Here it may be obſerved that *a* and *b* ſtrike together. They would do ſo if allowed; but one of them is held up by its detent till the workman ſees proper to diſengage it. Each peſtle, and the driver and diſcharger of the ſecond preſs, makes three ſtrokes for one turn of the wallower. But the driver *k* of the firſt preſs makes only one ſtroke in that time, namely, in the interval between the laſt ſtrokes of *e* and *g*. The diſcharger *i* of this preſs makes two ſtrokes; one of them in this ſame interval, and the other along with the firſt ſtroke of *e*. The ſecond preſſing requires a much more violent preſſure than the firſt, becauſe the cake muſt be left perfectly dry and hard.

Fig. G. Profile of the frame of timber which carries the wallower, and greatly contributes to render its motion ſteady.

Fig. H. Is a view of one of the milſtones.

1. The nether milſtones, and the maſonry ſupporting the whole.

2. The runner.

3. A ſort of caſe which encloſes the two wings of the milſtone at a very ſmall diſtance from it, in order to prevent the grain which ſticks to it from being ſcattered. There is another method practiſed at ſome mills.

Fig. I. Repreſents that of Sardamm. AA are two iron rods, about half an inch ſquare, hanging on the axle, on each ſide of the milſtone. Theſe rods are joined by a croſs piece C, which almoſt touches the milſtone. A piece of leather is put between, which rubs upon the milſtone, and clears it of the grain which chances to ſtick to it. N° 4. and 6. repreſent the ears of this frame, by which the end of the iron axle is ſupported, and carried round by the upright ſhaft n° 5.

Fig. K. Plan of the runner milſtones, and the frame which carries them round.

1, 1. Are the two milſtones.

3, 3, 3, 3. The outſide pieces of the frame.

4, 4, 4, 4. The croſs bars of the frame which embrace the upright ſhaft 5, and give motion to the whole.

6, 6. The iron axis upon which the runners turn.

7. The outer rake.

8. The inner ditto.

Fig. L. Repreſents the nether milſtone ſeen from above.

1. The wooden gutter, which ſurrounds the nether milſtone.

2. The border or hoop, about ſix inches high, all round, to prevent any ſeed from being ſcattered.

3. An opening or trap door in the gutter, which can be opened or ſhut at pleaſure. When open, it allows the bruiſed grain, collected and ſhoved along the gutter by the rakes, to paſs through into troughs placed below to receive it.

4. Portion of the circle deſcribed by the outer runner.

5. Portion of the circle deſcribed by the inner one. By theſe we ſee that the two ſtones have different routes round the axis, and bruiſe more ſeed.

6. The outer rake.

7. The inner ditto.

8. The ſweep, making part of the inner rake, occaſionally let down for ſweeping off all the ſeed when it has been ſufficiently bruiſed. The preſſure and action of theſe rakes is adjuſted by means of wooden ſprings, which cannot be eaſily and diſtinctly repreſented by any figure. The oblique poſition of the rakes (the outer point going foremoſt) cauſes them to ſhove the grain inwards or toward the centre, and at the ſame time to turn it over, ſomewhat in the ſame manner as the mould-board of a plough ſhoves the earth to the right hand, and partly turns it over. Some mills have but one ſweeper; and, indeed, there is great variety in the form and conſtruction of this part of the machinery.

Fig. M. Profile of the peſtle frame.

1. Section of the horizontal ſhaft.

2. Three wipers for lifting the peſtles.

3. Little wheel of 28 teeth for giving motion to the ſpatula.

4. Another wheel, which is driven by it, having 20 teeth.

5. Horizontal axle of ditto.

6. Another wheel on the ſame axle, having 13 teeth.

7. A wheel upon the upper end of the ſpindle, having 12 teeth.

8. Two guides, in which the ſpindle turns freely, and ſo that it can be ſhifted higher and lower.

9. A lever, moveable round the piece n° 14, and having a hole in it at 9, through which the ſpindle paſſes, turning freely. The ſpindle has in this place a ſhoulder, which reſts on the border of the hole 9; ſo that by the motion of this lever the ſpindle may be diſengaged from the wheel work at pleaſure. This motion is given to it by means of the lever 10, 10, moveable round its middle. The workman employed at the chauffer pulls at the rope 10, 11, and thus diſengages the ſpindle and ſpatula.

11. A peſtle ſeen ſidewiſe.

12. The *lift* of ditto.

13. The upper rails, marked n° 3. in fig. C.

14. The rail, marked n° 5. in fig. C. To this are fixed the detents, which ſerve to ſtop and hold up the peſtles.

15. A detent, which is moved by the rope at its outer end.

16. A bracket behind the peſtles, having a pulley, through which paſſes the rope going to the detent 15.

17. The ſaid pulley.

18. The rope at the workman's hand, paſſing through the pulley 17, and fixed to the end of the detent 15.

This detent naturally hangs perpendicular by its own weight. When the workman wants to ſtop a peſtle, he pulls at the rope 18, during the riſe of the peſtle. When this is at its greateſt height, the detent is horizontal, and prevents the peſtle from falling by means of a pin projecting from the ſide of the peſtle, which reſts upon the detent, the detent itſelf being held in that poſition by hitching the loop of the rope upon a pin at the workman's hand.

19. The two lower rails, marked n° 10. fig. C.

20. *Great* wooden, and ſometimes ſtone, *block*, in which the mortars are formed, marked n° 21. in fig. C.

21. Veſſel placed below the preſs boxes for receiving the oil.

22. Chauffer, or little furnace, for warming the bruiſed grain.

23. Backet in the front of the chauffer, tapering downwards, and opening below in a narrow ſlit. The hair bags in which the grain is to be preſſed after it has been warmed in the chauffer, are filled by placing them in this backet. The grain is lifted out of the chauffer with a ladle, and put into theſe bags; and a good quantity of oil runs from it through the ſlit at the bottom into a veſſel ſet to receive it.

