe of all the ſocial virtues. The eſtabliſhment of a fund for the relief of unfortunate brethren did not take place till the very end of the laſt century; and we may preſume, that it was brought about by the warm recommendations of ſome benevolent members, who would naturally enforce it by addreſſes to their aſſembled brethren. Hence the probable origin of thoſe philanthropic diſcourſes, which are occaſionally delivered in the lodges by one of the brethren as an official taſk.

The boaſted philanthropy of maſons ſerves, however, another purpoſe. The inquiſitive are always prying and teazing, eager to diſcover the ſecrets of their neighbours; and hence the brethren are induced to ſay, that univerſal beneficence is the great aim of the order, for it is the only point on which they are at liberty to ſpeak. They forget, that univerſal beneficence and philanthropy are inconſiſtent with the excluſive and monopolizing ſpirit of an aſſociation, which not only confines its benevolence to its own members (like any other charitable aſſociation), but hoards up in its boſom ineſtimable ſecrets, whoſe natural tendency, they ſay, is to form the heart to this generous and kind conduct, and inſpire us with love to all mankind. The profane world cannot ſee the beneficence of concealing from public view a principle or a motive which ſo powerfully induces a maſon to be good and kind. The brother ſays, that publicity would rob it of its force; and we muſt take him at his word: and our curioſity is ſo much the more excited, to learn what are the ſecrets which have ſo ſingular a quality, for they muſt be totally unlike the principles of ſcience, which produce their effects only when made public.

From this account of maſonry, it would appear to have been at firſt a loyal aſſociation, and as ſuch it was carried over from England to the continent; for all the maſons abroad profeſs to have received their myſteries from Great Britain. It was firſt tranſported into France by the zealous adherents of King James, who, together with their unfortunate maſter, took refuge in that country; and it was cultivated by the French in a manner ſuited to the taſte and habits of that highly poliſhed and frivolous people. To the three ſimple Britiſh degrees of *apprentice*, *fellow-craft*, and *maſter*, they gradually added degrees innumerable, all decorated with ſtars and ribbons; and into their lodges they introduced the impieties and ſeditious doctrines of Voltaire and the other philoſophiſts. Indeed, if the account which the Abbé Barruel gives of maſonry be juſt, it muſt be admitted, that even the ſecrets of the moſt ancient lodges, though in one ſenſe harmleſs and juſt, are ſo expreſſed, that they may be eaſily twiſted to very dangerous purpoſes. This author was advanced by a few friends to the degree of maſter, without being obliged to take the oath of ſecrecy; and being furniſhed with the ſigns, he got admiſſion into a lodge, where he heard the ſecret regularly communicated, with all the ordinary forms, to an apprentice. "It would be uſeleſs, ſays he, to deſcribe the ceremonials and trials on ſuch occaſions; for in the firſt degrees, they are nothing more than the play of children. The grand object was the communication of the famous ſecret, when the candidate was ordered to approach nearer to the venerable. At that moment, the brethren, who had been armed with ſwords for the occaſion, drawing up in two lines, held their ſwords elevated, leaning the points towards each other, and formed what in maſonry is called the *arch of ſteel*. The candidate paſſed under this arch to a ſort of altar elevated on two ſteps, at the fartheſt end of the lodge. The maſter, ſeated in an arm chair, or a ſort of throne, behind this altar, pronounced a long diſcourſe on the inviolability of the ſecret which was to be imparted, and on the danger of breaking the oath which the candidate was going to take. He pointed to the naked ſwords, which were always ready to pierce the breaſt of the traitor; and declared to him that it was impoſſible to eſcape their vengeance. The candidate then ſwore, "that rather than betray the ſecret, he conſented to have his head cut off, his heart and entrails torn out, and his aſhes caſt before the winds." Having taken the oath, the maſter ſaid the following words to him: "My dear brother, the ſecret of maſonry conſiſts in theſe words, EQUALITY AND LIBERTY; *all men are equal and free; all men are brethren.*" The maſter did not utter another ſyllable, and every body embraced the new *brother equal and free.* The lodge broke up, and we gayly adjourned to a maſonic repaſt."

In the Britiſh lodges, the author admits, that no other interpretation is given to this famous ſecret, than that, as all men are children of one common parent, and creatures of the ſame God, they are in duty bound to love and help each other as brethren; but he contends, that in France it was differently interpreted; and he ſupports his opinion by the following arguments:

On the 12th of Auguſt 1792, Louis XVI. was carried a priſoner to the tower of the *temple*, ſo called becauſe it formerly belonged to the knights templars. On that day, the rebel aſſembly decreed, that to the date of *liberty* the date of *equality* ſhould be added in future in all public acts; and the decree itſelf was dated the fourth year of *liberty*, the firſt year and firſt day of *equality*. It was on that day, for the firſt time, that the ſecret of free-maſonry was made public; that ſecret ſo dear to them, and which they preſerved with all the ſolemnity of the moſt inviolable oath. At the reading of this famous decree, they exclaimed, "We have at length ſucceeded, and France is no other than an immenſe lodge. The whole French people are free maſons, and the whole univerſe will ſoon follow their example."

"I witneſſed (ſays our author) this enthuſiaſm; I heard the converſations to which it gave riſe; I ſaw maſons, till then the moſt reſerved, who freely and openly declared, 'Yes, at length the grand object of free-maſonry is accompliſhed, EQUALITY and LIBERTY; *all men are equal and brothers; all men are free.* That was the whole ſubſtance of our doctrine, the object of our wiſhes, *the whole of our grand ſecret!*"

This is a very ſerious charge againſt the original ſecret of maſonry, as it was underſtood in France ; and though the author does not bring it directly againſt the ſame ſecret as underſtood in Britain, he yet ſeems to ſay, that in *all* lodges, the following queſtion is put to the candidate before he is entruſted with any ſecret :— " Brother, are you diſpoſed to execute all the orders of the grand-maſter, though you were to receive contrary orders from a king, an emperor, or any other ſovereign whatever ?" And as the brother is obliged to promiſe this unlimited obedience, it is eaſy to conceive how much a traiterous conſpiracy may be promoted by means of maſon lodges. The allegorical ſtory which is told at the conferring of the degree of maſter, is capable of various and even contrary interpretations ; for though in this country it was originally rendered ſubſervient to the purpoſes of the royaliſts, in the occult lodges on the continent it has been made the vehicle of treaſon and impiety.

When the degree of maſter-maſon is to be conferred, the lodge is hung round with black. In the middle is a coffin covered with a pall, the brethren ſtanding round it in attitudes denoting ſorrow and revenge. When the new adept is admitted, the maſter relates to him the following hiſtory or fable :

" Adoniram preſided over the payment of the workmen who were building the temple by Solomon's orders. They were three thouſand workmen. That each one might receive his due, Adoniram divided them into three claſſes, apprentices, fellow-crafts, and maſters. He entruſted each claſs with a word, ſigns, and a gripe, by which they might be recogniſed. Each claſs was to preſerve the greateſt ſecrecy as to theſe ſigns and words. Three of the fellow-crafts, wiſhing to know the word, and by that means obtain the ſalary, of maſter, hid themſelves in the temple, and each poſted himſelf at a different gate. At the uſual time when Adoniram came to ſhut the gates of the temple, the firſt of the three met him, and demanded the *word of the maſters ;* Adoniram refuſed to give it, and received a violent blow with a ſtick on his head. He flies to another gate, is met, challenged, and treated in a ſimilar manner by the ſecond : flying to the third door, he is killed by the fellow-craft poſted there, on his refuſing to betray the word. His aſſaſſins buried him under a heap of rubbiſh, and marked the ſpot with a branch of acacia.

" Adoniram's abſence gave great uneaſineſs to Solomon and the maſters. He is ſought for every where : at length one of the maſters diſcovers the corpſe, and, taking it by the finger, the finger parted from the hand ; he took it by the wriſt, and it parted from the arm ; when the maſter, in aſtoniſhment, cried out, *Mac Benac ;* which the craft interprets by " *the fleſh parts from the bones.*"

" Leſt Adoniram ſhould have revealed the *word*, the maſters convened and agreed to change it, and to ſubſtitute the words *Mac Benac ;* ſacred words, that free-maſons dare not pronounce out of the lodges, and there each only pronounces one ſyllable, leaving his neighbour to pronounce the other."

The hiſtory finiſhed, the adept is informed, that the object of the degree he has juſt received is to recover the word loſt by the death of Adoniram, and to revenge this martyr of the maſonic ſecrecy. The generality of maſons, looking upon this hiſtory as no more than a fable, and the ceremonies as puerile, give themſelves very little trouble to ſearch farther into theſe myſteries.

Theſe ſports, however, aſſume a more ſerious aſpect when we arrive at the degree of elect (*Elu*). This degree is ſubdivided into two parts ; the firſt has the revenging of Adoniram for its object, the other to recover the *word*, or rather the ſacred doctrine which it expreſſed, and which has been loſt.

In this degree of elect, all the brethren appear dreſſed in black, wearing a breaſt-piece on the left ſide, on which is embroidered a death's head, a bone, and a poignard, encircled by the motto of *Conquer or die.* The ſame motto is embroidered on a ribband which they wear in ſaltier. Every thing breathes death and revenge. The candidate is led into the lodge blindfolded, with bloody gloves on his hands. An adept with a poignard in his hand threatens to run him through the heart for the crime with which he is accuſed. After various frights, he obtains his life, on condition that he will revenge the father of maſonry in the death of his aſſaſſin. He is ſhewn to a dark cavern. He is to penetrate into it ; and they call to him, Strike all that ſhall oppoſe you ; enter, defend yourſelf, and avenge our maſter ; at that price you ſhall receive the degree of elect. A poignard in his right hand, a lamp in his left, he proceeds ; a phantom oppoſes his paſſage ; he hears the ſame voice repeat, Strike, avenge Hiram, there is his aſſaſſin. He ſtrikes, and the blood flows.—Strike off his head, the voice repeats ; and the head of the corpſe is lying at his feet. He ſeizes it by the hair (A), and triumphantly carries it back as a proof of his victory ; ſhows it to each of the brethren, and is judged worthy of the new degree.

Our author ſays, that he has queſtioned divers maſons whether this apprenticeſhip to ferocity and murder had never given them the idea, that the head to be cut off was that of kings ; but they all affirmed that ſuch an idea had never occurred to them till the French revolution had convinced them of the fact. At this indeed we are not ſurpriſed. The aſſaſſin of Hiram is no where ſaid to have been a king ; and why ſhould the young elect have ſuppoſed, that when ſtabbing that aſſaſſin, he was training to be a regicide ? The ceremony, however, is certainly ferocious in the higheſt degree, and obviouſly calculated to reconcile the maſons of the occult lodges to the practice of aſſaſſination at the command of their ſuperiors ; and when it is remembered, that they are bound to pay obedience to thoſe unſeen ſuperiors even againſt their lawful ſovereigns, the atrocities of the revolution would naturally make them interpret this ſhocking ceremony as it is interpreted by the Abbé.

It was the ſame with reſpect to the religious part of this degree, where the adept is at once pontiff and ſacrificer with the reſt of the brethren. Veſted in the ornaments of the prieſthood, they offer bread and wine, according to the order of Melchiſedec. The ſecret object of this ceremony is to re-eſtabliſh religious equality, and to exhibit all men equally prieſts and pontiffs, to recal the brethren to natural religion, and to perſuade them that the religion of Moſes and of Chriſt had violated religious equality and liberty by the diſtinction

---

(A) The reader may eaſily conceive that this corpſe is no more than a mannikin containing bladders full of blood.

of prieſts and laity. It was the revolution again which opened the eyes of many of the adepts, who then owned that they had been dupes to this impiety, as they had been to the regicide eſſay in the former part.

Our author treats the fraternity of the occult lodges through the higher degrees of Scotch maſonry, thoſe of the Roſicrucians, and that of the knights Kadoſch; and ſums up his account in the following terms:

“ In the two firſt degrees, that is to ſay, in thoſe of *apprentice* and *fellow-craft*, the ſect begins by throwing out its equality and liberty. After that, it occupies the attention of its novices with puerile games of fraternity or maſonic repaſts; but it already trains its adepts to the profoundeſt ſecrecy by the moſt frightful oaths.

“ In that of *maſter*, it relates the allegorical hiſtory of Adoniram, who is to be avenged; and of the *word*, which is to be recovered.

“ In the degree of *elect*, it trains the adepts to vengeance, without pointing out the perſon on whom it is to fall. It carries them back to the time of the patriarchs, when, according to them, men knew no religion but that of nature, and when every body was equally prieſt and pontiff. But it had not as yet declared that all religion revealed ſince the time of the patriarchs was to be thrown aſide.

“ This laſt myſtery is only developed in the Scotch degrees. There the brethren are declared free: The word ſo long ſought for is, Deiſm; it is the worſhip of Jehovah, ſuch as was known to the philoſophers of nature. The true maſon becomes the pontiff of Jehovah; and ſuch is the grand myſtery by which he is extricated from that darkneſs in which the prophane are involved.

“ In the degree *Roſæ Crucis*, he who wreſted the *word*, who deſtroyed the worſhip of Jehovah, is Chriſt himſelf, the author of Chriſtianity; and it is on the Goſpel and on the Son of Man that the adept is to avenge the brethren, the pontiffs of Jehovah.

“ At length, on his reception as Kadoſch, he learns that the aſſaſſin of Adoniram is the king, who is to be killed to avenge the grand maſter Molay, and the order of the maſons ſucceſſors of the knights templars. The religion which is to be deſtroyed to recover the *word*, or the true doctrine, is the religion of Chriſt, founded on revelation. This word in its full extent is *equality* and *liberty*, to be eſtabliſhed by the total overthrow of the altar and the throne.

“ Such are the incipient degrees, the proceſs, and the whole ſyſtem of maſonry; it is thus that the ſect, by its gradual explanation of its twofold principle of *equality* and *liberty*, of its allegory of the founder of maſonry to be avenged, of the word to be recovered, leading the adepts from ſecret to ſecret, at length initiates them into the whole Jacobinical code of revolution.”

If this account of maſonry be not greatly exaggerated, what are we to think of thoſe men among ourſelves, who, ſince the publication of the Abbé Barruel's book and Dr Robiſon's, have diſplayed a zeal for the propagation of their myſteries, by which they ſeemed not to be formerly actuated, and to which the importance of the buſineſs that, by their own account, is tranſacted in the lodges, cannot be thought to bear an adequate proportion? It is not enough to ſay that Britiſh maſonry is harmleſs, and that the *equality* and *liberty* taught in our lodges are the equality and liberty taught in the bible. Without directly queſtioning this aſſertion, we only beg leave to put our countrymen in remembrance, that French and German maſonry, as it was derived from Britain, muſt have been originally as harmleſs as our own; and to call their attention to the monſtrous ſuperſtructures of impiety and rebellion which in theſe countries have been raiſed upon our foundation. Have there been no ſymptoms of ſedition and irreligion among us, ſince the commencement of the French revolution, that we ſhould be ſo confident that the equality and liberty of our lodges will never degenerate into the equality and liberty of the French Jacobins? This cannot be ſaid; for it has been proved, that there are ſeveral occult lodges in Britain; and what ſecurity have we, or what ſecurity can we receive, that their number will not increaſe? The legiſlature indeed has lately laid ſome ſalutary reſtraints on the meetings of maſons; but ſuch is the nature of theſe meetings, that nothing can effectually ſecure us againſt the introduction of the higher myſteries, but the voluntary ſhutting up for a time of all lodges. This has been done by the honeſt maſons in Germany; and why may it not be done by the maſons in Britain? The fund for the relief of poor brethren may ſurely be managed without ſecrecy; the ſigns and gripe may be communicated without the *word*, or exacting a promiſe of implicit obedience; and the relinquiſhing of the joys of a ſocial hour would be no great ſacrifice to the peace of a country.

But is Britiſh maſonry really ſo harmleſs as the younger maſons wiſh us to believe? The writer of theſe reflections was never initiated in its myſteries, and therefore cannot, from his own knowledge, ſay what is their tendency; but he has no heſitation to affirm, becauſe he believes himſelf able to demonſtrate, that it is groſsly immoral to promiſe implicit obedience to unknown ſuperiors, or to ſwear that one will keep inviolate a ſecret, to the nature of which he is an abſolute ſtranger. He hopes, indeed, and is inclined to believe, that, in the decent lodges of Britain, the candidate is aſſured, before he is required to take the oath, that the ſecret to be communicated, and the obedience which he is to pay, militate in no reſpect againſt the civil government or the religion of his country; but ſtill if the ſecret contain information of value, it is, in his opinion, ſinful to keep it a ſecret; and he cannot conceive upon what principle a native of Britain can promiſe unlimited obedience to any human being. The myſteries of maſonry muſt relate to ſomething which is either important and laudable; frivolous, though innocent; or dangerous and immoral. To confine to a ſect any information which is laudable and important, is ſurely not to act the part of genuine philanthropiſts; to adminiſter the moſt tremendous oaths in the midſt of frivolous amuſements, is to violate one of the moſt ſacred precepts of our holy religion; and, as no man will pretend to vindicate dangerous and immoral myſteries, maſonry appears, in every point in which it can be placed, an aſſociation which no good Chriſtian will think himſelf at liberty to encourage.

MASUAH (See MASSUAH, *Encycl.*) is in latitude 15° 35′ 5″ north, and in longitude 39° 36′ 30″ eaſt of Greenwich. On the 22d of September 1769 Mr Bruce found the variation of the needle at Maſuah to be 12° 48′ weſt.

MATMAI, or MATSUMAI, is the largeſt of the Kurile iſlands; and if it be not independent, is tributary

Mayorga, Mayow.

to Japan. The capital town of the ſame name, Matmai, is ſituated on the ſea-ſhore, on the ſouth-weſt ſide. It was built and is inhabited by the Japaneſe. It is a fortified place, furniſhed with artillery, and defended by a numerous garriſon. The iſland of Matmai is the place of exile for perſons of diſtinction at Japan: it is ſeparated from that empire by only a narrow channel, but which is conſidered as dangerous, becauſe the capes, which project on both ſides, render the navigation difficult The people are ſaid to be ſenſible to friendſhip, hoſpitable, generous, and humane.

MAYORGA (Martin de). See *Don Martin*, &c. in this *Suppl.*

MAYOW (John), whoſe diſcoveries in chemiſtry have aſtoniſhed the ſcientific part of the public, deſcended, ſays Wood, from a genteel family living at *Bree* in the county of *Cornwall*. His father was probably a younger ſon, bred to buſineſs; for our author was born in Fleet-ſtreet, London, in the pariſh of St Dunſtan's in the Weſt. At what ſchool he received the rudiments of his education, a circumſtance which the biographers of men eminent in the republic of letters ſhould never omit, we have not been able to learn; but on the 27th of September 1661, when he had juſt completed his 16th year, he was admitted a ſcholar of Wadham college, Oxford. Some time afterwards, on the recommendation of Henry Coventry, Eſq; one of the ſecretaries of ſtate, he was choſen probationer fellow of All-ſouls college. As Wood informs us that he had here a *Legiſt's place*, an expreſſion by which we underſtand a law fellowſhip, it is not wonderful that he took his degrees in the civil law, though phyſic and the phyſical ſciences were the favourite objects of his ſtudy. He was indeed an eminent phyſician, practiſing both in London and in Bath, but in the latter city chiefly in the ſummer months, till the year 1679, when he died, ſome time during the month of September, in the houſe of an apothecary in York-ſtreet, Covent Garden, and was buried in the church of that pariſh He had been married, ſays Wood, a little before his death, not altogether to his content; and indeed he muſt have been very diſcontented, if he choſe to die in the houſe of a friend rather than in his own. He publiſhed, "Tractatus quinque medico phyſici, 1. De ſalnitro; 2. De reſpiratione; 3. De reſpiratione fœtus in utero et ovo; 4. De motu muſculari et ſpiritibus animalibus; 5. De Rachitide." Theſe were publiſhed together in 8vo at Oxford, in 1674; but there is an edition of two of them, "De reſpiratione," and "De Rachitide," publiſhed together at Leyden in 1671.

The fame of this author has been lately revived and extended by Dr Beddoes, who publiſhed, in 1790, "Chemical Experiments and Opinions, extracted from a work publiſhed in the laſt century," 8vo; in which he gives to Mayow the higheſt credit as a chemiſt, and aſcribes to him ſome of the greateſt modern diſcoveries reſpecting air, giving many extracts from the three firſt of his treatiſes. His chief diſcovery was, that oxygen gas, to which he gave the name of *fire air*, exiſts in the nitrous acid, and in the atmoſphere; which he proved by ſuch deciſive experiments, as to render it impoſſible to explain how Boyle and Hales could avoid availing themſelves, in their reſearches into air, of ſo capital a diſcovery. Mayow alſo relates his manner of paſſing aeriform fluids under water, from veſſel to veſſel, which is generally believed to be a new art. He did not collect dephlogiſticated air in veſſels, and transfer it from one jar to another, but he proved its exiſtence by finding ſubſtances that would burn in vacuo, and in water when mixed with nitre; and after animals had breathed and died in veſſels filled with atmoſpheric air, or after fire had been extinguiſhed in them, there was a reſiduum which was the part of the air unfit for reſpiration, and for ſupporting fire; and he further ſhewed, that nitrous acid cannot be formed, but by expoſing the ſubſtances that generate it to the atmoſphere. Mayow was undoubtedly no common man, eſpecially ſince, if the above dates are right, he was only 34 at the time of his death. But he was not ſo unknown as Dr Beddoes ſuppoſed; for ſince the repetition of the ſame diſcovery by Prieſtley and Scheele, reference has frequently been made by chemiſts to Mayow as the original inventor; thus allowing to him a ſpecies of merit, to which he has perhaps but a doubtful claim, and which, if that claim be well founded, muſt certainly be ſhared between him and Dr Hooke. See HOOKE in this *Supplement*.

Mean, Meaſure

MEAN, in general. See *Encycl.*

Arithmetical Mean, is half the ſum of the extremes. So 4 is an arithmetical mean between 2 and 6, or between 3 and 5, or between 1 and 7; alſo an arithmetical mean between a and b is $\frac{a+b}{2}$, or $\frac{1}{2}a+\frac{1}{2}b$.

Geometrical Mean, commonly called a mean proportional, is the ſquare root of the product of the two extremes; ſo that, to find a mean proportional between two given extremes, multiply theſe together, and extract the ſquare root of the product. Thus, a mean proportional between 1 and 9, is $\sqrt{1\times9}=\sqrt{9}=3$; a mean between 2 and $4\frac{1}{2}$ is $\sqrt{2\times4\frac{1}{2}}=\sqrt{9}=3$ alſo; the mean between 4 and 6 is $\sqrt{4\times6}=\sqrt{24}$; and the mean between a and b is $\sqrt{ab}$.

Harmonical Mean. See *Harmonical Proportion*, Encycl.

Mean and Extreme Proportion, or *Extreme and Mean Proportion*, is when a line or any quantity is ſo divided that the leſs part is to the greater, as the greater is to the whole.

Mean Anomaly of a Planet, is an angle which is always proportional to the time of the planet's motion from the aphelion or perihelion, or proportional to the area deſcribed by the radius vector; that is, as the whole periodic time in one revolution of the planet, is to the time paſt the aphelion or perihelion, ſo is 360° to the mean anomaly. See ANAMOLY, *Encycl.*

Mean Conjunction or *Oppoſition*, is when the mean place of the ſun is in conjunction, or oppoſition, with the mean place of the moon in the ecliptic.

Mean Diſtance of a Planet from the Sun, is an arithmetical mean between the planet's greateſt and leaſt diſtances.

Mean Motion, is that by which a planet is ſuppoſed to move equably in its orbit; and it is always proportional to the time.

Mean Time, or *Equal Time*, is that which is meaſured by an equable motion, as a clock; as diſtinguiſhed from apparent time, ariſing from the unequal motion of the earth or ſun.

UNIVERSAL or PERPETUAL MEASURE, is a kind of of meaſure unalterable by time or place, to which the meaſures of different ages and nations might be reduced, and by which they may be compared and eſtimated. Such a meaſure would be very uſeful if it could be attained; ſince, being uſed at all times, and in all places, a great deal of confuſion and error would be avoided.

It has been attempted, at different times and in different countries, more eſpecially by the French, who, ſince the commencement of their revolutionary government, have laboured hard to obtrude their innovations in arts and ſcience, as well as in politics, upon all nations. Propoſals, however, have been made by ſoberer men for a ſtandard both of weights and of meaſures for all nations; and ſome of the moſt rational of theſe ſhall be noticed under the word WEIGHTS in this *Supplement*.

MECHANICS.—Our readers will recollect that in the article PHYSICS, *Encycl.* we propoſed to diſtinguiſh by the term *Mechanical Philoſophy* that part of natural ſcience which treats of the local motions of bodies, and the cauſes of thoſe phenomena. And, although all the changes which we obſerve in material nature are accompanied by local motion, and, when completely explained, are the effects (perhaps very remote) of thoſe powers of matter which we call *moving forces*, and of thoſe alone, yet, in many caſes, this local motion is not obſerved, and we only perceive certain ultimate reſults of thoſe changes of place. This is the caſe (for example) in the ſolution of a grain of ſilver in a phial of aquafortis. In the beginning of the experiment, the particles of ſilver are contained in a ſmall ſpace at the bottom of the phial; but they are finally raiſed from the bottom, and uniformly diſſeminated over the whole fluid. If we fix our attention ſteadily on one particle, and trace it in its whole progreſs, we contemplate nothing but a particle of matter acted on by moving forces, and yielding to their action. Could we ſtate, for every ſituation of the particle, the direction and intenſity of the moving force by which it is impelled, we could conſtruct a figure, or a formula, which would tell us the preciſe direction and velocity with which it changes its place, and we could delineate its path, and tell the time when it will arrive at that part of the veſſel where it finally reſts in perfect equilibrium. Newton having done all this in the caſe of bodies acted on by the moving force called gravity, has given us a complete ſyſtem of mechanical aſtronomy. The philoſopher who ſhall be as fortunate in aſcertaining the paths and motions of the particles of ſilver, till the end of this experiment, will eſtabliſh a ſyſtem of the mechanical ſolution of ſilver in aquafortis; and the theorems and formulæ which characteriſe this particular moving force, or this modification of force, ſtating the laws of variation by a change of diſtance, will be the complete theory of this chemical fact. It is this modification of moving force which is uſually (but moſt vaguely) called the *chemical affinity*, or the *elective attraction of ſilver and aquafortis*.

But, alas! we are, as yet, far from having attained this perfection of chemical knowledge. All that we have yet diſcovered is, that the putting the bit of ſilver into the ſpirit of ſalt will not give occaſion to the exertion of this moving force; and we expreſs this obſervation, by calling that unknown force (unknown, becauſe we are ignorant of the law of its action) an *affinity*, an *elective* attraction. And we have obſerved many ſuch elections, and have been able to claſs them, and to tell on what occaſions they will or will not be exerted; and this ſcrap of the complete theory becomes a moſt valuable acquiſition, and the claſſification of thoſe ſcraps a moſt curious, and extenſive, and important ſcience. The chemical philoſopher has alſo the pleaſure of ſeeing gradual approaches made by ingenious men to the complete mechanical explanation of theſe unſeen motions and their cauſes, of which he has arranged the ultimate reſults.

The ordinary chemiſt, however, and even many moſt acute and penetrating enquirers, do not think of all theſe motions. Familiarly converſant with the reſults, they conſider them as principles, and as topics to reaſon from. They think a chemical phenomenon ſufficiently explained, when they have pointed out the affinity under which it is arranged. Thus they aſcribe the propagation of heat to the expanſive nature of fire, and imagine that they conceive clearly how the effect is produced. But if a mathematical philoſopher ſhould ſay, "What is this which you call an expanſive fluid? Explain to me diſtinctly, in what manner this property which you call expanſiveneſs operates in producing the propagation of heat."—We imagine that the chemiſt would find himſelf put to a ſtand. He will then, perhaps for the firſt time, try to form a diſtinct conception of an expanſive fluid, and its manner of operation. He will naturally think of air, and will reflect on the manner in which air actually expands or occupies more room; and he will thus contemplate local motion and mechanical preſſure. He will find, too late, that this gives him no aſſiſtance; becauſe the phenomena which he has been accuſtomed to explain by the expanſiveneſs of fluids have no reſemblance whatever to what we ſee reſult from the actual expanſion of air. Experience has made him acquainted with many effects which the air produces during its expanſion; but they are of a totally different kind from thoſe which he thought that he had ſufficiently explained by the expanſiveneſs of fire. The only reſemblance he obſerves is, that the air and the heat, which were formerly perceived only in a ſmall ſpace, now appear in a much larger ſpace. The mathematician now deſires him to tell in what manner he conceives this expanſiveneſs, or this actual expanſion of air or gas. The chemiſt is then obliged to conſider the air or gas as conſiſting of atoms or particles, which muſt be kept in their preſent ſituation by an external force, the moſt familiar of all to his imagination, namely, preſſure; and all preſſures are equally fit. Preſſure is a moving force, and can only be oppoſed to ſuch another moving force; therefore expanſiveneſs ſuppoſes, that the particles are under the influence of ſomething which would ſeparate them from each other, if it were not oppoſed by ſomething *perfectly of the ſame kind*. It cannot be oppoſed by greenneſs, nor by loudneſs, nor by fear, but only by what is competent to the production of motion; and it may be oppoſed by any *ſuch* natural power; therefore by gravity, or by magnetiſm, or electricity, or corpuſcular attraction, or by an elective attraction. The chemiſt, being thus led to the contemplation of the phenomenon in its moſt ſimple ſtate, can now judge with ſome diſtinctneſs, what is the nature of thoſe powers with which expanſiveneſs can

be

be brought to co-operate or combine. And only now will he be able to ſpeculate on the means for explaining the propagation of heat; and he will perceive, that the general laws of motion, and of the action of moving forces (doctrines which we comprehended under the title of DYNAMICS, *Suppl.*), muſt be reſorted to for a *complete* explanation of all chemical phenomena. The ſame may be ſaid of the phenomena perceived in the growth of vegetables and animals. All of them lead us ultimately to the contemplation of an atom, which is characteriſed by being ſuſceptible of local motion, and requires for this purpoſe the agency of what we call a moving force.

We would diſtinguiſh this particular OBJECT of our CONTEMPLATION (conſiſting of two conſtituent parts, the atom and the force, related, in fact, to each other by conſtant conjunction) by the term MECHANISM. We conceive it to be the characteriſtic of what we call MATTER; and we would conſider it as the moſt ſimple MECHANICAL PHENOMENON. We are diſpoſed to think, that this moving force is as ſimple and uniform as the atom to which it is related; and we would aſcribe the inconceivable diverſity of the moving forces which we ſee around us to combinations of this univerſal force exerted by many atoms at once; and therefore modified by this combination, in the very ſame manner as we frequently ſee thoſe ſeemingly different moving forces combine their influence on a ſenſible maſs of tangible matter, giving it a ſenſible local motion. Having formed ſuch notions, we would ſay that we do not conceive either the atom or the force as being matter, but the two thus related. And we would then ſay, that whatever object of contemplation does not ultimately lead us to this complex notion is IMMATERIAL; meaning by the epithet nothing more than the negation of this particular character of the object. It is equivalent to ſaying, that the phenomenon does not lead the mind to the conſideration of an atom actuated by a moving force; that is, moved, or prevented from moving, by an oppoſite preſſure or force.

Such is the extenſion which the diſcoveries of laſt century have enabled us to give to the uſe of the term mechaniſm, mechanical action, mechanical cauſe, &c.

The Greeks, from whom we have borrowed the term, gave it a much more limited meaning; confining it to thoſe motions which are produced by the intervention of machines. Even many of the naturaliſts of the preſent day limit the term to thoſe motions which are the *immediate* conſequences of impulſe, and which are caſes of ſenſible motion. Thus the chemiſt ſays, that printers ink is a mechanical fluid, but that ink for writing is a chemical fluid. We make no objection to the diſtinction, becauſe chemiſtry is really a vaſt body of real and important ſcience, although we have, as yet, been able to claſs only very complicated phenomena, and are far from the knowledge of its elements. This diſtinction made by the chemiſts is very clear, and very proper to be kept in view; but we ſhould be at a loſs for a term to expreſs the analogy which is perceivable between theſe ſenſible motions and the hidden motions which obtain even in the chemical phenomena, unleſs we give mechaniſm a ſtill greater extenſion than the effects of percuſſion or impulſion.

Mechanics, in the ancient ſenſe of the word, conſiders only the energy of *organa*, machines. The authors who have treated the ſubject ſyſtematically, have obſerved, that all machines derive their efficacy from a few ſimple forms and diſpoſitions, which may be given to that piece of matter called the *tool*, ’Οργανον, or *machine*, which is interpoſed between the workman or natural agent, and the taſk to be performed, which is always ſomething to be moved, in oppoſition to reſiſting preſſures. To thoſe ſimple forms they have given the name of MECHANICAL POWERS, ſimple powers, ſimple machines.

The machine is interpoſed for various reaſons.

1. In order to enable a natural power, having a certain determinate intenſity, which cannot be increaſed, to balance or overcome another natural power, acting with a greater intenſity. For this purpoſe, a piece of ſolid matter is interpoſed, connected in ſuch a manner with firm ſupports, that the preſſure exerted on the impelled point by the power occaſions the excitement of a preſſure at the working point, which is equal or ſuperior to the reſiſtance, ariſing from the work, to the motion of that point. Thus, if a rod three feet long be ſupported at one foot from the end to which the reſiſtance of two pounds is applied, and if a preſſure of one pound be applied to the other end of the rod, perpendicular to its length, the coheſive forces which connect the particles of the rod will all be excited, in certain proportions, according to their ſituation, and the ſupported point will be made to preſs on its ſupport as much as three pounds would preſs on it; and a preſſure in the oppoſite direction will be excited at the working point, equal to the preſſure of two pounds. The reſiſtance will therefore be balanced, and it will be overcome by increaſing the natural power acting on the long diviſion of the rod. This is called a LEVER. Toothed wheels and pinions are a perpetual ſucceſſion of levers in one machine or mechanical power.

2. The natural power may act with a certain velocity which cannot be changed, and the work requires to be performed with a greater velocity. A machine is interpoſed, moveable round a fixed ſupport, and the diſtances of the impelled and working points are taken in the proportion of the two velocities. Then are we certain, that when the power acts with its natural velocity, the working point is moving with the velocity we deſire.

3. The power may act only in one unchangeable direction, and the reſiſtance muſt be overcome in another direction. As when a quantity of coals muſt be brought from the bottom of a pit, and we have no power at command but the weight of a quantity of water. We let the water pull down one end of a lever, either immediately or by a rope, and we hang the coals on the other end, while the middle point is firmly ſupported. This lever may be made perpetual, by lapping the ropes round a cylinder which turns round an axis firmly ſupported. This is a FIXED PULLEY. We can ſet unequal powers in oppoſition, by lapping each rope round a different cylinder, having the ſame axis. This is a WINDLASS or GIN. All theſe forms derive their energy from the lever virtually contained in them.

Any of theſe three purpoſes may be gained by the interpoſition of a ſolid body in another way. Inſtead of being ſupported in one point, round which it is moveable, it may be ſupported by a ſolid path, along which it is impelled, and by its ſhape it thruſts the reſiſting body out of its way. This is the caſe with the WEDGE when it is employed to force up a ſwagging joiſt, or preſs things ſtrongly together. If this wedge be lapped or formed round an axis, it becomes a SCREW or a SPIRAL WIPER. This is alſo the operation of the balance wheel of a horizontal or cylinder watch. The oblique face of the tooth is a wedge, which thruſts the edge of the cylinder out of its way The pallet of a clock or watch is alſo a wedge, acted on in the oppoſite direction.

Theſe are the different forms in which a ſolid body is interpoſed as a mechanic power. All are reducible to the lever and the wedge.

But there are other mechanic powers beſides thoſe now mentioned. The carmen have a way of lowering a caſk of liquor into a cellar, by paſſing a rope under it, making the end faſt to ſome ſtake cloſe to the ground, and bringing the other end of the rope round the caſk, and thus letting it ſlip down in the bight of the rope. In this proceſs they feel but half of its weight, the other half being ſupported by the end of the rope that is faſtened to the ſtake. This is called a PARBUCKLE by the ſeamen. A hanging pulley is quite the ſame with this more artleſs method. The weight hangs by the axis of the pulley, and each half of the hanging rope carries half of the weight, and the perſon who pulls one of them upwards acts only againſt half of the weight, the other being carried by the hook to which the ſtanding rope is faſtened. This mechanical power does not (as is commonly imagined) derive its efficacy from the pulley's turning round an axis. If it were made faſt, or if the tackle rope merely paſſed through a loop of the rope which carries the weight, it would ſtill require only half of the weight acting on the running rope to balance it. The uſe of the motion round an axis is merely to avoid a very great friction. When the two hanging parts of the rope are not parallel, but inclined in any angle, the force neceſſary for balancing the weight is to the weight as the ſide is to the diagonal of the parallelogram formed by the directions of the three ropes. Varignon calls this the FUNICULAR MACHINE or power. Our ſailors call it the SWIGG.

We may employ the *quaqua verſum* preſſure of fluidity with great effect as a mechanic power. Thus, in the hydroſtatic bellows deſcribed by Graveſande, § 1451, and by Deſaguilliers, the weight of a few ounces of water is made to raiſe ſeveral hundred pounds. In like manner, Dr Wallis of Oxford, by blowing with a pipe into a bladder, raiſed 64 pounds lying on it. Otto Guericke of Magdeburgh made a child balance, and even overcome, the pull exerted by the emperor's ſix coach horſes, by merely ſucking the air from below a piſton. Mr Bramah, ironmonger in Piccadilly, London, has lately obtained a patent for a machine acting on this principle as a preſs*. A piſton of one-fourth of an inch in diameter, forces water into a cylinder of 12 inches diameter, and by this intervention raiſes the piſton of the cylinder. A boy, acting with the fourth part of his ſtrength on the ſmall piſton by means of a lever, raiſes 42 tons, or 94,080 libs, preſſing on the great piſton. It is very ſurpriſing, that this application of the *quaqua verſum* preſſure of fluids has been overlooked for more than a century, although the principle has been inculcated and lectured on by every itinerant teacher, and illuſtrated by the above mentioned experiments of Graveſande and Wallis; nay, it has been expreſsly taught as a mechanic power of great efficacy by the Profeſſor of Natural Philoſophy at Edinburgh every ſeſſion of the college for theſe twenty years paſt, but he never thought of putting it in practice. It forms a moſt compendious machine of prodigious power, and is ſuſceptible of the greateſt ſtrength. If the ſame multiplication of power be attempted by toothed wheels, pinions, and racks, it is ſcarcely poſſible to give ſtrength enough to the teeth of the racks, and the machine becomes very cumberſome and of great expence. But Mr Bramah's machine may be made abundantly ſtrong in very ſmall compaſs. It only requires very accurate execution. We give it all praiſe; but Mr Bramah is miſtaken when he publiſhes it as the invention or diſcovery of a new mechanic power: for it has been familiar to every ſtudent of mechanics and hydroſtatics ever ſince Boyle's firſt publication of his hydroſtatic paradoxes.

MEDICAL JURISPRUDENCE. See *MEDICINA Forenſis* in this *Suppl.*

MEDICI, is the name of an illuſtrious family in Florence, which contributed more than perhaps any other family whatever to the revival of letters in Europe. To trace this family from its origin, or even to give biographical ſketches of all the great men whom it produced, would occupy by far too great a part of our work; for, during ſome centuries, almoſt every individual of the houſe of Medici was diſtinguiſhed among his contemporaries. That houſe, after having rendered itſelf memorable in the annals of Florence, for oppoſing the encroachments of the nobles on the liberties of the people, had loſt much of its influence under the ariſtocratic government of the Albizi, when it was raiſed to a rank ſuperior to what it had ever held, by

Giovanni de MEDICI, who was born in the year 1360. This man determined to reſtore his family to ſplendour; but, conſcious of his critical ſituation, ſurrounded as he was by powerful rivals and enemies, he affected rather a ſecure privacy than a dangerous popularity. Even when raiſed to the office of gonfalonier, or generaliſſimo of the republic, he carefully avoided any deſire of partaking in the magiſtracy, and ſeemed to be entirely engroſſed by merchandize, which he extended from the Eaſt throughout Europe. This conduct, as on one hand it threw his enemies off their guard, on the other, enabled him to acquire an immenſe fortune, of which he made a proper diſpoſition amongſt all ranks of people.

Many, even of the ruling party, either gained by his liberality, or pleaſed with his amiable and retired conduct, propoſed to the ſeigniory to admit him into the magiſtracy; and though the propoſal met with great oppoſition, it was carried in the affirmative.

It was by raſhly declaring for the plebeians againſt the nobles that an anceſtor of Giovanni's had loſt to his family their rank in the ſtate. Giovanni, reſolving not to ſplit on the ſame rock, continued to affect privacy and retirement, accepting any office in the ſtate with the utmoſt appearance of reluctance, and never attending at the Palazzo, unleſs particularly ſent for by the ſeigniory. Riſing by theſe means in the eſteem of the people, his enemies became, of courſe, unpopular; and having obtained a decided ſuperiority over his opponents, he now ventured to procure, that thoſe taxes which the nobles had exacted with the utmoſt ſeverity and partiality from the people alone, ſhould be levied upon

---

* e MA- C ERY s S. l.

Medici.

upon the two firſt orders, in common with the plebeians; and that a law ſhould be ordained, by which perſonal property might be taxed.

The nobles ſeeing, with the deepeſt concern, their conſequence ſo ſenſibly wounded, and their power ſo much diminiſhed, held ſeveral conſultations in private how they might effect his ruin; but their want of unanimity prevented any thing deciſive from being carried into execution. The people, alarmed for the ſafety of their leader and patron, offered him the ſovereignty, which his relations and friends urged him to accept; but this his prudence forbad him to take, as with the title of lord he would have gained alſo that of tyrant. Thus, by his ſingular prudence, he died poſſeſſed of all the power of the ſtate, with the affectation of being the moſt diſintereſted citizen in the commonwealth. His death happened in the year 1428.

Giovanni was graceful in his perſon, and his affability to all eſtabliſhed his character for moderation. His extenſive knowledge and pleaſantry made his company eagerly ſought. As all his actions were placid and ſerene, he was not in want of that trumpet of ſedition, popular declamation, which he never attempted. Much to his honour, his elevation was not procured even by the baniſhment of a ſingle individual; a circumſtance until then unknown in Florence, where every new adminiſtration was marked with the ruin of families, and by ſcaffolds ſtained with blood.

"The maxims (ſays Mr Roſcoe) which, uniformly purſued, raiſed the houſe of Medici to the ſplendour which it afterwards enjoyed, are to be found in the charge given by this venerable old man, on his deathbed, to his two ſons Coſmo and Lorenzo. 'I feel (ſaid he) that I have lived the time preſcribed me. I die content, leaving you, my ſons, in affluence and in health, and in ſuch a ſtation, that, whilſt you follow my example, you may live in your native place honoured and reſpected. Nothing affords me more pleaſure than the reflection, that my conduct has given offence to no one; but that, on the contrary, I have endeavoured to ſerve all perſons to the beſt of my abilities. I adviſe you to do the ſame. With reſpect to the honours of the ſtate, if you would live with ſecurity, accept only ſuch as are beſtowed on you by the laws, and the favour of your fellow-citizens; for it is the exerciſe of that power which is obtained by violence, and not of that which is voluntarily given, that occaſions hatred and contention."

Medici (Coſmo de), the eldeſt ſon of the preceding, was born in 1389. During the life-time of his father, he had engaged himſelf deeply, not only in the extenſive commerce by which the family had acquired its wealth, but in the weightier matters of government. When Giovanni died he was in the prime of life; and though his complexion was ſwarthy, he had an agreeable perſon, was well made, of a proper ſtature, and in converſation united a happy intermixture of gravity with occaſional ſallies of pleaſantry and repartee. His conduct was uniformly marked by urbanity and kindneſs to the ſuperior ranks of his fellow-citizens, and by a conſtant attention to the intereſts and the wants of the lower claſs, whom he relieved with unbounded generoſity. By theſe means he acquired numerous and zealous partizans of every denomination; but he rather conſidered them as pledges for the continuance of the power which he poſſeſſed, than as inſtruments to be employed in extending it to the ruin and ſubjugation of the ſtate. An interchange of reciprocal good offices was the only tie by which the Florentines and the Medici were bound; and perhaps the long continuance of this connection may be attributed to the very circumſtance of its being in the power of either of the parties at any time to have diſſolved it.

Medici.

But the prudence and moderation of Coſmo could not repreſs the ambitious deſigns of thoſe rival families, who wiſhed to poſſeſs or to ſhare his authority. In the year 1433, Rinaldo de Albizi, at the head of a powerful party, carried the appointment of the magiſtracy. At that time Coſmo had withdrawn to his ſeat in the country, to avoid the diſturbances which he ſaw likely to enſue; but at the requeſt of his friends he returned to Florence, where he was led to expect ſuch a union of parties, as might at leaſt preſerve the peace of the city. No ſooner did he make his appearance in the palace, where his preſence had been requeſted, on pretence of his being intended to ſhare in the adminiſtration of the republic, than he was ſeized upon by his adverſaries, and committed to priſon.

The conſpirators were divided in their opinions as to the diſpoſal of their priſoner. Moſt of them inclined to follow the advice of Peruzzi, who recommended taking him off by poiſon. Coſmo, confined in the Alberzettino, a room in one of the turrets of the Palazzo, could hear this dreadful conſultation, which was determining, not in what manner he ſhould be tried, but in what manner he ſhould be put to death; and finding that he was to die by an infuſion of poiſon ſecretly adminiſtered to him, a ſmall portion of bread was the only food which he thought proper to take.

Coſmo lived in this manner four days; and, ſhut up from all his kindred and friends, he ſoon expected to be numbered with the dead; but here, as it ſometimes happens, he found relief where leaſt expected, from the man who had been engaged to take him off. Malavolta, the keeper of the priſon, either from compunction, diſſatisfaction, or the youth and misfortunes of the illuſtrious ſufferer, relented; and inſtead of purſuing any criminal intentions againſt the life of Coſmo, after upbraiding him with entertaining ſo unworthy an opinion of him, declared that his fears were entirely groundleſs. To convince him of this, he ſat down, and partook of every thing the priſoner choſe to eat of. The expreſſions of gratitude, together with his moſt engaging manners, and great promiſes, entirely won Malavolta, who, to ingratiate himſelf ſtill farther in the good opinion of Coſmo, invited Fargaccio, the moſt celebrated wit in Florence, to dine with him the next day, from the idea that his ſprightly mirth would contribute to lighten his misfortunes.

In the mean time, his brother Lorenzo, and his couſin Averardo, having raiſed a conſiderable body of men in Romagna and other neighbouring diſtricts, and being joined by the commander of the troops of the republic, approached towards Florence to his relief. The apprehenſion, however, that the life of Coſmo might be endangered, if they ſhould proceed to open violence, induced them to abandon their enterpriſe. At length Rinaldo and his adherents obtained a decree of the magiſtracy, by which Coſmo was baniſhed to Padua for ten years, his brother to Venice for five years; and ſeveral

veral of their relations and adherents ſhared the ſame fate.

Coſmo received this determination of his judges with a compoſure that gained him the compaſſion and the admiration of many of his moſt inveterate enemies. He would gladly have left the city purſuant to his ſentence; but he was detained by his enemies till their authority ſhould be eſtabliſhed: and it was not till he thought of bribing the gonfalonier, and another creature of Rinaldo's, that he was privately taken from his confinement, and conducted out of Florence.

Padua, to which he was confined by his ſentence, was in the dominions of Venice; but before he could reach that place, he received a deputation from the ſenate, the purport of which was to condole with him for his misfortunes, and to promiſe him their protection and aſſiſtance in whatever he ſhould deſire. He experienced the treatment of a prince rather than that of an exile. Nor were that wiſe people without good reaſons for ſuch a conduct. Venice had long regarded Florence as her rival in commerce, and hoped, by conferring upon Coſmo the moſt flattering diſtinctions, to prevail upon him to reſide there in future; prudently ſuppoſing, that the manufactories of Florence, and the great commerce the Medici had carried on throughout Italy, and extended far beyond it to the wealthieſt kingdoms in Europe, would become their own by enrolling him amongſt their ſubjects.

The readineſs with which Coſmo had given way to the temporary clamour raiſed againſt him, and the reluctance which he had ſhewn to renew thoſe rencounters which had ſo often deluged the ſtreets of Florence with blood, gained him new friends, even during his exile. The utmoſt exertions of his antagoniſts could not long prevent the choice of ſuch magiſtrates as were known to be attached to the cauſe of the Medici; and no ſooner did they enter on their office, than Coſmo and his brother were recalled, and Rinaldo with his adherents were compelled to quit the city. This event took place about a year after the baniſhment of Coſmo.

The ſubſequent conduct of this great man (for great all allow him to have been) has been painted in different colours by different writers. Mr Noble, after Machiavel, compares his cruelties to his fallen foes with thoſe of Sylla and Octavius to the partizans of Marius and Brutus; whilſt Roſcoe repreſents his conduct as in a high degree amiable and generous. It appears to us evident, from his own words, that he had exerciſed ſome cruelties on his exiled enemies; for when one of them wrote to him, that "the hen was hatching," he replied, "She will have but a bad time of it, ſo far from her neſt." When ſome other exiles acquainted him that "they were not aſleep," he anſwered, "he could eaſily believe that, for he thought he had ſpoiled their ſleeping." At another time, ſome of the citizens remonſtrated with him upon the odiouſneſs of his conduct in baniſhing ſo many perſons; telling him, "the republic would be extremely weakened, and God offended, by the expulſion of ſo many good and pious men as he was ſending into baniſhment." His anſwer was, "It would be better for the republic to be weakened than utterly ruined; that two or three yards of fine cloth made many a one look like a good man; but that ſtates were not to be governed or maintained by counting a ſtring of beads, and mumbling over a few *Pater noſters*."

From this time the life of Coſmo de Medici was an almoſt uninterrupted ſeries of proſperity. His misfortunes had taught him, that the affectation of grandeur is more dangerous in a free ſtate than uſurpation. He adopted, therefore, the dreſs, behaviour, and manners, of a private citizen. His clothes were of the ſame faſhion and materials as the reſt of the Florentines. In the ſtreets he walked alone and unguarded. His table was ſupplied from what his eſtate of Mugello produced, nor had he one ſervant more than was abſolutely neceſſary; thus endeavouring to unite the character of a prince with that of a merchant, and a private perſon in a republic.

Whilſt he rejected all offices in the magiſtracy, no buſineſs was tranſacted without its being firſt ſettled at Mugello: nor did he contract any alliances but with the ſons and daughters of the citizens of Florence; yet all foreign princes and courts paid his children the reſpect due only to thoſe of ſovereigns; and the family of Coſmo received educations equal to thoſe of the greateſt potentates.

A proper judgment may be formed of his immenſe traffic, and the prodigious advantages accruing from it: For though a private citizen of Florence only, yet he poſſeſſed at one time more money than what was in all the treaſuries of the different ſovereigns in Europe. When Alfonſo king of Naples leagued with the Venetians againſt Florence, Coſmo called in ſuch immenſe debts from thoſe places, as deprived them of reſources for carrying on the war. During the conteſt between the houſes of York and Lancaſter, he furniſhed Edward IV. with a ſum of money ſo great, that it might almoſt be conſidered as the means of ſupporting that monarch on the throne.

In his public and private charities, in the number and grandeur of the edifices he erected, not only in Florence, but in the moſt diſtant parts of the world, and in the foundations which he endowed, he ſeemed to more than vie with majeſty. He ſupplied moſt of the exigencies of the ſtate from his private purſe; and there were few citizens that had not experienced his liberality, and many without the leaſt application, particularly the nobles.

But in nothing did his munificence produce ſo much good to the world, or acquire ſuch honour to himſelf, as when it was exerted for the promotion of ſcience, and the encouragement of learned men; and upon nothing did Coſmo delight ſo much to exert it. The ſtudy of the Greek language had been introduced into Italy towards the latter part of the preceding century; but it had again fallen into neglect. After a ſhort interval, an attempt was made to revive it, by the intervention of Emanuel Chryſoloras, a noble Greek, who taught that language at Florence, and other cities of Italy, about the beginning of the 15th century. His diſciples, who were numerous and reſpectable, kept the flame alive till it received new aid from other learned Greeks, who were driven from Conſtantinople by the dread of the Turks, or by the total overthrow of the Eaſtern Empire. To theſe illuſtrious foreigners, as well as to the learned Italians, who ſhortly became their ſucceſsful rivals, even in the knowledge of their national hiſtory and language, Coſmo afforded the moſt liberal ſupport and protection. The very titles of the works of ancient authors, which were brought to light by his munificence, would extend this article beyond its proper limits. Such, indeed, was the eſtimation in which theſe works were then held in Italy, that a manuſcript of the hiſtory of Livy, ſent by Coſmo de Medici to Alfonſo king of Naples, with whom he was at variance, conciliated the breach between them.

As the natural diſpoſition of Coſmo led him to take an active part in collecting the remains of the ancient Greek and Roman writers, ſo he was enabled by his wealth, and by his extenſive mercantile intercourſe with different parts of Europe and of Aſia, to gratify a paſſion of this kind beyond any other individual. To this end he laid injunctions on all his friends and correſpondents, as well as on the miſſionaries and preachers who travelled into the remoteſt countries, to ſearch for and procure ancient manuſcripts, in every language, and on every ſubject. The ſituation of the Eaſtern Empire, then falling into ruins, afforded him an opportunity of obtaining many ineſtimable works in the Hebrew, Greek, Chaldaic, Arabic, and other eaſtern languages. From theſe beginnings aroſe the celebrated library of the Medici; which, after various viciſſitudes of fortune, and frequent and conſiderable additions, has been preſerved to the preſent times under the name of the *Bibliotheca Mediceo Laurentiana*.

Nor was Coſmo a mere collector of books, he was himſelf, even in old age, a laborious ſtudent. Having been ſtruck with the ſublime ſpeculations of Plato, which he had heard detailed in lectures by a Greek monk, who had come from Conſtantinople to the council of Florence, he determined to found an academy for the cultivation of that philoſophy. For this purpoſe he ſelected Marſilio Ficino, the ſon of his favourite phyſician, and deſtined him, though very young, to be the ſupport of his future eſtabliſhment. The education of Ficino was entirely directed to the Platonic philoſophy; nor were the expectations which Coſmo had formed of him diſappointed. The Florentine academy was ſome years afterwards eſtabliſhed with great credit, and was the firſt inſtitution in Europe for the purſuit of ſcience, detached from the ſcholaſtic method then univerſally adopted. It is true, the fanciful doctrines of Plato are as remote from the purpoſes of life as the ſubtleties of Ariſtotle; but, by dividing the attention of the learned between them, the dogmas of the Stagyrite were deprived of that ſervile reſpect which had ſo long been paid to them, and men learned by degrees to think for themſelves.

The foſtering hand of Coſmo was held out to art as well as to ſcience; and architecture, ſculpture, and painting, all flouriſhed under his powerful protection. The countenance ſhewn by him to theſe arts was not ſuch as their profeſſors generally receive from the great. It was not conceded as a bounty, nor received as a favour, but appeared in the friendſhip and equality that ſubſiſted between the artiſt and his patron; and the ſums of money, which Coſmo expended on pictures, ſtatues, and public buildings, appear almoſt incredible.

Coſmo now approached the period of his mortal exiſtence; but the faculties of his mind remained unimpaired. About twenty days before he died, he ſent for Ficino, and enjoined him to tranſlate from the Greek the treatiſe of Xenocrates on death. Calling into his chamber his wife and his ſon Piero, he entered into a narrative of all his public tranſactions; in which he gave a full account of his extenſive mercantile connections, and adverted to the ſtate of his domeſtic concerns. To Piero he recommended a ſtrict attention to the education of his ſons; and requeſted, that his funeral might be conducted with as much privacy as poſſible. He died on the firſt of Auguſt 1464, at the age of 75 years, deeply lamented by a great majority of the citizens of Florence. Their eſteem and gratitude had indeed been fully ſhewn ſome time before, when, by a public decree, he was honoured with the title of *Pater Patriæ*, an appellation which was inſcribed on his tomb; and which, as it was founded, ſays Roſcoe, on real merit, has ever ſince been attached to the name of Coſmo de Medici.

Medici (Lorenzo de), juſtly ſtyled the *magnificent*, was the grandſon of Coſmo, and about 16 years of age when his grandfather died. His father Piero de Medici, though poſſeſſed of more than ordinary talents, as well as of a very conſiderable ſhare of worth, was, from various circumſtances, little qualified to maintain the influence which his family had gained in the republic of Florence. From very early life he had been tortured by the gout; and almoſt uninterrupted pain had made him peeviſh. Such a diſpoſition was not calculated to retain the affections of the giddy Florentines, or to perſuade republicans that they were free, while they ſubmitted to the government of a ſingle individual. All this Coſmo had foreſeen, and had done what wiſdom could do to preſerve to his family that aſcendency in the republic which he had himſelf acquired. He exhorted Piero to beſtow the utmoſt care on the education of his ſons, of whoſe capacity he expreſſed a high opinion; he recommended to him Diotiſalvo Neroni, a man whom he had himſelf raiſed from obſcurity to an eminent rank, as a counſellor, in whoſe wiſdom and fidelity he might place the utmoſt confidence: and to bind the inhabitants of Florence to the houſe of Medici by the ſtrongeſt of all ties, he had diſtributed among them, under the denomination of loans, immenſe ſums, which he knew they would not ſoon be able to repay.

Piero paid the utmoſt deference to the dying injunctions of his father. He had himſelf an ardent love of letters; and under the eye of the venerable Coſmo, he had given his two ſons, Lorenzo and Juliano, the beſt poſſible domeſtic education. In the Greek language, in ethics, and in the principles of the Ariſtotelian philoſophy, Lorenzo, the eldeſt, had the advantage of the precepts of the learned Argyropylus (A), and in thoſe of the Platonic ſect he was ſedulouſly inſtructed by Marſilio Ficino (ſee Ficinus, *Encycl.*); but for his moſt valuable accompliſhments he was not indebted to any preceptor. To complete his education, however, it was judged expedient that he ſhould viſit ſome of the principal courts of Italy; and very ſoon after the death of his grandfather, he repaired to Rome, Bologna, Ferrara, Venice, and Milan, where he gained the eſteem of all whoſe eſteem was of value.

(A) This man had fled from Conſtantinople, when it was taken by the Turks, to Florence, where he was protected by Coſmo de Medici.

Thus attentive was Piero to the advice of his father with reſpect to the education of his eldeſt ſon; nor was he leſs attentive to it in the choice of his principal counſellor. He intruſted the whole of his affairs into the hands of Neroni, and gave him Coſmo's accounts to peruſe and ſettle. That ambition, which perhaps had lain lurking in this man's mind, was now called forth, and he baſely formed the ſcheme of ruining the ſon of his patron, by building upon his misfortunes his own future grandeur. For this purpoſe, he lamented the abſolute neceſſity there was for an immediate call upon thoſe who were indebted to Piero as Coſmo's repreſentative; telling him, that a delay might ſubject him to the greateſt inconveniences. Piero conſented, though with reluctance, to his ſuppoſed friend's advice. The reſult was ſuch as Neroni expected. Thoſe who were friends of the father became enemies of the ſon; and had not Piero diſcovered the ſnare, and deſiſted from ſuch rigorous proceedings, he might have found, when too late, that in ſupporting the character of the merchant, he had forgotten that of the ſtateſman; for all the citizens of Florence were his debtors.

Soon after this, an attempt was made to aſſaſſinate Piero, by a powerful party which had always been inimical to the houſe of Medici; but it was defeated by Lorenzo, who diſplayed on that occaſion a ſagacity and promptitude of mind which would have done honour to the oldeſt ſtateſman. A few of the conſpirators were declared enemies to the ſtate, and condemned to baniſhment; but by far the greater part of them were pardoned on the ſolicitation of Lorenzo, who declared, that "he only knows how to conquer, who knows how to forgive."

In the year 1469 Piero de Medici died; and Lorenzo ſucceeded to his authority as if it had been a part of his patrimony, being requeſted by the principal inhabitants of Florence, that he would take upon himſelf the adminiſtration of the republic in the ſame manner that his grandfather and father had done.

In the month of December 1470, a league was ſolemnly concluded between the pope, the king of Naples, the duke of Milan, and the Florentines, againſt Mahomet II. who had vowed not to lay down his arms till he had aboliſhed the religion of Chriſt, and extirpated all his followers. The pope, however (Paul II.), died on the 26th of July 1471; and Sixtus IV. ſucceeding to the chair of St Peter, Lorenzo was deputed from Florence to congratulate him on his elevation. Two more oppoſite characters can hardly be conceived than thoſe of Sixtus and Lorenzo. The former was cruel, treacherous, and ſordid; the latter was merciful, candid, and generous. Yet ſuch inſtances of mutual good will took place between them on this occaſion, that Lorenzo, who, under the direction of his agents, had a bank eſtabliſhed at Rome, was formally inveſted with the office of treaſurer of the Holy See.

Piſa had been under the dominion of Florence from the year 1406, and it had acquired ſome celebrity on account of its academy, which had exiſted almoſt two centuries. That academy, however, had fallen into decay; and, in the year 1472, the Florentines reſolved to reſtore it to its priſtine ſplendour. Five citizens, of whom Lorenzo de Medici was one, were appointed to ſuperintend the execution of their purpoſe; but Lorenzo, who was the projector of the plan, undertook the chief management of it; and, in addition to 6000 florins annually granted by the ſtate, expended, in effecting his purpoſe, a large ſum of money from his private fortune. In doing this, he only imitated the example of his father and grandfather; for in the courſe of 37 years, reckoning from the return of Coſmo from baniſhment, this illuſtrious family had expended on works of charity or public utility upwards of 660,000 florins. "Some perſons (ſaid Lorenzo) would perhaps be better pleaſed to have a part of it in their purſe; but I conceive that it has been of great advantage to the public, and well laid out, and am therefore perfectly ſatisfied."

In the year 1474, Lorenzo incurred the diſpleaſure of the pope for oppoſing ſome of his encroachments on the petty princes of Italy; and the revenge planned by Sixtus was of ſuch a nature as would have diſgraced, we do not ſay a Chriſtian biſhop, but the rudeſt ſavage. He began by depriving Lorenzo of the office of treaſurer of the Roman See, which he gave to the Pazzi, a Florentine family, who, as well as the Medici, had a public bank at Rome. By this ſtep he ſecured the intereſt of the Pazzi, who, it is probable, were to govern Florence under the pope, when Lorenzo and Juliano de Medici ſhould be cut off, and their friends and adherents driven from the republic. The principal agent engaged in the undertaking was Franſeſco Salviati archbiſhop of Piſa, to which rank he had lately been promoted by Sixtus, in oppoſition to the wiſhes of the Medici. The other conſpirators were Giacopo Salviati, brother to the archbiſhop; Giacopo Poggio, one of the ſons of the celebrated Poggio Bracciolini (ſee POGGIUS, *Encycl.*); Barnardo Bandini, a daring libertine, rendered deſperate by the conſequence of his exceſſes; Giovanni Battiſti Monteſicco, who had diſtinguiſhed himſelf as general of the pope's armies; Antonio Maffei, a prieſt of Volterra; and Stephano de Bagnona, one of the apoſtolic ſcribes; with ſeveral others of inferior note. The cardinal Riario, then at Piſa, was likewiſe an inſtrument in the conſpiracy; but he can hardly be conſidered as an agent, for he was kept ignorant of what was going on, and enjoined only to obey whatever directions he might receive from the archbiſhop of Piſa.

The aſſaſſination of the illuſtrious youths was fixed for Sunday, April 26. 1478; the place the cathedral of Florence, at the moment the hoſt was to be elevated; and their murder was to be the ſignal for ſeizing and expelling from the walls of the city all their relations and friends. What a tranſaction this for one who preſumed to ſtyle himſelf the vicar of Chriſt, the common father of Chriſtendom, to patronize!

The fatal day arrived, and Lorenzo was already in the church; but Juliano remained at home, occaſioned by a ſlight indiſpoſition. The conſpirators, determining not to loſe one of their victims, went to invite, to intreat him, to go. They embraced (B), and led him, by a tender violence, to the cathedral. The ſignal was

---

(B) The aſſaſſins embraced Juliano, to diſcover whether he wore any ſecret armour, that they might know where to ſtrike with the ſureſt aim.

given by the elevation of the conſecrated wafer; and whilſt the people fell upon their knees to adore, the aſſaſſins roſe, and, as was concerted, two of them, Franciſco Pazzi and Barnardo Bandini, fell upon Juliano. The latter directed his poignard ſo truly, that it entered into the boſom of the unoffending youth, and he fell mortally wounded at his feet.

In a moment, as muſt be ſuppoſed, all was confuſion. Lorenzo, alarmed, put himſelf in a poſture of defence, when, in an inſtant, Antonio of Volterra, and Stephano a prieſt, the dependant of the archbiſhop, who, upon Giovanni Battiſti's declining the infamous taſk, undertook his deſtruction, ruſhed upon him as their deſtined prey. The conteſt continued ſome time. Lorenzo had received a wound in his neck, and ſeemed to contend for his life in vain; but a ſervant, whom he had lately relieved from priſon, inſpired by gratitude, heroically threw himſelf between his beloved lord and his aſſaſſins, receiving in his body thoſe weapons that were aimed at the breaſt of Lorenzo. This fidelity ſaved him; for by one vigorous effort he broke from Antonio and Stephano, and with a few friends ruſhed into the ſacriſty, ſhutting the doors behind them, which were of braſs. Apprehenſions being entertained, that the weapon which had wounded him was poiſoned, a young man ſucked the wound, endangering his own life to ſave that of Lorenzo.

The rage of the people to ſee one of their favourites expiring, and the other covered with blood, was inexpreſſible. The cardinal Riario found it difficult to ſave his life at that altar which he had ſtained by ſo horrid a deed, and to which he then fled for protection.

Whilſt this infamous ſcene was acting in the cathedral, others of the conſpirators were attempting to ſeize the Palazzo; but with no better ſucceſs. The archbiſhop Salviatti, who had undertaken to head them, gave the magiſtrates ſuſpicion by thoſe violent emotions which agitated his whole frame. The nine ſenators who compoſed the magiſtracy, including the gonfalonier, who had been appointed by, and were, in other words, the privy council of the Medici, immediately attacked thoſe who intended to have ſurpriſed them; and Salviatti and his followers had no ſooner gained the ſecond floor, than they found themſelves priſoners.

Jacobo Pazzi ſoon appeared in the ſtreet, proclaiming, with exultation, the murder of Juliano; and inviting the Florentines to free themſelves from the Medicean ſlavery; but perceiving that he was not joined by the people, the magiſtrates ſent off 100 horſe to the reſcue of Lorenzo. This was the more to be commended, becauſe they continued to be aſſaulted by the conſpirators, who, finding their ſituation deſperate, forced themſelves to the ground floor, determining, if poſſible, to ſeize the Palazzo. The magiſtrates, with their attendants, acted with ſuch reſolution and valour, that as often as they gained an entrance, they drove them back, killing ſome of the aſſailants upon the ſpot, others they threw out of the windows upon the pavement; and to ſtrike an awe into thoſe that were without, they had the boldneſs and virtue to hang the archbiſhop from one of the windows, dreſſed as he was in his pontifical robes, with Poggio, another of the chief conſpirators. Florence reſounded in every part with the exclamation—Medici, Medici! down with their enemies!

Lorenzo was liberated from that part of the cathedral to which he had fled, and conveyed home in triumph, where his wounds were attended to, and where he found himſelf ſurrounded by his moſt valuable friends, to whom he was endeared by the ſhocking occurrences of the day. His partizans, however, did not ſpend their time only in lamentations for the death of one of the brothers, and exultations for the preſervation of the other; they united in purſuing the conſpirators, ſparing none that fell into their hands. Jacobo Pazzi was taken flying with his forces into Romania, and immediately hung. An officer of the pope's, who commanded a brigade under count Hirronimo, had alone the favour of decapitation. Bandini fled privately to Piſa, thence to Naples, and, laſtly, to Conſtantinople; but Mahomet, to oblige Lorenzo, ſeized, and ſent him back; and he was hung out of the ſame window from which the archbiſhop had ſuffered. An embaſſy was ſent from Florence to thank the ſultan in the name of the republic.

Throughout the whole of this juſt but dreadful retribution, Lorenzo had exerted all his influence to reſtrain the indignation of the populace. He entreated that they would reſign to the magiſtrates the taſk of aſcertaining and of puniſhing the guilty, leſt the innocent ſhould be incautiouſly involved in deſtruction; and his appearance and admonitions had an inſtantaneous effect. By his moderation, and even kindneſs to the relatives of the conſpirators, he ſought to obliterate the remembrance of paſt diſturbances; and by his interference, even the ſurvivors of the Pazzi were reſtored to their honours, of which they had been deprived by a decree of the ſtate.

The generoſity and moderation of Lorenzo had no effect on the temper of Sixtus, who ſolemnly excommunicated him, the gonfalonier, the magiſtrates, and their immediate ſucceſſors; and in the bull which he iſſued on this occaſion, he ſtyles Lorenzo de Medici "the child of iniquity, and the nurſling of perdition!" Not content with this ebullition of reſentment, he ſuſpended the biſhops and clergy of the Florentine territories from the exerciſe of their ſpiritual functions; thus laying the whole republic under an interdict. This had been a formidable weapon in the hands of his predeceſſors, who had, by means of it, overawed the moſt powerful monarchs; but the general character of Sixtus was ſo infamous, and his preſent injuſtice ſo manifeſt, that by the exertions of the biſhop of Arezzo, a convocation was held in the cathedral church of Florence, in which Sixtus was accuſed of *fornication* and *adultery*, with other infamous vices; declared to be the principal inſtigator of the conſpiracy againſt the Medici; and the ſentence of excommunication which he had fulminated againſt Lorenzo and the Florentine magiſtrates was called in direct terms, the "execrable malediction of a damned judge (*maledictam maledictionem damnatiſſimi judicis*)!

How ſuch language could be reconciled to the notions which then prevailed of the ſanctity of the pope, and the plenitude of his power it is needleſs to inquire; but the reader will not be ſurpriſed that the prelates, who made uſe of it, paid no regard to the interdict of Sixtus. The pontiff, however, did not relax from his purpoſe. Whilſt he brandiſhed with one hand the ſpiritual weapon, which the Florentines treated with ſuch contempt, in the other, he graſped a temporal ſword, which he now openly, as he had before ſecretly, aimed at the breaſt of Lorenzo. At his inſtigation the king of Naples

diſpatched

diſpatched an envoy to Florence, to require the citizens to baniſh Lorenzo from the Tuſcan territories, if they would not incur the vengeance both of him and of the pope. Theſe threats produced not the intended effect; for the Florentines avowed their firm reſolution to ſuffer every extremity, rather than betray the man whom they conſidered as guardian of the republic. War therefore was commenced; and the republic was on the point of being ruined, when Lorenzo taking advantage of a truce, threw himſelf, with a reſolution not to be equalled, into the hands of the king of Naples. He judged, perhaps, that any ſtipulations for his perſonal ſafety would be uſeleſs with a prince who had ſported with honour, juſtice, mercy, and the moſt ſolemn treaties. But, whilſt all viewed him as a victim who had devoted himſelf to ſave his country, he, by perſuaſive eloquence, obtained of this crafty perfidious monarch a ſeparate peace, and returned to Florence crowned with a ſucceſs that no one thought poſſible, and where he was received as its tutelar deity. The pope, however, continued inflexible, till a deſcent of the Turks upon Italy reſtored him to his ſenſes, and made him willing to receive the ſubmiſſion of Florence, and reconcile its inhabitants to the church.

Soon after the termination of the hoſtilities between Sixtus and the republic of Florence, Lorenzo began to unfold plans for ſecuring the peace of Italy, which confer the higheſt honour on his political life. To counterpoiſe all the jarring intereſts of the petty ſtates of which that country was compoſed, to reſtrain the powerful, ſuccour the weak, and to unite the whole in one firm body which might be able, on the one hand, ſucceſsfully to oppoſe the formidable power of the Turks, and, on the other, to repel the incurſions of the French and Germans, were the important ends which this great man propoſed to accompliſh. But before he engaged in theſe momentous undertakings, he had further perſonal dangers to encounter. By the inſtigation of Cardinal Riario, and ſome Florentine exiles, one Battiſta Fraſcobaldi, with only two aſſiſtants, undertook to aſſaſſinate him in the church of the Carmeli, on the feſtival of the aſcenſion 1481; but the plot was diſcovered, the conſpirators executed, and Lorenzo henceforth ſeldom went abroad without being ſurrounded by a number of tried friends.

Lorenzo was now at liberty to proſecute his benevolent purpoſes; and after contributing to the expulſion of the Turks from Italy, he ſet himſelf in good earneſt to ſupport the weak ſtates againſt the encroachments of the more powerful. This neceſſarily embroiled the republic at one time with the pope, at another with the king of Naples; now with the Venetians, and then with the Duke of Milan: but when ſome exclaimed againſt him as being too precipitate in involving the republic in dangerous and expenſive wars, he explained to them the neceſſity of maintaining the balance of power, if they would preſerve the independence of their own ſtate; and ſo completely had he made himſelf maſter of this ſubject, that he convinced the moſt incredulous of the propriety of his meaſures, which, in 1488, introduced general tranquillity into Italy.

At this period, the city of Florence was at its higheſt degree of proſperity. The vigilance of Lorenzo had ſecured it from all apprehenſions of external attack; and his acknowledged diſintereſtedneſs and moderation had almoſt extinguiſhed that ſpirit of internal diſſenſion for which it had been ſo long remarkable. The Florentines gloried in their illuſtrious citizen, and were gratified by numbering in their body a man who wielded in his hands the fate of nations, and attracted the reſpect and admiration of all Europe.

Yet amidſt public affairs ſo intricate and ſo momentous, ſuch was the capacity of this man's mind, and ſuch his verſatility of genius, that, for the greater part of his life, he carried on a commerce as extenſive as that of his grandfather, whilſt he afforded ſtill greater encouragement to learning and learned men. Coſmo had greatly promoted the ſtudy of the ancient languages and ancient philoſophy. Lorenzo did the ſame thing: but he did much more; he encouraged the cultivation of his own tongue, which had been neglected ſince the age of Petrarca; and by ſetting a great example himſelf, he produced a race of Italian poets, which have hardly been ſurpaſſed in any age or nation. To enumerate even the names of the elegant ſcholars whom he patroniſed, would extend this article far beyond its limits. In the academy of Piſa, of which mention has been already made, the ſtudies were chiefly confined to the Latin language, and to thoſe ſciences of which it was the principal vehicle. At Florence the Greek tongue was taught under the ſanction of a public inſtitution, either by native Greeks or learned Italians, whoſe ſervices were procured by the diligence of Lorenzo de Medici, and repaid by his bounty. He placed Michael Angelo at the head of an academy, which he erected for painting and ſculpture, furniſhing it with the beſt models of antiquity. He built and endowed a public library, and ſent Laſcaris, of imperial deſcent, to Conſtantinople more than once, to procure Greek manuſcripts. For father Moriano, the orator, a monaſtery was built; and Florence owed many of her fineſt edifices to him. Politiano and Ficino were among his moſt intimate friends; and it is not perhaps too much to ſay, that he did more for letters and ſcience and art than any other individual that ever exiſted. His own acquirements in learning were great; and his poetry, of which the reader will find many ſpecimens in the elegant work of Roſcoe, was exquiſite.

Is it ſurpriſing, when we examine Lorenzo's character, that all Italy, all Chriſtendom, even the Mahometans, gave him the moſt flattering marks of approbation, and ſtrove who ſhould oblige him moſt, by preſenting him with whatever was rare and valuable? His palace was conſtantly filled with men famous in every elegant, every uſeful ſcience, and the neighbouring princes flocked to it as to the temple of wiſdom. The celebrated prince of Mirandola, on his account, choſe Florence for his reſidence, and died there.

To a moſt engaging perſon was added each grace, and every accompliſhment. He was the favourite of the ladies, the envy of the men, and the admiration of both. The ſtateſman of his time; unrivalled in chivalry; one of the moſt eminent orators that the world has produced. His poetic merit, with his judgment in, and patronage of that art, procured him the title of "Father of the Muſes." In liberality to his fellow-citizens, as well as in every other reſpect, except as a general, he exceeded even Cæſar himſelf; and had not peace been his dear delight, his talents would have made him a conſummate commander. Yet with all theſe ſuperior

perior accompliſhments, he did not think it beneath him to indulge in amuſements which perſons, leſs wiſe, would have thought an impeachment of their underſtanding, and he would often ſeek pleaſure in his nurſery, ſpending hours there in all the frivolous pranks of childiſh diverſion. In fine, "the gravity of his life, if compared with its levity, muſt make him appear as a compoſition of two different perſons, incompatible, and, as it were, impoſſible to be joined with the other."

Lorenzo, like moſt other great men, had wiſhed to ſpend his laſt years in the tranquillity of retirement. He therefore at an early period wound up his mercantile concerns, and divided his time between the cares of the republic at Florence, and the cultivation of his eſtates in the country. He wiſhed even to diveſt himſelf of all public concerns, and get his ſecond ſon Giovanni admitted into holy orders at the age of ſeven years, that he might be fit for eccleſiaſtical preferment before he ſhould be deprived of the protection of his father. The young eccleſiaſtic, who afterwards made ſuch a figure as Leo X. was accordingly appointed by Louis XI. of France, abbot of Fonte Dolac, before he was eight years of age; and by Innocent VIII. a cardinal, when he was little more than thirteen. This added much to the influence of the family, not only in the Tuſcan ſtates, but through all Italy; and Lorenzo having introduced his eldeſt ſon into public life, and accompliſhed a marriage between him and the daughter of a noble family at Rome, thought he might commit the affairs of the republic in a great meaſure to Piero, and indulge his own taſte in the converſation of his learned friends. This dream of felicity however was not realized. Early in the year 1492, he was attacked by a diſeaſe, under which he had long laboured, with ſuch violence, that on the 8th of April he died in the midſt of his weeping friends, after having taken of them, one by one, an affectionate farewel, and given to his ſon Piero much ſalutary counſel, which he thought not fit to follow.

The character of this great and good man is developed in the detail which we have given of his conduct through life: But it may not be improper to add, that ſuch was the love and veneration of the citizens to him, that the phyſician, who had attended him on his deathbed, afraid to return to Florence, left the houſe in a ſtate of diſtraction, and plunged himſelf into a well. Throughout the reſt of Italy the death of Lorenzo was regarded as a public calamity of the moſt alarming kind. Of the arch which ſupported the political fabric of that country he had long been conſidered as the centre, and his loſs ſeemed to threaten the whole with immediate deſtruction. When Ferdinand king of Naples was informed of the event, he exclaimed, "This man has lived long enough for his own glory, but too ſhort a time for Italy."

MEDICINA FORENSIS, is a phraſe uſed in Germany to denote thoſe parts of anatomical and phyſiological knowledge, which enable phyſicians and ſurgeons to decide certain cauſes as judges in courts of juſtice. In that country it has long been law and cuſtom (if we miſtake not, by the Caraline code of Charles V.) to refer caſes of *poiſoning*, *child murder*, *rape*, *pregnancy*, *impotency*, *ideotiſm*, &c. to the medical faculty, which, in the univerſities and ſome other great towns, is conſtituted into a kind of court for the trial of ſuch queſtions. In this country there are no ſuch courts; but in criminal trials medical gentlemen are often called upon to deſcribe the ſymptoms of *poiſoning*, *child-murder*, *rape*, &c. and therefore it becomes them to obtain an accurate knowledge of theſe ſymptoms, and to ſtore their memories with a number of minute facts, to which they may have occaſion to appeal when giving their evidence.

The importance of this ſubject induced the profeſſor of the inſtitutes of phyſic in the univerſity of Edinburgh to reſolve lately to read an annual courſe of lectures on MEDICAL JURISPRUDENCE. This, we doubt not, will prove a valuable courſe; for though it is hardly conceivable that, under the head *medical juriſprudence*, any *knowledge* can be communicated which a well educated phyſician would not neceſſarily have acquired, without attending ſuch a courſe; yet it is very obvious, that the recollection of the young phyſician may receive great aid from his liſtening to the well arranged lectures of an accurate profeſſor. From theſe lectures he may ſtore his mind with a collection of aphoriſms which ſhall be always ready on the day of examination; or the lectures themſelves may be delivered in queſtions and anſwers with all the formalities of a criminal court.

We have heard it obſerved, that to attend a courſe of ſuch lectures would be of the utmoſt advantage to all who may be called upon to ſerve as jurymen in criminal trials; but of the truth of this obſervation we are more than doubtful. Perſons who are only *half* inſtructed are always conceited of their own attainments; and men not acquainted with anatomy and phyſiology cannot be *more* than half inſtructed by the ableſt courſe poſſible to be given of medical juriſprudence. Such perſons indeed can hardly avoid miſtaking the ſenſe of the profeſſor's language, however perſpicuous that language may be. Of this we had lately a very ſtriking inſtance. A gentleman, by no means illiterate, though a ſtranger to anatomical and phyſiological ſcience, was expatiating to the writer of this article upon the general importance of medical juriſprudence, a courſe of which, he ſaid, he had attended for the ſole purpoſe of qualifying himſelf for diſcharging the important duties of a juryman. Upon being aſked what he had learned? he replied, that he had been taught, among other things which we thought frivolous, to diſcern, from the ſymptoms of *hanging*, whether the dead man had been hanged by *himſelf* or by *another*. We need not ſurely obſerve, that no ſuch leſſon was ever taught in any univerſity, or by any medical lecturer; but it is worthy of conſideration, whether lectures on medical juriſprudence may not have the moſt pernicious effects on the minds of men ſo little qualified as this gentleman to profit by them. To the regularly educated phyſician and ſurgeon ſuch lectures may prove uſeful; to the plain citizen, not ſkilled in anatomy and phyſiology, they muſt prove dangerous; as their only tendency is to make him deſpiſe the evidence given before him by the regular phyſician or ſurgeon; to place implicit confidence in his own ſuperficial knowledge; and thus to decide at random on the life or death of his fellow-creature:

A little learning is a dangerous thing;
Drink deep, or taſte not the Pierian ſpring.

MEDINA, the capital of the kingdom of Woolli in Africa, is ſituated in 13° 40′ N. Lat. and 12° 40′ W. Long. It is a place of conſiderable extent, and may contain from 800 to 1000 houſes. It is fortified in the

edusa,
egame-
ter.

common African manner, by a ſurrounding high wall built of clay, and an outward fence of pointed ſtakes and prickly buſhes; but the walls are neglected, and the outward fence has ſuffered conſiderably from the active hands of buſy houſewives, who pluck up the ſtakes for firewood. Mr Park paſſed through it on his route eaſtward, and was treated with much kindneſs both by the king and the people. The good old ſovereign warned him of the dangers he was about to encounter, and endeavoured to perſuade him to relinquiſh all thoughts of his journey eaſtward; but when he could not prevail, he gave him a guide, who conducted him in ſafety to Koojar, the frontier town of the kingdom towards Bondou, from which it is ſeparated by an intervening wilderneſs of two days journey. Here our author was preſented, by way of refreſhment, with a liquor which taſted ſo much like the ſtrong beer of his native country (and very good beer too), as to induce him to inquire into its compoſition; and he learned, with ſome degree of ſurpriſe, that it was actually made from corn which had been previouſly malted, much in the ſame manner as barley is malted in Great Britain: a root yielding a grateful bitter was uſed in lieu of hops, the name of which he forgot; but the corn which yields the wort is the *holcus ſpicatus* of botaniſts.

Plate XXVI.

MEDUSA. In addition to the different ſpecies of this genus of vermes deſcribed in the *Encyclopædia*, that which is repreſented in two different attitudes, fig. 1. and 2. and which ſtrongly reſembles a bagpipe in ſhape, may be worthy of notice. It is merely a white tranſparent veſicle, furniſhed with ſeveral blue tentacles yellowiſh at their extremity; its long tail, which is alſo blue, appears to be compoſed of a number of ſmall glandulous grains, flattened and united together by a gelatinous membrane. The upper part of the veſicle exhibits a kind of ſeam with alternate punctures of three different ſizes; its elongated part, which may be conſidered as the head of the animal, is terminated by a ſingle trunk, the exterior edge of which is fringed with 25 or 26 tentacles, much ſmaller than thoſe which originate from the inſertion of its long tail, and the number of which ſometimes amounts to 30. By means of theſe laſt, the diameter of which it is capable of increaſing at pleaſure by forcing in a little of the air from its body, it fixed itſelf to the ſide of the veſſel, in which it was placed, in ſuch a manner as that the extremity of ſome of its tentacles occupied a ſurface of two or three lines from its body. The moſt moveable part of the veſicle is its elongation, or the head of the animal, as it is by means of this that it performs its different motions. The rounded ſubſtance, marked by the letter P, is ſituated in the centre of the larger tentacles, which are firmly fixed to the body of the animal near its tail; and is only an aſſemblage of a few minute gelatinous globules, from the middle of which ariſe other larger globules, with a ſmall peduncle, about the middle of which is fixed a curved bluiſh coloured body, which is repreſented magnified in two poſitions at R. Martiniere, the naturaliſt, who accompanied Perouſe in his voyage round the world, met with this animal in about the 20th degree of lat. and 179° of long. eaſt from Paris.

MEGAMETER, a name ſometimes given to the MICROMETER, which ſee, *Encycl.*

Mehall,
Meninſki.

MEHALL, in the language of Bengal, a place or diſtrict.

MENINSKI (Franciſcus), a moſt celebrated German orientaliſt, was born in Lorraine, then ſubject to the emperor, in the year 1623; and for copiouſneſs of learning, elegance of genius, and profound knowledge of languages, particularly thoſe of the Eaſt, proved undoubtedly one of the principal ornaments of the age in which he lived. He ſtudied at Rome under Giattino. When he was about 30, his love of letters induced him to accompany the Poliſh ambaſſador to Conſtantinople, where he ſtudied the Turkiſh language under Bobovius and Ahmed, two very ſkilful teachers. So ſucceſsful was he in this ſtudy, that when he had been there only two years, the place of firſt interpreter to the Poliſh embaſſy at the Porte was promiſed to him. When the place became vacant, he was accordingly appointed to it, and obtained ſo much credit by his conduct, that, after a time, he was ſent for into Poland, and again ſent out with full powers as ambaſſador to the Porte. For his able execution of this office, he was further honoured, by being naturalized in Poland; on which occaſion he added the Poliſh termination of *ſki* to his family name, which was Menin. Being deſirous afterwards to extend his ſphere of action, he went to the court of the emperor as interpreter of oriental languages in 1661. Here alſo, as in other inſtances, his talents and behaviour obtained the higheſt approbation; on which account he was not only ſent as interpreter to ſeveral imperial ambaſſadors at the Porte, but was intruſted in many important and confidential ſervices; and, in 1669, having paid a viſit to the holy ſepulchre at Jeruſalem, was made one of the knights of that order. After his return to Vienna he was advanced to further honours; being made one of the counſellors of war to the emperor, and firſt interpreter of oriental languages. At Vienna he died at the age of 75, in the year 1698. His great work, 1. The "Theſaurus linguarum orientalium," was publiſhed at Vienna in 1680, in 4 vols folio; to which was added, in 1687, another volume, intitled, "Complementum Theſauri linguarum orientalium, ſeu onomaſticum Latino-Turcico-Arabico Perſicum." The former volumes having become extremely ſcarce, partly on account of the deſtruction of a great part of the impreſſion, in the ſiege of Vienna by the Turks in 1683, a deſign was formed ſome time ago in England of reprinting the work, by a ſociety of learned men, among whom was Sir William Jones. But as this undertaking, probably on account of the vaſt expence which muſt have been incurred, did not proceed, the empreſs queen Maria Thereſa, who had heard of the plan, took it upon herſelf, and with vaſt liberality furniſhed every thing neceſſary for its completion. In conſequence of this, it was begun to be ſplendidly republiſhed at Vienna in 1780, with this title: "Franciſci a Meſgnien Meninſki Lexicon Arabico-Perſico-Turcicum, adjecta ad ſingulas voces et Phraſes interpretatione Latinâ, ad uſitatiores, etiam Italicâ." Of this edition only two vols folio are yet publiſhed, extending no farther than *zal*, the ninth letter of the Arabic alphabet, which is about a third of the whole. The delay of the reſt is much to be lamented. In this edition, ſay the editors, the Lexicon of Meninſki may be ſaid to be increaſed, diminiſhed, and amended. *Increaſed*, becauſe many Arabic and Perſian words are added, from Wankuli and Ferhengi, the beſt Arabic and Perſic lexicographers whom the Eaſt has produced; and from Herbelot are inſerted the names of kingdoms, cities, and rivers, as well as phraſes in common uſe among the Turks, &c. *Diminiſhed*, becauſe many uſeleſs ſynonyma are omitted, which rather puzzled than aſſiſted the ſtudent; as well as all the French, Poliſh, and German interpretations, the Latin being conſidered as ſufficient for all men of learning. *Amended*, with reſpect to innumerable typographical errors; which, however, from a work of this nature, no care can perhaps altogether exclude. The other works of Meninſki were occaſioned chiefly by a violent conteſt between him and a man named J. B. Podeſta, in which much acrimony was employed on both ſides. Theſe it is hardly worth while to enumerate, but they may all be ſeen in the account of his life from which this article is taken (A). It ſhould be obſerved, however, that in 1674, Podeſta publiſhed a book, intitled, "Prodromus novi linguarum orientalium collegii, juſſu Aug. &c. erigendi, in Univ. Viennenſi;" to which Meninſki oppoſed, 2. "Meninſkii Antidotum in Prodromum novi ling. orient. collegii, &c." 4to. But ſuch was the credit of his antagoniſt in the univerſity, that ſoon after there came out a decree in the name of the rector and conſiſtory, in which that antidote of Meninſki's is proſcribed and prohibited, for ſix ſpecific reaſons, as impious and infamous. Meninſki was defended againſt this formidable attack by a friend, in a ſmall tract, intitled, "Veritas defenſa, ſeu juſtitia cauſæ Dn. F. de M. M. [Meninſki] contra infame decretum Univerſitatis Viennenſis, Anno 1674, 23 Novembris, &c. ab Amico luci expoſita, Anno 1675," in which this friend expoſes, article by article, the falſehood of the decree, and exclaims ſtrongly againſt the arts of Podeſta. This tract is in the Britiſh Muſeum. Podeſta was oriental ſecretary to the emperor, and profeſſor of thoſe languages at Vienna; but is deſcribed in a very ſatirical manner by the defender of Meninſki. "Podeſta, natura Semi-Italus, ſtatura nanus, cæcutiens, balbus, imo bardus repertus, aliiſque vitiis ac ſtultitiis plenus, adeoque ad diſcendas linguas orientales inhabilis." A liſt of the works of Podeſta is, however, given by the late editors of Meninſki.

MERCHETTA, or *Marchetta Mulierum*, is commonly ſuppoſed to have been a right which, during the prevalence of the feudal ſyſtem, the lord had of paſſing the firſt night after marriage with his female villain. This opinion has been held by the greater part of our antiquarians; and we have adopted it in our hiſtory of Scotland publiſhed in the *Encyclopædia*. It appears, however, to be a miſtake. That there was a cuſtom called *merchetta mulierum*, which prevailed not only in England, Scotland, Wales, and the iſle of Guernſey, but alſo on the continent, is indeed a fact unqueſtionable; but Mr Aſtle has clearly proved, that, inſtead of being an adulterous connection, the *merchetta* was a compact between the lord and his vaſſal for the redemption of an *offence* committed by that vaſſal's *unmarried* daughter. He admits, however, that it denoted likewiſe a fine paid by a *ſokeman* or a *villain* to his lord, for a licence to marry his daughter to a free man; and that if the vaſſal gave her away without obtaining ſuch a licence, he was liable to pay a heavier fine. He quotes two authorities in ſupport of his opinion from Bracton; one of which we ſhall tranſcribe, as being alone complete evidence.

Archæologia, vol. xii.

"Ric. Burre tenet unum meſuagium et debet telliagium ſectam curiæ, et *merchet*, hoc modo, *quod ſi maritare voluerit filiam ſuam cum quodam libero homine, extra villam, faciet pacem domini pro maritagio, et ſi eam maritaverit alicui cuſtumario villæ, nihil debuit pro maritagio.*"

"The probable reaſon of the cuſtom (ſays Mr Aſtle) appears to have been this. Perſons of low rank, reſiding on an eſtate, were either *aſcripti glebæ*, or were ſubjected to ſome ſpecies of ſervitude ſimilar to the *aſcripti glebæ*. They were bound to reſide on the eſtate, and to perform ſeveral ſervices to the lord. As women neceſſarily followed the reſidence of their huſbands, the conſequence was, that when a woman of low rank married a ſtranger, the lord was deprived of part of his live ſtock; he therefore required a fine to indemnify him for the loſs of his property." Further particulars on the *merchetta* are to be found in the Appendix to vol. 1ſt of *Sir David Dalrymple's Annals of Scotland.*

MERIDIAN Line, an arch, or part of the meridian of the place, terminated each way by the horizon. Or, a meridian line is the interſection of the plane of the meridian of the place with the plane of the horizon, often called a north-and-ſouth line, becauſe its direction is from north to ſouth.

In the article Astronomy (*Encycl.*), n° 376 and 377, we have given two methods of drawing a meridian line; but it may be proper to add, in this place, the following improvement of the former of theſe from Dr Hutton's Mathematical Dictionary. "As it is not eaſy (ſays the Doctor) to determine preciſely the extremity of the ſhadow, it will be beſt to make the ſtile flat at the top, and to drill a ſmall hole through it, noting the lucid point projected by it on the ſeveral concentric circles, inſtead of marking the extremity of the ſhadow itſelf on theſe circles."

We ſhall give another method of drawing a meridian line from the ſame valuable dictionary.

"Knowing the ſouth quarter pretty nearly, obſerve the altitude FE of ſome ſtar on the eaſt ſide of it, and not far from the meridian HZRN: then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, direct it to the weſtern ſide of the meridian, and wait till you find the ſtar has the ſame altitude as before, as *fe*. Laſtly, biſect the angle EC*e*, formed by the interſection of the two planes in which the quadrant has been placed at the time of the two obſervations, by the right line HR, which will be the meridian ſought."

Plat
XXX

Magnetical Meridian, is a great circle paſſing thro' or by the magnetical poles; to which meridians the magnetical needle conforms itſelf. See Magnetism, *Suppl.*

MESOLABE, or Mesolabium, a mathematical inſtrument invented by the ancients, for finding two mean

---

(A) We have taken this article from the Biographical Dictionary; the editors of which took it from the life of Meninſki prefixed to the new edition of his great work.

mean proportionals mechanically, which they could not perform geometrically. It conſiſts of three parallelograms, moving in a groove to certain interſections. Its figure is deſcribed by Eutocius, in his Commentary on Archimedes. See alſo Pappus, lib. 3.

MESO-Logarithm, a term uſed by Kepler to ſignify the logarithms of the coſines and cotangents.

MESURATA, a ſeaport of the kingdom of Tripoli, in Africa. A caravan proceeds from this place to Fezzan, and other interior parts toward the ſouth of Africa. It is 260 miles north of Mourzook. E. lon. 15. 5. N. lat. 31. 3.

METALLIC Tractors. See Perkinism in this *Suppl.*

METONIC Cycle, called alſo the *Golden Number*, and *Lunar Cycle*, or *Cycle of the Moon*, that which was invented by Meton the Athenian; being a period of 19 years. See Cycle, *Encycl.*

MHA Rajah, the higheſt title of Hindoos.

MICROCOUSTICS, or Microphones, inſtruments contrived to magnify ſmall ſounds, as microſcopes do ſmall objects.

MICROCOSMIC Salt. See Chemistry-*Index*, *Suppl.*

MIDDLE Latitude, is half the ſum of two given latitudes; or the arithmetical mean, or the middle between two parallels of latitude. Therefore,

If the latitudes be of the ſame name, either both north or both ſouth, add the one number to the other, and divide the ſum by 2; the quotient is the middle latitude, which is of the ſame name with the two given latitudes. But

If the latitudes be of different names, the one north and the other ſouth; ſubtract the leſs from the greater, and divide the remainder by 2, ſo ſhall the quotient be the middle latitude, of the ſame name with the greater of the two.

MIDSUMMER-Day, is held on the 24th of June, the ſame day as the nativity of St John the Baptiſt is held.

MILK, or Milkyet, property in Bengal.

Mills.

MILLS of various kinds are deſcribed in the article Mechanics (*Encycl.*); and he who ſhall ſtudy that article, together with *Water-Works*, and Machinery, in this *Supplement*, will have a ſufficient knowledge of the principles upon which mills muſt be conſtructed ſo as that they may produce their proper effects. The ſubject is introduced into this place merely to put it into the power of our countrymen to adopt, if they ſhall think fit, the improvements which have been made in the machinery of flour mills in America.

The chief of theſe conſiſt in a new application of the ſcrew, and the introduction of what are called elevators, the idea of which was evidently borrowed from the chain pump. The ſcrew is made by ſticking ſmall thin pieces of board, about three inches long and two wide, into a cylinder, ſo as to form the ſpiral line. This ſcrew is placed in a horizontal poſition, and by turning on its axis it forces wheat or flour from one end of a trough to the other. For inſtance, in the trough which receives the meal immediately coming from the ſtones, a ſcrew of this kind is placed, by which the meal is forced on, to the diſtance of ſix or eight feet, perhaps, into a reſervoir; from thence, without any manual labour, it is conveyed to the very top of the mill by the elevators, which conſiſt of a number of ſmall buckets of the ſize of tea cups, attached to a long band that goes round a wheel at the top, and another at the bottom of the mill. As the band revolves round the wheels, theſe buckets dip into the reſervoir of wheat or flour below, and take their loads up to the top, where they empty themſelves as they turn round the upper wheel. The elevators are incloſed in ſquare wooden tubes, to prevent them from catching in any thing, and alſo to prevent duſt. By means of theſe two ſimple contrivances no manual labour is required from the moment the wheat is taken to the mill till it is converted into flour, and ready to be packed, during the various proceſſes of ſcreening, grinding, ſifting, &c.

That this is a conſiderable improvement is obvious; and we are not without hopes that it may be adopted. The licentiouſneſs of an Engliſh mob has indeed perſecuted an Arkwright, expelled the inventor of the fly-ſhuttle from his native country, and by ſuch conduct prevented the re-erection of the Albion mills, and the general eſtabliſhment of ſaw-mills through the kingdom; but their ſovereignty perhaps will not be rouſed by ſo eaſy and ſimple a contrivance as this to leſſen the quantity of manual labour. For an account of the Dutch oil-mill, which was ſomehow omitted in its proper place in the *Encyclopædia*, ſee *Oil-Mill* in this *Supplement*.

MINERALOGY

IS a ſcience, the object of which is the deſcription and arrangement of *inorganic bodies* or *minerals*; or of *all* the bodies which belong to our globe, excepting *animal* and *vegetable* ſubſtances.

Since the publication of the article Mineralogy, *Encycl.* ſcarcely a ſingle day has paſſed without the diſcovery of ſome new mineralogical fact, or the detection of ſome old and unſuſpected error. Theſe improvements cannot be overlooked in the preſent *Supplement*. But they are ſo numerous in every part of the ſcience, that we can hardly notice them without giving a pretty complete view of the preſent ſtate of mineralogy. This will ſcarcely occupy more room, and muſt be much more uſeful as well as entertaining, than an undigeſted maſs of annotations and remarks. We undertake this taſk the more readily, becauſe in the article Mineralogy in the *Encyclopædia*, the improvements of Mr Werner and his diſciples, to which the ſcience is indebted for a great part of its preſent accuracy, have been entirely overlooked.

2
Object.

The object of mineralogy is twofold. 1. To *deſcribe* every mineral with ſo much accuracy and preciſion, that it may be eaſily diſtinguiſhed from every other mineral; 2. To *arrange* them into a ſyſtem in ſuch a manner that every mineral may be eaſily referred to its proper place, and that a perſon may be able, merely by the help of the ſyſtem, to diſcover the *name* of any mineral whatever. When theſe two objects are accompliſhed, mineralogy, ſtrictly ſo called, is completed. But were we to ſtop here, the utility of the ſcience, if it would be entitled to the name of ſcience, could hardly be conſidered as very great. We muſt therefore apply *chemiſtry* to diſcover the ingredients of which minerals are compoſed, and to detect, if poſſible, the laws which theſe ingredients have obſerved in their combination. Thus we ſhall really extend our knowledge of inorganic nature, and be enabled to apply that knowledge to the improvement of almoſt every art and manufacture.

3 Diviſion of the article. Mineralogy naturally divides itſelf into three parts. The *firſt* treats of the method of deſcribing minerals; the *ſecond*, of the method of arranging them; and the *third* exhibits them in a ſyſtem deſcribed and arranged according to the rules laid down in the two firſt parts. Theſe three parts ſhall be the ſubjects of the following chapters; and we ſhall finiſh the article with a chapter on the chemical analyſis of minerals.

Chap. I. Of the Deſcription of Minerals.

Nothing, at firſt ſight, appears eaſier than to deſcribe a mineral, and yet, in reality, it is attended with a great deal of difficulty. The mineralogical deſcriptions of the ancients are ſo looſe and inaccurate, that many of the minerals to which they allude cannot be aſcertained; and conſequently their obſervations, however valuable in themſelves, are often, as far as reſpects us, altogether loſt. It it obvious, that to diſtinguiſh a mineral from every other, we muſt either mention ſome peculiar property, or a collection of properties, which exiſt together in no other mineral. Theſe properties muſt be deſcribed in terms rigidly accurate, which convey preciſe ideas of the very properties intended, and of no other properties. The ſmalleſt deviation from this would lead to confuſion and uncertainty. Now it is impoſſible to deſcribe minerals in this manner, unleſs there be a peculiar term for each of their properties; and unleſs this term be completely underſtood. Mineralogy therefore muſt have a language of its own; that is to ſay, it muſt have a *term* to denote every mineralogical property, and each of theſe terms muſt be accurately defined. The language of mineralogy was invented by the celebrated Werner of Freyberg, and firſt made known to the world by the publication of his treatiſe on *the external characters of minerals*. Of this language we ſhall give a view in the following general deſcription of the properties of minerals (A).

4 Properties of minerals. The properties of minerals may be divided into two claſſes. 1*ſt*, Properties diſcoverable without deſtroying the texture of the mineral; 2*d*, Properties reſulting from the action of other bodies on it. The firſt claſs has, by Werner and his diſciples, been called *external* properties, and by ſome French writers *phyſical*; the ſecond claſs has been called *chemical*.

The *external* properties may be arranged under the following heads:

1 Figure.
2 Surface.
3 Tranſparency.
4 Colour.
5 Scratch.
6 Luſtre.
7 Hardneſs.
8 Ductility.
9 Fracture.
10 Texture.
11 Structure.
12 Fragments.
13 Feel.
14 Sound.
15 Smell.
16 Taſte.
17 Gravity.
18 Magnetiſm.
19 Electricity.

5 Figure. I. By FIGURE is meant the ſhape or form which a mineral is obſerved to have. The *figure* of minerals is either *regular*, *particular*, or *amorphous*. 1. Minerals which aſſume a regular figure are ſaid to be cryſtallized *. The *ſides* of a cryſtal are called *faces*; the ſharp line formed by the inclination of two faces is called an *edge*; and the corner, or angle, formed by the meeting of ſeveral edges in one point, is called a *ſolid angle*, or ſimply *an angle*. Thus a cube has ſix faces, twelve edges, and eight angles. 2. Some minerals, though not cryſtallized, affect a *particular* figure. Theſe particular figures are the following: *Globular*, like a globe; *oval*, like an oblong ſpheriod; *ovate*, like an egg; *cheeſe-ſhaped*, a very flattened ſphere; *almond-ſhaped*, like an almond; *lenticular*, like a double convex lenſe, compreſſed and gradually thinner towards the edges; *cuneiform*, like a wedge; *nodulous*, having depreſſions and protuberances like a potatoe; *botryoidal*, like grapes cloſely preſſed together; *dentiform*, longiſh and tortuous, and thicker at the bottom than the top; *wireform*, like a wire; *capillary*, like hair, finer than the preceding; *retiform*, threads interwoven like a net; *dendritic*, like a tree, having branches iſſuing from a common ſtem; *ſhrubform*, branches not ariſing from a common ſtem; *coraloidal*, branched like coral; *ſtalactitical*, like iſicles; *clavated*, like a club, long, and thicker at one end than another; *faſciform*, long ſtraight cylindrical bodies, united like a bundle of rods; *tubular*, cylindrical and hollow. 3. When minerals have neither a regular nor particular ſhape, they are ſaid to be *amorphous*.

6 Surface. II. By SURFACE is meant the appearance of the external ſurface of minerals. The *ſurface* is either *uneven*, compoſed of ſmall unequal elevations and depreſſions; *ſcabrous*, having very ſmall *ſharp* and rough elevations, more eaſily felt than ſeen; *druſy*, covered with very minute cryſtals; *rough*, compoſed of very minute *blunt* elevations, eaſily diſtinguiſhable by the feel; *ſcaly*, compoſed of very minute thin ſcale-like leaves; *ſmooth*, free from all inequality or roughneſs; *ſpecular*, having a ſmooth poliſhed ſurface like a mirror; or *ſtreaked*, having elevated, ſtraight, and parallel lines. This laſt character is confined to the *ſurface* of cryſtals. The *ſtreaks* are either *tranſverſe*; *longitudinal*; *alternate*, in different directions on different faces; *plumoſe*, running from a middle rib; or *decuſſated*, croſſing each other.

7 Tranſparency. III. By TRANSPARENCY is meant the proportion of light which minerals are capable of tranſmitting. They are *tranſparent* or *pellucid*, when objects can be ſeen diſtinctly through them; *diaphanous*, when objects are ſeen

* See CHEMISTRY, Part III. ch. iv. Supp

(A) The fulleſt account of Werner's external characters which we have ſeen in the Engliſh language, has been given by Dr Townſon in his *Philoſophy of Mineralogy*. We have availed ourſelves of this book, in order to exhibit ſome of the lateſt improvements of Werner and his diſciples. The reader may alſo conſult *Werner's Treatiſe*, publiſhed at Leipſic in 1774; or the *French tranſlation* publiſhed at Dijon in 1790. See alſo *Romé de Liſle*. *Des caracters exterieur des mineraux*. And *Hauy Jour. d'hiſt. Nat.* II. 56.

ternal racters.

ſeen through them indiſtinctly; *ſubdiaphanous*, when light paſſes but in ſo ſmall a quantity that objects cannot be ſeen through them (B); *opaque*, when no light is tranſmitted.

When opaque minerals become tranſparent in water, they are called *hydrophanous*. When objects are ſeen double through a tranſparent mineral, it is ſaid to *refract doubly*.

8 lour.

IV. The colours of minerals may be reduced to eight claſſes.

1. *Whites*.

Snow white. Pure white.

Reddiſh white. White with a light tint of red.

Yellowiſh white. White with a light tint of yellow.

Silver white. Yellowiſh white with a metallic luſtre.

Greyiſh white. White with a light tint of black.

Greeniſh white. White with a light tint of green.

Milk white. White with a light tint of blue.

Tin white. Milk white of a metallic luſtre.

2. *Greys*.

Bluiſh grey. Grey with a little blue.

Lead grey. Bluiſh grey with a metallic luſtre.

Pearl grey. Light grey with a ſlight mixture of violet blue.

Smoke grey. Dark grey with a little blue and brown.

Greeniſh grey. Light grey tinged with green.

Yellowiſh grey. A light grey tinged with yellow.

Steel grey. A dark grey with a light tint of yellow and a metallic luſtre.

Black grey. The darkeſt grey with a tint of yellow.

3. *Blacks*.

Greyiſh black. Black with a little white.

Browniſh black. Black with a tint of brown.

Black. Pure black.

Iron black. Pure black with a ſmall mixture of white and a metallic luſtre.

Bluiſh black. Black with a tint of blue.

4. *Blues*.

Indigo blue. A dark blackiſh blue.

Pruſſian blue. The pureſt blue.

Azure blue. A bright blue with ſcarce a tint of red.

Smalt blue. A light blue.

Violet blue. A mixture of azure blue and carmine.

Lavender blue. Violet blue mixed with grey.

Sky blue. A light blue with a ſlight tint of green.

5. *Greens*.

Verdigris green. A bright green of a bluiſh caſt.

Seagreen. A very light green, a mixture of verdigris green and grey.

Beryl green. The preceding, but of a yellowiſh caſt.

Emerald green. Pure green.

Graſs green. Pure green with a tint of yellow.

Apple green. A light green formed of verdigris green and white.

Leek green. A very dark green with a caſt of brown.

Blackiſh green. The darkeſt green, a mixture of leek green and black.

Piſtachio green. Graſs green, yellow and a little brown.

External Characters.

Olive green. A pale yellowiſh green with a tint of brown.

Aſparagus green. The lighteſt green, yellowiſh with a little brown and grey.

6. *Yellows*.

Sulphur yellow. A light greeniſh yellow.

Braſs yellow. The preceding, with a little leſs green and a metallic luſtre.

Lemon yellow. Pure yellow.

Gold yellow. The preceding with a metallic luſtre.

Honey yellow. A deep yellow with a little reddiſh brown.

Wax yellow. The preceding, but deeper.

Pyritaceous. A pale yellow with grey.

Straw yellow. A pale yellow, a mixture of ſulphur yellow and reddiſh grey.

Wine yellow. A pale yellow with a tint of red.

Ochre yellow. Darker than the preceding, a mixture of lemon yellow with a little brown.

Iſabella yellow. A pale browniſh yellow, a mixture of pale orange with reddiſh brown.

Orange yellow. A bright reddiſh yellow, formed of lemon yellow and red.

7. *Reds*.

Aurora red. A bright yellow red, a mixture of ſcarlet and lemon yellow.

Hyacinth red. A high red like the preceding, but with a ſhade of brown.

Brick red. Lighter than the preceding; a mixture of aurora red and a little brown.

Scarlet red. A bright and high red with ſcarce a tint of yellow.

Copper red. A light yellowiſh red with the metallic luſtre.

Blood red. A deep red, a mixture of crimſon and ſcarlet.

Carmine red. Pure red verging towards a caſt of blue.

Cochineal red. A deep red; a mixture of carmine with a little blue and a very little grey.

Crimſon red. A deep red with a tint of blue.

Fleſh red. A very pale red of the crimſon kind.

Roſe red. A pale red of the cochineal kind.

Peach bloſſom red. A very pale whitiſh red of the crimſon kind.

Mordoré. A dark dirty crimſon red; a mixture of crimſon and a little brown.

Browniſh red. A mixture of blood red and brown.

8. *Browns*.

Reddiſh brown. A deep brown inclining to red.

Clove brown. A deep brown with a tint of carmine.

Yellowiſh brown. A light brown verging towards ochre yellow.

Umber brown. A light brown, a mixture of yellowiſh brown and grey.

Hair brown. Intermediate between yellow brown and clove brown with a tint of grey.

Tombac brown. A light yellowiſh brown, of a metallic luſtre, formed of gold yellow and reddiſh brown.

(B) After Mr Kirwan, we have denoted theſe three degrees of tranſparency by the figures 4, 3, 2. When a mineral is ſubdiaphanous only at the edges, that is denoted by the figure 1. Opacity is ſometimes denoted by 0.

External Characters. Liver brown. A dark brown; blackiſh brown with a tint of green.

Blackiſh brown. The darkeſt brown.

Colours, in reſpect of intenſity, are either *dark*, *deep*, *light*, or *pale*. When a colour cannot be referred to any of the preceding, but is a mixture of two, this is expreſſed, by ſaying, that the prevailing one *verges* towards the other, if it has only a ſmall tint of it; *paſſes* into it, if it has a greater.

9 Streak. V. By the SCRATCH or STREAK, is meant the mark left when a mineral is ſcratched by any hard body, as the point of a knife. It is either *ſimilar*, of the ſame colour with the mineral; or *diſſimilar*, of a different colour.

10 Luſtre. VI. LUSTRE, is the gloſs or brightneſs which appears on the external ſurface of a mineral, or on its internal ſurface when freſh broken. The firſt is called *external*, the ſecond *internal* luſtre. Luſtre is either *common*, that which moſt minerals poſſeſs; *ſilky*, like that of ſilk or mother-of-pearl; *waxy*, like that of wax; *greaſy*, like that of greaſe; or *metallic*, like that of metals.

As to the degree, the greateſt is called *ſplendent*, the next *ſhining*, the third *dulliſh*; and when only a few ſcattered particles ſhine, the luſtre is called *dull* (c).

11 Hardneſs. VII. We have uſed figures to denote the comparative HARDNESS of bodies; for an explanation of which, we refer to the article CHEMISTRY, Vol. I. p. 224. of this *Supplement*.

12 Ductility and brittleneſs. VIII. With reſpect to DUCTILITY and BRITTLENESS, minerals are either *malleable*; *ſectile*, capable of being cut without breaking, but not malleable; *flexile*, capable of being bent, and when bent retaining their ſhape; or *elaſtic*, capable of being bent, but recovering their former ſhape. Minerals deſtitute of theſe properties are *brittle*. Brittle minerals, with reſpect to the eaſe with which they may be broken, are either *very tough*, *tough*, *fragile*, or *very fragile*.

13 Fracture. IX. By FRACTURE is meant the freſh ſurface which a mineral diſplays when broken. It is either *flat*, without any general elevation or depreſſion; or *conchoidal*, having wide extended roundiſh hollows and gentle riſings. When theſe are not *very* evident, the fracture is called *flat* conchoidal; when they are ſmall, it is called *ſmall* conchoidal; and when of great extent, *great* conchoidal.

The fracture may alſo be *even*, free from all aſperities; *uneven*, having many ſmall, ſharp, abrupt, irregular elevations and inequalities; and from the ſize of theſe, this fracture is denominated *coarſe*, *ſmall*, or *fine*; *ſplintery*, having ſmall, thin, half detached, ſharp edged ſplinters, according to the ſize of which this fracture is donominated *coarſe* or *fine*; or *rugged*, having many very minute ſharp hooks, more ſenſible to the hand than the eye.

14 Texture. X. By TEXTURE is meant the internal ſtructure or diſpoſition of the matter of which a mineral is compoſed, which may be diſcovered by breaking it. The texture is either *compact*, without any diſtinguiſhable parts, or the appearance of being compoſed of ſmaller parts; *earthy*, compoſed of very minute *almoſt* imperceptible rough parts; *granular*, compoſed of ſmall ſhapeleſs grains; *globuliform*, compoſed of ſmall ſpherical bodies; *fibrous*, compoſed of fibres which may be *long*, *ſhort*, *ſtraight*, *crooked*, *parallel*, *divergent*, *ſtellated*, *faſciculated*, or *decuſſated*; *radiated*, conſiſting of long narrow flattiſh lamellæ; or *lamellar* or *foliated*, conſiſting of ſmooth continued plates covering each other: theſe plates may be either *ſtraight*, *crooked*, or *undulating*.

Extern Characte

15 Structur XI. The STRUCTURE OR COMPOUND TEXTURE is the manner in which the parts that form the texture are diſpoſed. It is either *ſlaty*, in ſtraight layers like ſlate; *teſtaceous*, in incurvated layers; *concentric*, in concentric layers; or *columnar*, in columns.

The *texture* and *ſtructure* may at firſt view appear the ſame; but in reality they are very different. Thus common ſlate has often the *ſlaty ſtructure* and *earthy texture*. The texture of pitcoal is compact, but its ſtructure is often ſlaty.

16 Fragme XII. By FRAGMENTS is meant the ſhape of the pieces into which a mineral breaks when ſtruck with a hammer. They are either *cubic*; *rhomboidal*; *wedgeſhaped*; *ſplintery*, thin, long, and pointed; *tabular*, thin, and broad, and ſharp at the corners, as common ſlate; or *indeterminate*, without any particular reſemblance to any other body. The *edges* of indeterminate fragments are either *very ſharp*, *ſharp*, *ſharpiſh*, or *blunt*.

17 Feel. XIII. By the FEEL of minerals is meant the ſenſation which their ſurfaces communicate when handled. The feel of ſome minerals is *greaſy*, of others *dry*, &c.

18 Sound XIV. Some minerals when ſtruck give a *clear* SOUND, as common ſlate; others a *dull* ſound.

The SMELL, TASTE, SPECIFIC GRAVITY, and MAGNETISM of minerals, require no explanation.

With reſpect to ELECTRICITY, ſome minerals become electric when *heated*, others when *rubbed*, others cannot be rendered electric. The electricity of ſome minerals is *poſitive* or *vitreous*, of others *negative* or *reſinous*.

As for the CHEMICAL properties of minerals, they have been already explained in the article CHEMISTRY, which makes a part of this *Supplement*. And for the deſcription of the blow-pipe, and the manner of uſing it, we refer the reader to a treatiſe on that ſubject prefixed to the article MINERALOGY in the *Encyclopædia*.

CHAP. II. OF THE ARRANGEMENT OF MINERALS.

MINERALS may be arranged two ways, according to their external characters, and according to their chemical compoſition. The firſt of theſe methods has been called an *artificial* claſſification; the ſecond, a *natural* one. The firſt is indiſpenſably neceſſary for the ſtudent of nature; the ſecond is no leſs indiſpenſable for the proficient who means to turn his knowledge to account. Without the firſt, it is impoſſible to diſcover the *names* of minerals; and without the ſecond, we muſt remain ignorant of their uſe.

Almoſt every ſyſtem of mineralogy hitherto publiſhed, at leaſt ſince the appearance of Werner's *external characters*, has attempted to combine theſe two arrangements, and to obtain at one and the ſame time the advantages peculiar to each. But no attempt of this kind has hitherto ſucceeded. Whether this be owing to any thing impoſſible in the undertaking, or to the preſent

---

(c) Theſe four degrees have been denoted by Kirwan by the figures 4, 3, 2, 1, and no luſtre by 0. We have imitated him in the preſent article.

tificial
ſtem.

Artificial
Syſtem.

preſent imperfect ſtate of mineralogy, as is more probable, we do not take upon us to determine. But ſurely the want of ſucceſs, which has hitherto attended all attempts to combine the two arrangements, ought to ſuggeſt the propriety of ſeparating them. By adhering ſtrictly to one language, the trouble of ſtudying two different ſyſtems would be entirely prevented. They would throw mutual light upon each other: the artificial ſyſtem would enable the ſtudent to diſcover the *names* of minerals; the natural would enable him to arrange them, and to ſtudy their properties and uſes.

The happy arrangement of Cronſtedt, together with the ſubſequent improvements of Bergman, Werner, Kirwan, Hauy, and other celebrated mineralogiſts, has brought the *natural* ſyſtem of mineralogy to a conſiderable degree of perfection. But an *artificial* ſyſtem is ſtill a deſideratum; for excepting Linnæus, whoſe ſucceſs was precluded by the ſtate of the ſcience, no one has hitherto attempted it. Though we are very far from thinking ourſelves ſufficiently qualified for undertaking ſuch a taſk, we ſhall nevertheleſs venture, in the next chapter, to ſketch out the rudiments of an artificial ſyſtem. The attempt, at leaſt, will be laudable, even though we ſhould fail.

CHAP. III. ARTIFICIAL SYSTEM.

19
ficial
s.

MINERALS may be divided into ſix claſſes:

1. Minerals that cannot be fuſed by the blow-pipe *per ſe*.

2. Minerals fuſible *per ſe* by the blow-pipe.

3. Minerals fuſible by the blow-pipe *per ſe* when expoſed to the blue flame, but not when expoſed to the yellow flame.

4. Minerals fuſible *per ſe* by the blow-pipe; and when in fuſion, partly evaporating in a viſible ſmoke.

5. Minerals which totally evaporate before the blow-pipe.

6. Minerals totally ſoluble in muriatic acid with effervescence, the ſolution colourleſs.

Under theſe heads we ſhall arrange the ſubjects of the mineral kingdom.

CLASS I. INFUSIBLE.

ORDER I. Specific gravity from 16 to 12.

GENUS I. Colour whitiſh iron grey.

Species 1. Native platinum.

ORDER II. Sp. gr. 8.5844 to 7.006.

GENUS I. Attracted by the magnet.

Sp. 1. Native iron.

GENUS II. Not attracted by the magnet.

Sp. 1. Native copper.

Flexible and malleable. Colour uſually red.

Sp. 2. Wolfram.

Brittle. Colour uſually brown or black.

ORDER III. Sp. gr. from 6.4509 to 5.8.

GENUS I. Forms a blue glaſs with microcoſmic ſalt, which becomes colourleſs in the yellow, but recovers its colour in the blue flame.

Sp. 1. Tungſtat of lime.

GENUS II. Forms with microcoſmic ſalt a permanently coloured bead.

Sp. 1. Sulphuret of cobalt.

ORDER IV. Sp. gr. from 4.8 to 4.5.

GENUS I. Tinges borax dark green.

Sp. 1. Common magnetic iron ſtone.

GENUS II. Tinges borax reddiſh brown.

Sp. 1. Grey ore of manganeſe.

ORDER V. Sp. gr. from 4.4165 to 3.092. Infuſible with fixed alkalies.

GENUS I. Hardneſs 20.

Sp. 1. Diamond.

GENUS II. Hardneſs 15 to 17. Cauſes ſingle refraction.

Sp. 1. Teleſia.

Sp. 2. Corundum.

GENUS III. Hardneſs 13. Single refraction.

Sp. 1. Ruby.

Cryſtallizes in octohedrons.

GENUS IV. Hardneſs 12. Single refraction.

Sp. 1. Chryſoberyl.

GENUS V. Hardneſs 12. Cauſes double refraction. Becomes electric when heated.

Sp. 1. Topaz.

GENUS VI. Hardneſs 10 to 16. Double refraction. Sp. gr. 4.2 to 4.165.

Sp. 1. Zircon.

GENUS VII. Hardneſs 6 to 9. Feels greaſy.

Sp. 1. Cyanite.

GENUS VIII. Hardneſs 9 to 10. Feel not greaſy. Double refraction. Sp. gr. 3.283 to 3.285.

Sp. 1. Chryſolite.

GENUS IX. Hardneſs 12. Infuſible with borax. Colour of large maſſes black, of thin pieces deep green.

Sp. Ceylanite.

(Phoſphat of lime.)

ORDER VI Sp. gr. from 2.9829 to 1.987. Infuſible with fixed alkalies.

GENUS I. Hardneſs 12.

Sp. 1. Emerald.

GENUS II. Hardneſs 10.

Sp. 1. Jade.

GENUS III. Hardneſs 6 to 7. Somewhat tranſparent.

Sp. 1. Phoſphat of lime.

Before the blow-pipe becomes ſurrounded with a luminous green vapour.

GENUS IV. Hardneſs 6. Opaque.

Sp. 1. Micarelle.

GENUS V. Stains the fingers. Colour lead grey.

Sp. 1. Plumbago.

Spaniſh wax rubbed with plumbago does not become electric; or if it does, the electricity is negative. Streak lead grey even on earthen ware.

ORDER VII. Sp. gr. from 4.7385 to 4.569. Fuſible with fixed alkalies.

GENUS I. Stains the fingers. Colour lead grey.

Sp. 1 Molybdena.

Spaniſh wax rubbed with molybdena becomes poſitively electric. Streak on earthen ware yellowiſh green.

ORDER VIII. Sp. gr. from 4.1668 to 2.479. Fuſible with fixed alkalies.

* Hardneſs from 10 to 12.

Artificial Syſtem.

Genus I. Uſually white. Cryſtals dodecahedrons. Double refraction. Fracture imperfectly conchoidal or ſplintery. Brittle.
Sp. 1. Quartz.

Genus II. Uſually dark brown. Fracture perfectly conchoidal. Brittle. Eaſily breaks into ſplinters.
Sp. 1. Flint.

Genus III. Not brittle. Fracture even or imperfectly conchoidal.
Sp. 1. Chalcedony.
Sp. 2. Jaſper.

Genus IV. Forms with potaſs a violet glaſs, with ſoda or borax a brown glaſs, with microcoſmic ſalt a honey yellow glaſs. Colour green. Amorphous.
Sp. 1. Chryſopraſium.

Genus V. Tinges ſoda red. The colour diſappears before the blue flame, and returns before the yellow flame.
Sp. 1. Oxyd of manganeſe and barytes.
Sp. 2. Black ore of manganeſe.
Sp. 3. Carbonat of manganeſe.
(*Brown ore of iron. Red ore of iron.*)
** Hardneſs 9 to 3.

Genus VI. Flexible and elaſtic in every direction.
Sp. 1. Elaſtic quartz.

Genus VII. Emits white flakes before the blow-pipe.
Sp. 1. Blende.

Genus VIII. Becomes electric when heated.
Sp. 1. Calamine.

Genus IX. Tinges borax green. Blackens before the blow-pipe.
Sp. 1. Mountain blue.
Colour blue.
Sp. 2. Green carbonat of copper.
Colour green.

Genus X. Tinges borax green. Becomes attractable by the magnet by the action of the blow-pipe.
Sp. 1. Brown iron ore.
Colour brown.
Sp. 2. Red iron ore.
Colour red.

Genus XI. Tinges borax ſmutty yellow. Becomes browniſh black before the blow-pipe.
Sp. 1. Carbonat of iron.

Genus XII. Feels greaſy.
Sp. 1. Steatites.
(*Black ore of Manganeſe. Carbonat of manganeſe. Mica.*)

ORDER IX. Sp. gr. from 2.39 to 1.7.

Genus I. Luſtre glaſſy.
Sp. 1. Opal.
Sp. 2. Hyalite.

Genus II. Luſtre greaſy.
Sp. 1. Pitchſtone.

Genus III. Luſtre waxy or pearly.
Sp. 1. Staurolite.

Class II. FUSIBLE.

ORDER I. Sp. gr. from 19 to 10.

Genus I. Colour Yellow.
Sp. 1. Native gold.

Genus II. Colour white.
Sp. 1. Native Silver.

Genus III. Colour yellowiſh white.
Sp. 1. Alloy of ſilver and gold.

ORDER II. Sp. gr. from 7.786 to 4.5.

Genus I. Flexible and malleable.
Sp. 1. Sulphuret of ſilver.
** Brittle.

Genus II. Tinges borax white.
Sp. 1. Tinſtone.

Genus III. Tinges borax green.
Sp. 1. Sulphuret of copper.
Colour bluiſh grey.
Sp. 2. Chromat of lead.
Colour aurora red.
Sp. 3. Purple copper ore.
Colour purple.

Genus IV. Tinges borax faint yellow. Becomes black when expoſed to the vapour of ſulphuret of ammonia.
Sp. 1. Galena.
Colour bluiſh grey. Luſtre metallic. Fragments cubic.
Sp. 2. Black lead ore.
Colour black. Luſtre metallic.
Sp. 3. Lead ochre.
Colour yellow, grey, or red. Luſtre 0.
Sp. 4. Carbonat of lead.
Colour white. Luſtre waxy.
Sp. 5. Phoſphat of lead.
Uſually green. Luſtre waxy. After fuſion by the blow-pipe cryſtallizes on cooling.
Sp. 6. Molybdat of lead.
Colour yellow. Streak white. Luſtre waxy.

ORDER III. Sp. gr. from 4.35 to 3.
* Hardneſs 14 to 9.

Genus I. Melts without frothing into a grey enamel.
Sp. 1. Garnet.
Colour red.

Genus II. Melts into a browniſh enamel.
Sp. 1. Shorl.
Colour black. Opaque.

Genus III. Froths and melts into a white enamel.
Sp. 1. Tourmaline.
Becomes electric by heat.

Genus IV. Froths and melts into a greeniſh black enamel.
Sp. 1. Baſaltine.

Genus V. Froths amd melts into a black enamel.
Sp. 1. Thallite.
Colour dark green.
Sp. 2. Thumeiſtone.
Colour clove brown.
** Hardneſs 5 to 8.

Genus VI. Melts into a tranſparent glaſs.
Sp. 1. Fluat of lime.
Powder phoſphoreſces when thrown on a hot iron.

Genus VII. Melts into a black glaſs.

ificial tem.

Artificial Syſtem.

Sp. 1. Hornblende.

Genus VIII. Melts into a black bead with a ſulphureous ſmell, and depoſits a blue oxyd on the charcoal.

Sp. 1. Sulphuret of tin.

Genus IX Melts into a brown glaſs. Tinges borax violet.

Sp. 1. Aſbeſtoid.

Colour green.

Genus X. Melts into a brown (?) glaſs. When fuſed with potaſs, and diſſolved in water, the ſolution becomes of a fine orange yellow.

Sp. 1. Chromat of iron.

Genus XI. Before the blow-pipe yields a bead of copper.

Sp. 1. Red oxyd of copper.

(Sulphuret of copper.)

ORDER IV. Sp. gr. from 2.945 to 2.437.

Genus I. Compoſed of ſcales.

Sp. 1. Talk.

Feels greaſy. Spaniſh wax rubbed by it becomes poſitively electric.

Genus II. Compoſed of thin plates, eaſily ſeparable from each other.

Sp. 1. Mica.

Plates flexible and elaſtic, may be torn but not broken. Spaniſh wax rubbed by it becomes negatively electric.

Sp. 2. Stilbite.

Plates ſomewhat flexible. Colour pearl white. Powder renders ſyrup of violets green. Froths and melts into an opaque white enamel.

Sp. 3. Lepidolite.

Colour violet. Powder white with a tint of red. Froths and melts into a white ſemitranſparent enamel full of bubbles.

Genus III. Texture foliated.

Sp. 1. Felſpar.

Fragments rhomboidal. Hardneſs 9 to 10.

Sp. 2. Leucite.

Always cryſtallized. White. Powder renders ſyrup of violets green. Hardneſs 8 to 10.

Sp. 3. Argentine felſpar.

Always cryſtallized. Two faces dead white, two ſilvery white.

Sp. 4. Prehnite.

Colour green. Froths and melts into a brown enamel.

Genus IV. Texture fibrous. Fibres eaſily ſeparated.

Sp. 1. Aſbeſtus.

Feels ſomewhat greaſy.

Genus V. Texture ſtriated.

Sp. 1. Ædelite.

Abſorbs water. Froths and melts into a frothy maſs.

Genus VI. Texture earthy or compact.

Sp. 1. Lazulite.

Froths and melts into a yellowiſh black maſs. If previouſly calcined, gelatinizes with acids.

Sp. 2. Borat of lime.

Tinges the flame greeniſh, froths and melts into a yellowiſh enamel garniſhed with ſmall projecting points. If the blaſt be continued, theſe dart off in ſparks.

ORDER V. Sp. gr. from 2.348 to 0.68.

Genus I. Hardneſs 10.

Sp. 1. Obſidian.

Colour blackiſh, in thin pieces green.

Genus II. Hardneſs 6 to 8.

Sp. 1. Zeolite.

Gelatinizes with acids. Becomes electric by heat.

Genus III. Hardneſs 3 to 4.

Sp. 1. Amianthus.

Feels greaſy. Texture fibrous.

Sp. 2. Mountain cork.

Elaſtic like cork.

Class III. FUSIBLE by the BLUE FLAME, INFUSIBLE by the YELLOW.

Genus I. Sp. gr. from 4.43 to 4.4.

Sp. 1. Sulphat of barytes.

Genus II. Sp. gr. from 3.96 to 3.51.

Sp. 1. Sulphat of ſtrontites.

Genus III. Sp. gr. from 2.311 to 2.167.

Sp. 1. Sulphat of lime.

Class IV. FUSIBLE, and partly EVAPORATING.

ORDER I. Sp. gr. from 10 to 5.

Genus I. Colour white or grey. Luſtre metallic.

* Sp. gr. 9 to 10.

Sp. 1. Native amalgam.

Tinges gold white. Creaks when cut.

Sp. 2. Alloy of ſilver and antimony.

Powder greyiſh black.

** Sp. gr. from 6 467 to 5.309.

Sp. 3. Sulphuret of biſmuth.

Melts when held to the flame of a candle.

Sp. 4. Dull grey cobalt ore.

Streak bluiſh grey. Hardneſs 10. When ſtruck, emits an arſenical ſmell. Luſtre ſcarcely metallic.

Genus II. Colour red, at leaſt of the ſtreak.

Sp. 1. Red ſilver ore.

Burns with a blue flame.

Sp. 2. Hepatic mercurial ore.

Does not flame, but gives out mercury before the blow-pipe.

Genus III. Colour blue.

Sp. 1. Blue lead ore.

Burns with a blue flame and ſulphureous ſmell, and leaves a button of lead.

Genus IV. Colour yellowiſh green.

Sp. 1. Phoſphat and arſeniat of lead combined.

When fuſed by the blow-pipe, cryſtallizes on cooling.

Genus V. Colour uſually that of copper. Sp. gr.

Artificial Syſtem.

gr. 6.6084 to 6.6481.
Sp. 1. Sulphuret of nickel.
Exhales before the blow-pipe an arſenical ſmoke.

ORDER II. Sp. gr. from 4.6 to 3.44.
Genus I. Colour grey.
Sp. 1. Grey ore of antimony.
Burns with a blue flame, and leaves a white oxyd.
Sp. 2. Grey copper ore.
Crackles before the blow-pipe.
Genus II. Colour yellow.
Sp. 1. Pyrites.
Burns with a blue flame and ſulphureous ſmell, and leaves a browniſh bead.
Sp. 2. Yellow copper ore.
Melts into a black maſs.

Class V. EVAPORATING.

ORDER I. Sp. gr. 13.6.
Genus I. Fluid.
Sp. 1. Native mercury.

ORDER II. Sp. gr. from 10 to 5.419.
Genus I. Colour red.
Sp. 1. Native cinnabar.
Genus II. Colour white or grey. Luſtre metallic.
Sp. 1. Native biſmuth.
Melts into a white bead, and then evaporates in a yellowiſh white ſmoke. Sp. gr. 9 to 9.5.
Sp. 2. Native antimony.
Melts and evaporates in a grey ſmoke. Sp. gr. 6.6 to 6.8.
Sp. 3. Native arſenic.
Evaporates without melting, and gives out a garlic ſmell.

ORDER III. Sp. gr. from 4.8 to 3.33.
Genus I. Colour red.
Sp. 1. Red antimonial ore.
Melts with a ſulphureous ſmell. Sp. gr. 4.7.
Sp. 2. Realgar.
Melts with a garlic ſmell. Sp. gr. 3.384.
Genus II. Colour yellow.
Sp. 1. Orpiment.

Class VI. SOLUBLE with EFFERVESCENCE in MURIATIC ACID.

Natural Syſtem.

Genus I. Sp. gr. from 4.338 to 4.3.
Sp. 1. Carbonat of barytes.
Genus II. Sp. gr. from 3.66 to 3.4.
Sp. 1. Carbonat of ſtrontites.
Genus III. Sp. gr. from 2.8 to 1 or under.
Sp. 1. Carbonat of lime.

We have purpoſely avoided giving names to the claſſes, orders, and genera; becauſe a more careful examination will doubtleſs ſuggeſt many improvements in the arrangement, and an artificial ſyſtem ought to be brought to a great degree of perfection before its claſſes, orders, and genera, be finally ſettled.

We have excluded from this arrangement all thoſe bodies which in the following ſyſtem are arranged under the claſs of combuſtibles; becauſe there can ſcarcely be any difficulty in diſtinguiſhing them both from the other claſſes and from one another. For ſimilar reaſons we have excluded the claſs of ſalts.

Chap. IV. Natural System.

Avicenna, a writer of the 11th century, divided minerals into four claſſes; ſtones, ſalts, inflammable bodies, and metals (D). This diviſion has been, in ſome meaſure, followed by all ſucceeding writers. Linnæus, indeed, the firſt of the moderns who publiſhed a ſyſtem of mineralogy, being guided by the external characters alone, divided minerals into three claſſes, *petræ*, *mineræ*, *foſſilia*: but Avicenna's claſſes appear among his orders. The ſame remark may be made with reſpect to the ſyſtems of Wallerius, Wolſterdorf, Cartheuſer, and Juſti, which appeared in ſucceſſion after the firſt publication of Linnæus's *Syſtema Naturæ*, in 1736. At laſt, in 1758, the ſyſtem of Cronſtedt appeared. He reinſtated the claſſes of Avicenna in their place; and his ſyſtem was adopted by Bergman, Kirwan, Werner, and the moſt celebrated mineralogiſts who have written ſince. We alſo ſhall adopt his claſſes, with a few ſlight exceptions; becauſe we are not acquainted with any other diviſion which is intitled to a preference.

20 Natural claſſes.

We ſhall therefore divide this treatiſe into four claſſes. I. Stones. II. Salts. III. Combuſtibles. IV. Ores.

The firſt claſs comprehends all the minerals which are compoſed chiefly or entirely of earths; the ſecond, all the combinations of acids and alkalies which occur in the mineral kingdom; the third, thoſe minerals which are capable of combuſtion, and which conſiſt chiefly of ſulphur, carbon, and oil; the fourth, the mineral bodies which are compoſed chiefly of metals.

Class I. EARTHS and STONES.

WE ſhall divide this claſs into three orders. The firſt order ſhall comprehend all chemical combinations of earths with each other; the ſecond order, chemical combinations of earths with acids; and the third order, mechanical mixtures of earths or ſtones. All the minerals belonging to the firſt order exhibit the ſame homogeneous appearance to the eye as if they were ſimple bodies. We ſhall therefore, for want of a better name, call the firſt order *ſimple*; the ſecond order we ſhall diſtinguiſh by the epithet of *ſaline*; and the third we ſhall call

---

(D) Corpora mineralia in quatuor ſpecies dividuntur, ſcilicet in lapides, et in liqueſactiva, ſulphurea, et ſales. Et horum quædam ſunt raræ ſubſtantiæ et debilis compoſitionis, et quædam fortis ſubſtantiæ, et quædam ductibilia, et quædam non. *Avicenna de congelatione et conglutinatione lapidum*, Cap. 3. *Theatrum Chemicum*, t. iv. p. 997.

Ea s and nes. call *aggregates*; becauſe moſt of the minerals belonging to it conſiſt of various *ſimple ſtones*, cemented, as it were, together.

Order I. SIMPLE STONES.

1 Cr ſtedt's ge a. CRONSTEDT divided this order into nine genera, correſponding to nine earths; one of which he thought compoſed the ſtones arranged under each genus. The names of his genera were, *calcareæ*, *ſiliceæ*, *granatinæ*, *argillaceæ*, *micaceæ*, *fluores*, *aſbeſtinæ*, *zeolithicæ*, *magneſiæ*. All his earths were afterwards found to be compounds, except the firſt, ſecond, fourth, and ninth. Bergman, therefore, in his Sciagraphia, firſt publiſhed in 1782, 2 Im oved. reduced the number of genera to five; which was the number of primitive earths known when he wrote. Since that period three new earths have been diſcovered. Accordingly, in the lateſt ſyſtems of mineralogy, the genera belonging to this order amount to eight. Each genus is named from an earth; and they are arranged in the neweſt Wernerian ſyſtem, which we have ſeen, as follows:

1. Jargon genus.
2. Siliceous genus.
3. Glucina genus.
4. Argillaceous genus.
5. Magneſian genus.
6. Calcareous genus.
7. Barytic genus.
8. Strontian genus.

Mr Kirwan, in his very valuable ſyſtem of mineralogy, has adopted the ſame genera. Under each genus, thoſe ſtones are placed, which are compoſed chiefly of the earth which gives a name to the genus, or which at leaſt are ſuppoſed to poſſeſs the characters which diſtinguiſh that earth.

3 Si efici- en. A little conſideration will be ſufficient to diſcover that there is no natural foundation for theſe genera. Moſt ſtones are compoſed of two, three, or even four ingredients; and, in many caſes, the proportion of two or more of theſe is nearly equal. Now, under what genus ſoever ſuch minerals are arranged, the earth which gives it a name muſt form the ſmalleſt part of their compoſition. Accordingly, it has not been ſo much the chemical compoſition, as the external character, which has guided the mineralogiſt in the diſtribution of his ſpecies. The genera cannot be ſaid properly to have any character at all, nor the ſpecies to be connected by any thing elſe than an arbitrary title. This defect, which muſt be apparent in the moſt valuable ſyſtems of mineralogy, ſeems to have ariſen chiefly from an attempt to combine together an artificial and natural ſyſtem. As we have ſeparated theſe two from each other, it becomes neceſſary for us to attend more accurately to the natural diſtribution of genera than has hitherto been done. We have accordingly ventured to form new genera for this order, and we have formed them according to the following rules.

4 N genera. The only ſubſtances which enter into the minerals belonging to this order, in ſuch quantity as to deſerve attention, are the following:

Alumina,
Silica,
Magneſia,
Lime,
Barytes,
Glucina,
Zirconia,
Oxyd of iron,
Oxyd of chromum,
Potaſs,

All thoſe minerals which are compoſed of the *ſame* ingredients we arrange under the *ſame* genus. According to this plan, there muſt be as many genera as there are varieties of combinations of the above ſubſtances exiſting in nature. The varieties in the *proportion* of the ingredients conſtitute ſpecies. We have not impoſed names upon our genera, but, in imitation of Bergman *, have denoted each by a ſymbol. This ſymbol is compoſed of the firſt letter of every ſubſtance which enters in any conſiderable quantity into the compoſition of the minerals arranged under the genus denoted by it. Thus, ſuppoſe the minerals of a genus to be compoſed of *alumina*, *ſilica*, and *oxyd of iron*, we denote the genus by the ſymbol *aſi*. The letters are arranged according to the proportion of the ingredients; that which enters in the greateſt proportion being put firſt, and the others in their order. Thus the genus *aſi* is compoſed of a conſiderable proportion of alumina, of a ſmaller proportion of ſilica, and contains leaſt of all of iron. By this contrivance, the ſymbol of a genus contains, within the compaſs of a few letters, a pretty accurate deſcription of its nature and character. Where the proportions of the ingredients vary in the ſame genus ſo much, that the letters which conſtitute its ſymbol change their place, we ſubdivide the genus into parts; and whenever the minerals belonging to any genus become too numerous, advantage may be taken of theſe ſubdiviſions, and each of them may be formed into a ſeparate genus. At preſent this ſeems unneceſſary (E).

* *Opuſc.* iv. 231.

The following is a view of the different genera belonging to this order, denoted each by its ſymbol. Every genus is followed by the ſpecies included under it; and the whole are in the order which we mean to follow in deſcribing them:

I. A.
    Teleſia,
    Corundum,
    Native alumina.
II. AMC.
    Ruby.
III. AIM.
    Ceylanite,
IV. S.
    Quartz,
    Elaſtic quartz,
    Flint,
    Opal,
    Pitchſtone,
    Chryſopraſium.
V. 1. AS.
    Topaz,
    Sommite,
    Shorlite.
  2. SA.
    Rubellite,
    Hornſlate,
    Hornſtone,
    Chalcedony,
    Jaſper,
    Tripoli.
VI. 1. ASI.
    Micarell,
    Shorl,
    Granatite,
  2. SAI.
    Tourmaline,
    Argentine felſpar,
    Mica,
    Talc,
    Baſaltine,
    Hornblende,
    Obſidian,
    Petrilite,
    Felſite.
VII. SAP.
    Felſpar,
    Lepidolite,
    Leucite.
VIII. SAG.
    Emerald.
IX. SAB.
    Staurolite.
X. 1. ASL.
    Chryſoberyl.
  2. SAL.
    Hyalite,
    Ædelite.
  3. SAWL.

(E) We need hardly remark, that the laſt three genera of Werner belong to the ſecond order of the firſt claſs of this treatiſe.

3. SAWL.
    Zeolite,
    Stilbite,
    Analcime.
4. SLA.
    Lazulite.
XI. SALI.
    Garnet,
    Thumerſtone,
    Prehnite,
    Thallite.
XII. 1. AMS.
    Cyanite.
  2. MSA.
    Serpentine.
XIII. MSAI.
    Potſtone,
    Chlorite.
XIV. SLAM.
    Siliceous ſpar.
XV. SAMLI.
    Argillite.
XVI. SM.
    Kiffekill,
    Steatites.
XVII. MSI.
    Chryſolite,
    Jade.
XVIII. SML.
    Aſbeſtus,
    Aſbeſtinite.
XIX. 1. SILM.
    Pyroxen,
    Aſbeſtoid.
  2. SMIL.
    Æctinolite.
XX. SL.
    Shiſtoſe horneſtone.
XXI. ZS.
    Zircon.

25
G. I. A.
Teleſia.

GENUS I. A.

SPECIES 1. Teleſia (F).

Oriental ruby, *ſapphire*, and *topaz* of mineralogiſts.—*Rubis d'orient* of De Liſle.

Three ſtones, diſtinguiſhed from each other by their colour, have long been held in high eſtimation on account of their hardneſs and beauty. Theſe ſtones were known among lapidaries by the names of *ruby*, *ſapphire*, and *topaz*, and the epithet *oriental* was uſually added, to diſtinguiſh them from other three, known by the ſame names and the ſame colours, but very inferior in hardneſs and beauty. Mineralogiſts were accuſtomed to conſider theſe ſtones as three diſtinct ſpecies, till Romé de Liſle obſerved that they agreed in the form of their cryſtals, their hardneſs, and moſt of their other properties. Theſe obſervations were ſufficient to conſtitute them one ſpecies; and accordingly they were made one ſpecies by Romé de Liſle himſelf, by Kirwan, and ſeveral other modern mineralogical writers. But this ſpecies was deſtitute of a proper name, till Mr Hauy, whoſe labours, diſtinguiſhed equally by their ingenuity and accuracy, have contributed not a little to the progreſs of mineralogy, denominated it *teleſia*, from the Greek word τελεσιος, which ſignifies *perfect*.

The teleſia is found in the Eaſt Indies, eſpecially in Pegu and the iſland of Ceylon; and it is moſt commonly cryſtallized. The cryſtals are of no great ſize: Their *primitive* form, according to Mr Hauy, is a regular ſix-ſided priſm, diviſible in directions parallel both to its baſes and its ſides; and conſequently giving for the form of its primitive nucleus, or of its *integrant molecule*, an equilateral three ſided priſm *. The moſt uſual variety is a dodecahedron, in which the teleſia appears under the form of two very long ſlender ſix-ſided pyramids, joined baſe to baſe †. The ſides of theſe pyramids are iſoſceles triangles, having the angle at their vertex 22° 54′, and each of thoſe at the baſe 78° 48′ (G). The inclination of a ſide of one pyramid to a contiguous ſide of the other pyramid is 139° 54′ †. In ſome ſpecimens the ſummits of the pyramids are wanting, ſo that the cryſtal has the appearance of a ſix-ſided priſm, ſomewhat thicker in the middle than towards the extremities *. The three alternate angles at each extremity of this priſm are alſo ſometimes wanting, and a ſmall triangular face inſtead of them, which renders the baſes of the ſuppoſed priſm nine-ſided. The inclination of each of theſe ſmall triangles to the baſe is 122° 18′ ‡. For figures of theſe cryſtals we refer the reader to Romé de Liſle and Hauy *.

* Ann de Chim. xvii. 313.
† Plate XXXVI. fig. 1.
† Ibid and Romé de Liſle, ii. 315.
* Fig. 2.
‡ Hauy, ib
* Ibid.

The texture of the teleſia is foliated, and the joints are parallel to the baſe of the priſm †. Its luſtre varies from 3 to 4 (H). Tranſparency uſually 3 or 4, ſometimes only 2. It cauſes only a ſingle refraction. Specific gravity from 4. to 4.288. Hardneſs from 15 to 17. It is either colourleſs, or red, yellow or blue. Theſe colours have induced lapidaries to divide the teleſia into the three following varieties.

† Hauy.

Variety 1. Red teleſia.
Oriental ruby.

Colour carmine red, ſometimes verging towards violet. Sometimes various colours appear in the ſame ſtone, as red and white, red and blue, orange red. Hardneſs 17. Sp. gr. 4.288.

Variety 2. Yellow teleſia.
Oriental topaz.

Colour golden yellow. Tranſp. 4. Hardneſs 15. Sp gr. 4.0106.

Variety 3. Blue teleſia.
Oriental ſapphyr.

Colour Berlin blue, often ſo very faint that the ſtone appears almoſt colourleſs. Tranſp. 3, 4, 2. Hardneſs 17. Sp. gr. 3 991 to 4 083 ‡. This variety is not probably the ſame with the ſapphyr of the ancients. Their ſapphyr was diſtinguiſhed by gold-coloured ſpots, none of which are to be ſeen in the ſapphyr of the moderns ‖.

‡ Grevill Nicholſon Jour. iii
‖ Hill's Theophraſtus, περι των λιθων p. 100.

A ſpecimen of this laſt variety, analyſed by Mr Klaproth, was found to contain in 100 parts,

98.5 alumina,
1.0 oxyd of iron,
0.5 lime,

100.0 *.

* Beiträg i. 81.

The colouring matter of all theſe varieties is, according to Bergman's experiments, iron, in different ſtates of oxydation. He found that the topaz contained .06, the ruby .1, and the ſapphyr .02 of that metal †. But when theſe experiments were made, the analyſis of ſtones was not arrived at a ſufficient degree of perfection to enſure accuracy. No concluſion, therefore, can be drawn from theſe experiments, even though we were certain that they were made upon the real varieties of teleſia.

† Bergm ii. 96.

SPECIES

(F) See *Kirwan's Mineralogy*, I. 250.—*Gmelin's Syſtema Naturæ of Linnæus*, III. 170.—*Romé de Liſle's Cryſtallographie*, II. 212.—*Bermanni Opuſcula*, II. 72.

(G) In ſome inſtances, the angle at the vertex is 31°, thoſe at the baſe 74° 30′, and the inclination of two triangles 122° 36′. See *Hauy*, *ibid*.

(H) When the *kind* of luſtre is not ſpecified, as in the preſent inſtance, the *common* is always meant.

dum.

SPECIES 2. Corundum (1).

Corundum of Gmelin—*Adamantine ſpar* of Klaproth and Kirwan—*Corindon* of Hauy—*Corivindum* of Woodward.

This ſtone, though it appears to have been known to Mr Woodward, may be ſaid to have been firſt diſtinguiſhed from other minerals by Dr Black. In 1768, Mr Berry, a lapidary in Edinburgh, received a box of it from Dr Anderſon of Madras. Dr Black aſcertained, that theſe ſpecimens differed from all the ſtones known to Europeans; and, in conſequence of its hardneſs, it obtained the name of *adamantine ſpar*. Notwithſtanding this, it could ſcarcely be ſaid to have been known to European mineralogiſts till Mr Greville of London, who has done ſo much to promote the ſcience of mineralogy, obtained ſpecimens of it, in 1784, from India, and diſtributed them among the moſt eminent chemiſts, in order to be analyſed. Mr Greville alſo learned, that its Indian name was Corundum. It is found in Indoſtan, not far from the river Cavery, which is ſouth from Madras, in a rocky matrix, of conſiderable hardneſs, partaking of the nature of the ſtone itſelf *. It occurs alſo in China; and a ſubſtance, not unlike the matrix of corundum, has been found in Teree, one of the weſtern iſlands of Scotland †.

The corundum is uſually cryſtallized. Its primitive form, diſcovered by Mr Hauy ‡ and the Count de Bournon *, is a rhomboidal parallelopiped, whoſe ſides are equal rhombs, with angles of 86° and 94°, according to Bournon, or whoſe diagonals are to each other as $\surd 17$ to $\surd 15$, according to Hauy; which is very nearly the ſame thing †. The moſt common variety, for the primitive form has never yet been found, is the regular ſix-ſided priſm, the alternate angles of which are ſometimes wanting ‖, and the triangular faces, which occupy their place, are inclined to the baſe at an angle of 122° 34′ ‡. Sometimes the corundum is cryſtallized in the form of a ſix-ſided pyramid, the apex of which is generally wanting. For a deſcription and figure of theſe, and all the other varieties of corundum hitherto obſerved, we refer the reader to the diſſertation of the Count de Bournon on the ſubject *.

The texture of the corundum is foliated, and the natural joints are parallel to the faces of the primitive rhomboidal parallelopiped. Luſtre, when in the direction of the laminæ, 3; when broken acroſs, 0. Opake, except when in very thin pieces. Hardneſs 15. Sp. gr. from 3.710 to 4.180 †. Colour grey, often with various ſhades of blue and green.

According to the analyſis of Klaproth, the corundum of India is compoſed of

89.5 alumina,
5.5 ſilica,
1.25 oxyd of iron,
———
96.25 ‡.

A ſpecimen from China of

84.0 alumina,
6.5 ſilica,
7.5 oxyd of iron,
———
98.0 ‖.

Notwithſtanding the quantity of ſilica and of iron which theſe analyſes exhibit in the corundum, we have been induced to include it in the preſent genus, on account of the ſtrong reſemblance between it and the third variety of teleſia. The ſtriking reſemblance between the cryſtals of teleſia and corundum will appear evident, even from the ſuperficial deſcription which we have given; and the obſervations of De Bournon * render this reſemblance ſtill more ſtriking. It is not improbable, therefore, as Mr Greville and the Count de Bournon have ſuggeſted, that corundum may be only a variety of teleſia, and that the ſeeming difference in their ingredients is owing to the impurity of thoſe ſpecimens of corundum which have hitherto been brought to Europe. Let not the difference which has been found in the primitive form of theſe ſtones be conſidered as an inſuperable objection, till the ſubject has been again examined with this preciſe object in view; for nothing is eaſier than to commit an overſight in ſuch difficult examinations.

27
Native alumina.

SPECIES 3. Native alumina (K).

This ſubſtance has been found at Halles in Saxony in compact kidney-form maſſes. Its conſiſtence is earthy. Luſtre 0. Opaque. Hardneſs 4. Brittle. Sp. gr. moderate. Feels ſoft, but meagre. Adheres very ſlightly to the tongue. Stains very ſlightly. Colour pure white. Does not readily diffuſe itſelf in water.

It conſiſts of pure alumina, mixed with a ſmall quantity of carbonat of lime, and ſometimes of ſulphat of lime †.

28
G. II. AMC.
Ruby.

GENUS II. AMC.

SPECIES 1. Ruby (L).

Spinel and *balaſs Ruby* of Kirwan—*Ruby* of Hauy—*Rubis ſpinelle octoedre* of De Liſle—*Spinellus.* of Gmelin.

This ſtone, which comes from the iſland of Ceylon, is uſually cryſtallized. The primitive form of its cryſtals is a regular octohedron, compoſed of two four-ſided pyramids applied baſe to baſe, each of the ſides of which is an equilateral triangle ‡ (M). In ſome caſes two oppoſite ſides of the pyramids are broader than the other two; and ſometimes the edges of the octohedron are wanting, and narrow faces in their place. For figures and deſcriptions of theſe, and other varieties of theſe cryſtals, we refer the reader to *Romé de Liſle* and the *Abbé Eſtner* *.

The texture of the ruby is foliated. Its luſtre is 3. Tranſp. 3.4. It cauſes a ſingle refraction. Hardneſs 13. Sp. gr. 3.570 † to 3.625 ‡. Colour red; if deep, the ruby is uſually called *balaſs*; if pale roſy, *ſpinell*.

(M) We ſhall afterwards diſtinguiſh this octohedron either by the epithet *regular* or *aluminiform*, becauſe it is the well known form of cryſtals of alum.

The ruby, according to the analyſis of Vauquelin, is compoſed of

86.00 alumina,
8.50 magneſia,
5.25 chromic acid.

99.75 *

The ancients ſeem to have claſſed this ſtone among their hyacinths †.

* Ann. de Chim. xxvii. 15.
† Plinii, l. 37. c. 9.

29 G. III. AIM. Ceylanite.

GENUS III. AIM.

SPECIES 1. Ceylanite.

The mineral denominated *ceylanite*, from the iſland of Ceylon, from which it was brought into Europe, had been obſerved by Romé de Liſle ‡; but was firſt deſcribed by La Metherie in the Journal de Phyſique for January 1793.

‡ Cryſtallog. iii. 180. Note 21.

It is moſt commonly found in rounded maſſes; but ſometimes alſo cryſtallized. The primitive form of its cryſtals is a regular octohedron: it commonly occurs under this form, but more commonly the edges of the octohedron are wanting, and ſmall faces in their place ‡.

‡ Hauy, Jour. de Min. N° xxxviii. 264.

The fracture of the ceylanite is conchoidal *. Its internal luſtre is glaſſy. Nearly opaque, except when in very thin pieces. Hardneſs 12. Sp. gr. from 3.7647† to 3.793‡. Colour of the maſs, black; of very thin pieces, deep green. Powder, greeniſh grey. According to the analyſis of Deſcotils the ceylanite is compoſed of

68 alumina,
16 oxyd of iron,
12 magneſia,
2 ſilica.

30 G. IV. S. Quartz.

GENUS IV. S.

SPECIES 1. Quartz ||.

This ſtone, which is very common in moſt mountainous countries, is ſometimes cryſtallized, and ſometimes amorphous. The primitive form of its cryſtals, according to Mr Hauy, is a rhomboidal parallelopiped; the angles of whoſe rhombs are 93° 22′, and 86° 38′; ſo that it does not differ much from a cube *. The moſt common variety is a dodecahedron ‡, compoſed of two ſix-ſided pyramids, applied baſe to baſe, whoſe ſides are iſoſceles triangles, having the angle at the vertex 40°, and each of the angles at the baſe 70°; the inclination of a ſide of one pyramid to the contiguous ſide of the other pyramid is 104°. There is often a ſix-ſided priſm interpoſed between the two pyramids, the ſides of which always correſpond with thoſe of the pyramids ||. For a deſcription and figure of the other varieties of quartz cryſtals, and for a demonſtration of the law which they have followed in cryſtallizing, we refer the reader to *Romé de Liſle* † and *Mr Hauy* ‡.

|| Kirwan's Min. i. 241.

|| Fig. 7.
† Cryſtal. ii. 71.
‡ Mem. Par. 1786, p. 78. See alſo Lametherie, Jour. de Phyſ. xlii. 470.

The texture of quartz is more or leſs foliated. Fracture, conchoidal or ſplintery. Its luſtre varies from 3 to 1, and its tranſparency from 4 to 1; and in ſome caſes it is opaque. It cauſes a double refraction. Hardneſs, from 10 to 11. Sp. gr. from 2.64 to 2.67, and in one variety 2.691. Its colour is exceedingly various; a circumſtance which has induced mineralogiſts to divide it into numerous varieties. Of theſe the following are the chief:

1. Pure colourleſs, perfectly tranſparent cryſtallized quartz, having much the appearance of artificial cryſtal; known by the name of *rock cryſtal.*

2. Quartz leſs tranſparent, and with a ſplintery fracture, has uſually been diſtinguiſhed by the name of *quartz*, and ſeparated from rock cryſtal. As there is no occaſion for this ſeparation, we have, in imitation of Mr Hauy, choſen the word quartz for the *ſpecific name*, comprehending under it all the varieties.

3. Blood red quartz; formerly called *compoſtella hyacinth*, and by Hauy *quartz hematoide.* It owes its colour to oxyd of iron. The mineral known to mineralogiſts by the name of *ſinople*, and conſidered by them as a variety of *jaſper*, has been diſcovered by Dolomieu to be merely this variety of quartz in an amorphous ſtate *.

4. Yellow quartz; called falſe topaz.

5. Roſy red quartz; called Bohemian ruby.

For a fuller enumeration of theſe varieties, we refer the reader to *Smeiſſer's Mineralogy* †, *Kirwan's Mineralogy* ‡, and Gmelin's edition of the *Syſtema Naturæ* of Linnæus §. This laſt writer, however, has arranged ſeveral minerals under quartz which do not belong to it.

* Jour. de Min. N° xxviii. 255
† i. 89.
‡ i. 244.
§ iii. 194.

Pure quartz is compoſed entirely of ſilica; but ſome of the varieties of this ſpecies are contaminated with metallic oxyds, and with a ſmall quantity of other earths.

31 Elaſtic quartz.

SPECIES 2. Elaſtic Quartz (N).

This ſingular ſtone is moderately elaſtic, and flexible in every direction. Texture, earthy. Luſtre, 0 or 1. Hardneſs, 9. Brittle. Sp. gr. 2.624. Colour, greyiſh white. Phoſphoreſces when ſcraped with a knife in the dark. The ſpecimen analyſed by Mr Klaproth contained

96.5 ſilica,
2.5 alumina,
5 oxyd of iron,

99.5 †

† Beiträge ii. 116.

32 Flint.

SPECIES 3. Flint (O).

Pyromachus — Pierre a fuſil — Silex of Hauy.

This ſtone, which has become ſo neceſſary in modern war, is found in pieces of different ſizes, and uſually of a figure more or leſs globular, commonly among chalk, and often arranged in ſome kind of order. In Saxony it is ſaid to have been found cryſtallized in hexahedrons, compoſed of two low three-ſided pyramids applied baſe to baſe *.

* Gmelin's Syſtema Naturæ, iii. 183.

Its texture is compact. Its fracture, ſmooth conchoidal. Luſtre, external 0, the ſtones being always covered by a white cruſt; internal 1, inclining to greaſy. Tranſp. 2; when very thin, 3. Hardneſs, 10 or 11. Sp. gr. from 2.58 to 2.63. Colour varies from honey yellow to browniſh black. Very brittle, and ſplits into ſplinters in every direction. Two pieces of flint rubbed ſmartly together phoſphoreſce, and emit a peculiar odour. When heated it decrepitates, and becomes white and opaque. When expoſed long to the air

---

(N) *Kirwan's Min.* I. 316.—*Gerhard Mem. Berlin*, 1783, 107.—*Klaproth's Beitrage* 2 *Band.* 113. See alſo *Jour. de Phyſ.* XLI. 91.

(O) *Kirwan's Min.* I. 301.—*Dolomieu Jour de Min.* N° XXXIII. 693. and *Salivet, ibid.* 713. Theſe laſt gentlemen give the only accurate account of the method of making gun flints.

air it often becomes covered with a white cruſt. A ſpecimen of flint analyſed by Klaproth contained

98.00 ſilica,
.50 lime,
.25 alumina,
0.25 oxyd of iron,
1.00 water.

100.00 [†]

Another ſpecimen analyſed by Dolomieu was compoſed of
97 ſilica,
1 alumina and oxyd of iron,
2 water.

100 [‡]

The white cruſt with which flint is enveloped, conſiſts of the ſame ingredients, and alſo a little carbonat of lime. Dolomieu diſcovered that water is eſſential to flint; for when it is ſeparated by heat the ſtone loſes its properties [§].

The manufacture of gun flints is chiefly confined to two or three departments in France. The operation is exceedingly ſimple: a good workman will make a 1000 flints in a day. The whole art conſiſts in ſtriking the ſtone repeatedly with a kind of mallet, and bringing off at each ſtroke a ſplinter, ſharp at one end and thicker at the other. Theſe ſplinters are afterward ſhaped at pleaſure, by laying the line at which it is wiſhed they ſhould break, upon a ſharp iron inſtrument, and then giving it repeatedly ſmall blows with a mallet. During the whole operation the workman holds the ſtone in his hand, or merely ſupports it on his knee [||].

SPECIES 4. Opal (p).

This ſtone is found in many parts of Europe. It is uſually amorphous. Its fracture is conchoidal, commonly ſomewhat tranſparent. Hardneſs from 6 to 10. Sp. gr. from 1.7 to 2.66. The lowneſs of its ſpecific gravity, in ſome caſes, is to be aſcribed to accidental cavities which the ſtone contains. Theſe are ſometimes filled with drops of water. Some ſpecimens of opal have the property of emitting various coloured rays, with a particular effulgency, when placed between the eye and the light. The opals which poſſeſs this property, are diſtinguiſhed by lapidaries by the epithet *oriental*; and often by mineralogiſts by the epithet *nobilis*. This property rendered the ſtone much eſteemed by the ancients.

Variety 1. Opal edler—*Opalus nobilis*.

Luſtre glaſſy, 3. Tranſp. 3 to 2. Hardneſs, 6 to 8. Colour, uſually light bluiſh white, ſometimes yellow or green. When heated it becomes opaque, and ſometimes is decompoſed by the action of the atmoſphere. Hence it ſeems to follow, that water enters eſſentially into its compoſition. A ſpecimen of this variety, analyſed by Klaproth, contained

90 ſilica,
10 water.

100 [¶]

Variety 2. Semi-opal.

Fracture, imperfectly conchoidal. Luſtre, glaſſy 2. Tranſp. 2 to 3. Hardneſs, 7 to 9. Its colours are very various, greys, yellows, reds, browns, greens of different kinds.

Specimens of this variety ſometimes occur with rifts: theſe readily imbibe water, and therefore adhere to the tongue. Theſe ſpecimens ſometimes become tranſparent when ſoaked in water, by imbibing that fluid. They are then called *hydrophanes*.

Variety 3. Cat's eye [*].

This variety comes from Ceylon, and is ſeldom ſeen by European mineralogiſts till it has been poliſhed by the lapidary. Mr Klaproth has deſcribed a ſpecimen which he received in its natural ſtate from Mr Greville of London. Its figure was nearly ſquare, with ſharp edges, a rough ſurface, and a good deal of brilliancy. Its texture is imperfectly foliated. Luſtre greaſy, 2. Tranſp. 3 to 2. Hardneſs 10. Sp. gr. 2.56 to 2.66. Colour, grey; with a tinge of green, yellow or white: or brown, with a tinge of yellow or red. In certain poſitions it reflects a ſplendid white, as does the eye of a cat; hence the name of this ſtone.

Two ſpecimens, analyſed by Klaproth, the firſt from Ceylon, the other from Malabar, were compoſed of

95.00	94.50 ſilica,
1.75	2.00 alumina,
1.50	1.50 lime,
0.25	0.25 oxyd of iron.
98.5 [*]	98.25 [†].

SPECIES 5. Pitchſtone [§].

34 Pitchſtone.

Menelites.

This ſtone, which occurs in different parts of Germany, France, and other countries, has obtained its name from ſome reſemblance which it has been ſuppoſed to have to pitch. It is moſt uſually in amorphous pieces of different ſizes; and it has been found alſo cryſtallized in ſix-ſided priſms, terminated by three-ſided pyramids.

Its texture is conchoidal and uneven, and ſometimes approaches the ſplintery. Luſtre greaſy, from 3 to 1. Tranſp. 2 to 1, ſometimes 0. Hardneſs 8 to 10. Exceedingly brittle; it yields even to the nail of the finger. Sp. gr. 2.049 to 2.39. Its colours are numerous, greyiſh black, bluiſh grey, green, red, yellow of different ſhades. Sometimes ſeveral of theſe colours appear together in the ſame ſtone. A ſpecimen of pitchſtone from Meſnil-montant near Paris [*], analyſed by Mr Klaproth, contained

85.5 ſilica,
11.0 air and water,
1.0 alumina,
.5 iron,
.5 lime and magneſia.

98.5 [†]

SPECIES 6. Chryſopraſium (q).

35 Chryſopraſium.

This mineral, which is found in different parts of Germany, particularly near Koſemütz in Sileſia, is always amorphous. Its fracture is either even or inclining to the ſplintery. Scarcely any luſtre. Tranſp. 2 to 3. Hardneſs 10 to 12. Sp. gr. 2.479. Colour, green. In a heat of 130° Wedgewood it whitens and becomes opaque.

‡ Beiträge, ii. 133.

36 G. V. 1 AS. Topaz.

GENUS V. 1. AS.

SPECIES 1. Topaz (R).

Occidental ruby, topaz, and ſapphyr.

The name *topaz* has been reſtricted by Mr Hauy to the ſtones called by mineralogiſts occidental ruby, topaz, and ſapphyr; which, agreeing in their cryſtallization and moſt of their properties, were arranged under one ſpecies by Mr Romé de Liſle. The word *topaz*, derived from an iſland in the Red Sea (s), where the ancients uſed to find topazes, was applied by them to a mineral very different from ours. One variety of our topaz they denominated *chryſolite.*

The topaz is found in Saxony, Bohemia, Siberia, and Brazil, mixed with other minerals in granite rocks.

It is commonly cryſtallized. The primitive form of its cryſtals is a priſm whoſe ſides are rectangles, and baſes rhombs, having their greateſt angles 124° 22′, and the integral molecule has the ſame form*; and the height of the priſm is to a ſide of the rhomboidal baſes as 3 to 2‡. The different varieties of topaz cryſtals hitherto obſerved, amount to 6. Five of theſe are eight-ſided priſms, terminated by four-ſided pyramids, or wedge-ſhaped ſummits, or by irregular figures of 7, 13, or 15 ſides‖; the laſt variety is a twelve-ſided priſm, terminated by ſix-ſided pyramids wanting the apex. For an accurate deſcription and figure of theſe varieties we refer the reader to Mr Hauy †.

* Hauy, Jour. de Min. N° xxviii, 287.
‡ Fig. 8.
‖ Fig. 9.
† Jour. de Min. ibid.

The texture of the topaz is foliated. Its luſtre is from 2 to 4. Tranſp. from 2 to 4. It cauſes a double refraction. Hardneſs 12 to 14. Sp. gr. from 3.5311 to 3.564. The Siberian and Brazil topazes, when heated, become poſitively electrified on one ſide, and negatively on the other §. It is infuſible by the blow-pipe. The yellow topaz of Brazil becomes red when expoſed to a ſtrong heat in a crucible; that of Saxony becomes white by the ſame proceſs. This ſhews us, that the colouring matter of theſe two ſtones is different.

§ Hauy, ibid.

The colour of the topaz is various, which has induced mineralogiſts to divide it into the following varieties:

1. Red topaz, of a red colour inclining to yellow; called *Brazilian* or *occidental ruby.*

2. Yellow topaz, of a golden yellow colour, and ſometimes alſo nearly white; called *occidental* or *Brazil topaz.* The powder of this and the following variety cauſes ſyrup of violets to aſſume a green colour ‖.

‖ Vauquelin, Jour. de Min N° xxix. 165.

3. *Saxon topaz.* It is of a pale wine yellow colour, and ſometimes greyiſh white.

4. *Aigue marine.* It is of a bluiſh or pale green colour.

5. *Occidental ſapphyr.* It is of a blue colour; and ſometimes white.

Simple Stones.

A ſpecimen of white Saxon topaz, analyſed by Vauquelin, contained

68 alumina,
31 ſilica.

37 Sommite.

SPECIES 2. Sommite.

This ſtone was called ſommite by La Metherie, from the moutain Somma, where it was firſt found. It is uſually mixed with volcanic productions. It cryſtallizes in ſix-ſided priſms, ſometimes terminated by pyramids. Colour white. Somewhat tranſparent. Sp. gr. 3.2741. Infuſible by the blow-pipe. According to the analyſis of Vauquelin, it is compoſed of

49 alumina,
46 ſilica,
2 lime,
1 oxyd of iron.
98 *

* Ibid. N° xxviii. 27

38 Shorlite.

SPECIES 3. Shorlite †.

This ſtone, which received its name from Mr Klaproth, is generally found, in irregular oblong maſſes or columns, inſerted in granite. Its texture is foliated. Fracture uneven. Luſtre 2. Tranſparency 2 to 1. Hardneſs 9 to 10. Sp. gr. 3.53. Colour greeniſh white, or ſulphur yellow. Not altered by heat. According to the analyſis of Klaproth, it is compoſed of

† Kirwan Min. i. 28

50 alumina,
50 ſilica.
100

39 G V. 2. 1 Rubellite.

GENUS V. 2 SA.

SPECIES 4. Rubellite (T).

Red ſhorl of Siberia.

This ſtone is found in Siberia mixed with white quartz. It is cryſtallized in ſmall needles, which are grouped together and traverſe the quartz in various directions. Texture fibrous. Fracture even, inclining to the conchoidal. Tranſparency 2; at the edges 3. Hardneſs 10. Brittle. Sp. gr. 3.1. Colour crimſon, blood or peach red. By expoſure to a red heat it becomes ſnow white; but loſes none of its weight. It tinges ſoda blue, but does not melt with it.

According to the analyſis of Mr Bindheim, it is compoſed of

57 ſilica,
35 alumina,
5 oxyds of iron and manganeſe.
97

40 Hornſlate

SPECIES 5. Hornſlate (U).

Shiſtoſe porphyry.

This ſtone, which occurs in mountains, is generally amorphous; but ſometimes alſo in columns. Structure

ture ſlaty. Texture foliated. Fracture uneven and ſplintery; ſometimes approaching the conchoidal. Luſtre 0. Tranſparency 1 or 0. Hardneſs about 10. Sp. gr. from 2.512 to 2.7. Colour different ſhades of *grey*, from *aſh* to *bluiſh* or *olive green*. Melts at 145° Wedgewood into an enamel. A ſpecimen, analyſed by Wedgewood, contained

73.0	ſilica,
23.9	alumina,
3.5	iron.
100.4	

Hor one.

SPECIES 6. Hornſtone (x).

Petroſilex—Chert.

This ſtone, which makes a part of many mountains, is uſually amorphous; but, as Mr Kirwan informs us, it has been found cryſtallized by Mr Beyer on Schneeberg. Its cryſtals are ſix ſided priſms, ſometimes terminated by pyramids; hexahedrons, conſiſting of two three-ſided pyramids applied baſe to baſe; and cubes, or ſix-ſided plates *. Its texture is foliated. Fracture ſplintery, and ſometimes conchoidal. Luſtre 0. Tranſparency 1 to 2. The cryſtals are ſometimes opaque. Hardneſs 7 to 9. Sp. gr. 2.532 to 2.653. Colour uſually dark blue: but hornſtone occurs alſo of the following colours; grey, red, blue, green, and brown of different ſhades †.

According to Kirwan, it is compoſed of

72	ſilica,
22	alumina,
6	carbonat of lime.

Cha do- ny.

SPECIES 7. Chalcedony.

This ſtone is found abundantly in many countries, particularly in Iceland and the Faro iſlands. It is moſt commonly amorphous, ſtalactitical, or in rounded maſſes; but it occurs alſo cryſtallized in ſix ſided priſms, terminated by pyramids, or more commonly in four or ſix ſided pyramids, whoſe ſides are convex. Surface rough. Fracture more or leſs conchoidal. Luſtre 1. Somewhat tranſparent. Hardneſs 10 to 11. Sp. gr. 2.56 to 2.665. Not brittle.

According to Bergman, the chalcedony of Faroe is compoſed of

84	ſilica,
16	alumina, mixed with iron.
100	

Variety 1. Common chalcedony.

Fracture even, inclining to conchoidal. Tranſparency 2 to 3; ſometimes 1. Its colours are various; it is moſt commonly greyiſh, with a tint of yellow, green, blue, or pearl; often alſo white, green, red, yellow, brown, black, or dotted with red. When ſtriped white and black, or brown, alternately, it is called *onyx*; when ſtriped white and grey, it is called *chalcedonix*. Black or brown chalcedony, when held between the eye and a ſtrong light, appears dark red.

Variety 2. Cornelian.

Fracture conchoidal. Tranſparency 3 to 1; often cloudy. Its colours are various ſhades of red, brown, and yellow. Several colours often appear in the ſame maſs. To this variety belong many of the ſtones known by the name of *Scotch pebbles*.

Simple Stones.

43 Jaſper.

SPECIES 8. Jaſper (y).

This ſtone is an ingredient in the compoſition of many mountains. It occurs uſually in large amorphous maſſes, and ſometimes alſo cryſtallized in ſix ſided irregular priſms. Its fracture is conchoidal. Luſtre from 2 to 0. Either opaque, or its tranſparency is 1. Hardneſs 9 to 10. Sp. gr. from 2.5 to 2.82. Its colours are various. When heated, it does not decripitate. It ſeems to be compoſed of ſilica and alumina, and often alſo contains iron.

Variety 1. Common jaſper.

Sp. gr. from 2.58 to 2.7. Its colours are, different ſhades of white, yellow, red, brown, and green; often variegated, ſpotted, or veined, with ſeveral colours.

Variety 2. Egyptian pebble.

This variety is found chiefly in Egypt. It uſually has a ſpheroidal or flat rounded figure, and is enveloped in a coarſe rough cruſt. It is opaque. Hardneſs 10. Sp. gr. 2.564. It is chiefly diſtinguiſhed by the variety of colours, which always exiſt in the ſame ſpecimen, either in concentric ſtripes or layers, or in dots or dentritical figures These colours are, different browns and yellows, milk white, and iſabella green; black alſo has been obſerved in dots.

Variety 3. Striped jaſper.

This variety is alſo diſtinguiſhed by concentric ſtripes or layers of different colours: theſe colours are, yellow, browniſh red, and green. It is diſtinguiſhed from the laſt variety by its occurring in large amorphous maſſes, and by its fracture, which is nearly even.

44 Tripoli.

SPECIES 9. Tripoli.

This mineral is found ſometimes in an earthy form, but more generally indurated. Its texture is earthy. Its fracture often ſomewhat conchoidal. Luſtre 0. Generally opaque. Hardneſs 4 to 7. Sp. gr. 2.080 to 2.529. Abſorbs water. Feel, harſh dry. Hardly adheres to the tongue. Takes no poliſh from the nail. Does not ſtain the fingers Colour generally pale yellowiſh grey, alſo different kinds of yellow, brown, and white.

It contains, according to Haaſſe, 90 parts of ſilica, 7 alumina, and 3 of iron. A mineral belonging to this ſpecies was analyſed by Klaproth, and found to contain

66.5	ſilica,
7.0	alumina,
2.5	oxyd of iron,
1.5	magneſia,
1.25	lime,
19.	air and water.

and it may be ſplit into thin plates. Luſtre metallic, 3. Opaque. Hardneſs 6. Sp. gr. 2.980. Colour browniſh black. At 153° Wedgewood, it melts into a black compact glaſs, the ſurface of which is reddiſh †.

† Kirw. ibid.

A ſpecimen analyſed by Klaproth contained

63.00	alumina,
29.50	ſilica,
6.75	iron.
99.25	

46 Shorl.

SPECIES 2. Shorl ‡.

‡ Ibid. i. 265.

No word has been uſed by mineralogiſts with leſs limitation than *ſhorl*. It was firſt introduced into mineralogy by Cronſtedt, to denote any ſtone of a columnar form, conſiderable hardneſs, and a ſpecific gravity from 3 to 3.4. This deſcription applied to a very great number of ſtones. And ſucceeding mineralogiſts, though they made the word more definite in its ſignification, left it ſtill ſo general, that under the deſignation of *ſhorl* almoſt 20 diſtinct ſpecies of minerals were included.

Mr Werner firſt defined the word *ſhorl* preciſely, and reſtricted it to one ſpecies of ſtones. We uſe the word in the ſenſe aſſigned by him.

Shorl is found abundantly in mountains, either maſſive or cryſtallized, in three or nine ſided priſms, often terminated by three ſided ſummits. The ſides of the cryſtals are longitudinally ſtreaked. Its texture is foliated. Its fracture conchoidal. Luſtre 2. Opaque. Hardneſs 10. Sp. gr. 2.92 to 3.212. Colour black. Streak grey. It does not become electric by heat. When heated to redneſs, its colour becomes browniſh red; and at 127° Wedgewood, it is converted into a browniſh compact enamel *. According to Wiegleb, it is compoſed of

* Ibid. i. 266.

47 Granatite.

SPECIES 3. Granatite.

Staurotide of Hauy—*Pierre de Croix* of De Liſle—*Staurolithe* of Lametherie.

We have adopted from Mr Vauquelin the term *granatite* to denote this ſtone, becauſe all the other names are ambiguous, having been applied to another mineral poſſeſſed of very different properties.

Granatite is found in Galicia in Spain, and Britanny in France. It is always cryſtallized in a very peculiar form; two ſix-ſided priſms interſect each other, either at right angles or obliquely ‡. Hence the name *croſsſtone*, by which it was known in France and Spain *. Mr Hauy has proved, in a very ingenious manner, that the primitive form of the granatite is a rectangular priſm, whoſe baſes are rhombs, with angles of 129½° and 50½°; and that the height of the priſm is to the greater diagonal of a rhomb as 1 to 6; and that its integrant molecules are triangular priſms, ſimilar to what would be obtained by cutting the primitive cryſtal in two, by a plane paſſing vertically through the ſhorter diagonal of the rhomboidal baſe. From this ſtructure he has demonſtrated the law of the formation of the cruciform varieties *. The colour of granatite is greyiſh or reddiſh brown.

‡ Fig. 10.

49 Argenti felſpar.

SPECIES 5. Argentine felſpar §.

§ Kirw i. 327.

This ſtone was diſcovered by Mr Dodun in the black mountains of Languedoc. It is either amorphous, or cryſtallized in rhomboidal tables, or ſix or eight ſided priſms. Its texture is foliated. Fragments rectangular. Laminæ inflexible. Internal luſtre 4. Tranſparency 2. Colour white; two oppoſite faces of the cryſtals are ſilver white, two others dead white. Hardneſs of the ſilvery laminæ 6, of the reſt 9. Brittle. Sp. gr. 2.5. When the flame of the blow-pipe is directed againſt the edges of the cryſtal (ſtuck upon glaſs), it eaſily melts into a clear compact glaſs; but when the flame is directed againſt the faces, they preſerve their luſtre, and the edges alone ſlowly melt.

According to the analyſis of Dodun, it is compoſed of

46	ſilica,
36	alumina,
16	oxyd of iron,
98	

When this ſtone is expoſed to the atmoſphere, it is apt

(z) *Kirw.* I. 271.—*Berg.* II. 118. and V. 402.—*Gerhard. Mem. Berlin*, 1777, p. 14.—*Hauy Mem. Par.* 1784, 270.—*Wilſon Phil. Tranſ.* XLI. 308.—*Æpinus. Recueil ſur la Tourmaline.* See alſo *La Porterie. Le Saphir, l'Oeil de Chat, et la Tourmaline de Ceylon demaſqués.*

apt to decay: Its ſurface becomes irideſcent, and at laſt changes to ochre yellow: Its ſpecific gravity is 2.3 or 2.212; and when breathed upon, it gives out an earthy ſmell.

M a.

SPECIES 6. Mica ‖.

‖ K v. i.
2 0 Gme-
lin, v.
Com etro
pol. 549.

This ſtone forms an eſſential part of many mountains, and has been long known under the names of *glacies mariæ* and *Muſcovy glaſs*. It conſiſts of a great number of thin laminæ adhering to each other, ſometimes of a very large ſize. Specimens have been found in Siberia nearly 2¼ yards ſquare (B).

It is ſometimes cryſtallized: Its primitive form is a rectangular priſm, whoſe baſes are rhombs, with angles of 120° and 60°†: Its integrant molecule has the ſame form. Sometimes it occurs in rectangular priſms, whoſe baſes alſo are rectangles, and ſometimes alſo in ſhort ſix-ſided priſms †; but it is much more frequently in plates or ſcales of no determinate figure or ſize *.

† F 11.

† F 12.

* H y,
Jou le
Mi N°
xxv 296.

Its texture is foliated. Its fragments flat. The lamellæ flexible, and ſomewhat elaſtic. Luſtre metallic, from 3 to 4. Tranſparency of the laminæ 3 or 4, ſometimes only 2 (C). Hardneſs 6. Very tough. Often abſorbs water. Sp. gr. from 2.6546 to 2.9342. Feels ſmooth, but not greaſy. Powder feels greaſy. Colour, when pureſt, ſilver white or grey; but it occurs alſo yellow, greeniſh, reddiſh, brown, and black. Mica is fuſible by the blow-pipe into a white, grey, green, or black, enamel; and this laſt is attracted by the magnet (D). Spaniſh wax rubbed by it becomes negatively electric *.

* I .

A ſpecimen of mica, analyſed by Vauquelin, contained

50.00	ſilica,
35.00	alumina,
7.00	oxyd of iron,
1.35	magneſia,
1.33	lime,
94.68 †.	

† I 302.

Mica has long been employed as a ſubſtitute for glaſs. A great quantity of it is ſaid to be uſed in the Ruſſian marine for panes to the cabin windows of ſhips; it is preferred, becauſe it is not ſo liable as glaſs to be broken by the agitation of the ſhip.

I
lc.

SPECIES 7. Talc ‡.

‡ I w. i.
15 -Pott
M Berl.
17 p 65.