24. The ſpatula attached to the lower end of the ſpindle, and turning round among the grain in the chauffer-pan, and thus preventing it from ſticking to the bottom or ſides, and getting too much heat.

Fig. N. Plan of part of the works.

1, 1. Furnaces for warming the grain.

2, 2. The backets for holding the ſacks while they are a-filling.

3, 3. The pan in which the bruiſed grain is heated by the chauffer.

4, 4. A trough for receiving the chips, into which the preſſed oil-cakes are cut, to be afterwards put into the pan and warmed.

5. The preſs-box for the ſecond preſſing.

6. The preſs-box for the firſt preſſing.

7. The ſix mortars.

8. The ſloping boards, to hinder the ſcattering of the oil ſeed.

9. The nether milſtone, but out of its place.

10. Its centre a little higher than the reſt.

11. A rib of wood going round the edge of the nether milſtone, and even with its ſurface, but riſing a very little outwards, and ſurrounded with a border or hoop about an inch high, to prevent the ſeed from being ſcattered on the ground.

Fig. Q. A ſection, lengthwiſe, of the great block, with the mortars and preſs-boxes.

1. The ſix peſtles.

2. The ſix mortars, each of which has an iron plate at its bottom.

3. The *driving* ſtamper, which falls on the wedge of the firſt preſſing.

4. Ditto, for the ſecond ditto.

5. The *diſcharger*, which ſtrikes on the inverted wedge in order to free the preſs.

6. Ditto, for the ſecond preſſing.

7. Wedge for freeing the preſs.

8. Wedge for preſſing.

9. Wooden *cheeks*, two inches thick, which are placed between the middle wedge and the *ſliding wedges* on each ſide.

10. Preſs-irons, between which are placed the hair-bags containing the bruiſed grain.

11. Iron plate, called the *fountain*, at the bottom, pierced with holes, correſponding with a hole in the block, for allowing the oil to run off from the preſſed grain.

12. Veſſel for receiving ditto.

13. A long iron plate at the bottom of the preſs box, under the drawing and diſcharging wedges.

Fig. R. Another view of the preſs-irons.

1. The ſide-irons laid flat.

2. The ſame ſeen edgewiſe.

3. The pierced iron plate, upon which the two irons, n° 1. ſtand upright, with the hair-bag between them.

4. One of the hair-bags. It may be obſerved that the ſeams of theſe bags are made on the flat ſides, and not on the edges, where they would be in danger of burſting.

5. A long hair-cloth, in which the bag is wrapped before it is ſet into the preſs. The bag, being filled with bruiſed grain, is placed with its bottom at *a*, and the top at *b*; the part *c a* is lapped over it, reaching to *b*, and then the other end *d* is lapped over that, and reaches to *a*, and the loop at its end ſerves as a handle by which to lift it, and place it properly between the preſs-irons.

Fig. S. The principal pieces of the preſs.

1. The wooden cheeks.

2. The diſcharging wedge.

3. The driving wedge.

4 and 5. The ſliding blocks, which tranſmit the preſſure produced by the driving wedge.

The foregoing enumeration and views of the different parts of a Dutch oil-mill, are ſufficient, we imagine, to enable an intelligent mill-wright, to whom the machine is altogether new, to underſtand its manner of working, and its adaptation to the various parts of the proceſs for extracting the oil from ſeeds or kernels. It would require a very minute deſcription indeed to explain it to a perſon altogether unacquainted with mill-work.

The firſt part of the proceſs is bruiſing the ſeed under the runner ſtones (A). That this may be more expeditiouſly done, one of the runners is ſet about $\frac{2}{3}$ds of its own thickneſs nearer the ſhaft than the other. Thus they have different treads; and the grain, which is a little heaped towards the centre, is thus bruiſed by both. The inner rake gathers it up under the outer ſtone into a ridge, of which the ſection is repreſented in Plate XL. fig. O. The ſtone paſſes over it and flattens it. It is gathered up again into a ridge, of the form of fig. P. under the inner ſtone, by the outer rake, which conſiſts of two parts. The outer part preſſes cloſe on the wooden border which ſurrounds the nether ſtone, and ſhoves the ſeed obliquely inwards, while the inner part of this rake gathers up what had ſpread toward the centre. The other rake has a joint near the middle of its length, by which the outer half of it can be raiſed from the nether ſtone, while the inner half continues preſſing on it, and thus ſcrapes off the moiſt paſte. When the ſeed is ſufficiently bruiſed, the miller lets down the outer end of the rake. This immediately gathers the whole paſte, and ſhoves it obliquely outwards to the wooden rim, where it is at laſt brought to a part that is left unboarded, and it falls through into troughs placed to receive it. Theſe troughs have holes in the bottom, through which the oil drips all the time of the operation. This part of the oil is directed into a particular ciſtern, being conſidered as the pureſt of the whole, having been obtained, without preſſure, by the mere breaking of the hull of the ſeed.

In ſome mills this operation is expedited, and a much greater quantity of this beſt oil is obtained, by having the bed of maſonry which ſupports the legger formed into a little furnace, and gently heated. But the utmoſt care is neceſſary to prevent the heat from becoming conſiderable. This, enabling the oil to diſſolve more of the fermentable ſubſtance of the ſeed, expoſes the oil to the riſk of growing ſoon very rancid; and, in general, it is thought a hazardous practice, and the oil does not bring ſo high a price.

When the paſte comes from under the ſtones, it is put into the hair bags, and ſubjected to the firſt preſſing. The oil thus obtained is alſo eſteemed as of the firſt quality, ſcarcely inferior to the former, and is kept apart (The great oil ciſtern being divided into ſeveral portions by partitions).