This ſtone has a very ſtrong reſemblance to mica, and was long conſidered as a mere variety of that mineral. It occurs ſometimes in ſmall looſe ſcales, and ſometimes in an indurated form; but it has not hitherto been found cryſtallized.

Its texture is foliated. The lamellæ are flexible, but not elaſtic. Its luſtre is from 2 to 4. Tranſparency from 2 to 4. Hardneſs 4 to 6. Sp. gr. when indurated, from 2.7 to 2.8. Feels greaſy. Colour moſt commonly whitiſh or greeniſh. Spaniſh wax rubbed with it becomes *poſitively* electric §.

§ H y,
Jo de
M N°
xx .291.

Variety 1. Scaly talc.

Talcite of Kirwan.

This variety occurs under the form of ſmall ſcales, ſcarcely cohering. Luſtre 3 to 4. Very light. Adheres to the fingers. When rubbed upon the ſkin, it gives it a gloſs. Colour white, with a ſhade of red or green; ſometimes leek green.

Simple
Stones.

Variety 2. Common talc.

Venetian talc.

This variety often occurs in oblong nodules. Luſtre, nearly metallic, 4. Tranſparency 2 to 3; when very thin 4. Hardneſs 4 to 5. Colour white, with a ſhade of green or red; or apple green, verging towards ſilver white. By tranſmitted light green.

Variety 3. Shiſtoſe talc.

Its ſtructure is ſlaty. Fracture hackly and long ſplintery. Eaſily crumbles when rubbed in the fracture. External luſtre 2 to 3; internal, 1; but ſometimes, in certain poſitions, 3. Colour grey, with a ſhade of white, green or blue. Becomes white and ſcaly when expoſed to the air.

A ſpecimen of *common talc*, analyſed by Mr Chenevix, contained

48.0	ſilica,
37.0	alumina,
6.0	oxyd of iron,
1.5	magneſia,
1.5	lime,
5.0	water,
99.0 *.

Hornblende.

SPECIES 9. Hornblende ¶.

Amphibole of Hauy (E).

¶ *Kirw.* i. 213.

This ſtone enters into the compoſition of various mountains. Its texture is very conſpicuouſly foliated. Fracture conchoidal. Fragments often rhomboidal. Luſtre 2. Opaque. Hardneſs 5 to 9. Tough. Sp. gr. 2.922 to 3.41. Colour black, blackiſh green, olive green

---

(B) *Hiſt. General de Voyages*, T. XVIII. 272, quoted by Hauy *Jour. de Min.* N° XXVIII. 299.

(C) Black mica is often nearly opaque.

(D) *Hauy, ibid.* p. 295. Bergman, however, found pure mica infuſible *per ſe*; and this has been the caſe with all the ſpecimens of Muſcovy glaſs which we have tried.

(E) We ſuſpect, that under this name Mr Hauy comprehends *ſhorl* alſo.

green, or leek green. Streak greeniſh. It neither becomes electric by friction nor heat [*]. Before the blow-pipe it melts into a black glaſs. A ſpecimen of black hornblende, analyſed by Mr Hermann, was compoſed of

37	ſilica,
27	alumina,
25	iron,
5	lime.
3	magneſia,
97 [†]	

54 Reſplendent hornblende.

SPECIES 10. Reſplendent Hornblende.

There are two minerals which Werner conſiders as varieties of hornblende, and Mr Kirwan as conſtituting a diſtinct ſpecies. Theſe, till future analyſes decide the point, we ſhall place here under the name of reſplendent hornblende, the name given them by Mr Kirwan; and we ſhall deſcribe them ſeparately.

Variety 1. Labradore hornblende.

Texture, curved foliated. Luſtre, in ſome poſitions, 0; in others metallic, and from 3 to 4. Opaque. Hardneſs 8 to 9. Sp. gr. from 3.35 to 3.434. Colour, in moſt poſitions, greyiſh black; in others, it reflects a ſtrong iron grey, ſometimes mixed with copper red.

Variety 2. Shiller ſpar [*].

Texture foliated. Luſtre metallic, 4. Tranſparency, in thin pieces, 1. Hardneſs 8 to 9. Sp. gr. 2.882. Colour green, often with a ſhade of yellow; alſo golden yellow. In ſome poſitions it reflects white, grey, or yellow. At 141° Wedgewood, hardened into a porcelain maſs. A ſpecimen, analyzed by Gmelin, was compoſed of

43.7	ſilica,
17 9	alumina,
23.7	iron,
11.2	magneſia.
96.5 [†]	

It has been found in the Hartz, ſtuck in a ſerpentine rock.

55 Obſidian.

SPECIES 11. Obſidian [‖].

Iceland agate.

This ſtone is found either in detached maſſes, or forming a part of the rocks which compoſe many mountains. It is uſually inveſted with a grey or opaque cruſt. Its fracture is conchoidal. Its internal luſtre 3. Tranſparency 1. Hardneſs 10. Sp. gr. 2.348. Colour black or greyiſh black; when in very thin pieces, green. It melts into an opaque grey maſs. According to Bergman, it is compoſed of

69	ſilica,
22	alumina,
9	iron.
100 [§].	

56 Petrilite.

SPECIES 12. Petrilite [*].

Cubic felſpar.

This ſtone is found in the maſs of mountains. It is amorphous. Texture foliated. Fracture ſplintery. Fragments cubic, or inclining to that form; their faces unpoliſhed. Luſtre 2. Tranſparency partly 2, partly 1. Hardneſs 9. Sp. gr. 3 081. Colour reddiſh brown. Does not melt at 160° Wedgewood.

57 Felſite.

SPECIES 13. Felſite [†].

Compact felſpar.

This ſtone alſo forms a part of many mountains, and is amorphous. Texture ſomewhat foliated. Fracture uneven, approaching to the ſplintery. Luſtre 1. Tranſparency ſcarce 1. Hardneſs 9. Colour azure blue, and ſometimes brown and green. Streak white. Before the blow-pipe, whitens and becomes rifty; but is infuſible *per ſe*.

58 G. VII. SAP. Felſpar.

GENUS VII. SAP.

SPECIES 1. Felſpar [‡].

This ſtone forms the principal part of many of the higheſt mountains. It is commonly cryſtallized. Its primitive form, according to De Liſle, is a rectangular priſm, whoſe baſes are rhombs, with angles of 65° and 115° [†]. Sometimes the edges of the priſm are wanting, and faces in their place; and ſometimes this is the caſe alſo with the acute angles of the rhomb. For a deſcription and figure of theſe, and other varieties, we refer the reader to *Romé de Liſle* [*], *Mr Hauy* [†], and *Mr Pini* [‡].

Its texture is foliated. Its croſs fracture uneven. Fragments rhomboidal, and commonly ſmooth and poliſhed on four ſides. Luſtre of the poliſhed faces often 3. Tranſparency from 3 to 1. Hardneſs 9 to 10. Sp. gr. from 2.437 to 2.7. Gives a peculiar odour when rubbed. It is made electric with great difficulty by friction. Fuſible *per ſe* into a more or leſs tranſparent glaſs. When cryſtallized, it decrepitates before the blow-pipe.

Variety 1. Pure Felſpar.

Moon ſtone—Adularia.

This is the pureſt felſpar hitherto found. It occurs in Ceylon and Switzerland; and was firſt mentioned by Mr Sage. Luſtre nearly 3. Tranſparency 2 to 3. Hardneſs 10. Sp. gr. 2.559. Colour white; ſometimes with a ſhade of yellow, green, or red. Its ſurface is ſometimes irideſcent.

Variety 2. Common Felſpar.

Luſtre of the croſs fracture 0; of the fracture, in the direction of the laminæ, from 3 to 1. Tranſparency 2 to 1. Colour moſt commonly fleſh red; but often bluiſh grey, yellowiſh white, milk white, browniſh yellow; and ſometimes blue, olive green, and even black.

Variety 3. Labradore felſpar.

This variety was diſcovered on the coaſt of Labradore by Mr Wolfe; and ſince that time it has been found in Europe. Luſtre 2 to 3. Tranſparency from 1 to 3. Sp. gr. from 2.67 to 2.6925. Colour grey. In certain poſitions, ſpots of it reflect a blue, purple, red, or green colour.

Variety 4. Continuous felſpar.

This variety moſt probably belongs to a different ſpecies; but as it has not hitherto been analyſed, we did not think ourſelves at liberty to alter its place.

It is found in large maſſes. Texture earthy. Fracture uneven, ſometimes ſplintery. Luſtre 0. Tranſparency 1. Hardneſs 10. Sp. gr. 2.609. Colour reddiſh grey, reddiſh yellow, fleſh red.

A ſpecimen of green felſpar from Siberia, analyſed by Vauquelin, contained

62.83	ſilica,
17.02	alumina,
16.00	potaſs,
3.00	lime,
1.00	oxyd of iron.

Simple Stones.

SPECIES 2. Lepidolite (F).

Lilalite.

This ſtone appears to have been firſt obſerved by the Abbé Poda, and to have been firſt deſcribed by De Born §. Hitherto it has only been found in Moravia in Germany, and Sudermania in Sweden *. There it is mixed with granite in large amorphous maſſes. It is compoſed of thin plates, eaſily ſeparated, and not unlike thoſe of mica †. Luſtre, pearly 3. Tranſparency between 1 and 2. Hardneſs 4 to 5. Not eaſily pulveriſed ‡. Sp. gr. from 2.816 ‖ to 2.8549 ¶. Colour of the maſs, violet blue; of the thin plates, ſilvery white. Powder white, with a tint of red §. Before the blowpipe, it froths, and melts eaſily into a white ſemitranſparent enamel, full of bubbles. Diſſolves in borax with effervescence, and communicates no colour to it *. Effervesces ſlightly with ſoda, and melts into a maſs ſpotted with red. With microcoſmic ſalt, it gives a pearl coloured globule †.

This ſtone was firſt called lilalite from its colour, that of the *lily*. Klaproth, who diſcovered its component parts, gave it the name of *lepidolite* (G).

It is compoſed of

53	ſilica,
20	alumina,
18	potaſs,
5	fluat of lime,
3	oxyd of manganeſe,
1	oxyd of iron.
100 ‡	

SPECIES 3. Leucite ‖.

Veſuvian of Kirwan—*White garnet* of Veſuvius.

This ſtone is uſually found in volcanic productions, and is very abundant in the neighbourhood of Veſuvius. It is always cryſtallized. The primitive form of its cryſtals is either a cube or a rhomboidal dodecahedron, and its integrant molecules are tetrahedrons; but the varieties hitherto obſerved are all polyhedrons: The moſt common has a ſpheroidal figure, and is bounded by 24 equal and ſimilar trapeziods †; ſometimes the faces are 12, 18, 36, 54, and triangular, pentagonal, &c. For a deſcription and figure of ſeveral of theſe, we refer the reader to Mr Hauy ‖. The cryſtals vary from the ſize of a pin head to that of an inch.

The texture of the leucite is foliated. Its fracture ſomewhat conchoidal. Luſtre 3; when in a ſtate of decompoſition 0. Tranſparency 3 to 2; when decompoſing 0. Hardneſs 8 to 10; when decompoſing 5 to 6. Sp. gr. 2.4648. Colour white, or greyiſh white (H). Its powder cauſes ſyrup of violets to aſſume a green colour *.

It is compoſed, as Klaproth has ſhewn, of

54	ſilica,
23	alumina,
22	potaſs.
99 (I)	

It was by analyſing this ſtone that Klaproth diſcovered the preſence of potaſs in the mineral kingdom; which is not the leaſt important of the numerous diſcoveries of that accurate and illuſtrious chemiſt.

Leucite is found ſometimes in rocks which have never been expoſed to volcanic fire; and Mr Dolomieu has rendered it probable, from the ſubſtances in which it is found, that the leucite of volcanoes has not been formed by volcanic fire, but that it exiſted previouſly in the rocks upon which the volcanoes have acted, and that it was thrown out unaltered in fragments of theſe rocks §.

§ *Jour. de Min.* N° xxxix. 177.

GENUS VIII. SAG.

61 G. VIII. SAG Emerald.

SPECIES 1. Emerald (K).

This ſtone has hitherto been only found cryſtallized. The primitive form of its cryſtals is a regular ſix-ſided priſm; and the form of its integrant molecules is a triangular priſm, whoſe ſides are ſquares, and baſes equilateral triangles *. The moſt common variety of its cryſtals is the regular ſix-ſided priſm, ſometimes with the edges of the priſm, or of the baſes, or the ſolid angles, or both wanting ‡, and ſmall faces in their place †. The ſides of the priſm are generally channelled.

* *Hauy, Jour. de Min.* N° xix. 72.

‡ Fig. 16.

† *Romé de Liſle*, ii. 245. and *Hauy, ibid.*

Its texture is foliated. Its fracture conchoidal. Luſtre uſually from 3 to 4. Tranſparency from 2 to 4. Cauſes a double refraction. Hardneſs 12. Sp. gr. 2.65 to 2.775. Colour green. Becomes electric by friction, but not by heat. Its powder does not phoſphoreſce when thrown on a hot iron †. At 150° Wedgewood it melts into an opaque coloured maſs. According to Dolomieu, it is fuſible *per ſe* by the blow-pipe ‡.

† *Dolomieu, Jour. de Min.* N° xviii. 19.

‡ *Ibid.*

This mineral was formerly ſubdivided into two diſtinct ſpecies, the *emerald*, and *beryl* or *aqua marina*. Hauy demonſtrated, that the emerald and beryl correſponded exactly in their ſtructure and properties, and Vauquelin found that they were compoſed of the ſame ingredients; henceforth, therefore, they muſt be conſidered as varieties of the ſame ſpecies.

The variety formerly called *emerald* varies in colour from the pale to the perfect green. When heated to 120° Wedgewood, it becomes *blue*, but recovers its colour when cold. A ſpecimen, analyſed by Vauquelin, was compoſed of

64.60	ſilica,
14.00	alumina,
13.00	glucina,
3.50	oxyd of chromum,
2.56	lime,
2.00	moiſture or other volatile ingredient.
99.66 ‖	

‖ *Ann. de Chim.* xxvi. 264.

The *beryl* is of a greyiſh green colour, and ſometimes blue, yellow, and even white: ſometimes different colours appear in the ſame ſtone §. It is found in Ceylon, different parts of India, Brazil, and eſpecially in Siberia and Tartary, where its cryſtals are ſometimes a foot long ¶.

ths and tones.

Simple Stones.

Genus X. 3. sawl.

species 4. Zeolite (n).

66 .X. 3. sawl. .eolite.

This ſtone was firſt deſcribed by Cronſtedt in the Stockholm Tranſactions for 1756. It is found ſometimes amorphous and ſometimes cryſtallized. The primitive form of its cryſtals is a rectangular priſm, whoſe baſes are ſquares. The moſt common variety is a long four ſided priſm, terminated by low four ſided pyramids*.

* Iauy, r. de n. Nº . 86.

Its texture is ſtriated or fibrous. Its luſtre is ſilky, from 3 to 1. Tranſparency from 2 to 4; ſometimes 1. Hardneſs 6 to 8; ſometimes only 4. Abſorbs water. Sp. gr. 2.07 to 2.3. Colour white, often with a ſhade of red or yellow; ſometimes brick red, green, blue. When heated, it becomes electric like the tourmaline†. Before the blow-pipe it froths (o), emits a phoſphoreſcent light, and melts into a white ſemitranſparent enamel, too ſoft to cut glaſs, and ſoluble in acids. In acids it diſſolves ſlowly and partially without effervescence; and at laſt, unleſs the quantity of liquid be too great, it is converted into a jelly.

† auy, ibid. xxviii.

A ſpecimen of zeolite (p), analyſed by Vauquelin, contained

53.00	ſilica,
27.00	alumina,
9.46	lime,
10.00	water.
99.46‡.	

‡ id. Nº .576.

species 5. Stilbite.

67 lbite.

This ſtone was firſt formed into a diſtinct ſpecies by Mr Hauy. Formerly it was conſidered as a variety of zeolite.

The primitive form of its cryſtals is a rectangular priſm, whoſe baſes are rectangles. It cryſtallizes ſometimes in dodecahedrons, conſiſting of a four-ſided priſm with hexagonal faces, terminated by four-ſided ſummits, whoſe faces are oblique parallelograms; ſometimes in ſix-ſided priſms, two of whoſe ſolid angles are wanting, and a ſmall triangular face in their place*.

* auy, r. de . Nº 86.

Its texture is foliated. The laminæ are eaſily ſeparated from each other; and are ſomewhat flexible. Luſtre pearly, 2 or 3 (q). Hardneſs inferior to that of zeolite, which ſcratches ſtilbite. Brittle. Sp. gr. 2.500†. Colour pearl white. Powder bright white, ſometimes with a ſhade of red. This powder, when expoſed to the air, cakes and adheres as if it had abſorbed water. It cauſes ſyrup of violets to aſſume a green colour. When ſtilbite is heated in a porcelain crucible, it ſwells up and aſſumes the colour and ſemitranſparency of baked porcelain. By this proceſs it loſes 0.185 of its weight. Before the blow-pipe it froths like borax, and then melts into an opaque white coloured enamel §.

† uy, ibid. xxviii.

§ uquelin, Nº x. 161.

According to the analyſis of Vauquelin, it is compoſed of

52.0	ſilica,
17.5	alumina,
9.0	lime,
18.5	water.
97.0‖	

‖ Ibid. 164.

species 6. Analcime.

68 Analcime.

This ſtone, which was diſcovered by Mr Dolomieu, is found cryſtallized in the cavities of lava. It was firſt made a diſtinct ſpecies by Mr Hauy. Mineralogiſts had formerly confounded it with zeolite.

The primitive form of its cryſtals is a cube. It is ſometimes found cryſtallized in cubes, whoſe ſolid angles are wanting, and three ſmall triangular faces in place of each; ſometimes in polyhedrons with 24 faces. It is uſuall ſomewhat tranſparent. Hardneſs about 8; ſcratches glaſs ſlightly. Sp. gr. above 2. When rubbed, it acquires only a ſmall degree of electricity, and with difficulty (r). Before the blow-pipe it melts without frothing, into a white ſemitranſparent glaſs*.

* Hauy, Jour. de Min. Nº xiv. 86. and xxviii. 278.

Genus X. 4. sla.

species 7. Lazulite†.

69 G.X.4.sla. Lazulite.

This ſtone, which is found chiefly in the northern parts of Aſia, has been long known to mineralogiſts by the name of *lapis lazuli*. This term has been contracted into *lazulite* by Mr Hauy; an alteration which was certainly proper, and which therefore we have adopted.

† Kirw. i. 283.

Lazulite is always amorphous. Its texture is earthy. Its fracture uneven. Luſtre 0. Opaque, or nearly ſo. Hardneſs 8 to 9. Sp. gr. 2.76 to 2.945‡. Colour blue (s); often ſpotted white from ſpecks of quartz, and yellow from particles of pyrites.

‡ Briſſon.

It retains its colour at 100° Wedgewood; in a higher heat it intumeſces, and melts into a yellowiſh black maſs. With acids it effervesces a little, and if previouſly calcined, forms with them a jelly.

Margraff publiſhed an analyſis of lazulite in the Berlin Memoirs for 1758. His analyſis has ſince been confirmed by Klaproth, who found a ſpecimen of it to contain

46.0	ſilica,
14.5	alumina,
28.0	carbonat of lime,
6.5	ſulphat of lime,
3.0	oxyd of iron,
2.0	water.

(n) *Kirw.* I. 278.—*Guettard*, IV. 637.—*Bucquet*, *Mem. Sav. Etrang.* IX. 576.—*Pelletier*, *Jour. de Phyſ.* XX. 420.

(o) Hence the name *zeolite*, given to this mineral by Cronſtedt; from ζεω, *to ferment*, and λιθος, *a ſtone*.

(p) Dr Black was accuſtomed to mention, in the courſe of his lectures, that Dr Hutton had diſcovered *ſoda* in zeolite. This diſcovery has not hitherto been verified by any other chemical mineralogiſt.

(q) Hence the name given to this mineral by Hauy, *ſtilbite*, from στιλβω, *to ſhine*.

(r) Hence the name *analcime* given it by Hauy, from αναλκις, *weak*.

(s) Hence the name *lazulite*, from an Arabian word *azul*, which ſignifies *blue*.

(t) *Kirw.* I. 258.—*Gerhard*, *Diſquiſitio phyſico-chymica Granatorum*, &c.—*Paſumot*, *Jour. de Phyſ.* III. 442.—*Wiegleb*, *Ann. de Chim.* I. 231.

cryſtals is a dodecahedron whoſe ſides are rhombs, with angles of 78° 31′ 44″, and 120° 28′ 16″. The inclination of the rhombs to each other is 120°. This dodecahedron may be conſidered as a four ſided priſm, terminated by four-ſided-pyramids *. It is diviſible into four parallelopipeds, whoſe ſides are rhombs; and each of theſe may be divided into four tetrahedrons, whoſe ſides are iſoſceles triangles, equal and ſimilar to either of the halves into which the rhomboidal faces of the dodecahedron are divided by their ſhorter diagonal. The integrant molecules of garnet are ſimilar tetrahedrons †. Sometimes the edges of the dodecahedron are wanting, and ſmall faces in their place; and ſometimes garnet is cryſtallized in polyhedrons, having 24 trapezoidal faces. For a deſcription and figure of theſe, and other varieties of garnet, we refer to *Romé de Liſle* and *Hauy* ‡.

76
G. XIII.
MSAI.
Potſtone.

GENUS XIII. MSAI.

SPECIES 1. Potſtone†.

† Kirw. i. 155.

This ſtone is found in neſts and beds, and is always amorphous. Its ſtructure is often ſlaty. Texture undulatingly foliated. Luſtre from 1 to 3. Tranſparency from 1 to 0; ſometimes 2. Hardneſs 4 to 6. Brittle. Sp. gr. from 2.8531 to 3.023. Feels greaſy. Sometimes abſorbs water. Colour grey with a ſhade of green, and ſometimes of red or yellow; ſometimes leek green; ſometimes ſpeckled with red.

Potſtone is not much affected by fire; and has therefore been made into utenſils for boiling water; hence its name.

According to Wiegleb, the potſtone of Como contains

38	magneſia,
38	ſilica,
7	alumina,
5	iron,
1	carbonat of lime,
1	fluoric acid.
90	

77
Chlorite.

SPECIES 2. Chlorite*.

* Kirw. i. 147.

This mineral enters as an ingredient into different mountains. It is ſometimes amorphous, and ſometimes cryſtallized in oblong, four-ſided, acuminated cryſtals. Its texture is foliated. Its luſtre from 0 to 2. Opaque. Hardneſs from 4 to 6; ſometimes in looſe ſcales. Colour green.

Variety 1. Farinaceous chlorite.

Compoſed of ſcales ſcarcely cohering, either heaped together, or inveſting other ſtones. Feels greaſy. Gives an earthy ſmell when breathed on. Difficult to pulveriſe. Colour graſs green; ſometimes greeniſh brown; ſometimes dark green, inclining to black. Streak white. When the powder of chlorite is expoſed to the blow-pipe it becomes brown. Before the blow-pipe, farinaceous chlorite froths and melts into a dark brown glaſs; with borax it forms a greeniſh brown glaſs*.

* Vauquelin, Jour. de Min. N° xxxix. 167.

Variety 2. Indurated chlorite.

This variety is cryſtallized. Luſtre 1. Hardneſs 6. Feel meage. Colour dark green, almoſt black. Streak mountain green.

Variety 3. Slaty chlorite.

Structure ſlaty. Fragments flatted. Internal luſtre 1 to 2. Hardneſs 5. Colour greeniſh grey, or dark green inclining to black. Streak mountain green.

A ſpecimen of the firſt variety, analyſed by Vauquelin, contained

43.3	oxyd of iron,
26.0	ſilica,
15.5	alumina,
8.0	magneſia,
2.0	muriat of potaſs,
4.0	water.
98.8†	

† Ann. de Chim. xxx. 106.

A ſpecimen of the ſame variety yielded Mr Hœpner

12.92	oxyd of iron,
37.50	ſilica,
4.17	alumina,
43.75	magneſia,
1.66	lime.
100.0‡	

‡ Sauſſure's Voyages, ii. 133.

A ſpecimen of the ſecond variety, analyſed by the ſame chemiſt, contained

10.15	oxyd of iron,
41.15	ſilica,
6.13	alumina,
39.47	magneſia,
1.50	lime,
1.50	air and water.
99.9 §	

§ Crell's Annals, 1790, p. 56.

On the ſuppoſition that theſe analyſes are accurate, the enormous difference between them is a demonſtration that chlorite is not a chemical combination, but a mechanical mixture.

78

G. XV.
SAMLI.
Argillite

GENUS XV. SAMLI.

SPECES 1. Argillite†.

† Kirw. i. 234.

Argillaceous ſhiſtus—Common ſlate.

This ſtone conſtitutes a part of many mountains.

Its ſtructure is ſlaty. Its texture foliated. Fracture ſplintery. Fragments often tabular. Luſtre moſt commonly ſilky, 2; ſometimes 0. Tranſparency from 0 to 1. Hardneſs from 5 to 8. Sp. gr. from 2.67 to 2.88. Does not adhere to the tongue. Gives a clear ſound when ſtruck. Often imbibes water. Streak white or grey. Colour moſt commonly grey, with a ſhade of blue, green, or black; ſometimes purpliſh, yellowiſh, mountain green, brown, bluiſh black; ſometimes ſtriped or ſpotted with a darker colour than the ground.

It is compoſed, according to Kirwan, of ſilica, alumina, magneſia, lime, oxyd of iron. In ſome varieties the

---

(D) Is this the *tremolite* of Lowitz from the lake Baikal in Siberia? If ſo, the name of the genus ought to be SLM; for he found it to contain no alumina. According to his analyſis, it was compoſed of

52	ſilica,
20	lime,
12	carbonat of lime,
12	magneſia,

the lime is wanting. Several varieties contain a conſiderable quantity of carbonaceous matter.

GENUS XVI. SLACMI.

SPECIES 1. Smaragdite.

This ſtone was called *ſmaragdite* by Mr Sauſſure, from ſome reſemblance which it has to the emerald. Its texture is foliated. The laminæ are inflexible. Fracture even. Hardneſs 7. Colour in ſome caſes fine green, in others it has the grey colour and metallic luſtre of mica: it aſſumes all the ſhades of colour between theſe two extremes †.

According to the analyſis of Vauquelin, it is compoſed of

50.0	ſilica,
13.0	lime,
11.0	alumina,
7.5	oxyd of chromum.
6.0	magneſia,
5.5	oxyd of iron,
1.5	oxyd of copper.
94.5 ‡	

GENUS XVII. SM.

SPECIES 1. Kiffekil*.

Myrſen—Seafroth.

This mineral is dug up near Konie in Natolia, and is employed in forming the bowls of Turkiſh tobacco pipes. The ſale of it ſupports a large monaſtery of derviſes eſtabliſhed near the place where it is dug. It is found in a large fiſſure ſix feet wide, in grey calcareous earth. The workmen aſſert, that it grows again in the fiſſure †, and puffs itſelf up like froth (E). This mineral, when freſh dug, is of the conſiſtence of wax; it feels ſoft and greaſy; its colour is yellow; its ſp. gr. 1.600 ‡: when thrown on the fire it ſweats, emits a fetid vapour, becomes hard, and perfectly white.

According to the analyſis of Klaproth, it is compoſed of

50.50	ſilica,
17.25	magneſia,
25.00	water,
5.00	carbonic acid,
.50	lime.
98.25 §	

SPECIES 2. Steatites (F).

Though this mineral was noticed by the ancients, little attention was paid to it by mineralogiſts, till Mr Pott publiſhed his experiments on it in the Berlin Memoirs for 1747.

It is uſually amorphous, but ſometimes it is cryſtallized in ſix-ſided priſms. Its texture is commonly earthy, but ſometimes foliated. Luſtre from 0 to 2. Tranſparency from 0 to 2. Hardneſs 4 to 7. Sp. gr. from 2.61 to 2.794 *. Feels greaſy. Seldom adheres to the tongue. Colour uſually white or grey; often with a tint of other colours; the foliated commonly green. Does not melt *per ſe* before the blow-pipe.

Simple Stones.

Variety 1. Semi-indurated ſteatites.

Texture earthy. Fracture ſometimes coarſe ſplintery. Luſtre 0. Tranſparency 0, or ſcarce 1. Hardneſs 4 to 5. Abſorbs water. Takes a poliſh from the nail. Colour white, with a ſhade of grey, yellow, or green; ſometimes pure white; ſometimes it contains dendritical figures; and ſometimes red veins.

Variety 2. Indurated ſteatites.

Fracture fine ſplintery, often mixed with imperfectly conchoidal. External luſtre 2 to 1, internal 0. Tranſparency 2. Often has the feel of ſoap. Abſorbs water. Colour yellowiſh or greeniſh grey; often veined or ſpotted with deep yellow or red.

Variety 3. Foliated or ſtriated ſteatites.

The texture of this variety is uſually foliated; ſometimes ſtriated. Fragments cubiform. Luſtre 3. Tranſparency 2 to 1. Hardneſs 6 to 7. Colour leek green, paſſing into mountain green or ſulphur yellow. Streak pale greeniſh grey. When heated to redneſs, it becomes grey; and at 147° Wedgewood, it forms a grey porous porcelain maſs*.

‡ *Ann. de Chim.* xxviii. 200.

GENUS XVIII. MSI.

SPECIES 1. Chryſolite (G).

Peridot of the French—*Topaz* of the ancients.

53 G. XVIII. MSI. Chryſolite.

The name *chryſolite* was applied, without diſcrimination, to a great variety of ſtones, till Werner defined it accurately, and confined it to that ſtone which the French chemiſts diſtinguiſh by the appellation of *peridot*. This ſtone is the *topaz* of the ancients; their chryſolite is now called *topaz* §.

§ *Plinii*, lib. 37. c. 8.

Chryſolite is found ſometimes in unequal fragments, and ſometimes cryſtallized †. The primitive form of its cryſtals is a right angled parallelopiped ‡, whoſe length, breadth, and thickneſs, are as 5, $\sqrt{8}$, $\sqrt{5}$*.

† Fig. 23.

‡ Fig. 24.

* *Hauy, Jour. de Min.* N° xxviii. 281.

The texture of the chryſolite is foliated. Its fracture conchoidal. Its internal luſtre from 2 to 4. Its tranſparency from 4 to 2. Cauſes double refraction. Hardneſs

---

The carbonat of lime was only mechanically interpoſed between the fibres of the ſtone. See *Pallas, Neu. Nord. Beiträge, 6 Band*, p. 146.

(E) Hence the name *kiff-kil*, or rather *keff-kelli*, "clay froth," or "light clay."

(F) *Kirw.* I. 151.—*Pott, Mem. Berlin*, 1747, p. 57.—*Wiegleb, Jour. de Phyſ.* XXIX. 60.—*Lavoiſier, Mem. Par.* 1778, 433.

(G) *Kirw.* I. 262.—*Cartheuſer, Min.* 94.—*Dolomieu, Jour. de Min.* N° xxix. 365.—*La Metherie, Nouv. Jour. de Phyſ.* I. 397.

Hardneſs 9 to 10. Brittle. Sp. gr. from 3.265 to 3.45. Colour green. It is infuſible at 150°, but loſes its tranſparency, and becomes blackiſh grey†. With borax it melts without efferveſcence into a tranſparent glaſs of a light green colour. Infuſible with microcoſmic ſalt ‡ and fixed alkali §.

Variety 1. Common chryſolite.

Found in Ceylon, and South America, and in Bohemia, amidſt ſand and gravel ‖. Luſtre 3 to 4. Tranſparency 4 to 3. Colour yellowiſh green, ſometimes verging to olive green, ſometimes to pale yellow.

Variety 2. Olive chryſolite—*Olivine* ¶,

Found commonly among traps and baſalts; ſometimes in ſmall grains, ſometimes in pretty large pieces; but it has not been obſerved in cryſtals. Luſtre 2 to 3. Tranſparency 3 to 2. Colour olive green.

The firſt variety, according to the analyſis of Klaproth, is compoſed of

41.5	magneſia,
38.5	ſilica,
19.0	oxyd of iron.
99.0 †	

According to that of Vauquelin, it is compoſed of

51.5	magneſia,
38.0	ſilica,
9.5	oxyd of iron.
99.0 ‡	

The ſecond variety, according to the analyſis of Klaproth, is compoſed of

37.58	magneſia,
50.00	ſilica,
11.75	oxyd of iron,
.21	lime.
99.54 §.	

84 Jade.

SPECIES 2. Jade (H).

This ſtone was formerly called *lapis niphriticus*, and was much celebrated for its medical virtues. It is found in Egypt, China, America, and in the Siberian and Hungarian mountains. It is ſometimes adhering to rocks, and ſometimes in detached round pieces.

Its ſurface is ſmooth. Its fracture ſplintery. External luſtre 0, or ſcarce 1; internal waxy, 1. Tranſparency from 2 to 1. Hardneſs 10. Not brittle. Sp. gr. from 2.95 to 2.9829; or, according to Sauſſure, to 3.389. Feels greaſy. Looks as if it had imbibed oil. Colour dark leek green, or verging towards blue; in ſome prominencies inclining to greeniſh or bluiſh white. When heated it becomes more tranſparent and brittle, but is infuſible *per ſe*. According to Hœpſner, it is compoſed of

47	ſilica,
38	carbonat of magneſia,
9	iron,
4	alumina,
2	carbonat of lime,
100	

This is the ſtone which the inhabitants of New Zealand make into hatchets and other cutting inſtruments.

85 G. XIX. SML. Aſbeſtus.

GENUS XIX. SML.

SPECIES 1. Aſbeſtus (I).

This mineral was well known to the ancients. They even made a kind of cloth from one of the varieties, which was famous among them for its incombuſtibility. It is found abundantly in moſt mountainous countries, and no where more abundantly than in Scotland.

It is commonly amorphous. Its texture is fibrous. Its fragments often long ſplintery. Luſtre from 0 to 2; ſometimes 3, and then it is metallic. Tranſparency from 0 to 2. Hardneſs from 3 to 7. Sp. gr. from 2.7 to 0.6806. Abſorbs water. Colour uſually white or green. Fuſible *per ſe* by the blow-pipe.

Variety 1. Common aſbeſtus.

Luſtre 2 to 1. Tranſparency 1. Hardneſs 6 to 7. Sp. gr. 2.577 to 2.7. Feels ſomewhat greaſy. Colour leek green; ſometimes olive or mountain green; ſometimes greeniſh or yellowiſh grey. Streak grey. Powder grey.

Variety 2. Flexible aſbeſtus.

Amiantus.

Compoſed of a bundle of threads ſlightly cohering. Fibres flexible. Luſtre 1 to 2, ſometimes 3. Tranſparency 1 to 2, ſometimes 0. Hardneſs 3 to 4. Sp. gr. before it abſorbs water, from 0.9088 to 2.3134; after abſorbing water, from 1.5662 to 2.3803†. Feels greaſy. Colour greyiſh or greeniſh white; ſometimes yellowiſh or ſilvery white, olive or mountain green, pale fleſh red, and mountain yellow.

Variety 3. Elaſtic aſbeſtus.

Mountain cork.

This variety has a ſtrong reſemblance to common cork. Its fibres are interwoven. Luſtre commonly 0. Opaque. Hardneſs 4. Sp. gr. before abſorbing water, from 0.6806 to 0.9933; after abſorbing water, from 1.2492 to 1.3492. Feels meagre. Yields to the fingers like cork, and is ſomewhat elaſtic. Colour white; ſometimes with a ſhade of red or yellow; ſometimes yellow or brown.

A ſpecimen of the firſt variety from Dalecarlia, analyſed by Bergman, contained

63.9	ſilica,
16.0	carbonat of magneſia,

Simple Stones.

89 G. XX. 2. SMIL. Shorlaceous actinolite.

GENUS XX. 2. SMIL.

SPECIES 3. Shorlaceous actinolite (M).

This ſtone cryſtallizes in four or ſix ſided priſms, thicker at one end than the other; hence it has been called by the Germans *ſtrahlſtein*, "arrow-ſtone." The cryſtals ſometimes adhere longitudinally. Fracture hackly. External luſtre glaſſy, 3 to 4; internal, 1 to 2. Tranſparency from 2 to 3; ſometimes 1. Hardneſs from 7 to 10. Sp. gr. 3.023 to 3.45. Colour leek or dark green.

This ſtone is often the matrix of iron, copper, and tin ores.

90 Lamellar actinolite.

SPECIES 5. Lamellar actinolite.

This ſtone reſembles hornblende. It is amorphous. Texture foliated. Luſtre various in different places. Tranſparency 0, or ſcarce 1. Sp. gr. 2.916. Colour dark yellowiſh or greeniſh grey.

91 Glaſſy actinolite.

SPECIES 6. Glaſſy actinolite.

This ſtone is found amorphous, compoſed of fibres adhering longitudinally, or in ſlender four or ſix ſided priſms. Texture fibrous. Fragments long ſplintery, ſo ſharp that they can ſcarcely be handled without injury. External luſtre glaſſy or ſilky, 3 to 4; internal 0. Tranſparency 2. Exceedingly brittle. Sp gr. 2.95 to 3.493. Colour leek green; ſometimes verging towards greeniſh or ſilver white; ſometimes ſtained with yellowiſh or browniſh red. According to Bergman it is compoſed of

72.0	ſilica,
12 7	carbonat of magneſia,
6.0	carbonat of lime,
7.0	oxyd of iron,
2.0	alumina.

92 G XXI. SL. Shiſtoſe hornſtone.

GENUS XXI. SL.

SPECIES 1. Shiſtoſe hornſtone †.

† Kirwan, i. 305.

The ſtructure of this ſtone is ſlaty. Luſtre from 0 to 1. Commonly opaque. Hardneſs 9 to 10. Sp. gr. from 2.596 to 2.641. Colour dark bluiſh or blackiſh grey. Infuſible *per ſe*.

Variety 1. Siliceous ſhiſtus.

Commonly interſected by reddiſh veins of iron ſtone. Fracture ſplintery. Luſtre 0. Tranſparency from 0 to 1.

Variety 2. Baſanite or Lydian ſtone.

Commonly interſected by veins of quartz. Fracture even; ſometimes inclining to conchoidal. Luſtre ſcarce 1. Hardneſs 10. Sp. gr. 2.590. Powder black. Colour greyiſh black.

This, or a ſtone ſimilar to it, was uſed by the ancients as a touchſtone. They drew the metal to be examined along the ſtone, and judged of its purity by the

---

(K) *Kirw. Min.* I. 165. Is this the *tremolite* of Werner? It certainly is not the *tremolite* of the French mineralogiſts.

(L) Hence the name *pyroxen* given it by Hauy; from πυρ *fire*, and ξενος, *a ſtranger*. It means, as he himſelf explains it, a *ſtranger in the regions of fire*. By this he means to indicate, that pyroxen, though preſent in lava, is not a volcanic production.

(M) In this and the following ſpecies we have followed Mr Kirwan's new arrangement exactly, without even venturing to give the ſynonimes of other authors. The deſcriptions which have been given are ſo many and incomplete, and the minerals themſelves are ſtill ſo imperfectly known, and have got ſo many names, that no part of mineralogy is in a ſtate of greater confuſion.

the colour of the metallic ſtreak. On this account they called it βασανος, *the trier.* They called it alſo *Lydian ſtone*, becauſe, as Theophraſtus informs us, it was found moſt abundantly in the river Tmolus in Lydia†.

† *Hill's Theopraſtus*, περι λιθων, p. 190.

A ſpecimen of the firſt variety, analyſed by Wiegleb, contained
75.0 ſilica,
10.0 lime,
4.6 magneſia,
3.5 iron,
5.2 carbon.
——
98.3

This ſpecies is rather a mechanical mixture than a chemical combination.

93
G. XXII.
zs.
Zircon.

Genus XXII. zs.

species 1. Zircon*.

Jargon—Hyacinth.

* *Kirwan*, i. 257. and 333.

This ſtone is brought from Ceylon, and found alſo in France, Spain, and other parts of Europe. It is commonly cryſtallized. The primitive form of its cryſtals is an octahedron§, compoſed of two four ſided pyramids applied baſe to baſe, whoſe ſides are iſoſceles triangles (N). The inclination of the ſides of the ſame pyramid to each other is 124° 12′; the inclination of the ſides of one pyramid to thoſe of another 82° 50′. The ſolid angle at the apex is 73° 44′†. The varieties of the cryſtalline forms of zircon amount to ſeven. In ſome caſes there is a four ſided priſm interpoſed between the pyramids of the primitive form; ſometimes all the angles of this priſm are wanting, and two ſmall triangular faces in place of each; ſometimes the cryſtals are dodecahedrons, compoſed of a flat four-ſided priſm with hexagonal faces, terminated by four ſided ſummits with rhomboidal faces ‖; ſometimes the edges of this priſm, ſometimes the edges where the priſm and ſummit join, and ſometimes both together, are wanting, and we find ſmall faces in their place. For an accurate deſcription and figure of theſe varieties, we refer to *Mr Hauy* ‡.

§ Fig. 25.
† *Hauy. Jour. de Min.* N° xxvi. 91.
‖ Fig. 26
‡ *Ibid.*

The texture of the zircon is foliated. Internal luſtre 3. Tranſparency from 4 to 2. Cauſes a very great double refraction. Hardneſs from 10 to 16. Sp. gr. from 4.2 to 4.165 †. Colour commonly reddiſh or yellowiſh; ſometimes it is limpid.

† *Ibid.*

Before the blow pipe it loſes its colour, but not its tranſparency. With borax it melts into a tranſparent glaſs. Infuſible with fixed alkali and microcoſmic ſalt.

1. The variety formerly called *hyacinth* is of a yellowiſh red colour, mixed with brown. Its ſurface is ſmooth. Its luſtre 3. Its tranſparency 3 to 4.

2. The variety formerly called *jargon of Ceylon*, is either grey, greeniſh, yellowiſh brown, reddiſh brown, or violet. It has little external luſtre. Is ſometimes nearly opaque.

The firſt variety, according to the analyſis of Vauquelin, is compoſed of
64.5 zirconia,
32.0 ſilica,
2.0 oxyd of iron.
——
98 5†

† *Ibid.* p. 106.

A ſpecimen analyſed by Klaproth contained
70.0 zirconia,
25.0 ſilica,
0.5 oxyd of iron.
——
95.5‡

‡ *Beiträge*, i. 231.

The ſecond variety, according to Klaproth, who diſcovered the component parts of both theſe ſtones, contains
68.0 zirconia,
31.5 ſilica,
0.5 nickel and iron.
——
100.0§

§ *Ibid.* i. 219.

Order II. SALINE STONES.

94
Genera.

Under this order we comprehend all the minerals which conſiſt of an earthy baſis combined with an acid. They naturally divide themſelves into five genera. We ſhall deſcribe them in the following order.

I. calcareous salts.
  Carbonat of lime,
  Sulphat of lime,
  Phoſphat of lime,
  Fluat of lime,
  Borat of lime.

II. barytic salts.
  Carbonat of barytes,
  Sulphat of barytes.

III. strontitic salts.
  Carbonat of ſtrontites,
  Sulphat of ſtrontites.

IV. magnesian salts.
  Sulphat of magneſia.

V. aluminous salts.
  Alum.

95
G. I. Calcareous ſalts.

Genus I. calcareous salts.

This genus comprehends all the combinations of lime and acids which form a part of the mineral kingdom.

96
Carbonat of lime.

species 1. Carbonat of lime.

No other mineral can be compared with carbonat of lime in the abundance with which it is ſcattered over the earth. Many mountains conſiſt of it entirely, and hardly a country is to be found on the face of the globe where, under the names of limeſtone, chalk, marble, ſpar, it does not conſtitute a greater or ſmaller part of the mineral riches.

It is often amorphous, often ſtalactitical, and often cryſtallized. The primitive form of its cryſtals is a parallelopiped, whoſe ſides are rhombs, with angles of 77° 30′ and 102° 30′ ‡. Its integrant molecules have the ſame form. The varieties of its cryſtals amount to more than 40; for a deſcription and figure of which we refer to *Romé de Liſle* * and *Hauy* (o).

‡ Fig. 28.
* *Cryſtal.* i. 497.

When cryſtallized, its texture is foliated; when amorphous, its ſtructure is ſometimes foliated, ſometimes ſtriated, ſometimes granular, and ſometimes earthy. Its luſtre

---

(N) Let ABC (fig. 27.) be one of the ſides. Draw the perpendicular BD; then AB = 5, BD = 4, AD = 3.

(o) *Eſſai d'une Theorie*, &c p. 75.—*Jour. de Phyſ.* 1793, Auguſt, p. 114.—*Jour. d'Hiſt. Nat.* 1792, February, p. 148.—*Ann. de Chim.* XVII. 249. &c.—*Jour de Min.* N° XXVIII. 304.

luſtre varies from 0 to 3. Tranſparency from 0 to 4. It cauſes double refraction; and it is the only mineral which cauſes double refraction through two parallel faces of the cryſtal. Hardneſs from 3 to 9. Sp. gr. from 2.315 to 2.78. Colour, when pure, white. Effervesces violently with muriatic acid, and diſſolves completely, or leaves but a ſmall reſiduum. The ſolution is colourleſs.

This ſpecies occurs in a great variety of forms; and therefore has been ſubdivided into numerous varieties. All theſe may be conveniently arranged under two general diviſions.

I. Soft carbonat of lime.

Variety 1. Agaric mineral.

Mountain milk, or *mountain meal* of the Germans.

This variety is found in the clefts of rocks, or the bottom of lakes. It is nearly in the ſtate of powder; of a white colour, ſometimes with a ſhade of yellow; and ſo light, that it almoſt floats on water.

Variety 2. Chalk.

The colour of chalk is white, ſometimes with a ſhade of yellow. Luſtre 0. Opaque. Hardneſs 3 to 4. Sp. gr. from 2.315 to 2.657. Texture earthy. Adheres ſlightly to the tongue. Feels dry. Stains the fingers, and marks. Falls to powder in water. It generally contains about $\frac{2}{100}$ of alumina, and $\frac{1}{100}$ of water; the reſt is carbonat of lime.

Variety 3. Arenaceous limeſtone.

Colour yellowiſh white. Luſtre 1. Tranſparency 1. So brittle, that ſmall pieces crumble to powder between the fingers. Sp. gr. 2.742. Phoſphoreſces in the dark when ſcraped with a knife, but not when heated. It conſiſts almoſt entirely of pure carbonat of lime.

Variety 4. Teſtaceous tufa.

The colour of this variety is yellowiſh or greyiſh white. It is exceedingly porous and brittle; and is either compoſed of broken ſhells, or reſembles mortar containing ſhells; or it conſiſts of fiſtulous concretions variouſly ramified, and reſembling moſs.

II. Indurated carbonat of lime.

Variety 1. Compact limeſtone.

The texture of this variety is compact. It has little luſtre; and is moſt commonly opaque. Hardneſs 5 to 8. Sp. gr. 1.3864 to 2.72. Colour grey, with various ſhades of other colours. It moſt commonly contains about $\frac{1}{10}$th of alumina, oxyd of iron, &c.; the reſt is carbonat of lime. This variety is uſually burnt as lime.

Variety 2. Granularly foliated limeſtone.

Structure ſometimes ſlaty. Texture foliated and granular. Luſtre 2 to 1. Tranſparency 2 to 1. Hardneſs 7 to 8. Sp. gr. 2.71 to 2.8376. Colour white, of various ſhades from other colours.

Variety 3. Sparry limeſtone.

Structure ſparry. Texture foliated. Fragments rhomboidal. Luſtre 2 to 3. Tranſparency from 2 to 4; ſometimes 1. Hardneſs 5 to 6. Sp. gr. from 2.693 to 2.718. Colour white: often with various ſhades of other colours. To this variety belong all the cryſtals of carbonat of lime.

Variety 4. Striated limeſtone.

Texture ſtriated or fibrous. Luſtre 1 to 0. Tranſparency 2 to 1. Hardneſs 5 to 7. Sp. gr. commonly from 2.6 to 2.77. Colours various.

Variety 5. Swine ſtone.

Texture often earthy. Fracture often ſplintery. Luſtre 1 to 0. Tranſparency 0 to 1. Hardneſs 6 to 7. Sp. gr. 2.701 to 2.7121. Colour dark grey, of various ſhades. When ſcraped or pounded, it emits an urinous or garlic ſmell.

Variety 6. Oviform.

This variety conſiſts of a number of ſmall round bodies, cloſely compacted together. Luſtre 0. Tranſparency 0 or 1. Hardneſs 6 to 7.

97
Sulphat of lime.

SPECIES 2. Sulphat of lime.

Gypſum—Selenite.

This mineral is found abundantly in Germany, France, England, Italy, &c.

It is found ſometimes in amorphous maſſes, ſometimes in powder, and ſometimes cryſtallized. The primitive form of its cryſtals, according to Romé de Liſle, is a decahedron ‡, which may be conceived as two four-ſided pyramids, applied baſe to baſe, and which, inſtead of terminating in pointed ſummits, are truncated near their baſes; ſo that the ſides of the pyramids are trapeziums, and they terminate each in a rhomb. Theſe rhombs are the largeſt faces of the cryſtal. The angles of the rhombs are 52° and 158°. The inclination of two oppoſite faces of one pyramid to the two ſimilar faces of the other pyramid is 145°, that of the other faces 110° *. Sometimes ſome of the faces are elongated: ſometimes it cryſtallizes in ſix-ſided priſms, terminated by three or four ſided ſummits, or by an indeterminate number of curvilinear faces. For a deſcription and figure of theſe varieties, we refer to *Romé de Liſle* †.

The texture of ſulphat of lime is moſt commonly foliated. Luſtre from 0 to 4. Tranſparency from 0 to 4. It cauſes double refraction. Its hardneſs does not exceed 4. Its ſp. gr. from 1.872 to 2.311. Colour commonly white or grey.

Before the blow-pipe, it melts into a white enamel, provided the blue flame be made to play upon the edges of its laminæ. When the flame is directed againſt its faces, the mineral falls into powder ‡.

It does not effervesce with muriatic acid, except it be impure; and it does not diſſolve in it.

The following varieties of this mineral are deſerving of attention.

Variety 1. Broad foliated ſulphat.

Texture broad foliated. Luſtre glaſſy, from 4 to 2. Tranſparency from 4 to 3. Hardneſs 4. Sp. gr. 2.311. Colour grey, often with a ſhade of yellow.

Variety 2. Grano-foliated ſulphat.

Texture foliated, and at the ſame time granular; ſo that it eaſily crumbles into powder. Luſtre 2 to 3. Tranſparency 2 to 3. Hardneſs 4 to 3. Sp. gr. from 2.274 to 2.310. Feels ſoft. Colour white or grey, often with a tinge of yellow, blue, or green; ſometimes fleſh red, brown, or olive green.

Variety 3. Fibrous ſulphat.

Texture fibrous. Fragments long ſplintery. Luſtre 2 to 3. Tranſparency 2 to 1; ſometimes 3. Hardneſs 4. Brittle. Sp. gr. 2.300. Colour white, often with a ſhade of grey, yellow, or red; ſometimes fleſh red, and ſometimes honey yellow; ſometimes ſeveral of theſe colours meet in ſtripes.

Variety 4. Compact ſulphat.

Texture compact. Luſtre 1 or 0. Tranſparency 2 to

---

† *Ibid.*

‡ *Le Lievre, Jour de Min*, No xxviii. 315.

Earth- and Stones.

1, ſometimes 0. Hardneſs 4. Sp. gr. from 1.872 to 2.288. Feels dry, but not harſh. Colour white, with a ſhade of grey, yellow, blue, or green; ſometimes yellow; ſometimes red; ſometimes ſpotted, ſtriped, or veined.

Variety 5. Farinaceous ſulphat.

Of the conſiſtence of meal. Luſtre 0. Opaque. Scarcely ſinks in water. Is not gritty between the teeth. Feels dry and meagre. Colour white. When heated below redneſs, it becomes of a dazzling white.

98 Phoſphat of lime.

SPECIES 3. Phoſphat of lime.

Apatite—*Phoſphorite*—*Chryſolite*—of the French.

This ſubſtance is found in Spain, where it forms whole mountains, and in different parts of Germany. It is ſometimes amorphous, and ſometimes cryſtallized. The primitive form of its cryſtals is a regular ſix-ſided priſm ‡. Its integrant molecule is a regular triangular priſm, whoſe height is to a ſide of its baſe as 1 to $\surd 2$ §. Sometimes the edges of the primitive hexagonal priſm are wanting, and ſmall faces in their place; ſometimes there are ſmall faces inſtead of the edges which terminate the priſm; ſometimes theſe two varieties are united; ſometimes the terminating edges and the angles of the priſm are replaced by ſmall faces †; and ſometimes the priſm is terminated by four-ſided pyramids *.

‡ Fig. 30.

§ Hauy, *Jour. de Min.* N° xxviii. p. 310.

† Fig. 31.

* Hauy, *ibid.*

Its texture is foliated. Its fracture uneven, tending to conchoidal. External luſtre from 2 to 3, internal 3 to 2. Tranſparency from 4 to 2. Cauſes ſingle refraction. Hardneſs 6 to 7. Brittle. Sp. gr. from 2.8249 to 3.218. Colour commonly green or grey; ſometimes brown, red, blue, and even purple.

It is infuſible by the blow-pipe. When its powder is thrown upon burning coals, it emits a yellowiſh green phoſphoreſcent light. It is ſoluble in muriatic acid without effervеſcence or decompoſition, and the ſolution often becomes gelatinous.

99 Fluat of lime.

SPECIES 4. Fluat of lime.

Fluor.

This mineral is found abundantly in different countries, particularly in Derbyſhire. It is both amorphous and cryſtallized.

The primitive form of its cryſtals is the regular octohedron; that of its integrant molecules the regular tetrahedron *. The varieties of its cryſtals hitherto obſerved amount to 7. Theſe are the primitive octohedron; the cube; the rhomboidal dodecahedron; the cubo-octohedron †, which has both the faces of the cube and of the octohedron; the octohedron wanting the edges; the cube wanting the edges, and either one face ‡, or two faces in place of each. For a deſcription and figure of theſe we refer to *Mr Hauy* †.

* Hauy, *ibid.* p. 325.

† Fig. 32.

‡ Fig. 33.

† *Ibid.*

The texture of fluat of lime is foliated. Luſtre from 2 to 3, ſometimes 0. Tranſparency from 2 to 4, ſometimes 1. Cauſes ſingle refraction. Hardneſs 8. Very brittle. Sp gr. from 3.0943 to 3.1911. Colours numerous, red, violet, green, red yellow, blackiſh purple. Its powder thrown upon hot coals emits a bluiſh or greeniſh light. Two pieces of it rubbed in the dark phoſphoreſce. It decrepitates when heated. Before the blow-pipe it melts into a tranſparent glaſs ‡.

‡ *Ibid.*

It admits of a poliſh, and is often formed into vaſes and other ornaments.

100 Borat of lime.

SPECIES 5. Borat of lime.

Boracite.

This mineral has been found at Kalkberg near Luneburg, ſeated in a bed of ſulphat of lime. It is cryſtallized. The primitive form of its cryſtals is the cube §. In general, all the edges and angles of the cube are truncated; ſometimes, however, only the alternate angles are truncated *. The ſize of the cryſtals does not exceed half an inch.

§ Hauy, *Jour. de Min.* N xxvii. 325

* Hauy Weſtru

The texture of this mineral is compact. Its fracture is flat conchoidal. External luſtre 3; internal, greaſy, 2. Tranſparency from 2 to 3. Hardneſs 9 to 10. Sp. gr. 2.566. Colour greyiſh white, ſometimes paſſing into greeniſh white or purpliſh.

When heated it becomes electric; and the angles of the cube are alternately poſitive and negative †.

† Hauy and An *Chim.* 59.

Before the blow-pipe it froths, emits a greeniſh light, and is converted into a yellowiſh enamel, garniſhed with ſmall points, which, if the heat be continued, dart out in ſparks ‖.

‖ Le L *Jour. d Min.* i

According to Weſtrum, who diſcovered its component parts, it contains

68	boracic acid,
13.5	magneſia,
11	lime,
1	alumina,
2	ſilica,
1	iron.
96 §	

§ *Ann. Chim.* i 116.

10 Nitrat lime.

SPECIES 6. Nitrat of lime.

Found abundantly mixed with native nitre. For a deſcription ſee the article CHEMISTRY in this *Supplement*, n° 672.

10 G. II. rytic ſ

GENUS II. BARYTIC SALTS.

This genus comprehends the combinations of barytes with acids.

10 Carbo baryte

SPECIES 1. Carbonat of barytes.

Witherite.

This mineral was diſcovered by Dr Withering; hence Werner has given it the name of *witherite*. It is found both amorphous and cryſtallized. The cryſtals are octohedrons or dodecahedrons, conſiſting of four or ſix ſided pyramids applied baſe to baſe; ſometimes the ſix-ſided pyramids are ſeparated by a priſm; ſometimes ſeveral of theſe priſms are joined together in the form of a ſtar.

Its texture is fibrous. Its fracture conchoidal. Its fragments long ſplintery. Luſtre 2. Tranſparency 2 to 3. Hardneſs 5 to 6. Brittle. Sp. gr. 4.3 to 4.338. Colour greeniſh white. When heated it becomes opaque. Its powder phoſphoreſces when thrown on burning coals *.

* Ha

It is ſoluble with effervеſcence in muriatic acid. The ſolution is colourleſs.

According to Pelletier it contains

62	barytes,
22	carbonic acid,
16	water.
100 †	

† Jou *Min.* xxi. 1

Sulph baryt

SPECIES 2. Sulphat of barytes.

Boroſelenite.

This mineral is found abundantly in many countries, particularly in Britain. It is ſometimes in powder, often in amorphous maſſes, and often cryſtallized. The primitive form of its cryſtals is a rectangular priſm, whoſe d whoſe baſes are rhombs, with angles of 101° 30′ and 78° 30′ ‡. The varieties of its cryſtals are very numerous. For a deſcription and figure of them we refer to *Romé de Liſle* || and *Hauy* *. The moſt common varieties are the octohedron with cuneiform ſummits, the ſix or four ſided priſm, the hexangular table with bevelled edges. Sometimes theſe cryſtals are needle form.

Its texture is commonly foliated. Luſtre from 0 to 2. Tranſparency from 2 to 0; in ſome caſes 3 or 4. Hardneſs from 5 to 6. Sp. gr. from 4.4 to 4.44. Colour commonly white, with a ſhade of yellow, red, blue, or brown.

When heated it decrepitates. It is fuſible *per ſe* by the blue flame of the blow-pipe, and is converted into ſulphurat of barytes. Soluble in no acid except the ſulphuric; and precipitated from it by water.

Variety 1. Foliated ſulphat.

Luſtre 3 to 3. Tranſparency from 4 to 2, ſometimes 1. Colours white, reddiſh, bluiſh, yellowiſh, blackiſh, greeniſh. Mr Werner ſubdivides this variety into three, according to the nature of the texture. Theſe three ſubdiviſions are *granularly foliated*, *ſtraight foliated*, *curve foliated*.

Variety 2. Fibrous ſulphat.

Texture fibrous; fibres converging to a common centre. Luſtre ſilky or waxy, 2. Tranſparency 2 to 1. Hardneſs 5. Colours yellowiſh, bluiſh, reddiſh.

Variety 3. Compact ſulphat.

Texture compact. Luſtre 0 to 1. Tranſparency 1 to 0. Feels meagre. Almoſt conſtantly impure. Colours light yellow, red, or blue.

Variety 4. Earthy ſulphat.

In the form of coarſe duſty particles, ſlightly cohering. Colour reddiſh or yellowiſh white.

GENUS III. STRONTITIC SALTS.

This genus comprehends all the combinations of ſtrontites and acids which form a part of the mineral kingdom.

SPECIES 1. Carbonat of ſtrontites.

This mineral was firſt diſcovered in the lead mine of Strontion in Argyleſhire; and ſince that time it is ſaid to have been diſcovered, though not in great abundance, in other countries. It is found amorphous, and alſo cryſtallized in needles, which, according to Hauy, are regular ſix ſided priſms.

Its texture is fibrous; the fibres converge. Fracture uneven. Luſtre 2. Tranſparency 2. Hardneſs 5. Sp. gr. from 3.4 to 3.66. Colour light green. Does not decrepitate when heated. Before the blow-pipe becomes opaque and white, but does not melt. With borax it effervеſces, and melts into a tranſparent colourleſs glaſs. Effervеſces with muriatic acid, and is totally diſſolved. The ſolution tinges flame purple.

SPECIES 2. Sulphat of ſtrontites.
Celeſtine.

This mineral has been found in Pennſylvania, in Germany, in France, in Sicily, and Britain. It was firſt diſcovered near Briſtol by Mr Clayfield. There it is found in ſuch abundance, that it has been employed in mending the roads.

It occurs both amorphous and cryſtallized. The cryſtals are moſt commonly bevelled tables, ſometimes rhomboidal cubes. Its texture is foliated. More or leſs tranſparent. Hardneſs 5. Sp. gr. from 3.51 to 3.96. Colour moſt commonly a fine ſky blue; ſometimes reddiſh; ſometimes white, or nearly colourleſs *.

Klaproth found a ſpecimen of this mineral from Pennſylvania compoſed of
58 ſtrontites,
42 ſulphuric acid.

100 †

According to the analyſis of Mr Clayfield, the ſulphat of ſtrontites found near Briſtol is compoſed of
58.25 ſtrontites,
41.75 ſulphuric acid of 2.24, and a little iron ‡.

100.00

According to the analyſis of Vauquelin, the ſulphat of ſtrontites found at Bouvron in France, which was contaminated with .1 of carbonat of lime, is compoſed of
54 ſtrontites,
45 ſulphuric acid.

99 §

GENUS IV. MAGNESIAN SALTS.

108
G IV.
Magneſian Salts.

This genus comprehends the combinations of magneſia and acids which occur in the mineral kingdom. Only two ſpecies have hitherto been found; namely,

109
Sulphat of magneſia.

SPECIES 1. Sulphat of magneſia.

It is found in Spain, Bohemia, Britain, &c.; and enters into the compoſition of many mineral waters.

For a deſcription of it, we refer to CHEMISTRY, n° 633. in this *Suppl.*

110
Nitrat of magneſia.

SPECIES 2. Nitrat of magneſia.

Found ſometimes aſſociated with nitre. For a deſcription ſee CHEMISTRY, n° 674.

GENUS V. ALUMINOUS SALTS.

111
G. V. Aluminous ſalts.

This genus comprehends thoſe combinations of alumina and acids which occur in the mineral kingdom.

112
Alum.

SPECIES 1. Alum.

This ſalt is found in cryſtals, in ſoft maſſes, in flakes, and inviſibly mixed with the ſoil. For a deſcription, we refer to CHEMISTRY, n° 636.

ORDER III. AGGREGATES.

THIS order comprehends all mechanical mixtures of earths and ſtones found in the mineral kingdom. Theſe are exceedingly numerous: the mountains and hills, the mould on which vegetables grow, and indeed the greater part of the globe, may be conſidered as compoſed of them. A complete deſcription of aggregates belongs rather to geology than mineralogy. It would be improper, therefore, to treat of them fully here. But they cannot be altogether omitted; becauſe aggregates are the firſt ſubſtances which preſent themſelves to the view of the practical mineralogiſt, and becauſe, without being acquainted with the names and component parts of many of them, the moſt valuable mineralogical works could not be underſtood.

113
Diviſion of aggregates.

Aggregates may be comprehended under four diviſions: 1. Mixtures of earths; 2. Amorphous fragments of ſtones agglutinated together; 3. Cryſtallized ſtones, either agglutinated together or with amorphous ſtones; 4. Aggregates formed by fire. It will be exceedingly

convenient

---

* Clayfield, Nicholſon's Jour. iii. 36.

† Beiträge, ii. 97.

‡ Ibid. Nicholſon's Journal.

§ Jour. de Min. N° xxxvii. 6.

convenient to treat each of theſe ſeparately. We ſhall therefore divide this order into four ſections.

SECT. I. *Aggregates of Earths.*

The moſt common earthy aggregates may be comprehended under the following genera:

1. Clay,
2. Colorific earths,
3. Marl,
4. Mould.

114 Clay.

GENUS I. CLAY.

Clay is a mixture of alumina and ſilica in various proportions. The alumina is in a ſtate of an impalpable powder; but the ſilica is almoſt always in ſmall ſtones, large enough to be diſtinguiſhed by the eye. Clay, therefore, exhibits the character of alumina, and not of ſilica, even when this laſt ingredient predominates. The particles of ſilica are already combined with each other; and they have ſo ſtrong an affinity for each other, that few bodies can ſeparate them; whereas the alumina, not being combined, readily diſplays the characters which diſtinguiſh it from other bodies. Beſides alumina and ſilica, clay often contains carbonat of lime, of magneſia, barytes, oxyd of iron, &c. And as clay is merely a mechanical mixture, the proportion of its ingredients is exceedingly various.

Clay has been divided into the following ſpecies:

115 Porcelain clay.

SPECIES 1. Porcelain clay.

Its texture is earthy. Its luſtre 0. Opaque. Hardneſs 4. Sp. gr. from 2.23 to 2.4. Colour white, ſometimes with a ſhade of yellow or red. Adheres ſlightly to the tongue. Feels ſoft. Falls to powder in water.

A ſpecimen, analyſed by Haſſenfratz, contained

62	ſilica,
19	alumina,
12	magneſia,
7	ſulphat of barytes.
100 *	

A ſpecimen, analyſed by Mr Wedgewood, contained

60	alumina,
20	ſilica,
12	air of water.
92	

116 Common clay.

SPECIES 2. Common clay.

Its texture is earthy. Luſtre 0. Opaque. Hardneſs 3 to 6. Sp. gr. 1.8 to 2.68. Adheres ſlightly to the tongue. Often feels greaſy. Falls to powder in water. Colour, when pure, white; often tinged blue or yellow.

Variety 1. Potter's clay.

Hardneſs 3 to 4. Sp. gr. 1.8 to 2. Stains the fingers ſlightly. Acquires ſome poliſh by friction. Colour white; often with a tinge of yellow or blue; ſometimes browniſh, greeniſh, reddiſh. Totally diffuſible in water; and, when duly moiſtened, very ductile.

Variety 2. Indurated clay.

Hardneſs 5 to 6. Does not diffuſe itſelf in water, but falls to powder. Diſcovers but little ductility. Colours grey, yellowiſh, bluiſh, greeniſh, reddiſh, browniſh.

Variety 3. Shiſtoſe clay.

Structure ſlaty. Sp. gr. from 2.6 to 2.68. Feels ſmooth. Streak white or grey. Colour commonly bluiſh, or yellowiſh grey; ſometimes blackiſh, reddiſh, greeniſh. Found in ſtrata, uſually in coal mines.

This variety is ſometimes impregnated with bitumen. It is then called bituminous *ſhale*.

117 Lithomarga.

SPECIES 3. Lithomarga.

Texture earthy. Fracture conchoidal. Luſtre from 0 to 2. Opaque. Hardneſs 3 to 7. Sp. gr. when pretty hard, 2.815. Surface ſmooth, and feels ſoapy. Adheres ſtrongly to the tongue. Falls to pieces, and then to powder, in water; but does not diffuſe itſelf through that liquid. Fuſible *per ſe* into a frothy maſs.

Variety 1. Friable lithomarga.

Formed of ſcaly particles ſlightly cohering. Luſtre 1 to 0. Hardneſs 3 to 4. Exceedingly light. Feels very ſmooth, and aſſumes a poliſh from the nail. Colour white; ſometimes tinged yellow or red.

Variety 2. Indurated lithomarga.

Hardneſs 4 to 7. The ſofter ſorts adhere very ſtrongly to the tongue when newly broken; the harder very moderately. Colours grey, yellow, red, brown, blue.

A ſpecimen of lithomarga from Oſmund, analyſed by Bergman, contained

60.0	ſilica,
11.0	alumina,
5.7	carbonat of lime,
4.7	oxyd of iron,
0.5	carbonat of magneſia,
18.0	water and air.
99.9 †	

118 Bole.

SPECIES 4. Bole.

Texture earthy. Fracture conchoidal. Luſtre 0. Tranſparency ſcarce 1. Hardneſs 4. Sp. gr. from 1.4 to 2. Acquires a poliſh by friction. Scarcely adheres to the tongue. Feels greaſy. Colour yellow or brown; ſometimes red; ſometimes ſpotted.

The lemnian earth which belongs to this ſpecies, according to the analyſis of Bergman, contains

47.0	ſilica,
19.0	alumina,
6.0	carbonat of magneſia,
5.4	carbonat of lime,
5.4	oxyd of iron,
17.0	water and air.
99.8 ‡	

119 Ful earth

SPECIES 5. Fullers earth.

Texture earthy. Structure ſometimes ſlaty. Fracture imperfectly conchoidal. Luſtre 0. Opaque. Hardneſs 4. Receives a poliſh from friction. Does not adhere to the tongue. Feels greaſy. Colour uſually light green.

A ſpecimen from Hampſhire, analyſed by Bergman, contained

51.8	ſilica,
25.0	alumina,
3.3	carbonat of lime,
3.7	oxyd of iron,
0.7	carbonat of magneſia,
15.5	moiſture.
100.0 §	

This

§ *Ibid,*

hs and' ones.

This earth is uſed by fullers to take the greaſe out of their cloth before they apply ſoap. It is eſſential to fullers earth that the particles of ſilica be very fine, otherwiſe they would cut the cloth. Any clay, poſſeſſed of this laſt property, may be conſidered as *fullers earth*; for it is the alumina alone which acts upon the cloth, on account of its ſtrong affinity for greaſy ſubſtances.

o Co- c s.

Genus II. Colorific Earths.

The minerals belonging to this genus conſiſt of clay, mixed with ſo large a quantity of ſome colouring ingredient as to render them uſeful as paints. The colouring matter is commonly oxyd of iron, and ſometimes charcoal.

r chalk.

Species 1. Red chalk.

Reddle.

Texture earthy. Fracture conchoidal. Luſtre 0. Opaque. Hardneſs 4. Sp. gr. inconſiderable. Colour dark red.

Feels rough. Stains the fingers. Adheres to the tongue. Falls to powder in water. Does not become ductile. When heated it becomes black, and at 159° Wedgewood melts into a greeniſh yellow frothy enamel.

Compoſed of clay and oxyd of iron.

2 w .

Species 2. Yellow chalk.

Texture earthy. Fracture conchoidal. Hardneſs 3. Sp. gr inconſiderable. Colour ochre yellow.

Feels ſmooth or greaſy. Stains the fingers. Adheres to the tongue. Falls to pieces in water. When heated becomes red; and at 156° Wedgewood melts into a brown porous porcelain.

According to Sage, it contains
50 alumina,
40 oxyd of iron,
10 water, with ſome ſulphuric acid.
——
100 *

3

Species 3. Black chalk.

Structure ſlaty. Texture earthy. Fragments ſplintery. Luſtre 0. Opaque. Hardneſs 5. Sp. gr. 2.144 to 2.277. Colour black. Streak black.

Feels ſmooth. Adheres ſlightly to the tongue. Does not moulder in water. When heated to redneſs it becomes reddiſh grey.

According to Wiegleb, it is compoſed of
64.50 ſilica,
11.25 alumina,
11.00 charcoal,
2.75 oxyd of iron,
7.50 water.
——
97.00 †

4

Species 4. Green earth.

Texture earthy. Luſtre 0. Opaque. Hardneſs 6 to 7. Sp gr. 2.637. Colour green.

Commonly feels ſmooth. Does not ſtain the fingers. Often falls to powder in water. When heated it becomes reddiſh brown; and at 147° Wedgewood melts into a black compact glaſs.

Compoſed of clay, oxyds of iron and nickel.

5 Marl.

Genus III. Marl.

A mixture of carbonat of lime and clay, in which the carbonat conſiderably exceeds the other ingredient, is called *marl*.

Its texture is earthy. Luſtre 0. Opaque. Hardneſs from 4 to 8; ſometimes in powder. Sp. gr. from 1.6 to 2.877. Colour uſually grey, often tinged with other colours. Effervеſces with acids.

Some marls crumble into powder when expoſed to the air; others retain their hardneſs for many years.

Marls may be divided into two ſpecies: 1. Thoſe which contain more ſilica than alumina; 2. Thoſe which contain more alumina than ſilica. Mr Kirwan has called the firſt of theſe *ſiliceous*, the ſecond *argillaceous*, marls. Attention ſhould be paid to this diſtinction when marls are uſed as a manure.

116 G. IV. Mould.

Genus IV. Mould.

By *mould* is meant the ſoil on which vegetables grow.

It contains the following ingredients: ſilica, alumina, lime, magneſia (ſometimes), iron, carbon derived from decayed vegetable and animal ſubſtances, carbonic acid, and water. And the good or bad qualities of *ſoils* depends upon a proper mixture of theſe ingredients. The ſilica is ſeldom in the ſtate of an impalpable powder, but in grains of a greater or ſmaller ſize: Its chief uſe ſeems to be to keep the ſoil open and pervious to moiſture. If we paſs over the carbon, the iron, and the carbonic acid, the goodneſs of a ſoil depends upon its being able to retain the quantity of moiſture which is proper for the nouriſhment of vegetables, and no more. Now the retentive power of a ſoil increaſes with the proportion of its alumina, lime, or magneſia, and diminiſhes as the proportion of its ſilica increaſes. Hence it follows, that in a dry country, a fertile ſoil ſhould contain leſs ſilica, and more of the other earths, than in a wet country.

Giobert found a fertile ſoil near Turin, where it rains annually 30 inches, to contain
From 77 to 79 ſilica,
9 — 14 alumina,
5 — 12 lime.

Near Paris, where it rains about 20 inches annually, Mr Tillet found a fertile ſoil to contain
Coarſe ſand 25
Fine ſand 21
— 46.0 ſilica,
16.5 alumina,
37.5 lime.
——
100.0 ‡

The varieties of mould are too numerous to admit an accurate deſcription: we ſhall content ourſelves, therefore, with mentioning the moſt remarkable.

127 Sand.

Species 1. Sand.

This conſiſts of ſmall grains of ſiliceous ſtones not cohering together, nor ſoftened by water. When the grains are of a large ſize, the ſoil is called *gravel*.

128 Clay.

Species 2. Clay.

This conſiſts of common clay mixed with decayed vegetable and animal ſubſtances.

129 Loam.

Species 3. Loam.

Any ſoil which does not cohere ſo ſtrongly as clay, but more ſtrongly than chalk, is called *loam*. There are many varieties of it. The following are the moſt common.

---

* m. 1779,

† de xxx. 13.

‡ Kirwan on Manures.

Earths and Stones.

Variety 1. Clayey loam; called alſo *ſtrong*, *ſtiff*, *cold*, and *heavy*, loam.

It conſiſts of a mixture of clay and coarſe ſand.

Variety 2. Chalky loam.

A mixture of clay, chalk, and coarſe ſand; the chalk predominating.

Variety 3. Sandy loam.

A mixture of the ſame ingredients; the ſand amounting to .8 or .9 of the whole.

130 Till.

SPECIES 4. Till.

Till is a mixture of clay and oxyd of iron. It is of a red colour, very hard and heavy.

SECT. II. *Aggregates of amorphous ſtones.*

THE aggregates which belong to this ſection conſiſt of amorphous fragments of ſtones cemented together. They may be reduced to the following genera:

1. Sandſtone,
2. Puddingſtone,
3. Amygdaloid,
4. Breccia.

131 G. I. Sandſtone.

GENUS I. SANDSTONE.

Small grains of ſand, conſiſting of quartz, flint, hornſtone, ſiliceous ſhiſtus, or felſpar, and ſometimes of mica, cemented together, are denominated ſandſtones. They feel rough and ſandy; and when not very hard, eaſily crumble into ſand. The cement or baſis by which the grains of ſand are united to each other is of four kinds; namely, lime, alumina, ſilica, iron. Sandſtones, therefore, may be divided into four ſpecies.

132 Calcareous.

SPECIES 1. Calcareous ſandſtones.

Calcareous ſandſtones are merely carbonat of lime or marl, with a quantity of ſand interpoſed between its particles. Though the quantity of ſand, in many caſes, far exceeds the lime, calcareous ſandſtones are ſometimes found cryſtallized: and, in ſome caſes, the cryſtals, as might be expected, have ſome of the forms which diſtinguiſh carbonat of lime. Thus the calcareous ſandſtone of Fountainbleau is cryſtallized in rhomboidal tables. It contains, according to the analyſis of Laſſone

62.5	ſiliceous ſand,
37.5	carbonat of lime.
100	

Calcareous ſandſtones have commonly an earthy texture. Their ſurface is rough. Their hardneſs from 6 to 7. Their ſpecific gravity about 2.5 or 2.6. Their colour grey; ſometimes yellowiſh or brown. They are ſometimes burned for lime.

133 Aluminous.

SPECIES 2. Aluminous ſandſtones.

The baſis of argillaceous ſandſtones is alumina, or rather clay. Their ſtructure is often ſlaty. Their texture is compact, and either fine or coarſe grained, according to the ſize of the ſand of which they are chiefly compoſed. Their hardneſs is from 6 to 8, or even 9. Their colour is uſually grey, yellow, or brown.

They are often formed into mill-ſtones, filtering-ſtones, and coarſe whet ſtones.

134 Siliceous.

SPECIES 3. Siliceous ſandſtones.

Siliceous ſandſtones conſiſt of grains of ſand cemented together by ſilica, or ſome ſubſtance which conſiſts chiefly of ſilica or flint. They are much harder than any of the other ſpecies.

Sometimes ſtones occur, conſiſting of grains of lime cemented together with ſilica. Theſe ſtones are alſo denominated ſiliceous ſandſtones.

135 Ferruginous.

SPECIES 4. Ferruginous ſandſtones.

The iron which acts as a cement in ferruginous ſandſtones is not far from a metallic ſtate. When iron is completely oxydated, it loſes the property of acting as a cement. This is the reaſon that ferruginous ſandſtones, when expoſed to the air, almoſt always crumble into powder.

The colour of ferruginous ſandſtones is uſually dark red, yellow, or brown. The grains of ſand which compoſe them are often pretty large. Their hardneſs is commonly inconſiderable.

136 G. II. P ding ſto

GENUS II. PUDDING STONE.

Pebbles of quartz, flint, or other ſimilar ſtones of a round or eliptical form, from the ſize of rape ſeed to that of an egg, cemented together by a ſiliceous cement, often mixed with iron, have been denominated *pudding ſtones*.

Pudding ſtones, of courſe, are not inferior in hardneſs to quartz, flint, chalcedony, &c. of which the pebbles may conſiſt. The colour of the cement is uſually yellow, brown, or red. Its fracture is conchoidal.

The finer ſorts of pudding ſtones are capable of a fine poliſh; the coarſe are uſed for mill-ſtones.

137 G. II Amygd loid.

GENUS III. AMYGDALOID.

Rounded or eliptical maſſes of chalcedony, zeolite, limeſtone, lithomarga, ſteatites, green earth, garnets, hornblend, or opal, cemented together by a baſis of indurated clay, trap, mullen, walken or kragg, conſtitute an *amygdaloid*.

Amygdaloids are opaque. They have no luſtre. Their fracture is uneven or conchoidal. Hardneſs 6 to 9. Their colours are as various as the ingredients of which they are compoſed.

138 G. IV Brecc

GENUS IV. BRECCIA.

Angular fragments of the ſame *ſpecies* of ſtone agglutinated together, conſtitute a *breccia*. Thus *calcareous* breccia conſiſts of fragments of marble cemented together by means of lime.

SECT. III. *Aggregates of Cryſtals.*

THE minerals belonging to this ſection conſiſt either of cryſtals of different kinds cemented together, or of cryſtals and amorphous ſtones cemented together.

They may be reduced under the following genera.

1. Granite.
2. Sienite.
3. Granatine.
4. Granitell.
5. Granilite.
6. Trap.
7. Porphyry.

1 G. I. nite.

GENUS I. GRANITE.

An aggregate of felſpath, quartz, and mica, whatever be the ſize or the figure of the ingredients, is denominated *granite*. This aggregate may be divided into two ſpecies, namely, *common* granite, and *ſhiſtoſe* granite or gneiſs.

14 Com

SPECIES 1. Common granite.

Its ſtructure is always granular. The felſpar is often amor-

Earths and Stones. amorphous, and conſtitutes moſt frequently the greateſt part of the aggregate.

Common granites differ much in their appearance, according to the ſize, proportion, colour, and figure of their component parts. They are commonly very hard: Their ſpecific gravity varies from 2.5388 to 2.9564.

141 Gneiſs.

SPECIES 2. Shiſtoſe granite or gneiſs.

The ſtructure of gneiſs is always ſlaty, and this conſtitutes its ſpecific character. In gneiſs, the proportion of quartz and felſpar is nearly equal: the proportion of mica is ſmalleſt. It is evidently ſubject to the ſame varieties with common granite.

142 G. II. Sienite.

GENUS II. Sienite.

Mr Werner has given the name of *ſienite* to aggregates compoſed of felſpar, hornblende, and quartz; or of felſpar, hornblende, quartz, and mica. Theſe aggregates were formerly confounded with quartz.

Sienite is found both of a granular and ſlaty ſtructure: it might, therefore, like granite, be divided into two ſpecies. In ſienite the quartz is commonly in by far the ſmalleſt proportion.

143 G. III. Granatine.

GENUS III. GRANATINE.

Mr Kirwan has applied the name *granatine* to the following aggregates.

Quartz, Felſpar, Shorl.	Quartz, Mica, Garnet.	Quartz, Hornblende, Jade.	Felſpar, Mica, Shorl.
Quartz, Felſpar, Jade.	Quartz, Shorl, Hornblende,	Quartz, Hornblende, Garnet,	Felſpar, Mica, Hornblende.
Quartz, Felſpar, Garnet.	Quartz, Shorl, Jade.	Quartz, Jade, Garnet.	Felſpar, Quartz, Serpentine.
Quartz, Mica, Shorl.	Quartz, Shorl, Garnet.	Quartz, Hornblende, Hornſtone,	Felſpar, Quartz, Steatites.
Quartz, Mica, Jade.			

One of theſe aggregates, namely, *quartz, mica, garnet*, was called by Cronſtedt *norka* or *murkſten*.

144 G. IV. Granitell.

GENUS IV. GRANITELL.

Mr Kirwan gives the name of *granitell* to all aggregates compoſed of any two of the following ingredients: quartz, felſpath, mica, ſhorl, hornblende, jade, garnet, ſteatites. The moſt remarkable of theſe are:

Quartz, Felſpar	Quartz, Hornblende.	Quartz, Steatites.	Felſpar, Hornblende.
Quartz, Mica.	Quartz, Jade.	Felſpar, Mica.	Felſpar, Jade.
Quartz, Shorl.	Quartz, Garnet.	Felſpar, Shorl.	Felſpar, Garnet.
Mica, Shorl.	Mica, Jade.	Hornblende, Jade.	Jade, Garnet.
Mica, Hornblende.	Mica, Garnet.	Hornblende, Garnet.	Steatites, Shorl.

Aggregates

Some of theſe aggregates have received particular names. The aggregate of *quartz* and *mica*, when its ſtructure is ſlaty, is called by Werner *ſhiſtoſe mica*: by the Swedes, it is denominated *ſtellſten*, whatever be its ſtructure.

The aggregate of hornblende and mica is called *grunſtein*, from the dark green colour which it uſually has.

145 G. V. Granilite.

GENUS V. GRANILITE.

Under the name of *granilite*, Mr Kirwan comprehends all aggregates containing more than three ingredients. Of theſe the following are the moſt remarkable.

Quartz, Felſpar, Mica, Shorl.	Quartz, Mica, Shorl, Garnet.	Quartz, Sulph. of barytes, Mica, Shorl.
Quartz, Felſpar, Mica, Steatites.	Quartz, Felſpar, Mica, Garnet.	Quartz, Sulph. of barytes, Mica, Hornblende.

146 G. VI. Trap.

GENUS VI. TRAP (P).

Under this genus we claſs not only what has commonly been called *trap*, but alſo wacken, and mullen, and kragſtone of Kirwan.

147 Common.

SPECIES 1. Common trap.

This ſtone is very common in Scotland, and is known by the name of *whinſtone*. Whole hills are formed of it; and it occurs very frequently in large rounded detached fragments. Sometimes it aſſumes the form of immenſe columns, and is then called *baſalt*. The Giants Cauſeway in Ireland, the iſland of Staffa, and the ſouth ſide of Arthur's Seat in Scotland, are well known inſtances of this figure.

Its texture is earthy or compact. Its fracture uneven. Its luſtre commonly 0. Opaque. Hardneſs 8 to 9. Not brittle. Sp. gr. from 2.78 to 3.021 *. Colour black, with a ſhade of grey, blue, or purple; ſometimes blackiſh or reddiſh brown; in ſome caſes greeniſh grey. By expoſure to the atmoſphere, it often becomes inveſted with a browniſh rind. Before the blow-pipe, it melts *per ſe* into a more or leſs black glaſs.

* *Kirwan.*

Trap conſiſts of ſmall cryſtals of hornblende, felſpar, olivine, &c. uſually ſet in a ground compoſed apparently of clay and oxyd of iron. A ſpecimen, in the form of baſaltes, from Staffa, analyſed by Dr Kennedy of Edinburgh, contained 48 ſilica,
16 alumina,
16 oxyd of iron,
9 lime,
5 moiſture,
4 ſoda,
1 muriatic acid.

99 †

† *Edin. Tranſ.* v. 89.

(P) *Kirw.* I. 231 and 431.—*Faujas de St Fond. Eſſai ſur l'Hiſt. Nat. des Roches de Trap.*—*Phil. Tranſ.* paſſim. See alſo a very ingenious ſet of experiments on the fuſion of trap, by Sir James Hall in *Tranſ. Edin.* V. 43.

A ſpecimen from Saliſbury rock, near Edinburgh, contained, according to the analyſis of the ſame gentleman,

46.0	ſilica,
19.0	alumina,
17.0	oxyd of iron,
8.0	lime,
4.0	moiſture,
3.5	ſoda,
1.0	muriatic acid.
98.5 ‡	

Dr Kennedy conducted theſe analyſes with great ingenuity and judgment; and the diſcovery in which they terminated, that trap contains ſoda, is certainly of importance, and may lead to valuable conſequences both in a geological and mineralogical view.

148 Wacken.

SPECIES 2. Wacken *.

This ſtone often forms conſiderable parts of hills, and, like trap, is amorphous. Its texture is earthy. Its fracture uſually even. Luſtre 0. Opaque. Hardneſs 6 to 9. Sp. gr. from 2.535 to 2.893 †. Colour grey, with a ſhade of green, black, red, brown. When expoſed to the atmoſphere, it withers and becomes more grey.

It melts into a grey porous ſlag.

149 Mullen.

SPECIES 3. Mullen ‡.

This ſtone is alſo found in conſiderable maſſes, and ſometimes has a tendency to a columnar form like baſalt. Texture earthy. Fracture uneven, and fine ſplintery. Luſtre 0, except from ſome ſhining particles of baſaltine. Opaque. Hardneſs from 7 to 9. Sp. gr. from 2.6 to 2.738. Colour aſh or bluiſh grey; ſometimes mixed with ochre yellow, in conſequence of the decompoſition of the ſtone. At 130° Wedgewood it melts into a black compact glaſs.

When mullen is expoſed to the air, its ſurface becomes covered with a greyiſh white rind, ſometimes ſlightly ochry.

150 Kragſtone.

SPECIES 4. Kragſtone *.

This ſtone, which, like the others, forms conſiderable parts of rocks, was formed into a diſtinct ſpecies by Mr Kirwan. Its texture is earthy. It is exceedingly porous, and the pores are often filled with the cryſtals of other minerals. Fracture uneven. Luſtre 0. Opaque. Hardneſs 5 to 7. Sp. gr. 2.314. Feels rough and harſh. Colour reddiſh grey. Streak yellowiſh grey. At 138° Wedgewood it melts into a reddiſh brown porcelain maſs.

151 G. VII. Porphyry.

GENUS VII. PORPHYRY.

Any ſtone which contains ſcattered cryſtals or grains of felſpar, viſible to the naked eye, is denominated a *porphyry*. Beſides felſpar, porphyries generally contain ſmall cryſtals of quartz, hornblende, and mica. Theſe cryſtals are uſually of a different colour from the ſtone in which they are found, and they are ſtuck in it as in a cement. It is evident from this definition, that the number of porphyries muſt be great. Each ſpecies receives its name from the ſtone which forms its baſis. To deſcribe them would be unneceſſary. We ſhall only give a catalogue of the principal ſpecies.

1. Hornſtone porphyry.
2. Pitchſtone porphyry.
3. Hornſlate porphyry.
4. Felſpar or petunſe porphyry.
5. Clay porphyry.
6. Hornblende porphyry.
7. Trap porphyry.
8. Wacken porphyry.
9. Mullen porphyry.
10. Krag porphyry.
11. Argillitic porphyry.
12. Potſtone porphyry.
13. Serpentine porphyry.
14. Sandſtone porphyry,

The aggregates belonging to this ſection compoſe moſt of the mountains of the globe. In giving an account of them, we have adhered implicitly to the arrangement moſt generally received by mineralogiſts. It muſt be acknowledged, that this arrangement is by no means complete, and that ſome of the genera are too vague to be of much uſe. The number of aggregates already diſcovered is too great for giving to each a particular name. Perhaps it would be better henceforth to adopt the method propoſed by Mr Hauy, namely, to conſtitute the genera from that ingredient which enters moſt abundantly into the aggregate, and which forms as it were its baſis, and to diſtinguiſh the ſpecies according to the nature and proportion of the other ingredients. According to this plan, the aggregates hitherto diſcovered have been divided by Hauy into the following genera:

1. Felſpathic rock.
2. Quartzous rock.
3. Micaceous rock.
4. Chloritous rock.
5. Serpentine rock.
6. Trappean rock.
7. Hornblendean rock.
8. Petro-ſiliceous rock.
9. Garnetic rock.
10. Calcareous rock.
11. Argillaceous rock.
12. Corneous rock.

SECT. IV. *Volcanic Aggregates.*

AGGREGATES formed by volcanoes may be reduced to the following genera.

1. Lava.
2. Tufa.
3. Pumice.
4. Aſhes.

152 G. I Lav

GENUS I. LAVA.

All ſubſtances which have iſſued out of a volcano in a ſtate of fuſion are called *lavas*. They have been divided into three ſpecies.

153 Vitreous

SPECIES 1. Vitreous lava.

Found in ſmall pieces.

Texture gloſſy. Fracture conchoidal. Luſtre 3. Tranſparency from 3 to 1. Hardneſs 9 to 10. Sp. gr. from 2 to 3. Colour blackiſh, greeniſh, or whitiſh. Commonly ſomewhat porous.

154 Cellular

SPECIES 2. Cellular lava.

This ſpecies is full of cells. Surface rough and full of cavities. Texture earthy. Luſtre 0. Opaque. Hardneſs 7 to 9. Sp. gr. varies, but does not exceed 2.8. Colour brown or greyiſh black. Commonly ſomewhat magnetic.

155 Compa

SPECIES 3. Compact lava.

This ſpecies is the moſt common of all; it runs into the

---

‡ *Edin. Tranſ.* v. 90.

* *Kirw.* i. 223.

† *Kirwan.*

‡ *Kirw.* i. 225.

* *Kirw.* i. 226.

the ſecond by inſenſible degrees; and indeed is ſeldom found of any conſiderable ſize without ſome pores. It bears in general a very ſtrong reſemblance to trap.

A ſpecimen of the lava of Catania in Sicily, analyſed by Dr Kennedy, contained

51.0 ſilica,
19.0 alumina,
14.5 oxyd of iron,
9.5 lime,
4.0 ſoda,
1.0 muriatic acid.

99.0 †

A ſpecimen of the lava of Sta. Venere in Sicily he found to contain

50.75 ſilica,
17.50 alumina,
14.25 oxyd of iron,
10.00 lime,
4.00 ſoda,
1.00 muriatic acid.

97.5 ‡.

Thus we ſee, that the reſemblance between trap and lava holds not only in their external appearance, but alſo in their component parts.

† T ſ. Edi v. 93.

‡ I 94.

156 G. II. Puzzolana.

Genus II. puzzolana.