The oil cakes of this preſſing are taken out of the bags, broken to pieces, and put into the mortars for the firſt *ſtamping*. Here the paſte is again broken down, and the parenchyma of the ſeed reduced to a fine meal. Thus free egreſs is allowed to the oil from every veſicle in which it was contained. But it is now rendered much more clammy, by the forcible mixture of the mucilage,

---

(A) We are told, that in a mill at Reichenhoffen in Alſace, a conſiderable improvement has been made by paſſing the ſeed between two ſmall iron rollers, before it is put under the milſtones. A great deal of work is ſaid to be ſaved by this preliminary operation, and finer oil produced, which we think very probable. The ſtamping and preſſing go on as in other mills.

cilage, and even of the finer parts of the meal. When ſufficiently pounded, the workman ſtops the peſtle of a mortar, when at the top of its lift, and carries the contents of the mortar to the firſt chauffer pan, where it is heated to about the temperature of melting bees wax (this, we are told, is the teſt), and all the while ſtirred about by the ſpatula. From thence it is again put into hair bags, in the manner already deſcribed; and the oil which drips from it during this operation is conſidered as the beſt of the ſecond quality, and in ſome mills is kept apart. The paſte is now ſubjected to the ſecond preſſing, and the oil is that of the ſecond quality.

All this operation of pounding and heating is performed by one workman, who has conſtant employment by taking the four mortars in ſucceſſion. The putting into the bags and conducting of the preſſing gives equal employment to another workman.

In the mills of Piccardy, Alſace, and moſt of Flanders, the operation ends here; and the produce from the chauffer is increaſed, by putting a ſpoonful or two of water into the pan among the paſte.

But the Dutch take more pains. They add no water to the paſte of this their *firſt ſtamping.* They ſay that this greatly lowers the quality of the oil. The cakes which reſult from this preſſing, and are there ſold as food for cattle, are ſtill fat and ſoftiſh. The Dutch break them down, and ſubject them to the peſtles for the *ſecond ſtamping.* Theſe reduce them to an impalpable paſte, ſtiff like clay. It is lifted out, and put into the *ſecond* chauffer pan; a few ſpoonfuls of water are added, and the whole kept for ſome time as hot as boiling water, and carefully ſtirred all the while. From thence it is lifted into the hare bags of the laſt preſs, ſubjected to the preſs; and a quantity of oil, of the loweſt quality, is obtained, ſufficient for giving a ſatisfactory profit to the miller. The cake is now perfectly dry, and hard, like a piece of board, and is ſold to the farmers. Nay, there are ſmall mills in Holland, which have no other employment than extracting the oil from the cakes which they purchaſe from the French and Brabanters; a clear indication of the ſuperiority of the Dutch practice.

The nicety with which that induſtrious people conduct all their buſineſs is remarkable in this manufacture.

In their oil ciſtern, the parenchymous part, which unavoidably gets through, in ſome degree, in every operation, gradually ſubſides, and the liquor, in any diviſion of the ciſtern, comes to conſiſt of ſtrata of different degrees of purity. The pumps which lift it out of each diviſion are in pairs; one takes it up from the very bottom, and the other only from half depth. The laſt only is barrelled up for the market, and the other goes into a deep and narrow ciſtern, where the dreg again ſubſides, and more pure oil of that quality is obtained. By ſuch careful and judicious practices, the Dutch not only ſupply themſelves with this important article, but annually ſend conſiderable quantities into the very provinces of France and Flanders where they bought the ſeed from which it was extracted. When we reflect on the high price of labour in Holland, on the want of timber for machinery, on the expence of building in that country, and on the enormous expence of wind mill machinery, both in the firſt erection and the ſubſequent wear and tear, it muſt be evident, that oil mills erected in England on water falls, and after the Dutch manner, cannot fail of being a great national advantage. The chatellanie or ſeigneurie of Lille alone makes annually between 30,000 and 40,000 barrels, each containing about 26 gallons.

What is here delivered is only a ſketch. Every perſon acquainted with machinery will underſtand the general movements and operations. But the intelligent mechanic well knows, that operations of this kind have many minute circumſtances which cannot be deſcribed, and which, nevertheleſs, may have a great influence on the whole. The rakes in the bruiſing-mill have an office to perform which reſembles that of the hand, directed by a careful eye and unceaſing attention. Words cannot communicate a clear notion of this; and a mill, conſtructed from the beſt drawings, by the moſt ſkilful workman, may gather the ſeed ſo ill, that the half of it ſhall not be bruiſed after many rounds of the machinery. This produces a ſcanty return of the fineſt oil; and the mill gets a bad character. The proprietor loſes his money, is diſcouraged, and gives up the work.—There is no ſecurity but by procuring a Dutch millwright, and paying him with the liberality of Britons. Such unhoped-for taſks have been performed of late years by machinery; and mechanical knowledge and *invention* is now ſo generally diffuſed, that it is highly probable that we ſhould ſoon excel our teachers in this branch. But this very diffuſion of knowledge, by encouraging ſpeculation among the artiſts, makes it a ſtill greater riſk to erect a Dutch oil-mill without having a Dutchman, acquainted with its moſt improved preſent form, to conduct the work. We do our duty in giving this counſel.