Found in ſmall pieces. Surface rough. Texture earthy and porous. Fracture uneven. Luſtre 0. Opaque. Hardneſs 3. Very brittle. Sp. gr. from 2.57 to 2.8. Colour brown or dark grey. Magnetic. Eaſily melts into a black ſlag.

When mixed with lime into a mortar, it poſſeſſes the property of hardening even under water. This property it owes moſt probably, as Mr Kirwan ſuppoſes, to the iron which it contains. The iron decompoſes the water of the mortar, and by this means it becomes too hard to be acted upon by water in a very ſhort time.

157 G. III. Pumice.

Genus III. pumice.

This is a very light ſubſtance ejected from volcanoes. It is porous. Hardneſs 3. Brittle. Sp. gr. below 1. Colour grey or brown.

In ſome varieties the luſtre and tranſparency are 0: in others, the luſtre is glaſſy, 2. Tranſparency from 1 to 2.

158 G. IV. Volcanic aſhes.

Genus IV. volcanic ashes.

Theſe are analogous to the aſhes of common pit coal. Looſe and ſmooth, very light, and fine. Slowly diffuſible in water, and when wet ſomewhat ductile.

Class II. SALTS.

UNDER this claſs we comprehend all the combinations of alkalies with acids which exiſt in the mineral kingdom. As they have been already deſcribed in the article Chemistry, *Suppl.* we ſhall here only give a liſt of their names.

9 Ge ra.

Genus I. potass.

Sp. 1. Sulphat of potaſs.
2. Nitrat of potaſs.

Genus II. soda.

Sp. 1. Carbonat of ſoda.
2. Sulphat of ſoda.
3. Muriat of ſoda.
4. Borax.

Genus III. ammonia.

Sp. 1. Sulphat of ammonia.
2. Muriat of ammonia.

Class III. COMBUSTIBLES.

0 Ge ra.

THE combuſtible ſubſtances belonging to the mineral kingdom, excluding the metals, may be comprehended under the following genera.

1. Sulphur.
2. Carbon.
3. Bitumen.
4. Coal.
5. Amber.

Sr G. Sulph

Genus I. sulphur.

species 1. Native ſulphur.

This ſubſtance is found abundantly in many parts of the world, eſpecially near volcanoes, as Hecla, Ætna, Veſuvius, the Lipari iſlands, &c. It is either in the ſtate of powder, or maſſive, or cryſtallized. The primitive form of its cryſtals is an octohedron, compoſed of two four-ſided pyramids, joined baſe to baſe †. The ſides of theſe pyramids are ſcalene triangles, and ſo inclined that the plane where the baſes of the pyramids join is a rhomb, whoſe long diagonal is to its ſhort as 5 to 4*. Sometimes the apices of the pyramids, to uſe the language of De Liſle, are truncated; ſometimes they are ſeparated from each other by a priſm; ſometimes they are truncated near their baſes, and a low four ſided pyramid riſes from the truncature: this pyramid is alſo ſometimes truncated near its apex ‡. Finally, one of the edges of the pyramids is ſometimes truncated. For figures of theſe varieties, and for the laws of their formation, we refer to *Mr Leſroy* †.

† I. 34.

* né de i. 292. and Jour. de Min. No xxi 337.

‡ Fig. 55.

† *Jour. de Min.* No xxix. 337.

Colour yellow, with a ſhade of green; ſometimes reddiſh (a). Luſtre greaſy, 2. Tranſparency varies from 0 to 4. Cauſes double refraction ‡. Texture compact. Hardneſs 4 to 5. Brittle.—For its other properties, we refer to Chemistry in this *Suppl.*

‡ *Hauy.*

Sometimes ſulphur is mixed with different proportions of earths. Theſe combinations are hardly ſuſceptible of accurate deſcription.

Sulphur combines alſo with metals. Theſe combinations ſhall be deſcribed in the fourth claſs.

161 G. II. Carbon.

Genus II. carbon.

This genus comprehends all minerals compoſed of pure carbon, or of carbon combined with a little earth.

163 Diamond.

species 1. Diamond.

This mineral, which was well known to the ancients, is

(a) It then contains arſenic.

Combuſtibles.

is found in different parts of Aſia, particularly in the kingdoms of Golconda and Viſapour; it is found alſo in Brazil.

It is always cryſtallized; but ſometimes ſo imperfectly, that at the firſt ſight it might paſs for amorphous. Its primitive form is a regular octogon †; but it more commonly aſſumes a ſpheroidal form, and then has uſually 36 curvilinear triangular faces, ſix of which are raiſed upon each of the faces of the primitive octogon ‡. Its integrant molecule, according to Hauy, is a regular tetrahedron.—For a more particular account of the cryſtals of this mineral, we refer the reader to *Mr Romé de Liſle** and *Mr Hauy*†.

† Fig. 36.

‡ Fig. 37.

* Cryſt. ii. 191

Texture foliated. Luſtre 4. Tranſparency from 2 to 4. Cauſes ſingle refraction. Hardneſs 20. Sp. gr. 3.5185 to 3.5310‡. Colour various; ſometimes limpid, ſometimes red, orange, yellow, green, blue, and even blackiſh.

† Jour. de Min. N° xxix. 343.

‡ Hauy, ibid.

When rubbed it becomes poſitively electric, even before it has been cut by the lapidary, which is not the caſe with any other gem ||.

It is compoſed of pure carbon §.

|| Id ibid.

§ Morveau, Ann. de Chim. xxxi. 72.

164 Mineral charcoal.

SPECIES 2. Mineral charcoal.

Kilkenny coal—Wales culm.

This mineral has been found in Hungary, Italy, France, Ireland, and Wales. It occurs in ſtratified maſſes, or in lumps neſted in clay.

Colour black. Luſtre 4, metallic. Opaque. Texture foliated. Hardneſs 5 to 7. Sp. gr. 1.4 to 1.526. Often ſtains the fingers. Inſoluble in acids. Deflagrates with nitre. Does not burn till wholly ignited, and then conſumes ſlowly without emitting flame or ſmoke.

It conſiſts almoſt entirely of *charcoal*, which, as Morveau has proved, is an oxyd of carbon *.

* Ibid.

165 Anthracite.

SPECIES 3. Anthracite (R).

Anthracolite.

This ſubſtance, as Dolomieu informs us, is found excluſively in the primitive mountains. It is always amorphous. Colour black or browniſh black. Luſtre 3 to 4. Structure ſlaty. Fragments rhomboidal. Hardneſs 6 to 7. Sp. gr. greater than that of coal. Often ſtains the fingers.

Burns preciſely like the laſt ſpecies, and leaves .40 of white aſhes. According to Dolomieu, it is compoſed of about

64.0	charcoal,
32.5	ſilica,
3.5	iron,
100.0†	

† Jour. de Min N° xxix. 338.

It is probable that the charcoal in the two laſt ſubſtances is in the ſame ſtate in which it exiſts in plumbago, combined with oxygen, but not containing ſo much as charcoal does ‡.

‡ Morveau, ibid.

166 G. III. Bitumen.

GENUS III. BITUMEN.

By bitumen we underſtand, with mineralogiſts in general, an oil, which is found in different parts of the earth, in various ſtates of conſiſtence. Theſe different ſtates form diſtinct ſpecies; in our arrangement of which we ſhall be guided by the obſervations which Mr Hatchett has made in his valuable paper on bituminous ſubſtances *.

* Nicholſon's Journal, ii. 201, 248.

167 Naphtha.

SPECIES 1. Naphtha.

This ſubſtance is found ſometimes on the ſurface of the water of ſprings, and ſometimes iſſuing from certain ſtrata. It is found in great abundance in Perſia.

It is as fluid and tranſparent as water. Colour white or yellowiſh white. Smell ſtrong, but not diſagreeable. Sp. gr. when white, .708* or .729†; when yellowiſh, .8475‡. Feels greaſy. Catches fire on the approach of flame, burns with a white flame, and leaves ſcarce any reſiduum.

* Muſchroek

† Bould

‡ Briſſo

Inſoluble in alcohol. Does not freeze at 0° Fahrenheit. When pure naphtha is expoſed to the air, it becomes yellow and then brown; its conſiſtence is increaſed, and it paſſes into *petroleum* *.

* Hatc

168 Petrol

SPECIES 2. Petroleum.

This ſubſtance is alſo found in Perſia, and likewiſe in many countries in Europe, particularly Italy, France, Switzerland, Germany, Sweden, England, and Scotland.

Not ſo fluid nor tranſparent as water. Colour yellow, either pale or with a ſhade of red or green; reddiſh brown and reddiſh black. Smell that of naphtha, but leſs pleaſant. Sp. gr. .8783 *. When burned it yields a ſoot, and leaves a ſmall quantity of coally reſiduum.

* Briſſ

By expoſure to the air it becomes like tar, and is then called *mineral tar* †.

† Hatc ibid.

169 Mineral tar.

SPECIES 3. Mineral tar.

This ſubſtance is found in many parts of Aſia, America, and Europe. It is viſcid, and of a black, browniſh black, or reddiſh colour. Smell ſometimes ſtrong, but often faint. Sp. gr. 1.1. When burned, emits a diſagreeable bituminous ſmell. By expoſure to the air it paſſes into *mineral pitch* and *maltha* *.

* Hat ibid.

170 Mineral pitch and maltha

SPECIES 4. Mineral pitch and maltha.

This ſubſtance has a ſtrong reſemblance to common pitch. When the weather is warm it is ſoft, and has ſome tenacity; it is then called *adheſive mineral pitch*: when the weather is cold, it is brittle; its hardneſs is 5; and its fracture has a glaſſy luſtre. In this ſtate it is called *maltha*. Colour black, dark brown, or reddiſh. Luſtre 0. Opaque. Sp gr. from 1.45 to 2.07. Does not ſtain the fingers. On a white hot iron it flames with a ſtrong ſmell, and leaves a quantity of grey aſhes. It is to the preſence of the earths which compoſe theſe aſhes that the great ſpecific gravity of this bitumen is to be aſcribed. By farther induration, it paſſes into *aſphalt*.

171 Aſphal

SPECIES 5. Aſphalt.

This ſubſtance is found abundantly in many parts of Europe, Aſia, and America, eſpecially in the iſland of Trinidad.

Colour black or browniſh black. Luſtre greaſy 2. Opaque. Fracture conchoidal, of a glaſſy luſtre. Hardneſs from 7 to 8. Very brittle. Sp gr 1.07 to 1.165*. Feel ſmooth, but not greaſy. Does not ſtain the fingers. Has little or no ſmell, unleſs when rubbed or heated. When heated melts, ſwells, and inflames; and when pure, burns without leaving any aſhes.

* Kir

172 Elaſtic tumen

SPECIES 6. Elaſtic bitumen.

Mineral caoutchouc.

This ſubſtance was found about the year 178[illegible] in the lead

---

(R) This name was given by Hauy from ανθραξ, *a coal.*

ibuſ- es. lead mine of Odin, near Caſtletown, Derbyſhire. It was firſt mentioned by Mr De Born.

Colour yellowiſh or reddiſh brown, ſometimes blackiſh brown. In its appearance it has a ſtrong reſemblance to caoutchouc or Indian rubber; hence its name. Conſiſtency various: ſometimes ſo ſoft as to adhere to the fingers; ſometimes nearly as hard as aſphalt. When ſoft it is elaſtic; when hard brittle. Sp. gr. 0.9053 to 1.0233‡.

‡ chett, ii.

Inſoluble in alcohol, ether, and oil of turpentine, but ſoluble in oil of olives Not affected by nitric acid. When diſtilled, it yields a bituminous oil inſoluble in alcohol; the reſiduum is carbonaceous*.

* metlie- ri our. de P xxxi. 3

There is a variety of this ſubſtance found in a rivulet near the mine of Odin, which, when freſh cut, exactly reſembles fine cork in colour and texture; but in a few days after being expoſed to the air, becomes of a pale reddiſh brown. This ſubſtance contains within it a nucleus of elaſtic bitumen. It ſeems to be the elaſtic bitumen altered in its texture by the water †.

† tebett, ii.

73 /. Coal.

Genus IV. coal.

The ſubſtances belonging to this genus are compoſed of carbon or rather charcoal, and bitumen.

74 Jet.

species 1. Jet (s).

This ſubſtance is found in France, Spain, Germany, Britain, and other countries. It is found in detached kidneyform maſſes, of various ſizes, from an inch to ſeven or eight feet in length.

Colour full black. Luſtre 3 to 4; internal glaſſy. Opaque. Hardneſs 7 to 8. Not near ſo brittle as aſphalt. Texture ſtriated. Fracture conchoidal. Sp. gr. 1.259*. It has no odour except when heated, and then it reſembles the odour of aſphaltum. Melts in a ſtrong heat, burns with a greeniſh flame, and leaves an earthy reſiduum†.

Becomes ſomewhat electric by friction‡. When diſtilled yields a peculiar acid §.

This mineral is formed into buttons, beads, and other trinkets. The manufacture has been almoſt confined to France ||.

riſſon. atchett. irwan. auquelin. our. de n Nº iv.

175 nnel l.

species 2. Cannel coal.

This mineral is found in Lancaſhire, and in different parts of Scotland, where it is known by the name of *parrot coal*.

Colour black. Luſtre common, 2. Opaque. Structure ſometimes ſlaty. Texture compact. Fracture conchoidal. Hardneſs 5 to 8. Brittle. Sp. gr. 1.232 to 1.426. Does not ſtain the fingers.

Kindles eaſily, and burns with a bright white flame like a candle (T), which laſts but a ſhort time. It does not cake. It leaves a ſtony or ſooty reſiduum.

A ſpecimen of Lancaſhire cannel coal, analyſed by Mr Kirwan, contained 75.20 charcoal,
21.68 maltha,
3.10 alumina and ſilica.

99.98†

Mineral. 523.

A ſpecimen of the ſlaty kind from Airſhire, called *ſplent coal*, was compoſed of
47.62 charcoal,
32.52 maltha,
20.00 earths.

100.14‡

‡ Ibid. 524.

Cannel coal is ſuſceptible of poliſh, and, like jet, is often wrought into trinkets.

176 Common coal.

species 3. Common coal.

This very uſeful combuſtible is never found in the primitive mountains, but only in the ſecondary mountains, or in plains formed of the ſame materials with them. It is always in ſtrata, and generally alternates with clay, ſandſtone, or limeſtone.

Colour black, more or leſs perfect. Luſtre uſually greaſy or metallic, 2 to 4. Opaque. Structure generally ſlaty. Texture often foliated. Fracture various. Hardneſs 4 to 6. Sp. gr. 1.25 to 1.37. Uſually ſtains the fingers. Takes fire more ſlowly, and burns longer, than the laſt ſpecies. Cakes more or leſs during combuſtion.

Of this ſpecies there are many varieties, diſtinguiſhed in Britain by the names of caking coal, rock coal, &c. Theſe are too well known to require any deſcription.

Mr Kirwan analyſed a variety of different kinds of coal: The reſult of his experiments may be ſeen by the following table.

Whitehaven coal.	Wigan.	Swanſey.	Leeirim	
57.0	61.73	73.53	71.43	charcoal.
41.3	36.7	23.14	23.37	maltha & aſph.
1.7	1.57	3.33	5.20	earths ‡.
100.0	100.00	100.00	100.00	

‡ Mineral. ii 525.

177 Spurious coal.

species 4. Spurious coal.

This mineral is generally found amidſt ſtrata of genuine coal. It is alſo called *parrot coal* in Scotland.

Colour greyiſh black. Luſtre 0 to 1. Structure uſually ſlaty. Texture earthy. Hardneſs 7 to 8. Sp. gr. 1.5 to 1.6 Generally explodes, and burſts when heated.

Compoſed of charcoal, maltha, and aſphalt, and above .20 of ſtony matter.

178 G V. Amber.

Genus V. amber.

species 1. Common amber.

This ſubſtance, called *electrum* by the ancients, is found in different countries; but moſt abundantly in Pruſſia, either on the ſea ſhore, or under ground at the depth of about 100 feet, repoſing on *wood coal**. It is in lumps of different ſizes.

* Kirw. Min. ii. 66.

Colour yellow. Luſtre 3 to 2. Tranſparency 2 to 4. Fracture conchoidal. Hardneſs 5 to 6. Sp. gr. 1.078 to 1.085. Becomes electric by friction.

If a piece of amber be fixed upon the point of a knife, and then kindled, it burns to the end without melting †.

† Hauy.

By diſtillation it yields ſuccinic acid.

Class

(s) It was called *gagathes* by the ancients, from the river Gages in Licia, near which it was found; *jayet* in French, *azabache* in Spaniſh, *gagath* in German.

(T) Hence it has been called *cannel coal*. *Candle*, in the Lancaſhire and Scotch dialect, is pronounced *cannel*.

Metallic Ores.

Gold, Silver.

CLASS IV. METALLIC ORES.

THIS claſs comprehends all the mineral bodies, compoſed either entirely of metals, or of which metals conſtitute the moſt conſiderable and important part. It is from the minerals belonging to this claſs that all metals are extracted; for this reaſon they have obtained the name of *ores*.

179 Orders. The metals hitherto diſcovered amount to 21; we ſhall therefore divide this claſs into 21 orders, allotting a diſtinct order for the ores of every particular metal.

Metals exiſt in ores in one or other of the four following ſtates. 1. In a metallic ſtate, and either ſolitary or combined with each other. 2. Combined with ſulphur. 3. In the ſtate of oxyds. 4. Combined with acids. Each order therefore may be divided into the four following genera.

180 Genera,

1. Alloys.
2. Sulphurets.
3. Oxyds.
4. Salts.

It muſt be obſerved, however, that every metal has not hitherto been found in all theſe four ſtates, and that ſome of them are hardly ſuſceptible of them all. Some of the orders therefore want one or more genera, as may be ſeen from the following table.

ORDER I. *Gold ores.*
  1. Alloys.
ORDER II. *Silver ores.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
  4. Salts.
ORDER III. *Platinum ores.*
  1. Alloys.
ORDER IV. *Ores of mercury.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
  4. Salts.
ORDER V. *Copper ores.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
  4. Salts.
ORDER VI. *Iron ores.*
  1. Alloys.
  2. Sulphurets.
  3. Carburets.
  4. Silicated iron.
  5. Oxyds.
  6. Salts.
ORDER VII. *Tin ores.*
  1. Sulphurets.
  2. Oxyds.
ORDER VIII. *Lead ores.*
  1. Sulphurets.
  2. Oxyds.
  3. Salts.
ORDER IX. *Zinc ores.*
  1. Sulphurets.
  2. Oxyds.
  3. Salts.
ORDER X. *Antimonial ores.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
  4. Salts.
ORDER XI. *Biſmuth ores.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
ORDER XII. *Arſenic ores.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
ORDER XIII. *Cobalt ores.*
  1. Alloys.
  2. Sulphurets.
  3. Oxyds.
  4. Salts.
ORDER XIV. *Nickel ores.*
  1. Sulphurets.
  2. Oxyds.
  3. Salts.
ORDER XV. *Mangancſe ores.*
  1. Oxyds.
  2. Salts.
ORDER XVI. *Tungsten ores.*
  1. Oxyds.
  2. Salts.
ORDER XVII. *Ores of molybdenum.*
  1. Sulphurets.
ORDER XVIII. *Ores of uranium.*
  1. Oxyds.
  2. Salts.
ORDER XIX. *Ores of titanium.*
  1. Oxyds.
ORDER XX. *Ores of tellurium.*
  1. Alloys.
ORDER XXI. *Ores of chromum.*
  1. Oxyds.

ORDER I. GOLD ORES.

181 Where found. No metal perhaps, if we except iron, is more widely ſcattered through the mineral kingdom than gold *. Hitherto it has been found only in a metallic ſtate; moſt commonly in grains, ramifications, leaves, or rhomboidal, octohedral, or pyramidal cryſtals. It is generally mixed with quartz, though there are inſtances of its having occurred in calcareous rocks. It is not uncommon alſo to find it diſſeminated through the ores of other metals; eſpecially iron, mercury, copper, and zinc. The greateſt quantity of gold is found in the warmer regions of the earth. It abounds in the ſands of many African rivers, and is very common in South America and India. Europe, however, is not deſtitute of this metal. Spain was famous in ancient times for its gold mines, and ſeveral of the rivers in France contain it in their ſands †. But the principal gold mines in Europe are thoſe of Hungary, and next to them thoſe of Salzburg. Gold alſo has been diſcovered in Sweden and Norway, and more lately in the county of Wicklow in Ireland ‡.

GENUS I. Alloys of gold.

SPECIES 1. Native gold.

182 G. I. Nati gold. Native gold is never completely pure; it is alloyed with ſome ſilver or copper, and ſometimes with iron. In the native gold found in Ireland, indeed, the quantity of alloy appears to have been exceedingly ſmall.

Its colour is yellow. Luſtre metallic. Fracture hackly. Hardneſs 5. Sp. gr. from 12 to 19.

ORDER II. SILVER ORES.

183 Where found. SILVER is found moſt commonly in quartz, limeſtone, hornſtone; or combined with the ores of other metals, moſt commonly with copper, antimony, zinc, cobalt, and lead. This laſt metal indeed is ſeldom totally deſtitute of ſilver.

GENUS I. Alloys of ſilver.

SPECIES 1. Native ſilver *.

184 G. I. Nati ſilver. Native ſilver, ſo called becauſe the ſilver is nearly in a ſtate of purity, forms the principal part of ſome of the richeſt ſilver mines in the world. It is ſometimes in ſmall lumps; ſometimes cryſtallized in cubes, hexahedrons, octohedrons, or dodecahedrons; ſometimes in leaves, or threads, often ſo connected with each other as to reſemble branches of trees, and therefore called *dendrites*. The ſilver in the famous mines of Potoſi has this laſt form. When newly extracted, it is not unlike ſmall branches of fir †.

The colour of native ſilver is white; often tarniſhed. Luſtre metallic. Fracture hackly. Hardneſs 6. Malleable. Sp. gr. from 10 to 10.338.

The ſilver in this ſpecies is almoſt conſtantly alloyed with from .03 to .05 of ſome other metal, frequently gold or arſenic.

loy of
ver and
ld.

SPECIES 2. Alloy of ſilver and gold.
Auriferous native ſilver.

This alloy is not uncommon in ſilver mines. Its colour is yellowiſh white. Its luſtre metallic. Hardneſs 5. Malleable. Sp. gr. above 10.6. Dr Fordyce found a ſpecimen from Norway compoſed of

72 ſilver,
28 gold.

100[*]

186
loy of
ver and
timony.

SPECIES 3. Alloy of ſilver and antimony[†].
Antimoniated ſilver ore.

This alloy, which is found in the ſilver mines of Spain and Germany, is ſometimes in grains or lumps, and ſometimes cryſtallized in ſix-ſided priſms, whoſe ſides are longitudinally channelled[‡].

Its colour is white. Its luſtre metallic. Hardneſs 10. Brittle. Sp. gr. from 9.4406[§] to 10[||]. Texture foliated. Fracture conchoidal. Before the blow-pipe the antimony evaporates in a grey ſmoke, and leaves a browniſh ſlag, which tinges borax green. If borax be uſed at firſt, a ſilver bead may be obtained.

This alloy was long ſuppoſed to contain arſenic. Bergman examined it, and found only ſilver and antimony[¶]. His analyſis has been confirmed by the experiments of Vauquelin and Selb[*]. According to Selb, it is compoſed of 89 ſilver,

11 antimony.

100

A ſpecimen, analyſed by Klaproth, contained

84 ſilver,
16 antimony.

100

Another ſpecimen contained

76 ſilver,
24 antimony.

100[†]

187
. II. Sul-
iurets.
ommon
lphuret of
lver.

GENUS II. SULPHURETS OF SILVER.

SPECIES 1. Common ſulphuret of ſilver[‡].
Vitreous ſilver ore.

This ore occurs in the ſilver mines of Germany and Hungary. It is ſometimes in maſſes, ſometimes in threads, and ſometimes cryſtallized. Its cryſtals are either cubes or regular octohedrons, whoſe angles and edges are often variouſly truncated. For a deſcription of the varieties produced by theſe truncatures, we refer the reader to *Romé de Liſle*[¶].

Its colour is dark bluiſh grey, inclining to black; often tarniſhed. Internal luſtre metallic. Texture foliated. Fracture uneven. Hardneſs 4 to 5. May be cut with a knife like lead. Flexible and malleable. Sp. gr. 6.909[*] to 7.215[†]. In a gentle heat the ſulphur evaporates. Melts when heated to redneſs.

A ſpecimen of this ore, analyſed by Klaproth, contained

85 ſilver,
15 ſulphur.

100[‡]

188
Antimoniated ſilver ore.

SPECIES 2. Antimoniated ſilver ore[*].
Sulphuret of ſilver with antimony and iron.

This ore, which occurs in Saxony and Hungary, ſeems to be ſulphuret of ſilver contaminated with antimony and iron, and ought therefore, in all probability, to be conſidered merely as a variety of the laſt ſpecies. It is ſometimes in maſſes, but more frequently cryſtallized in ſix-ſided priſms, tables, or rhomboids; generally indiſtinct and accumulated together.

Its colour is iron grey; often tarniſhed. Its luſtre metallic. Fracture uneven. Hardneſs 4 to 5. Brittle. Sp. gr. 7.208[†]. Before the blow-pipe the ſulphur and antimony exhale, leaving a bead, which may be freed from iron by fuſion with nitre and borax.

A ſpecimen of this ore, analyſed by Klaproth, contained

66.5 ſilver,
12.0 ſulphur,
10.0 antimony,
5.0 iron,
1.0 ſilica,
0.5 arſenic and copper.

95.0[‡]

189
Sulphuret of ſilver and copper.

SPECIES 3. Sulphuret of ſilver and copper[*].
Cupriferous ſulphurated ſilver ore.

This ore, which is found in the Korbolokinſk mountains in Siberia, was firſt deſcribed by Mr Renovantz. It is in amorphous maſſes, varying in ſize from that of the thumb to that of the fiſt.

Its colour is bluiſh grey like lead. Luſtre metallic. Hardneſs 5 to 6. Brittle. Its powder, when rubbed on the ſkin, gives it a black colour and a leaden gloſs. Before the blow-pipe the ſulphuret of ſilver melts readily; that of copper with difficulty. This ore is compoſed of about

42 ſilver,
21 copper,
35 ſulphur.

98

190
G. III.
Oxyds.
Calciform ſilver ore.

GENUS III. OXYDS OF SILVER.

SPECIES 1. Calciform ſilver ore[†].

This ore was firſt deſcribed by Mr Widenman. It is ſometimes in maſſes, ſometimes diſſeminated through other minerals.

Its colour is greyiſh black. Its ſtreak bright. Its luſtre metallic. Its fracture uneven. Hardneſs 4 to 5. Brittle. Sp. gr. conſiderable. Effervesces with acids. Melts eaſily before the blow-pipe. Froths with borax.

According to Selb, it contains 72.5 ſilver,

15.5 copper,
12.0 carbonic acid.

100.0

191
Red ſilver ore.

SPECIES 2. Red ſilver ore (υ).

This ore is very common in ſeveral German ſilver mines. It occurs in maſſes, diſſeminated and cryſtallized. The primitive form of its cryſtals is a dodecahedron[‡], whoſe ſides are equal rhombs, and which may be con-

† *Vauquelin, ibid.*

Variety 1. Light red.

Colour intermediate between blood and cochineal red; ſometimes variegated. Streak orange red. Powder black.

Variety 2. Dark red.

Colour commonly between dark cochineal red and lead grey; ſometimes nearly black and without any ſhade of red. Streak dark crimſon red.

This ore was long ſuppoſed to contain arſenic. Klaproth firſt aſcertained its real compoſition‡; and his analyſis has been confirmed by Vauquelin, who found a ſpecimen compoſed of 56.6748 ſilver,
16.1300 antimony,
15.0666 ſulphur,
12.1286 oxygen.

100.

‡ *Ann. de Chim.* xviii. 81.

Klaproth proved, that the ſilver and antimony are in the ſtate of oxyds; and Vauquelin, that the ſulphur is combined partly with the oxyd of ſilver and partly with the oxyd of antimony. Klaproth obtained a little ſulphuric acid; but this acid, as Vauquelin, with his uſual ingenuity, demonſtrated, was formed during the analyſis.

This ore ſometimes contains a minute portion of arſenic, but never more than .02*.

* *Vauquelin, ibid.* p. 8.

GENUS IV. SALTS OF SILVER.

192 G. IV. Salts. Muriat of ſilver.

SPECIES 1. Muriat of ſilver (x).

Corneous ſilver ore.

This ore occurs at Johanngeorgenſtadt in Saxony, in South America, &c. It is often amorphous, ſometimes nearly in powder, and ſometimes cryſtallized in cubes or parallelopipeds.

Its colours are various: when expoſed to the light it becomes brown. Internal luſtre greaſy, 2; external, 2 to 1. Acquires a gloſs when ſcraped with a knife. Tranſparency 2 to 1. Texture foliated. Hardneſs 4 to 5. Sp. gr. 4.745* to 4.804†. Before the blowpipe it inſtantly melts, and gradually evaporates, but may be reduced by adding an alkali.

* *Briſſon.*
† *Gellert.*

That this ore contains muriatic acid, has been long known. Mr Woulfe firſt ſhewed that it contained alſo ſulphuric acid‡: and this diſcovery has been confirmed by Klaproth, according to whoſe analyſis this ore is compoſed of 67.75 oxyd of ſilyer,
6.00 oxyd of iron,
21.00 mnriatic acid,
.25 ſulphuric acid,
1.75 alumina.

96.75¶

‡ *Phil. Tranſ.* 1776.
¶ *Beiträge* i. 134.

The alumina can only be conſidered as mixed with the ore. Sometimes its quantity amounts to .67 of the whole§.

§ *Ibid.* p. 137.

ORDER III. ORES OF PLATINUM (Y).

193 Mines.

HITHERTO no mine of platinum has been diſcovered. It is found in ſmall ſcales or grains on the ſands of the river Pinto, and near Carthagena in South America. It is always in a metallic ſtate, and always combined with iron.

GENUS I. ALLOYS OF PLATINUM.

194 G. I Alloy Native pl tinum.

SPECIES 1. Native platinum.

Its colour is whitiſh iron grey. Magnetic. Sp. gr. from 12 to 16. Soluble in nitro-muriatic and oxymuriatic acids.

ORDER IV. ORES OF MERCURY.

MERCURY is employed in medicine; it ſerves to ſeparate ſilver and gold from their ores; the ſilvering of looking glaſſes, gilding, &c. are performed by means of it; and its ſulphuret forms a beautiful paint.

195 Mines.

Mercury abounds in Europe, particularly in Spain, Germany, and Hungary: it is found alſo in China(Z), the Philippines*, and in Peru, and perhaps Chili (A) in South America. The moſt productive mines of mercury are thoſe of Idria†; of Almaden, near Cordova in Spain, which were wrought by the Romans (B); of the Palatinate‡; and of Guanca Velica in Peru(C).

Mercury has never been found in Britain, nor has any mine worth working been diſcovered in France It occurs moſt commonly in argillaceous ſhiſtus, limeſtones, and ſandſtones.

res of ercury.

SPECIES 2. Amalgam of ſilver *.

Native amalgam.

197 alalgam ilver.

This mineral has been found in the ſilver mine of Sahlberg †, in the province of Dalecarlia, in Sweden; in the mines of Deux Ponts ‡, in the Palatinate; and in other places. It is in thin plates, or grains, or cryſtallized in cubes, parallelopipeds, or pyramids.

Kirwan, i25. *onſtedt's n.* † *eyer. ll's An-* ‡ , 1790.

Its colour is ſilvery white or grey. Luſtre metallic. Creaks when cut. Sp. gr. above 10. Tinges gold white. Before the blow-pipe the mercury evaporates and leaves the ſilver.

A ſpecimen of this amalgam, analyſed by Klaproth, contained

64	mercury,
36	ſilver.
100 §	

itrâge, 53.

Sometimes it contains a mixture of alumina, and ſometimes the proportion of mercury is ſo great that the amalgam is nearly as ſoft as paſte.

198 II. Sulirets. mmon hurer.

GENUS II. SULPHURETS OF MERCURY.

SPECIES 1. Common ſulphuret *.

Native cinnabar.

Kirwan, 228.

This ore, which is found in almoſt all mercurial mines, is ſometimes in veins, ſometimes diſſeminated, ſometimes in grains, and ſometimes cryſtallized. The form of its cryſtals is a tetrahedron or three-ſided pyramid, moſt commonly wanting the ſummit; ſometimes two of theſe pyramids are joined baſe to baſe; and ſometimes there is a three-ſided priſm interpoſed between them †.

Romé de e, iii. 4.

Its colour is red. Its ſtreak red and metallic. Luſtre when cryſtallized 2 to 3; when amorphous, often 0. Tranſparency, when cryſtallized, from 1 to 3; when amorphous, often 0. Texture generally foliated. Hardneſs from 3 to 8. Sp. gr. from 5.419 to 10.1285.

Before the blow-pipe evaporates with a blue flame and ſulphureous ſmell. Inſoluble in nitric acid ‡.

Variety 1. Dark red.

Hauy, ir. de in. N° *xi.* p. 8. *Briſſon. Muſchenek.* *Briſſon. Gellert.*

Colour cochineal red. Hardneſs 6 to 7. Sp. gr. when pure, 10.1285 §; ſometimes only 7.2, or even 6.188 ¶.

Variety 2. Bright red.

Colour commonly ſcarlet. Sp. gr. 6.9022 † to 5.419 ‡.

199 . III. yds. patic ercurial .

GENUS III. OXYDS OF MERCURY.

SPECIES 1. Hepatic mercurial ore *.

This ore, which is the moſt common in the mines of Idria, is always amorphous, and is often mixed with native mercury and cinnabar.

Kirwan, 224. *Briſſon.* *Kirwan.*

Its colour is ſomewhat red. Its ſtreak dark red and brighter. Luſtre commonly metallic. Hardneſs from 6 to 8. Sp. gr. from 9.2301 † to 7.186 ‡. When heated the mercury evaporates.

age, ir. de yſ. xxiv. *copoli, ir. de in.* N° *vi.* p. *irwan,* 126.

Though this ore has never been accurately analyſed, chemiſts have concluded that the mercury which it contains is in the ſtate of a red oxyd, becauſe it is inſoluble in nitric and ſoluble in muriatic acid ¶. When pureſt, it contains about .77 of mercury §. It contains alſo ſome ſulphur and iron.

Werner has divided this ſpecies into two varieties, the *compact* and the *ſlaty*. The ſecond is often nothing more than bituminous ſhale impregnated with oxyd of mercury ‡.

200 Mercurial Salts Muriat of mercury.

GENUS IV. MERCURIAL SALTS.

SPECIES 1. Muriat of mercury *.

Corneous mercury.

This ore, which occurs in the Palatinate, is ſometimes in ſcales, ſometimes in grains, and ſometimes cryſtallized. Its cryſtals are either ſmall four or ſix ſided priſms whoſe ſides are rhombs †, or cubes, or four-ſided pyramids wanting their angles. They are always very ſmall and generally confuſed.

* *Kirwan,* ii. 226.
† *Romé de Liſle,* iii. 161.

Its colours are various; but it is moſt frequently white. Its luſtre, when white, is pearly. Sometimes opaque, and ſometimes ſemitranſparent. Evaporates before the blow-pipe.

Mr Woulfe diſcovered, that this ore generally contains ſome ſulphuric acid ‡. Specimens have been found in which the quantity of ſulphuric acid exceeds that of the muriatic §.

‡ *Phil. Tranſ.* lxvi. 618.
§ *Suckow.*

ORDER V. COPPER ORES.

Many of the moſt uſeful utenſils are formed of copper: it enters largely into the compoſition of braſs, bronze, and bell metal; not to mention the dyes and paints of which it is the baſis.

201 Mines.

Copper mines abound in moſt countries. They are wrought in China, Japan, Sumatra; the north of Africa; in Chili and Mexico; and in moſt parts of Europe; eſpecially Britain, Germany, Ruſſia, Hungary.

Copper is found moſt commonly in rocks of hornblende, ſhiſtus, and quartz.

202 G. I. Alloys. Native copper.

GENUS I. ALLOYS OF COPPER.

SPECIES 1. Native copper *.

Native copper occurs now and then in the greater number of copper mines: Sometimes it is in maſſes, ſometimes in plates and threads, which aſſume a variety of forms; and ſometimes, as in Siberia, it is cryſtallized in cubes, or other forms nearly reſembling cubes †.

Colour commonly that of copper, but ſometimes dark brown. Luſtre metallic. Streak brighter. Fracture hackly. Flexible and malleable. Hardneſs 6 to 7. Sp. gr. from 7.6 ‡ to 8.5844 ¶.

* *Kirwan,* ii. 127.—*Cartheuſer.*
† *Hauy, Jour. de Min.* N° xxxi. 509.
‡ *Kirwan's Min.* ii. 128.
¶ *Hauy, ibid.* p. 509.

203 White copper ore

SPECIES 2. White copper ore §.

Alloy of copper, iron, and arſenic.

This ore, which is ſaid to be uncommon, occurs in maſſes. Colour white. Luſtre metallic. Fracture uneven. Hardneſs 8 to 9. Brittle. Sp. gr. conſiderable.

Before the blow-pipe gives out a white arſenical ſmoke, and melts into a greyiſh black ſlag *.

§ *Kir. Min.* ii. 152.
* *Widenman.*

204 G. II. Sulphurets. copper. Common ſulphuret of copper.

GENUS II. SULPHURETS OF COPPER.

SPECIES 1. Common ſulphuret of copper †.

Vitreous copper ore.

This ore, which is found in Cornwal, Hungary, and Siberia, occurs in maſſes, plates, threads, and cryſtallized in ſix-ſided priſms, or four ſided pyramids, joined baſe to baſe.

Colour bluiſh grey. Streak brighter grey, Luſtre metallic. Hardneſs 4 to 7. Sp. gr. 5.452 ‡ to 5.565 §; ſometimes ſo low as 4.129 *. Detonates with nitre.

Before the blow-pipe it melts eaſily; and while in fuſion exhibits a green pearl, which, on cooling, is covered with a brown cruſt. Tinges borax green.

Werner makes two varieties of this ore: the firſt he

† *Kirwan,* ii. 144.
‡ *Kirwan.*
§ *Gellert.*
* *Kirwan.*

calls *compact*, from its fracture; and the ſecond, for the ſame reaſon, he calls *foliated*. This laſt is ſomewhat darker coloured than the firſt, but in other reſpects they agree.

205
Copper pyrites

SPECIES 2. Copper pyrites*.

Yellow copper ore.

This ore, which is probably nothing elſe than ſulphuret of iron combined with copper, and which, therefore, would be more properly placed among iron ores, is found frequently in copper mines, and mixed with common pyrites or ſulphuret of iron. It is ſometimes amorphous, and ſometimes cryſtallized. Its cryſtals are either three or four ſided pyramids applied baſe to baſe, or ſix-ſided plates.

Its colour is yellow; often tarniſhed. Its internal luſtre metallic. Hardneſs 6 to 7; ſometimes 9. Brittle. Sp. gr. 4.314 † to 4.08 ‡. Deflagrates; but does not detonate with nitre ‖.

Before the blow-pipe decrepitates, gives a greeniſh ſulphureous ſmoke, and melts into a black maſs, which tinges borax green. Does not efferveſce with nitric acid.

* *Kirwan*, ii. 140.

† *Briſſon.*

‡ *Kirwan*

‖ *Id. Min.* ii. 141.

206
Purple copper ore.

SPECIES 3. Purple copper ore*.

This ore is found in maſſes, or plates, or diſſeminated; ſometimes, alſo, it is cryſtallized in octohedrons. Colour various, but moſt commonly purple; internally reddiſh. Streak reddiſh and bright. Luſtre metallic. Hardneſs 6 to 7. Brittle. Sp. gr. 4.956 to 4.983†.

Efferveſces with nitric acid, and tinges it green. Deflagrates with nitre. Before the blow-pipe melts readily, without ſmoke, vapour, or ſmell; but is not reduced. Tinges borax a bright green.

A ſpecimen of this ore, analyſed by Klaproth, contained

58 copper,
18 iron,
19 ſulphur,
5 oxygen.

100 ‡

* *Kirwan*, ii. 142.

† *Ibid.* ii. 143.

‡ *Beiträge*, ii. 286.

207
Grey copper ore.

SPECIES 4. Grey copper ore §.

This ore is found in Cornwal, Saxony, Hungary, &c. It is often amorphous, but often alſo cryſtallized. The primitive form of its cryſtals is the regular tetrahedron; but, in general, either the angles or the edges, or both, are truncated or bevelled ‖.

Colour ſteel grey; often tarniſhed, and then dark grey. Streak dark grey; ſometimes reddiſh brown. Powder blackiſh; ſometimes with a tint of red. Luſtre metallic Hardneſs 7 or 8. Very brittle. Sp. gr. 4.8648 *. Deflagrates with nitre. Before the blow-pipe crackles, but at laſt melts, eſpecially if aſſiſted by borax. The bead gives a white ſmoke, without any particular ſmell; tinges borax yellow or browniſh red, but does not unite with it.

A ſpecimen of this ore from Cremnitz, analyſed by Klaproth, contained

31 copper,
14 ſilver,
34 antimony,
3 iron,
11 ſulphur.

93

§ *Kirwan*, ii. 146.

‖ *Romé de Liſle*, iii. 315.

* *Hauy, Jour. de Min.* Nº xxxi. 512.

Napion, in an ore from the valley of Lanzo, found copper, ſilver, and antimony, nearly in the ſame proportions, but more iron, and ſome arſenic †. Savoreſi, as Baron Born informs us, beſides the ingredients of Klaproth's analyſis, found ſome gold and mercury in grey copper ore ‡: and Klaproth himſelf found lead in moſt of the other ſpecimens which he examined.

† *Mem. Turin*, v. 173.

‡ *Catal.* ii. 498.

208
G. III. Oxyds. Red oxyd of copper.

GENUS III. OXYDS OF COPPER.

SPECIES 1. Red oxyd of copper §.

Florid red copper ore—Red copper glaſs.

This ore is found in Cornwal, and many other countries. It occurs in maſſes, diſſeminated, in ſcales, and cryſtallized. The figure of its cryſtals is moſt commonly the regular octohedron *.

Colour commonly cochineal red. Streak brick red. Luſtre ſemimetallic. Tranſparency, when amorphous, generally 0; when cryſtallized, 3 or 4. Hardneſs from 4 to 7. Soluble with efferveſcence in nitric acid. Before the blow-pipe melts eaſily, and is reduced.

This ore was ſuppoſed to be compoſed of carbonic acid and red oxyd of copper; but a ſpecimen, examined by Vauquelin, which conſiſted of pure cryſtals, contained no acid †. It muſt therefore be conſidered as an oxyd of copper.

Werner has made three varieties of this ore, which, from their texture, he has denominated *compact*, *foliated*, and *fibrous*. The firſt is ſeldom or never found cryſtallized, and is opaque; the ſecond occurs amorphous, cryſtallized, and in ſcales; the third is carmine, ruby, or ſcarlet red; and occurs always in ſhort capillary cryſtals, or delicate flakes.

This ore ſometimes contains a mixture of red oxyd of iron; it is then called *brick red, copper ore*, *copper malm, or copper ochre.*

This ore is ſometimes mixed with bitumen. Its colour is then browniſh black, and it is called *pitch ore.*

§ *Kirwan*, ii. 135.

* *Hauy, Jour. de Min.* Nº xxxi. 517.

† *Ibid.*

209
Green oxy of copper.

SPECIES 3. Green oxyd of copper §.

Green ſand of Peru.

This ore, which was brought from Peru by Dombey, is a graſs green powder, mixed with grains of quartz. When thrown on burning coals, it communicates a green colour to the flame. It is ſoluble both in nitric and muriatic acids without efferveſcence. The ſolution is green. It was ſuppoſed to contain muriatic acid *; but Vauquelin has diſcovered, that the appearance of this acid was owing to the preſence of ſome common ſalt, which is accidentally mixed with the ſand ‡.

§ *Kirwan*, ii. 149.

* *Bertbollet Mem. Par.* 1786, 462.

‡ *Jour de Min.* Nº xxxi. 519.

210
G. IV. Salts Blue carbonat of copper.

GENUS IV. SALTS OF COPPER.

SPECIES 1. Blue carbonat of copper (D).

Mountain blue—Azur de cuivre—Blue calx of copper—Kupfer lazur.

This ore, which occurs in the copper mines of Siberia, Sweden, Germany, Hungary, Cornwal, &c. is either amorphous or cryſtallized. The cryſtals are ſmall, and difficult to examine. According to Romé de Liſle, their primitive form is an octohedron, the ſides of which are iſoſceles triangles, and two of them more inclined than the others §. Be that as it may, the cryſtals of blue carbonat of copper are often rhomboidal priſms, either regular, or terminated by dihedral ſummits *.

Its colour is azure or ſmalt blue. Streak blue. Hardneſs

§ *Cryſtal.* iii 343

* *Ibid.* p. 345.

pper
res.

ſon.

neſs 4 to 6. Brittle. Sp. gr. 3.608 ‡. It effervesces with nitric acid, and gives it a blue colour. Before the blow-pipe it blackens, but does not melt. Tinges borax green with effervescences.

The cryſtals, according to Pelletier, are compoſed of

66 to 70 copper,
18 — 20 carbonic acid,
8 — 10 oxygen,
2 — 2 water.

Fontana firſt diſcovered that this ore contained carbonic acid gas.

Variety 1. Earthy blue carbonat.
Mountain blue.

This variety generally contains a mixture of lime. It is never cryſtallized; and ſometimes is almoſt in the ſtate of powder. Luſtre 0. Texture earthy.

Variety 2. Striated blue carbonat of copper.

Luſtre glaſſy. Tranſparency, when cryſtallized, 2; when amorphous, 1. Texture ſtriated; ſometimes approaching to the foliated.

1
car-
of
r.

SPECIES 2. Green carbonat of copper (E).
Oxygenated carbonat of copper—Malachite.

This ore is generally amorphous, but ſometimes it is cryſtallized in four-ſided priſms, terminated by four-ſided pyramids.

ſon.
wan.

Colour green. Luſtre ſilky. Hardneſs 5 to 7. Brittle. Sp. gr. 3.571 * to 3.653 ‡. Effervesces with nitric acid, and gives a blue colour to ammonia. Before the blow pipe it decrepitates and blackens, but does not melt. Tinges borax yellowiſh green. It is compoſed of carbonic acid and green oxyd of iron.

Variety 1. Fibrous malachite.

Texture fibrous. Opaque when amorphous; when cryſtallized its tranſparency is 2. Colour generally graſs green.

Variety 2. Compact malachite.

Texture compact. Opaque. Colour varies from the dark emerald green to blackiſh green.

A ſpecimen of malachite from Siberia, analyſed by Klaproth, contained

58.0 copper,
18.0 carbonic acid,
12 5 oxygen,
11.5 water.

---

100 *

räge,
).

This ſpecies is ſometimes mixed with clay, chalk, and gypſum, in various proportions; it is then known by the name of

Common mountain green.

Its colour is verdigris green. Luſtre 0. Tranſparency 0 to 1. Hardneſs 3 to 4. Brittle. Texture earthy. Effervesces feebly with acids. Before the blow-pipe it exhibits the ſame phenomena with malachite.

2
it of

SPECIES 3. Sulphat of copper.

For a deſcription of this ſalt, ſee CHEMISTRY, n° 648. in this *Supplement*.

3
at of

van,

SPECIES 4. Arſeniat of copper ‡.
Olive copper ore.

This ore is found at Carrarach in Cornwal. It is generally cryſtallized in ſix-ſided compreſſed priſms. Its colour is olive green. Streak ſometimes ſtraw coloured, ſometimes olive green. Luſtre glaſſy. Tranſparency from 4 to 2. Fracture conchoidal. Hardneſs 4 to 7. Before the blow-pipe deflagrates with an arſenical ſmoke, and melts into a grey coloured bead. This bead, fuſed with borax, leaves a button of pure copper ‖.

Metallic
Ores.

Klaproth diſcovered that it was compoſed of oxyd of copper and arſenic acid.

Sometimes this ore is combined with iron. It then cryſtallizes in cubes. Theſe cubes are of a dark green colour; before the blow-pipe they frothe, give out an arſenical ſmoke, and do not ſo quickly form a grey bead as the arſeniat of copper *.

‖ *Klaproth's Obſervations on Cornwal*, p. 29.

* *Ibid.* p. 29.

ORDER VI. IRON ORES.

To deſcribe the uſes of iron, would be to write the hiſtory of every art and manufacture, ſince there is not one which is not more or leſs dependent upon this uſeful metal. Nor is its abundance inferior to its utility. It exiſts almoſt everywhere, and ſeems, as it were, the bond which connects the mineral kingdom together.

214
Mines.

215
G. I. Alloys.
Native
iron.

GENUS I. ALLOYS OF IRON
SPECIES 1. Native iron (F).

Native iron has been found in Siberia and in Peru in immenſe maſſes, which ſeemed as if they had been fuſed. Theſe maſſes evidently did not originate in the place where they were found. See *FIRE-BALLS, Suppl.*

Colour bluiſh white Fracture hackly. Luſtre metallic. Malleable. Magnetic. Hardneſs 8 to 9. Sp. gr. 7.8. Prouſt has diſcovered, that the native iron found in Peru is alloyed with nickel ¶.

¶ *Nicholſon's Jour.* iii. 374.

216
G. III. Sulphurets.
Common
ſulphuret of
iron.

GENUS II. SULPHURETS OF IRON.
SPECIES 1. Common ſulphuret of iron *.
Pyrites.

This mineral occurs very frequently both in ores and mixed with other bodies, for inſtance in ſlates. It is often amorphous, and often alſo cryſtallized. The primitive form of its cryſtals is either a regular cube or an octohedron. The varieties of its form hitherto deſcribed amount to 30; for a deſcription of which we refer the reader to *Romé de Liſle* †.

* *Kirwan*, ii. 76.—*Henkel's Pyritologia.*

† *Cryſtal.* iii. 208.

Its colour is yellow. Its luſtre metallic. Hardneſs 8 to 10. Brittle. Sp. gr. 3.44 to 4.6. Soluble in nitric acid with effervescence. Scarce ſoluble in ſulphuric acid. Before the blow-pipe burns with a blue flame and a ſulphureous ſmell, and leaves a browniſh bead, which tinges borax of a ſmutty green.

Variety 1. Common pyrites.

Fracture uneven. Hardneſs 10. Decrepitates when heated. Emits a ſulphureous ſmell when rubbed. Not magnetic. It occurs often in coal mines and in ſlates.

Variety 2. Striated pyrites.

Texture ſtriated. Hardneſs 10. Not magnetic.

Variety 3. Capillary.

Colour often ſteel grey. Found in needle-form cryſtals. Uncommon. Not magnetic.

Variety 4. Magnetic pyrites.

Found in maſſes. Texture compact. Hardneſs 8, 9. Slightly magnetic. Seems to contain leſs ſulphur than the other varieties.

In pyrites the proportion of the ſulphur to the iron is variable, and this explains the variety of its cryſtalline forms.

218
G. IV.
Emery.

GENUS IV. IRON COMBINED WITH SILICA.

SPECIES I. Emery *.

* Kirwan, ii. 193.

This mineral is commonly diſſeminated through other foſſils, but ſometimes in the Eaſt Indies it occurs in large maſſes.

Its colour is bluiſh grey, greyiſh brown, or bluiſh black, often covered with a yellowiſh rind; internally it diſcovers red or purple ſpots. Luſtre 1 or 0; in ſome parts 2, and metallic. Opaque. Hardneſs 14. Brittle. Sp. gr. 3.92 †. Before the blow pipe it blackens and gives a ſmutty yellow tinge to borax.

† Briſſon.

According to Wieglеb it contains
95.6 ſilica,
4.3 iron.
——
99.9

219
G. V.
Oxyds.

GENUS V. OXYDS OF IRON.

This genus is very extenſive; for iron is much more frequently found in the ſtate of an oxyd than in any other.

220
Black oxyd of iron.

SPECIES I. Black oxyd of iron ‡.

Common magnetic iron ſtone—Blackiſh octohedral iron ore.

‡ Kirwan, ii. 158.

This ſpecies of ore is very common in Sweden; it is found alſo in Switzerland, Norway, Ruſſia, &c. It occurs in maſſes, plates, grains, and cryſtallized. The primitive form of its cryſtals is a regular octohedron †. Sometimes two oppoſite ſides of the pyramids are trapeziums, which renders the apex of the pyramids cuneiform. Sometimes the cryſtals paſs into rhomboidal parallelopipeds, and into dodecahedrons with rhomboidal faces §.

Its ſurface is browniſh black; internally bluiſh grey. Powder black *. Streak blackiſh grey, brighter. Luſtre metallic. Hardneſs 9 to 10. Brittle. Sp. gr. from 4.094 to 4.688 †. Attracted by the magnet, and generally poſſeſſed of more or leſs magnetic virtue ‡. To this ſpecies belongs the magnet. Before the blow-pipe it becomes browner, but does not melt. Tinges borax dark green.

† Romé de Liſle, iii. 178.
§ Ibid.
* Hauy, Jour. de Min, Nº xxxiii. 659.
† Kirwan's Min. ii. 159.
‡ Hauy, Jour. de Min. Nº xxxi. 527.

Metalli Ores.

When pure it conſiſts entirely of oxyd of iron; and this oxyd appears to contain from .15 to .24 oxygen, and from .76 to .85 iron §. Undoubtedly it conſiſts of a mixture of iron in two different ſtates of oxydation. It is often alſo mixed and contaminated with foreign ingredients.

§ Kirwa Min. ii. 159.

There are two varieties of this ore. The firſt is what we have juſt deſcribed; the ſecond is in the form of ſand, and has therefore been called

Magnetic ſand *.

This ſubſtance is found in Italy, Virginia, St Domingo, the Eaſt Indies, and in the ſand of the river Don at Aberdeen in Scotland. It is black, very hard, magnetic. Sp. gr. about 4.6. Not altered by the blow-pipe *per ſe*; melts into a black glaſs with potaſs, and into a green glaſs with microcoſmic ſalt, both opaque †. It probably contains ſome ſilica, as Kirwan has ſuppoſed ‡.

* Kirw ii.—Du get, Jou Min. N xxi. p. 7
† Fourcr Ann. de Chim. ii 127.
‡ Min. 161.

221
Specula iron ore

SPECIES 2. Specular iron ore ¶.

Fer oligiſte.

This ore is found abundantly in the iſle of Elba near Tuſcany. It is either in maſſes or cryſtallized. The primitive form of its cryſtals, and of its integrant molecules, is the cube *. The varieties hitherto obſerved amount to 7. Theſe are the rhomboidal parallelopiped; the cube, with three triangular faces inſtead of two of its angles diagonally oppoſite; two ſix ſided pyramids, applied baſe to baſe, wanting the ſummits ‡, and ſometimes the angles at the baſes, and ſometimes the alternate edges of the pyramid; a polyhedron of 24 ſides, reſembling a cube with three triangular faces for two angles diagonally oppoſite, and two triangles for the reſt of its angles. For a deſcription and figure of theſe varieties, we refer to *Romé de Liſle* † and *Hauy* ‡.

¶ Kirw 162.— drai, J de Phyſ 52.
* Hauy Jour. d Min. N xxxiii.
‡ Fig.
† Cryſt. 189.
‡ Ibid.

Colour ſteel grey; often tarniſhed, and beautifully irideſcent, reflecting yellow, blue, red. Streak red. Powder dark red. Luſtre metallic. Hardneſs 9 to 10. Not brittle. Sp. gr. 5.0116 † to 5.218 ‡. Slightly magnetic. Little altered by the blow-pipe. Tinges borax an obſcure yellow.

† Hauy
‡ Briſ

This ore, according to Mr Muſhet, is compoſed of
66.1 iron,
21.2 oxygen,
10.7 water and carbonic acid,
2.0 lime.
——
100.0 †

† Phil Mag. 354.

The quantity of oxygen here ſtated is probably too ſmall, owing to the unavoidable inaccuracy which reſults from the *dry way* of analyſis which Mr Muſhet followed.

Micaceous iron ore

Is generally conſidered as a variety of this ſpecies. Kirwan, however, ſuppoſes it to contain carbon, and to be a diſtinct ſpecies.

It is found in Saxony, and in the iſle of Elba, &c. generally in amorphous maſſes, compoſed of thin ſix-ſided laminæ. Colour iron grey. Streak bluiſh grey. Luſtre metallic. Opaque. Feel greaſy. Hardneſs 5 to 7. Brittle. Sp. gr. from 4.5 to 5.07. Slightly magnetic.

magnetic. Infuſible by the blow-pipe. Tinges borax greeniſh brown.

SPECIES 3. Laminated ſpecular iron ore.

Fer pyrocete of Hauy.

This ore, which is found at Montd'or in Auvergn, was uſually arranged under the laſt ſpecies; but has been ſeparated from it, we think properly, by Mr Hauy, becauſe the form of its cryſtals is incompatible with the ſuppoſition that their primitive nucleus is a cube, as we have ſeen is the caſe with common ſpecular iron ore. Its cryſtals are thin octagonal plates, bounded by ſix linear trapeziums, alternately inclined different ways†.

Colour ſteel grey. Powder reddiſh black. Luſtre metallic; ſurface poliſhed. Fracture glaſſy. Very brittle ‡. Hauy ſuppoſes that this ore has been produced by fire, and accordingly has given it a name which denotes its origin.

SPECIES 4. Brown iron ore ¶.

This ſpecies of ore is found abundantly in Britain, particularly in Cumberland and Lancaſhire; and it is alſo very common in other counties. It conſiſts of the brown oxyd of iron, more or leſs contaminated with other ingredients.

Its colour is brown. Its ſtreak reddiſh brown. Sp. gr. from 3.4771 to 3.951. Before the blow pipe blackens, but does not melt. Tinges borax greeniſh yellow.

Variety 1. Brown hæmatites.

The name hæmatites (bloodſtone) was probably applied by the ancients only to thoſe ores which are of a red colour, and have ſome reſemblance to clotted blood; but by the moderns it is applied to all the ores of iron which give a reddiſh coloured powder, provided they be of a fibrous texture.

Brown hæmatites occurs in maſſes of various ſhapes, and it is ſaid alſo to have been found cryſtallized in five or ſix ſided acute angled pyramids. Colour of the ſurface brown or black, ſometimes irideſcent; internally nut brown. Powder red. Texture fibrous. Hardneſs 8 to 10. Brittle. Sp. gr. 3.789† to 3.951‡. Not magnetic.

This variety has not been analyſed, but it ſeems to conſiſt of brown oxyd of iron, oxyd of mangancſe, and alumina ¶.

Variety 2. Compact brown iron ſtone.

This variety occurs in maſſes of very various and often fantaſtical ſhapes.

Colour brown. Internal luſtre metallic. Texture compact. Hardneſs 6 to 9. Brittle. Sp. gr. 3.4771† to 3.551‡.

Variety 3. Brown Scaly iron ore.

This variety is generally incumbent on other minerals. Colour brown. Luſtre metallic. Stains the fingers, marks ſtrongly. Feels unctuous. Texture foliated. Hardneſs 3 to 5. Brittle. So light as often to float on water.

Variety 4. Brown iron ochre.

This variety occurs both maſſive and diſſeminated. Colour from nut brown to orange. Luſtre 0. Strongly ſtains the fingers. Texture earthy. Hardneſs 3 to 4. When ſlightly heated reddens.

SPECIES 5. Red iron ore†.

Colour red. Streak blood red. Sp. gr. from 3.423 to 5.005. Before the blow pipe blackens, but does not melt. Tinges borax yellowiſh olive green. When digeſted in ammonia, it becomes black and often magnetic.

Variety 1. Red hæmatites.

Found in maſſes, and all the variety of forms of ſtalactites. Colour between browniſh red and ſteel grey. Powder red. Internal luſtre metallic. Texture fibrous Hardneſs 9 to 10. Brittle. Sp. gr. 4.74† to 5.005‡.

When pure it conſiſts of red oxyd of iron, but it often contains mangancſe and alumina §.

Variety 2. Compact red iron ore.

Found maſſive and ſtalactitic; ſometimes in cryſtals of various forms, but they ſeem to be only ſecondary; ſometimes in columns like baſalt.

Colour between brown red and ſteel grey. Stains the fingers. Luſtre 1 to 0; often ſemimetallic. Texture compact. Hardneſs 7 to 9. Brittle. Sp. gr. 3.423 to 3.76† Sometimes inveſted with a roſy red ochre.

Variety 3. Red ochre.

Found ſometimes in powder, ſometimes indurated. Colour blood red. Stains the fingers. Luſtre 0. Texture earthy. Hardneſs 3 to 5. Brittle.

Variety 4. Red ſcaly iron ore.

This variety is generally found incumbent upon other iron ores. Colour between cherry red and ſteel grey. Stains the fingers. Luſtre ſilky, inclining to metallic. Texture foliated. Feels unctuous. Hardneſs 3 to 4. Brittle. Heavy.

SPECIES 6. Argillaceous iron ore †.

Oxyd of iron combined or mixed with clay.

This ore is exceedingly common; and though it contains leſs iron than the ſpecies already deſcribed, it is, in this country at leaſt, preferred to them, becauſe the method of extracting pure iron from it is eaſier, or rather becauſe it is better underſtood.

Colour moſt commonly dark brown. Streak red or yellowiſh brown. Sp gr. from 2.673 to 3.471‡. Before the blow-pipe blackens, and tinges borax olive green and blackiſh. It is compoſed of oxyd of iron, alumina, lime, ſilica in various proportions It generally yields from 30 to 40 *per cent.* of iron.

Variety 1. Common argillaceous iron ore.

The minerals arranged under this variety differ conſiderably from each other in their external characters. They are found in maſſes of various ſhapes, and often form large ſtrata.

Colour various ſhades of grey, brown, yellow, and red. Streak reddiſh yellow or dark red. Luſtre 0. Hardneſs from 3 to 8. Smell earthy when breathed upon.

Variety 2. Columnar or ſcapiform iron ore.

This variety is found in columns, adhering to each other, but eaſily ſeparable: They are commonly incurvated, and their ſurface is rough. Colour browniſh red. Streak dark red. Slightly ſtains the fingers. Luſtre 0. Adheres ſtrongly to the tongue. Sound hollow. Feel dry. Texture earthy.

Variety 3. Acinoſe iron ore.

This variety is found in maſſes, and is commonly lenticular. Colour generally browniſh red. Luſtre metallic, nearly. Texture granular. Hardneſs 5 to 9. Brittle.

† Kirwan.

215 Argillaceous iron ore.

† Kirw. ii. 173.

‡ Kirwan.

Variety 4. Nodular, or kidney-form iron ore.

Ætites or *Eagleſtone.*

This variety, which was mentioned by the ancients, is generally found under the form of a rounded knob, more or leſs reſembling a kidney, though ſometimes it is quadrangular; and it contains within it a kernel, which is ſometimes looſe, and ſometimes adheres to the outſide rind. Colour of the ſtone yellowiſh brown; of the kernel ochre yellow. Surface generally fouled with earth. Luſtre of the rind metallic; of the kernel 0. Hardneſs from 4 to 7. Brittle.

Variety 5. Piſiform or granular iron ore.

This variety occurs in rounded maſſes, from the ſize of a pea to that of a nut. Surface rough. Colour commonly dark brown. Streak yellowiſh brown. Hardneſs 5 to 6. Brittle.

The oolitic ore found at Creuſot, near mount Cenis, belongs to this variety. It is compoſed of

50 lime,
30 iron,
20 alumina.

100

226 Lowland iron ore. * Kirw. ii. 179.

SPECIES 7. Lowland iron ore *.

This ſpecies of ore is ſuppoſed to conſiſt of oxyd of iron, mixed with clay and phoſphuret or phoſphat of iron. It is called lowland ore, becauſe it is found only in low grounds; whereas the laſt ſpecies is more commonly in high grounds; and is therefore called *highland ore.*

This ore occurs in amorphous maſſes, and alſo in grains or powder. Its colour is brown. Streak yellowiſh brown. Luſtre 0, or common. Texture earthy. Hardneſs 3 to 5.

Variety 1. Meadow lowland ore.

Colour blackiſh or yellowiſh brown: Both colours often meet in the ſame ſpecimen. Found in lumps of various ſizes, often perforated. Fracture compact. Moderately heavy.

Frequently yields from 32 to 38 *per cent.* of iron.

Variety 2. Swampy iron ore.

This variety is generally found under water. It is in lumps, which are commonly perforated or corroded, and mixed with ſand. Colour dark yellowiſh brown, or dark nut brown. Hardneſs 3 to 4. Brittle. Sp. gr. 2.944. It often contains .36 of iron.

Variety 3. Moraſſy iron ore.

This variety is found either in a looſe form or in perforated lumps. Colour light yellowiſh brown. Stains the fingers. Hardneſs 3. Friable.

227 G.VI. Salts. Sparry iron ore.

GENUS VI. SALTS OF IRON.

SPECIES 1. Sparry iron ore (G).

This ore is common in Germany, France, and Spain. It is found ſometimes in amorphous maſſes, and ſometimes cryſtallized.

Its colour is white; but it becomes tarniſhed by expoſure to the air, and then aſſumes various colours. Streak grey or white. External luſtre often metallic; internal common or glaſſy. Tranſparency 1 or 2; ſometimes 0. Texture foliated. Fragments rhomboidal. Hardneſs 5 to 7. Brittle. Sp. gr. 3.6 to 3.810. Not magnetic. Soluble in acids with very little efferveſcence. Before the blow-pipe decrepitates, becomes browniſh black, and magnetic; but is ſcarcely fuſible. Tinges borax ſmutty yellow, with ſome efferveſcence.

This ore, as Bergman aſcertained, conſiſts of iron, manganeſe, lime, and carbonic acid.

One ſpecimen, according to his analyſis, contained

38 iron,
24 manganeſe,
38 carbonat of lime.

100

Another contained 22 iron,
28 manganeſe,
50 carbonat of lime.

100

Whether the iron be combined with the carbonic acid is ſtill a diſputed point. The cryſtals of this ore are rhomboidal parallelopipeds; which is preciſely the form of carbonat of lime. This amounts nearly to a demonſtration, that the carbonic acid is combined with the lime; and that, as Cronſtedt and Hauy have ſuppoſed, this ore is merely carbonat of lime, contaminated with a quantity of the oxyds of iron and manganeſe.

228 Arſenia iron.

SPECIES 2. Arſeniat of iron.

Mr Prouſt has diſcovered this ore in Spain. Its colour is greeniſh white. Its texture granular. Inſoluble in water and nitric acid. When melted on charcoal, the arſenical acid eſcapes with efferveſcence ‡.

‡ Ann. Chim. i. 195.

229 Sulphat iron.

SPECIES 3. Sulphat of iron.

For a deſcription of this ſalt, ſee CHEMISTRY, n° 631. in this *Suppl.*

ORDER VII. TIN ORES (H).

TIN is employed to cover plates of iron and copper, and to ſilver the backs of looking glaſſes: It enters into the compoſition of pewter; and forms a very important article in dyeing.

23 Mine

Tin ores are by no means ſo common as the ores of the metals which we have already deſcribed. They are found only in the *primitive mountains* (1). Hence Werner ſuppoſes them to be the moſt ancient of all metallic ores. They occur moſt frequently in granite, ſometimes in porphyry, but never in limeſtone.

Almoſt

(G) *Kirw.* II. 190.—*Bergman,* II. 184.—*Bayen. Jour. de Phyſ.* VII. 213.—*Razowmowſki, Mem. Lauſanne,* 1783, p. 149.

(H) *Geoffroy, Mem. Par.* 1738, p. 103.—*Morveau, Ann. de Chim.* XXIV. 127.

(1) Geologiſts have divided mountains into three claſſes; *primitive, ſecondary,* and *tertiary.* The *primitive* occupy the centre of all extenſive chains; they are the higheſt, the moſt rugged, and exhibit the moſt pointed tops. They are conſidered as the moſt ancient mountains of the globe.

The *ſecondary* mountains occupy the outſide of extenſive ranges. They are uſually compoſed of ſtrata, more or leſs inclined, and commonly reſt againſt the ſides of the primitive mountains.—The *tertiary* mountains are much ſmaller than the others, and are often ſolitary. We uſe the terms *primitive, ſecondary,* &c. merely as

proer

'in Ores.

Almoſt the only tin mines known to Europeans are thoſe of Cornwal, Devonſhire, Saxony, Bohemia, Sileſia, Hungary, Gallicia; thoſe of the iſland of Banca and the peninſula of Malacca in India; and thoſe of Chili and Mexico in America.

231
. I. Sul-
urets.
lphuret
tin and
pper.
Kirw. ii.
o.

Genus I. sulphurets of tin.

Species 1. Sulphuret of tin and copper *.

Tin pyrites.

Hitherto this ore has only been found in Cornwal. There is a vein of it in that county, in the pariſh of St Agnes, nine feet wide, and twenty yards beneath the ſurface †.

Its colour is yellowiſh grey, paſſing into the ſteel grey. Not unlike grey copper ore. Luſtre metallic. Hardneſs 5 to 6. Very brittle. Sp. gr. 4.35 ‡. Before the blow-pipe it melts eaſily, with a ſulphureous ſmell, into a black bead, and depoſits a bluiſh oxyd on the charcoal.

The compoſition of this ore, as Klaproth informs us, was firſt diſcovered by Mr Raſpe. According to Klaproth's analyſis, it is compoſed of

34 tin,
36 copper,
25 ſulphur,
3 iron,
2 earth.

100 §

232
. II. Ox-
ls. Brown
yd of tin.
Kirw. ii.
7.

Genus II. oxyds of tin.

Species 1. Brown oxyd of tin *.

Tinſtone—Woodtin.

This ore, which may be conſidered as almoſt the only ore of tin, occurs in maſſes, in rounded pieces, and cryſtallized. Theſe cryſtals are very irregular. Hauy ſuppoſes, that their primitive form is a cube †; but Romé de Liſle, with more probability, makes it an octohedron ‡; and in this opinion Mr Day agrees with him ‖. The octohedron is compoſed of two four-ſided pyramids, applied baſe to baſe. The ſides of the pyramids are iſoſceles triangles, the angle at the vertex of which is 70°, and each of the other angles 55°. The ſides of the two pyramids are inclined to each other at an angle of 90° §. This primitive form, however, never occurs, but cryſtals of tinſtone are ſometimes found, in which the two pyramids are ſeparated by a priſm. For a complete deſcription of the varieties of the cryſtals of tinſtone, we refer the reader to *Romé de Liſle* and *Mr Day* *.

Its colour is commonly brown. Streak grey. Hardneſs 9 to 10. Sp. gr. 6.9 to 7.0. Brittle.

Variety 1. Common tinſtone.

Colour dark brown; ſometimes yellowiſh grey, and ſometimes nearly white. Streak light grey. Somewhat tranſparent when cryſtallized. Hardneſs 10. Sp. gr. 6.9 to 6.97. Before the blow-pipe it decrepitates, and on charcoal is partly reduced. Tinges borax white.

According to Klaproth, it is compoſed of

77.50 tin,
21.50 oxygen,
.25 iron,
.75 ſilica.

100.00 †

Variety 2. Woodtin.

This variety has hitherto been found only in Cornwal. It occurs always in fragments, which are generally rounded. Colour brown; ſometimes inclining to yellow. Streak yellowiſh grey. Opaque. Texture fibrous. Hardneſs 9. Sp. gr. 7.0. Before the blow-pipe becomes browniſh red; decrepitates when red hot, but is not reduced.

Klaproth obtained from it .63 of tin; and, in all probability, it is an oxyd of tin nearly pure.

Order VIII. ORES OF LEAD.

The uſeful purpoſes to which lead in its metallic ſtate is applied, are too well known to require deſcription. Its oxyds are employed in painting, in dyeing, and ſometimes alſo in medicine.

Ores of lead occur in great abundance in almoſt every part of the world. They are generally in veins; ſometimes in ſiliceous rocks, ſometimes in calcareous rocks.

233
G. I. Sulphurets.
Galena, or pure ſulphuret of lead.

Genus I. sulphurets of lead.

Species 1. Galena, or pure ſulphuret of lead ‡.

This ore, which is very common, is found both in maſſes and cryſtallized. The primitive form of its cryſtals is a cube. The moſt common varieties are the cube, ſometimes with its angles wanting, and the octohedron, compoſed of two four-ſided pyramids applied baſe to baſe: The ſummits of theſe pyramids are ſometimes cuneiform, and ſometimes their ſolid angles are wanting ‖.

Its colour is commonly bluiſh grey, like lead. Streak bluiſh grey and metallic. Luſtre metallic. Sometimes ſtains

proper names, without affirming or denying the truth or falſehood of the theory on which theſe names are founded. That the reader may have a more accurate idea of the compoſition of theſe different claſſes of mountains, we have ſubjoined a liſt of the ſubſtances which, according to Werner, enter into the compoſition of each.

I. Primary Mountains.

1. Granite,
2. Gneiſs,
3. Micaceous ſhiſtus
4. Argillaceous ſhiſtus,
5. Syenite,
6. Porphyry,
7. Shiſtoſe porphyry,
8. Quartz,
9. Primitive limeſtone,
10. Serpentine,
11. Topaz rock.

II. Secondary Mountains.

1. Argillaceous ſhiſtus,
2. Rubble ſtone,
3. Secondary limeſtone,
4. Shiſtoſe hornblende,
5. Grunſtein,
6. Amygdaloid.

III. Tertiary Mountains.

1. Trap,
2. Argillaceous ſhiſtus,
3. Stratified limeſtone,
4. Sandſtone,
5. Breccia,
6. Coal,
7. Chalk,
8. Sulphat of lime,
9. Rock ſalt,
10. Ferruginous clay,
11. Potters earth.

ſtains the fingers. Texture foliated. Fragments cubical. Hardneſs 5 to 7; ſometimes even 9. Brittle. Sp. gr. 6.884 to 7.786 [§]. Effervesces with nitric and muriatic acids. Before the blow-pipe decrepitates, and melts with a ſulphureous ſmell; part ſinks into the charcoal.

§ *Watſon.*

It is compoſed of from .45 to .83 lead, and from .086 to .16 of ſulphur. It generally contains ſome ſilver, and ſometimes alſo antimony aud zinc.

Variety 1. Common galena.

This variety correſponds nearly with the above deſcription. Sp. gr. 7.051 to 7.786. Sometimes ſtains the fingers.

Compact galena.

Found only in amorphous maſſes. Texture compact, inclining to foliated. Hardneſs 6 to 8. Sp. gr. 6.886 to 7.444. Luſtre common. Streak lead grey, brighter and metallic. Often feels greaſy, and ſtains the fingers.

234
Sulphuret of lead, with ſilver and antimony
* *Kirw.* ii. 119.

SPECIES 2. Sulphuret of lead, with ſilver and antimony [*].

Plumliferous antimoniated ſilver ore.

Found in amorphous maſſes. Colour grey. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.2 to 8.

Variety 1. Light grey ſilver ore.

Colour light bluiſh grey. Streak light bluiſh grey, and brighter. Luſtre metallic. Texture compact. Before the blow pipe partly evaporates, and leaves a ſilver bead on the charcoal, ſurrounded by yellow duſt.

According to Klaproth, it contains

48.06 lead,
20.40 ſilver,
7.88 antimony,
12.35 ſulphur,
2.25 iron,
7.00 alumina,
.25 ſilica.

98.09 [†]

† *Beiträge,* i. 172.

Variety 2. Dark grey ſilver ore.

Colour iron grey, verging on black. Powder black, and ſtains the fingers. Luſtre 0. Texture earthy.

According to Klaproth, it contains

41.00 lead,
21.50 antimony,
29.25 ſilver,
22.00 ſulphur,
1 75 iron,
1.00 alumina,
.75 ſilica.

97.25 [‡]

* *Ibid.* 175.

235
Blue lead ore.
* *Kirw.* ii. 220.

SPECIES 3. Blue lead ore [*].

This ore, which is found in Siberia, Germany, and Hungary, and is very rare, occurs ſometimes in maſſes, and ſometimes cryſtallized in ſix-ſided priſms.

Colour between indigo blue and lead grey; ſometimes inclining to black. Internal luſtre metallic. Streak brighter. Texture compact. Hardneſs 6. Sp. gr. 5.461 [†]. Before the blow pipe melts with a low blue flame and a ſulphureous ſmell, and is eaſily reduced.

† *Gellert.*

236
Black lead ore.
‡ *Kirw.* ii. 221.

SPECIES 4. Black lead ore [‡].

This ore, which is found in Germany and Brittanny, and which is ſuppoſed to be common galena decayed, is ſometimes in ſtalactites of various forms, and ſometimes cryſtallized in ſix-ſided priſms, which are generally truncated and confuſed.

Colour black, often with ſome ſtreaks of red. Streak light bluiſh grey. Internal luſtre metallic. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.744 [||] to 5.77 [*]. Before the blow-pipe decrepitates, melts eaſily, and is reduced.

|| *Briſſon.*
* *Gellert.*

According to the experiments of Laumont, this ore is a ſulphuret of lead (or rather ſulphuret of oxyd of lead), mixed with ſome phoſphat of lead.

237
Sulphuret of lead, biſmuth, and ſilver.

SPECIES 5. Sulphuret of lead, biſmuth, and ſilver.

This ore, which occurs in the valley of Schapbach in Saxony, was firſt taken notice of by Selb, and afterwards deſcribed by Weidenmann and Emerling.

Its colour is light bluiſh grey. Its luſtre metallic. Its fracture uneven. Hardneſs 5. Melts eaſily before the blow pipe, emitting ſome ſmoke, and leaves a ſilver bead.

A ſpecimen, analyſed by Mr Klaproth, contained

33.0 lead,
27.0 biſmuth,
15.0 ſilver,
16.3 ſulphur,
4.3 iron,
0.9 copper.

96.5 [†]

† *Beiträge,* ii. 297.

238
G. II. Oxyds. Lead ochre.
‡ *Kirw.* ii. 205.

GENUS II. OXYDS OF LEAD.

SPECIES 1. Lead ochre [‡].

This ore, which is a mixture of the oxyd of lead with various earths, is found maſſive, and of various degrees of hardneſs.

Its colour is either yellow, grey, or red. Luſtre 0. Tranſparency 0 to 1. Hardneſs 6 to 8; ſometimes in powder. Sp. gr. from 4.165 to 5.545 [§]. Texture compact. Effervesces with nitric and muriatic acids. Eaſily reduced by the blow-pipe, leaving a black ſlag, unleſs the lead be mixed with too great a proportion of earth.

§ *Kirwan.*

239
G. III. Salts. Carbonat of lead.
‡ *Kirw.* ii. 203.

GENUS III. SALTS OF LEAD.

SPECIES 1. Carbonat of lead [‡].

White lead ſpar.

This ore of lead, which is very common, is ſometimes in maſſes, and ſometimes cryſtallized. But the cryſtallization is in general ſo confuſed, that the primitive form of the cryſtals has not yet been aſcertained (K).

Its colour is white. External luſtre, waxy or ſilky, from 3 to 1; internal 1 to 2. Generally ſomewhat tranſparent. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.349 [||] to 6.92 [§]. Effervesces with nitric and muriatic acids when they are heated. Soluble in fat oils. Blackened by ſulphuret of ammonia [*]. Decrepitates when heated. Before the blow-pipe, in a ſilver ſpoon, it becomes red by the yellow cone of the flame, while the blue cone renders it yellow [†]. On charcoal it is immediately reduced.

|| *Kirwan.*
§ *Gellert.*
* *Pelletier Ann. de Chim.* ix. 56.
† *Ribbentropp, Ann. de Chim.* xxv. 159.

It contains from .60 to .85 of lead, and from .18 to .24 of carbonic acid. It is generally contaminated with carbonat of lime and oxyd of iron.

hoſphat
lead.
Kirw. ii.
07.

SPECIES 2. Phoſphat of lead †.

This ore, which is found in Siberia, Scotland, England, Germany, Carinthia, Brittany. &c. is ſometimes amorphous, and ſometimes cryſtallized. The primitive form of its cryſtals, according to Romé de Liſle, is a dodecahedron, conſiſting of a ſix-ſided rectangular priſm, terminated by ſix ſided pyramids, the ſides of which are iſoſceles triangles (L). Sometimes the pyramids are truncated, and even altogether wanting. The cryſtals of this ore are often acicular.

Its colour is commonly green; ſometimes yellowiſh or browniſh, or greyiſh white. Streak commonly greeniſh white. Powder yellowiſh. External luſtre, waxy, 2 to 3. Somewhat tranſparent, except when its colour is greyiſh white. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.86 * to 6.27 †. Inſoluble in water and ſulphuric acid, and nearly inſoluble in nitric acid; ſoluble in hot muriatic acid, with a ſlight effervefcence ‡. Before the blow-pipe it eaſily melts on charcoal, and cryſtallizes on cooling: with ſoda the lead is in ſome meaſure reduced.

oxyd might be employed with advantage as a white paint.

Ores of zinc are very abundant; they generally accompany lead ores, particularly galena. Calamine, or oxyd of zinc, has never been diſcovered in the primitive mountains.

245
G. I. Sulphurets. Common ſulphuret of zinc.

Genus I. SULPHURETS OF ZINC.

SPECIES I. Common ſulphuret of zinc*.

Blende.

This ore very commonly accompanies ſulphuret of lead. It occurs both in amorphous maſſes and cryſtallized. The primitive form of its cryſtals is a rhomboidal dodecahedron, conſiſting of a ſix-ſided priſm, terminated by three-ſided pyramids. All the faces of the cryſtals are equal rhombs. This dodecahedron may be mechanically divided into four equal rhomboidal parallelopipeds, and each of theſe into ſix tetrahedrons, whoſe faces are equal iſoſceles triangles. The figure of its integrant particles is the tetrahedron, ſimilar to theſe *.

* Kirw. ii 238.—Berg. ii. 329.

* Hauy, Jour. de Min. N° xxxiii. 669.

The principal varieties of its cryſtals are the tetrahedron; the octohedron; the octohedron with its edges wanting*; a 24-ſided cryſtal, 12 of whoſe faces are trapezoids, and 12 elongated triangles†; and, laſtly, a 28-ſided figure, which is the laſt variety, augmented by four equilateral triangles †.

* Fig. 40.

† Fig. 41.

† See Hauy, ibid and Romé de Liſle, iii. 65.

Colour yellow, brown, or black. Streak reddiſh, browniſh, or grey. Luſtre commonly metallic. Generally ſomewhat tranſparent. Texture foliated. Hardneſs 6 to 8. Sp. gr. 3.93‡ to 4.1665¶. Before the blow-pipe decrepitates, and gives out white flowers of zinc, but does not melt. Borax does not affect it. When breathed upon, loſes its luſtre, and recovers it very ſlowly‖.

‡ Gellert.

¶ Briſſon.

‖ Hauy, Jour de Min. ibid.

Variety 1. Yellow blende.

Colour commonly ſulphur yellow, often paſſing into olive green or browniſh red. Powder pale yellow. Streak yellowiſh or reddiſh grey, not metallic. Luſtre metallic. Tranſparency 2 to 4. Often phoſphoreſces when ſcraped or rubbed*.

* Bergman, ii. 345.

According to Bergman, it is compoſed of
64 zinc,
20 ſulphur,
5 iron,
4 fluor acid,
1 ſilica,
6 water.

100†

† Ibid. 347.

Variety 2. Brown blende.

Colour different ſhades of brown. Surface often tarniſhed. Powder browniſh grey. Streak reddiſh or yellowiſh grey, not metallic. Luſtre commonly metallic. Tranſparency 0 to 2.

A ſpecimen of this variety, analyſed by Bergman, contained
44 zinc,
17 ſulphur,
24 ſilica,
5 iron,
5 alumina,
5 water.

100‡

‡ Ibid. 333.

Variety 3. Black blende.

Colour black, or browniſh black; ſurface often tarniſhed blue; tips of the cryſtals often blood red. Powder browniſh black. Streak reddiſh, browniſh, or grey. Luſtre common or metallic. Tranſparency 0 to 1; the red parts 2. Hardneſs 8.

A ſpecimen of this variety, analyſed by Bergman, contained
52 zinc,
26 ſulphur,
4 copper,
8 iron,
6 ſilica,
4 water.

100‡

‡ Bergman, ii. 335.

246
G. II. Oxyds. White oxyd of zinc.

Genus II. OXYDS OF ZINC.

SPECIES I. White oxyd of zinc†.

Calamine.

This ore is either found looſe, or in maſſes, or cryſtallized. The primitive form of its cryſtals appears, from the mechanical diviſion of one of them by Mr Hauy, to be an octohedron compoſed of two four-ſided pyramids, whoſe ſides are equilateral triangles †. But the cryſtals are minute, and their figure not very diſtinct. They are either four or ſix ſided tables with bevelled edges, ſix-ſided priſms, or three-ſided pyramids.

† Kirw. ii. 233—Berg. ii. 321.

† Jour. de Min. N° xxxii. 596.

Colour commonly white, grey, or yellow. Luſtre often 0, ſometimes 2 or 1. Opaque. The cryſtals are ſomewhat tranſparent. Hardneſs from 4 to 9, ſometimes in powder. Sp. gr. from 2.585 to 3.674‡. When heated, becomes electric, without friction, like the tourmaline†. Not blackened by ſulphuret of ammonia. Soluble in ſulphuric acid. Before the blow-pipe decrepitates, and does not melt.

‡ Kirwan.

† Hauy, Jour. de Min. ibid.

This ore conſiſts of oxyd of zinc more or leſs contaminated with iron, ſilica, lime, and other foreign ingredients. In one ſpecimen Bergman found the following ingredients:
84 oxyd of zinc,
3 oxyd of iron,
12 ſilica,
1 alumina.

100 ¶

¶ Bergman, ii. 323.

In another ſpecimen, which gelatinized with acids, like zeolite, Klaproth found
66 oxyd of zinc,
33 ſilica.

99

In another ſpecimen, analyſed by Pelletier, the contents were
52 ſilica,
36 oxyd of zinc.
12 water.

100 *

* Jour. de Phyſ. xl. 428.

Mr Kirwan has divided this ſpecies into three varieties.

Variety 1. Friable calamine.

In maſſes which eaſily crumble between the fingers. Luſtre 0. Opaque. Texture earthy. When its colour is white, it is pure oxyd of zinc; when yellow, it is mixed with oxyd of iron. The white often becomes yellow when placed in a red heat, but reſumes its colour on cooling. Common in China, where it is called *wohan* or *ore of Tutenago*.

Variety 2. Compact calamine.

Colour different ſhades of grey; ſometimes yellow or browniſh red. Luſtre 0. Opaque. Texture compact.

Variety 3. Striated calamine.

This variety alone is found cryſtallized; but, like the others, it is alſo often amorphous. Colour white, and alſo various ſhades of grey, yellow, and red. Somewhat tranſparent. Texture ſtriated. Luſtre 2 to 1.

GENUS III. SALTS OF ZINC.

SPECIES 1. Sulphat of zinc.

For a deſcription of this ſalt, we refer to CHEMISTRY, n° 643. *Suppl.*

ORDER X. ORES OF ANTIMONY.

ANTIMONY is much uſed to give hardneſs to thoſe metals which otherwiſe would be too ſoft for certain purpoſes: printers types, for inſtance, are compoſed of lead and antimony. It is uſed alſo in medicine.

Ores of antimony are found abundantly in Germany, Hungary, France, Spain, Britain, Sweden, Norway, &c. They often accompany galena and hæmatites. They are found both in the ſecondary and primitive ſtratified mountains. Their gangue (o) is often quartz and ſulphat of barytes.

GENUS I. ALLOYS OF ANTIMONY.

SPECIES 1. Native antimony [*].

This mineral, which was firſt diſcovered by Dr Swab, has been found in Sweden and in France, both in maſſes and kidney-ſhaped lumps. Colour white, between that of tin and ſilver. Luſtre metallic. Texture foliated. Hardneſs 6. Sp. gr. above 6. Deflagrates with nitre. Before the blow-pipe melts and evaporates, depoſiting a white oxyd of antimony.

It conſiſts of antimony, alloyed with 3 or 4 *per cent.* of arſenic.

GENUS II. SULPHURETS OF ANTIMONY.

SPECIES 1. Grey ore of antimony [*].

This ore, which is the moſt common, and indeed almoſt the only ore of antimony, occurs both maſſive, diſſeminated, and cryſtallized. Its cryſtals are four-ſided priſms, ſomewhat flattened, whoſe ſides are nearly rectangles, terminated by ſhort four-ſided pyramids, whoſe ſides are trapeziums [†]. Sometimes two of the edges are wanting, which renders the priſm ſix-ſided [‡].

Colour grey. Luſtre metallic. Streak grey, metallic, and brighter. Powder black or greyiſh black. Hardneſs 6 to 7. Sp. gr. from 4.1327 to 4.516 [¶]. Often ſtains the fingers. Before the blow-pipe melts eaſily, burns with a blue flame, and depoſits a white oxyd on the charcoal. When placed in an open veſſel, over a ſlow fire, the ſulphur evaporates, and leaves a grey oxyd of antimony. This oxyd, if fuſed with tartar, is reduced.

This ore, when taken out of the mine, almoſt always contains a large proportion of quartz or other ſtony matter. When pure, it is compoſed of about

74	antimony,
26	ſulphur.
100	

Werner has divided this ſpecies into three varieties.

Variety 1. Compact ſulphuret.

Colour bluiſh grey, ſurface often tarniſhed, and then it is blue or purpliſh. Luſtre 1 to 2. Texture compact. Fracture fine grained, uneven. Powder black, dull, and earthy. Slightly ſtains the fingers.

Variety 2. Foliated ſulphuret.

Colour light ſteel grey. Luſtre 3 to 4. Texture foliated. Powder as that of the laſt variety.

Variety 3. Striated ſulphuret.

Colour dark ſteel grey, and light bluiſh grey; ſurface often tarniſhed, and then it is dark blue or purpliſh. Luſtre 3 to 2. Texture ſtriated. Powder greyiſh black. This variety alone has been hitherto found cryſtallized.

250
Plumoſe antimonial ore.

SPECIES 2. Plumoſe antimonial ore [†].

Sulphurets of antimony and arſenic.

This ſpecies, which is ſometimes found mixed with the cryſtals of ſulphurated antimony, is in the form of brittle, capillary, or lanuginous cryſtals, often ſo ſmall that they cannot be diſtinctly ſeen without a microſcope.

Colour ſteel or bluiſh grey, often tarniſhed, and then brown or greyiſh black. Luſtre 1, ſemimetallic. Before the blow-pipe emits a ſmoke, which depoſits a whitiſh and yellowiſh powder on the charcoal: it then melts into a black ſlag.

It is ſuppoſed to conſiſt of ſulphur, antimony, arſenic, and ſome ſilver.

[†] *Kirw.* ii. 250.

251
Red antimonial ore.

SPECIES 3. Red antimonial ore [†].

Hydroſulphuret of antimony.

This ſpecies is generally found in cavities of ſulphurated antimonial ore. It is cryſtallized in delicate needles, often diverging from a common centre.

Colour red. Luſtre 2, ſilky. Sp. gr. 4.7. Before the blow-pipe melts eaſily, and evaporates with a ſulphureous ſmell.

This ore has not been analyſed. Mineralogiſts have ſuppoſed it to be a natural kermes. If ſo, we may conclude, from the experiments of Berthollet [*], that it is a hydroſulphuret of antimony, and conſequently compoſed of oxyd of antimony, ſulphur, and ſulphurated hydrogen gas.

[†] *Kirw.* ii. 250.

[*] *Ann. de Chim.* xxv. 259.

252
G. III.
Oxyds of antimony.

GENUS III. OXYDS OF ANTIMONY.

There is a ſubſtance found incumbent on ſulphuret of antimony, of a yellow colour, and an earthy appearance, which has been ſuppoſed an oxyd of antimony, and denominated antimonial ochre. But hitherto it has not been analyſed.

GENUS

(o) The word *gang* is uſed by German mineralogiſts to denote a metallic vein. Now, it is not often that theſe veins conſiſt entirely of *ore*; in general, they contain ſtony matter beſides. For inſtance, in the copper mine at Airthry, near Stirling, the copper ore is merely a narrow ſtripe in the middle of the vein, and the reſt of it is filled up with ſulphat of barytes. We uſe the word *gangue* (as the French do), to denote, not the *metallic* vein, but the *ſtony* matter which accompanies the ore in the vein. The gangue of the copper ore at Airthry is ſulphat of barytes.

Ores of Bifmuth.

253 G. IV. Salts Muriat of antimony.

GENUS IV. SALTS OF ANTIMONY.

SPECIES 1. Muriat of antimony[*].

This ore, which has been found in Bohemia, is fometimes in quadrangular tables; fometimes in acicular cryſtals grouped like zeolites; and fometimes in priſms.

Colour pale yellowiſh or greyiſh white. Luſtre 3 to 1, nearly metallic. Tranſparency 2. Texture foliated. Melts eaſily by the flame of a candle, and emits a white vapour.[†]. Before the blow-pipe decrepitates; when powdered, and juſt ready to melt, it evaporates, and leaves a white powder around. Between two pieces of coal it is reducible to a metallic ſtate.

[*] Kirw. ii. 251.

[†] Hauy, Jour. de Min. No xxxii. 609.

ORDER XI. ORES OF BISMUTH[*].

BISMUTH is employed in the manufacture of pewter, of printers types, in ſoldering; and perhaps alſo its property of rendering other metals more fuſible, might make it uſeful in anatomical injections. The quantity conſumed in commerce is not great.

It has been found only in the primitive mountains, and is by no means common. When unaccompanied by any other metal, it does not form veins, but kidney-form maſſes. It often accompanies cobalt. Its gangue is commonly quartz. Its ores are not very abundant. They have been found chiefly in Sweden, Norway, Tranſylvania, Germany, France, and England

[*] Pott, Obſerv. Chym. 134—Geoffroy, Mem. Par. 1753, p. 296.

254 G. I. Alloys. Native bifmuth.

GENUS I. ALLOYS OF BISMUTH.

SPECIES 1. Native biſmuth[*].

This mineral, which is found at Schneeberg, Johangeorgenſtadt, &c. in Germany, has commonly the form of ſmall plates lying above one another. Sometimes it is cryſtallized in four-ſided tables, or indiſtinct cubes.

Colour white with a ſhade of red; ſurface often tarniſhed red, yellow, or purple. Luſtre metallic, 3 to 2. Opaque. Texture foliated or ſtriated. Hardneſs 6. Sp. gr. 9.022[†] to 9.57[‡]. Exceedingly fuſible. Before the blow-pipe gives a ſilvery white bead, and at laſt evaporates in a yellowiſh white ſmoke, which is depoſited on the charcoal.

It is generally accompanied by cobalt, and ſometimes contains arſenic.

[*] Kirw. ii. 264.

[†] Briſſon.

[‡] Kirwan.

255 G. II. Sulphurets. Common ſulphuret of biſmuth.

GENUS II. SULPHURETS OF BISMUTH.

SPECIES 1. Common ſulphuret of biſmuth[*].

This ore, which is found in Sweden, Saxony, and Bohemia, occurs ſometimes in amorphous maſſes, and ſometimes in needleform cryſtals.

Colour commonly bluiſh grey, ſometimes white; ſurface often tarniſhed yellow, red, and purple. Powder black and ſhining. Luſtre metallic, 2 to 3. Streak obſcurely metallic. Texture foliated. Hardneſs 5. Brittle. Sp gr. 6.131[†] to 6.4672[‡]. When held to the flame of a candle, it melts with a blue flame and ſulphureous ſmell. Before the blow-pipe emits a reddiſh yellow ſmoke, which adheres to the charcoal. This powder becomes white when it cools, and reſumes its former colour when the flame is directed upon it[*].

This ore, according to Sage, contains 60 biſmuth, And, according to La Perouſe, it holds 36 ſulphur.

[*] Kirw. ii. 266.—Sage, Mem. Par. 1782, 307.

[†] Kirwan

[‡] Briſſon.

[*] Gillot, Jour. de Min. No xxxii. 585.

A ſpecimen, analyſed by Klaproth, contained

5 ſulphur.
———
100[†]

It is commonly accompanied by quartz, aſbeſtos, or ſparry iron ore.

[†] Be i. 25

G O Yel oxy biſm

GENUS III. OXYDS OF BISMUTH.

SPECIES 1. Yellow oxyd of biſmuth[‡].

Biſmuth ochre.

This ore generally accompanies the two ſpecies already deſcribed. It is found in two ſtates; either of an earthy conſiſtence, or cryſtallized in cubes or quadrangular plates.

Colour uſually greeniſh yellow, ſometimes grey. Soluble in nitrous acid without effervefcence, and may in a great meaſure be precipitated by the effuſion of water.

[‡] K 265

ORDER XII. ORES OF ARSENIC.

ARSENIC is uſed as an alloy for ſeveral other metals, eſpecially copper. It is ſometimes employed to facilitate the fuſion of glaſs, or to render it opaque, in order to form an enamel. Preparations of arſenic are employed as paints; and, like moſt other violent poiſons, it has been introduced into medicine.

This metal is ſcattered in great abundance over the mineral kingdom, accompanying almoſt every other metal, and forming alſo ſometimes peculiar veins of its own. Of courſe it occurs in almoſt every ſpecies of mountain, and is accompanied by a variety of gangues.

G. I Na ſen

GENUS I. ALLOYS OF ARSENIC.

SPECIES 1. Native arſenic[†].

This mineral is found in different parts of Germany. It occurs generally in maſſes of various ſhapes, kidney-form, botryoidal, &c.

Colour that of ſteel. Its ſurface quickly becomes tarniſhed by expoſure to the air. Luſtre metallic (when freſh), 3 to 2. Streak bluiſh grey, metallic, and bright. Powder dull and black. Texture compact. Hardneſs 7 to 8. Brittle. Sp. gr. 5.67[†] to 5.7249[‡]. Gives an arſenical ſmell when ſtruck. Before the blow-pipe emits a white ſmoke, diffuſes a garlic ſmell, burns with a blue flame, gradually evaporates, depoſiting a white powder.

It is always alloyed with ſome iron[§], and often contains ſilver, and ſometimes gold.

[†] K 255

G. ph Or

GENUS II. SULPHURETS OF ARSENIC.

SPECIES 1. Orpiment (P).

Auripigmentum.

This ore, which is found in Hungary, Wallachia, Georgia, and Turkey in Aſia, is either maſſive or cryſtallized. The cryſtals are confuſed, and their figure cannot be eaſily determined; ſome of them appear octohedrous, and others minute four-ſided priſms.

Its colour is yellow. Streak orange yellow. Luſtre waxy, 2 to 3. Tranſparency from 0 to 2. Texture foliated. Hardneſs 4 to 8. Sp. gr. from 3.048[*] to 3.521[‡]. Effervefces with hot nitric acid. Burns with a

---

(P) *Kirw.* II. 260.—*Alberti de Auripigmento.*—*Scopoli in Anno 5to Hiſt. Naturali*, p. 59,—*Berg.* II. 297.

a bluiſh white flame. Before the blow-pipe melts, ſmokes, and evaporates, leaving only a little earth and ſome traces of iron.

Compoſed of 80 ſulphur,
20 arſenic.

100

SPECIES 2. Realgar*.

This mineral is found in Sicily, about Mount Veſuvius, in Hungary, Tranſylvania, and various parts of Germany. It is either maſſive or cryſtallized. The primitive form of the cryſtals is, according to Romé de Liſle, a four-ſided rhomboidal priſm, terminated by four-ſided pyramids, the ſides of which are rhombs †. It commonly appears in 4, 6, 8, 10, or 12 ſided priſms, terminated by four-ſided ſummits ‡.

Colour red. Streak yellowiſh red. Powder ſcarlet. Luſtre 3 to 2. Tranſparency from 2 to 3; ſometimes c. Hardneſs 5 to 6. Sp. gr. 3.3384 §. It is an electric *per ſe*, and becomes negatively electric by friction ||. Nitric acid deprives it of its colour. Before the blow pipe it melts eaſily, burns with a blue flame and garlic ſmell, and ſoon evaporates.

Compoſed of 20 ſulphur,
80 arſenic.

100

GENUS III. OXYDS OF ARSENIC.

SPECIES 1. White oxyd of arſenic *.

Native calx of arſenic.

This ore is found in various parts of Germany, Hungary, &c. either in powder, or maſſive, or cryſtallized in priſmatic needles.

Colour white or grey, often with a tint of red, yellow, green, or black. Luſtre common, 1 to 2. Tranſparency 1 to 0; when cryſtallized, 2. Texture earthy. Hardneſs 6. Brittle. Sp. gr. 3.7 †. Soluble in hot diluted nitric acid without effervescence. Soluble at 60° Fahrenheit in 80 times its weight of water. Before the blow-pipe ſublimes, but does not inflame. Tinges borax yellow.

ORDER XIII. COBALT ORES.

COBALT is employed to tinge glaſs of a blue colour, and is uſeful in painting upon porcelain.

Cobalt ores are found almoſt excluſively in the ſtratified mountains, except one ſpecies, ſulphuret of cobalt, which affects the primitive mountains. They are not very abundant; and for that reaſon cobalt is more valuable than many of the other metals which have been already treated of. They are commonly accompanied by nickel, biſmuth, or iron. They are moſt abundant in Germany, Sweden, Norway, and Hungary; they have been found alſo in Britain and France, but not in any great quantity.

GENUS I. ALLOYS OF COBALT.

SPECIES 1. Cobalt alloyed with arſenic †.

Dull grey cobalt ore.

This ore, which occurs in different parts of Germany, is either amorphous or cryſtallized. The forms of its cryſtals are the cube; ſometimes the cube with its angles, or edges, or both wanting; and the octohedron ‡.

Its colour, when freſh broken, is whitiſh or bluiſh grey, ſometimes with a ſhade of red; when expoſed to the air it ſoon becomes tarniſhed. Streak bluiſh grey and metallic. Luſtre ſcarcely metallic, 0 to 1. Texture compact. Hardneſs 10. Difficultly frangible. Sp. gr. when amorphous, 5.309 to 5.571 §; when cryſtallized 7.7207 † When ſtruck it gives out an arſenical ſmell. Before the blow-pipe it gives out an arſenical vapour, becomes magnetic, and melts eaſily, unleſs it contains a great quantity of iron. Tinges borax dark blue, and a ſmall metallic bead is obtained.

A ſpecimen of this ore from Cornwall, examined by Mr Klaproth, contained 20 cobalt,
24 iron,
33 arſenic,

77

with ſome biſmuth and ſtony matter *.

Another ſpecimen from Tunaberg, according to the analyſis of the ſame chemiſt, contained

55.5 arſenic,
44.0 cobalt,
.5 ſulphur.

100 †

262
G. II. Sulphurets.
White cobalt ore.

GENUS II. SULPHURETS OF COBALT.

SPECIES 1. White cobalt ore ‡.

Sulphuret of cobalt, arſenic, and iron.

The deſcriptions which different mineralogiſts have given of this ore are ſo various, that it is impoſſible not to ſuppoſe that diſtinct ſubſtances have been confounded together.

It occurs either in maſſes, or cryſtallized in cubes, dodecahedrons, octohedrons, and icoſahedrons.

Colour tin white, ſometimes tarniſhed reddiſh or yellowiſh. Powder ſteel grey. Luſtre partly metallic, and from 2 to 4; partly 0 or 1. Texture foliated. Hardneſs 8 to 9. Sp. gr. from 6.284 † to 6.4509 ‡. Before the blow-pipe generally gives out an arſenical vapour, and does not melt.

The analyſes that have been given of this ore are very various. Sometimes it has been found to contain no arſenic nor iron, and ſometimes to contain both. A ſpecimen from Tunaberg in Sweden, which ought to belong to this ſpecies, was analyſed by Taſſaert, and found to conſiſt of 49 arſenic,
36.6 cobalt,
5.6 iron,
6.5 ſulphur.

97.8 †

Klaproth found a ſpecimen of the ſame ore to contain
55.5 arſenic,
44.0 cobalt,
0.5 ſulphur.

100.0 ‡

G. IV.
Salts.
Arſeniat of cobalt.
‡ *Id.* 278.

GENUS IV. SALTS OF COBALT.

SPECIES 1. Arſeniat of cobalt ‡.

Red cobalt ore.

This ſpecies, like moſt other ores of cobalt, has neither been accurately deſcribed nor analyſed.

It is found in maſſes of various ſhapes, and cryſtallized in quadrangular tables or acicular priſms.

Colour red. Luſtre from 2 to 3, ſometimes 0. Tranſparency 0 to 2. Hardneſs 5 to 7. Brittle. Before the blow-pipe becomes blackiſh grey. Diffuſes a weak arſenical ſmell. Tinges borax blue.

ORDER XIV. ORES OF NICKEL.

HITHERTO nickel has been found in too ſmall quantities to be applied to any uſe; of courſe there are, properly ſpeaking, no mines of nickel. It occurs only (as far as is yet known) in the ſecondary mountains, and it commonly accompanies cobalt. It has been found in different parts of Germany, in Sweden, Siberia, Spain, France, and Britain.

267
G. I. Sulphurets.
Sulphuret of nickel with arſenic and iron.
* *Ibid.* 286.

GENUS I. SULPHURETS OF NICKEL.

SPECIES 1. Sulphuret of nickel with arſenic and iron.

*Kupfer nickel**.

This, which is the moſt common ore of nickel, occurs either maſſive or diſſeminated, but never cryſtallized.

Colour often that of copper, ſometimes yellowiſh white or grey. Recent fracture often ſilver white. Luſtre metallic, 2 to 3. Texture compact. Hardneſs 8. Sp. gr. 6.6086 to 6.6481 ‡. Soluble in nitric and nitro-muriatic acids. Solution green. Before the blow-pipe exhales an arſenical ſmoke, and melts into a bead which darkens by expoſure to the air.

‡ *Briſſon.*

It is compoſed of various proportions of nickel, arſenic, iron, cobalt, ſulphur; often contains biſmuth, and ſometimes ſilver and copper.

268
G. II. Oxyds.
Nickel ochre.
* *Kirw.* ii. 284.

GENUS II. OXYDS OF NICKEL.

SPECIES 1. Nickel ochre *.

This mineral occurs either in the form of a powder, or indurated, and then is either amorphous, or cryſtallized in acicular form cryſtals. The powder is generally found on the ſurface of other nickel ores.

Colour different ſhades of green. Luſtre 1 to 0. Texture earthy. Sp. gr. conſiderable. Slowly diſſolves in acids: ſolution green. Before the blow-pipe does not melt; but gives a yellowiſh or reddiſh brown tinge to borax.

This ore often contains ſulphat of nickel, which is ſoluble in water. The ſolution, when evaporated, gives oblong rhomboidal cryſtals, from which alkalies precipitate a greyiſh green oxyd. This oxyd is ſoluble by acids and by ammonia. The acid ſolution is green; the alkaline blue.

Metal. Ores

269
G. II
Salts
Arſenia
nickel.
† *Kirw*
285.

GENUS III. SALTS OF NICKEL.

SPECIES 1. Arſeniat of nickel †.

This ore, which was lately diſcovered at Regendorff by Mr Gmelin, is found in ſhapeleſs maſſes, and is often mixed with plates of ſulphat of barytes.

Colour pale grey, here and there mixed with pale green. Streak white. Luſtre 0. Texture compact. Hardneſs 7. Difficultly frangible. Sp. gr. conſiderable. Adheres ſlightly to the tongue, and gives an earthy ſmell when breathed on. Soluble in hot nitric and muriatic acids: ſolution green.

Contains ſome cobalt and alumina.

ORDER XV. ORES OF MANGANESE (q).

HITHERTO manganeſe, in its metallic ſtate, has ſcarcely been put to any uſe; but under the form of an oxyd it has become of great importance. The oxyd of manganeſe has the property of rendering colourleſs a variety of bodies which injure the tranſparency of glaſs; and it has been long uſed in glaſs manufactories for this purpoſe under the name of *glaſs ſoap*. By means of the ſame oxyd, oxy-muriatic acid is prepared, which has rendered manganeſe of great importance in bleaching. Not to mention the utility of manganeſe to the chemiſt, the property which it has of facilitating the oxydation of other metals, and of rendering iron more fuſible—will probably make it, in no very remote period, of very conſiderable importance in numerous manufactories.

Ores of manganeſe occur often in ſtrata, both in the primitive and ſecondary mountains; ſcarcely ever, however, we believe, in thoſe mountains which are conſidered as the moſt ancient of all. They are very common, having been found abundantly in Germany, France, Spain, Britain, Sweden, Norway, Siberia, and other countries.

2
G.I.

GENUS I. OXYDS OF MANGANESE.

Hitherto manganeſe has only been found in the ſtate of oxyd. La Perouſe, indeed, ſuſpected that he had found it in a metallic ſtate: but probably there was ſome miſtake or other in his obſervations.

2
Oxy
man
com
with
rytes

SPECIES 1. Oxyd of manganeſe combined with barytes.

This ſpecies, which exiſts in great abundance in Romaneche near the river Soane in France, is found maſſive, forming a ſtratum in ſome places more than 12 feet thick.

Colour greyiſh black or browniſh black, of great intenſity. Luſtre, external, 0; internal, metallic, 1. Soon tarniſhes by expoſure to the air, and then becomes intenſely black. Texture granular. Fracture uneven; ſometimes conchoidal. Often porous. Hardneſs 11. Difficultly frangible. Sp. gr. from 3.950 to 4.10. Abſorbs water. When taken out of water after a minute's immerſion, it has a ſtrong argillaceous ſmell. Conducts electricity nearly as well as if it were in a metallic ſtate ‡. Infuſible by the blow-pipe. Tinges ſoda red; the colour diſappears before the blue cone of flame, and is reproduced by the action of the yellow flame.

From

(q) *Pott. Miſcelan. Berolens*, VI. 40.—*Margraff*, *Mem. Berlin*, 1773, p. 3.—*La Perouſe*, *Jour. de Phyſ.* XVI. 156. and XV. 67. and XXVIII. 68.—*Sage*, *Mem. Par.* 1785, 235.

¶ omieu, Jo de M N° xii 2.

72 Gi ore of m anese. * rwan, ii. 1.

Spcies 2. Grey ore of manganeſe *.

This ore occurs both maſſive and diſſeminated; it is alſo ſometimes cryſtallized in ſlender four ſided priſms or needles.

Colour uſually duſky ſteel grey; ſometimes whitiſh grey, or reddiſh grey. Streak and powder black. External luſtre 3 to 2; internal metallic, 2 to 1. Texture ſtriated or foliated. Hardneſs 4 to 5. Brittle. Sp. gr. from 4.073 † to 4.8165 ‡. Before the blow-pipe darkens: tinges borax reddiſh brown.

† i quelin ‡ ſon.

A ſpecimen of oxyd of manganeſe from the mountains of Voſges, which probably belonged to this ſpecies, and which was analyſed by Vauquelin, was compoſed of
82 oxyd of manganeſe,
7 carbonat of lime,
6 ſilica,
5 water.
100 §

§ ur. de . N° xi 13.

Sometimes it contains a little barytes and iron.

73 B k or b n ore o anga- n * rwan, ii 92 — Il rewood, . Tranſ. i. 284

Species 3. Black or brown ore of manganeſe *

This ore is found ſometimes in the ſtate of powder, and ſometimes indurated in amorphous maſſes of various figures. Colour either black, ſometimes with a ſhade of blue or brown; or reddiſh brown. Streak of the harder ſorts metallic; of the others, black. Luſtre 0 to 1; internal (when it is indurated), metallic. Texture compact. Hardneſs 5 to 7. Sp. gr. 3.7076 to 3.9039; that of the powdery ſometimes only 2. Before the blow-pipe it exhibits the ſame phenomena as the laſt ſpecies.

A ſpecimen of this ore, analyſed by Weſtrum, contained
45.00 manganeſe,
14.00 oxyd of iron,
11.00 ſilica,
7.25 alumina,
2.00 lime,
1.50 oxyd of copper,
18.00 air and water.

174 C I. Salts. C bonat o anga- n † irwan, ii 97.

Genus II. Salts of manganese.

Species 1. Carbonat of manganeſe †.

White ore of manganeſe.

This ſpecies occurs in Sweden, Norway, and Tranſylvania. It is either in the form of looſe ſcales, or maſſive, or cryſtallized in needles.

Colour white, or reddiſh white. Texture either radiated or ſcaly. Luſtre of the ſcaly 2. Tranſparency 1 to 2. Hardneſs of the maſſive 6 to 9. Sp. gr. 2.794. Effervesces with mineral acids. Heated to redneſs, blackens. Tinges borax violet.

275 Red ore of manganeſe.

Species 2. Red ore of manganeſe †.

Carbonat of manganeſe and iron.

This ſpecies has been found in Piedmont and in the Pyrenees. It is ſometimes in powder, ſometimes maſſive, ſometimes cryſtallized in rhomboidal priſms or needles.

† Kirwan, ii. 297 — Napion, Mem. Turin, iv. 303.

Colour pale roſy red, mixed with white. Powder nearly white. Luſtre 0. Tranſparency 1. Hardneſs 8. Sp. gr. 3.233. Effervesces with nitric and muriatic acids. When heated to redneſs becomes reddiſh brown. Tinges borax red.

A ſpecimen, analyſed by Ruprecht, contained
55 ſilica,
35 oxyd of manganeſe,
7 oxyd of iron,
1.5 alumina.

§ Jour. de Phyſ. xxxi. 32.

Order XVI. ORES OF TUNGSTEN.

As no eaſy method has hitherto been diſcovered of reducing tungſten to a metallic ſtate, we need not be ſurpriſed that it has been applied to no uſe. Ores of tungſten are by no means common. They have hitherto been found only in the primitive mountains. Their gangue is commonly quartz. They very often accompany tin ores.

276 G I. Oxyds. Wolfram.

Genus I. Oxyds of tungsten.

Species 1. Wolfram (r).

Oxyds of tungſten, iron, and *manganeſe—Tungſtat of iron* and *manganeſe.*

This ſpecies is found in different parts of Germany, in Sweden, Britain, France, and Spain; and is almoſt conſtantly accompanied by ores of tin. It occurs both maſſive and cryſtallized. The primitive form of its cryſtals, according to the obſervations of Mr Hauy, is a rectangular parallelopiped ‡, whoſe length is 8.66, whoſe breadth is 5, and thickneſs 4.33 *. It is not common, however, to find cryſtals of this perfect form; in many caſes, the angles, and ſometimes the edges, of the cryſtal are wanting ‡; owing, as Mr Hauy has ſhewn, to the ſuperpoſition of plates, whoſe edges or angles decreaſe according to a certain law †.

‡ Fig. 42.
* Jour. de Min. N° xix. 8.
‡ Fig. 43.
† Jour. de Min. N° xix. 8.

Colour brown or browniſh black. Streak reddiſh brown. Powder ſtains paper with the ſame colour. Luſtre external, 2; internal, 2 to 3; nearly metallic. Texture foliated. Eaſily ſeparated into plates by percuſſion. Hardneſs 6 to 8. Sp. gr. from 7.006 * to 7.333 †. Moderately electric by communication. Not magnetic. Infuſible by the blow-pipe. Forms with borax a greeniſh globule, and with microcoſmic ſalt a tranſparent globule of a deep red ¶.

* Kirwan.
† Hauy.
¶ Vauquelin, Jour. de Min, N° xix. 11.

The ſpecimen of this ore examined by Meſſrs d'Elhuyarts, was compoſed of 65 oxyd of tungſten,
22 oxyd of manganeſe,
13 oxyd of iron.
100

Another ſpecimen from Pays le Mines in France, analyſed by Vauquelin and Hecht, contained

67.00 oxyd of tungſten,
18.00 black oxyd of iron,
6.25 black oxyd of manganeſe,
1.50 ſilica,
7.25 oxyd of the iron and manganeſe.

100.00 §

§ *Vauquelin, Jour. de Min* Nº xix. 11.

Genus II. salts of tungsten.

species 1. Tungſtat of lime (s).

Tungſten.

277 G. II Salts. Tungſtat of lime. This ore, which is now exceedingly ſcarce, has hitherto been found only in Sweden and Germany. It is either maſſive or cryſtallized; and, according to Hauy, the primitive form of its cryſtals is the octohedron †.

† *Jour. de Min.* Nº xxxiii. 657.

Colour yellowiſh white or grey. Luſtre 3 to 2. Tranſparency 2 to 3. Texture foliated. Hardneſs 6 to 9. Sp. gr, 5.8 to 60665. Becomes yellow when digeſted with nitric or muriatic acids. Infuſible by the blow-pipe. With borax forms a colourleſs glaſs, unleſs the borax exceed, and then it is brown. With microcoſmic ſalt it forms a blue glaſs, which loſes its colour by the yellow flame, but recovers it in the blue flame ‡.

‡ *Scheele* and *Bergman.*

It is compoſed of about 70 oxyd of tungſten,
30 lime,

100

with a little ſilica and iron §.

§ *Scheele.*

species 2. Brown tungſtat.

278 Brown tungſtat. This ore is found in Cornwal, and is either maſſive or compoſed of ſmall cryſtalline grains.

Colour grey, variegated with yellow and brown. Luſtre 2, waxy. Hardneſs 6 to 7. Sp. gr. 5.57. Its powder becomes yellow when digeſted in aqua regia.

According to Klaproth, it is compoſed of

88 oxyd of tungſten,
11.5 lime.

99.5

Order XVII. ORES OF MOLYBDENUM.

If ever molybdenum be found in abundance, it will probably be uſeful in dyeing and painting. At preſent it is very ſcarce, having only been found in Sweden, Germany, Carniola, and among the Alpes. Like tin and tungſten, it affects the primitive mountains.

Genus I. sulphuret of molybdenum.

species 1. Common ſulphuret (t).

Molybdena.

279 G. I. Sulphuret. Common ſulphuret. This ore, which is the only ſpecies of molybdenum ore at preſent known, is found commonly maſſive; ſometimes, however, it is cryſtallized in hexahedral tables.

Colour light lead grey; ſometimes with a ſhade of red. Streak bluiſh grey, metallic. Powder bluiſh. Luſtre metallic, 3 to 2. Texture foliated. Lamellæ ſlightly flexible. Hardneſs 4. Sp. gr. 4.569 * to 4.7385 †. Feels greaſy; ſtains the fingers. Marks bluiſh black. A piece of reſin rubbed with this mineral becomes poſitively electric ‡. Inſoluble in ſulphuric and muriatic acids; but in a boiling heat colours them green. Effervesces with warm nitric acid, leaving a grey oxyd undiſſolved. Before the blow-pipe, on a ſilver ſpoon, emits a white ſmoke, which condenſes into a white powder, which becomes blue in the internal, and loſes its colour in the external, flame. Scarcely affected by borax or microcoſmic ſalt. Effervesces with ſoda, and gives it a reddiſh pearl colour.

* *Karſten.*
† *Briſſon.*
‡ *Hauy, Jour. de Min.* Nº xix. 70.

Compoſed of about 60 molybdenum,
40 ſulphur.

100 *

* *Klaproth*

Order XVIII. ORES OF URANIUM.

Uranium has hitherto been found only in Germany, and has not been applied to any uſe. The only two mines where it has occurred are in the primitive mountains.

Genus I. oxyds of uranium.

species 1. Sulphuret of uranium †.

Pechblende.

280 G I. Oxyd Sulphuret of uranium. This ore, which has been found at Johanngeorgenſtadt in Saxony, and Joachimſthal in Bohemia, is either maſſive or ſtratified with other minerals.

† *Kirwan,* ii. 305.

Colour black or browniſh black; ſometimes with a ſhade of grey or blue. Streak darker. Powder opaque and black. Luſtre ſemimetallic, from 3 to 1. Fracture conchoidal. Hardneſs 7 to 8. Very brittle. Sp. gr. from 6.3785 ‡ to 7.5, and even higher §. Imperfectly ſoluble in ſulphuric and muriatic acids; perfectly in nitric acid and aqua regia. Solution wine yellow. Infuſible with alkalies in a crucible: infuſible by the blow-pipe *per ſe*. With borax and ſoda forms a grey opaque ſlag; with microcoſmic ſalt, a green glaſs.

‡ *Morveau, Jour. de Min* Nº xxxii. 610.
§ *Klaproth, Beiträge,* ii. 197.

Compoſed of oxyd of uranium and ſulphur, and mixed with iron and ſilica, and ſometimes lead.

A ſpecimen of this ore from Joachimſthal, analyſed lately by Klaproth, contained

86.5 uranium,
6.0 ſulphuret of lead,
5.0 ſilica,
2.5 oxyd of iron,

100.0 *

* *Beiträge,* ii. 221.

species 2. Yellow oxyd of uranium ‡.

Uranitic ochre.

281 Yellow oxyd of uranium. This ore is generally found on the ſurface of the laſt ſpecies at Johanngeorgenſtadt, and is either maſſive or in powder.

‡ *Kirwan* ii. 303.

Colour yellow, red, or brown. Streak of the yellow ſorts yellow; of the red, orange yellow. Luſtre 0. Slightly ſtains the fingers. Feels meagre. Texture earthy. Hardneſs 3 to 4. Sp. gr. 3.2438 ‖. Infuſible by the blow-pipe; but in a ſtrong heat becomes browniſh grey.

‖ *Hauy, Jour. de Min, ibid.*

Compoſed of oxyd of uranium and oxyd of iron.

Genus II. salts of uranium.

species 1. Carbonat of uranium ¶.

282 l. Salts bot at ranium. This ſubſtance is alſo found at Johanngeorgenſtadt, and near Eibenſtock and Rheinbreidenbach §. It is ſometimes amorphous, but more commonly cryſtallized. Its cryſtals are ſquare plates, octohedrons, and ſix ſided priſms.

¶ irwan, 04.
§ nelin.

Colour green ; ſometimes nearly white ; ſometimes, though rarely, yellow. Streak greeniſh white. Luſtre 3 to 2 ; internal, 2 ; ſometimes pearly ; ſometimes nearly metallic. Tranſparency 2 to 3. Texture foliated. Hardneſs 5 to 6. Brittle. Soluble in nitric acid without efferveſcence. Infuſible by alkalies.

Compoſed of carbonat of uranium, with ſome oxyd of copper. When its colour is yellow it contains no copper.

Order XIX. ORES OF TITANIUM.

Titanium has been known for ſo ſhort a time, and its properties are yet ſo imperfectly aſcertained, that many of its uſes muſt remain to be diſcovered. Its oxyd, as we learn from Mr Darcet, has been employed in painting on porcelain *. Hitherto it has been found only in the primitive mountains, the Crapacks †, the Alpes (u), and the Pyrenees ‡. It has been found alſo in Brittany ‖ and in Cornwal.

* four. de in. N° 27.
† bid, N° 51.
‡ our. de in. N° ii. 614.
‖ bid.

Genus I. oxyds of titanium.

species 1. Red oxyd of Titanium.

Red ſhorl—Sagenite.

283 l. Oxyds. d oxyd i.anium. This ore has been found in Hungary, the Pyrenees, the Alpes, and in Brittany in France. It is generally cryſtallized. The primitive form of its cryſtals, according to the obſervations of Mr Hauy, is a rectangular priſm, whoſe baſe is a ſquare ; and the form of its molecules is a triangular priſm, whoſe baſe is a right angled iſoſceles triangle, and the height is to any of the ſides of the baſe about the right angle as $\surd 12$ to $\surd 5$, or nearly as 3 : 2 ¶. Sometimes the cryſtals of titanium are ſix ſided, and ſometimes four-ſided, priſms, and often they are implicated together ‡.

¶ Jour. de in. N° . 28. and xii. 615.
‡ ig, 44.

Colour red or browniſh red. Powder brick or orange red. Luſtre 3. Tranſparency commonly 0 ; ſometimes 1. Texture foliated. Hardneſs 9. Brittle. Sp. gr. from 4.18 * to 4.2469 †. Not affected by the mineral acids. When fuſed with carbonat of potaſs, and diluted with water, a white powder precipitates, heavier than the titanium employed. Before the blow-pipe it does not melt, but becomes opaque and brown. With microcoſmic ſalt it forms a globule of glaſs, which appears black ; but its fragments are violet. With borax it forms a deep yellow glaſs, with a tint of brown. With ſoda it divides and mixes, but does not form a tranſparent glaſs.

* Klaproth.
† Vauquelin d Hecht.

When pure, it is compoſed entirely of oxyd of titanium.

species 2. Menachanite (x).

Oxyd of titanium combined with iron.

284 enachate. This ſubſtance has been found abundantly in the valley of Menachan in Cornwal ; and hence was called menachanite by Mr Gregor, the diſcoverer of it. It is in ſmall grains, like gunpowder, of no determinate ſhape, and mixed with a fine grey ſand. Colour black. Eaſily pulverized. Powder attracted by the magnet. Sp. gr. 4.427. Does not detonate with nitre. With two parts of fixed alkali it melts into an olive coloured maſs, from which nitric acid precipitates a white powder. The mineral acids only extract from it a little iron. Diluted ſulphuric acid, mixed with the powder, in ſuch a proportion that the maſs is not too liquid, and then evaporated to dryneſs, produces a blue coloured maſs. Before the blow pipe does not decrepitate nor melt. It tinges microcoſmic ſalt green ; but the colour becomes brown on cooling : yet microcoſmic ſalt does not diſſolve it. Soluble in borax, and alters its colour in the ſame manner.

According to the analyſis of Mr Gregor, it is compoſed of
46 oxyd of iron,
45 oxyd of titanium.
—
91 with ſome ſilica and manganeſe †.

According to Mr Klaproth's analyſis, it is compoſed of
51.00 oxyd of iron,
45.25 oxyd of titanium,
3.50 ſilica,
.25 oxyd of manganeſe.
—
100.00 ‡

† Mr Gregor, Jour. de Phyſ. xxxix. 72. 152.
‡ Beiträge, ii. 231.

A mineral, nearly of the ſame nature with the one juſt deſcribed, has been found in Bavaria. Its ſpecific gravity, however, is only 3.7. According to the analyſis of Vauquelin and Hecht, it is compoſed of
49 oxyd of titanium,
35 iron,
2 manganeſe,
14 oxygen combined with the iron and manganeſe.
—
100 §

§ Jour. de Min. No xix. 57.

species 3. Calcarco ſiliceous ore of titanium.

Oxyd of titanium combined with lime and ſilica—Titanite †.

285 Calcareo-ſiliceous ore of titanium. This ore has hitherto been found only near Paſſau. It was diſcovered by Profeſſor Hunger. It is ſometimes maſſive, but more commonly cryſtallized in four ſided priſms, not longer than one fourth of an inch.

† Kirwan, ii. 331.

Colour reddiſh, yellowiſh, or blackiſh brown ; ſometimes whitiſh grey. Powder whitiſh grey. Luſtre waxy or nearly metallic, 2 to 3. Tranſparency from 0 to 2. Texture foliated. Hardneſs 9 or more. Brittle. Sp. gr. 3.510. Muriatic acid, by repeated digeſtion, diſſolves one-third of it. Ammonia precipitates from this ſolution a clammy yellowiſh ſubſtance. Infuſible by the blow-pipe, and alſo in a clay crucible ; but in charcoal is converted into a black opaque porous ſlag.

According to the analyſis of Klaproth, it is compoſed of
33 oxyd of titanium,
35 ſilica,
33 lime.
—

ORDER XX. ORES OF TELLURIUM.

HITHERTO tellurium has only been found in Tranſylvania. It occurs in three different mines; that of Fatzbay, Offenbanya, and Nagyag, which are conſidered as gold mines, becauſe they contain leſs or more of that metal. Its gangue is commonly quartz.

GENUS I. ALLOYS OF TELLURIUM.

286 G. I. Alloys. White gold ore of Fatzbay.

SPECIES 1. White gold ore of Fatzbay.

Alloy of tellurium and iron, with ſome gold.

This ſpecies is generally maſſive. Its colour is between tin white and lead grey. Luſtre conſiderable, metallic. Texture granular *.

According to Klaproth's analyſis, it is compoſed of

72.0 iron,
25.5 tellurium,
2.5 gold.

100.0 †

287 Graphic golden ore of Offenbanya.

SPECIES 2. Graphic golden ore of Offenbanya.

Tellurium alloyed with gold and ſilver.

This ore is compoſed of flat priſmatic cryſtals; the arrangement of which has ſome reſemblance to Turkiſh letters. Hence the name of the ore.

Colour tin white, with a tinge of braſs yellow ‡. Luſtre metallic, 3. Hardneſs 4 to 5. Brittle. Sp. gr. 5.723. Before the blow-pipe decrepitates, and melts like lead. Burns with a lively brown flame and diſagreeable ſmell, and at laſt vaniſhes in a white ſmoke, leaving only a whitiſh earth ‖.

According to Klaproth's analyſis, it is compoſed of

60 tellurium,
30 gold,
10 ſilver,

100 §

The yellow gold ore of Nagyag would belong to this ſpecies were it not that it contains lead. Its compoſition, according to Klaproth's analyſis, is as follows:

45.0 tellurium,
27.0 gold,
19.5 lead,
8.5 ſilver,

100.0 and an atom of ſulphur *

288 Grey foliated gold ore of Nagyag.

SPECIES 3. Grey foliated gold ore of Nagyag.

This ore is found in plates, of different degrees of thickneſs, adhering to one another, but eaſily ſeparable: theſe are ſometimes hexahedral, and often accumulated ſo as to leave cells between them.

Colour deep lead grey, paſſing to iron black, ſpotted. Luſtre metallic, moderate. Texture foliated; leaves ſlightly flexible †. Hardneſs 6. Sp. gr. 8.919. Stains the fingers. Soluble in acids with efferveſcence ‡.

According to Klaproth, it is compoſed of

50.0 lead,
33.0 tellurium,
8.5 gold,
7.5 ſulphur,
1.0 ſilver and copper.

100.0 §

ORDER XXI. ORES OF CHROMUM.

CHROMUM has hitherto been found in too ſmall quantities for its extenſive application to the arts. Whenever it becomes plentiful, its properties will render it of great importance both to the dyer and painter. Nature has uſed it to colour ſome of her moſt beautiful mineral productions: And can art copy after a better model? Hitherto it has been found only in two places, near Ekaterinbourg in Siberia, and in the department of the Var in France. In the firſt of theſe places, and probably alſo in the ſecond, its gangue is quartz.

GENUS I. SALTS OF CHROMUM.

289 G. I. Salts. Chromat of lead.

SPECIES 1. Chromat of lead.

Red lead ore of Siberia.

This ſingular mineral, which has now become ſcarce, is found in the gold mines of Bereſof near Ekaterimbourg in Siberia, cryſtallized in four-ſided priſms, ſometimes terminated by four-ſided pyramids, ſometimes not.

Colour red, with a ſhade of yellow. Streak and powder a beautiful orange yellow. Luſtre from 2 to 3. Tranſparency 2 to 3. Structure foliated. Texture compact. Fracture uneven. Hardneſs 5 to 4. Sp. gr. 6.0269 † to 5.75 ‡. Does not effervеſce with acids. Before the blow-pipe decrepitates; ſome lead is reduced, and the mineral is converted to a black ſlag, which tinges borax green.

According to the analyſis of Vauquelin, it is compoſed of

65.12 oxyd of lead,
34.88 chromic acid.

100.00 ‖.

290 Chromat of iron.

SPECIES 2. Chromat of iron.

This mineral, which has been found only near Gaſſin in the department of Var in France, is in irregular maſſes.

Colour brown, not unlike that of brown blende. Luſtre metallic. Hardneſs moderate. Sp. gr. 4.0326. Melts with difficulty before the blow pipe; to borax it communicates a dirty green. Inſoluble in nitric acid. Melted with potaſs, and diſſolved in water, the ſolution aſſumes a beautiful orange yellow colour.

It is compoſed of 63.6 chromic acid,
36.0 oxyd of iron.

99.6 †

CHAP. IV. OF THE CHEMICAL ANALYSIS OF MINERALS.

291 Analyſis of minerals.

THE progreſs which the art of analyſing minerals has made within theſe laſt twenty years is truly aſtoniſhing. To ſeparate five or ſix ſubſtances intimately combined together, to exhibit each of them ſeparately, to aſcertain the preciſe quantity of each, and even to detect the preſence and the weight of ſubſtances which do not approach $\frac{1}{100}$th part of the compound, would, at no very remote period, have been conſidered as a hopeleſs, if not an impoſſible, taſk; yet this can now be done with the moſt rigid accuracy.

292 Begun by Margraff.

The firſt perſon who undertook the analyſis of minerals was Margraff of Berlin. His attempts were indeed rude; but their importance was ſoon perceived by other chemiſts, particularly by Bergman and Scheele, whoſe

Ana is of Mi als.

whoſe induſtry and addreſs brought the art of analyſing minerals to a conſiderable degree of perfection.

Imp ed by K . prot

But their methods, though they had very conſiderable merit, and, conſidering the ſtate of the ſcience, are wonderful proofs of the genius of the inventors, were often tedious and uncertain, and could not in all caſes be applied with confidence. Theſe defects were perceived by Mr Klaproth of Berlin, who applied himſelf to the analyſis of minerals with a perſevering induſtry which nothing could fatigue, and an ingenuity and accuracy which nothing could perplex. He corrected what was wrong, and ſupplied what was wanting, in the analytical method; invented new proceſſes, diſcovered new inſtruments; and it is to his labours, more than to thoſe of any other chemiſt, that the degree of perfection, to which the analyſis of minerals has attained, is to be aſcribed. Many improvements, however, were introduced by other chemiſts, eſpecially by Mr Vauquelin, whoſe analyſes in point of accuracy and ingenuity rival thoſe of Klaproth himſelf.

And her cher ts.

We ſhall, in this chapter, give a ſhort deſcription of the moſt perfect method of analyſing minerals, as far as we are acquainted with it. We ſhall divide the chapter into four ſections. In the firſt, we ſhall give an account of the inſtruments uſed in analyſes; in the ſecond, we ſhall treat of the method of analyſing ſtones; in the third, of analyſing combuſtibles; and in the fourth, of the analyſes of ores.

SECT. I. *Of the Inſtruments of Analyſes.*

Me d of obta ng cher al a- gent ure.

I. The chemical agents, by means of which the analyſis of minerals is accompliſhed, ought to be prepared with the greateſt care, becauſe upon their purity the exactneſs of the operation entirely depends. Theſe agents are the three alkalies, both pure and combined with carbonic acid; the ſulphuric, nitric, and muriatic acids; hydroſulphuret of potaſs and ſulphurated hydrogen gas diſſolved in water; pruſſic alkali, and a few neutral ſalts.

1. Potaſs and ſoda may be obtained pure, either by means of alcohol, or by the method deſcribed in the article CHEMISTRY, nº 372. *Suppl.* Theſe alkalies are known to be pure when their ſolution in pure water occaſions no precipitate in lime and barytic water; when the precipitate which it produces in a ſolution of ſilver is completely diſſolved by nitric acid; and, laſtly, when ſaturated with carbonic acid it depoſits no ſilica.

2. Ammonia is procured by diſtilling one part of muriat of ammonia with two parts of quicklime, and receiving the gas in a diſh containing a quantity of pure water, equal in weight to the muriat employed. Its purity is known by the ſame teſts which aſcertain the purity of fixed alkalies.

3. The carbonats of potaſs and ſoda may be formed by diſſolving the potaſs and ſoda of commerce in pure water, ſaturating the ſolution with carbonic acid, and cryſtallizing them repeatedly. When pure, theſe cryſtals effloreſce in the air; and the precipitate which they occaſion in ſolutions of barytes and of ſilver is completely ſoluble in nitric acid. Carbonat of ammonia is obtained by diſtilling together one part of muriat of ammonia and two parts of carbonat of lime.

4. The ſulphuric acid of commerce often contains nitric acid, potaſs, lead, &c. It may be purified by diſtillation in a low cucurbite. The firſt portion, when it comes over, muſt be ſet aſide; it contains the nitric acid. The other impurities remain behind in the cucurbite. Sulphuric acid, when pure, diſſolves indigo without altering its colour, does not attack mercury while cold, and cauſes no precipitate in pure alkaline ſolutions.

Analyſis of Minerals.

5. Nitric acid often contains both ſulphuric and muriatic acids. It is eaſily purified by throwing into it about three parts of litharge in fine powder for every 100 parts of the acid, allowing the mixture to remain for 24 hours, ſhaking it occaſionally, and then diſtilling it. The ſulphuric and muriatic acids combine with the lead, and remain behind in the retort. Pure nitric acid occaſions no precipitate in the ſolutions of barytes and ſilver.

6. The muriatic acid of commerce uſually contains ſulphuric acid, oxymuriatic acid, and oxyd of iron. It may be purified by diſtillation with a little muriat of ſoda; taking care to ſet aſide the firſt portion which comes over. When pure it cauſes no precipitate in the ſolution of barytes, nor of pure alkalies, and does not attack mercury while cold.

7. Hydroſulphuret of potaſs is made by ſaturating a ſolution of pure potaſs with ſulphurated hydrogen gas; and water may be ſaturated with ſulphurated hydrogen gas in the ſame manner. See CHEMISTRY, nº 857. *Suppl.*

8. The method of preparing pruſſic alkali, oxalic acid, and the other ſubſtances uſed in analyſes, has been already deſcribed in the article CHEMISTRY, *Suppl.* it is unneceſſary therefore to repeat it here.

296
How to reduce the mineral to powder.

II. Before a mineral is ſubmitted to analyſis, it ought to be reduced to an impalpable powder. This is by no means an eaſy taſk when the ſtone is extremely hard It ought to be raiſed to a bright red or white heat in a crucible, and then inſtantly thrown into cold water. This ſudden tranſition makes it crack and break into pieces. If theſe pieces are not ſmall enough, the operation may be repeated on each till they are reduced to the proper ſize. Theſe fragments are then to be beaten to ſmall pieces in a poliſhed ſteel mortar; the cavity of which ſhould be cylindrical, and the ſteel peſtle ſhould fit it exactly, in order to prevent any of the ſtone from eſcaping during the act of pounding. As ſoon as the ſtone is reduced to pretty ſmall pieces, it ought to be put into a mortar of rock cryſtal or flint, and reduced to a coarſe powder. This mortar ſhould be about four inches in diameter, and rather more than an inch in depth. The peſtle ſhould be formed of the ſame ſtone with the mortar, and care ſhould be taken to know exactly the ingredients of which this mortar is compoſed. Klaproth's mortar is of flint. We have given its analyſis in nº 32. of this article.

When the ſtone has been reduced to a coarſe powder, a certain quantity, whoſe weight is known exactly, 100 grains for inſtance, ought to be taken and reduced to as fine a powder as poſſible. This is beſt done by pounding ſmall quantities of it at once, not exceeding 10 grains. The powder is as fine as poſſible when it feels ſoft, adheres together, and as it were forms a cake under the peſtle. It ought then to be weighed exactly. It will almoſt always be found heavier after being pounded than it was before; owing to a certain quantity of the ſubſtance of the mortar which has been rubbed off during the grinding and mixed with the powder.

der. This additional weight muſt be carefully noted ; and after the analyſis, a portion of the ingredients of the mortar, correſponding to it, muſt be ſubtracted.

297 Chemical diſhes. III. It is neceſſary to have a crucible of pure ſilver, or, what is far preferable, of platinum, capable of holding rather more than ſeven cubic inches of water, and provided with a cover of the ſame metal. There ſhould alſo be ready a ſpatula of the ſame metal about four inches long.

The diſhes in which the ſolutions, evaporations, &c. are performed, ought to be of glaſs or porcelain. Thoſe of porcelain are cheaper, becauſe they are not ſo apt to break. Thoſe which Mr Vauquelin uſes are of porcelain ; they are ſections of ſpheres, and are glazed both within and without, except that part of the bottom which is immediately expoſed to the fire.

Sect. II. *Analyſis of Stones* (y).

298 Ingredients of ſtones. The only ſubſtances which enter into the compoſition of the ſimple ſtones, as far at leaſt as analyſis has diſcovered, are the ſix earths, ſilica, alumina, zirconia, glucina, lime, and magneſia ; and the oxyds of iron, mangaeſe, nickel, chromum, and copper (z). Seldom more than four or five of theſe ſubſtances are found combined together in the ſame ſtone : we ſhall ſuppoſe, however, in order to prevent unneceſſary repetitions, that they are all contained in the mineral which we are going to analyſe.

259 Method of decompoſing ſtones. Let 100 or 200 grains of the ſtone to be analyſed, previouſly reduced to a fine powder, be mixed with three times its weight of pure potaſs and a little water, and expoſed in the ſilver or platinum crucible to a ſtrong heat. The heat ſhould at firſt be applied ſlowly, and the matter ſhould be conſtantly ſtirred, to prevent the potaſs from ſwelling and throwing any part out of the crucible. When the whole water is evaporated, the mixture ſhould be kept for half an hour or three quarters in a ſtrong red heat.

If the matter in the crucible melts completely, and appears as liquid as water, we may be certain that the ſtone which we are analyſing conſiſts chiefly of ſilica ; if it remains opaque, and of the conſiſtence of paſte, the other earths are moſt abundant ; if it remains in the form of a powder, alumina is the prevalent earth. If the matter in the crucible be of a dark or browniſh red colour, it contains oxyd of iron ; if it is graſs green, mangaeſe is preſent ; if it is yellowiſh green, it contains chromum.

When the crucible has been taken from the fire and wiped on the outſide, it is to be placed in a capſule of porcelain, and filled with water. This water is to be renewed from time to time till all the matter is detached from the crucible. The water diſſolves a part of the combination of the alkali with the ſilica and alumina of the ſtone, and if a ſufficient quantity were uſed, it would diſſolve the whole of that combination.

Muriatic acid is now to be poured in till the whole of the matter is diſſolved. At firſt a flaky precipitate appears, becauſe the acid combines with the alkali which kept it in ſolution. Then an efferveſcence takes place, owing to the decompoſition of ſome carbonat of potaſs formed during the fuſion. At the ſame time the flaky precipitate is rediſſolved ; as is alſo that part of the matter which, not having been diſſolved in the water, had remained at the bottom of the diſh in the form of a powder. This powder, if it conſiſts only of ſilica and alumina, diſſolves without efferveſcence ; but if it contains lime, an efferveſcence takes place.

If this ſolution in muriatic acid be colourleſs, we may conclude that it contains no metallic oxyd, or only a very ſmall portion ; if its colour be purpliſh red, it contains mangaeſe ; orange red indicates the preſence of iron ; and golden yellow the preſence of chromum.

This ſolution is to be poured into a capſule of porcelain, covered with paper, and evaporated to dryneſs in a ſand bath. When the evaporation is drawing towards its completion, the liquor aſſumes the form of jelly. It muſt then be ſtirred conſtantly with a glaſs or porcelain rod, in order to facilitate the diſengagement of the acid and water, and to prevent one part of the matter from being too much, and another not ſufficiently dried. Without this precaution, the ſilica and alumina would not be completely ſeparated from each other.

300 How the ſilica is ſeparated. When the matter is reduced almoſt to a dry powder, a large quantity of pure water is to be poured on it ; and, after expoſure to a ſlight heat, the whole is to be poured on a filter. The powder which remains upon the filter is to be waſhed repeatedly, till the water with which it has been waſhed ceaſes to precipitate ſilver from its ſolutions. This powder is the whole of the *ſilica* which the ſtone that we are analyſing contained. It muſt firſt be dried between folds of blotting paper, then heated red hot in a platinum or ſilver crucible, and weighed while it is yet warm. It ought to be a fine powder, of a white colour, not adhering to the fingers, and entirely ſoluble in acids. If it be coloured, it is contaminated with ſome metallic oxyd ; and ſhews, that the evaporation to dryneſs has been performed at too high a temperature. To ſeparate this oxyd, the ſilica muſt be boiled with an acid, and then waſhed and dried as before. The acid ſolution muſt be added to the water which paſſed through the filter, and which we ſhall denominate A.

The watery ſolution A is to be evaporated till its quantity does not exceed 30 cubic inches, or nearly an Engliſh pint. A ſolution of carbonat of potaſs is then to be poured into it till no more matter precipitates. It ought to be boiled a few moments to enable all the precipitate to fall to the bottom. When the whole of the precipitate has collected at the bottom, the ſupernatant liquid is to be decanted off ; and water being ſubſtituted in its place, the precipitate and water are to be thrown upon a filter. When the water has run off, the filter with the precipitate upon it is to be placed between folds of blotting paper. When the precipitate has acquired ſome conſiſtence, it is to be carefully collected by an ivory knife, mixed with a ſolution of pure potaſs, and boiled in a porcelain capſule. If any alumina

---

(y) Part of this ſection is to be conſidered as an abſtract of a treatiſe of Vauquelin on the analyſis of ſtones, publiſhed in the *Annales de Chimie*, Vol. XXX. p. 66.

(z) Barytes has alſo been diſcovered in one ſingle ſtone, the *ſtaurolite* ; but its preſence in ſtones is ſo uncommon, that it can ſcarcely be looked for. The method of detecting it ſhall be noticed afterwards.

alumina or glucina be preſent, they will be diſſolved in the potaſs; while the other ſubſtances remain untouched in the form of a powder, which we ſhall call B.

3 And e alun 3,

Into the ſolution of potaſs as much acid muſt be poured as will not only ſaturate the potaſs, but alſo completely rediſſolve any precipitate which may have at firſt appeared. Carbonat of ammonia is now to be added in ſuch quantity that the liquid ſhall taſte of it. By this addition the whole of the alumina will be precipitated in white fleaks, and the glucina will remain diſſolved, provided the quantity of carbonat of ammonia uſed be not too ſmall. The liquid is now to be filtered, and the alumina which will remain on the filter is to be waſhed, dried, heated red hot, and then weighed. To ſee if it be really alumina, diſſolve it in ſulphuric acid, and add a ſufficient quantity of ſulphat or acetite of potaſs; if it be alumina, the whole of it will be converted into cryſtals of alum.

Glu a,

Let the liquid which has paſſed through the filter be boiled for ſome time, and the glucina, if it contains any, will be precipitated in a light powder, which may be dried and weighed. When pure, it is a fine, ſoft, very light, taſteleſs powder, which does not concrete when heated, as alumina does.

Li e,

The reſiduum B may contain lime, magneſia, and one or more metallic oxyds. Let it be diſſolved in weak ſulphuric acid, and the ſolution evaporated to dryneſs. Pour a ſmall quantity of water on it. The water will diſſolve the ſulphat of magneſia, and the metallic ſulphats; but the ſulphat of lime will remain undiſſolved. Let it be heated red hot in a crucible, and weighed. The lime amounts to 0.41 of the weight.

Let the ſolution containing the remaining ſulphats be diluted with a large quantity of water, let a ſmall exceſs of acid be added, and then let a ſaturated carbonat of potaſs be poured in. The oxyds of chromum, iron, and nickel, will be precipitated, and the magneſia and oxyd of mangneſe will remain diſſolved. The precipitate we ſhall call C.

M a- nef

Into the ſolution let a ſolution of hydroſulphuret of potaſs be poured, and the manganeſe will be precipitated in the ſtate of a hydroſulphuret. Let it be calcined in contact with air, and weighed.

Ma ſia,

The magneſia may then be precipitated by pure potaſs, waſhed, expoſed to a red heat, and then weighed.

Chr um,

Let the reſiduum C be boiled repeatedly with nitric acid, then mixed with pure potaſs; and after being heated, let the liquid be decanted off. Let the precipitate, which conſiſts of the oxyds of iron and nickel, be waſhed with pure water; and let this water be added to the ſolution of the nitric acid and potaſs. That ſolution contains the chromum converted into an acid. Add to this ſolution an exceſs of muriatic acid, and evaporate till the liquid aſſumes a green colour; then add a pure alkali: The chromum precipitates in the ſtate of an oxyd, and may be dried, and weighed.

Ir ,

Let the precipitate, conſiſting of the oxyds of iron and nickel, be diſſolved in muriatic acid; add an exceſs of ammonia: the oxyd of iron precipitates. Let it be waſhed, dried, and weighed.

3 And kel.

Evaporate the ſolution, and the oxyd of nickel will alſo precipitate; and its weight may be aſcertained in the ſame manner with the other ingredients.

The weights of all the ingredients obtained are now to be added together, and their ſum total compared with the weight of the matter ſubmitted to analyſis. If the two are equal, or if they differ only by .03 or .04 parts, we may conclude that the analyſis has been properly performed: but if the loſs of weight be conſiderable, ſomething or other has been loſt. The analyſis muſt therefore be repeated with all poſſible care. If there is ſtill the ſame loſs of weight, we may conclude that the ſtone contains ſome ſubſtance, which has either evaporated by the heat, or is ſoluble in water.

309 Method of detecting volatile bodies.

A freſh portion of the ſtone muſt therefore be broken into ſmall pieces, and expoſed in a porcelain crucible to a ſtrong heat. If it contains water, or any other volatile ſubſtance, they will come over into the receiver; and their nature and weight may be aſcertained.

If nothing comes over into the receiver, or if what comes over is not equal to the weight wanting, we may conclude that the ſtone contains ſome ingredient which is ſoluble in water.

310 Method of aſcertaining whether ſtones contain potaſs

To diſcover whether it contains *potaſs*, let the ſtone, reduced to an impalpable powder, be boiled five or ſix times in ſucceſſion, with very ſtrong ſulphuric acid, applying a pretty ſtrong heat towards the end of the operation, in order to expel the exceſs of acid; but taking care that it be not ſtrong enough to decompoſe the ſalts which have been formed.

Water is now to be poured on, and the reſiduum, which does not diſſolve, is to be waſhed with water till it becomes taſteleſs. The watery ſolution is to be filtered, and evaporated to dryneſs, in order to drive off any exceſs of acid which may be preſent. The ſalts are to be again diſſolved in water: and the ſolution, after being boiled for a few moments, is to be filtered and evaporated to a conſiſtence proper for cryſtallizing. If the ſtone contains a ſufficient quantity of alumina, and if potaſs be preſent, cryſtals of alum will be formed; and the quantity of potaſs may be diſcovered by weighing them, it being nearly $\frac{1}{10}$th of their weight. If the ſtone does not contain alumina, or not in ſufficient quantity, a ſolution of pure alumina in ſulphuric acid muſt be added. Sometimes the alum, even when potaſs is preſent, does not appear for ſeveral days, or even weeks; and ſometimes, when a great quantity of alumina is preſent, if the ſolution has been too much concentrated by evaporation, the ſulphat of alumina prevents the alum from cryſtallizing at all. Care, therefore, muſt be taken to prevent this laſt ſource of error. The alum obtained may be diſſolved in water, and barytic water poured into it as long as any precipitate forms. The liquor is to be filtered, and evaporated to dryneſs. The reſiduum will conſiſt of potaſs and a little carbonat of potaſs. The potaſs may be diſſolved in a little water. This ſolution, evaporated to dryneſs, gives us the potaſs pure; which may be examined and weighed.

311 Or ſoda.

If no cryſtals of alum can be obtained, we muſt look for ſome other ſubſtance than potaſs. The ſtone, for inſtance, may contain ſoda. The preſence of this alkali may be diſcovered by decompoſing the ſolution in ſulphuric acid, already deſcribed, by means of ammonia. The liquid which remains is to be evaporated to dryneſs, and the reſiduum is to be calcined in a crucible. By this method, the ſulphat of ammonia will be volatilized, and the ſoda will remain. It may be rediſſolved in water, cryſtallized, and examined.

If ſulphuric acid does not attack the ſtone, as is often the caſe, it muſt be decompoſed by fuſion with ſoda, da, in the ſame manner as formerly directed with potaſs. The matter, after fuſion, is to be diluted with water, and then ſaturated with ſulphuric acid. The ſolution is to be evaporated to dryneſs, the reſiduum again diſſolved in water, and evaporated. Sulphat of ſoda will cryſtallize firſt; and by a ſecond evaporation, if the ſtone contains potaſs and alumina, cryſtals of alum will be depoſited.

The preſence of potaſs may be diſcovered, by mixing with a ſomewhat concentrated ſolution of muriat of platinum, the ſalt obtained, either by decompoſing the ſtone immediately by an acid, or by ſaturating with an acid the matter obtained by fuſing the ſtone with ſoda. If any potaſs be preſent, a very red precipitate will be formed. This precipitate is a triple ſalt, compoſed of potaſs, muriatic acid, and oxyd of platinum. Ammonia, indeed, produces the ſame precipitate; but ammonia has not hitherto been diſcovered in ſtones.

312 Analyſis of ſaline ſtones,

In this manner may ſimple ſtones and aggregates be analyſed. As to ſaline ſtones, their analyſis muſt vary according to the acid which they contain. But almoſt all of them may be decompoſed by one or other of two methods; of each of which we ſhall give an example.

I. Analyſis of Carbonat of Strontites.

313 Of Carbonats,

Klaproth analyſed this mineral by diſſolving 100 parts of it in diluted muriatic acid: during the ſolution, 30 parts of carbonic acid eſcaped. The ſolution cryſtallized in needles, and when diſſolved in alcohol, burnt with a purple flame. Therefore it contained ſtrontites. He diſſolved a grain of ſulphat of potaſs in ſix ounces of water, and let fall into it three drops of the muriatic ſolution. No precipitate appeared till next day. Therefore the ſolution contained no barytes; for if it had, a precipitate would have appeared immediately.

He then decompoſed the muriatic acid ſolution, by mixing it with carbonat of potaſs. Carbonat of ſtrontites precipitated. By the application of a ſtrong heat, the carbonic acid was driven off. The whole of the earth which remained was diſſolved in water. It cryſtallized; and when dried, weighed 69½ *.

II. Analyſis ol Sulphat of Strontites.

Mr Vauquelin analyſed an impure ſpecimen of this mineral as follows:

314 Sulphats,

On 200 parts of the mineral, diluted nitric acid was poured. A violent effervescence took place, and part of the mineral was diſſolved. The undiſſolved portion, after being heated red hot, weighed 167. Therefore 33 parts were diſſolved.

The nitric ſolution was evaporated to dryneſs: A reddiſh ſubſtance remained, which indicated the preſence of oxyd of iron. This ſubſtance was rediſſolved in water, and ſome ammonia mixed with it; a reddiſh precipitate appeared, which, when dried, weighed 1, and was oxyd of iron. The remainder of the ſolution was precipitated by carbonat of potaſs. The precipitate weighed, when dried, 20, and poſſeſſed the properties of carbonat of lime. Therefore 200 parts of this mineral contain 20 of carbonat of lime, 1 of oxyd of iron, and the remainder of the 33 parts he concluded to be water.

The 167 parts, which were inſoluble in nitric acid, were mixed with 500 parts of carbonat of potaſs, and 7000 parts of water, and boiled for a conſiderable time. The ſolution was then filtered, and the reſiduum waſhed and dried. The liquid ſcarcely effervesced with acids; but with barytes it produced a copious precipitate, totally indiſſoluble in muriatic acid. Therefore it contained ſulphuric acid.

The undiſſolved reſiduum, when dried, weighed 129 parts. It diſſolved completely in muriatic acid. The ſolution cryſtallized in needles; when diſſolved in alcohol, it burnt with a purple flame; and, in ſhort, had all the properties of muriat of ſtrontites. Therefore theſe 129 parts were carbonat of ſtrontites. Now, 100 parts of this carbonat contain 30 of carbonic acid; therefore 129 contain 38.7. Therefore the mineral muſt contain in 200 parts 90.3 of ſtrontites.

Now, the inſoluble reſiduum of 167 parts was pure ſulphat of ſtrontites; and we have ſeen that it contained 90.3 of ſtrontites. Therefore the ſulphuric acid muſt amount to 76.7 parts †.

Nearly in the ſame manner as in the firſt of theſe examples, may the analyſis of carbonat of lime and barytes be performed; and nearly in the ſame manner with the ſecond, we may analyſe the ſulphats of lime and barytes.

315 Phoſphat

Phoſphat of lime may be diſſolved in muriatic acid, and the lime precipitated by ſulphuric acid, and its quantity aſcertained by decompoſing the ſulphat of lime obtained. The liquid ſolution may be evaporated to the conſiſtence of honey, mixed with charcoal powder, and diſtilled in a ſtrong heat. By this means phoſphorus will be obtained. The impurities with which the phoſphat may be contaminated will partly remain undiſſolved, and be partly diſſolved, in muriatic acid. They may be detected and aſcertained by the rules laid down in the ſecond ſection of this chapter.

316 Fluat.

The fluat of lime may be mixed with ſulphuric acid and diſtilled. The fluoric acid will come over in the form of gas, and its weight may be aſcertained. What remains in the retort, which will conſiſt chiefly of ſulphat of lime, may be analyſed by the rules already laid down.

317 And borats.

The borat of lime may be diſſolved in nitric or ſulphuric acid: The ſolution may be evaporated to dryneſs, and the boracic acid ſeparated from the reſiduum by means of alcohol, which will diſſolve it without acting on any of the other ingredients. The remainder of the dry maſs may be analyſed by the rules laid down in Sect. II. of this Chapter.

SECT. III. *Of the Analyſis of Combuſtibles.*

THE only combuſtibles of whoſe analyſis it will be neceſſary to ſpeak are coals and ſulphur; for the method of analyſing the diamond and oil has already been given in the article CHEMISTRY, *Suppl.*

318 Earths coal ho examin

Coal is compoſed of carbon, bitumen, and ſome portion of earth. The earths may be detected by burning completely a portion of the coal to be analyſed. The aſhes which remain after incineration conſiſt of the earthy part. Their nature may be aſcertained by the rules laid down in Sect. II. of this Chapter.

For the method of aſcertaining the proportion of carbon and bitumen in coal, we are indebted to Mr Kirwan.

31 Metho detect the re propo of cha and bi men.

When nitre is heated red hot, and charcoal is thrown on it, a violent detonation takes place; and if the quantity of charcoal be ſufficient, the nitre is completely decompoſed. Now, it requires a certain quantity of pure carbon

---

* *Klaproth's Beiträge*, i. 260.

† *Jour. de Min* N° xxxvii. p.

carbon to decompoſe a given weight of nitre. From the experiments of Lavoiſier, it follows, that when the detonation is performed in cloſe veſſels under water, 13.31 parts of charcoal are capable of decompoſing 100 parts of nitre*. But when the detonation is performed in an open crucible, a ſmaller proportion of charcoal is neceſſary, becauſe part of the nitre is decompoſed by the action of the ſurrounding air. Scheele found, that under theſe circumſtances 10 parts of plumbago were ſufficient to decompoſe 96 parts of nitre, and Mr Kirwan found, that nearly the ſame quantity of charcoal was ſufficient for producing the ſame effect.

Macquer long ago obſerved, that no volatile oily matter will detonate with nitre, unleſs it be previouſly reduced to a charcoal; and that then its effect upon nitre is preciſely proportional to the charcoal which it contains†. Mr Kirwan, upon trying the experiment with *vegetable pitch* and *maltha*, found, that theſe ſubſtances did not detonate with nitre, but merely burn upon its ſurface with a white or yellow flame; and that after they were conſumed, nearly the ſame quantity of charcoal was neceſſary to decompoſe the nitre which would have been required if no bitumen had been uſed at all‡. Now coals are chiefly compoſed of charcoal and bitumen. It occurred therefore to Mr Kirwan, that the quantity of charcoal which any coal contains may be aſcertained by detonating it with nitre: For ſince the bitumen of the coal has no effect in decompoſing nitre, it is evident that the detonation and decompoſition muſt be owing to the charcoal of the coal; and that therefore the quantity of coal neceſſary to decompoſe a given portion of nitre will indicate the quantity of carbon which it contains: and the proportion of charcoal and earth which any coal contains being aſcertained, its bituminous part may be eaſily had from calculation.

The crucible which he uſed in his experiments was large; it was placed in a wind furnace at a diſtance from the flue, and the heat in every experiment was as equal as poſſible. The moment the nitre was red hot, the coal, previouſly reduced to ſmall pieces of the ſize of a pin head, was projected in portions of one or two grains at a time, till the nitre would no longer detonate; and every experiment was repeated ſeveral times to enſure accuracy.

He found, that 480 grains of nitre required 50 grains of Kilkenny coal to decompoſe it by this method. Therefore 10 grains would have decompoſed 96 of nitre; preciſely the quantity of charcoal which would have produced the ſame effect. Therefore Kilkenny coal is compoſed almoſt entirely of charcoal.

Cannel coal, when incinerated, left a reſiduum of 3.12 in the 100 parts of earthy aſhes. 66.5 grains of it were required to decompoſe 480 grains of nitre; but 50 parts of charcoal would have been ſufficient: therefore 66.5 grains of cannel coal contain 50 grains of charcoal, and 2.08 of earth; the remaining 14.42 grains muſt be bitumen. In this manner may the compoſition of any other coal be aſcertained.

20 M hod of ar ſing fu ur.

As for ſulphur, in order to aſcertain any accidental impurities with which it may be contaminated, it ought to be boiled in thirty times its weight of water, afterwards in diluted muriatic acid, and laſtly in diluted nitro-muriatic acid. Theſe ſubſtances will deprive it of all its impurities without acting on the ſulphur itſelf, at leaſt if the proper cautions be attended to. The ſulphur may then be dried and weighed. The deficiency in weight will mark the quantity of the ſubſtances which contaminate the ſulphur. The ſolutions may be evaporated and examined, according to the rules laid down in the ſecond and fourth ſections of this chapter.

SECT. IV. *Of the Analyſis of Ores.*

321 No general method of analyſing ores.

THE method of analyſing ores muſt vary conſiderably, according to the metals which they are ſuſpected to contain. A general method, therefore, of analyſing would be of no uſe, even if it could be given, becauſe it would be too complicated ever to be practiſed. We ſhall content ourſelves with exhibiting a ſufficient number of the analyſes of ores, to take in moſt of the caſes which can occur. He who wiſhes for more information on the ſubject, may conſult the treatiſe of Bergman on the *Analyſes of Ores*; Mr Kirwan's treatiſe on the ſame ſubject; and, above all, he ought to ſtudy the numerous analyſes of ores which have been publiſhed by Mr Klaproth.

I. Analyſis of Red Silver Ore.

322 Method of analyſing red ſilver ore.

Mr Vauquelin analyſed this ore as follows:

He reduced 100 parts of it to fine powder, poured over it 500 parts of nitric acid previouſly diluted with water, and applied a gentle heat to the mixture. The colour of the powder, which before the mixture with nitric acid was a deep purple, became gradually lighter, till at laſt it was pure white. During this change no nitrous gas was extricated; hence he concluded, that the metals in the ore were in the ſtate of oxyds.

When the nitric acid, even though boiled gently, did not appear to be capable of diſſolving any more of the powder, it was decanted off, and the reſiduum, after being carefully waſhed, weighed 42.06.

Upon theſe 42.06 parts concentrated muriatic acid was poured; and by the application of heat, a conſiderable portion was diſſolved. The reſiduum was repeatedly waſhed with muriatic acid, and then dried. Its weight was 14.6666. One portion of theſe 14.6666 parts, when thrown upon burning coals, burnt with a blue flame and ſulphureous ſmell. Another portion ſublimed in a cloſe veſſel without leaving any reſiduum. In ſhort, they had all the properties of ſulphur. Therefore 100 parts of red ſilver ore contain 14.6666 of ſulphur.

The muriatic acid ſolution was now diluted with a great quantity of water; it became milky, and depoſited a white flaky powder, which when waſhed and dried weighed 21.25. This powder, when heated with tartar in a crucible, was converted into a bluiſh white brittle metal, of a foliated texture, and poſſeſſing all the other properties of antimony. Red ſilver ore therefore contains 21.25 of oxyd of antimony.

The ſolution in nitric acid remained now to be examined. When muriatic acid was poured into it, a copious white precipitate appeared, which, when waſhed and dried, weighed 72.66. It had all the properties of muriat of ſilver. According to Mr Kirwan's tables, 72.66 of muriat of ſilver contain 60.57 of oxyd of ſilver. Therefore red ſilver ore, according to this analyſis, is compoſed of

60.57 oxyd of ſilver,
21.25 oxyd of antimony,
14.66 ſulphur.
96.48

---

* em. Sç E- trc xi. 62

† acquer's D onary, 2 dit. p. 1.

‡ inera- lo ii. 5

The loſs, which amounts to 3.52 parts, is to be aſcribed to unavoidable errors which attend ſuch experiments.

II. Antimoniated Silver Ore.

323 Analyſis of antimoniated ſilver ore. Klaproth analyſed this ore as follows:

On 100 parts of the ore, reduced to a fine powder, he poured diluted nitric acid, raiſed the mixture to a boiling heat, and after pouring off the acid, added new quantities repeatedly, till it would diſſolve nothing more. The reſiduum was of a greyiſh yellow colour, and weighed, when dry, 26.

Theſe 26 parts he digeſted in a mixture of nitric and muriatic acid; part was diſſolved, and part ſtill remained in the form of a powder. This reſiduum, when waſhed and dried, weighed 13 parts. It had the properties of ſulphur; and when burnt, left a reſiduum of one part, which had the properties of ſilica. Antimoniated ſilver ore, therefore, contains, in the 100 parts, 12 parts of ſulphur and 1 of ſilica.

When the nitro-muriatic ſolution was diluted with about 20 times its weight of water, a white precipitate appeared; which, when heated to redneſs, became yellow. Its weight was 13. No part evaporated at a red heat: therefore it contained no arſenic. On burning coals, eſpecially when ſoda was added, part was reduced to a metal, having the properties of antimony; and in a pretty high heat, the whole evaporated in a grey ſmoke. Theſe 13 parts were therefore oxyd of antimony: They contain about 10 parts of metallic antimony; and as the ſtate of oxyd was produced by the action of the nitric acid, we may conclude, that antimoniated ſilver ore contains 10 parts of antimony.

The nitric acid ſolution remained ſtill to be examined. It was of a green colour. When a ſolution of common ſalt was poured in, a white precipitate was obtained, which poſſeſſed the properties of muriat of ſilver. When dried, it weighed 87.75 parts; and when reduced, 65.81 parts of pure ſilver were obtained from it. Antimoniated ſilver ore, therefore, contains 65.81 of ſilver.

Into the nitric acid ſolution, thus deprived of the ſilver, he dropped a little of the ſolution of ſulphat of ſoda; but no precipitate appeared. Therefore it contained no lead.

He ſuperſaturated it with pure ammonia, on which a grey precipitate appeared. When dried, it weighed 5 parts. This, on burning coals, gave out an arſenical ſmell. It was rediſſolved in nitric acid; ſulphurated alkali occaſioned a ſmutty brown precipitate; and pruſſic alkali a pruſſian blue, which, after torrefaction, was magnetic. Hence he concluded, that theſe 5 parts were a combination of iron and arſenic acid.

The nitric ſolution, which had been ſuperſaturated with ammonia, was blue; he therefore ſuſpected that it contained copper. To diſcover this, he ſaturated it with ſulphuric acid, and put into it a poliſhed plate of iron. The quantity of copper was ſo ſmall, that none could be collected on the iron.

III. Grey Copper Ore.

324 Analyſis of grey copper ore. Klaproth analyſed this ore as follows:

Three hundred grains of it, not completely freed from its matrix, were reduced to a fine powder; four times their weight of nitric acid was poured on them, and the whole was digeſted. The acid was then poured off, and an equal quantity again digeſted on the reſiduum. The two acid ſolutions were mixed together. The reſiduum was of a yellowiſh grey colour, and weighed 188 grains.

On this reſiduum ſix times its weight of muriatic acid was boiled. The reſiduum was waſhed, firſt with muriatic acid, and afterwards with alcohol, and the waſhings added to the muriatic acid ſolution. The reſiduum, when dried, weighed 105.5 grains. Part of it burned with a blue flame; and was therefore ſulphur. The reſiduum amounted to 80.25 grains, and had the properties of ſilica. When melted with black flux, about $\frac{3}{4}$ths of a grain of ſilver were obtained from it. Thus 300 parts of grey copper ore contain 25.25 gr. of ſulphur, and 79.5 of ſilica.

The muriatic acid ſolution, which was of a light yellow colour, was concentrated by diſtillation, a few cryſtals of muriat of ſilver appeared in it, which contained about $\frac{1}{4}$th grain of ſilver. The ſolution, thus concentrated, was diluted with a great quantity of water; a white precipitate was depoſited, which, when dried, weighed 97.25 grains. It poſſeſſed the properties of oxyd of antimony, and contained 75 grains of antimony. Therefore 300 grains of grey copper ore contain 70 of antimony.

The nitric acid ſolution was of a clear green colour. A ſolution of common ſalt occaſioned a white precipitate, which was muriat of ſilver, and from which 31.5 grains of ſilver were obtained.

A little ſulphat of potaſs, and afterwards ſulphuric acid, were added, to ſee whether the ſolution contained lead; but no precipitate appeared.

The ſolution was then ſuperſaturated with ammonia; a looſe fleaky browniſh red precipitate appeared, which, when heated to redneſs, became browniſh black, and weighed $9\frac{1}{4}$th grains. This precipitate was diſſolved in muriatic acid; half a grain of matter remained undiſſolved, which was ſilica. The muriatic acid ſolution, when pruſſic alkali was added, afforded a blue precipitate; and ſoda afterwards precipitated 1.5 grains of alumina. Therefore 300 grains of grey copper ore contain 7.25 grains of iron, and 1.5 of alumina.

Into the nitric ſolution ſuperſaturated with ammonia, and which was of an azure blue colour, a poliſhed plate of iron was put: By this method 69 grains of copper were obtained.

IV. Sulphuret of Tin.

325 Analyſis of ſulphuret of tin. Klaproth analyſed this ore as follows*:

On 120 grains of the ore reduced to powder, ſix times their weight of nitro muriatic acid, compoſed of 2 parts of muriatic, and 1 of nitric acid, were poured. There remained undiſſolved 43 grains, which had the appearance of ſulphur; but containing green ſpots, was ſuſpected not to be pure. After a gentle combuſtion, 13 grains remained; 8 of which were diſſolved in nitro-muriatic acid, and added to the firſt ſolution. The remaining 5 were ſeparated by the filtre, and heated along with wax. By this method about a grain of matter was obtained, which was attracted by the magnet; and which therefore was iron. The reſiduum weighed 3 grains, and was a mixture of alumina and ſilica. Thus 120 grains of ſulphuret of tin contain 30 grains of ſulphur, 1 of iron, and 3 of alumina and ſilica.

---

* *Obſervations on the Foſſils of Cornwall*, p. 48.

The nitro-muriatic ſolution was completely precipitated by potaſs. The precipitate was of a greyiſh green colour. It was waſhed and dried, and again diſſolved in diluted muriatic acid. Into the ſolution a cylinder of pure tin was put, which weighed exactly 217 grains. The ſolution became gradually colourleſs, and a quantity of copper precipitated on the cylinder of tin, which weighed 44 grains. To ſee whether it was pure, a quantity of nitric acid was digeſted on it; the whole was diſſolved, except one grain of tin. Therefore 120 grains of ſulphuret of tin contains 43 grains of copper.

The cylinder of tin now weighed only 128 grains; ſo that 89 grains had been diſſolved. Into the ſolution a cylinder of zinc was put; upon which a quantity of tin precipitated. When waſhed and dried, it weighed 130 grains. The tin he melted with tallow and powdered charcoal; and when cold, he waſhed off the charcoal. Among the tin globules were found ſome black flocculi of iron, which weighed one grain. Deducting this grain, and the 89 grains of the tin cylinder which had been diſſolved, we ſee that the 120 grains of ſulphuret of tin contained 40 grains of tin beſides the grain which had been detected in the copper.

V. Plumbiferous Antimoniated Silver Ore.

6
A ſis of pl bife- ro nti- m ated ſil ore.

Klaproth analyſed this ore as follows:

He digeſted 400 grains of it, reduced to a fine powder, firſt in five times its weight of nitric acid, and then in twice its weight of the ſame acid. He then diluted this laſt portion of acid with eight times its weight of water, and continued the digeſtion. The undiſſolved reſiduum, when waſhed and dried, weighed 326 grains.

On this reſiduum he boiled muriatic acid repeatedly. The ſolution, on cooling, depoſited acicular cryſtals. Theſe he carefully ſeparated, and put by. The undiſſolved reſiduum weighed 51 grains. It had the properties of ſulphur. When burned, it left one grain of ſilica.

The muriatic acid ſolution was concentrated to half its former bulk by diſtillation: this made it depoſite more acicular cryſtals. He continued the diſtillation as long as any cryſtals continued to appear. He then collected the whole of theſe cryſtals together. They had the properties of muriat of lead. When mixed with twice their weight of black flux, and heated in a crucible lined with charcoal, they yielded 160$\frac{1}{8}$ grains of lead.

Sulphuret of ammonia was now added to the muriatic acid ſolution; an orange-coloured precipitate appeared, which ſhewed that the ſolution contained antimony. It was precipitated by a copious effuſion of water, and by ſoda. The oxyd of antimony being reduced to a maſs with Spaniſh ſoap, mixed with black flux, and heated in a lined crucible, yielded 28.5 grains of antimony.

Into the nitric acid ſolution, obtained by the firſt part of the proceſs, a ſolution of muriat of ſoda was dropped; a white precipitate was depoſited, and over it acicular cryſtals. Theſe cryſtals he diſſolved, by pouring boiling water on the precipitate. The water was added to the nitric acid ſolution. The white precipitate was muriat of ſilver: when heated with twice its weight of ſoda, it yielded 81.5 grains of ſilver.

He now concentrated the nitric acid ſolution by evaporation; and then adding a ſolution of ſulphat of ſoda, a white precipitate was obtained, which had the properties of ſulphat of lead, and weighed 43 grains. It contained 32 grains of pure lead.

He now poured ammonia into the ſolution; a pale brown precipitate was obtained, which weighed 40 grains, and which appeared to conſiſt of oxyd of iron and alumina. He rediſſolved it in nitric acid, precipitated the iron by pruſſic alkali, and the alumina by ſoda. The alumina, after being heated to redneſs, weighed 28 grains; conſequently the oxyd of iron was 12 grains, which is equivalent to 9 grains of iron.

VI. Molybdat of Lead.

327
Analyſis of molybdat of lead.

Mr Hatchett analyſed this ore as follows †:

On 250 grains of the ore, reduced to a fine powder, he poured an ounce of ſtrong ſulphuric acid, and digeſted the mixture in a ſtrong heat for an hour. When the ſolution was cool, and had ſettled, he decanted it off, and waſhed the undiſſolved powder with pure water, till it came away taſteleſs. This operation was repeated twice more; ſo that three ounces of ſulphuric acid were uſed All theſe ſolutions were mixed together, and filtered.

Four ounces of a ſolution of carbonat of ſoda were poured upon the powder which remained undiſſolved, and which conſiſted of ſulphat of lead. The mixture was boiled for an hour, and then poured off. The powder was then waſhed, and diluted nitric acid poured on it: The whole was diſſolved, except a little white powder, which, when waſhed, and dried on a filter by the heat of boiling water, weighed ſeven-tenths of a grain. It poſſeſſed the properties of ſilica.

The nitric acid ſolution was ſaturated with pure ſoda; a white precipitate was obtained, which, when waſhed, and dried for an hour in a heat rather below redneſs, weighed 146 grains. It poſſeſſed the properties of oxyd of lead.

To ſee whether this oxyd of lead contained any iron, it was diſſolved in diluted nitric acid, and the lead precipitated by ſulphuric acid. The ſolution was then ſaturated with ammonia; a brown powder precipitated, which, when dried, weighed one grain, and had the properties of oxyd of iron.

The ſulphuric acid ſolution was of a pale blue colour: It was diluted with 16 times its weight of pure water, and then ſaturated with ammonia. It became of a deep blue colour, and appeared turbid. In 24 hours a pale yellow precipitate ſubſided, which, when collected on a filter, and dried by a boiling water heat, weighed 4.2 grains. Its colour was yellowiſh brown. Muriatic acid diſſolved it, and pruſſiat of potaſs precipitated it from its ſolution in the ſtate of pruſſian blue. It was therefore oxyd of iron.

The ſulphuric acid ſolution, ſaturated with ammonia, was gradually evaporated to a dry ſalt. This ſalt was a mixture of molybdat of ammonia and ſulphat of ammonia. A ſtrong heat was applied, and the diſtillation continued till the whole of the ſulphat of ammonia was driven off; and to be certain that this was the caſe, the fire was raiſed till the retort became red hot. The reſiduum in the retort was a black bliſtered maſs; three ounces of nitric acid, diluted with water, were poured upon it, and diſtilled off. The operation was again repeated.

---

† *Phil. Tranſ* lxxxvi. 320.

peated. By this method the oxyd of molybdenum was converted into a yellow powder, which was yellow acid of molybdenum. It weighed 95 grains.

VII. Grey Ore of Manganeſe.

328 Analyſis of grey ore of manganeſe.

Mr Vauquelin analyſed this ore as follows ‡ :

When 200 grains of it were expoſed to a ſtrong heat in a retort, there came over 10 grains of water, and 18 cubic inches of oxygen gas, mixed with a little carbonic acid gas. The mineral now weighed only 176 grains. Therefore the weight of the gas was 14 grains.

On 200 grains of the ſame mineral muriatic acid was poured, and heat applied. 75 cubic inches of oxy muriatic acid gas came over, which, though mixed with ſome carbonic acid gas, enflamed metals when reduced to powder. When no more gas came over, the reſiduum was boiled. The whole was diſſolved, except a white powder, which weighed 12 grains, and which poſſeſſed the properties of ſilica.

Carbonat of potaſs was poured into the ſolution ; a white precipitate was obtained, which became black by expoſure to the air, and weighed 288 grains. Strong nitric acid was boiled on it repeatedly to dryneſs. It became of a deep black colour, and, when well waſhed with water and dried, weighed 164 grains. This powder was black oxyd of manganeſe.

To ſee whether it contained iron, nitric acid, with a little ſugar, was poured upon it, and digeſted on it. The acid diſſolved it completely. Therefore no oxyd of iron was preſent.

Into the water with which the black oxyd of manganeſe had been waſhed, carbonat of potaſs was poured ; a white powder precipitated, which, when dried, weighed 149 grains, and which poſſeſſed the poperties of carbonat of lime.

VIII. Wolfram.

329 Analyſis of wolfram.

Meſſrs Vauquelin and Hecht analyſed this mineral as follows :

On 200 parts of Wolfram in powder, three times its weight of muriatic acid were poured, and the mixture boiled for a quarter of an hour : a yellow powder appeared, and the ſolution was of a brown colour. The acid was allowed to cool, and then carefully decanted off, and the reſiduum waſhed. The reſiduum was then digeſted for ſome hours with ammonia, which diſſolved a part of it. The reſiduum was waſhed, and new muriatic acid again poured over it ; then the reſiduum was digeſted with ammonia, as before : and the operation was continued till the whole wolfram was diſſolved.

All the ammoniacal ſolutions being joined together, were evaporated to dryneſs, and the ſalt which remained was calcined : a yellow powder was obtained ; it weighed 134 grains, and was yellow acid of tungſten.

Into the muriatic acid ſolutions, which were all mixed together, a ſufficient quantity of ſulphuric acid was poured to decompoſe all the ſalts. The ſolution was then evaporated to dryneſs ; and the ſalts which were obtained by this evaporation were rediſſolved in water. A white powder remained, which weighed three grains, and which poſſeſſed the properties of ſilica.

The exceſs of acid of the ſolution was ſaturated with carbonat of potaſs ; the liquor became brown, but nothing precipitated. When boiled, a red powder precipitated, and the brown colour diſappeared. The addition of more carbonat of potaſs cauſed a farther precipitation of a yellowiſh powder. This precipitate conſiſted of the oxyds of iron and manganeſe combined. Nitric acid was diſtilled off it repeatedly ; it was then boiled in acetous acid. The acetous ſolution was precipitated by potaſs. Nitric acid was again diſtilled off it, and it was again boiled in acetous acid. This proceſs was repeated till nitric acid produced no further change. The different powders which could not be diſſolved in the acetous acid were collected, mixed with a little oil, and heated red hot. The powder became black, and was attracted by the magnet. It was therefore oxyd of iron. It weighed 36 grains.

The acetous ſolution contained the oxyd of manganeſe : It was precipitated by an alkali, and, when dried, weighed 12.5 grains.

IX. Oxyd of Titanium and Iron.

330 Analyſis oxyd of t tanium a iron.

Vauquelin analyſed this ore as follows :

A hundred parts of the ore, reduced to a fine powder, and mixed with 400 parts of potaſs, were melted in a ſilver crucible for an hour and a half. When cool, the mixture was diluted with water ; a powder remained of a brick red colour, which, when waſhed and dried, weighed 124 parts.

The watery ſolution had a fine green colour ; when an exceſs of muriatic acid was added, it became red. By evaporation the liquor loſt its colour. When evaporated to dryneſs, a ſalt remained, which was totally diſſolved by water. From this ſolution carbonat of potaſs precipitated two parts, which had the properties of oxyd of manganeſe.

The 124 parts of reſiduum were boiled in a ſolution of pure potaſs for an hour. The ſolution was ſaturated with an acid, filtered, and carbonat of potaſs added, which precipitated three parts. Theſe had the properties of oxyd of titanium.

The remainder of the 124 parts of reſiduum, which ſtill was undiſſolved, was boiled with diluted muriatic acid. The liquor became yellow, and depoſited 46 parts of a white powder, with a tint of red. This powder was ſoluble in ſulphuric and muriatic acids : from theſe ſolutions, it was precipitated of a brick red colour by the infuſion of nut galls ; of a green colour by ſulphuret of ammonia and pruſſiat of potaſs ; and of a white colour by carbonat of potaſs and pure ammonia. A rod of tin made theſe ſolutions red ; a rod of zinc made them violet. Theſe 46 parts, therefore, are oxyd of titanium.

The muriatic ſolution, from which theſe 46 parts were depoſited, formed, with pruſſiat of potaſs, a pruſſian blue ; and ammonia precipitated from it 50 parts, which had the properties of yellow oxyd of iron.

‡ Jour. de Min N° xvii. p. 12.

INDEX.

Mirabeau.

MIRABEAU (Honnoré Gabriel, Comte de), well known both by his writings, and the active part which he took in bringing about the French revolution, was born in 1749 of a noble family. Throughout life, he diſplayed a ſpirit averſe from every reſtraint, and was one of thoſe unhappy geniuſes in whom the moſt brilliant talents ſerve only as a ſcourge to themſelves and all around them. It is told by his democratical panegyriſts, as a wonderful proof of family tyranny under the old government, that not leſs than 67 *lettres de cachet* had been obtained by Mirabeau the father againſt this ſon and others of his relatives. This ſtory, if true, proves, with at leaſt equal force, what many anecdotes confirm, that, for his ſhare of them, the ſon was not leſs indebted to his own ungovernable diſpoſition than to the ſeverity of his parent. He was indeed a monſter of wickedneſs. Debauchery, gaming, impiety, and every kind of ſenſuality, were not enough for him. He was deſtitute of decency in his vices; and to ſupply his expences, ſcrupled not to perform tricks which would diſgrace a thief-catcher. His father and mother diſagreeing, commenced a proceſs of ſeparation; when Mirabeau, juſt liberated from priſon for a groſs miſdemeanor, was in want of money. He went to his father, ſided with him againſt his mother, on whom he poured a torrent of invectives; and, for 100 guineas, wrote his father's memorial for the court. He then went to his mother; and by a ſimilar conduct got the ſame ſum from her; and both memorials were preſented. That the father of ſuch a man ſhould frequently get him ſhut up in priſon, can excite no ſurpriſe; for confinement only could withhold him from the perpetration of crimes.

The talents of Mirabeau led him frequently to employ his pen; and his publications form the chief epochas of his life. His firſt publication was, 1. *Eſſai ſur le Deſpotiſme*, "An Eſſay on Deſpotiſm," in 8vo. Next, in one of his confinements, he wrote, 2. a work in 2 vols 8vo, *On Lettres de Cachet*. 3. *Conſiderations ſur l'Ordre de Cincinnatus*, 8vo. A remonſtrance againſt the order of Cincinnatus, propoſed at one time to be eſtabliſhed in America. The public opinion in America favoured this remonſtrance, and it proved effectual. 4. His next work was in favour of the Dutch, when Joſeph II. demanded the opening of the Scheldt, in behalf of the Brabançons. It is entitled, *Doutes ſur la Liberté de l'Eſcaut*, 8vo. 5. *Lettre à l'Empereur Joſeph II. ſur ſon Réglement concernant l'Emigration*; a pamphlet of forty pages, in 8vo. 6. *De la Caiſſe d'Eſcompte*; a volume in 8vo, written againſt that eſtabliſhment. 7. *De la Banque d'Eſpagne*, 8vo; a remonſtrance againſt eſtabliſhing a French bank in Spain. A controverſy

controverſy ariſing upon this ſubject, he wrote again upon it. 8. Two pamphlets on the monopoly of the water company in Paris.