OKU-JESSO. See SEGALIEN in this *Suppl.*

OMPHALOPTER, or OMPHALOPTIC, in optics, a glaſs that is convex on both ſides, popularly called a *convex lens.*

ONISCUS (See *Encycl.*). Two new ſpecies of this genus of inſects were diſcovered by *La Martiniere*, the naturaliſt who accompanied Perouſe on his laſt voyage of diſcovery. For the information of ſuch of our readers as are entomologiſts, we ſhall give the author's deſcription of theſe ſpecies. Of the firſt, which he ſays only *nearly* anſwers to the *generic* character of oniſcus, E (fig. 1.) is a view of the upper part of its body, and at F of the lower. Its body is cruſtaceous, and of an opaque white, with two round ruſt-coloured ſpots on the anterior part of its corſlet; two others, much larger, in the form of a creſcent, are on the *elytræ;* its ſhield is alſo of the ſame colour. The under part of the thorax is furniſhed with four pair of legs: the firſt and third of which are terminated with ſharp claws; the ſecond, from its form, ſerves it to ſwim with; the fourth is very ſmall, conſiſting of two membranaceous threads. Some ſcales, alſo membranaceous and very channelled, may alſo perform the office of legs: of theſe the two lower are the largeſt. Its belly is filled with vermicular inteſtines of the ſize of a hair; its mouth is placed between the firſt and ſecond pair of legs, and is of the form of a ſmall trunk placed between two lips, joined only at the upper extremity.

Plat
XXX

Fig. 2. repreſents an inſect of the genus *oniſcus Linn.* Its body is nearly of the form, conſiſtence, and colour, of the *oniſcus aſellus*, except that it is not divided

vided by ſegments as this laſt is. It has a double tail, three times as long as the body; from the inſertion of which, at the hinder part of the body, ſpring two legs, uſed chiefly by the animal in ſwimming upon its back. The inſect, viewed on the lower part H, preſents ſix pair of legs; the two firſt of which terminate in very ſharp and thick points; it makes uſe of the third to ſwim with, and to balance its body, together with that pair which is inſerted at the baſe of the tail; the fourth pair, and the largeſt of all, is armed with two very ſharp points, which the animal forces into the body of any fiſh on which it ſeizes; the two laſt pair are nothing more than very finely divided membranes. Between the two firſt is ſituated its trunk, ſmooth, and about half a line long; at the baſe of the third pair are two points, of a horny conſiſtence, very hard, and firmly fixed. The two horns alſo below the large pair of legs are, in like manner, very firmly united to its body. Martiniere imagines it to be by means of theſe darts that it pierces the body of the fiſh on which it is found, and that then, changing its ſituation, it finds means to introduce its trunk into the holes thus formed. When put into a glaſs it ſinks to the bottom, and riſes again to the ſurface with the greateſt eaſe, advancing with the edge of its body, and deſcribing curves. Its two long tails are very eaſily pulled off, without the animal appearing to ſuffer any pain.

OPAQUE, not tranſlucent, nor tranſparent, or not admitting a free paſſage to the rays of light.

OPARO or OPARRO, the name given by Captain Vancouver to a ſmall iſland which he diſcovered in latitude 27° 36′ ſouth, and in longitude 215° 49′ eaſt from Greenwich. It was eſtimated at about 6½ miles in length, and no other land was in ſight. Its principal character is a cluſter of high craggy mountains, forming, in ſeveral places, moſt romantic pinnacles, with perpendicular cliffs nearly from their ſummits to the ſea: the vacancies between the mountains would more properly be termed chaſms than valleys. The tops of ſix of the higheſt hills bore the appearance of fortified places, reſembling redoubts; having a ſort of blockhouſe, in the ſhape of an Engliſh glaſs-houſe, in the centre of each, with rows of palliſadoes a conſiderable way down the ſides of the hills, nearly at equal diſtances. Theſe overhanging, ſeemed intended for advanced works, and apparently capable of defending the citadel by a few againſt a numerous hoſt of aſſailants. On all of them people were noticed as if on duty, conſtantly moving about. What we conſidered (ſays the author) as block-houſes, from their great ſimilarity in appearance to that ſort of building, were ſufficiently large to lodge a conſiderable number of perſons, and were the only habitations we ſaw. Yet, from the number of canoes that in ſo ſhort a time aſſembled round the Engliſh ſhip, it is natural to conclude, that the inhabitants are very frequently afloat; and to infer, that the ſhores, and not thoſe fortified hills which appeared to be in the centre of the iſland, would be preferred for their general reſidence.

Whether the fortified places here deſcribed were intended for defences of the iſlanders againſt each other, or againſt attacks from ſome more powerful neighbours, could only be conjectured; but the latter idea ſeems the moſt probable. From the language of the people, and their reſemblance to the Friendly iſlanders, Captain Vancouver conſiders them all as having ſprung from the ſame original ſtock. The people of Oparo, however, are diſtinguiſhed by two circumſtances, certainly in their favour. Not one of them was tattowed; and though they appeared not to have ever ſeen a European before, they all ſeemed perfectly well acquainted with the uſes to which they could apply iron, and preferred articles of it to looking glaſſes, beads, and other trinkets, with which ſavages are uſually delighted. Though there appeared to be anchoring ground near the north weſt end of the iſland, circumſtances rendered it inconvenient for Captain Vancouver to land on it; ſo that we are yet in a great meaſure ſtrangers to the diſpoſitions of the people, though they appeared to be hoſpitable.

OPEN FLANK, in fortification, is that part of the flank which is covered by the orillon or ſhoulder.

OPENING *of the Trenches*, is the firſt breaking of ground by the beſiegers, in order to carry on their approaches towards a place.

OPERA GLASS, is a diagonal perſpective, of which the following conciſe and perſpicuous deſcription is taken from Dr Hutton's Mathematical Dictionary.—ABCD (Plate XLI.) repreſents a tube about four inches long; in each ſide of which there is a hole EF and GH, exactly againſt the middle of a plane mirror IK, which reflects the rays falling upon it to the convex glaſs LM; through which they are refracted to the concave eye-glaſs NO, whence they emerge parallel to the eye at the hole rs, in the end of the tube. Let PaQ be an object to be viewed, from which proceed the rays Pc, ab, and Qd: theſe rays, being reflected by the plane mirror IK, will ſhew the object in the direction cp, ba, dq, in the image pq, equal to the object PQ, and as far behind the mirror as the object is before it: the mirror being placed ſo as to make an angle of 45 degrees with the ſides of the tube. And as, in viewing near objects, it is not neceſſary to magnify them, the focal diſtances of both the glaſſes may be nearly equal; or, if that of LM be three inches, and that of NO one inch, the diſtance between them will be but two inches, and the object will be magnified three times, being ſufficient for the purpoſes to which this glaſs is applied.