Soon after the publication of theſe works, he was ſent in a public character to the court of Berlin; where he conducted the king's affairs juſt as he had formerly done thoſe of his father and mother, fully ready to ſacrifice all parties, and to ſell himſelf to the higheſt bidder. With ſuch a diſpoſition, he could not long avoid the notice of the Pruſſian illuminees; and Nicolai Bieſter, Gedicke, and Leuchſenring, ſoon became his conſtant companions. At Brunſwick he met with Mauvillon, the worthy diſciple of Philo Knigge, and at that time a profeſſor in the Caroline college. This was the man who initiated the profligate Marquis in the laſt myſteries of illuminiſm.

Mirabeau was ſtill at Berlin when Frederick II. died. That monarch, as is well known, was a naturaliſt, who, holding this life for his all, encouraged the propagation of infidelity in his dominions, from which reſulted the very worſt conſequences to the peace of ſociety. Of this truth his ſucceſſor Frederick William was duly ſenſible; and determined to ſupport the church eſtabliſhment in the moſt peremptory manner, conſiſtent with the principles of religious toleration. He publiſhed, therefore, ſoon after his acceſſion, an edict on religion, which is a model worthy of imitation in every country; but it was attacked with the greateſt virulence in numberleſs publications. It was called an unjuſtifiable tyranny over the conſciences of men; the dogmas ſupported by it were termed abſurd ſuperſtitions; the king's private character and his religious opinions were ridiculed and ſcandalouſly abuſed. The moſt daring of theſe attacks was a collection of anonymous letters on the conſtitution of the Pruſſian ſtates, univerſally believed to be the compoſition of Mirabeau, who certainly wrote a French tranſlation, with a preface and notes more impudent than the work itſelf. The monarch is declared to be a tyrant; the people of the Pruſſian dominions are addreſſed as a parcel of tame wretches, crouching under oppreſſion; and the inhabitants of Sileſia, repreſented as ſtill in a worſe condition, are repeatedly called upon to rouſe themſelves, and aſſert their rights.

About this time he publiſhed, 9 An *Eſſai ſur le Secte des Illuminés;* one of the ſtrangeſt and moſt impudent books that ever appeared. In it he deſcribes a ſect exiſting in Germany, called the *Illuminated;* and ſays, that they are the moſt abſurd and groſs fanatics imaginable, waging war with every appearance of reaſon, and maintaining the moſt *ridiculous ſuperſtitions.* He gives ſome account of theſe, and of their rituals and ceremonies, as if he had ſeen them all; yet no ſuch ſociety as he deſcribes ever exiſted: and Mirabeau employed his powers of deception, merely to ſcreen from obſervation the real *illuminati*, by holding out to the rulers of ſtates this *ignis fatuus* of his own brain. For a while the eſſay certainly contributed to blind the eyes of the German princes; and Nicolai. with others of the junto, adopting the whim, called Mirabeau's fanatics *Obſcuranten*, and joined with him in placing on the liſt of *Obſcuranten* ſeveral perſons whom they wiſhed to make ridiculous.

Long before his initiation in the myſteries of illuminiſm, Mirabeau had been acquainted with all the revolutionary powers of the maſonic lodges; nor did he, when initiated, undervalue thoſe which flowed, or might flow, from Weiſhaupt's inventive genius. On his return to France, he began to introduce the new myſteries among ſome of his maſonic brethren. His firſt aſſociate was the Abbé Talleyrand de Perigord, who had already begun to act the part of Judas in the firſt order of the church. But to have only introduced the myſteries was not ſufficient for the Marquis; he would have teachers come from Germany, who were better verſed than he was in the illuminizing arts. Well acquainted with the reaſons that had induced the chiefs of the order to defer the converſion of France, he found means to convince them, that the time was now come for the accompliſhment of their views; and at his requeſt a deputation was ſent by Spartacus to illuminize that great kingdom. See Illuminati, n° 40, 41, *Suppl.*

When the aſſembly of Notables was convened at Paris, Mirabeau foretold that it would ſoon be followed by a meeting of the States; and at that period he publiſhed a volume againſt the ſtockjobbing, then carried to a great height, intitled, 10. *Denonciation de l'agiotage au Roi, et a l'Aſſemblée de Notables*, 8vo. A *lettre de cachet* was iſſued againſt him in conſequence of this publication; but he eluded purſuit, and publiſhed a pamphlet as a ſequel to the book. His next work was againſt M. Necker, 11. *Lettre á M. de Cretelle, ſur l'Adminiſtration de M. Necker*, a pamphlet in 8vo. 12. A volume, in 8vo. againſt the Stadtholderſhip: *Aux Bataves, ſur le Stadthouderat.* 13. *Obſervations ſur la maiſon de force appellé Bicetre*, an 8vo pamphlet. 14. Another tract, intitled, *Conſeils à un jeune Prince qui ſent la néceſſité de refaire ſon education.* 15. He now proceeded to a larger and more arduous work than any he had yet publiſhed, on the Pruſſian monarchy under Frederick the Great: *De la Monarchie Pruſſienne ſous Fréderic le Grand*, 4 vols, 4to, or eight in 8vo. In this work, he undertakes to define preciſely how a monarchy ſhould be conſtituted. When the orders were iſſued for convening the States-general, Mirabeau returned into Provence; and at the ſame time publiſhed, 16. *Hiſtoire Secrette de la Cour de Berlin*, two volumes of letters on the Secret Hiſtory of the Court of Berlin. This work was condemned by the parliament of Paris, for the unreſerved manner in which it delivered the characters of many foreign princes. As the elections proceeded, he offered himſelf a candidate in his own order at Aix; but he was ſo abhorred by the nobleſſe, that they not only rejected him, but even drove him from their preſence. This affront ſettled his meaſures, and he determined on their ruin. He went to the commons, diſclaimed his being a gentleman, ſet up a little ſhop in the market-place of Aix, where he ſold trifles; and now, fully reſolved what line he ſhould purſue, he courted the commons, by joining in all their exceſſes againſt the nobleſſe, and was at laſt returned a member of the aſſembly.

In conſequence of this, he went to Paris; where the part he took was active, and ſuch as tended, in general, to accelerate all the violences of the revolution. He now publiſhed, periodically, 17. his *Lettres à ſes Commettans*, Letters to his Conſtituents, which form, when collected, 5 vols, 8vo. It is ſuppoſed, that the fatal meaſure of the junction of the three orders into one national

tional aſſembly, was greatly promoted by theſe letters. The public events of theſe times, and the part taken in them by Mirabeau, are the ſubject of general hiſtory. He lived to ſee the conſtitution of 1789 eſtabliſhed, but not to ſee its conſequences—the deſtruction of the monarchy, the death of the king, and the ruin of all property! He was accuſed, as well as the duke of Orleans, of hiring the mob which attacked Verſailles on the 5th and 6th of October 1789; but with him was alſo acquitted by the tribunal of the Châtelet. The dominion of his eloquence in the National Aſſembly had long been abſolute, and, on the 29th of January 1791, he was elected preſident. At the latter end of March, in the ſame year, he was ſeized by a fever, and died on the 2d of April.

The talents of Mirabeau will not be doubted, though they were certainly rather brilliant than profound. To be noticed, and to lead, were the ſole objects of his ambition; and for the attainment of them, he took the ſide of the diſcontented, as the beſt field for his matchleſs eloquence. Yet there was no man more devoted to the principles of a court than this Marquis, provided he could have a ſhare in the adminiſtration; and a ſhare he would have obtained, if any thing moderate would have ſatisfied him: But he thought nothing worthy of him but a place of active truſt, and a high department; ſtations which all knew him not qualified to fill. Wanting knowledge of great things, he was learned only in the buſtling detail of intrigue, and would, at any time, have ſacrificed his deareſt friend, and the intereſts of his country, for an opportunity of exerciſing his brilliant eloquence, and indulging his propenſity to ſatire and lampoon. But the greateſt obſtacle to his advancement under the old government was the abject worthleſſneſs of his character. Drinking was the only vice in which he did not indulge; and from this he was reſtrained by his exhauſted conſtitution. To his brother, the Viſcount, who was frequently intoxicated, the Marquis one day ſaid, "How can you, brother, ſo expoſe yourſelf?" "What (replied the Viſcount)! how inſatiable are you? Nature has given you every vice; and having left me only this one, you grudge it me!"

MISTRAL, the name of a wind, which is mentioned in almoſt every account that we have of Provence, and which is remarkable for blowing almoſt the whole year from north weſt or weſt-north-weſt, in a climate where the wind ſhould be variable. It is ſaid to contribute to the ſalubrity of the air, by diſperſing the exhalations of the marſhes and ſtagnant waters, ſo common in the ſouth of Languedoc and Provence; but at times it is alſo very injurious, or at leaſt very troubleſome. It is not, however, on either of theſe accounts that it is introduced into this Work, but for the ſake of the cauſes aſſigned by Sauſſure for its conſtancy, which may be applied to other winds that nearly reſemble it; and which he found might be reduced to three.

"The firſt and moſt effectual cauſe (he ſays) is the ſituation of the Gulf of Lyons, the banks of which are the principal theatre of its ravages. This Gulf, in fact, is ſituated at the bottom of a funnel, formed by the Alps and Pyrenees. All the winds blowing from any point between weſt and north, are forced by theſe mountains to unite in the Gulf. Thus, winds which would not have prevailed but at one extremity of the Gulf, or even much beyond it, are obliged to take this route, after having undergone the repercuſſion of theſe mountains; and the middle of the Gulf, inſtead of the calm which it might have enjoyed, is expoſed to the united efforts of two ſtreams of wind, deſcending in different directions. Hence ariſe thoſe whirlwinds which ſeem to characteriſe the miſtral, and appear to have induced the ancients to call it *Circius, à turbine ejus ac vertigine*. See *Aul. Gellius*, l. ii. cap. 22.

"The ſecond cauſe is, the general ſlope of the grounds, deſcending from all ſides towards the Gulf; which becoming all at once lower and more ſoutherly than the lands extending behind it, is, from theſe joint circumſtances, rendered the hotteſt point of all the adjacent country: and, as the air on the ſurface of the earth always tends from the colder to the warmer regions, the Gulf of Lyons is actually the centre towards which the air from all colder points between eaſt and weſt muſt preſs. This cauſe, then, alone would be productive of winds directed to the Gulf, even if the repercuſſion of the mountains did not exert its influence.

"Finally, it is well known, that in all gulfs the land-winds blow more forcibly than oppoſite to plains and promontories, whatever be the ſituation of thoſe gulfs. I apprehend, indeed, on ſtrict examination (ſays our author), that this cauſe is blended with the preceding; but as the fact is generally admitted, and in ſome caſes can be explained only by reaſons drawn from the effects of heat, it may not improperly, perhaps, be diſtinctly mentioned. It is, at leaſt, neceſſary to ſuppoſe, that ſeveral cauſes produce the miſtral, in order to underſtand why, notwithſtanding the variableneſs of the ſeaſons and temperatures, that wind is ſo ſingularly conſtant in Lower Languedoc and Lower Provence. A very remarkable inſtance of this conſtancy is recorded by the Abbé Papon, in his *Voyage de Provence*, tom. ii. p. 81. He aſſerts, that during the years 1769 and 1770, the miſtral continued for fourteen months ſucceſſively. But the three cauſes which I have ſtated, taken ſeparately, will explain its frequency, and, united, will account for its force."

MIXT ANGLE, or *Figure*, is one contained by both right and curved lines

Mixt Number, is one that is partly an integer and partly a fraction; as $3\frac{1}{2}$.

Mixt Ratio, or *Proportion*, is when the ſum of the antecedent and conſequent is compared with the difference of the antecedent and conſequent;

$$\text{as if} \left\{ \begin{array}{l} 4 : 3 :: 12 : 9 \\ a : b :: c : d \end{array} \right.$$

$$\text{then} \left\{ \begin{array}{l} 7 : 1 :: 21 : 3 \\ a + b : a - b :: c + d : c - d. \end{array} \right.$$

MOCASSIMAH, in Bengal, revenue ſettled by a diviſion of the produce.

MOCHULKAH, bond or obligation.

MŒRIS, a lake in EGYPT, occaſionally mentioned in that article (*Encycl.*), and generally ſuppoſed the production of human art. Of this, however, Mr Brown ſays it bears no mark. "The ſhape, as far as was diſtinguiſhable, ſeems not inaccurately laid down in D'Anville's map, unleſs it be, that the end neareſt the Nile ſhould run more in a north-weſt and ſouth-eaſt direction. The length may probably be between 30 and 40 miles; the breadth, at the wideſt part he could gain, was 5000 toiſes, as taken with a ſextant; that is, nearly ſix miles. The utmoſt poſſible extent of circuit muſt of courſe be 30 leagues. On the north-eaſt and ſouth is a rocky ridge, in every appearance primeval. In ſhort, nothing can preſent an appearance more unlike the works of men. Several fiſhermen, in miſerable boats, are conſtantly employed on the lake. The water is brackiſh, like moſt bodies of water under the ſame circumſtances. It is, in the language of the country, *Birket-el-kerun*, probably from its extremities bearing ſome reſemblance to horns.

MOFUSSEL, a relative term, ſignifying the ſubordinate lands or diſtricts, oppoſed to Sudder, which is the head.

MOHACZ, Mohatz, or *Mohoz*, a town in the Lower Hungary, upon the Danube, between the river Sarwiza to the north, and the Drave to the ſouth; four German miles from either, ſix from Eſſeck to the north, and nine from Colocoa to the ſouth. This otherwiſe ſmall place is memorable for two great battles here fought; the firſt between Lewis king of Hungary and Solyman the Magnificent, in 1526: in which that unfortunate Prince Lewis (being about 20 years old), with 25,000 men, fought 300,000 Turks; when, being overpowered by numbers, 22,000 of the Chriſtian army were ſlain upon the place; 5000 waggons, eighty great cannon, 600 ſmall ones, with all their tents and baggage, were taken by the victors; and the King, in his flight over the brook Curaſs, fell into a quagmire, and was ſwallowed up. After which, Solyman took and ſlew 200,000 Hungarians, and got ſuch a footing in that kingdom, that he could never be expelled. This fatal battle was fought October 29. The ſecond, in ſome part, retrieves the loſs and infamy of the former. The Duke of Loraine being ſent by the Emperor, with expreſs orders to paſs the Drave and take Eſſeck, his highneſs, July 10, 1687, with great difficulty paſſed that river, then extremely ſwelled with rains; but finding the Prime Viſier encamped at Eſſeck, with an army of 100,000 men, ſo ſtrongly, that it was not poſſible to attack him in that poſt without the ruin of the Chriſtian army, he retreated, and repaſſed it the 23d of the ſame month; where, upon the 29th, the Prime Viſier paſſed that river at Eſſeck; and upon Auguſt 12th, there followed a bloody fight, in which the Turks loſt 100 pieces of cannon, 12 mortars, all their ammunition, proviſions, tents, baggage, and treaſure, and about 8000 men upon the place of battle, beſides what were drowned in paſſing the river, which could never be known. After which victory, General Dunewalt, September 30th, found Eſſeck totally deſerted by the Turks, and took poſſeſſion of it.

MOHER, in Bengal, a gold coin, worth about 33 ſhillings.

MOHERIR, a writer of accounts.

MOINEAU, a flat baſtion raiſed before a curtin when it is too long, and the baſtions of the angles too remote to be able to defend one another. Sometimes the moineau is joined to the curtin, and ſometimes it is divided from it by a moat. Here muſquetry are placed to fire each way.

MOLE (See Talpa, *Encycl.*), is an animal exceedingly troubleſome, both to gardeners and farmers; and there are perſons who contrive to make a livelihood by the trade of *mole-catching*. Theſe men, it is well known, are generally quacks and cheats; and the ſecrets which they ſell for extirpating thoſe deſtructive animals are of very little avail. Even poiſon ſeldom produces any conſiderable effect; becauſe the mole, while it does not drink, lives only on roots and worms. Under the word Mole (*Encycl.*), ſome directions will be found for clearing fields of this deſtructive animal; but the following are perhaps preferable, as they ſeem to have been the reſult of much experience:

Mole.

Immediately at day-break, it will be neceſſary to make a tour round the garden or meadow, from which it is wiſhed to extirpate the moles; for at that time they will be all found at work, as may be ſeen by the hills newly thrown up. If the perſon is then cloſe to the hill, he muſt proceed as the gardeners do, and turn up with a ſtroke of the ſpade the hill together with the digger. The paſſage is then cut through before the animal is aware of the attack; and therefore it has not power to eſcape. If the mole-hill be freſh, even though the animal may not be throwing up earth, the perſon ought not to loſe his time in waiting, but ſhould immediately proceed to the operation above-mentioned.

If you find a freſh hill ſtanding by itſelf, which ſeems to ſhew by its ſituation that it has no communication with any other, which is always the caſe when the mole has worked from the ſurface downwards in endeavouring to procure a more convenient habitation, after the hill has been turned up with the ſpade, a bucket of water ſhould be poured over the mouth of the paſſage. By theſe means the animal, which is at no great diſtance, will be obliged to come forth, and may be eaſily caught with the hand.

You may diſcover alſo whether a hill has any communication with another, if you apply your ear to it, and then cough or make a loud noiſe. If it has no communication with the neighbouring hills, you will hear the terrified animal make a noiſe by its motion. It will then be impoſſible for it to eſcape; and you may either pour water into the hole, or turn up the hill with a ſpade, until the mole is found; for, in general, it never goes deeper into the earth than from fifteen to eighteen inches.

When any of the beds in a garden have been newly watered, the mole, attracted by the coolneſs and moiſture, readily repairs thither, and takes up its reſidence in them, making a paſſage at the depth of ſcarcely an inch below the ſurface. In that caſe it may eaſily be caught. When you ſee it at work, you need only tread behind the animal with your feet on the paſſage to prevent its retreat, and then turn up the hill with a ſpade; by which means you will be ſure to catch it.

When you dig after it with a ſpade, the animal forces its way downwards into the earth in a perpendicular direction, in order that it may the better eſcape the threatened danger. In that caſe it will not be neceſſary to dig long, but to pour water over the place, which will ſoon make the animal return upwards.

People, in general, are not aware of the great miſchief occaſioned in fields and gardens by theſe animals. We are, however, informed by Buffon, that in the year 1740 he planted fifteen or ſixteen acres of land with acorns, and that the greater part of them were in a little time carried away by the moles to their ſubterranean retreats. In many of theſe there were found half a buſhel, and in others a buſhel. Buffon, after this circumſtance, cauſed a great number of iron traps to be conſtructed; by which, in leſs than three weeks, he caught 1300. To this inſtance of the devaſtation occaſioned by theſe animals, we may add the following: In the year 1742 they were ſo numerous in ſome parts of Holland, that one farmer alone caught between five and ſix thouſand of them. The deſtruction occaſioned by theſe animals is, however, no new phenomenon. We are informed by hiſtory, that the inhabitants of the iſland of Tenedos, the Trojans, and the Æolians, were infeſted by them in the earlieſt ages. For this reaſon a temple was erected to Apollo Smynthius, the deſtroyer of moles. See *Economiſche Hefte*. Vol. VII. Part 5. and Vol IX. Part 4.; or *Phil. Magazine*, N° 5.

MOMENTS, in the new doctrine of infinites, denote the indefinitely ſmall parts of quantity; or they are the ſame with what are otherwiſe called infiniteſimals and differences, or increments and decrements; being the momentary increments or decrements of quantity conſidered as in a continual flux.

Moments are the generative principles of magnitude; they have no determined magnitude of their own, but are only inceptive of magnitude.

Hence, as it is the ſame thing if, inſtead of theſe moments, the velocities of their increaſes and decreaſes be made uſe of, or the finite quantities that are proportional to ſuch velocities; the method of proceeding which conſiders the motions, changes, or fluxions of quantities, is denominated by Sir Iſaac Newton, the *method of fluxions*.

Leibnitz, and moſt foreigners, conſidering theſe infinitely ſmall parts, or infiniteſimals, as the differences of two quantities, and thence endeavouring to find the differences of quantities, *i. e.* ſome moments, or quantities indefinitely ſmall, which taken an infinite number of times ſhall equal given quantities, call theſe moments differences; and the method of procedure, the differential calculus.

MONGEARTS, one of the tribes of wandering Arabs which inhabit the SAHARA, or Great Deſert of Africa. Their time is wholly occupied by tending their cattle; and becauſe they are little ſkilled in the uſe of arms, *Mongeart* is a term of contempt among the people by whom they are ſurrounded. Their country, with its produce, will be deſcribed under the title SAHARA in this *Supplement;* it is the buſineſs of this article merely to exhibit the manners of the people.

They are all Mahometans, and offer up prayers three times a-day, ſometimes oftener; but having no moſques, theſe prayers are never pronounced in public, except when the horde is viſited by a prieſt, who ſeldom comes but upon account of the childrens education. Then all the Arabs aſſemble at the hour of prayer, place themſelves in a line, turn to the eaſt, and, wanting water in the deſert, rub their face and arms with ſand; while the prieſt recites aloud the general prayer. It is the ſame as that which is rehearſed by the public crier in the moſques in civilized countries.

The prieſts are employed in travelling about the country to inſtruct the children. There is nothing like force in their education. The little boys meet in the morning of their own accord, at the place of inſtruction, which is to them a place of recreation. They go there with a ſmall board inſcribed with the Arabic characters, and a few maxims of the Koran. The oldeſt, and the beſt informed, receive their leſſons directly from the prieſts, and afterwards communicate them to their fellows. They are never corrected; becauſe it would be a crime to beat a child, who, according to the received notions, has not ſufficient reaſon to diſtinguiſh good from evil. This lenity extends even to the children of Chriſtians, though in a ſtate of ſlavery. They are treated in all reſpects like the children of Arabs; and the man who ſhould be raſh enough to ſtrike one of them, would endanger his life. Very different is their treatment of Negro children; who may indeed join in all the amuſements of the young Arabs, and even attend the public ſchools; but if they be guilty of a fault, they are ſeverely puniſhed.

When the child of a Mongeart becomes tired of the places of public inſtruction, he quits them at pleaſure, and, without feeling conſtraint, or hearing reproach, goes and employs himſelf in tending his father's flocks: and accordingly there are very few among them who can read. Thoſe who perſevere in the ſtudy of the Koran are made prieſts, after having paſt an examination before the learned elders, and enjoy the greateſt public conſideration. They have no need of cattle; for thoſe of the nation being theirs, they find their ſubſiſtence everywhere.

It is generally at ſeven or eight years of age that children undergo the painful operation of circumciſion. Their head is alſo ſhaved, nothing being left but four locks of hair; one of which is cut off in a meeting of the family, at each remarkable action performed by the child. If, at the age of 12 or 13, he kill a wild boar, or other beaſt of prey, that ſhould fall upon his flock, he loſes one of his locks. If, in the paſſage of a river, a camel be carried away by the ſtream, and he ſave it by ſwimming to its aſſiſtance, another is cut off. If he kill a lion, a tiger, or a warrior of an hoſtile nation, in a ſurpriſe or an attack, he is conſidered as a man, and his head is entirely ſhaved.

Different from the other Arabs their neighbours, and indeed from the Mahometans in general, the Mongearts trouble no man on account of his religion. The only one which they do not tolerate is the Jewiſh; and were a Jew to enter their territory, and have the miſfortune to be taken, he would certainly be burnt alive.

According to M. Saugnier, the women are much more reſpected among the Mongearts than among the neighbouring nations; but the evidences which he gives of that reſpect are very extraordinary.

When a Mongeart is deſirous of undertaking the care of a family, he pitches upon the girl that pleaſes him the moſt, and aſks her of her father without further formality; nor can the latter refuſe her, unleſs the man who pretends to her hand have done ſomething contrary to the laws of the nation. The girl is conducted by her parents to the tent of her future huſband, where there is always an abundant repaſt prepared for the ceremony. Preſents are made to the father; but if the ſon-in law be poor, his wife's family aſſiſt him, and furniſh him with the means of increaſing his flocks; if, on the contrary, he be rich, and the father poor, he ſupports the whole family in his own tent. The employment of the wife, thus married, is to prepare the food; to ſpin the goats and camels hair, of which the tents are made; to milk the cattle; to pick up the neceſſary ſupply of wood for the night; and when the hour of repaſt is come, to wait upon her huſband. She then eats by herſelf what has been left by him and his male ſlaves. She is, indeed, in no great danger of having a rival brought into the family; for though polygamy be allowed by his religion, the poverty of the Mongeart generally prevents him from taking a plurality of wives. She is, however, liable to be divorced at will when ſhe does not bear boys; but if ſhe have the good fortune to have one or more male children, her huſband's regard for her is inconceivable. She has no longer a divorce to fear, has an abſolute authority in the tent, and paſſes her whole time in converſation, ſleep, or dancing, as ſhe thinks fit. The captive negreſſes do all her work, and are no longer aſſiſted in their labour by the Arab's wife, who treats them, on the contrary, with the greateſt harſhneſs and arrogance.

When a woman is not agreeable to her huſband, or when he is diſagreeable to her, they have it in their power to part. The formality in this caſe conſiſts in the wife's retiring to her parents. If the huſband be attached to her, he goes thither in queſt of her; but if ſhe perſiſt in refuſing to return, ſhe is free, and at liberty to marry another. If, however, ſhe have had a child, eſpecially a boy, ſhe has not the ſame privilege; in that caſe, if her retreat ſhould laſt more than eight days, it might be puniſhed with death.

When a man beats his wife, it is a ſure ſign that he is ſincerely attached to her, and that he does not mean to part with her; if he content himſelf with reproaches, the wife thinks herſelf deſpiſed, and infallibly retires to her parents. Hence it is, that in the moſt trifling diſputes the women are cruelly beaten: they prefer it to the complaints that the huſband might make to their parents; this proof being the moſt certain one of a man's fondneſs for his wife. When a girl marries, ſhe makes up her mind to ſuch treatment, deeming it much more ſupportable than the humiliations ſhe would otherwiſe experience from her family, in conſequence of her huſband's complaints.

The conjugal fidelity of the Mongeart women is incorruptible. Differing in their opinions from many other Mahometans, they believe themſelves immortal like the men; but they do not flatter themſelves with the poſſibility of happineſs in the other world, unleſs they ſhall have been faithful to their huſbands in this. Women, who have been falſe to their huſband's bed, will be doomed, they think, to eternal ſlavery to the more virtuous part of their ſex, without ever partaking, in the ſmalleſt degree, of their bliſs.

Mongeart women often viſit one another; and on theſe occaſions, the honour conſiſts in letting the female who comes to ſee her friend or relation do all the work of the tent. The viſitor aſſumes the management of every thing, dreſſes the victuals, churns the butter, and keeps herſelf continually employed; while her friend entertains her with an account of the different affairs of the family or nation. The heartineſs of the welcome is meaſured by the extent of the work ſubmitted to the gueſt, who generally prepares double the uſual quantity of food; ſo that the Arab is obliged to invite his neighbours to partake of the repaſt. The ſlaves are always pleaſed with theſe entertainments, a larger portion then coming to their lot. It is the buſineſs of the viſitor to do the honours; nor will ſhe ſuffer any body about her to remain diſſatisfied.

The laws of hoſpitality are obſerved among the Mongearts as among all the wandering Arabs. Indeed they are carried to ſuch a length, that were a man to enter the tent of him whom he had wounded, or even killed, he would there meet with a ſacred and inviolable aſylum, although ſurrounded by thoſe who muſt naturally deſire his ruin. The tent of the chief is always that to which ſtrangers, upon their arrival in the horde, are directed. But the chief could not entertain, at his own expence, all the ſtrangers that happen to paſs; and therefore every tent in the horde is obliged to furniſh him with two pounds of ground barley *per* week, to enable him to maintain the ancient hoſpitality.

The chiefs of hordes are always the eldeſt of their families. The difference of wealth is not conſidered; the chief often having ſeveral individuals at his houſe richer than himſelf, who nevertheleſs obey him in every particular. He is, properly ſpeaking, their king: examines their difference with the old men, and judges without appeal. As to himſelf, he cannot be tried but by the chiefs of ſeveral hordes aſſembled. It is his buſineſs to determine the ſpots where the tents are to be pitched, the moment of departure, and the place where the caravan is to ſtop. If the paſturage do not ſuffice for the herds of all the horde, it divides, and the chief aſſigns the ground for the different encampments. They are very often compoſed of no more than ſeven or eight tents, according to the quality of the ground they meet with. The tent of the chief is always the largeſt and moſt lofty, and is placed in the centre of the diviſions. When it is determined upon to quit an encampment, which never happens till the paſture is exhauſted, the chief ſets off to chooſe another ſpot. In theſe removals the women alone do all the work. Early in the morning they fold up the tent, and load every thing upon the camels backs; they then move ſlowly on, that the cattle may have time to feed upon the way.

Great reſpect is paid by the Mongearts to all old men, who enjoy the ſame prerogatives as the prieſts, and ſuch Arabs as have viſited the tomb of Mahomet at Mecca. Together with the chief they are the judges of the horde, and take cognizance of all offences. the pain of death being the only puniſhment which they cannot decree. An aſſembly of ſeveral chiefs is the only tribunal which can inflict capital puniſhment; but as the accuſed has generally a number of friends, it ſeldom happens that he is capitally convicted.

A war between two Mongeart tribes ſeldom happens, and is never bloody; but the different families deſtroy one another faſt enough in their inteſtine broils. They are all thieves; and indeed theft is a crime only in the day time, being authoriſed by law during the night, in order to compel them to take care of their cattle. Could they find redreſs when robbed by night, they would be leſs vigilant; and their herds and flocks would be more expoſed to the wild beaſts that over-run their country; but being obliged to be on their guard even againſt their neareſt neighbours, they are always ready to repel both the lion and the tiger. Theft, even in the day-time, is ſo far from being puniſhed, unleſs detected at the inſtant of commiſſion, that when any thing is ſtolen unperceived, it becomes the lawful property of the thief. In vain would the rightful owner recognize it in his neighbour's tent; he cannot reclaim it; it ceaſes to be his from the moment he has been negligent in its care. Hence ariſes this peoples inclination for rapine:

they do not think they commit a crime, and only follow, in this regard, a cuſtom allowed by their laws.

When an Arab is going to market, or on his return from thence, if he do not take the greateſt care to keep his journey a ſecret, he is often attacked. Neighbouring Arabs are deſirous of profiting by his induſtry; and as there are no perſons in the country appointed to apprehend robbers, the hope of booty ſpurs them on to the attack. That they may have nothing to fear, they lie in wait, when the night is coming on, for him whom they mean to pillage. Their intention is never to kill; they only endeavour to ſurprize, to diſarm, and to make themſelves maſters of every thing that comes in their way. But it ſometimes happens, that the man they intend to plunder, being acquainted with the cuſtoms of his country, keeps an attentive ear, ſtands on his guard, fires upon his aſſailants at the firſt motion he obſerves, and then fights deſperately with his dagger. The report of the muſket almoſt always brings out the neighbouring Arabs, who, in virtue of the laws of hoſpitality, take the defence of the weaker ſide. They run up well armed; and then woe to the aggreſſors, if they do not ſave themſelves by a ſpeedy flight.

The flocks and herds of the Mongearts are compoſed of nothing but ſheep, goats, and camels; all animals patient of thirſt. Horſes are very ſcarce in theſe cantons, none but the poſſeſſors of numerous herds being able to keep them; becauſe, for want of water, it is neceſſary to have milk in ſufficient abundance to give it them to drink. Great care is taken to preſerve the camel's urine, both to mix with milk, and to waſh the different veſſels in which they put their food. Deteſtable as is this mixture of milk and urine, they are often reduced to the uſe of it; hunger and thirſt give a reliſh to every thing.

The only workmen uſeful to this nation are blackſmiths or goldſmiths, as they may be called indifferently. The Mongearts not being ſufficiently laborious to apply themſelves to ſuch occupations, theſe workmen come from Bilidulgerid, and diſperſe themſelves all over the different parts of the deſert. Wherever there are tents they are ſure to find work. They are fed for nothing, and receive beſides the hire for their labour. They make trinkets for the women, ſuch as ear-rings and bracelets, &c. mend the broken veſſels, by rivetting them, and clean the arms. They are generally paid in ſkins, goats and camels hair, or oſtrich feathers, according to their agreement. Thoſe who have ſilver pay them a tenth part of its weight for any thing wrought out of that metal. On their return they ſell what they have earned; four or five excurſions at moſt enabling them to live afterwards at their eaſe in their own country.

The Mongearts always carry a leathern bag, ſuſpended from their neck, in which they put their tinder, their pipe, and their tobacco. Their daggers are elegant; the hilt is always black, and inlaid with ivory; the blade is crooked, and ſharp on either ſide; the ſheath is of braſs on one ſide, and of ſilver on the other, and of very tolerable workmanſhip. They wear ſabres when they can get them, and prefer thoſe of Spaniſh make. Their muſkets are always highly ornamented; the ſtock is very ſmall, and inlaid on every ſide with ivory, and the barrel emboſſed with braſs or ſilver, according to the opulence of the owner. There is a ſpring to the lock, covering the priming, to prevent the piece from going off, contrary to the intention of him who carries it. The poor, who do not poſſeſs muſkets, wear daggers, made like the Flemiſh knives, with leathern ſheaths. They arm themſelves alſo with a thick ſtick, to the end of which they fix a kind of iron wedge. This weapon is exceedingly dangerous at cloſe quarters. Others carry *zagays*, or ſlender javelins. In a word, the principal riches of an Arab, and his higheſt gratifications, are a handſome muſket and a good dagger. He prefers them to neatneſs of apparel; for as to dreſs, it is indifferent to him whether he be clothed in Guinea blues, woollen ſtuffs, or goats ſkins. Their arms being their principal ornament, they take particular care to put the muſkets in leathern bags, by way of keeping them in good order, and preſerving them from the ruſt.

All the riches of the Mongearts conſiſt in their herds; and accordingly they take the greateſt care to preſerve them. If a beaſt be ſick, every thing is done to cure it; no care is ſpared; it is even treated with more attention than a man: but when it evidently appears that there is no hope of ſaving its life, they kill and eat it. If it be a camel, the neighbours are called in to partake of the repaſt; if a goat, the inhabitants of the tent ſuffice for its conſumption. An animal that dies without ſhedding blood is unclean. Its throat muſt be cut; the perſon who kills it turning to the eaſt, and pronouncing beforehand the firſt words of the general prayer. An animal killed by a wild boar is unclean; nor is it eaten although its blood has been ſhed, becauſe the wild boar is itſelf an unclean beaſt. That ſpecies is ſo numerous in the deſart, that they do more miſchief than all the other wild beaſts together. The Arabs kill as many as they can; but never taſte their fleſh.

Whatever loſſes an Arab may meet with, he is never heard to complain; he riſes ſuperior to poverty, ſupports hunger, thirſt, and fatigue, with patience, and his courage is proof againſt every event. God will have it ſo, ſays he: he employs, however, every means in his power to avert misfortune; and often expoſes himſelf to the greateſt dangers to procure matters of no real utility.

When a father of a family dies, all the effects in his tent are ſeized upon by the eldeſt ſon preſent at his deceaſe. Gold, ſilver, trinkets, every thing diſappears; and the abſent children have only an equal ſhare in the diviſion of the cattle and the ſlaves. The girls are entirely excluded from all participation, and take up their reſidence with their eldeſt brother. If the deceaſed leave children in helpleſs infancy, the mother takes them with her to her ſiſter's, if ſhe have a ſiſter married; if not, to her own maternal roof. The dead man's poſſeſſions, however, are not loſt; the chief of the horde takes care of them, and delivers them in equal portions to the heirs, as ſoon as they are old enough to manage their own property. If an Arab die without male children, his wife returns to her relations, and his brother inherits his effects.

The Mongearts have a rooted abhorrence of the Spaniards, and never fail to maſſacre every man of that nation who is ſo unfortunate as to be ſhipwrecked on their coaſts, while they reſerve the women for ſale at Morocco. The reaſon of this hatred is, that the inhabitants of the Canaries make frequent deſcents on the Mongeart coaſts, and carry off men, women, cattle, and every

every thing that they meet with ; and theſe people, being ignorant of the fate of their countrymen, retaliate by death on all Spaniards that fall into their hands, whilſt they treat the Britiſh and French as well as they can.

MONNIER (Peter Charles Le), was born at Paris on the 20th of November 1715 The profeſſion of his father, or the rank which he held in ſociety, we have not learned ; and we are equally ignorant of the mode in which he educated his ſon. All that we know is, that young Monnier, from his earlieſt years, devoted himſelf to the ſtudy of aſtronomy ; and that, when only ſixteen years of age, he made his firſt obſervation, viz. of the oppoſition of Saturn. At the age of twenty he was nominated a member of the Royal Academy of Sciences at Paris. In the year 1735 he accompanied Maupertuis in the celebrated expedition to Lapland, to meaſure a degree of latitude. In 1748 he went to Scotland with Lord Macclesfield, to obſerve the annular eclipſe of the ſun, which was moſt viſible in that country ; and he was the firſt aſtronomer who had the pleaſure to meaſure the diameter of the moon on the diſk of the ſun.

Louis XV. it is well known, was extremely fond of aſtronomy, and greatly honoured its profeſſors : he loved and eſteemed Le Monnier. I have ſeen the king himſelf (ſays Lalande) come out of his cabinet, and look around for Le Monnier ; and when his younger brother was preſented to him on his appointment to the office of firſt phyſician, his Majeſty was pleaſed to wiſh him the merit and reputation of his brother the aſtronomer. All the remarkable celeſtial phenomena were always obſerved by the king, in company with Le Monnier. Thus he obſerved with him, at his chateau of St Hubert, the two celebrated tranſits of Venus thro' the diſk of the ſun in the years 1761 and 1769; as appears from the Memoirs of the Royal Pariſian Academy of Sciences. It well deſerves to be here recorded in what manner the king behaved during theſe important obſervations, and how little he diſturbed his aſtronomers (the celebrated La Condamine being likewiſe permitted to obſerve the tranſit in his preſence) in this occupation ; the proper time for which, if permitted to paſs by, could not be recalled. Le Monnier relates in his Diſſertation, that "his Majeſty perceiving that we judged the laſt contacts to be of the greateſt importance, a profound ſilence at that moment reigned around us." At the tranſit of Venus in 1769, the king allowed the Marquis de Chabert, an intelligent and expert naval officer, who was juſt returned from a literary voyage to the Levant, to aſſiſt at the obſervation. In a court like that of Louis XV. ſo ſcrupulouſly obſervant of etiquette, theſe will be allowed to have been moſt diſtinguiſhed marks of honour, and of royal favour and condeſcenſion.

In the year 1750, Le Monnier was ordered to draw a meridian at the royal Chateau of Bellevue, where the king frequently made obſervations. The monarch on this occaſion rewarded him with a preſent of 15,000 livres; but Le Monnier applied this ſum of money likewiſe in a manner that redounded to the honour of his munificent ſovereign and of his country, by procuring new and accurate inſtruments, with which he afterwards made his beſt and moſt remarkable obſervations. In 1742, the king gave him in Paris *Reu de la Poſte*, a beautiful free dwelling, where, till the breaking out of the revolution, he reſided, and purſued his aſtronomical labours, and where his inſtruments in part yet remain. Some of them the preſent French government has, at the inſtance of Lalande, purchaſed for the National Obſervatory. In 1751, the king preſented him with a block of marble, eight feet in height, ſix feet in breadth, and fifteen inches in thickneſs, to be uſed for fixing his mural quadrant of five feet. This marble wall, together with the inſtruments appended to it, turns on a large braſs ball and ſocket, by which the quadrant may be directed from ſouth to north ; thus ſerving to rectify the large mural quadrant of eight feet, which is immoveably made faſt to a wall towards the ſouth.

With theſe quadrants Le Monnier obſerved, for the long period of forty years, the moon with unwearied perſeverance at all hours of the night. It is requiſite, to be a diligent aſtronomer, to be able to conceive to what numberleſs inconveniences the philoſopher is expoſed during an uninterrupted ſeries of lunar obſervations. As the moon during a revolution may paſs through the meridian at all hours of the day or night ; the aſtronomer who, day after day, proſecutes ſuch obſervations, muſt be prepared at all, even the moſt inconvenient, hours, and ſacrifice to them his ſleep and all his enjoyments. How ſecluded from all the pleaſures of ſocial intercourſe, and how fatiguing ſuch a mode of life is, thoſe aſtronomers, indeed, know not who then only ſet their pendulum clocks in motion, when ſome of the eclipſes of the ſun, moon, or of the ſatellites of Jupiter, are to be viewed. At this time, and in the preſent ſtate of the ſcience, theſe are juſt the moſt inſignificant obſervations; and an able aſtronomer, well ſupplied with accurate inſtruments, may *every day*, if he take into his view the whole of his profeſſion, make more important and more neceſſary obſervations.

Le Monnier was Lalande's preceptor, and worthy of ſuch a ſcholar ; and he promoted his ſtudies by his advice, and by every other means in his power. Le Monnier's penetrating mind, indeed, preſaged in young Lalande, then only ſixteen years old, what in the ſequel has been ſo ſplendidly confirmed. In his twentieth year, he became, on the recommendation of his preceptor, a member of the Royal Academy: and in 1752 he was propoſed by him as the fitteſt perſon to be ſent to Berlin, to make with La Caille's, who had been ſent to the Cape of Good Hope, correſpondent obſervations, for the purpoſe of determining the parallaxes of the moon, then but imperfectly known. Le Monnier lent his pupil for this expedition his mural quadrant of five feet. His zeal for aſtronomy knew no bounds. For this reaſon Lalande, in his *Notice des Travaux du C. Le Monnier*, ſays of himſelf : "*Je ſuis moi-meme le principal reſultat de ſon zele pour l'aſtronomie.*"

Le Monnier was naturally of a very irritable temper: as ardently as he loved his friends, as eaſily could he be offended ; and his hatred was then implacable. Lalande, as he himſelf expreſſes it, had the misfortune to incur the diſpleaſure of his beloved preceptor ; and he never after could regain his favour. But Lalande's gratitude and reſpect for him always continued undiminiſhed, and were on every occaſion with unremitting conſtancy publicly declared : patiently he endured from him undeſerved ill treatment ; ſo much did he love and

eſteem

eſteem his inſtructor and maſter to the day of his death. "I have not ceaſed to exclaim (writes Lalande), as Diogenes exclaimed to his maſter Antiſthenes, You cannot find a ſtick ſtrong enough to drive me away from you!"

What a noble trait in the character of Lalande, who in 1797 wrote likewiſe an eulogium on Le Monnier in the ſtyle of a grateful pupil, penetrated with ſentiments of profound veneration and eſteem for his beloved maſter; but Le Monnier would not read it. This is not the place to give a circumſtantial account of this intricate quarrel; we ſhall only further remark, that Lalande was the warm friend and admirer of the no leſs eminent aſtronomer La Caille, whom Le Monnier mortally hated. An intimate friendſhip likewiſe ſubſiſted between Le Monnier and D'Alembert; but Lalande had no friendly intercourſe with the latter.

Among the ſcholars of Le Monnier may likewiſe be reckoned Henwart, the celebrated geometrician and profeſſor of mathematics at Utrecht; who, in a letter to Von Zach, aſtronomer to the Duke of Saxe Gotha, dated the 26th of May 1797, ſays, "Le Monnier is a penetrating and philoſophical aſtronomer: I learned much from him in Paris; though I lodged with the late De l'Iſle, where I frequently made obſervations in company with Meſſier. Le Monnier was the friend of D'Alembert; and conſequently an oppoſer of Lalande."

This great man, who had, for ſome years, ceaſed to exiſt either for the ſcience of aſtronomy, or for the comfort of his friends, died at Lizeaux, in the province of Normandy, in 1799, aged 84 years. He left behind him ſome valuable manuſcripts, and a number of good obſervations; with reſpect to which he had always been very whimſical, and of which in his latter years he never would publiſh any thing. He had by him a ſeries of lunar obſervations, and a multitude of obſervations of the ſtars, for a catalogue of the ſtars, which he had announced ſo early as the year 1741; among which was twice to be found the new planet Uranus: (See *Lalande's Aſtronomie, Tables*, p. 188, (A). The more he was requeſted to communicate his obſervations, the more obſtinate he became; he even threatened to deſtroy them. At the breaking out of the revolution, Lalande was greatly alarmed for the ſafety of theſe papers; he wiſhed to preſerve them from deſtruction, and made an attempt to get them into his poſſeſſion; but all his endeavours were in vain. He was only able to learn, that Le Monnier had hidden them under the roof of his houſe. Le Monnier having been firſt ſeized with a fit of the apoplexy ſo early as the 10th of November 1791, Lalande apprehended, leſt, if no one except himſelf ſhould know where he had hidden his papers, the infirm old man might perhaps have himſelf forgot it. He hopes, however, that La Grange, who married his ſecond daughter, may have ſome information concerning them. Le Monnier left behind him no ſon.

MONOMIAL, in algebra, is a ſimple or ſingle nomial, conſiſting of only one term; as a or $a x$, or $a^2 b x^3$, &c.

MONOTRIGLYPH, a term in architecture, denoting the ſpace of one triglyph between two pilaſters, or two columns.

MONSELEMINES, are a people which inhabit that part of BILEDULGERID (ſee *Encycl.*) that borders on the territories of the Emperor of Morocco. They are a mixed race, being deſcended from the ancient Arabs and fugitive Moors; and they occupy a ſpace of land, of which the limits are indicated by lofty columns placed at intervals towards the deſart. Their territory extends from about 30 leagues beyond Cape Non, to the diſtance of 20 leagues from St Croix or Agader. Though of different qualities, it is, for the moſt part, very fertile, and produces the neceſſaries of life with little cultivation. The plains are watered by an infinite number of ſtreams, and abound with palm, date, fig, and almond trees. The gardens produce excellent grapes, which are dried by the Arabs, and converted into brandy by the Jews. Great quantities of oil, wax, and tobacco, appear in the public markets.

More induſtrious and more laborious than their neighbours, the Monſelemine nation cultivates the earth. The chiefs of families chooſe the ground moſt fit for cultivation. Its ſurface is turned ſlightly over with a kind of hoe, and then the ſeed is ſown upon it: the field is ſurrounded with buſhes, to mark the ſpot, and to preſerve it from the cattle of the wandering Arabs. When the crop is ripe, which is generally at the end of Auguſt, three months after the ſowing of the ſeed, it is cut about ſix inches from the ear, and formed into little bundles; during which time every one labours without intermiſſion from morning to night. The corn is brought before the tent, thraſhed, winnowed, and placed in the magazines. When the harveſt is over, they ſet fire to the long ſtubble, and abandon the field for two or three years. Their magazines are large holes in the earth, formed like the fruſtum of a cone, the inſides of which are hardened by burning wood in them, before the half winnowed corn be depoſited. When filled with corn, they are covered with planks placed cloſe to each other; over which a layer of earth is laid level with the ſoil, to prevent it from being diſcovered by enemies. In theſe magazines every one ſhares in proportion to the number of men he employed in the common labour.

The inhabitants of the plains remain by the cultivated fields in ſeed time, and return at the time of harveſt. During the intervals they wander in all directions with their cattle, taking only neceſſaries along with them, and having recourſe to the magazines when they require

---

(A) Such is the French and German account of his diſcovery of this planet; but our readers have been very inattentive, if they have not perceived, in various articles of this Work, complete proofs of the plagiariſm of our neighbours on the Continent, from the celebrated philoſophers and divines of England. As it is extremely probable that, half a century hence, a claim may be put in for Le Monnier's diſcovery of the Georgium Sidus (*Uranus*), ſimilar to that which in 1757 the editor of Abbé St Real's works put in for that Abbé being the author of Leſlie's *Short Method with the Deiſts* (ſee LESLIE in this *Suppl.*), we think it our duty to declare, that in 1800 there was no evidence whatever on which to found that claim, and that the diſcovery was then univerſally allowed to have been made by Herſchel.

M ſele-
r es.

quire a ſupply. The more opulent people, and the artizans who are engaged in ſedentary occupations, dwell in towns, which are all ſituated upon the declivity of hills. Their houſes are built of ſtone and earth, according to the Mooriſh conſtruction, low and covered with ſloping terraces; yet they are ſo much injured by the heavy rains which prevail for three months of the year, as to be rendered uninhabitable in 15 or 20 years. Thoſe who reſide in towns are generally weavers, ſhoemakers, goldſmiths, potters, &c. and have no cattle; but the more opulent perſons have flocks and herds of cows, horſes, camels, ſheep, goats, beſides poultry, which are kept by their ſlaves at a diſtance from the towns. In the towns they take two meals a day; one at ten o'clock, and the other at the ſetting of the ſun, though the inhabitants of the country only eat in the evening. In the towns they ſleep in mats upon the floors of their apartments, and make uſe of linen; but the inhabitants of the country ſleep upon terraces in the open air. The paſtoral families of the country practiſe hoſpitality like thoſe of the deſart, and make the traveller pay nothing for his entertainment. In the towns this practice is impoſſible, as the concourſe of ſtrangers, eſpecially on market-days, would ſoon impoveriſh the inhabitants. In this manner hoſpitality is always extinguiſhed among a trading and commercial people. It is only where the ſuperfluity of commodities runs neceſſarily to waſte, that it is ever practiſed in a great extent; but where every commodity can find a market, every kind of property acquires a definite value, and will be preſerved with the ſame care as money.

By M. Saugnier the government of the Monſelemines is ſaid to be republican; but he writes inconſiſtently about it In one place, he ſays that they chooſe their chiefs annually; in another, that in the time of war they chooſe from the natives or fugitive Moors indiſcriminately, chiefs, whoſe authority laſts no longer than the campaign, during which it is abſolute; and he afterwards repreſents their government as a kind of theocracy, during war as well as peace. But we muſt follow him in his detail, as it has been well arranged in a late anonymous publication, entitled, *An Hiſtorical Sketch of Diſcoveries in Africa*.

At the end of each campaign, he ſays the chief gives an account of his actions to the aſſembled aged men, and is rewarded or puniſhed according to his conduct; after which his ſucceſſor is appointed, and he ſerves in the army he commanded as an undiſtinguiſhed individual. The country is populous, and would be ſtill more ſo, were it not for the continual wars which its inhabitants are obliged to ſupport againſt the Emperor of Morocco. The liberty they enjoy imparts energy and courage to their character, and renders their arms invincible to the Moors. They conſider it as the moſt invaluable poſſeſſion, and defend it to the laſt extremity. The nature of the country, ſurrounded on every ſide by ſteep and arid mountains, contributes to fruſtrate the efforts of their enemies. The Monſelemine, richer than the ſubject of Morocco, is always well clothed and armed. He pays no tribute, enjoys the fruit of his labour and commerce, and, as no contributions are requiſite for the charges of the ſtate, whatever he acquires is his own. The fugitive Moors are never armed, except when they go to battle; but the natives go continually armed, whether they reſide in the country, reſort to the markets, attend the aſſemblies of the nation, or pay viſits.

Monſelemines.

As the Monſelemine territory is the retreat of the rich Moors, who wiſh to fly from the tyranny of the Emperor of Morocco, they are too well acquainted with the Mooriſh cuſtoms to be ſurpriſed by that prince. No ſooner does a Mooriſh army take the field, than the inhabitants of the country cantons mount their horſes, and occupy the paſſes of the mountains; while the women and ſlaves, eſcorted by a ſufficient number of warriors, retire to the interior parts of the country, or, if they be hard preſſed, to the deſart. Among the paſtoral tribes there are many that addict themſelves entirely to arms, and ſerve as cavalry in the time of war. During peace they eſcort caravans, or exerciſe themſelves in military evolutions, and the management of their horſes. Being almoſt always on horſeback, and wearing no boots, they have a callous lump on that part of the leg that comes in contact with the iron of the ſtirrup. Their horſes, which they break in an admirable manner, are the beſt in the world: as they are treated with great care by their maſters, they know them, and are obedient to their voice, and will admit no ſtranger to mount them.

The Monſelemines derive their origin and name from Moſeílama, a contemporary of Mahomet; and, in their love of liberty, as well as in many of their cuſtoms, reſemble the Arabs of remoter times. They reſpect the prophet like other Mahometans; but neither believe that he was infallible, nor that his deſcendants are all inſpired by God, nor that their will ſhould be a law, nor that ſuch faith is neceſſary in order to be a good Mahometan. Their prieſts are reſpected, and in old age generally become the civil judges of the nation; but the influence of the high prieſt is almoſt deſpotic. Though he has no troops, he may command the nation; and war and peace depend upon his will. Though he has no property, every thing is at his diſpoſal: he requires nothing from any one, and yet all are inclined to give. He adminiſters juſtice according to the opinion of his counſel, without pretending to be inſpired by the prophet.

On Friday the Monſelemines aſſemble in their moſques to pray: this is likewiſe the day of their principal market, when their merchandize is expoſed to ſale in the public ſquares, where the old men judge without appeal, when diſputes ariſe. Different from their neighbours of Morocco and Sahara, the Monſelemines never attempt to make proſelytes. Their Chriſtian ſlaves are treated with humanity; but they owe this to the avarice of their maſters. Theſe deteſt Chriſtians, but they love money, and are afraid leſt ſickneſs or death ſhould deprive them of the ranſom of the ſlave, or of the advantage of his labour. Among the inhabitants of the deſart, a Chriſtian, that adopts the religion of Mahomet, is admitted as a citizen and member of the family, and is preſented with cattle to form an eſtabliſhment. The Monſelemines pay more attention to the value of their property than the ſituation of the infidel. A Chriſtian who enters a moſque at Morocco is put to death, or forced to aſſume the turban. The Monſelemines would turn him civilly out, and content themſeles with impoſing the higheſt poſſible fine. Among the Moors, a Chriſtian diſcovered in an intrigue with a woman of that nation ſuffers death, or ſubmits to

con-

Monſelemines, Monterey.

converſion; but the Monſelemines prefer money to religion. From them the Chriſtian has nothing to fear: the woman alone is puniſhed, being put into a ſack, and thrown into the ſea. If a Chriſtian ſlave among the neighbouring nations defends himſelf againſt his maſter, he is puniſhed with death; but money ſaves him among the Monſelemines; he would at moſt receive a ſlight correction.

The Jews are allowed the free exerciſe of their religion among the Monſelemines, but are treated with the ſame indignity as among other Mahometan tribes. A Jew is not permitted to carry arms; and if he ſhould make uſe of them againſt an Arab, he would be puniſhed with death, and probably involve his family in his fate. The Jews inhabit the towns only, where they follow trade and various arts, but are not allowed to cultivate the earth.

Polygamy is permitted, as in other Mahometan countries; but the ſituation of the women is more reſpectable, and they are not ſo much ſecluded as among the Moors. They mingle more in ſociety, walk at large, and viſit their friends; neither are their apartments ſo inviolable. Among the Monſelemines, that degrading picture of humanity is never ſeen which ſometimes occurs in Morocco, a woman drawing the plough with an aſs, a mule, or ſome other beaſt of burden. More happy than the women of the Sahara, and treated with greater attention by their huſbands, they are more humane in their diſpoſitions. Like other Arab women, they ſtain the edges of their eyelids black with henna, and paint their faces red and yellow. Their children are brought up with great care, and are not obliged to exhibit proofs of their courage before they can be conſidered as men, as is the cuſtom in the deſart. Avarice is the principal defect in the character of the Monſelemines. They hoard their money with the utmoſt care, bury it in the earth, and in many caſes die without diſcovering their ſecret even to their children. Miſers, ſays M. Saugnier, ſhould go to that country, where they would learn means of economy; which would ſhew them, that, in compariſon with the Monſelemines, they are themſelves perfect prodigals.

The medicinal applications of the Monſelemines, which differ not from thoſe of the MONGEARTS and other inhabitants of the deſart, are extremely ſimple, but appear ſufficiently complex from the mummery of the prieſts, who are the depoſitories of their medical ſcience. Fleſh wounds are cauteriſed with a hot iron, and then covered with herbs dipped in turtles oil and tar. In headachs, a compreſs is applied with ſuch violence that the blood ſtarts from the forehead. In internal diſeaſes, the general remedies are regimen, reſt, and a few maxims of the Koran myſteriouſly applied to the affected parts.

MONTEREY BAY, in North California, was viſited in 1786 by La Perouſe, who places it in 36° 58′ 43″ N. Lat. and 124° 40′ W. Long. from Paris. It is formed by New-year Point to the north, and by that of Cyprus to the ſouth; has an opening of eight leagues in this direction, and nearly ſix of depth to the eaſtward, where the land is ſandy and low. The ſea breaks there as far as the foot of the ſandy downs with which the coaſt is ſurrounded, with a roaring which may be heard more than a league off. The lands north and ſouth of this bay are high, and covered with trees. Thoſe ſhips which are deſirous of touching there ought to follow the ſouth coaſt, and after having doubled the Point of Pines, which ſtretches to the northward, they get ſight of the preſidency, and may come to an anchor in ten fathoms within it, and a little within the land of this point, which ſhelters from the winds from the offing. The Spaniſh ſhips, which propoſe to make a long ſtay at Monterey, are accuſtomed to bring up within one or two cable's lengths of the land, in ſix fathoms, and make faſt to an anchor, which they bury in the ſand of the beach; they have then nothing to fear from the ſoutherly winds, which are ſometimes very ſtrong; but, as they blow from the coaſt, do not expoſe them to any danger. The two French frigates, which our author commanded, found bottom over the whole bay, and anchored four leagues from the land, in 60 fathoms, ſoft muddy ground; but there is a very heavy ſea, and it is only an anchorage fit for a few hours, in waiting for day, or the clearing up of the fog. At full and change of the moon it is high water at half paſt one o'clock: the tide riſes ſeven feet; and as this bay is very open, the current in it is nearly imperceptible. It abounds with whales; a genus of fiſhes, of which our *ſcientific* voyagers knew ſo little, that they were ſurpriſed at their ſpouting water!

The coaſts of Monterey Bey are almoſt continually enveloped in fogs, which cauſe great difficulty in the approach to them. But, for this circumſtance, there would be few more eaſy to land upon; there is not any rock concealed under water that extends a cable's length from the ſhore; and if the fog be too thick, there is the reſource of coming to an anchor, and there waiting for a clear, which will enable you to get a good ſight of the Spaniſh ſettlement, ſituated in the angle formed by the ſouth and eaſt coaſt. The ſea was covered with pelicans. Theſe birds, it ſeems, never go farther than five or ſix leagues from the land; and navigators, who ſhall hereafter meet with them during a fog, may reſt aſſured that they are within that diſtance of it.

A lieutenant-colonel, whoſe reſidence is at Monterey, is governor of the Californias: the extent of his government is more than 800 leagues in circumference, but his real ſubjects conſiſt only of 282 cavalry, whoſe duty it is to garriſon five ſmall forts, and to furniſh detachments of four or five men to each of the 25 miſſions, or pariſhes, eſtabliſhed in old and new California. So ſmall are the means which are adequate to the reſtraining about 50,000 wandering Indians in this vaſt part of America, among whom, nearly 10,000 have embraced Chriſtianity. Theſe Indians are, in general, ſmall and weak (A), and diſcover none of that love of liberty and independence which characteriſes the northern nations, of whoſe arts and induſtry they are alſo deſtitute. Their colour very nearly approaches that of the negroes whoſe hair is not woolly; the hair of theſe people is ſtrong, and of great length; they cut it four or five inches from the roots. Several among them have a beard; others, according to the miſſionary fathers, have never had any; and this is a queſtion which is even undecided

---

(A) The chief ſurgeon of the expedition ſays they are *ſtrong*, but ſtupid.

decided in the country. The governor, who had travelled a great way into the interior of theſe lands, and who had paſſed 15 years of his life among the ſavages, aſſured our author, that thoſe who had no beards had plucked them up with bivalve ſhells, that ſerved them as pincers: the preſident of the miſſions, who had reſided an equal length of time in California, maintained the contrary;—it was difficult, therefore, for travellers to decide between them." The difficulty, ſurely, was not great. By their own account, the governor had travelled much farther into the country than the miſſionary; and his report being confirmed by the evidence of their own ſenſes, was intitled to unlimited credit.

Theſe Indians are extremely ſkilful in drawing the bow; they killed, in the preſence of the French, the ſmalleſt birds: it is true, they diſplay an inexpreſſible patience in approaching them; they conceal themſelves, and, as it were, glide along near to the game, ſeldom ſhooting till within 15 paces. Their induſtry in hunting the larger animals is ſtill more admirable. Perouſe ſaw an Indian, with a ſtag's head fixed upon his own, walk on all-fours, as if he were browſing the graſs; and he played this pantomime to ſuch perfection, that all the French hunters would have fired at him at 30 paces, had they not been prevented. In this manner they approach herds of ſtags within a very ſmall diſtance, and kill them with a flight of arrows.

Before the Spaniſh ſettlements, the Indians of California cultivated nothing but maize, and almoſt entirely lived by fiſhing and hunting. There is not any country in the world which more abounds in fiſh and game of every deſcription: hares, rabbits, and ſtags are very common there; ſeals and otters are alſo found there in prodigious numbers; but to the northward, and during the winter, they kill a very great number of bears, foxes, wolves, and wild cats. The thickets and plains abound with ſmall grey tufted partridges, which, like thoſe in Europe, live in ſociety, but in large companies of three or four hundred; they are fat, and extremely well flavoured. The trees ſerve as habitations to the moſt delightful birds; and the ornithologiſts of the voyage ſtuffed a great variety of ſparrows, titmice, ſpeckled wood-peckers, and tropic birds. Among the birds of prey are found the white-headed eagle, the great and ſmall falcon, the goſs hawk, the ſparrow hawk, the black vulture, the large owl, and the raven. On the ponds and ſea-ſhore are ſeen the wild duck, the grey and white pelican with yellow tufts, different ſpecies of gulls, cormorants, curlews, ring-plovers, ſmall ſea water hens, and herons; together with the bee-eater, which, according to moſt ornithologiſts, is peculiar to the old continent.

The country about Monterey Bay is inexpreſſibly fertile. The crops of maize, barley, corn, and peaſe, cannot be equalled but by thoſe of Chili; our European cultivators can have no conception of a ſimilar fertility; the medium produce of corn is from ſeventy to eighty for one; the extremes ſixty and a hundred. Fruit trees are ſtill very rare there, but the climate is extremely ſuitable to them: it differs a little from that of the ſouthern French provinces. The foreſt trees are, the ſtone-pine, cyprus, evergreen oak, and occidental plane tree. There is no underwood; and a verdant carpet, over which it is very agreeable to walk, covers the ground. There are alſo vaſt ſavannahs, abounding with all ſorts of game.

Perouſe writes with great reſpect of the wiſe and pious conduct of the Spaniſh miſſionaries at Monterey, who ſo faithfully fulfil the purpoſe of their inſtitution. Totally unlike the monks at Conception in Chili (ſee that article in this *Suppl.*), they have left the lazy life of a cloiſter, to give themſelves up to cares, fatigues, and ſolicitudes of every kind. They invited the officers of the frigates to dine with them at their monaſtery, contiguous to which ſtands the Indian village, conſiſting of about 50 cabins, which ſerve as dwelling-places to 740 perſons of both ſexes, compriſing their children, which compoſe the miſſion of Saint Charles, or of Monterey. Theſe cabins are the moſt miſerable that are to be met with among any people; they are round, ſix feet in diameter, by four in height; ſome ſtakes, of the ſize of an arm, fixed in the earth, and which approach each other in an arch at the top, compoſe the timber work of it; eight or ten bundles of ſtraw, very ill arranged over theſe ſtakes, defend the inhabitants, well or ill, from the rain and wind; and more than half of this cabin remains open when the weather is fine; their only precaution is to have each of them two or three bundles of ſtraw at hand by way of reſerve.

All the exhortations of the miſſionaries have never been able to procure a change of this general architecture of the two Californias. The Indians ſay, that they like plenty of air; that it is convenient to ſet fire to their houſes when they are devoured in them by too great a quantity of fleas; and that they can build another in leſs than two hours. The independent Indians, who as hunters ſo frequently change their places of abode, have a ſtronger motive.

The monks gave the moſt complete information reſpecting the government of this ſpecies of religious community; for no other name can be given to the legiſlation they have eſtabliſhed. They are ſuperiors both in ſpiritual and temporal affairs: the products of the land are entirely entruſted to their adminiſtration. There are ſeven hours allotted to labour in the day, two hours to prayers, and four or five on Sundays and feſtivals, which are altogether dedicated to reſt and divine worſhip. Corporal puniſhments are inflicted on the Indians of both ſexes who neglect pious exerciſes; and ſeveral ſins, the puniſhment of which in Europe is reſerved only to Divine Juſtice, are puniſhed with chains or the ſtocks.

The Indians, as well as the miſſionaries, riſe with the ſun, and go to prayers and maſs, which laſt an hour; and during this time there is cooked in the middle of the ſquare, in three large kettles, barley meal, the grain of which has been roaſted previous to being ground; this ſpecies of boiled food, which the Indians call *atole*, and of which they are very fond, is ſeaſoned neither with ſalt nor butter, and to us would prove a very inſipid meſs. Every cabin ſends to take the portion for all its inhabitants in a veſſel made of bark: there is not the leaſt confuſion or diſorder; and when the coppers are empty, they diſtribute that which ſticks to the bottom to the children who have beſt retained their leſſons of catechiſm. This meal continues three quarters of an hour, after which they all return to their labours; ſome go to plough the earth with oxen, others to dig the garden; in a word, every one is employed in different

Mongearts. rent domeſtic occupations, and always under the ſuperintendance of one or two of the religious.

The women are charged with little elſe but the care of their houſewifery, their children, and roaſting and grinding the ſeveral grains: this laſt operation is very long and laborious, becauſe they have no other means of doing it but by cruſhing the grain in pieces with a cylinder upon a ſtone. M. de Langle, being a witneſs of this operation, made the miſſionaries a preſent of his mill; and a greater ſervice could not have been rendered them, as by theſe means four women would in a day perform the work of a hundred, and time enough will remain to ſpin the wool of their ſheep, and to manufacture coarſe ſtuffs.

At noon the dinner was announced by the bell; the Indians quitted their work, and ſent to fetch their rations in the ſame veſſels as at breakfaſt: but this ſecond meſs was thicker than the firſt; there was mixed in it corn and maize, and peaſe and beans; the Indians name it *pouſſole*. They return again to their labour from two o'clock till four or five; afterwards they attend evening prayers, which continue near an hour, and are followed by a new ration of *atole* like that at breakfaſt. Theſe three diſtributions are ſufficient for the ſubſiſtence of the far greater number of Indians; and this very economical ſoup might perhaps be very profitably adopted in our years of ſcarcity; ſome ſeaſoning would certainly be neceſſary to be added to it, their whole knowledge of cookery conſiſting in being able to roaſt the grain before it is reduced into meal. As the Indian women have no veſſels of earth or metal for this operation, they perform it in large baſkets made of bark, over a little lighted charcoal; they turn theſe veſſels with ſo much rapidity and addreſs, that they effect the ſwelling and burſting of the grain without burning the baſket, though it is made of very combuſtible materials.

The corn is diſtributed to them every morning; and the ſmalleſt diſhoneſty, when they give it out, is puniſhed by whipping: but it is very ſeldom, indeed, they are expoſed to it. Theſe puniſhments are adjudged by Indian magiſtrates, called *caciques;* there are in every miſſion three of them, choſen by the people from amongſt thoſe whom the miſſionaries have not excluded: but theſe caciques are like the governors of a plantation, paſſive beings, blind executors of the will of their ſuperiors; and their principal functions conſiſt in ſerving as beadles in the church, and their maintaining order and an air of contemplation. The women are never whipped in public, but in an incloſed and ſomewhat diſtant place, leſt perhaps their cries might inſpire too lively a compaſſion, which might ſtimulate the men to revolt; theſe laſt, on the contrary, are expoſed to the view of all their fellow-citizens, that their puniſhment may ſerve as an example. In general they aſk pardon; in which caſe the executioner leſſens the force of his laſhes, but the number of them is never receded from.

The rewards are particular ſmall diſtributions of grain, of which they make little thin cakes, baked on burning coals: and on the great feſtivals the ration is in beef; many of them eat it raw, eſpecially the fat, which they eſteem equal to the beſt butter or cheeſe. They ſkin all animals with the greateſt addreſs; and when they are fat, they make, like the ravens, a croaking of pleaſure, devouring, at the ſame time, the moſt delicate parts with their eyes.

They are frequently permitted to hunt and fiſh on their own account; and on their return they generally make the miſſionaries ſome preſent in game and fiſh; but they always proportion the quantity to what is abſolutely neceſſary for them, always taking care to increaſe it if they hear of any new gueſts who are on a viſit to their ſuperiors. The women rear fowls about their cabins, the eggs of which they give their children. Theſe fowls are the property of the Indians, as well as their clothes, and other little articles of houſehold furniture, and thoſe neceſſary for the chace. There is no inſtance of their having robbed each other, though their faſtenings to the doors conſiſt only of a ſimple bundle of ſtraw, which they place acroſs the entrance when all the inhabitants are abſent.

The men in the miſſions have ſacrificed much more to Chriſtianity than the women; becauſe they were accuſtomed to polygamy, and were even in the cuſtom of eſpouſing all the ſiſters of a family. The women, on the other hand, have acquired the advantage of excluſively receiving the careſſes of one man only. With this, however, it would appear that they are not ſatisfied; for the religious have found it neceſſary to conſtitute themſelves the guardians of female virtue. At an hour after ſupper, they have the care of ſhutting up, under lock and key, all thoſe whoſe huſbands are abſent, as well as the young girls above nine years of age; and during the day they are entruſted to the ſuperintendance of the matrons. So many precautions are ſtill inſufficient; for our voyagers ſaw men in the ſtocks, and women in irons, for having deceived the vigilance of theſe female arguſſes, who had not been ſufficiently ſharp-ſighted.

The converted Indians have preſerved all the ancient uſages which their new religion does not prohibit; the ſame cabins, the ſame games, the ſame dreſſes: that of the richeſt conſiſts of an otter's ſkin cloak, which covers their loins, and deſcends below their groin; the moſt lazy have only a ſimple piece of linen cloth, with which they are furniſhed by the miſſion, for the purpoſe of hiding their nakedneſs; and a ſmall cloak of rabbit's ſkin covers their ſhoulders, which is faſtened with a pack-thread under the chin; the head and the reſt of the body is abſolutely naked; ſome of them, however, have hats of ſtraw, very neatly matted. The womens dreſs is a cloak of deer ſkin, ill tanned; thoſe of the miſſions have a cuſtom of making a ſmall boddice, with ſleeves, of them: it is their only apparel, with a ſmall apron of ruſhes, and a petticoat of ſtag's ſkin, which covers their loins, and deſcends to the middle of the leg. The young girls, under nine years of age, have merely a ſimple girdle; and the children of the other ſex are quite naked.

The independent ſavages are very frequently at war; but the fear of the Spaniards makes them reſpect their miſſions; and this, perhaps, is not one of the leaſt cauſes of the augmentation of the Chriſtian villages. Their arms are the bow, and arrow pointed with a flint very ſkilfully worked: theſe bows are made of wood, and ſtrung with the ſinews of an ox. Our author was aſſured, that they neither eat their priſoners, nor their enemies killed in battle; that, nevertheleſs, when they

had

had vanquiſhed, and put to death on the field of battle, chiefs, or very courageous men, they have eaten ſome pieces of them, leſs as a ſign of hatred or revenge, than as a homage which they paid to their valour, and in the full perſuaſion that this food would be likely to increaſe their own courage. They ſcalp the vanquiſhed as in Canada, and pluck out their eyes; which they have the art of preſerving free from corruption, and which they carefully keep as precious ſigns of their victory. Their cuſtom is to burn their dead, and to depoſit their aſhes in morais.

MOORS, in common language, are the natives of Morocco, of whom an account is given under that title in the *Encyclopædia;* but there is another people, a mixed race, called alſo Moors, who lead a wandering and paſtoral life in the habitable parts of the Great Deſert, and in the countries adjacent to it. Of the origin of theſe Mooriſh tribes, as diſtinguiſhed from the inhabitants of Barbary, nothing farther ſeems to be known than what is related by John Leo the African; whoſe account may be abridged as follows:

Before the Arabian conqueſt, about the middle of the ſeventh century, all the inhabitants of Africa, whether they were deſcended from Numidians, Phœnicians, Carthaginians, Romans, Vandals, or Goths, were comprehended under the general name of *Mauri* or Moors. All theſe nations were converted to the religion of Mahomet, during the Arabian empire under the Kaliphs. About this time many of the Numidian tribes, who led a wandering life in the deſert, and ſupported themſelves upon the produce of their cattle, retired ſouthward acroſs the Great Deſert, to avoid the fury of the Arabians; and by one of thoſe tribes, ſays Leo (that of Zanhaga), were diſcovered, and conquered, the Negro nations on the Niger. By the Niger, is here undoubtedly meant the river of Senegal, which in the Mandingo language is called *Baſing*, or the Black River.

To what extent theſe people are now ſpread over the African continent, it is difficult to aſcertain. There is reaſon to believe, that their dominion ſtretches from weſt to eaſt, in a narrow line or belt, from the mouth of the Senegal (on the northern ſide of that river) to the confines of Abyſſinia. Mr Park deſcribes them as reſembling, in complexion, the Mulattoes of the Weſt Indies, and as having cruelty and low cunning pictured in their countenances. "From the ſtaring wildneſs in their eyes (ſays he), a ſtranger would immediately ſet them down as a nation of lunatics. The treachery and malevolence of their character are manifeſted in their plundering excurſions againſt the Negro villages. Oftentimes, without the ſmalleſt provocation, and ſometimes under the faireſt profeſſions of friendſhip, they will ſuddenly ſeize upon the Negroes cattle, and even on the inhabitants themſelves. The Negroes very ſeldom retaliate. The enterpriſing boldneſs of the Moors, their knowledge of the country, and, above all, the ſuperior fleetneſs of their horſes, make them ſuch formidable enemies, that the petty Negro ſtates, which border upon the deſert, are in continual alarm while the Mooriſh tribes are in the vicinity, and are too much awed to think of reſiſtance.

"Like the roving Arabs, the Moors frequently remove from one place to another, according to the ſeaſon of the year, or the convenience of paſturage. In the month of February, when the heat of the ſun ſcorches up every ſort of vegetation in the deſert, they ſtrike their tents, and approach the Negro country to the ſouth; where they reſide until the rains commence, in the month of July. At this time, having purchaſed corn, and other neceſſaries from the Negroes, in exchange for ſalt, they again depart to the northward, and continue in the deſert until the rains are over, and that part of the country becomes burnt up and barren.

"This wandering and reſtleſs way of life, while it inures them to hardſhips, ſtrengthens, at the ſame time, the bonds of their little ſociety, and creates in them an averſion towards ſtrangers, which is almoſt inſurmountable. Cut off from all intercourſe with civilized nations, and boaſting an advantage over the Negroes, by poſſeſſing, though in a very limited degree, the knowledge of letters, they are at once the vaineſt and proudeſt, and perhaps the moſt bigotted, ferocious, and intolerant, of all the nations on the earth; combining in their character the blind ſuperſtition of the Negro, with the ſavage cruelty and treachery of the Arab." But for them Mr Park would have accompliſhed the utmoſt object of his miſſion, and have reached Tombuctoo, and even Houſſa, with no other danger than what ariſes neceſſarily from the climate, from wild beaſts, and from the poor accommodation afforded in the huts of the hoſpitable Negroes. The wandering Moors, however, have all been taught to regard the Chriſtian name with inconceivable abhorrence; and to conſider it nearly as lawful to murder a European as it would be to kill a dog. It is, therefore, much leſs ſurpriſing that our traveller did not proceed farther along the banks of the Niger, than that he eſcaped the ſnares of ſo relentleſs a people.

MORINDA, is a plant, of which a very meagre deſcription has been given in the *Encyclopædia*, though it is of much importance in oriental commerce. It is cultivated to a great extent in the province of *Malwa* in the Eaſt Indies, where it furniſhes a valuable dye-ſtuff; and is thus deſcribed by William Hunter, Eſq; in the fourth volume of the Aſiatic Reſearches:

"It is a tree of a middling ſize; the *root* branchy; the *trunk* columnar, erect, covered with a ſcabrous bark. *Branches*, from the upper part of the trunk, ſcattered; of the ſtructure of the trunk. *Leaves* (ſeminal) oval, obtuſe, entire (mature), oppoſite, decuſſated, ovate, pointed at both ends, ſmooth, with very ſhort petioles. *Stipules*, lanced, very ſmall, withering. *Peduncles*, from the axils of the leaves, ſolitary, bearing an aggregate flower. *Calyx*, common receptacle roundiſh, collecting the ſeſſile flowers into an irregular head. *Perianth*, moſt entire, ſcarce obſervable above. *Coral*, one-petalled, funnel-form. *Tube*, cylindric: *Border*, five cleft; the *diviſions* lanced. *Stamen: Filaments*, five, thread-form, ariſing from the tube, and adhering to it through two thirds of their length, a little ſhorter than the tube. *Anthers*, linear, erect. *Piſtil. Germ*, beneath, four celled, containing the rudiments of four ſeeds. *Style*, thread-form, longer than the ſtamens. *Stigma*, two-cleft, thickiſh. *Pericarp*, common, irregular, divided on the ſurface into irregular angular ſpaces; compoſed of berries, pyramidal, compreſſed on all ſides by the adjacent ones, and concreted with them; lopped; containing towards the baſe a fleſhy pulp. *Seeds*, in each berry four; towards the point oblong, externally convex, internally angular."

The ſpecies here deſcribed is the *morinda arborea pedunculis ſolitariis* of Linnæus. It grows beſt in a black rich ſoil, free from ſtones, in ſituations moderately moiſt, not too high, yet ſufficiently elevated to prevent the rain water from ſtagnating, and where a ſupply of water can be had for the dry months. As the colouring matter, for which alone it is valuable, reſides chiefly in the bark of the root, the ſmall twigs, which contain little wood, bear a higher price than the larger pieces. The natives employ it in dyeing a pale red, or clay colour; which Mr Hunter ſays is more valuable for its durability than for its beauty. They likewiſe uſe it in dyeing a dark purple or chocolate colour: but for the proceſs, in both caſes, we muſt refer to the original memoir.

MORION, in botany, a name given by the ancients to a kind of nightſhade. See SOLANUM, *Encycl.*

MORION, in ancient mineralogy, a name given to one of the ſemipellucid gems, more commonly called *pramnion*. It is a ſtone appearing externally of a fine deep black; but when held up againſt a candle, or againſt the ſun-beams, it gives a very beautiful red in different degrees.

MOSHAIRA, or MOSHAHEREH, penſion or allowance in Bengal.

MOSS, the name given in Scotland, and we believe alſo in ſome parts of England, to what is more properly called a *moraſs*, a *fen*, or a *bog*. On the formation of theſe moſſes ſome conjectures have been hazarded in the *Encyclopædia*, where the reader will likewiſe find a copious account of the method which has for many years been ſucceſsfully employed to convert the MOSS OF KINCARDINE into an arable ſoil, or rather to remove the ſubſtance called *moſs* or *peat* from the rich ſoil which is found below it. A method, however, has been invented by Mr John Smith of Swindrig-muir, in the ſhire of Ayr, for *actually* converting the ſubſtance called moſs into a vegetable mould, which has been found by experience to carry rich crops of corn, hay, potatoes, &c. Of this gentleman's practice we have the following account in a ſmall pamphlet publiſhed in Edinburgh, 1798, by Fairbairn and Dickſon.

"The firſt thing to be done is to mark off, and cut out, proper main or maſter drains, in order to carry off the ſuperfluous water, taking care to preſerve the greateſt poſſible level; which drains are ſo conſtructed as to divide the field into incloſures from ſix to ten Scotch acres. If the moſs hangs or declines, the incloſures may be of any dimenſion whatever. The dimenſions of theſe drains when firſt made are eight feet wide, by four and a half feet deep, declining to two and a half feet at bottom, and coſt at the rate of one ſhilling per fall of eighteen and a half feet, running meaſure. The ridges are then to be marked off regularly, ſix or ſeven yards broad, formed with the ſpade in the manner following.

"In the centre of each ridge, a ſpace of about 20 inches is allowed to remain untouched, on each ſide of which a furrow is opened, and turned upon the untouched ſpace, ſo as completely to cover it (like what is called the feering of a gathered ridge). Thus begun, the work is continued, by cutting with the ſpade, in width about 12 inches, and turning it over to appearance as if done with a plough, until you come to the diviſion furrow, which ſhould be two feet wide, cut out and thrown upon the ſides of the ridges. The depth of the diviſion furrow is to be regulated by circumſtances, according as the moſs is wet or dry, but ſo as to anſwer the purpoſe of as it were bleeding the moſs, and conducting the water to the main drains.

"It may be here obſerved, that the ſucceſs of the aftercrops depends very much upon a proper formation of the ridges. They muſt not be made too high in the middle, for there they will be too dry like a peat, upon which the lime cannot act, and near the furrows they will be too wet, which is equally prejudicial; they ſhould therefore be conſtructed with a gentle declivity to the furrows, ſo as the rain which falls may rather filtrate through the ridge to the furrows than run quickly off the ſurface.

"The next operation is to top-dreſs the ridges with lime, at the rate of from four to eight chalders per acre. Five Wincheſter buſhels make a boll, and eight bolls a chalder of ſhell lime, producing ſixteen bolls powdered lime. The quicker the lime is put on after being ſlacked the better.

"The proper ſeaſon to prepare the moſs for a firſt crop is early the preceding ſummer; in that caſe the lime, aided by the heat, the after rains, and the winter froſts, makes conſiderable progreſs in the proceſs of putrefaction, conſequently forms a mould to receive the ſeed.

"Though oats have ſometimes ſucceeded as a firſt crop, potatoes have been found greatly preferable. The method of planting them is ſimple, and attended with little expence. The moſs, prepared by ridges, and limed as before deſcribed, beds for the potatoes are, in the ſpring, marked off, acroſs the ridges, five or ſix feet broad, with intermediate ſpaces of about two feet, as furrows or trenches. The beds are covered over with a thin ſtratum of dung, about eighteeen ſingle-horſe carts to an acre, the cuttings of the potatoes are laid or placed upon the beds, about ten or twelve inches aſunder, and the whole covered over with a thin ſtratum of moſs from the intermediate trenches, which is followed by another covering from the trenches when the potatoe plants make their firſt appearance; the covering in whole four or five inches. In this ſtate they remain without any hoeing till the crop is taken up. The produce on Mr Smith's moſs has never been leſs than from forty to fifty bolls of excellent potatoes, eight Wincheſter buſhels to the boll, and the buſhel a little heaped.

"When the potatoe crop is removed, the ridges are again formed as before deſcribed, and the diviſion-furrow cleared out. In performing this part of the work, it will naturally occur, that a great part of the manured ſurface will be buried in filling up the trenches between the potatoe beds: but that is not the caſe; the workman makes two cuts with the ſpade, at eighteen inches diſtance, upon the ſide of the trench; another, one foot from the edge of it, as deep as the trench; which, inſtead of turning over, he preſſes a foot forward into the trench, which is continued the length of it; and when he comes to the other ſide he does the ſame, making both meet, and ſo proceeds; ſo that no part of the manured ſurface is thrown down, and the ridge is left in the ſame form as before the lazy-beds* were made.

"When the potatoe crop is taken off, and the ridges formed as before deſcribed, they remain in that ſtate till ſpring, when oats are ſown (a wet or dry ſeaſon has

---

tatoe.

from experience been found a matter of indifference), and harrowed in with a ſmall harrow drawn by two men. Four men with eaſe harrow at leaſt one acre one rood per day, two and two by turns with the harrow, and the other two in the interim with ſpades, ſmoothing the inequalities, breaking and dividing the mould, and clearing out the diviſion furrows; which laſt in all operations upon moſs are eſſentially neceſſary. The early or hot ſeed oats are always preferred for ſeed. The late or cold ſeed runs too much to ſtraw, falls down, and becomes ſloomy, conſequently the grain is of mean quality, and unproductive in meal.

"The produce of the firſt crop of oats after potatoes is ſeldom leſs than ten bolls per acre, the Linlithgow boll of ſix Wincheſter buſhels, and conſiderably more has been known; as good grain in quality, and meals as well as any in the country. It has been ſold when growing, what is called upon the foot, including the ſtraw, from eight to ten pounds per acre. To prepare for a ſecond crop of oats, the ridges muſt be dug acroſs, and turned over in the manner before deſcribed, and the diviſion furrows cleared out as ſoon as convenient after the firſt crop is removed.

"Such is the effect of lime in conſolidating moſs, aided by the draining, that often after the ſecond, and always after the third year, it can be ploughed by horſes within two bouts or ſtitches of the diviſion furrow; and alſo harrowed by horſes, and the crops taken off by carts.

"Five and often ſix conſecutive crops of oats are taken, without any other manure than what it received the firſt year for potatoes, without any apparent ſigns of it being exhauſted. The produce of the firſt two crops of oats has been mentioned to be ten bolls, and the third, fourth, fifth, and ſixth, produce from ſix to ten bolls per acre. The moſs is now turned into a ſeeming rich dark brown mould; and what renders it leſs productive of corn crops the fourth, fifth, and ſixth years is, its naturally running into ſweet and luxuriant graſſes. The ſoft meadow graſs, the daiſy, ſome plaintain, but principally the white clover, are the moſt prevalent graſſes; or more probably it may be aſcribed to theſe crops being ploughed, in place of being dug with the ſpade, as the former years were. Along with the fifth or ſixth crop of oats, rye graſs is ſown, which, with the natural graſſes in general, produce an abundant crop of hay.

"If the moſs in the original ſtate has been wet and ſpongy, it will be found to have ſubſided ſome feet after the third or fourth year's operation has been performed; but care muſt always be taken to deepen, clear out, and keep clear the main drains and the diviſion furrows, to prevent a ſuperabundance of moiſture, which would infallibly be the caſe were they neglected in conſequence of the ſubſidence of the moſs. Indeed moſs of all ſorts will ſubſide leſs or more, in proportion as it has been dry or wet in its original ſtate; at the ſame time, as ſtated before, care muſt be taken not to lay it too dry, but to keep in a proper degree of temperature between theſe two extremes."

By having recourſe to the pamphlet from which this extract has been made, the reader may ſatiſfy himſelf of the real advantages of this ſpecies of agriculture. The author calculates, with much apparent fairneſs, the expence of improvement, and the value of each crop, and concludes that no waſte can be improved with equal advantage as moſs. It muſt not, however, be concealed, that we have heard practical farmers, who ſeemed to be acquainted with the ſubject, give it as their opinion that this mode of cultivation anſwers only in moſſes of no great depth; though our author affirms that it has with great ſucceſs been practiſed by Mr Smith in moſſes of the depth of 14 feet.

MOTION in fluids. When in the publication of this *Supplement* we had arrived at the title FLUIDS, we were ſtruck with the importance given, in ſome of the journals, to *The Experimental Reſearches of* Venturi *concerning the Principle of the lateral communication of Motion in Fluids, applied to the Explanation of various Hydraulic Phenomena.* Of theſe reſearches we intended to lay an abridged account before our readers under the preſent title; but having examined the work with ſome attention, we find in it hardly any thing of conſequence which the mechanical philoſopher may not learn from our articles RESISTANCE *of Fluids* and RIVER in the *Encyclopædia*. That our readers, however, may find ſomething under a title to which we raſhly referred them, we ſhall, in the words of Nicholſon's Journal of Natural Philoſophy, &c. inform them what Venturi's work contains.

"This author, who is profeſſor of experimental philoſophy at Modena, has introduced an horizontal current of water into a veſſel filled with the ſame fluid at reſt. This ſtream entering the veſſel with a certain velocity, paſſes through a portion of the fluid, and is then received in an inclined channel, the bottom of which gradually riſes until it paſſes over the border or rim of the veſſel itſelf. The effect is found to be, not only that the ſtream itſelf paſſes out of the veſſel through the channel, but carries along with it the fluid contained in the veſſel; ſo that after a ſhort time no more of the fluid remains than was originally below the aperture at which the ſtream enters. This fact is adopted as a principle or primitive phenomenon by the author, under the denomination of the lateral communication of motion in fluids, and to this he refers many important hydraulic facts. He does not undertake to give an explanation of this principle, but ſhews that the mutual attraction of the particles of water is far from being a ſufficient cauſe to account for it.

The firſt phenomenon which the author propoſes to explain by this eſtabliſhed principle, is the emiſſion of a fluid through different adjutages applied to the reſervoir which contains it. It is known that the vein of fluid which iſſues from an orifice or perforation through a thin plate, becomes contracted, ſo as to exhibit a ſection equal to about 0,64 of the orifice itſelf, ſuppoſed to be circular; and that the place of the greateſt contraction is uſually at the diſtance of one ſemi-diameter of the orifice itſelf. If a ſmall adjutage be adapted to the orifice, having its internal cavity of the ſame conoidal form as the fluid itſelf affects in that interval, the expenditure is the ſame as by the ſimple orifice. But if at the extremity of this adjutage a cylindric tube be affixed, of a greater diameter than that of the contracted vein, or a divergent conical tube, the expence of fluid increaſes, and may exceed the double of that which paſſes through the aperture in the thin plate, though the adjutage poſſeſs an horizontal or even aſcending direction.

By the interpoſition of a ſmall adjutage, adapted to the form of the contracted vein, Venturi aſcertained, in the firſt place, that there is an increaſe of velocity in the tubes he employed, though the velocity of emiſſion itſelf be leſs than that of the ſtream which iſſues from a hole in a thin plate. He afterwards proves, by the fact, that the interior velocity and expenditure of fluid, which is increaſed through tubes, even in the horizontal or aſcending direction, is owing to the preſſure of the atmoſphere. If the ſmalleſt hole be made in the ſide of the tube near the place of contraction of the vein, the increaſed expenditure does not take place; and when a vertical tube is inſerted in ſuch a hole, the lower end of which tube is immerſed in water or mercury, it is found that aſpiration takes place, and the water or mercury riſes; and this aſpiration in conical tubes is leſs in proportion, as the place of inſertion of the upright tube is more remote from the ſection where the greateſt contraction would have taken place. And, laſtly, the difference between the expenditure of fluid, through an orifice made in a thin plate, and that which is obſerved through an additional tube, does not take place in vacuo.

The influence of the weight of the atmoſphere on the horizontal or aſcending flux being thus eſtabliſhed, the author conſiders it as a ſecondary cauſe, referable to, and explicable by, his principle of the lateral communication of motion in fluids. In conical divergent tubes, for example, the effect of this lateral communication is, that the central cylindrical jet, having for its baſis the ſection of the contracted vein, carries with it the lateral fluid which would have remained ſtagnant in the enlarged part of the cone. Hence a vacuum tends to be produced in this enlarged part which ſurrounds the central cylindric ſtream; the preſſure of the atmoſphere becomes active to ſupply the void, and is exerted on the ſurface of the reſervoir, ſo as to increaſe the velocity of the fluid at the interior extremity of the tube.

The author proves, that the velocity or total expenditure of fluid through an aperture of given dimenſions, may be increaſed by a proper adjutage in the proportion of 24 to 10: he applies this reſult to the conſtruction of the funnels of chimneys. He determines the loſs of emitted fluid, which may be ſuſtained by ſinuoſity in pipes. He ſhews by experiment, that a pipe which is enlarged in any part affords a much leſs quantity of fluid than if it were throughout of a diameter equal to that of its ſmalleſt ſection. This, as he remarks, is a circumſtance to which ſufficient attention has not been paid in the conſtruction of hydraulic machines. It is not enough to avoid elbows and contractions; for it ſometimes happens that, by an intermediate enlargement, the whole of the advantage ariſing from other judicious diſpoſitions of the parts of the machine is loſt.

There are two cauſes of the increaſe of expenditure through deſcending pipes. The firſt is owing to the lateral communication of motion which takes place in deſcending pipes, in the ſame manner as in thoſe which poſſeſs an horizontal ſituation; the ſecond ariſes from the acceleration by gravity which takes place in the fluid while it falls through the deſcending tube. This ſecond kind of augmentation was known to the ancients, though they poſſeſſed no good theory nor deciſive experiments reſpecting it. The author endeavours to eſtabliſh a theory on the principle of virtual aſcenſion combined with the preſſure of the atmoſphere. His deductions are confirmed by experiment, in which he has ſucceeded ſo far as to ſeparate the two cauſes of augmentation, and aſſigned to each their reſpective degree of influence.

Profeſſor Venturi then proceeds to different objects of enquiry, to which his principle ſeemed applicable. He gives the theory of the water blowing machine (ſee *Water Blowing Machine* in this *Suppl.*), and he determines by calculation the quantity of air which one of theſe machines can afford in a given time. He obſerves, that the natural falls of water in the mountains always produce a local wind; and he even thinks, that the falling ſtreams in the internal parts of mountains are in ſome inſtances the cauſe of the winds which iſſue from caves. He proves, by the facts, that it is poſſible, in certain inſtances, to carry off, without any machinery, the waters from a ſpot of ground, though it may be ſituated on a lower level than that of the channel which is to receive the water.

The whirlpools, or circular eddies of water ſo frequent in rivers, are, according to the theory of our author, the effect of motion communicated from the parts of the current which are moſt rapid, to thoſe lateral parts which are leaſt ſo. In the application of this principle, he points out the circumſtances adapted to produce ſuch eddies at the ſurface or at the bottom of rivers. He concludes, that every movement of this kind deſtroys a part of the force of the current, and that in a channel through which water conſtantly flows, the height of this fluid will be greater than it would have been if the dimenſions of the channel had been uniformly reduced to the meaſure of its ſmalleſt ſection.

There is another kind of whirling motion ſomewhat different in its nature from theſe laſt. It is produced in the water of a reſervoir, when it is ſuffered to flow through an horizontal orifice. The author deduces the theory of theſe vortices from the doctrine of central forces. The form of the hollow funnel, which in this caſe opens through the fluid of the reſervoir, is a curve of the 64th ſpecies of the lines of the third order, enumerated by Newton. Theory and experiment both unite here in proving, that it is not only poſſible, but that there really exiſts in nature a vortex, the concavity of which is convex towards the axis, and of which the revolutions of its different parts follow the ratio of the ſquare of the diſtance from the centre. Daniel Bernoulli was in the wrong, in his Hydrodynamics, to reproach Newton for having ſuppoſed a vortex to be moved according to this law.

In the laſt place, the author conſiders that lateral communication of motion which takes place in the air as well as in the water. This is the cauſe of ſuch local and partial winds as ſometimes blow contrary to the direction of the general wind. It is by virtue of the ſame principle, that the reſonant vibration, excited laterally in the extremity of an organ pipe, is communicated to the whole column of air contained in the pipe itſelf.

From the ſame principle, the author deduces the augmentation of force which ſound receives in conical divergent tubes, compared with thoſe of a cylindrical form. On this occaſion, he points out the remarkable diffe-

differences which appear to take place between the reſonant vibrations of air contained in a tube, and the ſonorous pulſations propagated through the open atmoſphere. See *Speaking Trumpet*, Encycl.

In an appendix, Venturi relates different experiments which he has made to determine the convergence and velocity of the fluid filaments which preſs forward to iſſue out of a reſervoir by an orifice through a thin plate. He proves, by a very clear experiment, that the contraction of the vein is made at a greater diſtance from the orifice under ſtrong than under weak preſſures. He explains why, in a right-lined orifice, the ſides of the contracted vein correſpond with the angles of the orifice and the angles with the ſides. He examines the expenditure through a tube, the extremity of which is thruſt into the reſervoir itſelf, according to the method of Borda in the Memoirs of the Academy of Sciences for the year 1766."

For a full account of the author's experiments, and his deductions from them, we refer the reader either to the original work, intitled, *Recherches expérimentales ſur le Principe de la Communication latérale du Mouvement dans les Fluides, appliqué à l'Explication de différens Phénomènes hydrauliques. Par le Citoyen J. B. Venturi, Profeſſeur de Phyſique expérimentale à Modène, Membre de la Societé Italienne, &c. &c. A Paris chez Houel et Ducros, Rue du Bacq,* N° 940—*Théophile Barrois, Rue Haute-feuille,* N° 22. *Ann.* VI. 1797—or to the 2d and 3d vols of the valuable Journal from which this abſtract is taken.

MOURZOUK, the capital of Fezzan in Africa, is ſituated on a ſmall river, and ſupplied with water from a multitude of ſprings and wells. Being formerly built of ſtone, it ſtill retains the appellation of a Chriſtian town; and the medley which it preſents to the eye, of the vaſt ruins of ancient buildings, and the humble cottages of earth and ſand that form the dwellings of its preſent Arab inhabitants, is ſingularly groteſque and ſtrange. It is ſurrounded by a high wall, which not only affords the means of defence, but enables the government to collect, at its three gates, a tax on all goods (proviſions excepted) that are brought for the ſupply of its people A caravan ſets out annually from Meſurata to this place; and hence the Fezzaners themſelves diſpatch every year a caravan to Caſhna and another to Bornou. For the latitude of Mourzouk, ſee Fezzan in this *Suppl.* Dr Brookes, in his Gazetteer, places it in 15° 5′ E. Long.

MOWAZZEF, in Bengal, fixed revenue.

MOZART, the celebrated German muſician, was born at Salzburg in the year 1756. His father was alſo a muſician of ſome eminence, but not to be compared with the ſon; of whom we have the following account in one of the monthly miſcellanies, taken by Mr Buſhby from ſome biographical ſketches by two eminent German profeſſors.

At the age of three years, young Mozart, attending to the leſſons which his ſiſter, then ſeven years old, was receiving at the harpſichord, he became captivated with harmony; and when ſhe had left the inſtrument, he would inſtantly place himſelf at it, find the thirds, ſound them with the livelieſt joy, and employ whole hours at the exerciſe. His father, urged by ſuch early and ſtriking indications of genius, immediately began to teach him ſome little airs; and ſoon perceived that his pupil improved even beyond the hopes he had formed of him. Half an hour was generally ſufficient for his acquiring a minuet or a little ſong, which, when once learned, he would of himſelf perform with taſte and expreſſion.

Mozart.

At the age of ſix years he had made ſuch a progreſs as to be able to compoſe ſhort pieces for the harpſichord, which his father was obliged to commit to paper for him. From that time nothing made any impreſſion upon him but harmony; and infantine amuſements loſt all their attractions unleſs muſic had a ſhare in them. He advanced from day to day, not by ordinary and inſenſible degrees, but with a rapidity which hourly excited new ſurpriſe in his parents—the happy witneſſes of his progreſs.

His father returning home one day with a ſtranger, found little Mozart with a pen in his hand. "What are you writing," ſaid he? "A concerto for the harpſichord," replied the child. "Let us ſee it (rejoined the father); it is a marvellous concerto without doubt." He then took the paper, and ſaw nothing at firſt but a maſs of notes mingled with blots of ink by the mal-addreſs of the young compoſer, who, unſkilled in the management of the pen, had dipped it too freely in the ink; and having blotted and ſmeared his paper, had endeavoured to make out his ideas with his fingers; but on a cloſer examination, his father was loſt in wonder; and his eyes delighted and flowing with tears, became rivetted to the notes. "See (exclaimed he to the ſtranger) how juſt and regular it all is! but it is impoſſible to play it; it is too difficult." "It is a concerto (ſaid the child), and muſt be practiſed till one can play it. Hear how this part goes." He then ſat down to perform it; but was not able to execute the paſſages with ſufficient fluency to do juſtice to his own ideas. Extraordinary as his manual facility was univerſally allowed to be for his age, it did not keep pace with the progreſs of his knowledge and invention. Such an inſtance of intellectual advancement, in a child only ſix years of age, is ſo far out of the common road of nature, that we can only contemplate the fact with aſtoniſhment, and acknowledge, that the poſſible rapidity of mental maturation is not to be calculated.

In the year 1762, his father took him and his ſiſter to Munich, where he performed a concerto before the elector, which excited the admiration of the whole court; nor was he leſs applauded at Vienna, where the emperor called him the *little ſorcerer*.

His father gave him leſſons only on the harpſichord; but he privately taught himſelf the violin; and his command of the inſtrument afforded the elder Mozart the utmoſt ſurpriſe, when he one day at a concert took a ſecond violin, and acquitted himſelf with more than paſſable addreſs. True genius ſees no obſtacles. It will not therefore excite our wonder, if his conſtant ſucceſs in whatever he attempted begot an unbounded confidence in his own powers; he had even the *laudable* hardihood to undertake to qualify himſelf for the *firſt* violin, and did not long remain ſhort of the neceſſary proficiency.

He had an ear ſo correct, that he felt the moſt minute diſcordancy; and ſuch a fondneſs for ſtudy, that it was frequently neceſſary to take him by force from the inſtrument. This love of application never diminiſhed. He every day paſſed a conſiderable time at his harpſichord, and generally practiſed till a late hour at night.

Mozart.

night. Another characteriſtical trait of real genius; always full of its object, and loſt as it were in itſelf.

In the year 1763 he made, with his father and ſiſter, his firſt grand muſical journey. He viſited Paris; and was heard by the French court in the chapel-royal at Verſailles, where his talent on the organ was admired even more than on the harpſichord. At Paris the muſical travellers gave two concerts, which procured them the higheſt reputation, and the diſtinction of public portraits. It was here that a ſet of ſonatas for the harpſichord, ſome of his earlieſt compoſitions, were engraved and publiſhed.

From Paris they went to London, where they alſo gave two concerts, conſiſting of ſymphonies compoſed by young Mozart, who even at that early age ſang alſo with much expreſſion, and practiſed publicly with his ſiſter. Mozart played already at ſight, and in a concert, at which the king was one of his auditors, a baſs being placed before him as a *ground*, immediately applied to it a moſt beautiful melody. Thoſe who are beſt acquainted with the extent of ſuch a taſk, will be the moſt aſtoniſhed at ſuch mature familiarity with the intricacies of the ſcience, and ſuch prompt and ready invention in ſo juvenile a mind.

From London, where Mozart alſo publiſhed ſix ſonatas for the harpſichord, the muſical family went to Holland, thence again to France, and in 1766 returned to Salzburg. There this extraordinary youth remained more than a year in perfect repoſe; devoting the whole of his time to the ſtudy of compoſition, the principles of which he ſcrutinized with the depth and penetration of confirmed manhood. Emmanuel Bach, Haſſe, and Handel, were his chief guides and models; though he by no means neglected the old Italian maſters.

In 1768 he again viſited Vienna, where Joſeph II. engaged him to ſet to muſic a comic opera, entitled, *La Finta Semplice*, which obtained the approbation of Haſſe and Metataſio. At the houſe of the prince of Kaunitz, it often happened that the firſt Italian air which came to hand would be given him, that in the preſence of the company he might add to it accompaniments for numerous inſtruments; which he would write in the firſt ſtyle of excellence, and without the leaſt premeditation. This is at once a proof with what acuteneſs of obſervation he had liſtened to the muſic of the beſt maſters; how intimate he had already rendered himſelf with the characters, capacities, and effects of the different inſtruments; and what ſkill he had acquired in that abſtruſe art of mixed combination which, while it calculates the conjoint effect of ſounds, as they regard the eſtabliſhed laws of harmony, accommodates the different parts to the ſcales, tones, and powers of the reſpective inſtruments by which they are to be executed. It was at this time alſo that, although but twelve years of age, he compoſed the muſic for the conſecration of the church of orphans, at the performance of which he himſelf preſided.

In 1769 Mozart again returned to Salzburg, where he became *maitre de concert*. Not having yet ſeen Italy, in December of the ſame year he ſet out for that ſeat of the fine arts. Thoſe talents which had already excited the admiration of Germany, France, and England, now awakened in that land of muſical taſte the moſt lively enthuſiaſm.

In 1771 he had no ſooner given perſonal proofs of his genius, than *la ſcrittura* for the following carnival was conferred upon him. He viſited Bologna, then as famous for harmonic excellence as Naples, where the celebrated theoriſt Martini was amazed to ſee a German boy work and execute the theme of a fugue which he preſented to him, in the extraordinary ſtyle in which Mozart acquitted himſelf. He next went to Florence. Florence even enhanced the eulogiums which Bologna had laviſhed upon him.

During the holy week he arrived at Rome, and aſſiſted at the *Miſerere* in the Sixtine chapel; which performance is juſtly conſidered as the *ne plus ultra* of vocal muſic. This circumſtance claims particular notice, as inducing a proof of another faculty of his mind, only to be equalled by thoſe wonderful powers which he had already demonſtrated. He was prohibited from taking a copy of this *Miſerere*, and therefore piqued himſelf on retaining it in his memory. Having heard it with attention, he went home, made out a manuſcript from recollection, returned the next day to the chapel, heard the piece a ſecond time, corrected the rough draught, and produced a tranſcript which ſurpriſed all Rome. This *Miſerere* formed a *ſcorer* numerous in its parts, and extremely difficult of execution. His mind had embraced and retained the whole!

He ſoon after received from the Pope the order of the gilt ſpur; and at Bologna was complimented, by an unanimous deciſion, with the title of *Member and Maſter of the Phil-harmonic Academy*. As a proof, *pro forma*, of his qualifications for this academical honour, a fugue, for four voices, in the church ſtyle, was required of him, and he was ſhut up alone in his chamber. He completed it in half an hour, and received his diploma. This evinced that he poſſeſſed an imagination conſtantly at his command, and that his mind was ſtored with all the riches of his beloved ſcience.

The opera which he compoſed for Milan was called *Mithridates*. This piece procured him *la ſcrittura* for the grand opera of the carnival of 1773, which was his *Lucio Sulla*. At length, after a tour of fifteen months, he returned to Salzburg.

In 1771 Mozart viſited Paris; but not reliſhing the muſic of that capital, he ſoon quitted it, and returned to his domeſtic comforts. In 1781, at the requeſt of the elector of Bavaria, he compoſed the opera of *Idomeneo* for the carnival of that year. The general merit of this opera is ſo great, that it might ſerve alone for the baſis of a diſtinguiſhed reputation. At his twenty-fifth year he was invited to Vienna, where he continued ſpreading, as from a centre, the taſte of his compoſitions through all Germany, and the luſtre of his name over the whole of Europe.

Of all the virtuoſi of the piano forte who then crowded Vienna, Mozart was much the moſt ſkilful. His finger was extraordinarily rapid and taſteful, and the execution of his left hand exceeded every thing that had before been heard. His touch was replete with delicacy and expreſſion; and the profound ſtudy he had beſtowed on his art, gave his performance a ſtyle the moſt brilliant and finiſhed. His compoſitions had a rapid circulation; and in every new piece the connoiſſeurs were ſtruck with the originality of its caſt, the novelty of the paſſages, and the energy of the effect.

Joſeph II. ſolicitous for the perfection of the German opera, engaged Mozart to compoſe a piece. He aczart.

cordingly produced *L'enlevement du Serail;* performed for the firſt time in 1782. It excited the jealouſy of the Italian company, who therefore ventured to cabal againſt it. The emperor, addreſſing himſelf to the compoſer, ſaid, "It is *too fine* for our ears, my dear Mozart, and moſt *charmingly crowded* with notes." "Preciſely what it ought to be," replied the ſpirited muſician, who juſtly ſuſpected that this remark had been ſuggeſted to Joſeph by the envious Italians. "Though I cannot deſcribe, as an auricular evidence, (ſays the faithful author of the biography), the applauſes and the admiration which this opera produced at Vienna, yet I have witneſſed the enthuſiaſm it excited at Prague among all the connoiſſeurs, as well as among thoſe whoſe ears were leſs cultivated. It was ſaid, that all which had been heard before was not muſic: it drew the moſt overflowing audiences: every body was amazed at its new traits of harmony, and at paſſages ſo original, and till then ſo unheard from wind inſtruments."

The cautious reader will perhaps heſitate to admit, in its fulleſt extent, this account by the author of the biography; but even after an allowance for ſome exaggeration, the moſt phlegmatic will grant that much muſt have been atchieved by this great maſter, to afford a baſis for ſo glowing a picture of the merit and ſucceſs of *L'enlevement du Serail.* During the compoſition of this opera, he married Mademoiſelle Weber, a diſtinguiſhed virtuoſa; and the piece was ſuppoſed to owe to this felicitous circumſtance much of that endearing character, that tone of tenderneſs, and that expreſſion of the ſofter paſſions, which form its principal attractions.

"The Marriage of Figaro," which was in the higheſt repute at all the theatres, was in the year 1787 transformed into an Italian opera; and Mozart, at the inſtance of the emperor, ſet it to muſic. This piece was highly received everywhere, and kept poſſeſſion of the theatre at Prague during almoſt the whole of the winter in which it firſt appeared: numerous extracts were made from it, and the ſongs and dances of Figaro were vociferated in the ſtreets, the gardens, and the taverns. Mozart came that very winter to Prague, and performed in public on the piano forte. His auditors at all times liſtened to him with admiration; but whenever he played extempore, and indulged the ſpontaneous and uninterrupted ſallies of his fancy, which he ſometimes would for more than half an hour, every one was ſeized with the moſt enthuſiaſtic raptures, and acknowledged the unrivalled reſources of his imagination. About this time the manager of the theatre contracted with him for the compoſition of a new opera, which, when produced, was called *Il diſſoluto Punito*, or *Don Giovanni.* His reputation was now ſo exalted, that the Bohemians piqued themſelves on the circumſtance that this opera was compoſed for their entertainment.

But this fame, this great and univerſal applauſe, had not yet produced to the admired artiſt any ſolid advantages; he had obtained no place, no ſettled income; but ſubſiſted by his operas, and the inſtructions and occaſional concerts which he gave. The profits of theſe proved inſufficient for the ſtyle which he was obliged to ſupport; and his finances became much deranged. The critical ſituation in which he now found himſelf, made him reſolve to quit Vienna, and ſeek an aſylum in London; to which metropolis he had often been invited; but Joſeph nominating him *compoſiteur de la chambre*, though, with a very inadequate ſalary, he was induced to accept it; and Germany had the advantage of retaining him.

Mozart.

It is lamentable that premature genius too rarely enjoys a long career: The acceleration of nature in the mental powers ſeems to hurry the progreſs of the animal œconomy, and to anticipate the regular cloſe of temporal exiſtence.

In the year 1791, Mozart, juſt after he had received the appointment of *Maitre de chapelle* of the church of St Peter, and when he was only thirty-five years of age, paid the laſt tribute; and left the world at once to admire the brilliancy, and lament the ſhortneſs of his earthly ſojournment.

Indefatigable, even to his death, he produced, during the laſt few months of his life, his three great maſter pieces *La Flutte Enchantée*, *La Clemence de Titus*, and a *Requiem*, his laſt production. *La Flutte Enchantée* was compoſed for one of the theatres at Vienna; and no dramatic *Olio* could ever boaſt a greater ſucceſs. Every air ſtruck the audience with a new and ſweet ſurpriſe; and the *tout enſemble* was calculated to afford the deepeſt and moſt varied impreſſions. This piece had, in fact, ſo great a number of ſucceſſive repreſentations, that for a long time it was unneceſſary to conſult the opera-bill; which only announced a permanent novelty. And the airs ſelected from it, and repeated throughout the empire, as well in the cottage as in the palace, and which the echoes have reſounded in the moſt diſtant provinces, favoured the idea that Mozart had actually the deſign to enchant all Germany with his *Flutte Enchantée.*

La Clemence de Titus was requeſted by the ſtates of Bohemia for the coronation of Leopold. The compoſer began it in his carriage during his route to Prague, and finiſhed it in eighteen days.

Some circumſtances attending the compoſition of the piece which we have already mentioned as the laſt effort of his genius, are too intereſting to be omitted. A ſhort time before his death, a ſtranger came to him with the requeſt that he would compoſe, as ſpeedily as poſſible, a *requiem* for a catholic prince, who, perceiving himſelf on the verge of the grave, wiſhed, by the execution of ſuch a piece, to ſoothe his mind, and familiariſe it to the idea of his approaching diſſolution. Mozart undertook the work; and the ſtranger depoſited with him as a ſecurity 400 ducats, though the ſum demanded was only 200. The compoſer immediately began the work, and during its progreſs felt his mind unuſually raiſed and agitated. He became at length ſo infatuated with his *requiem*, that he employed not only the day, but ſome hours of the night in its compoſition. One day, while he was converſing with Madame Mozart on the ſubject, he declared to her that he could not but be perſuaded that it was for himſelf he was writing this piece. His wife, diſtreſſed at her inability to diſſipate ſo melancholy an impreſſion, prevailed on him to give her the *ſcore.* He afterwards appearing ſomewhat tranquillized, and more maſter of himſelf, ſhe returned the *ſcore* to him, and he ſoon relapſed into his former deſpondency. On the day of his death he aſked for the *requiem*, which was accordingly brought to his bed: "Was I not right (ſaid he), when I declared that it was for myſelf I was compoſing this funeral piece?" And the tears trickled from his eyes. This production of a man, impreſſed during its compoſition with a preſentiment of his approaching death, is *unique* in its kind, and contains paſſages which have frequently drawn tears from the performers.

Only one complaint eſcaped him during his malady: "I muſt quit life (ſaid he), preciſely at the moment when I could enjoy it, free from care and inquietude; at the very time when, independent of ſordid ſpeculations, and at liberty to follow my own principles and inclinations, I ſhould only have to write from the impulſes of my own heart: and I am torn from my family juſt when in a ſituation to ſerve it." Mozart, at the time of his death, was conſiderably involved in debt; but Vienna and Prague diſputed the honour of providing for his widow and children.

The countenance of this great maſter did not indicate any thing uncommon. He was ſmall of ſtature; and, except his eyes, which were full of fire, there was nothing to announce ſuperiority of talent. His air, unleſs when he was at the harpſichord, was that of an abſent man. But when he was performing, his whole phyſiognomy became changed: a profound ſeriouſneſs recalled and fixed his eyes; and his ſentiments were expreſſed in every movement of his muſcles. Never has a muſician more ſucceſsfully embraced the whole extent of his art, and ſhone with greater luſtre in all its departments. His great operas, no leſs than his moſt ſimple ſongs; his learned ſymphonies as well as his airy dances—all carry the ſtamp of the richeſt imagination, the deepeſt ſenſibility, and the pureſt taſte. All his works develope the originality of his genius; and imply a mind great and exalted; an imagination which ſtrikes out for itſelf a new courſe. He therefore merits to be ranked with that ſmall number of original geniuſes, thoſe *phænomena ſplendida*, who form an epoch in their art, by carrying it to perfection, or giving it an unknown career.

It is in the employment of wind inſtruments that Mozart diſplays his greateſt powers. His melody is always ſimple, natural, and full of force; and expreſſes with preciſion the ſentiments and individual ſituations of his perſonages. He wrote with extraordinary facility. "*La Clemence de Titus*," the reader will recollect, coſt him the ſtudy of but eighteen days; and his *requiem*, which is equal in length to an opera, was produced in four weeks. It is alſo worthy of remark, that the overture to his *Don Giovanni* was not begun till the night before the piece was to be performed. At midnight, after having devoted the evening to amuſement, he locked himſelf up in his ſtudy, and compoſed it in a few hours. His memory was wonderfully retentive, as we may judge from his copying by recollection the *miſerere* at Rome. But a fact equally aſtoniſhing is, that, ſoon diſcovering the eagerneſs of people to procure his works, and fearful that they might be pirated, it was his conſtant cuſtom to tranſcribe from the *ſcores* of his ſonatas only a part for one hand, and at the public performance to ſupply the other by memory.

He very early began to diſplay that true dignity of an artiſt which renders him indifferent to the praiſes of thoſe who are unqualified to judge. The commendations of the ignorant great he never conſidered as fame. His hearers, whether the wealthy or the titled, muſt have acquired ſome credit for their judgment before he could be ambitious of their applauſe. Indeed he entertained ſo juſt a ſenſe of ſcientific elevation and importance, that he would inſiſt upon reſpect. And the leaſt noiſe or idle babble, while he was at the inſtrument, excited a diſpleaſure which he was too indignant to conceal. Once, to the honour of his feelings, he ſuddenly roſe from his ſeat, and left his inattentive auditory to experience the keen though ſilent reproach of inſulted genius.

His mind was by no means unlettered; nor was it embelliſhed with one ſcience alone. He was maſter of ſeveral languages, and had made conſiderable progreſs in the mathematics. He was honeſt, mild, generous, full of frankneſs; and with his friends had an air at once amiable, gay, and free from the leaſt tincture of pedantry.

Far from viewing with envy the ſucceſs of others, a weakneſs too cloſely interwoven in the general nature of man, he was always juſt to the talents of his fellow profeſſors; and valued and reſpected merit wherever he found it; a clearer proof of which cannot be adduced than the following circumſtance: At a concert, where a new piece compoſed by the celebrated Joſeph Haydn was performed, a certain muſician, who never diſcovered any thing worthy of praiſe except in his own productions, did not fail to criticiſe the muſic; exclaiming to Mozart, "There now! there again! why, that is not what *I* ſhould have done:" "No; neither ſhould I (replied Mozart); but do you know why? Becauſe neither you nor I ſhould have been able to conceive it."

MUMBO-JUMBO, a ſtrange bugbear employed by the Pagan Mandingoes (ſee MANDING, *Suppl.*) for the purpoſe of keeping their women in ſubjection. Polygamy being allowed among theſe people, every man marries as many wives as he can conveniently maintain; and the conſequence is, that family quarrels ſometimes riſe to ſuch a height, that the huſband's authority is not ſufficient to reſtore peace among the ladies. On theſe occaſions, the interpoſition of *Mumbo-Jumbo* is called in; and it is always deciſive. This ſtrange miniſter of juſtice, who is either the huſband himſelf, or ſome perſon inſtructed by him, diſguiſed in a ſort of maſquerade habit, made of the bark of trees, and armed with the rod of public authority, announces his coming by loud and diſmal ſcreams in the woods near the town. He begins the pantomime at the approach of night; and as ſoon as it is dark, he enters the town, and proceeds to the *Bentang* or market-place, at which all the inhabitants immediately aſſemble.

It may eaſily be ſuppoſed that this exhibition is not much reliſhed by the women; for as the perſon in diſguiſe is entirely unknown to them, every married female ſuſpects that the viſit may poſſibly be intended for herſelf; but they dare not refuſe to appear when they are ſummoned; and the ceremony commences with ſongs and dances, which continue till midnight, about which time Mumbo fixes on the offender. This unfortunate victim being thereupon immediately ſeized, is ſtripped naked, tied to a poſt, and ſeverely ſcourged with Mumbo's rod, amidſt the ſhouts and deriſion of the whole aſſembly; and it is remarkable, that the reſt of the women are the loudeſt in their exclamations on this occaſion againſt their unhappy ſiſter. Daylight puts an end to this

ſhy
ll
rray.

indecent and unmanly revel. It is truly aſtoniſhing that the women ſhould be deluded by ſo clumſy an impoſture, and that the men ſhould ſo faithfully keep their own ſecret. That the women are deluded ſeems evident; for Mr Park aſſures us, that the dreſs of Mumbo is ſuffered to hang on a tree at the entrance of each town; which could hardly be the caſe, if the women were not perſuaded that it is the dreſs of ſome ſupernatural being.

MUNSHY, a Perſian ſecretary or writer.

MUNSUB, in the language of Bengal, a dignity or command conferred by the emperor.

MUNSUBDAR, a dignitary or commander.

Murray.

MURRAY (William), afterwards Earl of Manſfield and Lord Chief Juſtice of England, was the fourth ſon of David Viſcount Stormont. He was born on the 2d day of March 1705 at Perth, in the kingdom of Scotland, of which kingdom his father was a peer. His reſidence in Scotland, however, was of ſhort duration; for he was carried up to London at the early age of three years. Hence his total exemption from the peculiarities of the dialect of his native country.

At the age of fourteen he was admitted as a king's ſcholar of Weſtminſter ſchool; and during his reſidence in that ſeminary, ſays his contemporary Biſhop Newton, he gave early proofs of his uncommon abilities, not ſo much in his poetry, as in his other exerciſes; and particularly in his declamations, which were ſure tokens and prognoſtics of that eloquence which grew up to ſuch maturity and perfection at the bar, and in both houſes of parliament. At the election in May 1723, he ſtood firſt on the liſt of thoſe gentlemen who were ſent to Oxford, and was entered of Chriſt Church, June the 18th, in that year. In the year 1727 he had taken the degree of B. A. and on the death of King George the Firſt, was amongſt thoſe of the univerſity who compoſed verſes on that event.

In April 1724 he was admitted a ſtudent of Lincoln's Inn, though he ſtill continued to reſide much in the univerſity; where, on the 26th of June 1730, he took the degree of M. A. and ſoon afterwards left Oxford, determined to make the tour of Europe before he ſhould devote himſelf ſeriouſly to buſineſs. About this period he wrote two letters to a young nobleman on the ſtudy of ancient and modern hiſtory, which are publiſhed by his biographer Mr Holliday, and ſhew how amply his own mind was then ſtored with general literature.

On his return to England he commenced his legal ſtudies; but proceeded not in the way then uſually adopted, of labouring in the chambers of a ſpecial pleader, or copying (to uſe the words of Blackſtone) the traſh of an attorney's office. Being bleſſed with the powers of oratory in their higheſt perfection, and having ſoon an opportunity of diſplaying them, he very early acquired the notice of the chancellor and the judges, as well as the confidence of the inferior practiſers. How much he was regarded in the houſe of lords, Pope's well-known couplet will prove:

Grac'd as thou art with all the power of words,
So known, ſo honour'd at the houſe of lords.

The graces of his elocution, however, produced their uſual effect with a certain claſs of people, who would not believe that ſuch bright talents could aſſociate with the more ſolid attainments of the law, or that a man of genius and vivacity could be a profound lawyer. As Pope obſerved at that time,

The Temple late two brother ſerjeants ſaw,
Who deem'd each other oracles of law;
With equal talents theſe congenial ſouls,
One lull'd the exchequer, and one ſtunn'd the rolls;
Each had a gravity would make you ſplit,
And ſhook his head at Murray as a wit.

It is remarkable that this ridiculous prejudice accompanied Lord Manſfield to the end of his judicial life, in ſpite of daily proofs exhibited in the court of King's Bench and in the Houſe of Lords, of very profound knowledge of the abſtruſeſt points of juriſprudence. Lord Cheſterfield has given his ſanction to this unfounded opinion. In a letter to his ſon, dated Feb. 12. 1754, he ſays, "The preſent Solicitor General Murray has leſs law than many lawyers, but he has more practice than any, merely upon account of his eloquence, of which he has a never-failing ſtream."

In the outſet of Lord Manſfield's life, it will be the leſs ſurpriſing, that a notion ſhould have been entertained of his addicting himſelf to the purſuits of Belles Lettres too much, when the regard ſhewn to him by Mr Pope, who deſpotically ruled the regions of literature at that period, is conſidered. That great Poet ſeemed to entertain a particular affection for our young lawyer, and was eager to ſhew him marks of his regard. He addreſſed to him his imitation of the 6th Epiſtle of the Firſt Book of Horace; and even condeſcended to become his maſter in the art of elocution. "Mr Murray (ſays his biographer) was one day ſurpriſed by a gentleman of Lincoln's Inn, who could take the liberty of entering his rooms without the ceremonious introduction of a ſervant, in the ſingular act of practiſing the graces of a ſpeaker at a glaſs, while Pope ſat by in the character of a friendly preceptor. Mr Murray, on this occaſion, paid that poet the handſome compliment of, *Tu es mihi Mæcenas* (A)."

Whatever propenſities this ſprightly lawyer might have towards polite literature, he did not permit them to divert his attention from his profeſſion. He ſoon diſtinguiſhed himſelf in an extraordinary manner, as may be ſeen by thoſe who are converſant with, or chuſe to refer to the Books of Reports. In the year 1736, the murder of Captain Porteous by a mob in Edinburgh, after he had been reprieved, occaſioned a cenſure to fall on that city, and a bill of pains and penalties was brought into Parliament againſt the Lord Provoſt and the corporation; which, after various modifications, and a firm and unabated oppoſition in every ſtage of its progreſs, paſſed into a law. In both Houſes Mr Murray was employed as an advocate, and ſo much to the ſatisfaction of his clients, that afterwards, in September 1743, he was preſented with the freedom of Edinburgh in a gold box, profeſſedly, as it was decla-

---

(A) It is thus that eminence is attained even by genius, and Mr Murray was properly employed; though we do not clearly perceive the uſe of the glaſs, when his maſter was watching all his geſtures.

red, for his ſignal ſervices by his ſpeeches to both Houſes of Parliament in the conduct of that buſineſs.

On the 24th of November 1738, he had married Lady Elizabeth Finch, daughter of the Earl of Winchelſea, and in the month of November 1742, was appointed Solicitor General in the place of Sir John Strange, who reſigned (B). He likewiſe was choſen to repreſent the town of Boroughbridge in Parliament, for which place he was alſo returned in 1747 and 1754.

In the month of March 1746-7 he was appointed one of the managers for the impeachment of Lord Lovat by the Houſe of Commons, and it fell to his lot to obſerve on the evidence previous to the Lords giving their judgment. This taſk he executed with ſo much candour, moderation, and gentleman-like propriety, that Lord Talbot, at the concluſion of his ſpeech, paid him the following compliment: “The abilities of the learned manager who juſt now ſpoke, never appeared with greater ſplendour than at this very hour, when his candour and humanity has been joined to thoſe great abilities which have already made him ſo conſpicuous, that I hope one day to ſee him add luſtre to the dignity of the firſt civil employment in this nation.” Lord Lovat himſelf alſo bore teſtimony to the abilities of his adverſary: “I thought myſelf (ſays his lordſhip) very much loaded by one Murray (C), who your Lordſhips know was the bittereſt evidence there was againſt me. I have ſince ſuffered by another Mr Murray, who, I muſt ſay with pleaſure, is an honour to his country, and whoſe eloquence and learning is much beyond what is to be expreſt by an ignorant man like me. I heard him with pleaſure, though it was againſt me. I have the honour to be his relation, though perhaps he neither knows it nor values it. I wiſh that his being born in the North may not hinder him from the preferment that his merit and learning deſerve.”

During the time that Mr Murray continued in office, he ſupported, with great ability, the adminiſtration with which he was connected; and, of courſe, rendered himſelf obnoxious to thoſe who were in oppoſition. Nothing, however, could be urged either againſt his public conduct or his private life; but he was involved in ſome trouble by an ill-deviſed tale, concurring with the known principles of the family of Stormont, to make him ſuſpected of Jacobitiſm. Of this affair, a full and particular account is given by the late Lord Melcombe in the following words:

“Meſſrs Murray, Fawcett, and Stone, were much acquainted, if not ſchool-fellows, in earlier life. Their fortune led them different ways; Fawcett's was to be a country lawyer and recorder of Newcaſtle. Johnſon, now Biſhop of Glouceſter, was one of their aſſociates. On the day the King's birth-day was kept, they dined at the Dean of Durham's at Durham; this Fawcett, Lord Ravenſworth, Major Daviſon, and one or two more, who retired after dinner into another room. The converſation turning upon the late Biſhop of Glouceſter's preferments, it was aſked who was to have his prebend of Durham? The Dean ſaid, that the laſt news from London was, that Dr Johnſon was to have it: Fawcett ſaid, he was glad that Johnſon got off ſo well, for he remembered him a Jacobite ſeveral years ago, and that he uſed to be with a relation of his who was very diſaffected, one Vermon, a mercer, where the Pretender's health was frequently drunk. This paſſing among a few familiar acquaintance, was thought no more of at the time: it ſpread, however, ſo much in the North (how I never heard accounted for), and reached town in ſuch a manner, that Mr Pelham thought it neceſſary to deſire Mr Vane, who was a friend to Fawcett, and who employed him in his buſineſs, to write to Fawcett, to know if he had ſaid this of Johnſon, and if he had, if it was true.

“This letter was written on the 9th of January; it came to Newcaſtle the Friday following. Fawcett was much ſurpriſed; but the poſt going out in a few hours after its arrival, he immediately acknowledged the letter by a long, but not very explicit, anſwer. This Friday happened to be the club day of the neighbouring gentlemen at Newcaſtle. As ſoon as Lord Ravenſworth, who was a patron and employer of Fawcett, came into the town, Fawcett acquainted him with the extraordinary letter he had received; he told him that he had already anſwered it; and being aſked to ſhew the copy, ſaid he kept none; but deſired Lord Ravenſworth to recollect if he held ſuch a converſation at the Deanry of Durham the day appointed for the birth-day. Ravenſworth recollected nothing at all of it: they went to the club together, and Ravenſworth went the next morning to ſee his mother in the neighbourhood, with whom he ſtaid till Monday; but this thing of ſuch conſequence lying upon his thoughts, he returned by Newcaſtle. He and Fawcett had another converſation; and in endeavouring to refreſh each other's memory about this dreadful delinquency of Johnſon, Fawcett ſaid he could not recollect poſitively at ſuch a diſtance of time, whether Johnſon drank theſe healths, or had been preſent at the drinking of them, but that Murray and Stone had done both ſeveral times. Ravenſworth was exceſſively alarmed at this with relation to Stone, on account of his office about the prince; and thus the affair of Johnſon was quite forgotten, and the epiſode became the principal part. There were many more conferences between Ravenſworth and Fawcett

---

(B) On this occaſion a doggrel poem was publiſhed by one Morgan, a perſon then at the bar, entitled, “The Cauſidicade,” in which all the principal lawyers were ſuppoſed to urge their reſpective claims to the poſt. At the concluſion it is ſaid,

Then Murray, prepar'd with a fine panegyric
In praiſe of himſelf, would have ſpoke it like Garrick;
But the Preſident ſtopping him ſaid, “As in truth
“Your worth and your praiſe is in every one's mouth,
“'Tis needleſs to urge what's notoriouſly known,
“The office, by merit, is your's all muſt own;
“The voice of the public approves of the thing,
“Concurring with that of the Court and the King.”

(C) One of the evidences againſt him.

cett upon this ſubject, in which the latter always perſiſted that Stone and Murray were preſent at the drinking, and did drink thoſe healths. It may be obſerved here, that when he was examined upon oath, he ſwore to the year 1731 or 1732, at lateſt. Fawcett comes up as uſual about his law buſineſs, and is examined by Meſſrs Pelham and Vane, who never had heard of Murray or Stone being named: he is aſked, and anſwers only with relation to Johnſon, never mentioning either of the others; but the love of his country, his king, and poſterity, burned ſo ſtrongly in Ravenſworth's boſom, that he could have no reſt till he had diſcovered this enormity. Accordingly, when he came to town, he acquainted the miniſtry and almoſt all his great friends with it, and inſiſted upon the removal of Stone. The miniſtry would have ſlighted it as it deſerved; but as he perſiſted, and had told ſo many of it, they could not help laying it before the king, who, though he himſelf ſlighted it, was adviſed to examine it; which examination produced this moſt injudicious proceeding in parliament *."

This is Lord Melcombe's account; and the ſame author informs us, that Mr Murray, when he heard of the committee being appointed to examine this idle affair, ſent a meſſage to the king, humbly to acquaint him, that if he ſhould be called before ſuch a tribunal on ſo ſcandalous and injurious an account, he would reſign his office, and would refuſe to anſwer. It came, however, before the Houſe of Lords, 22d January 1753, on the motion of the Duke of Bedford.

The debate was long and heavy, ſays Lord Melcombe; the Duke of Bedford's performance moderate enough; he divided the Houſe, but it was not told, for there went below the bar with him the Earl Harcourt, Lord Townſhend, the Biſhop of Worceſter, and Lord Talbot only. The Biſhop of Norwich and Lord Harcourt both ſpoke, not to much purpoſe; but neither of them in the leaſt ſupported the Duke's queſtion.

Upon the whole, Lord Melcombe concludes, "It was the worſt judged, the worſt executed, and the worſt ſupported point that I ever ſaw of ſo much expectation."

The King, his late Majeſty, viewed it in its true light; and is reported to have ſaid, "Whatever they were when Weſtminſter boys, they are now my very good friends." He was likewiſe, as we have been informed by a gentleman connected with the family of Stormont, ſo delighted with Mr Murray's ſpeech in his own vindication, that he deſired to have a copy of it, as a model of dignified and candid eloquence. Fawcett, the original author of the ſtory, ſeems indeed to have been a very ſneaking knave, totally unworthy of credit. Biſhop Johnſon, who was overlooked in the turmoil, excited by the ſuppoſed guilt of Murray and Stone (ſee STONE, in this *Suppl.*), went to Fawcett's chambers in the Temple, and deſired an interview. Being told by the ſervant that his maſter was not at home, he renewed his viſit very early next morning, and declared his reſolution to wait till Mr Fawcett ſhould riſe, the laundreſs having inadvertently confeſſed that he was ſtill in bed. Fawcett, upon this, left his thorny pillow with reluctance; for ſomething ſharper than thorns (ſays Mr Holliday) awaited him, which he could not now poſſibly avoid. The reſult of the interview produced expreſſions of deep contrition, together with a letter, addreſſed to the Lord Biſhop of Glouceſter, acknowledging, in the moſt explicit terms, that his Lordſhip was innocent of the charge which he had been the inſtrument of bringing againſt him.

On the advancement of Sir Dudley Rider to the chief juſticeſhip of the King's Bench in 1754, Mr Murray ſucceeded him as attorney general; and on his death, November 1756, again became his ſucceſſor as chief juſtice, when he was created Baron of Mansfield, in the county of Nottingham, with remainder to the heirs male of his body lawfully begotten.

As ſoon as Lord Mansfield was eſtabliſhed in the King's Bench, he began to make improvements in the practice of that court. On the 12th of November, four days after he had taken his ſeat, he made a very neceſſary regulation, obſerving, "Where we have no doubt, we ought not to put the parties to the delay and expence of a farther argument; nor leave other perſons, who may be intereſted in the determination of a point ſo general, unneceſſarily under the anxiety of ſuſpence."

The anxiety of ſuſpence, from this period, was no longer to be complained of in the court of King's Bench. The regularity, punctuality, and diſpatch of the new chief juſtice, afforded ſuch general ſatisfaction, that they, in proceſs of time, drew into that court moſt of the cauſes which could be brought there for determination.

Sir James Burrows ſays, "I am informed, that at the ſittings for London and Middleſex only, there are not ſo few as 800 cauſes ſet down in a year, and all diſpoſed of. And though many of them, eſpecially in London, are of conſiderable value, there are not more, upon an average, than between 20 and 30 ever heard of afterwards in the ſhape of ſpecial verdicts, ſpecial caſes, motions for new trials, or in arreſt of judgment. Of a bill of exceptions there has been no inſtance (I do not include judgments upon criminal proſecutions; they are neceſſary conſequences of the convictions). My reports give but a very faint idea of the extent of the whole buſineſs which comes before the court: I only report what I think may be of uſe as a determination or illuſtration of ſome matter of law. I take no notice of the numerous queſtions of fact which are heard upon affidavits (the moſt tedious and irkſome part of the whole buſineſs). I take no notice of a variety of conteſtations, which, after having been fully diſcuſſed, are decided without difficulty or doubt. I take no notice of many caſes which turn upon a conſtruction ſo peculiar and particular, as not to be likely to form a precedent for any other caſe. And yet, notwithſtanding this immenſity of buſineſs, it is notorious, that, in conſequence of method, and a few rules which have been laid down to prevent delay (even where the parties themſelves would willingly conſent to it), nothing now hangs in court. Upon the laſt day of the very laſt term, if we exclude ſuch motions of the term as by deſire of the parties went over of courſe as peremptories, there was not a ſingle matter of any kind that remained undetermined, excepting one caſe relating to the proprietary Lordſhip of Maryland, which was profeſſedly poſtponed on account of the preſent ſituation of America. One might ſpeak to the ſame effect concerning the laſt day of any former term for ſome years backward."

The ſame author alſo informs us, that, excepting two

y, p 10.

Murray.

caſes, there had not been, from the 6th of November 1756 to the time of his then preſent publication, 26th May 1776, a final difference of opinion in the court in any caſe, or upon any point whatſoever. "It is remarkable, too (he adds), that, excepting theſe two caſes, no judgment given during the ſame period has been reverſed, either in the exchequer chamber or in parliament: and even theſe reverſals were with great diverſity of opinion among the judges." Of the two caſes here mentioned, one was the famous queſtion concerning literary property, which the majority of the judges of the court of King's Bench held to be permanent; and in ſupport of which opinion, ſuch arguments were urged by the chief juſtice, as have not yet perhaps been completely anſwered.

The ill ſucceſs of the war, which had lately been begun, occaſioned a change in the adminiſtration; and the conflicts of contending parties rendered it impracticable for the crown, at that juncture, to ſettle a new miniſtry. In order, therefore, to give pauſe to the violence of both ſides, Lord Mansfield was induced to accept the poſt of chancellor of the exchequer on the 9th of April 1757; which he held until the 2d of July in the ſame year. During this interval, he employed himſelf, with great ſucceſs, to bring about a coalition; which being effected, produced a ſeries of events, which raiſed the glory of Great Britain to the higheſt point at which it has ever been ſeen. In the ſame year he was offered, but refuſed, the office of Lord High Chancellor; and in November 1758, he was elected a governor of the charter houſe, in the room of the Duke of Marlborough, then lately deceaſed.

For ſeveral years after this period, the tenor of Lord Mansfield's life was marked only with a moſt ſedulous diſcharge of the duties of his office. In 1760 Geo. II. died, and the new reign commenced with alterations in the adminiſtration; which gave riſe to a virulent ſpirit of oppoſition, conducted with a degree of violence and aſperity never known at any former time. As a friend to the then adminiſtration, Lord Mansfield was marked out for a more than ordinary ſhare of malicious invective. It is in alluſion to this, that Warburton, after tracing the riſe and progreſs of the irreligion and licentiouſneſs which then prevailed, and obſerving that, amid ſuch general corruption, the pure adminiſtration of public juſtice ſtill afforded a cheerful conſolation to thinking men, proceeds thus:

"But the evil genius of England would not ſuffer us to enjoy it long; for, as if envious of this laſt ſupport of government, he hath now inſtigated his blackeſt agents to every extent of their malignity; who, after the moſt villainous inſults on all other orders and ranks in ſociety, have at length proceeded to calumniate even the king's ſupreme court of juſtice, under its ableſt and moſt unblemiſhed adminiſtration. After this, who will not be tempted to deſpair of his country, and ſay with the good old man in the ſcene,

——"*Ipſa ſi cupiat ſalus*
"*Servare, prorſus non poteſt, hanc Familiam* (D)?"

A change of adminiſtration again took place in 1765, which introduced the Marquis of Rockingham and his friends to govern the country; and the meaſures then adopted not agreeing with Lord Mansfield's ſentiments, he, for the firſt time, became an opponent of government. On the bill for repealing the ſtamp act, he ſpoke, and divided againſt it; and is ſuppoſed to have had ſome ſhare in the compoſition of the proteſts on that occaſion, though he did not ſign them. In the ſame year, he is ſaid to have animadverted, with no ſmall degree of ſeverity, on the incautious expreſſions of Lord Camden, on the affair of prohibiting the exportation of corn, that it was but a 40 days tyranny at the outſide (E).

In 1767, the Diſſenters cauſe was determined, in which Lord Mansfield delivered a ſpeech, which has ſince been printed, and ſhews his Lordſhip to have been a ſteady friend to religious toleration, as well as to the rights of the eſtabliſhed church. The conſcientious Diſſenters themſelves laviſhed upon that ſpeech the higheſt praiſe; whilſt others of them, in the ſucceeding year, deluged the public prints with torrents of abuſe on the Chief Juſtice. In that year was the general election. Mr Wilkes returned from abroad, became a candidate for the city of London, and afterwards was choſen repreſentative for the county of Middleſex. Having been outlawed ſome years before, he now applied for a reverſal of that proceeding. On the 8th of June, the conſideration of it came before the court of King's Bench; when the judges delivered their opinions very fully, and were unanimous that the outlawry was illegal, and muſt be reverſed. On this occaſion Lord Mansfield took the opportunity of entering into a full ſtatement of the caſe, and a juſtification of his own conduct. The reader will find the caſe reported by Sir James Burrow; from whom we ſhall extract the following, which appears to have been the moſt important part of his Lordſhip's ſpeech:

"It is fit to take ſome notice of the various terrors hung out; the numerous crowds which have attended, and now attend, in and about the hall, out of all reach of hearing what paſſes in court; and the tumults which in other places have ſhamefully inſulted all order and government. Audacious addreſſes in print dictate to us, from thoſe they call the people, the judgment to be given now, and afterwards upon the conviction. Reaſons of policy are urged, from danger to the kingdom, by commotions and general confuſion.

"Give me leave to take the opportunity of this great and reſpectable audience, to let the whole world know all ſuch attempts are vain. Unleſs we have been able to find an error which will bear us out to reverſe the outlawry, it muſt be affirmed. The conſtitution does not allow reaſons of ſtate to influence our judgment: God

---

(D) See the dedication of the 5th edition of the Divine Legation of Moſes, which deſerves to be read at preſent with peculiar attention, as the work of a man of gigantic talents, deeply read in law as well as in theology.

(E) The ſpeeches in the debate were never printed; but the ſubſtance of them all was conſolidated in a pamphlet publiſhed at the time, intitled, "A Speech againſt the ſuſpending and diſpenſing prerogative," 8vo. Since reprinted in Debrett's Debates, Vol. IV. p. 384.

God forbid it ſhould! We muſt not regard political conſequences, how formidable ſoever they may be; we are bound to ſay, *Fiat Juſtitia, ruat Cœlum.* The conſtitution truſts the king with reaſons of ſtate and policy: He may pardon offences; it is his to judge whether the law or the criminal ſhould yield. We have no election. None of us encouraged or approved the commiſſion of either of the crimes of which the defender is convicted: none of us had any hand in his being proſecuted. As to myſelf, I took no part (in another place) in the addreſſes for that proſecution. We did not adviſe or aſſiſt the defender to fly from juſtice; it was his own act, and he muſt take the conſequences. None of us have been conſulted, or had any thing to do with the preſent proſecution. It is not in our power to ſtop it; it was not in our power to bring it on. We cannot pardon. We are to ſay what we take the law to be. If we do not ſpeak our real opinions, we prevaricate with God and our own conſciences.

"I paſs over many anonymous letters I have received: thoſe in print are public; and ſome of them have been brought judicially before the court. Whoever the writers are, they take the wrong way. I will do my duty unawed. What am I to fear? That *mendax infamia* from the preſs, which daily coins falſe facts and falſe motives? The lies of calumny carry no terror to me. I truſt, that my temper of mind, and the colour and conduct of my life, have given me a ſuit of armour againſt theſe arrows. If, during this king's reign, I have ever ſupported his government, and aſſiſted his meaſures, I have done it without any other reward than the conſciouſneſs of doing what I thought right. If I have ever oppoſed, I have done it upon the points themſelves, without any collateral views. I honour the king, and reſpect the people. But many things acquired by the favour of either are, in my account, objects not worth ambition. I wiſh popularity; but it is that popularity which follows, not that which is run after.—It is that popularity which, ſooner or later, never fails to do juſtice to the purſuit of noble ends by noble means. I will not do that which my conſcience tells me is wrong upon this occaſion, to gain the huzzas of thouſands, or the daily praiſe of all the papers which come from the preſs. I will not avoid doing what I think is right, though it ſhould draw on me the whole artillery of libels, all that falſehood and malice can invent, or the credulity of a deluded populace can ſwallow. I can ſay with a great magiſtrate, upon an occaſion, and under circumſtances not unlike, '*Ego hoc animo ſemper fui, ut invidiam virtute partam, gloriam, non invidiam putarem.*'

"The threats go further than abuſe: Perſonal violence is denounced. I do not believe it: it is not the genius of the worſt men of this country in the worſt of times. But I have ſet my mind at reſt. The laſt end that can happen to any man never comes too ſoon, if he falls in ſupport of the law and liberty of his country (for liberty is ſynonymous to law and government). Such a ſhock, too, muſt be productive of public good: It might awake the better part of the kingdom out of that lethargy which ſeems to have benumbed them; and bring the mad part back to their ſenſes, as men intoxicated are ſometimes ſtunned into ſobriety

"Once for all, let it be underſtood, that no endeavours of this kind will influence any man who at preſent ſits here. If they had any effect, it would be contrary to their intent: Leaning againſt their impreſſion might give a bias the other way. But I hope, and I know, that I have fortitude enough to reſiſt even that weakneſs. No libels, no threats, nothing that has happened, nothing that can happen, will weigh a feather againſt allowing the defendant, upon this and every other queſtion, not only the whole advantage he is intitled to from ſubſtantial law and juſtice, but every benefit from the moſt critical nicety of form, which any other defender could claim under the like objection. The only effect I feel is an anxiety to be able to explain the grounds upon which we proceed; ſo as to ſatisfy all mankind, that a flaw of form given way to in this caſe, could not have been got over in any other."

In January 1770, Lord Mansfield again was offered the Great Seal, which was given to Mr Charles York: and in Hilary Term 1771, he a third time declined the ſame offer, and the Seal was entruſted to Lord Bathurſt.

The year 1770 was alſo memorable for various attacks made on his Lordſhip's judicial character, in both the Houſes of Lords and Commons. In one of theſe, the propriety of a direction given to the jury in the caſe of the king and Woodfal was called in queſtion; which occaſioned his Lordſhip to produce to the Houſe a copy of the unanimous opinion of the court of King's Bench in that cauſe; which, after being much canvaſſed and oppoſed, was ſuffered to ſtand its ground without being over-ruled.

On the 19th of October 1776, his Lordſhip was advanced to the dignity of an Earl of Great Britain, by the title of the Earl of Mansfield, and to his male iſſue; and for want of ſuch iſſue, to Louiſa Viſcounteſs Stormont, and to her heirs male by David Viſcount Stormont her huſband. The ſame title, in 1792, was limited to Lord Stormont himſelf; who afterwards ſucceeded to it.

We come now to a period of his Lordſhip's life, which furniſhes an event diſgraceful to the age and country in which the fact was committed. An union of folly, enthuſiaſm, and knavery, had excited alarms in the minds of ſome weak people, that encouragements were given to the favourers and profeſſors of the Roman Catholic faith inconſiſtent with religion and true policy. The act of Parliament, which excited the clamour, had paſſed with little oppoſition, and had not received any extraordinary ſupport from Lord Mansfield. The minds of the public were inflamed by artful miſrepreſentations; the rage of a popular mob was ſoon directed towards the moſt eminent perſons. Accordingly, in the night between Tueſday the 6th and Wedneſday the 7th of June 1780, his Lordſhip's houſe in Bloomſbury Square was attacked by a party of rioters, who, on the Friday and Tueſday preceding, had, to the amount of many thouſands, ſurrounded the avenues of both Houſes of Parliament, under pretence of attending Lord George Gordon when he preſented the petition from the Proteſtant Aſſociation. On Tueſday evening the priſon of Newgate had been thrown open, all the combuſtible part reduced to aſhes, and the felons let looſe upon the public. It was after this attempt to deſtroy the means of ſecuring the victims of criminal juſtice that the rioters aſſaulted the reſidence of the chief magiſtrate of the firſt criminal court in the kingdom; nor were they diſperſed till they had burnt all the furniture, pictures, books, manuſcripts, deeds, and, in ſhort, every thing which fire could conſume in his Lord-

Murray.

ſhip's houſe ; ſo that nothing remained but the walls, which were ſeen next morning almoſt red-hot from the violence of the flames, preſenting a melancholy and awful ruin to the eyes of the paſſengers. For a fuller account of thoſe dreadful riots, ſee Britain, n° 644. *Encyclopædia*.

So unexpected was this daring outrage on order and government, that it burſt on Lord Mansfield without his being prepared in the ſlighteſt manner to reſiſt it. He eſcaped with his life only, and retired to a place of ſafety, where he remained until the 14th of June, the laſt day of term, when he again took his ſeat in the court of King's Bench. "The reverential ſilence (ſays Mr Douglas) which was obſerved when his Lordſhip reſumed his place on the Bench, was expreſſive of ſentiments of condolence and reſpect, more affecting than the moſt eloquent addreſs the occaſion could have ſuggeſted.

"The amount of that part of Lord Mansfield's loſs which might have been eſtimated, and was capable of a compenſation in money, is known to have been very great. This he had a right to recover againſt the *hundred*. Many others had taken that courſe ; but his Lordſhip thought it more conſiſtent with the dignity of his character not to reſort to the indemnification provided by the legiſlature. His ſentiments, on the ſubject of a reparation from the ſtate, were communicated to the Board of Works in a letter, dated 18th July 1780, written in conſequence of an application which they had made to him (as one of the principal ſufferers), purſuant to directions from the treaſury, founded on a vote of the Houſe of Commons, requeſting him to ſtate the nature and amount of his loſs. In that letter, after ſome introductory expreſſions of civility to the ſurveyor general, to whom it was addreſſed, his Lordſhip ſays, 'Beſides what is irreparable, my pecuniary loſs is great. I apprehended no danger, and therefore took no precaution. But how great ſoever that loſs may be, I think it does not become me to claim or expect reparation from the ſtate. I have made up my mind to my misfortune, as I ought, with this conſolation, that it came from thoſe whoſe object manifeſtly was general confuſion and deſtruction at home, in addition to a dangerous and complicated war abroad. If I ſhould lay before you any account or computation of the pecuniary damage I have ſuſtained, it might ſeem a claim or expectation of being indemnified. Therefore you will have no further trouble upon this from, &c.—*Mansfield*."

From this time the luſtre of Lord Mansfield continued to ſhine with unclouded brightneſs until the end of his political life, unleſs his oppoſition to the meaſures of the preſent adminiſtration, at the early period of their appointment, ſhall be thought to detract, in ſome ſmall degree, from his merit. It is certain many of his admirers ſaw, with concern, a connection with the opponents of government at that juncture, ſcarce compatible with the dignity of the chief juſtice of Great Britain. At length infirmities preſſed upon him, and he became unable to attend his duty with the ſame punctuality and aſſiduity with which he had been accuſtomed. It has been ſuppoſed, that he held his office after he was diſabled from executing the duties of it, from a wiſh to ſecure the ſucceſſion of it to a very particular friend. Be this as it may, the chief juſtice continued in his office until the month of June 1788, when he ſent in his reſignation.

Murra

From this period the bodily powers of his Lordſhip continued to decline ; his mental faculties, however, remained without decay almoſt to the laſt. During this time he was particularly inquiſitive and anxious about the proceedings in France, and felt his ſenſibility, in common with every good man, wounded by the horrible inſtance of democratic infatuation in the murder of the innocent Louis XVI. He lived juſt long enough to expreſs his ſatisfaction at the check given to the French by the Prince of Cobourg in March 1793; on the 20th of which month, after continuing ſome days in a ſtate of inſenſibility, he departed this life, at the age of 88 years.

"In his political oratory (ſays a writer of the preſent times), he was not without a rival; no one had the honour of *ſurpaſſing* him ; and let it be remembered, that his competitor was Pitt.

"The rhetorician that addreſſed himſelf to Tully in theſe memorable words—*Demoſthenes tibi præripuit ne primus eſſes Orator, tu illi ne ſolus*—anticipated their application to Mansfield and Pitt. If the one poſſeſſed Demoſthenean fire and energy, the other was at leaſt a Cicero. Their oratory differed in ſpecies, but was equal in merit. There was, at leaſt, no ſuperiority on the ſide of Pitt. Mansfield's eloquence was not, indeed, of that daring, bold, declamatory kind, ſo irreſiſtibly powerful in the momentary buſtle of popular aſſemblies ; but it was poſſeſſed of that pure and Attic ſpirit, and ſeductive power of perſuaſion, that delights, inſtructs, and eventually triumphs. It has been very beautifully and juſtly compared to a river, that meanders through verdant meads and flowery gardens, reflecting in its cryſtal boſom the varied objects that adorn its banks, and refreſhing the country through which it flows.

"To illuſtrate his oratory by example, would require voluminous tranſcripts from the records of Parliament ; and it is unneceſſary, as we can appeal to living recollection.

"Having added weight and dignity to the offices of attorney and ſolicitor general, his reputation as a ſpeaker, a lawyer, and a politician, elevated him to the peerage, and the exalted poſt of chief juſtice of England. He aſcended to the dignities of ſtate by rapid ſtrides : they were not beſtowed by the caprice of party favour or affection. They were (as was ſaid of Pliny) liberal diſpenſations of power upon an object that knew how to add new luſtre to that power, by the rational exertion of his own.

"Here we can ſpeak of this great man within our own recollection ; and however party prejudices may adopt their different favourites, and each contend in detracting from the merit of the other, it is, we believe, generally underſtood, that precedence is allowed the Earl of Mansfield, as the firſt magiſtrate that ever ſo pre-eminently graced that important ſtation. The wiſdom of his deciſions, and unbiaſſed tenor of his public conduct, will be held in veneration by the ſages of the law, as long as the ſpirit of the conſtitution, and juſt notions of equity, continue to have exiſtence. No man has ever, in an equal degree, poſſeſſed that wonderful ſagacity in diſcovering chicanery and artifice, and ſeparating fallacy from truth, and ſophiſtry from argument, ſo as to hit the exact equity of the caſe. He ſuffered not juſtice to be ſtrangled in the nets of form.

"His memory was aſtoniſhing—he never took notes, or, or, if he did, ſeldom or ever conſulted them." His references to expreſſions which fell from him in the courſe of the debate, or his quotations from books, were ſo faithful, that they might have been ſaid to have been repeated *verbatim*. The purpoſes to which he employed theſe amazing talents were ſtill more extraordinary: if it was the weak part of his opponent's arguments that he referred to, he was ſure to expoſe its fallacy, weakneſs, or abſurdity, in the moſt poignant ſatire, or hold it up in the moſt ridiculous point of view. If, on the contrary, it were a point on which his adverſaries laid their chief ſtreſs, he ſtated the words correctly; collected their obvious meaning, conſidered the force of the ſeveral arguments that had or might have been raiſed upon them, with a preciſion that would induce an auditor almoſt to ſuppoſe that he had previouſly conſidered the whole, and that his ſpeech was the reſult of much previous ſtudy.

"It may be ſaid of Mansfield as of Virgil, that if he had any faults, they might be conſidered in the ſame manner with thoſe of ſome eminent fixed ſtar, which, if they exiſt at all, are above the reach of human obſervation. The luminous æther of his life was not obſcured by any ſhade dark enough to be denominated a defect. On account of his deſcent, local prejudices and propenſities were imputed to him, and his conduct, on that account, examined with a microſcopic eye; but the optic through which it was viewed poſſeſſed a party tinge, equally odious and deceptive.

"His political principles were ever conſiſtent; and to preſerve conſiſtency in ſuch ſtations and in ſuch times as occupied the life of Mansfield, conſtitutes an ordeal ſtrongly impreſſive of virtue. It has been ſaid that he wanted ſpirit. Is the uniform oppoſition of popular opinion, and apparently the contempt of it, any proof of the aſſertion? His ſpeech and conduct in the affair of Wilkes's outlawry, when popular prejudice ran in torrents, illuſtrate each other. He deſpiſed (to borrow an expreſſion of his own) that muſhroom popularity that is raiſed without merit, and loſt without a crime. He diſdained being the ſlave of popular impulſe, or to acknowledge the ſhouts of a mob for the trumpet of fame."

He had a mind too great to be aſhamed of revering the ordinances of religion; and as, after the moſt impartial inquiry, he was a firm believer of the truth and importance of Chriſtianity, he frequented the church regularly, and received the holy ſacrament on the higher feſtivals. Mr Holliday has publiſhed a ſermon, which he ſays was dictated by Lord Mansfield to his friend biſhop Johnſon, and preached by that prelate before the Houſe of Lords. It is a very ſerious and appropriate diſcourſe; but judging upon internal evidence, we ſhould not have ſuppoſed it the compoſition of the eloquent and argumentative chief juſtice of England. His Lordſhip's will, which was written with his own hand, upon little more than half a ſheet of paper, begins with the following elegant and pious paragraph, with which we ſhall conclude this ſketch of his character:

"When it ſhall pleaſe Almighty God to call me to that ſtate, to which, of all I now enjoy I can carry only the ſatisfaction of my own conſcience, and a full reliance upon his mercy through Jeſus Chriſt, I deſire that my body may be interred as privately as may be: and out of reſpect for the place of my early education, I ſhould wiſh it to be in Weſtminſter Abbey." It was interred in Weſtminſter Abbey, in the ſame vault with the Counteſs (who had died April 10. 1784), between the late Earl of Chatham and Lord Robert Manners.

MUSEUM, in the language of the preſent day, is a building in which are depoſited ſpecimens of every object that is in any degree curious, whether ſuch objects be natural or artificial. What the word *muſeum* expreſſed originally, has been told under that title in the *Encyclopædia*.

A complete muſeum contains collections of preſerved beaſts, birds, fiſhes, reptiles, &c.; models of machines; rare manuſcripts; and indeed ſpecimens of every thing neceſſary to illuſtrate phyſical ſcience, to improve art, to aid the antiquarian in his reſearches, and to exhibit the manners and cuſtoms of men in diſtant ages and nations. As natural objects of uncommon ſize or beauty, and other rare productions, were, in the earlieſt periods, conſecrated to the gods, the temples were, of courſe, the firſt repoſitories of ſuch collections, or, in other words, the firſt *Muſeums*. This, we think, has been completely proved by Profeſſor Beckmann *.

"When Hanno (ſays he) returned from his diſtant voyages, he brought with him to Carthage two ſkins of the hairy women whom he found on the Gorgades iſlands, and depoſited them as a memorial in the temple of Juno, where they continued till the deſtruction of the city. The horns of a Scythian animal, in which the Stygian water that deſtroyed every other veſſel could be contained, were ſent by Alexander as a curioſity to the temple of Delphi, where they were ſuſpended, with an inſcription, which has been preſerved by Ælian. The monſtrous horns of the wild bulls which had occaſioned ſo much devaſtation in Macedonia, were, by order of King Philip, hung up in the temple of Hercules. The unnaturally formed ſhoulder bones of Pelops were depoſited in the temple of Elis. The horns of the ſo called Indian ants were ſhewn in the temple of Hercules at Erythræ; and the crocodile found in attempting to diſcover the ſources of the Nile was preſerved in the temple of Iſis at Cæſarea. A large piece of the root of the cinnamon tree was kept in a golden veſſel in one of the temples at Rome, where it was examined by Pliny. The ſkin of that monſter which the Roman army in Africa attacked and deſtroyed, and which probably was a crocodile, an animal common in that country, but never ſeen by the Romans before the Punic war, was, by Regulus, ſent to Rome, and hung up in one of the temples, where it remained till the time of the Numantine war (A). In the temple of Juno, in the iſland of Melita, there were a pair of elephants teeth of extraordinary ſize, which were carried away by Maſiniſſa's admiral, and tranſmitted to that prince, who, though he ſet a high value upon them, ſent them again back, becauſe he heard they had been taken from a temple. The head of a baſiliſc was exhibited in one of the temples of Diana; and the bones of that ſea monſter, probably a whale, to which Andromeda was expoſed, were preſerved at Joppa, and afterwards brought to Rome.

* Inventions, vol. ii. p. 44.

(A) We think, with the tranſlator of Beckmann's Hiſtory, that this animal was not the crocodile, but the *Boa conſtrictor*. See Boa and Serpent, *Encycl.*

Rome. In the time of Pauſanias, the head of the celebrated Calydonian boar was ſhewn in one of the temples of Greece; but it was then deſtitute of briſtles, and had ſuffered conſiderably by the hand of time. The monſtrous tuſks of this animal were brought to Rome, after the defeat of Anthony, by the Emperor Auguſtus, who cauſed them to be ſuſpended in the temple of Bacchus. Apollonius tells us, that he ſaw in India ſome of thoſe nuts which in Greece were preſerved in the temples as curioſities."

Though theſe curioſities were preſerved in the temples for purpoſes very different from thoſe for which our collections are made, there can be no doubt but that they contributed to promote the knowledge of natural hiſtory. If it be true, as Pliny and Strabo inform us, that Hippocrates availed himſelf of the accounts which were hung up in the temple of Æſculapius of different diſeaſes, and of the medicines and mode of treatment by which they were cured; it will eaſily be believed, that the natural hiſtorians availed themſelves, in a ſimilar manner, of the various rare objects which were preſerved in the temples of the other gods. This, we ſee, Pliny actually did.

Suetonius informs us, that Auguſtus had, in his palace, a collection of natural curioſities; and it is well known that Alexander gave orders to all huntſmen, bird-catchers, fiſhermen, and others, to ſend to Ariſtotle whatever rare animals they could procure. M. Beckmann ſeems to be of opinion, that the firſt private muſeum was formed by Apuleius, who, next to Ariſtotle and his ſcholar Theophraſtus, certainly examined natural objects with the greateſt ardour and judgment; who cauſed animals of every kind, and particularly fiſh, to be brought to him either dead or alive, in order to deſcribe their external and internal parts, their number and ſituation, and to determine their characteriſing marks, and eſtabliſh their real names; who undertook diſtant journeys to become acquainted with the ſecrets of nature; and who, on the Getulian mountains, collected petrefactions, which he conſidered as the effects of Deucalion's flood.

The principal cauſe why collections of natural curioſities were ſcarce in ancient times, muſt have been the ignorance of naturaliſts in regard to the proper means of preſerving ſuch bodies as ſoon ſpoil or corrupt. Some methods were indeed known and practiſed, but they were all defective and inferior to that by ſpirit of wine, which prevents putrefaction, and which, by its perfect tranſparency, permits the objects which are covered by it to be at all times viewed and examined. Theſe methods were the ſame as thoſe employed to preſerve proviſions, or the bodies of great men deceaſed. They were put into ſalt brine or honey, or were covered over with wax. Thus the hippopotamus, deſcribed by Columna, was ſent to him from Egypt preſerved in ſalt. The body of Ageſipolis King of Sparta, who died in Macedonia, was ſent home in honey; the celebrated purple dye of the ancients was preſerved freſh for many years by the ſame means; and at this day, when the Orientals are deſirous of tranſporting fiſh to any diſtance, they cover them over with wax.

In thoſe centuries which are uſually called the middle ages, the Profeſſor finds no traces of what can be called a muſeum, except in the treaſuries of emperors, kings, and princes, where, beſides articles of great value, curioſities of art, antiquities, and relics, one ſometimes found ſcarce and ſingular foreign animals, which were dried and preſerved. Such objects were to be ſeen in the old treaſury at Vienna; and in that of St Denis was exhibited the claw of a griffin, ſent by a king of Perſia to Charlemagne; the teeth of the hippopotamus, and other things of the like kind. In theſe collections, the number of the rarities always increaſed in proportion as a taſte for natural hiſtory became more prevalent, and as the extenſion of commerce afforded better opportunities for procuring the productions of remote countries. Menageries were eſtabliſhed to add to the magnificence of courts; and the ſtuffed ſkins of rare animals were hung up as memorials of their having exiſted. Public libraries alſo were made receptacles for ſuch natural curioſities as were from time to time preſented to them; and as in univerſities the faculty of medicine had a hall appropriated for the diſſection of human bodies, curioſities from the animal kingdom were collected there alſo by degrees; and it is probable that the profeſſors of anatomy firſt made attempts to preſerve different parts of animals in ſpirit of wine, as they were obliged to keep them by them for the uſe of their ſcholars; and becauſe in old times dead bodies were not given up to them as at preſent, and were more difficult to be obtained. Private collections appear for the firſt time in the 16th century; and there is no doubt (ſays our author) that they were formed by every learned man who at that period applied to the ſtudy of natural hiſtory.

MUSHROOM, a fungus, of which ſome of the principal ſpecies have been deſcribed in the *Encyclopædia* under the generic name AGERICUS. There is, however, one ſpecies not mentioned there—the *Boletus hirſutus* of Bulliard, which is certainly worthy of notice, ſince one of the French chemiſts has lately extracted from it a bright, ſhining, and very durable yellow dye. This pretty large muſhroom grows commonly on walnut and apple-trees. Its colouring-matter is contained in abundance, not only in the tubular part, but alſo in the parenchyma of the body of the muſhroom. In order to extract it, the muſhroom is pounded in a mortar, and the liquor thence obtained is boiled for a quarter of an hour in water. An ounce of liquor is ſufficient to communicate colouring-matter to ſix pounds of water. When the liquor has been ſtrained, the ſtuff to be dyed is put into it, and boiled for a quarter of an hour. All kinds of ſtuff receive this colour and retain it; but on linen and cotton it is leſs bright. This colour may be modified, in a very agreeable manner, by the effect of mordants.

The proceſs ſucceeded beſt on ſilk. When this ſubſtance, after being dyed, is made to paſs through a bath of ſoft ſoap, it acquires a ſhining golden yellow colour, which has a perfect reſemblance to the yellow of that ſilk employed to imitate embroidery in gold, and which has hitherto been brought from China and ſold at a dear rate, as the method of dyeing it is unknown in Europe. The yellow colour extracted from this muſhroom may be employed alſo with advantage for painting in water-colours as well as in oil.

MUTSUDDIES, in Bengal, writers, accountants, officers of government.

MUZCOORET, allowances to zemindars in land or money. See ZEMINDAR, *Suppl.*

N.

abob ‖ cowry.

Nancowry.

NABOB, or Nowab, a title of courteſy given in India to Mahomedans high in ſtation, particularly provincial governors.

The Sun's NADIR, is the axis of the cone projected by the ſhadow of the earth: ſo called, becauſe that axis being prolonged, gives a point in the ecliptic diametrically oppoſite to the ſun.

NAIB, a deputy.

NAKED, in architecture, as the naked of a wall, &c. is the ſurface, or plane, from whence the projectures ariſe; or which ſerves as a ground to the projectures.

NANCOWRY, or Soury, as it is ſometimes called, is one of the Nicobar iſles, and ſituated nearly in the centre of the cluſter (See Nicobar, *Encycl.*). Its length may be about eight miles, and its breadth nearly equal. The iſland of Comerty, which is near it, is more extenſive, but does not perhaps contain more ſolid land, being excavated by a very large bay from the ſea. The ſpace between theſe two iſlands forms a capacious and excellent harbour, the eaſtern entrance of which is ſheltered by another iſland, called Trikut, lying at the diſtance of about a league. The inlet from the weſt is narrow, but ſufficiently deep to admit the largeſt ſhips when the wind is fair.

The Danes have long maintained a ſmall ſettlement at this place, which ſtands on the northern-moſt point of Nancowry, within the harbour. A ſerjeant and three or four ſoldiers, a few black ſlaves, and two ruſty old pieces of ordnance, compoſe the whole of their eſtabliſhment. They have here two houſes; one of which, built entirely of wood, is their habitation; the other, formerly inhabited by their miſſionaries, ſerves now for a ſtorehouſe.

Theſe iſlands are in general woody, but contain likewiſe ſome portions of clear land. From the ſummits of their hills the proſpects are often beautiful and romantic. The ſoil is rich, and probably capable of producing all the various fruits and vegetables common to hot climates. The natural productions of this kind, which moſtly abound, are cocoa nuts, *papias*, plantains, limes, tamarinds, beetle nuts, and the *melóri*, a ſpecies of breadfruit; yams, and other roots are cultivated and thrive; but rice is here unknown. The *mangoſtain*-tree, whoſe fruit is ſo juſtly extolled, grows wild; and pineapples of a delicious flavour are found in the woods.

Of all the Nicobar iſles Nancowry and Comerty are ſaid to be the beſt peopled; the population of both being ſuppoſed to amount to eight hundred. The natives of Nancowry and of the Nicobar iſlands in general, live in villages on the ſea-ſhore, and never erect their habitations inland (a). Their houſes are of a circular form, and are covered with elliptical domes, thatched with graſs and the leaves of cocoa nut. They are raiſed upon piles to the height of ſix or eight feet above the ground; the floor and ſides are laid with planks, and the aſcent is by a ladder. In thoſe bays or inlets which are ſheltered from the ſurf, they erect them ſometimes ſo near the margin of the water as to admit the tide to flow under, and waſh away the ordure from below.

In front of their villages, and a little advanced in the water, they plant beacons of a great height, which they adorn with tufts made of graſs, or the bark of ſome tree. Theſe objects are diſcernible at a great diſtance, and are intended probably for landmarks; their houſes, which are overſhadowed by thick groves of cocoa-nut trees, ſeldom being viſible from afar.

The Nicobareans, though indolent, are in general robuſt and well-limbed. Their features are ſomewhat like the Malays, and their colour is nearly ſimilar. The women are much inferior in ſtature to the men, but more active in all domeſtic affairs. Contrary to the cuſtom of other nations, the women ſhave the hair of their heads, or keep it cloſe cropt, which gives them an uncouth appearance, in the eyes of ſtrangers at leaſt.

The inhabitants of Nancowry perform, every year, a very extraordinary ceremony in honour of the dead. It is thus deſcribed by Lieutenant Colebrooke:

"On the anniverſary of this feſtival, if it can be ſo called, their houſes are decorated with garlands of flowers, fruits, and branches of trees. The people of each village aſſemble, dreſt in their beſt attire, at the principal houſe in the place, where they ſpend the day in a convivial manner; the men, ſitting apart from the women, ſmoke tobacco, and intoxicate themſelves; while the latter are nurſing their children, and employed in preparations for the mournful buſineſs of the night. At a certain hour of the afternoon, announced by ſtriking the *Goung*, the women ſet up the moſt diſmal howls and lamentations, which they continue without intermiſſion till about ſun-ſet; when the whole party get up, and walk in proceſſion to the burying-ground. Arrived at the place, they form a circle around one of the graves, when a ſtake, planted exactly over the head of the corpſe, is pulled up. The woman who is neareſt of kin to the deceaſed, ſteps out from the crowd, digs up the ſkull, and draws it up with her hands. At ſight of the bones, her ſtrength ſeems to fail her; ſhe ſhrieks, ſhe ſobs; and tears of anguiſh abundantly fall on the mouldering object of her pious care. She clears it from the earth, ſcrapes off the feſtering fleſh, and laves it plentifully with the milk of freſh cocoa-nuts, ſupplied by the byſtanders; after which ſhe rubs it over with an infuſion of ſaffron, and wraps it carefully in a piece of new cloth. It is then depoſited again in the earth, and covered up; the ſtake is replanted, and hung with the various trappings and imple-

---

(a) The great Nicobar iſland is perhaps an exception, where, it is ſaid, a race of men exiſts, who are totally different in their colour and manners. They are conſidered as the *Aborigines* of the country. They live in the interior parts among the mountains, and commit frequent depredations on the peaceable inhabitants of the coaſts.

implements belonging to the deceaſed. They proceed then to the other graves; and the whole night is ſpent in repetitions of theſe diſmal and diſguſtful rites.

"On the morning following, the ceremony is concluded by an offering of many fat ſwine; when the ſacrifice made to the dead affords an ample feaſt to the living: they beſmear themſelves with the blood of the ſlaughtered hogs, and ſome, more voracious than others, eat the fleſh raw. They have various ways, however, of dreſſing their meat, but always eat it without ſalt. A kind of paſte made of the *melóri*, ſerves them for bread; and they finiſh their repaſt with copious potations of *taury*, an inebriating liquor."

The Nicobareans are hoſpitable and honeſt, and are remarkable for a ſtrict obſervance of truth, and for punctuality in adhering to their engagements. Such crimes as theft, robbery, and murder, are unknown in theſe iſlands; but they do not want ſpirit to revenge their injuries, and will fight reſolutely, and ſlay their enemies, if attacked or unjuſtly dealt with. Their only vice, if this failing can be ſo called, is inebriation; but in their cups they are generally jovial and good-humoured. It ſometimes, however, happens at their feaſts, that the men of different villages fall out; and the quarrel immediately becomes general. In theſe caſes they terminate their differences in a pitched battle; where the only weapons uſed are long ſticks, of a hard and knotty wood. With theſe they drub one another moſt heartily, till, no longer able to endure the conflict, they mutually put a ſtop to the combat, and all get drunk again.

NANKAR, ancient allowance to zemindars in land or money.

NANKEEN, or NAN-KING, is a well-known cotton ſtuff, which derives its name from the ancient capital of China (See NAN-KING, *Encycl.*). It is, however, according to Van Braam, manufactured at a great diſtance from that city, in the diſtrict of *Fong-kiang-fou*, ſituated in the ſouth-eaſt of the province of *Kiang-nam* upon the ſea-ſhore. The colour of nankeen is natural, the down of which it is made being of the ſame yellow tinge with the cloth. The colour, as well as ſuperior quality of this cotton, ſeems to be derived from the ſoil; for it is ſaid that the ſeeds of the nankeen cotton degenerate in both particulars when tranſplanted to another province, however little different in its climate. The common opinion, that the colour of the ſtuff is given by a dye, occaſioned an order from Europe, ſome years ago, to dye the pieces of nankeen of a deeper colour than they had at that period; and the reaſon of their being then paler than formerly is as follows:

Shortly after the Americans began to trade with China, the demand increaſed to nearly double the quantity it was poſſible to furniſh. To ſupply this deficiency, the manufacturers mixed common white cotton with the brown; this gave it a pale caſt, which was immediately remarked; and for this lighter kind no purchaſer could be found, till the other was exhauſted. As the conſumption is grown leſs during the laſt three years, the mixture of cotton is no longer neceſſary, and nankeen is become what it was before. By keeping them two or three years, it even appears that they have the property of growing darker. This kind of ſtuff muſt be acknowledged to be the ſtrongeſt yet known. Many perſons have found that clothes made of it will laſt three or four years, although for ever in the waſh. This it is that makes them the favourite wear for breeches and waiſtcoats both in Europe and America. The white nankeen is of the ſame quality, and is made of white cotton as good as the brown, and which alſo grows in Kiang-nam.

NAPLES-YELLOW, called alſo *Neapolitan earth*, in Italian *Giallolino*, and in French *Jaune de Naples*, is a beautiful pigment, concerning which we have much information from the indefatigable Beckmann. "It has (ſays he) the appearance of an earth, is of a pale orange-yellow colour, ponderous, granulated, exceedingly friable, does not effloreſce, nor become moiſt when expoſed to the air, but when applied to the tongue ſeems to adhere to it. When reduced to a fine powder, it remains for ſome time ſuſpended in water, but ſoon depoſits itſelf at the bottom in the form of a ſlime. When boiled with water, the water, at leaſt ſometimes, is obſerved to have a ſomewhat ſaline taſte. It does not efferveſce with acids, but is in part diſſolved by aqua regia (nitro-muriatic acid). In the fire it emits no ſulphureous vapour, is difficult to be fuſed, and by that operation undergoes no material change, only that its colour becomes ſomewhat redder. When fuſed with colourleſs glaſs, it gives it a milk-white colour, a ſure proof that it contains no iron; and, with inflammable ſubſtances, there is obtained from it a regulus which has the appearance of a mixture of lead and antimony.

"This article is brought from Naples for the moſt part in the form of an earthy cruſt about three or four lines in thickneſs, and it ſometimes retains the form of the veſſel in which it has hardened. It can be procured alſo as a fine powder, as the colourmen keep it ſometimes ready pounded for uſe."

About the nature of the ſubſtance called Naples yellow there has been much diverſity of opinion. Moſt of thoſe who have written about it, conſider it as originating from fire, and as a volcanic production of Mount Veſuvius or Mount-Ætna; others have pronounced it to be a natural ochre. Guettard thought it rather a kind of bole; but Pott approached neareſt the truth, by aſſerting it to be an artificial preparation *. Fougeroux is entitled to the merit of having proved this, and of having ſhewn the poſſibility of preparing it. According to his experiments, Naples yellow will be obtained, if you boil for ſeven or eight hours, firſt over a ſlow and then over a ſtrong fire, a mixture finely pulveriſed of twelve parts of pure white lead, one part of alum, one part of ſal ammoniac, and three parts of diaphoretic antimony † (white oxyd of antimony by nitre). But before Fougeroux, who may have obtained an account of the proceſs during his travels through Italy, a more certain proceſs was publiſhed in the year 1758, by Giambattiſta Paſſeri, in his intereſting work on the painting of earthen-ware ‡. The articles to be employed, according to this author, are, "one pound of antimony, a pound and a half of lead, one ounce of *alume di feccia*, and the ſame quantity of common ſalt." I am inclined (ſays M. Beckmann) to think that this receipt was not unknown to Fougeroux, and that he conſidered *alume di feccia* to be alum. Profeſſor Leonhardi, a man of very ſound learning, has tranſlated this expreſſion by the word alum. I will, however, freely confeſs, that I conſider *alume di feccia* not to mean alum, but ſalt of tartar, or potaſh. Paſſeri

* *Lithognoſie*, v. ii p. 15.

† *Mem. of the Acad. of Sciences*, 1766.

‡ *In Nuo raccolta d'opuſculi ſcientifici*, t iv.

ſeri ſays, that the proportions may be varied different ways; and he gives ſix other receipts, in which he does not mention *alume di feccia*, but only *feccia ;* and this word certainly means *weinheſen* or wineſtone (tartar). Profeſſor Leonhardi himſelf ſeems to confirm this opinion, by ſaying, that Vairo, profeſſor of chemiſtry at Naples, has tranſlated "the aſhes of wine lees" (*cineres inſectorii*) by the words *alume di feccia.*

After Fougeroux's paper was printed, De la Lande publiſhed a receipt which he had received from the well-known prince San Severo, and in which lead and antimony only are employed ; but no mention is made either of alum, tartar, or any other ſalt. This receipt is as follows :

Take lead well calcined and ſifted, with a third part of its weight of antimony pounded and ſifted alſo. Mix theſe ſubſtances well together, and ſift them again through a piece of ſilk. Then take large flat earthen diſhes, not varniſhed, cover them with white paper, and ſpread out the powder upon them to the depth of about two inches. Place theſe diſhes in a potter's furnace, but only at the top, that they may not be expoſed to too violent a heat. The reverberation of the flame will be ſufficient. The diſhes may be taken out at the ſame time as the earthen-ware, and the ſubſtance will then be found hard, and of a yellow colour. It is then pounded on a piece of marble with water, and afterwards dried for uſe.

The enamel-painters in Germany prepare a yellow glazing, not very different from the real Naples yellow, by a preſcription, according to which, "one pound of antimony, ſix ounces of red lead, and two ounces of white ſand, are to be fuſed together. The produce, which appears quite black, is to be pounded, and then fuſed again ; and this proceſs is to be repeated till the whole maſs becomes thoroughly yellow. Half a pound of this maſs is to be mixed with two ounces of red lead, and afterwards fuſed ; and by this tedious proceſs an orange-yellow pigment will be obtained."

All artiſts who ſpeak of the uſe of Naples yellow, give cautions againſt applying iron to it, as the colour by theſe means becomes greeniſh, or at leaſt dirty. For this reaſon, it muſt be pounded on a ſtone, and ſcraped together with an ivory ſpatula. It is employed chiefly in oil painting, becauſe the colour is ſofter, brighter, and richer than that of ochre, yellow lead, or orpiment, and becauſe it far exceeds theſe pigments in durability. It is employed in particular when the yellow ought to have the appearance of gold, and in this reſpect it may be prepared with gum water, and uſed as a water colour. A ſtill greater advantage of it is, that it is proper for enamel painting, and on that account may be employed on porcelain or earthen ware (A). Profeſſor Beckmann, however, recommends to artiſts to examine whether the oxyd prepared from wolfram, by boiling in the muriatic acid, which has a beautiful yellow colour, might not be uſed in the ſame manner as Naples yellow.

NARDUS. Under this generic term we have, in the *Encyclopædia*, given, from the *Philoſophical Tranſactions*, a deſcription of the plant or graſs which Dr Blane conſiders as the ſpikenard of the ancients. It is our duty, in this place, to inform our readers, that Sir William Jones, in the 2d and 4th volumes of the *Aſiatic Reſearches*, ſeems to have completely proved that the ſpikenard of Dioſcorides and Galen, or *Nardus Indica*, was a very different plant from the Andropogon of Dr Blane, and that it grows in a country far diſtant from *Mackran.* The proofs brought by the illuſtrious preſident of the Aſiatic Society, in ſupport of his own opinion, are too numerous and circumſtantial to be introduced into ſuch a work as this. We ſhall therefore only give one of them ; which though, when ſeparated from the reſt, it loſes much of its force, muſt be allowed, even ſingly, to have great weight.

The true Indian ſpikenard is confeſſedly called by the Arabs *Sumbulu'l Hind;* for ſo they tranſlate the name of it in Dioſcorídes. Now (ſays Sir William) I put a fair and plain queſtion ſeverally to three or four Muſſulman phyſicians : "What is the Indian name of the plant which the Arabs call *Sumbulu'l Hind?*" They all anſwered, but ſome with more readineſs than others, *Játámansí.* After a pretty long interval, I ſhewed them the ſpikes (as they are called) of *Játámansí*, and aſked, what was the Arabic name of that Indian drug? They all anſwered readily, *Sumbulu'l Hind.* The ſame evidence may be obtained in this country by any other European who ſeeks it ; and if among twelve native phyſicians, verſed in Arabian and Indian philology, a ſingle man ſhould, after due conſideration, give different anſwers, I will cheerfully ſubmit to the Roman judgment of *non liquet.* But the *Játámansí* * evidently belongs to the natural order which Linnæus calls *aggregate ;* with the following *characters :*

* Plate XXX.

Calyx, ſcarce any ; *margin*, hardly diſcernible. *Corolla*, one petal ; *tube* ſomewhat gibbous ; *border* five cleft. *Stamina*, three *Anthers*. *Piſtula*, *Germ* beneath ; one *Style* erect. *Seed*, ſolitary, crowned with a pappus. *Root*, fibrous. *Leaves*, hearted, fourfold ; *radical* leaves petioled.

It appears therefore (continues the learned author) to be the Protean plant Valerian, a ſiſter of the Mountain and Celtick Nard, and of a ſpecies which I ſhould deſcribe in the Linnean ſtyle, *Valeriana Játámansí floribus triandris, foliis cordatis quaternis, radicalibus petiolatis.* The radical leaves, riſing from the ground, and enfolding the young ſtem, are plucked up with a part of the root, and being dried in the ſun or by an artificial heat, are ſold as a drug, which, from its appearance, has been called ſpikenard. The Játámansí is a native of the moſt remote and hilly parts of India, ſuch as NE'PA'L, Marang Butan, near which Ptolemy fixes the native ſoil of the *Nardus Indica.* It grows erect above the ſurface of the ground, reſembling an ear of green wheat ; and when recent, it has a faint odour, which is greatly increaſed by the ſimple proceſs of drying it.

NARES (JAMES), doctor of muſic, an eminent compoſer and teacher in that ſcience, under whom ſome of the firſt muſicians of the preſent day received the whole or part of their education, was the ſon of Mr Nares, who was, for many years, ſteward to Montague and

Biog. Dict. new edit.

(A) In the Memoirs of the Academy of Sciences for 1767, Fougeroux has proved that the giallolino prepared by him produced on porcelain a much more beautiful colour than the Naples yellow ſold in the ſhops.

and Willoughby, earls of Abingdon. He was born, as well as his brother, the late Mr Juſtice Nares, at Stanwell in Middleſex; the former in 1715, the latter in 1716. His muſical education he commenced under Mr Gates, then maſter of the royal choriſters; and completed it under the celebrated Dr Pepuſch. Thus prepared, he officiated, for ſome time, as deputy to Mr Pigott, organiſt of Windſor; but on the reſignation of Mr Saliſbury, organiſt of York, in 1734, was choſen to ſucceed him, being then only nineteen. It is related, on undoubted authority, that, when the old muſician firſt ſaw his intended ſucceſſor, he ſaid, rather angrily, "What! is that child to ſucceed me?" which being mentioned to the organiſt-elect, he took an early opportunity, on a difficult ſervice being appointed, to play it throughout half a note below the pitch, which brought it into a key with ſeven ſharps; and went through it without the ſlighteſt error. Being aſked why he did ſo? he ſaid, that "he only wiſhed to ſhew Mr Saliſbury what a child could do." His knowledge in all branches of his profeſſion was equal to his practical ſkill in this inſtance; and, during his reſidence at York, where he was abundantly employed as a teacher, and where he married, Mr Nares, by his good conduct, as well as profeſſional merit, obtained many powerful friends. Among the foremoſt of theſe was Dr Fontayne, the reſpectable and venerable dean of York; who, when Dr Green died, towards the latter end of 1755, exerted his intereſt ſo ſucceſsfully, that he obtained for him the united places of organiſt and compoſer to his majeſty. He removed therefore to London in the beginning of 1756; and, about the ſame time, was created doctor in muſic at Cambridge.