When the object is very near, as XY, it is viewed through a hole xy, at the other end of the tube AB, without an eye-glaſs; the upper part of the mirror being poliſhed for that purpoſe as well as the under. The tube unſcrews near the object-glaſs LM, for taking out and cleanſing the glaſſes and mirror. The poſition of the object will be erect through the concave eye-glaſs.

The peculiar artifice of this glaſs is to view a perſon at a ſmall diſtance, ſo that no one ſhall know who is obſerved; for the inſtrument points to a different object from that which is viewed; and as there is a hole on each ſide, it is impoſſible to know on which hand the object is ſituated which you are viewing. It is chiefly uſed in play-houſes; and hence its name: but we have ſeen it moſt indecently employed by thoſe who ſhould have ſet a better example, even in a cathedral church!

OPHRYS (See *Encycl.*). A new ſpecies of this plant has been lately deſcribed in the *Annual Hampſhire Repoſitory*, by a Fellow of the Linnean Society, in the following words:

“ *Stem*—about 12 inches high, erect, ſtipulate, geniculate, pubeſcent at the upper genicles. *Spike*—ſtrictly ſpiral, flowers ſpirally aſcending, about 24, brightly white. Upper petal ovato-acuminate, pubeſcent, lightly ciliate, ſtraight. Two middle *petals* oblong-recurved. Two lower *petals* oblong-acuminate, lightly ciliate only on the lower ſide near the baſe, projecting like elephant's tuſks. *Nectary*, broad, recurved, ragged, bicipitate. *Leaves floral*—carinate acuminate, ciliate reaching and pointing to the middle of the flowers. *Leaves radical*—five or ſix, about ſix inches long, narrow, attenuate both ways, acuminate, the lower more haſtate. *Leaves cauline*—lanceolate, alternate.

“ Obſervation.—This plant has much the habit, as well as autumnal floreſcence, of Oriental ſpiralis, and is ſo perfectly ſpiral alſo, that the ſpecific name of the other ſhould be altered, as being no longer excluſively ſpiral; at the ſame time that a ſpecific name ſhould be given to this: neither of which (ſays the author) I ſhall preſume to do, but ſhall ſuggeſt it to the Linnean Society, of which I have the honour to be a Fellow.”—This ophrys flowered, for the firſt time, it is believed, in England, in Hampſhire, October 1796.

OPHIUCUS, a conſtellation of the northern hemiſphere; called alſo *Serpentarius*.

OPIUM (See *Encycl.*), is a medicine of ſuch intrinſic value, and of ſo high a price, that every method which promiſes to increaſe the quantity in the market muſt be of importance. It was therefore, with much propriety, that *the Society for the Encouragement of Arts, &c.* ſome time ago, voted 50 guinueas to Mr John Ball of Williton, Somerſetſhire, for the diſcovery of his method of preparing opium from poppies of the growth of England. The poppies, which he recommends as the moſt productive, are the *double* or *ſemi-double*, of a dark colour; the ſeeds of which he adviſes to be ſown the latter end of February, and again about the ſecond week in March, in beds three feet and a half wide (well prepared with good rotten dung, and often turned or ploughed, in order to mix it well, and have it fine), either in ſmall drills, three in each bed, in the manner ſallads are ſown, and when about two inches high, to thin them one foot apart; or otherwiſe, to ſow them in beds, in the broad-caſt way, and thin them to the ſame diſtance. If they be kept free from weeds, they will grow well, and will produce from four to ten heads, ſhewing large and different coloured flowers; and when their leaves die away, and drop off, the pods then being in a green ſtate, is the proper time for extracting the opium, by making ſuch longitudinal inciſions as are, for this purpoſe, made in the eaſt (See OPIUM and PAPAVER, *Encycl.*). Immediately on the inciſion being made, a milky fluid will iſſue out; which is the opium, and which, being of a glutinous nature, will adhere to the bottom of the inciſion; but ſome poppies are ſo productive, that it will drop from the pod on the leaves underneath. The next day, if the weather ſhould be fine, and a good deal of ſunſhine, the opium will be found a greyiſh ſubſtance, and ſome almoſt turning black: it is then to be ſcraped from the pods, and (if any there) from the leaves, with the edge of a knife, or other inſtrument for that purpoſe, into pans or pots; and in a day or two it will be of a proper conſiſtence to make into a maſs, and to be potted.

According to Mr Ball, fields cannot be ſown with any thing more lucrative to the farmer than poppies, eſpecially if thoſe fields have a ſouth expoſure. “ By a calculation (ſays he) which I have made, ſuppoſing one poppy to grow in one ſquare foot of earth, and to produce only one grain of opium, more than L. 50 will be collected from one ſtatute acre of land; but if we conſider, that one poppy produces from three or four to ten heads, that in each head from ſix to ten inciſions may be made, and that from many of them (I mean from one inciſion) I have taken away two or three grains of opium—What muſt then be the produce?”

Mr Ball produced to the Society letters from Dr Latham of Bedford-row, Dr Pearſon of Leiceſter-ſquare, and Mr Wilſon of Bedford-ſtreet, declaring, that, in their opinion, his Engliſh opium is equal in effect, and ſuperior in purity, to the beſt foreign opium.