On the reſignation of Mr Gates, in 1757, Dr Nares obtained alſo the place of maſter of the choriſters; which having been, for a long time, without increaſe, notwithſtanding the increaſe of expences attending it, was, by royal favour, augmented about 1775, firſt with the ſalary of the violiſt; and, on the revival of that place for Mr Croſdill, in 1777, with that of lutaniſt, which was annexed to it for ever. It was in this ſituation that Dr Nares ſuperintended the education of many pupils, who have ſince become famous; particularly Dr Arnold, who, though with him only for a ſhort time, was highly diſtinguiſhed by him for talents and application. The anthems and ſervices which Dr Nares produced, as compoſer to the royal chapel, were very numerous; many of them have ſince been printed, and many which exiſt only in manuſcript ſtill continue to be performed in the choirs with much effect. Having been originally a muſician rather by accident than choice, with very ſtrong talents and propenſities alſo for literature, Dr Nares was particularly attentive to expreſs the ſenſe of the words he undertook to ſet; and was the firſt who attempted to compoſe the Te Deum for the choir-ſervice, in ſuch a manner as to ſet off the ſentiments it contains to advantage. Before his time, it had been ſet rather to a regular ſtrain of chaunt than to any expreſſive melodies. The merits of Dr Nares were not overlooked by his royal patrons, whom he had occaſionally the honour to attend in private, though not a part of his regular duty. To manifeſt his reſpect and gratitude for them, he compoſed his dramatic ode, entitled The Royal Paſtoral, the words of which were written by Mr Bellamy, author of a book, entitled Ethic Amuſements.

In July 1780, Dr Nares was obliged, by declining health, to reſign the care of the choriſters, in which place he was ſucceeded by Dr Ayrton, his pupil and valued friend. In his ſixty-eighth year, a conſtitution, never robuſt, gave way, and he died on February 10. 1783. Teſtimony has been borne to the merits of Dr Nares by ſeveral writers, but more particularly by Mr Maſon, in his preface to a book of anthems, printed for the uſe of York Cathedral; and in his late Eſſays on Church Muſic, page 138. The late Lord Mornington, ſo well known for muſical talents, frequently conſulted him; and Sir John Hawkins derived advantage from his acquaintance, in the progreſs of his Hiſtory of Muſic. Throughout life, he was not leſs reſpected as a man than admired as a muſician; he had a vivacity that rendered his ſociety always pleaſing; and a generous contempt for every thing baſe, that manifeſted itſelf on all proper occaſions, and very juſtly commanded eſteem.

His printed works are theſe: 1. Eight Sets of Leſſons for the Harpſichord; dedicated to the Right Hon. Willoughby Earl of Abingdon. Printed in 1748; reprinted in 1757. 2. Five Leſſons for the Harpſichord, with a Sonata in ſcore for the Harpſichord or Organ; dedicated to the Right Honourable the Counteſs of Carliſle; publiſhed in 1758 or 1759. 3. A Set of Eaſy Leſſons for the Harpſichord, three in number; with a dedication to the public, ſigned J. N. 4. A Treatiſe on Singing, ſmall ſize. 5. Il Principio; or A regular Introduction to playing on the Harpſichord or Organ. This was the firſt ſet of progreſſive leſſons publiſhed on a regular plan. 6. The Royal Paſtoral, a Dramatic Ode; dedicated to his Royal Highneſs the Prince of Wales; printed in ſcore, with an overture and choruſes. 7. Catches, Canons, and Glees; dedicated to the late Lord Mornington. 8. Six Fugues, with Introductory Voluntaries for the Organ or Harpſichord. 9. A Conciſe and Eaſy Treatiſe on Singing, with a Set of Engliſh Duets for Beginners. A different work from the former ſmall treatiſe. 10. Twenty Anthems, in ſcore, for one, two, three, four, and five Voices. Compoſed for the Uſe of his Majeſty's Chapels Royal, 1778. 11. Six Eaſy Anthems, with a favourite Morning and Evening Service, left for publication at his death, and publiſhed in 1788, with a portrait and a conciſe account of the author. Of theſe compoſitions the following ſhort character is given by an eminent muſician, to whom they are all well known: "The leſſons are compoſed in a maſterly and pleaſing ſtyle; free from thoſe tricks and unmeaning ſucceſſions of ſemitones, to which a good ear and ſound judgment never can be reconciled. The treatiſes on ſinging contain duets compoſed for the uſe of the children of the royal chapels, ſuperior to any thing yet publiſhed; and ſuch as every teacher ought to peruſe. His catches, canons, and glees, are natural and pleaſing; eſpecially the glee to all Lovers of Harmony, which gained the prize medal at the catch-club in 1770. The Royal Paſtoral is compoſed throughout in a very maſterly manner; particularly the choruſes, with which each part concludes. This ode, containing 108 pages, was written, and all the vocal and inſtrumental parts tranſcribed for performing, within twelve days. The ſix fugues, with introductory voluntaries for the organ, contain the ſtrongeſt proofs of ingenuity and judgement; few, if any, have ever been written that can be preferred to them. In both ſets of the anthems, the ſame characteriſtics appear; and the ſervice of the latter very juſtly acquired the title of *favourite;* nor can there be any doubt that the works of this author will be admired as long as a taſte for muſic ſhall ſubſiſt."

NAVIGATORS ISLANDS, an archipelago in the South Sea, diſcovered by Bougainville, who gave to them that name, becauſe the natives do not paſs between the different villages, which are all built in creeks and bays, but in their canoes. The Navigators Iſlands are ten in number; namely, *Opoun*, *Leoné*, *Fanfoué*, MAOUANA, *Oyolava*, *Calinaſſé*, *Pola*, *Shika*, *Oſſamo*, and *Ouera*.

We have already given an account of the ſoil and productions of MAOUANA; and as the other iſlands of this cluſter are equally fertile, we need not go over the ſame ground again. It may be proper, however, to obſerve, that in ſome of them the ſugar-cane was found growing ſpontaneouſly, though its juice contained leſs of the ſaccharine ſubſtance than the ſugar cane of the Weſt Indies, which our voyagers attributed to its growing in a richer ſoil and in the ſhade. According to Perouſe, the Navigators Iſlands are ſituated about the 14th degree of ſouth latitude, and between the 171ſt and 175th degrees of longitude weſt from Paris. In Oyolava the ſmoke was ſeen hovering over a village as over a large European town; and the number of canoes which from that iſland ſurrounded the frigates was immenſe. Theſe are very tickliſh veſſels, and would be abſolutely uſeleſs to any body but ſuch excellent ſwimmers as the iſlanders, who are no more ſurpriſed or uneaſy at their overſetting than we are at the fall of a hat. Taking up the canoe on their ſhoulders, they empty it of water, and then get in again, with the certainty of having the ſame operation to perform a ſecond time in half an hour. Sometimes they join two canoes together by means of a croſs piece of wood, in which they make a ſtep to receive the maſt; and in this way they are leſs liable to be overſet, ſometimes performing a long voyage without any ſuch accident. It is needleſs to add, that theſe canoes are very ſmall, generally containing only five or ſix perſons, though ſome few of them may contain as many as fourteen.

The natives of the Navigators Iſlands are tall and well made. Their uſual height is five feet nine, ten, and eleven inches; but their ſtature is leſs aſtoniſhing than the coloſſal proportions of the different parts of their bodies. "Our curioſity (ſays Perouſe), which often led us to meaſure them, gave them an opportunity of making frequent compariſons of their bodily ſtrength with ours. Theſe compariſons were not to our advantage; and we perhaps owe our misfortunes (ſee MAOUANA in this *Suppl.*) to the idea of individual ſuperiority reſulting from repeated trials. Their countenances often appeared to expreſs a ſentiment of diſdain, which I hoped to deſtroy, by ordering our arms to be uſed in their preſence: but my end could only have been gained by directing them againſt human victims; for otherwiſe they took the noiſe for ſport, and the trial for a diverſion.

"Among theſe Indians a very ſmall number is below the height indicated above. I have, however, meaſured ſeveral who were only five feet four inches, but theſe are the dwarfs of the country; and although their ſtature reſembles ours, their ſtrong and nervous arms, their broad cheſts, and their legs and thighs, are of a very different proportion.

"The men have the body painted or tatowed, ſo that any one would ſuppoſe them clad, although they go almoſt naked. They have only a girdle of ſea-weeds encircling their loins, which comes down to their knees, and gives them the appearance of the river gods of fabulous hiſtory, whom it is cuſtomary to depict with ruſhes round their waiſt. Their hair is very long. They often twiſt it round their heads, and thus add to their native ferocity of countenance, which always expreſſes either ſurpriſe or anger. The leaſt diſpute between them is followed by blows of ſticks, clubs, or paddles; and often, without doubt, coſts the combatants their lives. They are almoſt all covered with ſcars, which can only be the conſequence of their individual quarrels. The ſtature of the women is proportioned to that of the men. They are tall, ſlender, and not without grace; but they loſe, while yet in their prime, thoſe elegant forms, of which nature has not broken the mould among this barbarous race, but of which ſhe appears to leave them in poſſeſſion only for a moment, and with reluctance. Among a great number of women that I had an opportunity of ſeeing, I only obſerved three really pretty. The groſs effrontery of the reſt, the indecency of their motions, and the diſguſting offers which they made of their favours, rendered them fit mothers and wives for the ferocious beings that ſurrounded us." Our author gives the following inſtance of indecent manners, which is, perhaps, without a parallel.

The young and pretticſt females ſoon attracted the attention of ſeveral Frenchmen, who, in ſpite of the Commodore's prohibition, endeavoured to form a connection with them, and were ſucceſsful. The looks of the Europeans expreſſing deſires which were ſoon divined, ſome old women undertook the negociation. The altar was prepared in the handſomeſt hut in the village, all the blinds were let down, and the inquiſitive were excluded. The victim was then laid in the arms of an old man, who exhorted her, during the ceremony, to moderate the expreſſion of her pain; while the matrons ſang and howled: the ceremony being performed in their preſence, and under the auſpices of the old man, who ſerved at once as prieſt and altar. All the women and children in the village were round the houſe, gently lifting up the blinds, and ſeeking to enjoy the ſight through the ſmalleſt crevices in the mats. Whatever former navigators may have ſaid, Perouſe was convinced that, in the Navigators Iſlands at leaſt, the young girls, before they are married, are miſtreſſes of their perſons, and that they are not diſhonoured by their complaiſance. It is even more than probable, that in marrying they are called to no account concerning their paſt conduct; but he had no doubt that they are obliged to be more reſerved when provided with a huſband.

Theſe people cultivate certain arts with ſucceſs. Under the article MAOUANA mention has been made of the elegant form which they give to their huts. It is not with ſuch folly as is commonly ſuppoſed that they diſdain our inſtruments of iron; for they finiſh their work very neatly with tools made of a very fine and compact ſpecies of baſaltes in the form of an adze. For a few glaſs beads they ſold to Perouſe large three-legged diſhes of a ſingle piece of wood, and ſo well poliſhed that they ſeemed to have been laid over with a coat of the fineſt varniſh. It would take an European workman ſeveral days to produce one of theſe diſhes, which, for want of proper inſtruments, muſt coſt an Indian ſeveral months labour. They ſet, however, ſcarcely any value upon them, becauſe they ſet little upon the time they employ. The fruit trees and nutritious roots that grow ſpontaneouſly around them, inſure to them their ſubſiſtence, as well as that of their hogs, dogs, and fowls; and if they ſometimes ſtoop to work, it is to procure enjoyments rather agreeable than uſeful. They manufacture very fine mats, and ſome paper ſtuffs. Our author remarked two or three of them, whom he took for chiefs, with a piece of cloth tied round their waiſt like a petticoat, inſtead of a girdle of weeds. It is compoſed of real thread, prepared no doubt from ſome filamentous plant like the nettle or flax; and is manufactured without a ſhuttle, the threads being abſolutely laid over one another like thoſe of their mats. This cloth, which has all the ſuppleneſs and ſolidity of ours, is very fit for the ſails of their canoes; and appeared far ſuperior to the paper ſtuff of the Society and Friendly Iſlands, which they manufacture alſo. Their canoes are well conſtructed, and furniſh a good proof of the ſkill with which they work in wood. For a few glaſs beads they gave to the Frenchmen, among other things, a wooden veſſel filled with cocoa nut oil, exactly of the ſhape of our earthen pots, and ſuch as no European would undertake to faſhion by any other means than a turning lathe. Their ropes are round, and twiſted like watch chains of ribbon: their mats are very fine; but their ſtuffs are inferior to thoſe of the Eaſter and Sandwich Iſlands.

Perouſe derives the natives of thoſe iſlands, whoſe colour, he ſays, nearly reſembles that of the Algerines and other nations on the coaſt of Barbary, from the Malays; and as we do not vouch for the truth of his theory, though we admit it to be ingenious, we ſhall give the reaſoning by which he ſupports it in his own words.

"We did not at firſt diſcover (ſays he) any identity between their language and that of the natives of the Society and Friendly Iſlands, of which we had vocabularies; but a more mature examination convinced us, that they ſpeak a dialect of the ſame language. A fact which tends to prove it, and which confirms the opinion of the Engliſh concerning the origin of theſe people, is, that a young domeſtic, a native of the province of Tagayan in the north of Manilla, underſtood and explained to us the greater part of their words. It is well known that the Tagayan, the Talgal, and the generality of languages ſpoken in the Philippines, are derived from the Malay: a language more diffuſed than were thoſe of the Greeks and Romans, and common to the numerous tribes that inhabit the iſlands of the great Pacific Ocean. It appears to me evident, that all theſe different nations are the progeny of Malay colonies, which, in ſome age extremely remote, conquered the iſlands they inhabit. I ſhould not even wonder, if the Chineſe and Egyptians, whoſe antiquity is ſo much vaunted, were mere moderns in compariſon of the Malays. But however this may be, I am ſatisfied that the aborigines of the Philippine Iſlands, Formoſa, New Guinea, New Britain, the New Hebrides, the Friendly Iſlands, &c. in the ſouthern hemiſphere, and thoſe of the Marianna and Sandwich iſlands in the northern, were that race of woolly headed men ſtill found in the interior of the iſlands of Luconia and Formoſa. They were not to be ſubjugated in New Guinea, New Britain, and the New Hebrides; but being overcome in the more eaſtern iſlands, which were too ſmall to afford them a retreat in the centre, they mixed with the conquering nation. Thence has reſulted a race of very black men, whoſe colour is ſtill ſeveral ſhades deeper than that of certain families of the country, probably becauſe the latter have made it a point of honour to keep their blood unmixed. I was ſtruck with theſe two very diſtinct races in the Iſlands of Navigators, and cannot attribute to them any other origin.

"The deſcendants of the Malays have acquired in thoſe iſlands a degree of vigour and ſtrength, a lofty ſtature, and a Herculean form, which they do not inherit from their forefathers, but which they owe, without doubt, to an abundance of food, to a mild climate, and to the influence of different phyſical cauſes which have been conſtantly acting during a long ſeries of generations. The arts which they perhaps brought with them may have been loſt for want of materials and inſtruments to practiſe them; but the identity of language, like Ariadne's clue, enables the obſerver to follow all the windings of this new labyrinth. The feudal government is alſo preſerved here: that government which little tyrants may regret; which was the diſgrace of Europe for ſeveral centuries; and of which the Gothic remains are ſtill to be found in our laws, and are the medals that atteſt our ancient barbariſm: that government, which is the moſt proper to keep up a ferocity of manners, becauſe the ſmalleſt diſputes occaſion wars of village againſt village, and becauſe wars of this nature are conducted without magnanimity, and without courage. Surpriſes and treachery are employed by turns; and in theſe unfortunate countries, inſtead of generous warriors, nothing is to be found but baſe aſſaſſins (A). The Malays are ſtill the moſt perfidious nation

---

(A) This was written under the old government of France by a man who, like other declaimers in the cauſe of liberty, forgot the excellencies, and inſiſted only on the defects of the feudal inſtitutions. Had Perouſe, however, returned to Europe, and witneſſed the *philoſophic* government of his country, he would have perceived, that *liberty* and *equality*, and *the rights of man*, are as well calculated to generate baſe aſſaſſins, as the Gothic remains of that government by which he ſuppoſed Europe to have been ſo long diſgraced. He might even have lived to regret, that his lot was not caſt among the bold and ferocious inhabitants of Maouana; for the treachery and cruelty of theſe people bears no proportion, even in his affecting narrative, to the ſyſtematic cruelty of thoſe who decreed, that the end ſanctifies the means, and that nothing, however atrocious in the eſtimation of antiquated moraliſts, is to be omitted, which contributes to elevate the mean above the noble.

tion of Aſia; and their children have not degenerated, becauſe the ſame cauſes have led to and produced the ſame effects. It may be objected, perhaps, that it muſt have been very difficult for the Malays to make their way from weſt to eaſt, to arrive at theſe different iſlands; but the weſterly winds blow as frequently as the eaſterly in the vicinity of the equator, along a zone of ſeven or eight degrees from north to ſouth, where the wind is ſo variable, that it is hardly more difficult to navigate eaſt than weſt. Beſides, theſe different conqueſts may not have been effected at the ſame time: the people in queſtion may, on the contrary, have ſpread themſelves by little and little, and gradually have introduced that form of government which ſtill exiſts in the peninſula of Malacca, at Java, Sumatra, and at Borneo, as well as in all the other countries ſubject to that barbarous nation."

NAZER, Nazr, Nezer, Nuzzer, Nuzzerana; a preſent from an inferior; fees of office.

NEBULOUS, or Cloudy, a term applied to certain fixed ſtars which ſhew a dim hazy light; being leſs than thoſe of the ſixth magnitude, and therefore ſcarcely viſible to the naked eye, to which at beſt they only appear like little duſky ſpecks or clouds. Through a moderate teleſcope, theſe nebulous ſtars plainly appear to be congeries or cluſters of ſeveral little ſtars.

NECKAR isle, a ſmall barren iſland, or rather rock, diſcovered by Perouſe in the Pacific Ocean. Though its ſterility renders it of no importance in itſelf, its exact ſituation muſt be intereſting to navigators, who are therefore obliged to the French Commodore for having aſcertained its latitude to be 23° 34′ north, and its longitude to be 166° 52′ weſt from Paris. From the ſoundings the *Neckar* ſeemed to be only the top or nucleus of a much more conſiderable iſland, which, probably from being compoſed of a ſoft and diſſoluble ſubſtance, the ſea had gradually waſhed away. In proportion as the frigates left the ſhore, the depth, which at the diſtance of a mile was very little, gradually increaſed, till, at the diſtance of about ten miles, no bottom was found with a line of 150 fathoms; and over the whole of that ſhore the bottom conſiſted of coral and broken ſhells.

NEPAL, a kingdom of India, ſituated to the north-eaſt of the city of Patna, at the diſtance of ten or twelve days journey. Within the diſtance of four days journey from Nepal the road is good in the plains of Hindoſtan, but in the mountains it is bad, narrow, and dangerous. At the foot of the hills the country is called *Teriani*; and there the air is very unwholeſome from the middle of March to the middle of November; and people in their paſſage catch a diſorder called in the language of that country *aul;* which is a putrid fever, and of which the generality of people, who are attacked with it, die in a few days; but on the plains there is no apprehenſion of it. Although the road be very narrow and inconvenient for three or four days at the paſſes of the hills, where it is neceſſary to croſs and recroſs the river more than fifty times, yet, on reaching the interior mountain before you deſcend, you have an agreeable proſpect of the extenſive plain of Nepal, reſembling an amphitheatre covered with populous towns and villages: the circumference of the plain is about 200 miles, a little irregular, and ſurrounded by hills on all ſides, ſo that no perſon can enter or come out of it without paſſing the mountains.

There are three principal cities in the plain, each of which was the capital of an independent kingdom; the principal city of the three is ſituated to the northward of the plain, and is called *Cat'hmandu:* it contains about 18,000 houſes; and this kingdom, from ſouth to north, extends to the diſtance of twelve or thirteen days journey as far as the borders of Tibet, and is almoſt as extenſive from eaſt to weſt. The king of Cat'hmandu has always about 50,000 ſoldiers in his ſervice. The ſecond city to the ſouth-weſt of Cat'hmandu is called *Lelit Pattan*; it contains near 24,000 houſes. The third principal city to the eaſt of Lelit Pattan is called *B'hatgan:* it contains about 12,000 families; and is the metropolis of a diſtrict which extends towards the eaſt to the diſtance of five or ſix days journey; and borders upon another nation, alſo independent, called *Ciratas*, who profeſs no religion. Beſides theſe three principal cities, there are many other large and leſs conſiderable towns or fortreſſes; one of which is *Timi*, and another *Cipoli*, each of which contains about 8000 houſes, and is very populous. All thoſe towns, both great and ſmall, are well built; the houſes are conſtructed of brick, and are three or four ſtories high; their apartments are not lofty; they have doors and windows of wood well worked and arranged with great regularity. The ſtreets of all their towns are paved with brick or ſtone, with a regular declivity to carry off the water. In almoſt every ſtreet of the capital towns there are alſo good wells made of ſtone, from which the water paſſes through ſeveral ſtone canals for the public benefit. In every town there are large ſquare varandas well built, for the accommodation of travellers and the public: theſe varandas are called *Pali;* and there are alſo many of them, as well as wells, in different parts of the country for public uſe. There are alſo, on the outſide of the great towns, ſmall ſquare reſervoirs of water, faced with brick, with a good road to walk upon, and a large flight of ſteps for the convenience of thoſe who chooſe to bathe.

The religion of Nepal is of two kinds: the more ancient is profeſſed by many people who call themſelves *Baryeſu;* they pluck out all the hair from their heads; their dreſs is of coarſe red woollen cloth, and they wear a cap of the ſame: they are conſidered as people of the religious order, and their religion prohibits them from marrying, as it is with the Lamas of Tibet, from which country their religion was originally brought; but in Nepal they do not obſerve this rule, except at their diſcretion. They have large monaſteries, in which every one has a ſeparate apartment or place of abode. They obſerve alſo particular feſtivals, the principal of which is called *Yatra* in their language, and continues a month or longer according to the pleaſure of the king. The ceremony conſiſts in drawing an idol, which at Lelit Pattan is called *Baghero*, in a large and richly ornamented car, covered with gilt copper: round about the idol ſtand the king and the principal Baryeſus; and in this manner the vehicle is almoſt every day drawn thro' ſome one of the ſtreets of the city by the inhabitants, who run about beating and playing upon every kind of inſtrument their country affords, which make an inconceivable noiſe.

The other religion, the more common of the two, is that of the Brahmens, and is the ſame as is followed in Hindoſtan, with the difference that, in the latter country the Hindus being mixed with the Mahommedans, their religion alſo abounds with many prejudices, and is not ſtrictly obſerved; whereas in Nepal, where there are no Muſſelmans (except one Caſhmirian merchant), the Hindu religion is practiſed in its greateſt purity: every day of the month they claſs under its proper name, when certain ſacrifices are to be performed and certain prayers offered up in their temples: the places of worſhip are more in number in their towns than are to be found in the moſt populous and moſt flouriſhing cities of Chriſtendom; many of them are magnificent according to their ideas of architecture, and conſtructed at a very conſiderable expence; ſome of them have four or five ſquare cupolas, and in ſome of the temples two or three of the extreme cupolas, as well as the doors and windows of them, are decorated with gilt copper.

In the city of Lelit Pattan the temple of Baghero is more valuable, on account of the gold, ſilver, and jewels it contains, than even the houſe of the king. Beſides the large temples, there are alſo many ſmall ones, which have ſtairs, by which a ſingle perſon may aſcend, on the outſide all around them; and ſome of thoſe ſmall temples have four ſides, others ſix, with ſmall ſtone or marble pillars poliſhed very ſmooth, with two or three pyramidal ſtories, and all their ornaments well gilt, and neatly worked according to their ideas of taſte. On the outſide of ſome of their temples there are great ſquare pillars of ſingle ſtones from twenty to thirty feet high, upon which they place their idols ſuperbly gilt. The greateſt number of their temples have a good ſtone ſtaircaſe in the middle of the four ſquares, and at the end of each flight of ſtairs there are lines cut out of ſtone on both ſides: around about their temples there are alſo bells, which the people ring on particular occaſions; and when they are at prayers, many cupolas are alſo quite filled with little bells hanging by cords in the inſide about the diſtance of a foot from each other, which make a great noiſe on that quarter where the wind conveys the ſound. There are not only ſuperb temples in their great cities, but alſo within their caſtles.

To the eaſtward of Cat'hmandu, at the diſtance of about two or three miles, there is a place called *Tolu*, by which there flows a ſmall river, the water of which is eſteemed holy, according to their ſuperſtitious ideas, and thither they carry people of high rank, when they are thought to be at the point of death: at this place there is a temple, which is not inferior to the beſt and richeſt in any of the capital cities. They alſo have it on tradition, that at two or three places in Nepal valuable treaſures are concealed under ground: one of thoſe places they believe is Tolu; but no one is permitted to make uſe of them except the king, and that only in caſes of neceſſity. Thoſe treaſures, they ſay, have been accumulated in this manner: When any temple had become very rich from the offerings of the people, it was deſtroyed, and deep vaults dug under ground one above another, in which the gold, ſilver, gilt copper, jewels, and every thing of value, were depoſited. This was found to be actually the caſe when the miſſionary, from whoſe memoir this account of Nepal is taken, was at Cat'hmandu. One of the kings, or pretenders to the crown, who were then at war with each other, being in the utmoſt diſtreſs for want of money to pay his troops, ordered the vaults at Tolu to be opened; and found in the firſt vault more money, beſides ſilver and gold idols, than he had immediate occaſion for.

To the weſtward alſo of the great city of Lelit Pattan, at the diſtance of only three miles, is a caſtle called *Banga*, in which there is a magnificent temple. No one of the miſſionaries ever entered into this caſtle; becauſe the people who have the care of it, have ſuch a ſcrupulous veneration for the temple, that no perſon is permitted to enter it with his ſhoes on; and the miſſionaries, unwilling to ſhew ſuch reſpect to their falſe deities, never entered it. The author of this memoir, however, who acted as phyſician to the commandant, was of courſe admitted within the caſtle, and got a ſight of the celebrated temple, which he declares, that for magnificence he believes ſuperior to every thing in Europe.

Beſides the magnificence of the temples, which their cities and towns contain, there are many other rarities. At Cat'hmandu, on one ſide of the royal garden, there is a large fountain, in which is one of their idols called *Narayan*. This idol is of blue ſtone, crowned and ſleeping on a mattraſs alſo of the ſame kind of ſtone, and the idol and the mattraſs appear as floating upon the water. This ſtone machine is very large, being about 18 or 20 feet long, and broad in proportion, but well worked, and in good repair.

In a wall of the royal palace of Cat'hmandu, which is built upon the court before the palace, there is a great ſtone of a ſingle piece, which is about fifteen feet long, and four or five feet thick; on the top of this great ſtone there are four ſquare holes at equal diſtances from each other; in the inſide of the wall they pour water into the holes; and in the court ſide, each hole having a cloſed canal, every perſon may draw water to drink. At the foot of the ſtone is a large ladder, by which people aſcend to drink; but the curioſity of the ſtone conſiſts in its being quite covered with characters of different languages cut upon it. Some lines contain the characters of the language of the country, others the characters of Tibet, others Perſian, others Greek, beſides ſeveral others of different nations; and in the middle there is a line of Roman characters, which appears in this form, AVTOMNEW INTER LHIVERT; but none of the inhabitants have any knowledge how they came there, nor do they know whether or not any European had ever been in Nepal before the miſſionaries, who arrived there only the beginning of the preſent century. They are manifeſtly two French names of ſeaſons, with an Engliſh word between them.

There is alſo to the northward of the city of Cat'hmandu a hill called *Simbi*, upon which are ſome tombs of the Lamas of Tibet, and other people of high rank of the ſame nation. The monuments are conſtructed after various forms: two or three of them are pyramidal, very high, and well ornamented; ſo that they have a very good appearance, and may be ſeen at a conſiderable diſtance. Round theſe monuments are remarkable ſtones covered with characters, which probably are the inſcriptions of ſome of the inhabitants of Tibet whoſe bones were interred there. The natives of Nepal not only look upon the hill as ſacred, but imagine it is protected by their idols; and from this erroneous ſuppoſition never think of ſtationing troops there for the defence ſton. defence of it, although it be a poſt of great importance, and only at a ſhort mile's diſtance from the city. During the hoſtilities, however, which prevailed when our author was in the country, this ſacred hill was fortified by one of the armies, who, in digging their ditches among the tombs, found conſiderable pieces of gold, with a quantity of which metal the corpſes of the grandees of Tibet are always interred.

The kingdom of Nepal our author believes to be very ancient, becauſe it has always preſerved its peculiar language and independence. It was completely ruined, however, about thirty or forty years ago by the diſſenſions of its nobles, who, on the death of their ſovereign, and, as it would ſeem, the extinction of the royal line, could not agree in their choice of a proper ſucceſſor. The conſequence was, that different ſovereigns were ſet up by the nobles of different diſtricts; and theſe waged war with each other, with a degree of treachery and ſavage atrocity that has hardly a parallel in the annals of the world. Even the Brahmens, whom we are accuſtomed to conſider as a mild and innocent people, were, in the civil wars of Nepal, guilty of the meaneſt and baſeſt villanies: they brought about treaties between the rival ſovereigns, and then encouraged him whom they favoured, to maſſacre the adherents of the other in cold blood.

NEWTON (John), an eminent Engliſh mathematician, was born at Oundle in Northamptonſhire, 1622. After a proper foundation at ſchool, he was ſent to Oxford, where he was entered a commoner of St Edmund's Hall in 1637. He took the degree of bachelor of arts in 1641; and the year following was created maſter, among ſeveral gentlemen that belonged to the king and court, then reſiding in the univerſity. At which time, his genius being inclined to aſtronomy and the mathematics, he applied himſelf diligently to thoſe ſciences, and made a great proficiency in them, which he found of ſervice during the times of the uſurpation. After the reſtoration of Charles II. he reaped the fruits of his loyalty; being created doctor of divinity at Oxford Sept. 1661, he was made one of the king's chaplains, and rector of Roſs in Herefordſhire, in the place of Mr John Toombes, ejected for nonconformity. He held this living till his death, which happened at Roſs on Chriſtmas-day 1678. Mr Wood gives him the character of a capricious and humourſome perſon: however that may be, his writings are ſufficient monuments of his genius and ſkill in the mathematics. Theſe are, 1. *Aſtronomia Britannica*, &c. in three parts, 1656, in 4to. 2. Help to Calculation; with Tables of Declination, Aſcenſion, &c. 1657, 4to. 3. *Trigonometria Britannica*, in two books, 1658, folio; one compoſed by our author, and the other tranſlated from the Latin of Henry Gellibrand. 4. *Chiliades centum Logarithmorum*, printed with, 5. Geometrical Trigonometry, 1659. 6. Mathematical Elements, three parts, 1660, 4to. 7. A perpetual Diary or Almanac, 1662. 8. Deſcription of the Uſe of the Carpenter's Rule, 1667. 9. Ephemerides, ſhewing the Intereſt and rate of Money at 6 *per cent.* &c. 1667. 10. *Chiliades centum Logarithmorum, et Tabula Partium proportionalium*, 1667. 11. The Rule of Intereſt, or the Caſe of Decimal Fractions, &c. Part II. 1668, 8vo. 12. School-Paſtime for young Children, &c. 1669, 8vo. 13. Art of practical Gauging, &c. 1669. 14. Introduction to the Art of Rhetoric, 1671. 15. The Art of Natural Arithmetic, in whole Numbers, and Fractions Vulgar and Decimal, 1671, 8vo. 16. The Engliſh Academy, 1677, 8vo. 17. Coſmography. 18. Introduction to Aſtronomy. 19. Introduction to Geography, 1678, 8vo *.

Nicole.

NICOLE (Francis), a very celebrated French mathematician, was born at Paris December 23. 1683. His early attachment to the mathematics induced M. Montmort to take the charge of his education; and he opened out to him the way to the higher geometry. He firſt became publicly remarkable by detecting the fallacy of a pretended quadrature of the circle. This quadrature a M. Mathulon ſo aſſuredly thought he had diſcovered, that he depoſited, in the hands of a public notary at Lyons, the ſum of 3000 livres, to be paid to any perſon who, in the judgment of the Academy of Sciences, ſhould demonſtrate the falſity of his ſolution. M. Nicole, piqued at this challenge, undertook the taſk, and expoſing the paralogiſm, the Academy's judgment was, that Nicole had plainly proved that the rectilineal figure which Mathulon had given as equal to the circle, was not only unequal to it, but that it was even greater than the polygon of 32 ſides circumſcribed about the circle. The prize of 3000 livres Nicole preſented to the public hoſpital of Lyons.

The Academy named Nicole, Eleve-Mechanician, March 12. 1707; Adjunct in 1716, Aſſociate in 1718, and Penſioner in 1724; which he continued till his death, which happened the 18th of January 1758, at 75 years of age.

His works were all inſerted in the different volumes of the Memoirs of the Academy of Sciences; and are as follow: 1. A General Method for determining the Nature of Curves formed by the Rolling of other Curves upon any Given Curve; in the volume for the year 1707. 2. A General Method for Rectifying all Roulets upon Right and Circular Baſes, 1708. 3. General Method of determining the Nature of thoſe Curves which cut an Infinity of other Curves given in Poſition, cutting them always in a Conſtant Angle, 1715. 4. Solution of a Problem propoſed by M. de Lagny, 1716. 5. Treatiſe of the Calculus of Finite Differences, 1717. 6. Second Part of the Calculus of Finite Differences, 1723. 7. Second Section of ditto, 1723. 8. Addition to the two foregoing papers, 1724. 9. New Propoſition in Elementary Geometry, 1725. 10. New Solution of a Problem propoſed to the Engliſh Mathematicians, by the late M. Leibnitz, 1725. 11. Method of Summing an Infinity of New Series, which are not ſummable by any other known method, 1727. 12. Treatiſe of the Lines of the Third Order, or the Curves of the Second Kind, 1729. 13. Examination and Reſolution of ſome Queſtions relating to Play, 1730. 14. Method of determining the Chances at Play. 15. Obſervations upon the Conic Sections, 1731. 16. Manner of generating in a Solid Body all the Lines of the Third Order, 1731. 17. Manner of determining the Nature of Roulets formed upon the Convex Surface of a Sphere; and of determining which are Geometric and which are Rectifiable, 1732. 18. Solution of a Problem in Geometry, 1732. 19. The Uſe of Series in reſolving many Problems in the Inverſe Method of Tangents, 1737. 20. Obſervations on the Irreducible Caſe in Cubic Equations, 1738. 21. Obſervations upon Cubic Equations, 1738. 22. On the Triſection of an

Nieuwland.

an Angle, 1740. 23. On the Irreducible Caſe in Cubic Equations, 1741. 24. Addition to ditto, 1743. 25. His Laſt Paper upon the ſame, 1744. 26. Determination, by Incommenſurables and Decimals, the Values of the Sides and Areas of the Series in a Double Progreſſion of Regular Polygons, inſcribed in and circumſcribed about a Circle, 1747 *.

NIEUWLAND (Peter), profeſſor of mathematics and natural philoſophy in the univerſity of Leyden, was born at Diemermeer, a village near Amſterdam, on the 5th of November, 1764. His father, by trade a carpenter, having a great fondneſs for books, and being tolerably well verſed in the mathematics, inſtructed his ſon himſelf till he attained to his eleventh year. Young Nieuwland appears to have diſplayed ſtrong marks of genius at a very early period. When about the age of three, his mother put into his hand ſome prints, which had fifty verſes at the bottom of them by way of explanation. Theſe verſes ſhe read aloud, without any intention that her ſon ſhould learn them; and ſhe was much ſurpriſed ſome time after to hear him repeat the whole from memory, with the utmoſt correctneſs, on being only ſhewn the prints.

Before he was ſeven years of age he had read more than fifty different books, and in ſuch a manner that he could frequently repeat paſſages from them both in proſe and in verſe. When about the age of eight, Mr Aeneæ at Amſterdam, one of the greateſt calculators of the age, aſked him if he could tell the ſolid contents of a wooden ſtatue of Mercury which ſtood upon a piece of clock-work. "Yes (replied young Nieuwland), provided you give me a bit of the ſame wood of which the ſtatue was made; for I will cut a cubic inch out of it, and then compare it with the ſtatue." Poems which (ſays his eulogiſt) diſplay the utmoſt livelineſs of imagination, and which he compoſed in his tenth year, while walking or amuſing himſelf near his father's houſe, were received with admiration, and inſerted in different poetical collections.

Such an uncommon genius muſt ſoon burſt through thoſe obſtacles which confine it. Bernardus and Jeronimo de Boſch, two of the firſt and wealthieſt men at Amſterdam, became young Nieuwland's benefactors, and contributed very much to call forth his latent talents. He was taken into the houſe of the former in his eleventh year, and he received daily inſtruction from the latter for the ſpace of four years. While in this ſituation he made conſiderable progreſs in the Latin and Greek languages, and he ſtudied philoſophy and the mathematics under Wyttenbach. In the year 1783 he tranſlated the two diſſertations of his celebrated inſtructors, Wyttenbach and de Boſch, on the opinions which the ancients entertained of the ſtate of the ſoul after death, which had gained the prize of the Teylerian theological ſociety.

From the month of September 1784 to 1785, Nieuwland reſided at Leyden as a ſtudent in the univerſity, and afterwards applied with great diligence, at Amſterdam, to natural philoſophy and every branch of the mathematics, under the direction of Profeſſor van Swinden. He had ſcarcely begun to turn his attention to chemiſtry, when he made himſelf maſter of the theory of the much-lamented Lavoiſier, and could apply it to every phenomenon. He could read a work through with uncommon quickneſs, and yet retain in his mind the principal part of its contents.

Nieuwlan

Nieuwland's attention was directed to three principal purſuits, which are ſeldom united; poetry, the pure mathematics, and natural philoſophy. In the latter part of his life he added to theſe alſo aſtronomy. Among the poems which he publiſhed, his Orion alone has rendered his name immortal in Holland. Of the ſmall eſſays which he publiſhed in his youth, the two following are particularly deſerving of notice: 1. A Comparative View of the Value of the different Branches of Science; and, 2. The beſt Means to render general, not Learning, but Soundneſs of Judgment and Good Taſte.

One of his great objects was to bring the pure mathematics nearer to perfection, to clear up and connect their different parts, and in particular to apply them to natural philoſophy and aſtronomy. Cornelius Douwes diſcovered an eaſy method of determining the latitude of a place at ſea, not by the meridian altitude of the ſun, but by two obſervations made at any other period of the day. This method, however, being ſtill imperfect, Nieuwland turned his thoughts towards the improvement of it, and in the beginning of the year 1789 wrote a paper on the ſubject, which he tranſmitted to M. de Lalande at Paris, from whom it met with great approbation. In the year 1792, when Nieuwland reſided two months at Gotha with Major von Zach, theſe two learned men often converſed on this method of finding the latitude, and calculated the reſult of obſervations which they had made with a ſextant and an artificial horizon. The above paper, enlarged by theſe obſervations, was inſerted by Major von Zach with Nieuwland's name in the firſt Supplement to Bode's Aſtronomical Almanack, Berlin, 1793.

This, however, was not the only ſervice which Nieuwland endeavoured to render to aſtronomy. It had been obſerved by Newton, Euler, De la Place, and others, that the axes of the planets do not ſtand perpendicular, but inclined, to the plane of their orbits; and Du Sejour, in his analytical treatiſe on the apparent motion of the heavenly bodies, conſiders it as highly probable that this phenomenon depends on ſome *phyſical* cauſe; which, however, he does not venture to aſſign. Nieuwland proceeded farther, and laid down principles, from which he drew this concluſion, that the above phenomenon is intimately connected with the whole ſyſtem of attraction. On theſe principles he made calculations, the reſult of which was exactly equal to the angle of the inclination of the earth's axis to the plane of its orbit. Nieuwland communicated his diſcovery with much modeſty to the celebrated Profeſſor Damen at Leyden, who propoſed ſome objections to it which diſcouraged Nieuwland, and induced him to reviſe his calculations with more accuracy. Major von Zach tranſmitted the paper which contained them to M. De la Place at Paris, and cauſed it to be printed alſo, for the opinion of the learned, in the Supplement to Profeſſor Bode's Aſtronomical Almanack for the year 1793.

The writer of this article is not acquainted either with the principles which this young aſtronomer aſſumed, or with the calculations which he made from them; but if he holds gravitation to be eſſential to matter, and the inclination of the axes of the planets to be the neceſſary reſult of the law of gravitation, he is undoubtedly

---

* Hutton's Dictionary.

doubtedly in an error. The axes of the planets are not all equally inclined, nor does the inclination vary in exact proportion to the ſquares of the diſtances.

Nieuwland's talents and diligence ſoon recommended him to the notice of his country. In his twenty-ſecond year, he was appointed a member of the commiſſion choſen by the College of Admiralty at Amſterdam for determining the longitude and improving marine charts. On this labour he was employed eight years, and undertook alſo to prepare a nautical almanack, and to calculate the neceſſary tables. The mathematical part was in general entruſted to Nieuwland; but he aſſiſted alſo his two colleagues van Swinden and van Keulen, in the departments aſſigned to them, with ſuch aſſiduity, that moſt of the work publiſhed on the longitude, together with the three additional parts, were the fruits of his labour. In the ſecond edition of the explanation of the nautical almanack, he had alſo the principal ſhare; and he was the author, in particular, of the explanation of the equation of time, the method of determining the going of a time-piece, and of calculating the declination of the moon.

Soon after Nieuwland engaged in this employment, it appeared as if his deſtination was about to be changed. In the year 1787, he was choſen by the States of Utrecht to ſucceed Profeſſor Hennert; but on account of certain circumſtances this appointment did not take place. He was, however, invited to Amſterdam by the magiſtrates of that city, to give lectures on mathematics, aſtronomy, and navigation. While in this ſituation, he wrote his uſeful and excellent treatiſe on navigation, the firſt part of which was publiſhed at Amſterdam in 1793, by George Hulſt van Keulen; and it is much to be wiſhed that M. van Swinden would complete this work from the papers bequeathed to him by his deceaſed friend the author.

In aſtronomical purſuits, Nieuwland applied not only to the theoretical, but alſo to the practical part; and in this ſtudy he was encouraged and aſſiſted by Major von Zach, with whom he reſided ſome time in the courſe of the year 1792, and who inſtructed him in the proper uſe of the ſextant. This affectionate friend publiſhed alſo all his obſervations and calculations in the beforementioned Supplement to Bode's Aſtronomical Almanack.

In the year 1789, Nieuwland was choſen member of a learned ſociety whoſe object was chemical experiments; and ſo apt was his genius for acquiring knowledge, that in a little time he made himſelf completely maſter of the theory of chemiſtry. A proof of this is the treatiſe which he read on the 24th of May 1791, in the ſociety, diſtinguiſhed by the motto of *Felix Meritis*, and which has been printed in the firſt part of the New General Magazine (*Niew Algemeen Magazyn*). At the ſame time he was able to examine the important diſcoveries made by the ſociety, to aſſiſt in preparing an account of them for the preſs, and to publiſh them with ſufficient accuracy in the French language. Three parts of this work appeared under the title of *Recherches Phyſico-chymiques*. The firſt part appeared in 1792, and was afterwards reprinted in the *Journal de Phyſique*. The ſecond was publiſhed in 1793, and the fourth in 1794. Some letters of his on chemiſtry may be found alſo in a periodical work called *The Meſſenger* (*Letterbode*).

This ingenious and diligent man was of great ſervice alſo in the philoſophical department to the above ſociety, *Felix Meritis*, of which he had been choſen a titular member on the 25th of January 1788, and an honorary member on the 15th of March 1791. The papers for which it was indebted to him are as follows:—1. On the Neweſt Diſcoveries in Aſtronomy, and the Progreſs lately made in that Science, 1788. This is an extract from a Latin oration which he intended to deliver at Utrecht when he expected to ſucceed Profeſſor Hennert.—2. On the Figure of the Earth, 1789.—3. On the Courſe of Comets, and the Uncertainty of the Return of the Comet now Expected, 1790.—4. On the Nature of the Mathematics. The principal object of this paper was to illuſtrate the idea, that the mathematics may be conſidered as a beautiful and perfect language.—5. On the Periodical Decreaſe or Increaſe in the Light of Certain Fixed Stars, and Particularly of the Star Algol, 1790.—6. On the Solution of Spherical Trigonometry by Means of a New Inſtrument Invented by Le Guin, 1791. M. le Guin having tranſmitted to the College of Admiralty at Amſterdam an inſtrument which might be uſed with great advantage in trigonometrical operations, and by which, in calculating the longitude, one could deduce the real from the apparent diſtance, the admiralty charged Nieuwland to examine this inſtrument; and he found that it might be of excellent ſervice for the above purpoſe.—7. On the Relative Value or Importance of the Sciences, 1791.—8. On the Syſtem of Lavoiſier, 1792.—9. On the Selenotopographia of Schröder, 1793.—10. On what is Commonly Called Cultivation, Inſtruction, or Enlightening, 1793.

Nieuwland had applied cloſely to the mathematics, aſtronomy, and navigation, for ſix years; during which time he made conſiderable improvements in nautical charts, and filled up his vacant hours with the ſtudy of philoſophy and chemiſtry. In the month of July 1793 he was invited to the univerſity of Leyden, to be profeſſor of philoſophy, aſtronomy, and the higher mathematics, in the room of the celebrated Damen; and the admiralty of Amſterdam requeſted him to continue his nautical reſearches, which he did with great aſſiduity till the period of his death. The only variation which he now made in his ſtudies related to natural philoſophy, for with the mathematics he was already ſufficiently acquainted. He applied therefore to the experimental part, and ſpared no pains nor labour to become perfect in it; which would certainly have been the caſe, had he not been ſnatched from ſcience and his friends at the early age of thirty. He died of an inflammation in his throat, accompanied with a fever, on the 13th of November 1794.

In his external appearance, Nieuwland was not what might be called handſome, nor had he ever been at pains to acquire that eaſe of deportment which diſtinguiſhes thoſe who have frequented polite company. His behaviour and converſation were however agreeable, becauſe he could diſcourſe with facility on ſo many ſubjects, and never wiſhed to appear but under his real character. On the firſt view one might have diſcerned that he was a man of great modeſty and the ſtricteſt morality. His father was a Lutheran, and his mother a baptiſt; but he himſelf was a member of what is called the reformed church, *i. e.* a Calviniſt, and always ſhewed the utmoſt reſpect for the Supreme Being both by his words and his actions.

NIGER, a large river in Africa, of which many erroneous accounts have been publiſhed, and among them that which we have given in the *Encyclopædia Britannica*. By Herodotus, Pliny, Ptolemy, and other ancient authors, it is uniformly ſaid to flow from *weſt* to *eaſt*, dividing Africa as the Danube divides Europe; and from the report of the Africans, the firſt of theſe authors calls it a large river abounding with crocodiles. In the twelfth century, however, Edriſi deſcribes the Niger, which he calls the Nile of the negroes, as running from *eaſt* to *weſt*, and falling into the Atlantic Ocean; and his account was univerſally adopted by ſubſequent writers, till its falſehood was diſcovered by the African Aſſociation. From a number of concurring reports, Major Houghton was led to believe that the courſe of the Niger is from *weſt* to *eaſt*, according to the moſt ancient account; and the truth of theſe reports has been eſtabliſhed beyond all controverſy by Mr Park, who ſaw the Niger himſelf, and actually accompanied it for many miles in its majeſtic courſe as laid down by Herodotus.

This river riſes in or near the country of MANDING (which ſee in this *Supplement*), between the parallels of 10 and 11 degrees of north latitude, and between the 5th and 9th degree of weſt longitude, which comprehends a ſpace the moſt elevated of all this portion of Africa. This is evident from the oppoſite courſes of the three great rivers which riſe in it. Theſe are the Gambia, which runs to the weſt-north-weſt; the Senegal, which runs to the north-weſt; and the Joliba (A), or Niger, running to the eaſt-north-eaſt. The head of the principal branch of the Senegal river is about 80 geographical miles to the weſt of that of the Niger; and the head of the Gambia is again about 100 miles weſt of the Senegal.

Mr Park traced the Niger to Silla, a conſiderable town about 420 miles from its ſource; and it was there larger than the Thames at Weſtminſter. But 420 miles are but a very ſmall part of the courſe of the Niger, which doubtleſs receives many tributary ſtreams before it reach Kaſſina, 700 miles farther eaſtward, where there is every reaſon to believe that it was viewed by the ancient Romans. Our traveller collected at Silla what information he could from the Mooriſh and Negro traders concerning the further courſe of this majeſtic ſtream, as well as of the kingdoms through which it runs; and the following notices he believes to be authentic:

Two ſhort days journey to the eaſtward of Silla, is the town of Jenne, which is ſituated on a ſmall iſland in the river; and is ſaid to contain a greater number of inhabitants than Sego itſelf, or any other town in Bambarra. (See SEGO, *Suppl.*) At the diſtance of two days more, the river ſpreads into a conſiderable lake, called *Dibbie* (or the dark lake); concerning the extent of which, all the information which our author could obtain was, that in croſſing it, from weſt to eaſt, the canoes loſe ſight of land one whole day. From this lake, the water iſſues in many different ſtreams, which terminate in two large branches, one whereof flows towards the north eaſt, and the other to the eaſt; but theſe branches join at Kabra, which is one day's journey to the ſouthward of Tumbuctoo, and is the port or ſhipping-place of that city. The tract of land which the two ſtreams encircle, is called Jinbala, and is inhabited by negroes; and the whole diſtance, by land, from Jenne to Tumbuctoo, is twelve days journey.

From Kabra, at the diſtance of eleven days journey, down the ſtream, the river paſſes to the ſouthward of Houſſa, which is two days journey diſtant from the river. Of the further progreſs of this great river, and its final exit, all the natives with whom Mr Park converſed ſeemed to be entirely ignorant. Their commercial purſuits ſeldom induce them to travel further than the cities of Tumbuctoo and Houſſa; and as the ſole object of thoſe journeys is the acquirement of wealth, they pay but little attention to the courſe of rivers, or the geography of countries. It is, however, highly probable that the Niger affords a ſafe and eaſy communication between very remote nations. All our author's informants agreed, that many of the negro merchants who arrive at Tumbuctoo and Houſſa, from the eaſtward, ſpeak a different language from that of Bambarra, or any other kingdom with which they are acquainted. But even theſe merchants, it would ſeem, are ignorant of the termination of the river; for ſuch of them as can ſpeak Arabic, deſcribe the amazing length of its courſe in very general terms, ſaying only, that they believe *it runs to the world's end*.

Major Rennel, by comparing a great many accounts of the progreſs of this river beyond Houſſa, with the idea which prevails in that city of its termination, has ſhewn it to be in a very high degree probable, that the waters of the Niger have no direct communication with the ſea, but that they are ſpread out into a great lake in Wangara and Ghana, and evaporated by the heat of the ſun. See WANGARA in this *Supplement*.

NILE, the name of a celebrated river, which, as it has been deſcribed in the *Encyclopædia*, ſhould not have been introduced into this place, did we not think ourſelves bound candidly to confeſs that, in our opinion, its ſources, at leaſt thoſe ſources which were the objects of ancient curioſity, have never yet been ſeen by any European. This ſeems to be proved, beyond the poſſibility of controverſy, by Major Rennel in the Appendix to Mr Park's Travels, and by Mr Browne in his account of the *Bahr-el-abiad*, and *Dar-Fur* or *Soudan*. See SOUDAN in this *Supplement*.

Mr Bruce himſelf acknowledges that the Nile, which waters Egypt, is the confluence of two ſtreams, and that the weſtern ſtream, which he, with others, calls *Bahr-el-abiad*, or the *white river*, is the largeſt of the two. Were a man therefore to travel from Cairo up the banks of the Nile in queſt of its ſource, he would, doubtleſs, when he ſhould arrive at the diviſion of the river into two channels, continue his journey up the greater of theſe; for what could induce him to turn aſide with the leſs? Not the *name*; for neither the leſs nor the greater has by itſelf the name which, in Egypt, is given to both when united. The former, which undoubtedly has its ſource in Abyſſinia, is there called the Abay or Abavi; and, in other countries through which

---

(A) This is the negro name of the river, and ſignifies the *great water*.

ile, iquas.

which it runs, the Bahr-el Aſrek; the latter is, from its ſource to its junction with the Abay, called the Bahr-el abiad. Pliny believed that the Nile came from the weſt; and Ptolemy ſays expreſsly that its remote ſource is in the *mountains of the moon*. But this Nile muſt be the White River, which certainly riſes to the weſtward of Abyſſinia, and, according to Abulfeda, in the mountains of Komri or Kummeri; which, in Arabic, ſignifies *lunar*, being the adjective of Kummer, the moon.

In perfect conformity with this ancient account of the ſource of the Nile, Mr Ledyard was told at Cairo by certain perſons from Dar-Fur, that this celebrated river has its coy fountains in their country, at the diſtance of 55 days journey to the weſtward of Senaar, which brings them to the Komri mountains of Abulfeda, who, as well as Ptolemy and Edriſi, places the head of the Nile in a quarter far removed from Abyſſinia. Ptolemy has indeed mentioned both branches; and while he deſcribes the eaſtern in ſuch a way as that it cannot be taken for any other than the Abyſſinian branch, or the Nile of Bruce and the Portugueſe Jeſuits, ſpeaks of a larger branch flowing from a more diſtant ſource, ſituated to the ſouth-weſt. But this can be no other than Bruce's white river, the *Bahr-el-abiad* of Ledyard and Browne. It is true, there is an apparent difference in the account given by theſe two laſt mentioned travellers of the country in which the Bahr-el-abiad riſes; but it is a difference only apparent. Ledyard was told at Cairo that it riſes in Dar-Fur; Mr Browne, who reſided long in Dar-Fur, was there told, that the ſources of the river are near to a place called *Donga*, the reſidence of the chief or king of an idolatrous nation to the ſouthward of Dar-Fur. It is to be obſerved, however, that the ſlave-merchants who trade between Donga and Cairo are always attached to the Soudan or Dar-Fur caravan; and that therefore the perſons who told Ledyard that the Nile riſes in their country were probably from Donga, though he took them for Furians from the name of their caravan. Mr Browne informs us, that the country about Donga is very mountainous, and that in the ſpot where the river riſes there are ſaid to be forty diſtinct hills, which are called *Kumri*. From them iſſues a great number of ſprings, that, uniting into one great channel, form the Bahr-el abiad, which ſuffers the ſame periodical increaſe and diminution as the Nile in Egypt. The people of Donga are quite naked, black, and, as we have already obſerved, idolaters. Major Rennel places the mountains of the moon between 5° 40′ and 8° 10′ N. Lat. and between 24° 30′ and 30° 25′ E. Long. Their latitude and longitude, as laid down by Mr Browne, are ſomewhat, tho' very little, different; whilſt Geeſh, the ſource of Bruce's Nile, lies between the 10th and 11th degree of N. Lat. and in about the 37th degree of E. Long.

NIMIQUAS, a nation, or, more properly, two tribes in South Africa, called by Vaillant the *Leſs* and *Greater* Nimiquas.

Nimiquas.

The country of the Leſs Nimiquas extends in longitude from the mountains of Camis to the ſea on the weſt, *i. e.* from 15° 25′ to 18° 25′ eaſt from London, and in latitude from 28° 12′ to 29° 36′ ſouth. From the information which our author could collect, he thinks that the number of inhabitants throughout the whole of this tract does not exceed 6000 ſouls. Even this number is annually diminiſhed by the frequent attacks of Boſhmen, and the aridity of the ſoil. Of the BOSHMEN we have already given ſuch an account as can leave no doubt of the deſtructive nature of their incurſions; and the ſoil muſt be arid indeed, if it be true, as Vaillant aſſures us, that in the country of the Leſs Nimiquas rain never falls except when it thunders, and that thunder is ſo rare as frequently not to be heard for the ſpace of a whole year.

For this want of rain our author accounts in a ſatiſfactory manner: "The country (he ſays) having neither foreſts nor lofty mountains to arreſt the clouds, thoſe which come from the north paſs freely over it, and proceed on to Camis, where they burſt and fall, either in rain in the valleys, or in ſnow on the ſummits of theſe mountains, which are the loftieſt throughout the ſouth of Africa." The country is of courſe not fruitful, and its ſterility obliges the inhabitants frequently to change their reſidence, ſo that they are the moſt wandering of all the Hottentot tribes. In this barren region the Dutch coloniſts ſuppoſe that gold mines may be found; but our author diſcovered among the hordes no traces of this metal, though he found many indications of rich copper mines.

The Leſs Nimiquas, though of a tolerable ſtature, are not ſo tall as their neighbours to the eaſtward; and indeed Vaillant affirms, that the people to the eaſt in the ſouthern part of Africa are much ſuperior to thoſe of the weſt both in moral and phyſical qualities, while the animals are far inferior. The Leſs Nimiquas are great believers in witchcraft; and our author gives a ridiculous account of an interview that he had with an old witch named *Kakoes*, who had a complete aſcendency, not only over the whole horde, but alſo over the ſavage Boſhmen. Theſe robbers, he ſays, never attempted to plunder the territory where ſhe took up her reſidence; and ſhe has been known, when their thefts came to her knowledge, to proceed alone, and unguarded, to their retreats in the midſt of the woods, to threaten them with her vengeance, and thus compel them to a reſtitution of the ſtolen property. All her influence, however, over her own tribe, could procure for our author and his attendants only ſix ſheep.

The women of the horde received his Hottentots with great kindneſs; and permitted them to diſcover very ſingular charms, of which it is needleſs here to inſert a deſcription. Among this people he ſaw abundance of bracelets, necklaces, and ear-rings of copper; and ſome of theſe ornaments were ſo well made and finely poliſhed, that they muſt have been manufactured in Europe, and the fruits of an intercourſe with the whites. But he ſaw ſeveral others, which, from their groteſque ſhape and rude workmanſhip, evidently ſhewed that they were fabricated by the ſavages themſelves.

"Theſe ornaments (ſays he) are worn by the Nimiquas in the ſame manner as by the other ſavages; yet I obſerved among them ſome whimſical peculiarities. I have ſeen perſons with ſix ear-rings of the ſame ſhape in one ear, and none in the other: I have ſeen ſome with bracelets from the wriſt to the elbow on one arm, while the other arm was bare: I have ſeen others with one ſide of the face painted in compartments of various colours, while on the other ſide both the colours and figures were different. In general, I obſerved great propenſity to ornaments among the Leſs Nimiquas;

for their kroſſes and all their garments were plentifully covered with glaſs and copper beads, ſtrung on threads, and faſtened on every part of their dreſs. They even wore them in their hair, which was plaſtered with greaſe in the moſt diſguſting manner. Many had their heads covered with a reddiſh incruſtation, compoſed of greaſe and a powder reſembling brick duſt, with which their hair was ſo paſted together, that you would have ſworn it to be a cap of red mortar. Thoſe who had it in their power to diſplay this luxury of dreſs, were as proud as are our *petits-maitres*, when they can ſhake a head loaded with powder, perfume, and pomatum. The *nuyp-kros*, or ſhort apron, of the women, was adorned with rows of glaſs beads hanging down to their feet; in other reſpects they were dreſſed like the other Hottentots."

The country of the *Greater Nimiquas* is placed by the author in nearly the ſame longitude with that of the Leſs, and between 25° and 28° ſouth latitude. It is barren like the other; but the people are much taller, being generally about five feet ten inches high. The men are dull and ſtupid, but the women are lively and extremely amorous; and both men and women are comparatively handſome and of a ſlender make. Extravagantly addicted to ſmoking tobacco, the young girls bartered their favours for a ſingle pipe; and as Vaillant was chief of the caravan, a white, and poſſeſſor of tobacco of much better quality, many advances were made to him. "I have do doubt (ſays he) but I might have formed, for a few pipefuls only, an alliance with every family in the horde. I was even preſſed ſo cloſely, as to be obliged to employ ſome reſiſtance: but, at the ſame time, I muſt confeſs, that my refuſals were given in ſuch a way as not to offend; and they who, in conſequence of their advances, had been expoſed to them, having ſoon found other arrangements to make, did not ſhew me the leſs friendſhip. I muſt here add, that the girls alone appeared to me thus free; while the married women on the contrary were modeſt and reſerved. This is a characteriſtic difference, which diſtinguiſhes the Greater Nimiquas from the Hottentot people in general; as likewiſe does the low cringing air they aſſume when they have any thing to aſk."

It has been ſaid by Kolben, that the Nimiqua women, when they bear twins, deſtroy one of the infants; but Vaillant aſſures us that this is a falſehood, as is likewiſe another tale which is current in the colony. It has been ſaid that the fathers, to ſhew what affection they bear their children, feed their eldeſt in a particular manner, as being of right the firſt object of paternal care. For this purpoſe they put him in a coop as it were; that is, they ſhut him up in a trench made under their hut, where, being deprived of motion, he loſes little by perſpiration, while they feed and cram him in a manner with milk and greaſe. By degrees the child fattens, and gets as round as a barrel; and when he is come to ſuch a ſtate as not to be able to walk, but to bend under his own weight, the parents exhibit him to the admiration of the horde; who from that period conceive more or leſs eſteem and conſideration for the family, according as the monſter has acquired more or leſs rotundity.

Such was the account given to our author by a man who affirmed that he had been an eye-witneſs of this mode of cramming the heir-apparent; but whenever any queſtions were aſked on the ſubject of the Nimiquas themſelves, the perſons addreſſed were ready to laugh in our author's face. "Still (ſays he), as it appeared ſtrange to me, that a man ſhould talk of what he had ſeen, when he had in reality ſeen nothing; as it was poſſible that the fable might have ſome foundation, without being true in all particulars—I was willing to convince myſelf what could have given riſe to it; and every time I viſited a horde, I took care, under different pretences, to examine, one after another, all the huts of the kraal, and to aſk which was the eldeſt child of the family: but I nowhere ſaw any thing that indicated either this pretended coop, or this pretended cramming."

The Nimiquas are great cowards; yet, like the ſurrounding nations, they have their aſſagays and poiſoned arrows; and, like them, can handle theſe arms with dexterity. They poſſeſs alſo thoſe war oxen, ſo formidable in battle, and ſo favourable to the cowardice or inactivity of the combatants. They have even a peculiar implement of war, which their neighbours have not. This is a large buckler, of the height of the perſon who bears it, behind which the Nimiqua can completely conceal himſelf. But, beſide that his natural apathy prevents him from giving or taking offence, he is in reality puſillanimous and cowardly from the coldneſs of his diſpoſition. To utter only the name of *Houzouana* before him is ſufficient to make him tremble. See Houzouanas in this *Suppl.*

Notwithſtanding his frigidity, the Nimiqua is not inſenſible to pleaſure. He even ſeeks with avidity thoſe which, requiring but little exertion, are capable of agitating him and procuring agreeable ſenſations. Their muſical inſtruments are the ſame as thoſe of the other Hottentots; but their dancing is very different, and reſembles the temper of the nation. If the countenance have received from nature features that can expreſs our paſſions, the body alſo has its attitudes and movements that paint our temper and feelings. The dance of the Nimiqua is frigid like himſelf, and ſo devoid of grace and hilarity, that, were it not for the extreme gaiety of the women, it might be called the dance of the dead.

Theſe tortoiſes, to whom dancing is a fatigue, ſhew little eagerneſs for any thing but wagers, games of calculation and chance, and all the ſedentary amuſements which require patience and reflection, of which they are more capable than they are of motion. When our author, with great propriety, prohibited gaming in his camp, the Nimiquas, who had ſtaid long with him, took their departure.

NITTA, a ſpecies of the Mimosa, which flouriſhes on the banks of the Senegal in Africa. It is valuable to the inhabitants for its fruit, the pods of which are long and narrow, containing a few black ſeeds enveloped in a fine mealy powder, of a bright yellow colour, which reſembles the flour of ſulphur, and has a ſweet mucilaginous taſte. When eaten by itſelf it is clammy; but when mixed with milk or water, it conſtitutes a very pleaſant and nouriſhing food, ſupplying the place of corn to the negroes.—*Park's Travels.*

NIZOLIUS (Marius), a grammarian of Italy, who by his wit and erudition contributed much to the promotion of letters in the 16th century. He publiſhed, in 1553, *Lib.* 4. *De veris Principiis et vera Ratione philoſo-*

philoſophandi, contra Pſeudo-philoſophos. In this work he attacks, with much vivacity, the ſchoolmen, not only for the barbariſm of their terms, but for many ridiculous opinions which they held. Leibnitz was ſo ſtruck with its ſolidity and elegance, that, to expoſe the obſtinacy of thoſe who were zealouſly attached to Ariſtotle, he gave a new edition of it, with critical notes of his own, 1670, in 4to. Nizolius publiſhed alſo, *Theſaurus Ciceronianus, ſive Apparatus Linguæ Latinæ e Scriptis Tullii Ciceronis collectus*, in folio. This is a good Latin dictionary, compoſed of the words and expreſſions of Cicero; to which, it ſeems, Nizolius ſhewed as much bigotry as the ſchoolmen to their notions; and fell under the character of thoſe pedants whom Eraſmus has ridiculed in his *Ciceronianus*. We do not find the year either of his birth or death.

NOCTURNAL ARCH, is the arch of a circle deſcribed by the ſun, or a ſtar, in the night.

NONAGESIMAL, or NONAGESIMAL *Degree*, called alſo the *Mid-heaven*, is the higheſt point, or 90th degree of the ecliptic, reckoned from its interſection with the horizon at any time; and its altitude is equal to the angle that the ecliptic makes with the horizon at their interſection, or equal to the diſtance of the zenith from the pole of the ecliptic. It is much uſed in the calculation of ſolar eclipſes.

NONAGON, a figure having nine ſides and angles. In a regular nonagon, or that whoſe angles and ſides are all equal, if each ſide be 1, its area will be 6·1818242 = $\frac{9}{4}$ of the tangent of 70°, to the radius 1.

NORMAL, is uſed ſometimes for a perpendicular.

NUEL, or NEWEL, the upright poſt about which ſtairs turn, being that part of the ſtaircaſe which ſuſtains one end of the ſteps.

O.

OASIS (plur. OASES), a fertile ſpot in the midſt of a ſandy deſart. In the SAHARA, or Great Deſart of Africa, there are many *Oaſes* of extreme fertility.

OBLATE, flatted or ſhortened; as an oblate ſpheroid, having its axis ſhorter than its middle diameter; being formed by the rotation of an ellipſe about the ſhorter axis.

OBLIQUE ASCENSION, is that point of the equinoctial which riſes with the centre of the ſun, or ſtar, or any other point of the heavens, in an oblique ſphere.

OBLIQUE *Circle*, in the ſtereographic projection, is any circle that is oblique to the plane of projection.

OBLIQUE *Deſcenſion*, that point of the equinoctial which ſets with the centre of the ſun, or ſtar, or other point of the heavens, in an oblique ſphere.

OBLIQUE *Force*, or *Percuſſion*, or *Power*, or *Stroke*, is that made in a direction oblique to a body or plane. It is demonſtrated, that the effect of ſuch oblique force, &c. upon the body, is to an equal perpendicular one, as the ſine of the angle of incidence is to radius.

OBLONG SPHEROID, is that which is formed by an ellipſe revolved about its longer or tranſverſe axis; in contradiſtinction from the *oblate ſpheroid*, or that which is flatted at its poles, being generated by the revolution of the ellipſe about its conjugate or ſhorter axis.

OBSERVATORY, PORTABLE. See ASTRONOMY, n° 504, *Encycl.*

OCCIDENT EQUINOCTIAL, that point of the horizon where the ſun ſets, when he croſſes the equinoctial, or enters the ſign Aries or Libra.

OCCIDENT *Eſtival*, that point of the horizon where the ſun ſets at his entrance into the ſign Cancer, or in our ſummer when the days are longeſt.

OCCIDENT *Hybernal*, that point of the horizon where the ſun ſets at midwinter, when entering the ſign Capricorn.

OCTANT, the eighth part of a circle.

ODD, in arithmetic, is ſaid of a number that is not even. The ſeries of odd numbers is 1, 3, 5, 7, &c.

ODDLY-ODD. A number is ſaid to be oddly-odd, when an odd number meaſures it by an odd number. So 15 is a number oddly odd, becauſe the odd number 3 meaſures it by the odd number 5.

ODOUR, that quality of certain bodies which excites the ſenſation of ſmell. In the *Annales de Chimie*, Vol. XXI. p. 254, we have a detailed account of certain experiments made by M. Benedict Prevoſt of Geneva, with a view to render the *emanations of odorant bodies perceptible to ſight*. The account is by much too long for a work like ours; eſpecially as we feel not ourſelves inclined to attribute to the experiments all the importance which ſeems to have been allowed to them by the firſt claſs of the French National Inſtitute. We ſhall therefore ſtate only a few of them, which ſeem moſt to favour the author's hypotheſis.

1. A concrete odorant ſubſtance, laid upon a wet glaſs or broad ſaucer, covered with a thin ſtratum of water, immediately cauſes the water to recede, ſo as to form a ſpace of ſeveral inches around it.

2. Fragments of concrete odorant matter, or ſmall morſels of paper or cork, impregnated with an odorant liquor, and wiped, being placed on the ſurface of water, are immediately moved by a very ſwift rotation. Romieu had made this obſervation on camphor, and erroneouſly attributed the effect to electricity. The motion was perceptible even in pieces of camphor of ſeven or eight gros.

3. An odorant liquor being poured on the water, ſtops the motion till it is diſſipated by evaporation. Fixed oil arreſts the motion for a much longer time,

and until the pellicle it forms on the water is taken off.

4. When the ſurface of the water is cleaned by a leaf of metal, of paper, or of glaſs, plunged in and withdrawn ſucceſſively until the pellicle is removed, the gyratory motion is renewed. If a piece of red wax or of taper be dipped in water, and the drops ſhaken off into a glaſs of water containing odorant bodies in motion, the movement will be ſtopped. The ſame effect is not produced by metal.

5. A morſel of camphor, plunged to the depth of three or four lines in water, without floating, excites a movement of trepidation in the ſurrounding water, which repels ſmall bodies in its vicinity, and carries them again to the camphor by ſtarts. The author concludes, that an elaſtic fluid eſcapes from the odorant body in the manner of the fire of a fuſee or the diſcharge of fire-arms.

6. When there is a certain proportion between the height of the water and that of the ſmall fragment of camphor, the water is briſkly driven off, returns again to the camphor, and again retires, as if by an exploſion, the recoil of which often cauſes the camphor to make part of a revolution on its axis.

7. Camphor evaporates thirty or forty times more ſpeedily when placed upon water, than when entirely ſurrounded with air.

8. Camphor, during the act of diſſipation in the air, preſerves its form and its opaque whiteneſs; upon water it is rounded, and becomes tranſparent as if it had undergone a kind of fuſion. It may be inferred, that this ariſes from the acquired motion, which cauſes it to preſent a greater ſurface to the air.

9. When ſmall pieces of camphor are plunged in water, the camphor becomes rounded and tranſparent, does not acquire any motion, and its diſſipation is leſs perceptible than in the air. The concurrence of air and water is therefore neceſſary to diſengage the fluid which is the cauſe of the motion and total diſſipation of odorant bodies.

10. The motion of odorant bodies upon water decays and ceaſes ſpontaneouſly at the end of a certain time; becauſe the water having then contracted a ſtrong ſmell, the volatilization takes place in all the points of its ſurface; and the ſmall maſs being thus ſurrounded by the odorant fluid, which is no longer air, diſſolves, as in the ordinary odorant fluids, without forming the gaſeous jet which is the cauſe of the motion. The author compares the volatilization of the aromatic ſubſtance to a combuſtion excited by water.

M. Prevoſt hopes, that theſe, and other experiments which he explains, will contribute to the theory of odours, which ſo nearly reſembles that of the gaſes. He does not flatter himſelf with having exhauſted this ſubject, but conſiders his diſcoveries as the means of rendering odour perceptible by water, not only to the ſight, but even to the touch, as are likewiſe the vibrations of ſonorous bodies. Men deprived of the ſenſe of ſmell, and even the blind, according to him, may in this manner diſtinguiſh odorant bodies from thoſe which have no ſmell. "Perhaps (ſays he) this kind of odoroſcope may, by improvement, become an odorimeter. The exceptions, ſuch for example as that of the cerumen of the ears, which produces much effect on water without being perceptibly odorant, and that of the fingers when hot or moiſt, are merely apparent; for if our ſenſes do not in thoſe caſes diſcover odour, thoſe of animals more powerfully energetic, ſuch as the dog, perceive and diſtinguiſh individuals by its peculiar character. The odoroſcope may afford the information which is wanting reſpecting theſe effluvia. Thus it is that the fat of game, the ſmell of which is nearly to us imperceptible, is very much ſo to dogs, and exhibits ſenſible marks by the odoroſcope."

Profeſſor Venturi of Modena, who heard Prevoſt's memoir read in the National Inſtitute, had himſelf made ſome experiments with camphor kept ſeparately in the air, in the water, and at the ſurface of the water; whence he deduces, that the moſt active virtue for diſſolving camphor reſides at that part where both the air and the water touch the camphor at the ſame time. Hence he explains why, in like circumſtances, camphor evaporates more quickly in a moiſt than in a dry air; and why the Hollanders uſe water in their proceſs for ſubliming this ſubſtance.

It might be thought that the camphor was decompoſed at the ſurface of the water; that the water might ſeize the acidifying part, which renders the camphor concrete; and that the volatile part is diſſipated in the atmoſphere. The author rejects this notion. He thinks that water with camphor floating on its ſurface becomes charged with no more than a very ſmall portion: 1. Becauſe in theſe circumſtances the water acquires the ſame taſte and ſmell of camphor as it obtains when a ſmall quantity of this ſubſtance is kept plunged in the ſame fluid. This water, by expoſure to the air, loſes the qualities with which it had been charged, and becomes inſipid, and without ſmell. 2. Becauſe when the water is ſaturated with all it can take up, the diſſipation of the camphor continues at its ſurface as before. 3. Becauſe the aerial emanations of camphor made at the ſurface of water do themſelves cryſtallize into camphor.

Camphor at the ſurface of the water does nothing, therefore, but diſſolve; and when diſſolved at the ordinary temperature of the atmoſphere, it is not at firſt in the ſtate of vapour, as has been thought. It is ſimply a liquid which extends itſelf over the ſurface of water itſelf; and by this means coming into contact with a great ſurface of air, it is afterwards abſorbed and evaporated. This is proved by the following facts: 1. The ſolution of camphor at the ſurface of water is more rapid in proportion to the extent of the ſurface. In narrow veſſels, the ſection of the column would not be completed in ten days, even though the water might be extremely pure. 2. When the column of camphor has projecting parts, the liquid may be ſeen iſſuing by preference from certain points of the column, covering the ſurface of the water, and driving ſmall floating bodies before it, in the ſame manner as floating bodies go and return in a baſon into which the water of a canal enters with rapidity. 3. If a ſmall piece of camphor, already wetted at one end, be brought near the edge of water contained in a broad ſaucer, and be made to touch the ſaucer itſelf, it depoſits a viſible liquor, which is oily; and by attaching itſelf to the ſaucer, deſtroys the adheſion between the veſſel and the border of the water, ſo that the water retires on account of the affinity of aggregation, which not being oppoſed by the attraction of the ſaucer, cauſes the water to terminate in a round edge.

Odour, Œconomiſts.

edge. If you remove the piece of camphor, the water will not return to its place until the oily fluid is evaporated. 4. In the ſame manner, when the column of camphor is half immerſed in the water, the oily liquor which iſſues forth deſtroys the adheſion of the water to the column, and produces a ſmall ſurrounding cavity. The ſolution ſtops, or is retarded for a moment, until the fluid, extending itſelf over the water, becomes evaporated: the water then returns to its place, and touches the ſame part of the camphor; the ſolution begins again, and in this manner the proceſs is effected by alternations of contact and apparent repulſion.

Of theſe memoirs by Prevoſt and Venturi, the Engliſh reader will find accurate and full tranſlations in the firſt volume of *Nicholſon's Philoſophical Journal*, together with ſome judicious obſervations on them by the editor, which we ſhall take the liberty to adopt. “The philoſophical conſideration of odorant bodies is ſomewhat obſcured by the old method of generaliſing, or referring the properties of bodies to ſome diſtinct principle or thing ſuppoſed capable of being ſeparated from the body itſelf. Thus the odours of bodies have been ſuppoſed to depend on a ſubſtance imagined in a looſe way to be common to them all and ſeparable from them. Hence the terms, principle of ſmell, ſpiritus rector, and even in the modern nomenclature we find *aroma*. There does not in effect ſeem to be any more reaſon to infer the exiſtence of a common principle of ſmell than of taſte. The ſmell of ammoniac is the action of that gas upon the organ of ſenſe; and this odorant inviſible matter is exhibited to the ſight when combined with an acid gas. But in the ſame manner as ammoniac emanates from water, and leaves moſt part of that fluid behind, ſo will the volatile parts of bodies be moſt eminently productive of this action; and very few, if any, natural bodies will be found which riſe totally. The moſt ſtriking circumſtance in the effect is, that an act of ſuch power ſhould be attended with a loſs by exhalation which is ſcarcely to be appreciated by weight, or in any other method during a ſhort interval of time. But we know ſo little of nervous action, and of other phenomena of electricity, of galvaniſm (See GALVANISM in this *Suppl.*), or even of heat, which ſtrongly affect the ſenſes, but elude admeaſurement by gravitation, that the difficulty of weighing the effluvia of odorant bodies becomes leſs aſtoniſhing.”

ŒCONOMISTS, a ſect of philoſophers in France, who have made a great noiſe in Europe, and are generally believed to have been unfriendly to religion. The founder of this ſect was a *Dr Duqueſnai*, who had ſo well inſinuated himſelf into the favour of Louis XV. that the king uſed to call him his *thinker*. The ſect was called *œconomiſts*, becauſe the œconomy and order to be introduced into the finances, and other means of alleviating the diſtreſſes of the people, were perpetually in their mouths. The Abbé Barruel admits, that there may have been ſome few of them who directed their ſpeculations to no other object; but he brings very ſufficient proof that the great aim of the majority of the ſect was to eradicate from the minds of the people all reverence for divine revelation.

“Duqueſnai (ſays he) and his adepts had more eſpecially undertaken to perſuade their readers, that the country people, and mechanics in towns, were entirely deſtitute of that kind of inſtruction neceſſary for their

Œconomiſts.

profeſſions; that men of this claſs, unable to acquire knowledge by reading, pined away in an ignorance equally fatal to themſelves and to the ſtate; that it was neceſſary to eſtabliſh free ſchools, and particularly throughout the country, where children might be brought up to different trades, and inſtructed in the principles of agriculture. D'Alembert, and the Voltairean adepts, ſoon perceived the advantages they could reap from theſe eſtabliſhments. In union with the œconomiſts, they preſented various memorials to Louis XV. in which not only the temporal but even the ſpiritual advantages of ſuch eſtabliſhments for the people are ſtrongly urged. The king, who really loved the people, embraced the project with warmth. He opened his mind on the ſubject to Mr Bertin, whom he honoured with his confidence, and had entruſted with his privy purſe;” and it was with great difficulty that this miniſter could convince him of the dangerous deſigns of the ſect.

“Determined (ſays he) to give the king poſitive proof that the œconomiſts impoſed upon him, I ſought to gain the confidence of thoſe pedlars who travel through the country, and expoſe their goods to ſale in the villages, and at the gates of country ſeats. I ſuſpected thoſe in particular who dealt in books to be nothing leſs than the agents of philoſophiſm with the good country folks. In my excurſions into the country I fixed my attention above all on the latter. When they offered me a book to buy, I queſtioned them what might be the books they had? Probably catechiſms or prayer-books? Few others are read in the villages? At theſe words I have ſeen many ſmile. No, they anſwered, thoſe are not our works; we make much more money of Voltaire, Diderot, and other philoſophic writings. What! ſaid I; the country people buy Voltaire and Diderot? Where do they find the money for ſuch dear works? Their conſtant anſwer was, we have them at a much cheaper rate than prayer-books; we can ſell them at ten ſols (5d.) a volume, and have a pretty profit into the bargain. Queſtioning ſome of them ſtill farther, many of them owned that thoſe books coſt them nothing; that they received whole bales of them without knowing whence they came, but being ſimply deſired to ſell them in their journeys at the loweſt price.”

“Louis XV. warned by the diſcovery made by his miniſter, was at length ſatisfied that the eſtabliſhment of theſe ſchools, ſo much urged by the conſpirators, would only be a new inſtrument of ſeduction in their hands. He abandoned the plan; but, perpetually haraſſed by the protecting ſophiſters, he did not ſtrike at the root of the evil, and but feebly impeded its progreſs. The pedlars continued to promote the meaſures of the conſpirators; yet this was but one of the inferior means employed to ſupply the want of their free ſchools, as a new diſcovery brought to light one far more fatal.

“About the middle of the month of September 1789, little more than a fortnight antecedent to the atrocious 5th and 6th of October, at a time when the conduct of the National Aſſembly, having thrown the people into all the horrors of a revolution, indicated that they would ſet no bounds to their pretenſions, Mr Le Roy, lieutenant of the King's Hunt, and an academician, being at dinner at the houſe of Mr D'Angevilliers, intendant of the buildings of his majeſty, the

Œconomiſts.

converſation turned on the diſaſters of the revolution, and on thoſe that were too clearly to be foreſeen. Dinner over, the nobleman above-mentioned, a friend of Le Roy, hurt at having ſeen him ſo great an admirer of the ſophiſters, reproached him with it in the following expreſſive words: *Well! this, then, is the work of Philoſophy!* Thunderſtruck at theſe words—Alas! cried the academician, *to whom do you ſay ſo? I know it but too well, and I ſhall die of grief and remorſe!* At the word *remorſe*, the ſame nobleman queſtioned him whether he had ſo greatly contributed towards the revolution as to upbraid himſelf with it in that violent manner? ‘Yes (anſwered he), I have contributed to it, and far more than I was aware of. I was ſecretary to the committee to which you are indebted for it; but I call heaven to witneſs, that I never thought it would go to ſuch lengths. You have ſeen me in the king's ſervice, and you know that I love his perſon. I little thought of bringing his ſubjects to this pitch, *and I ſhall die of grief and remorſe!*’

“Preſſed to explain what he meant by this committee, this ſecret ſociety, entirely new to the whole company, the academician reſumed: ‘This ſociety was a ſort of club that we philoſophers had formed among us, and only admitted into it perſons on whom we could perfectly rely. Our ſittings were regularly held at the Baron D'Holbach's. Leſt our object ſhould be ſurmiſed, we called ourſelves œconomiſts. We created Voltaire, though abſent, our honorary and perpetual preſident. Our principal members were D'Alembert, Turgot, Condorcet, Diderot, La Harpe, and that Lamoignon, keeper of the ſeals, who on his diſmiſſion ſhot himſelf in his park.’

“The whole of this declaration was accompanied with tears and ſighs; when the adept, deeply penitent, continued: ‘The following were our occupations; the moſt of thoſe works which have appeared for this long time paſt againſt religion, morals, and government, were ours, or thoſe of authors devoted to us. They were all compoſed by the members or by the orders of the ſociety. Before they were ſent to the preſs, they were delivered in at our office. There we reviſed and corrected them; added to, or curtailed them, according as circumſtances required. When our philoſophy was too glaring for the times, or for the object of the work, we brought it to a lower tint; and when we thought that we might be more daring than the author, we ſpoke more openly. In a word, we made our writers ſay exactly what we pleaſed. Then the work was publiſhed under the title or name we had choſen, the better to hide the hand whence it came. Many, ſuppoſed to have been poſthumous works, ſuch as *Chriſtianity Unmaſked*, and divers others *attributed to Freret and Boulanger* after their deaths, were iſſued from our ſociety.

‘When we had approved of thoſe works, we began by printing them on fine or ordinary paper, in ſufficient number to pay our expences, and then an immenſe number on the commoneſt paper. Theſe latter we ſent to hawkers and bookſellers free of coſt, or nearly ſo, who were to circulate them among the people at the loweſt rate. Theſe were the means uſed to pervert the people, and bring them to the ſtate you now ſee them in. I ſhall not ſee them long, *for I ſhall die of grief and remorſe!*’

This recital is too well authenticated to be called in queſtion, and too plain to need a commentary. Let it be a warning againſt all ſecret ſocieties, by whatever title of benevolence they may be deſigned by thoſe who form them.

Oil.

OIL-MILL, a mill for expreſſing the oils from fruits, or grains, &c. As theſe kingdoms do not produce the olive, it would be needleſs to deſcribe the mills which are employed in the ſouthern parts of Europe. We ſhall content ourſelves, therefore, with a deſcription of a Dutch oil-mill, employed for grinding and preſſing lintſeed, rape-ſeed, and other oleaginous grains. Farther, to accommodate our deſcription ſtill more to our local circumſtances, we ſhall employ water as the firſt mover; thus avoiding the enormous expence and complication of a windmill.

In Plate XXXVIII. fig. A,

1. Is the elevation of a wheel, over or underſhot, as the ſituation may require.

2. The bell-metal ſocket, ſupported by maſonry, for receiving the outer gudgeon of the water wheel.

3. The water courſe.

Fig. B.

1. A ſpur wheel upon the ſame axis, having 52 teeth.

2. The trundle that is driven by N° 1. and has 78 ſtaves.

3. The *wallower*, or axis for raiſing the peſtles. It is furniſhed round its circumference with *wipers* for lifting the *peſtles*, ſo that each may fall twice during one turn of the water wheel, that is, three *wipers* for each peſtle.

4. A frame of timber, carrying a concave half cylinder of bell-metal, in which the wallower (caſed in that part with iron plates) reſts and turns round. It will be ſeen in profile, fig. G.

5. Maſonry ſupporting the inner gudgeon of the water wheel and the above-mentioned frame.

6. Gudgeon of the wallower, which bears againſt a bell-metal ſtep fixed in the wall. This double ſupport of the wallower is found to be neceſſary in all mills which drive a number of heavy ſtampers.

Fig. C, Is the elevation of the peſtle and preſs-frame, their furniture, the mortars, and the preſs-peſtles.

1. The ſix peſtles.

2. Croſs pieces between the two rails of the frame, forming, with theſe rails, guides for the perpendicular motion of the peſtles.

3. The two rails. The back one is not ſeen. They are checked and bolted into the ſtandards N° 12.

4. The tails of the *lifts*, correſponding to the wipers upon the wallower.

5. Another rail in front, for carrying the *detents* which hold up the peſtles when not acting. It is marked 14 in fig. M.

6. A beam a little way behind the peſtles. To this are fixed the pulleys for the ropes which lift and ſtop the peſtles. It is repreſented by 16 in fig. M.

7. The ſaid pulleys with their ropes.

8. The *driver*, which ſtrikes the wedge that preſſes the oil.

9. The *diſcharger*, a ſtamper which ſtrikes upon the inverted wedge, and looſens the preſs.

10. The lower rail with its croſs pieces, forming the lower guides of the peſtles.

11. A ſmall cog wheel upon the wallower, for turning the *ſpatula*, which ſtirs about the oil-ſeed in the *chauffer-pan*. It has 28 teeth, and is marked N° 6 in fig. M.

12. The four ſtandards, mortiſed below into the *block*, and above into the joiſts and beams of the building.

13. The ſix *mortars* hollowed out of the block itſelf, and in ſhape pretty much like a kitchen pot.

14. The feet of the peſtles, rounded into cylinders, and ſhod with a great lump of iron.

15. A board behind the peſtles, ſtanding on its edge, but inclining a little backwards. There is ſuch another in front, but not repreſented here. Theſe form a ſort of trough, which prevents the ſeed from being ſcattered about by the fall of the peſtles, and loſt.

16. The firſt *preſs-box* (alſo hollowed out of the block), in which the grain is ſqueezed, after it has come for the firſt time from below the milſtones.

17. The ſecond *preſs-box*, at the other end of the block, for ſqueezing the grain after it has paſſed a ſecond time under the peſtles.

18. Frame of timber for ſupporting the other end of the wallower, in the ſame manner as at N° 4. fig B.

19. Small cog wheel on the end of the wallower for giving motion to the milſtones. It has 28 teeth.

20. Gudgeon of the wallower, bearing on a bell metal ſocket fixed in the wall.

21. Veſſels for receiving the oil from the preſs-boxes.

22. Joiſts ſupporting the block.

Fig. D Elevation and mechaniſm of the milſtones.

1. *Upright ſhaft*, carrying the great cog wheel above, and the *runner milſtones* below in their frame.

2. Cog-wheel of 76 cogs, driven by N° 19. of fig C.

3. The frame of the *runners*. This will be more diſtinctly underſtood in N° 4. fig. H.

4. The innermoſt runner, or the one neareſt the ſhaft.

5. Outermoſt ditto, being farther from the ſhaft.

6. The *inner rake*, which collects the grain under the outer runner.

7. The *outer rake*, which collects the grain under the inner runner. In this manner the grain is always turned over and over, and cruſhed in every direction. The inner rake lays the grain in a ſlope, of which fig. O. is a ſection; the runner flattens it, and the ſecond rake lifts it again, as is marked in fig. P; ſo that every ſide of a grain is preſented to the milſtone, and the reſt of the *legger* or *nether milſtone* is ſo ſwept by them, that not a ſingle grain is left on any part of it. The outer rake is alſo furniſhed with a rag of cloth, which rubs againſt the border or hoop that ſurrounds the nether milſtone, ſo as to drag out the few grains which might otherwiſe remain in the corner.

8. The ends of the iron axle which paſſes through the upright ſhaft, and through the two runners. Thus they have two motions: 1*mo*, A rotation round their own axis. 2*do*, That by which they are carried round upon the nether milſtone on which they roll. The holes in theſe milſtones are made a little widiſh; and the holes in the ears of the frame, which carry the ends of the iron axis, are made oval up and down. This great freedom of motion is neceſſary for the runner milſtones, becauſe frequently more or leſs of the grain is below them at a time, and they muſt therefore be at liberty to get over it without ſtraining, and perhaps breaking, the ſhaft.

9. The ears of the frame which lead the two extremities of the iron axis. They are mortiſed into the under ſide of the bars of the ſquare frame, that is carried round with the ſhaft.

10. The border or hoop which ſurrounds the nether milſtone.

11. and 12. The nether milſtone and maſonry which ſupports it.

Fig. E. Form of the wallower, ſhewing the diſpoſition of the wipers along its ſurface.

1. Two parts of this ſhaft, which are nicely rounded, and fortified with iron plates, and which reſt upon the bell-metal concaves, which are repreſented in n° 4. of fig. C.

2. The little wheels at each end, for giving motion to the two ſpatulæ, marked n° 11. fig. C.

3. The wipers for the ſecond preſs.

4. The wipers for the firſt preſs.

5. The wipers for the ſix peſtles.

Fig. F Repreſents the ſurface of the wallower unfolded into a rectangular parallelogram, in order to ſhew the diſtribution of the wipers, and conſequently the ſucceſſion of the ſtrokes given by the different peſtles. This diſtribution has ſomething peculiar. Each peſtle has three wipers; and there are alſo three for the driver and diſcharger of the ſecond preſs. The driver and wiper of the firſt preſs have but one and a half; one for the driver, and the half for the diſcharger; ſo that it ſtrikes twice, and the driver only once, in a turn of the ſhaft. This is the Dutch practice, which differs from that of Flanders. The ſucceſſion of the ſtrokes may be conceived as follows: Reckon the ſtampers, including thoſe of the preſſes, from the water wheel toward the other end of the wallower, and calling them *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *k*, and ſuppoſing that *a* makes the firſt ſtroke, they proceed in the following order for one turn of the wallower:

ab, d, f, h, c, e, g, ab, d, f, h, c, e, g, ab, d, f, h, c, e, g.