OPTIC INEQUALITY, in aſtronomy, is an apparent irregularity in the motions of far diſtant bodies; ſo called, becauſe it is not really in the moving bodies, but ariſing from the ſituation of the obſerver's eye. For if the eye were in the centre, it would always ſee the motions as they really are.

OPTIC *Pyramid*, in perſpective, is a pyramid formed by the viſible object which is the *baſe*, and the rays drawn from the perimeter of that object, which meet at the eye in a point, which is the *apex* of the pyramid. Hence, alſo, we may know what is meant by an *optic triangle*.

OPTIC *Rays*, particularly means thoſe by which an optic pyramid, or optic triangle, is terminated.

ORAN, a conſiderable city. occupied by the Spaniards, in the province of *Maſcara*, in the country of Algiers. It has ſtrong and regular fortifications, and can eaſily be ſupplied from Spain with proviſions and warlike ſtores. It lies in 35′ of longitude weſt from Greenwich, and in 35° 55′ north latitude. Since the year 1732, the Spaniards have held uninterrupted poſſeſſion of Oran. It has a pariſh-church, three monaſteries, an hoſpital: and the number of the inhabitants, according to the account given of it by the Spaniards, amount to 12,000. Towards the ſea, the city riſes in the form of an amphitheatre, and is ſurrounded with forts and batteries. Cloſe to the city lies a ſtrong caſtle, *Alcazava*, in which the Spaniſh governor reſides. On the higheſt hill ſtands Fort St Croix, whoſe guns command the city and the adjacent country. From this fort they make ſignals of the approach of ſhips, and carefully watch the motions of the Moors, who often attempt predatory incurſions into the neighbouring diſtricts. A conſiderable number of Mahomedans take refuge in Oran; they dwell in a diſtinct part of the city, receive pay from the court of Spain, and render ſignal ſervices againſt the Moors. The greateſt part of the inhabitants of Oran conſiſts of ſuch as have been baniſhed from Spain; and the ſame may, in a great meaſure, be ſaid of the ſoldiers who compoſe the garriſon. Five regiments are commonly ſtationed here; but, owing to continual deſertion, their ſtrength ſcarcely equals that of four complete regiments. One of them wholly conſiſts of malefactors, who have been condemned to remain here for life; the reſt are ſuch as have been tranſported for one or more years. There is here likewiſe a military ſchool. Around the city are pleaſant gardens; but it is very dangerous to cultivate them, on account of the Moors and Arabs, who frequently lie in ambuſh among them. The ſame reaſon prevents the cultivation of the fields in the vicinity; and the garrirange-Men.

ſon and inhabitants muſt be ſupplied with proviſions immediately from Spain.

ORANGE-MEN, an appellation aſſumed by certain ſocieties in Ireland, of which the firſt was formed in the county of Armagh, on the 21ſt of November 1795, others in ſome towns of Ulſter and Leinſter in the year 1797, another in the city of Dublin 1798; and ſince that period, theſe ſocieties have ſpread over the whole of our ſiſter kingdom. The object of theſe aſſociations is exhibited in the following authentic *Declaration of the Principles of Orange-men*, publiſhed 1799.

"From the various attempts that have been made to poiſon the public mind, and ſlander thoſe who have had the ſpirit to adhere to their king and conſtitution, and to maintain the laws:—

"We, the Proteſtants of Dublin, aſſuming the name of Orange-men, feel ourſelves called upon, not to vindicate our principles, for we know that our honour and loyalty bid defiance to the ſhafts of malevolence and diſaffection, but openly to avow thoſe principles, and declare to the world the objects of our inſtitution.

"We have long obſerved, with indignation, the efforts that have been made to foment rebellion in this kingdom, by the ſeditious, who have formed themſelves into ſocieties, under the ſpecious name of *United Iriſhmen*.

"We have ſeen with pain the lower orders of our fellow-ſubjects, forced or ſeduced from their allegiance, by the threats or machinations of *traitors*.

"And we have viewed with horror the ſucceſsful exertions of *miſcreants*, to encourage a foreign enemy to invade this happy land, in hopes of riſing into conſequence on the downfal of their country.

"We therefore thought it high time to rally round the conſtitution, and there pledge ourſelves to each other, to maintain the laws, and ſupport our good king againſt all his enemies, whether *rebels* to their God or to their country; and by ſo doing, ſhew to the world that there is a body of men in this iſland, who are ready, in the hour of danger, to ſtand forward in defence of that grand palladium of our liberties, the conſtitution of Great Britain and Ireland, obtained and eſtabliſhed by the courage and loyalty of our anceſtors under the Great King William.

"Fellow-ſubjects, we are accuſed with being an *inſtitution*, founded on principles too ſhocking to repeat, and bound together by oaths, at which human nature may ſhudder: but we caution you not to be led away by ſuch malevolent falſehoods; for we ſolemnly aſſure you, in the preſence of the Almighty God, that the idea of injuring any one, on account of his religious opinion, never entered into our *hearts:* we regard every loyal ſubject as our friend, be his religion what it may; we have no enmity but to the enemies of our country.

"We farther declare, that we are ready, at all times, to ſubmit ourſelves to the orders of thoſe in authority under his majeſty, and that we will cheerfully undertake any duty which they ſhall think proper to point out for us, in caſe either a foreign enemy ſhall dare to invade our coaſts, or that a domeſtic foe ſhall preſume to raiſe the ſtandard of rebellion in the land. To theſe principles we are pledged—and in ſupport of them we are ready to ſpend the laſt drop of our blood.—(Signed) Thomas Verner, *Grand Maſter;* John Clau. Beresford, *Grand Secretary;* William James, J. De Joncourt, Edward Ball."

Orchard.

ORCHARD. As an appendix to this article in the *Encycl.* ſome of our readers will be pleaſed with the following means, employed by the Rev. Mr *Germerſhauſen*, for promoting the growth of young trees, and increaſing the ſize and flavour of the fruit in orchards.

Having planted ſeveral young plum-trees in an orchard, he covered the ground, for ſome years, around the trunks, as far as the roots extended, with flax-ſhows (A); by which means theſe trees, though in a graſs-field, increaſed in a wonderful manner, and far excelled others planted in cultivated ground. As far as the ſhows reached, the graſs and weeds were choaked; and the ſoil under them was ſo tender and ſoft, that no better mould could have been wiſhed for by a floriſt.

When he obſerved this, he covered the ground with the ſame ſubſtance, as far as the roots extended, around an old plum-tree, which appeared to be in a languiſhing ſtate, and which ſtood in a graſs-field. The conſequences were, that it acquired a ſtrong new bark; produced larger and better-taſted fruit; and that thoſe young ſhoots, which before grew up around the ſtem, and which it was every year neceſſary to deſtroy, were prevented from ſprouting forth, as the covering of flax-ſhows impeded the free acceſs of air at the bottom of the trunk.

In the year 1793, he tranſplanted, from ſeed-beds, into the nurſery, ſeveral fruit-trees; the ground around ſome of which he covered, as above, with flax-ſhows. Notwithſtanding the great heat of the ſummer, none of thoſe trees where the earth was covered with ſhows died or decayed; becauſe the ſhows prevented the earth under them from being dried by the ſun. Of thoſe trees, around which the ground was not covered as before mentioned, the fourth part miſcarried; and thoſe that continued alive were far weaker than the former.

The leaves which fall from trees in autumn may alſo be employed for covering the ground in like manner; but ſtones, or logs of wood, muſt be laid on them, to prevent their being diſperſed by the wind. In graſs-land, a ſmall trench may be made around the roots of the tree, when planted, in order to receive the leaves. If flax ſhows are uſed, this is not neceſſary; they lie on the ſurface of the ground ſo faſt as to reſiſt the force of the moſt violent ſtorm. The leaves which our author found moſt effectual in promoting the growth and fertility of fruit trees, are thoſe of the walnut-tree. Whether it is, that, on account of their containing a greater abundance of ſaline particles, they communicate manure to the ground, which thereby becomes tender under them; or that they attract nitrous particles from the atmoſphere; or that, by both theſe means, they tend to nouriſh the tree both above and below.

Thoſe who are deſirous of raiſing tender exotic trees from the ſeed, in order to accuſtom them to our climate, may, when they tranſplant them, employ flax-ſhows

---

(A) Shows are the refuſe of flax when it is ſcutched or heckled.

with great advantage. This covering will prevent the froſt from making its way to the roots; and rats and mice, on account of the ſharp prickly points of the flax-ſhows, will not be able to ſhelter themſelves under them.

ORCHILLA, a weed uſed in dyeing, which grows in the Canary iſlands, and is monopolized by the government. "It is a minute vegetable (ſays Sir George Staunton), of the lichen kind, growing chiefly upon rocks of a looſe texture, and produces a beautiful violet blue colour."

ORDEAL. See this article in the *Encyclopædia*, at the end of which we have given, from Dr Henry's Hiſtory of England, ſome ſtrong reaſons for ſuſpecting that the ordeal, by fire at leaſt, was a groſs impoſition on the credulity of an ignorant and ſuperſtitious age. This ſuſpicion of impoſture is raiſed to certainty by Profeſſor Beckmann, who, in his Hiſtory of Inventions, gives us the whole proceſs by which the clergy conducted the trial, and brought proofs of innocence or of guilt at their pleaſure. The perſon accuſed was put entirely under their management for three days before the trial, and for as many after it. They covered his hands (when he was to lift red-hot iron) both before and after the proof; ſealed and unſealed the covering. The former was done, as they pretended, to prevent the hands from being prepared any how by art; the latter, that it might be accurately known whether or not they were burnt.

Some artificial preparation was therefore known, elſe no precautions would have been neceſſary. It is highly probable, that during the three firſt days the preventative was applied to thoſe perſons whom they wiſhed to appear innocent; and that the three days after the trial were requiſite to let the hands reſume their natural ſtate. The ſacred ſealing ſecured them from the examination of preſumptuous unbelievers; for to determine whether the hands were burnt, the three laſt days were certainly not wanted. When the ordeal was aboliſhed, and this art rendered uſeleſs, the clergy no longer kept it a ſecret. In the 13th century, an account of it was publiſhed by Albertus Magnus, a Dominican monk (A). If his receipt be genuine, it ſeems to have conſiſted rather in covering the hands with a kind of paſte than in hardening them. The ſap of the *althæa* (marſhmallow), the ſlimy ſeeds of the flea-bane, which is ſtill uſed for ſtiffening by the hat-makers and ſilk-weavers, together with the white of an egg, were employed to make the paſte adhere. And by theſe means the hands were as ſafe as if they had been ſecured by gloves.

Hutton's Dictionary.

ORFFYREUS's WHEEL, in mechanics, is a machine ſo called from its inventor, which he aſſerted to be a perpetual motion. This machine, according to the account given of it by Graveſande, in his *Oeuvres Philoſophiques*, publiſhed by Allemand, Amſt. 1774, conſiſted externally of a large circular wheel, or rather drum, 12 feet in diameter, and 14 inches deep; being very light, as it was formed of an aſſemblage of deals, having the intervals between them covered with waxed cloth, to conceal the interior parts of it. The two extremities of an iron axis, on which it turned, reſted on two ſupports. On giving a ſlight impulſe to the wheel, in either direction, its motion was gradually accelerated; ſo that, after two or three revolutions, it acquired ſo great a velocity as to make 25 or 26 turns in a minute. This rapid motion it actually preſerved during the ſpace of two months, in a chamber of the Landgrave of Heſſe, the door of which was kept locked, and ſealed with the Landgrave's own ſeal. At the end of that time it was ſtopped, to prevent the wear of the materials. The Profeſſor, who had been an eye witneſs to theſe circumſtances, examined all the external parts of it, and was convinced that there could not be any communication between it and any neighbouring room. Orffyreus, however, was ſo incenſed, or pretended to be ſo, that he broke the machine in pieces; and wrote on the wall, that it was the impertinent curioſity of Profeſſor Graveſande which made him take this ſtep. The Prince of Heſſe, who had ſeen the interior parts of this wheel, but ſworn to ſecrecy, being aſked by Graveſande, whether, after it had been in motion for ſome time, there was any change obſervable in it, and whether it contained any pieces that indicated fraud or deception? anſwered both queſtions in the negative, and declared, that the machine was of a very ſimple conſtruction.

ORICOU, a new ſpecies of the vulture, diſcovered by Vaillant at Orange river in South Africa. As he thinks it unqueſtionably the moſt beautiful of its genus, and tells, as uſual with him, a wonderful ſtory about it, we have given a figure of this vulture in Plate XLI. Our traveller ſays, that it is more than three feet high, and eight or nine in breadth of wing. Its feathers, the general hue of which is a light brown, are of a particular kind on the breaſt, belly, and ſides, where they are of unequal lengths, pointed, curved like the blade of a ſabre, and briſtle up diſtinct from each other. The feathers being thus ſeparated, would diſcloſe to view the ſkin on the breaſt, if it were not completely covered with a very thick and beautiful white down, which is eaſily ſeen between the ruffled plumage.

A celebrated naturaliſt has ſaid, that "no bird has eye-laſhes or eye-brows, or, at leaſt, hair round the eyes like that in quadrupeds." This aſſertion, advanced as a general law of Nature, is a miſtake. Not only the oricou has this peculiarity, but we know of many other ſpecies in which it exiſts; ſuch as, in general, all the calaos, the ſecretary, and ſeveral other birds of prey. Beſide theſe eye laſhes, the vulture in queſtion has ſtiff black hairs on its throat. All the head and part of the neck are bare of feathers; and the naked ſkin, which is of a reddiſh colour, is daſhed in certain places with blue, violet, and white. The ear, in its external circumference, is bounded by a prominent ſkin, which forms a

---

(A) In his work *De Mirabilibus Mundi*, at the end of his book *De Secretis Mulierum*, Amſtelod. 1702, 12mo, p. 100. Experimentum mirabile quod facit hominem ire in ignem ſine læſione, vel portare ignem vel ferrum ignitum ſine læſione in manu. Recipe ſuccum biſmalvæ, et albumen ovi, et ſemen pſylli et calcem, et pulveriza, et confice cum illo albumine ovi ſuccum raphani; commiſce; ex hac confectione illineas corpus tuum vel manum, et dimitte ſiccari, et poſtea iterum illineas, et poſt hoc poteris audacter ſuſtinere ignem ſine nocumento.

ſort of rounded conch, that muſt neceſſarily heighten the faculty of hearing in this ſpecies. This kind of conch is prolonged for ſome inches, and deſcends down the neck; which induced our author to give it the name of *oricou*.

Its ſtrength, he ſays, muſt be very conſiderable, if we may judge from its muſcles and ſinews; and he is perſuaded, that there is not a ſtronger among the whole order of carnivorous birds, not excepting the famous condor, which ſo many travellers have ſeen, but of which their deſcriptions are ſo different as to render its exiſtence extremely doubtful. But there was no occaſion for this reaſoning, and thoſe inferences, if what he relates as facts deſerve any credit. The oricou which he deſcribes, he firſt perceived perched on the carcaſe of a hippopotamos, eagerly devouring its fleſh. He ſhot at it, and wounded it ſlightly; upon which, "though it had already gorged itſelf with a conſiderable quantity of fleſh (for upon opening it, he found in its ſtomach no leſs a quantity than *ſix pounds and a half*), yet its hunger and voracity were ſuch, that it ſtruck its beak into the carcaſe when attempting to take wing, as if deſirous of carrying the whole of it away.

"On the other hand, the weight of the fleſh it had devoured rendering it the more heavy, it could not eaſily riſe; ſo that we had time (ſays he) to reach it before it was on the wing, and we endeavoured to knock it on the head with the but-ends of our muſkets. It defended itſelf a long time with great intrepidity. It bit or ſtruck at our weapons with its beak, and its ſtrength was ſtill ſo great, that every ſtroke made a mark on the *barrel of the piece*."

ORIENT, the eaſt, or the eaſtern point of the horizon.

ORIENT *Equinoctial*, is uſed for that point of the horizon where the ſun riſes when he is in the equinoctial, or when he enters the ſigns Aries and Libra.

ORIENT *Aeſtival*, is the point where the ſun riſes in the middle of ſummer, when the days are longeſt.

ORIENT *Hybernal*, is the point where the ſun riſes in the middle of winter, when the days are ſhorteſt.

OROTAVA, a town in the iſland of Teneriffe, at the bottom of thoſe mountains out of which the Peek riſes, neatly built of ſtone, on an irregular ſurface. The moſt remarkable object near it is a dragon's blood tree, of which the trunk meaſures, at the height of ten feet from the ground, 36 feet in girth. Concerning this tree there is a tradition current in the iſland, that it exiſted, of no inconſiderable dimenſions, when the Spaniards made the conqueſt of Teneriffe, about three centuries ago; and that it was then, what it ſtill is, a landmark, to diſtinguiſh the boundaries of landed poſſeſſions near it.

Diſtant about three miles on the ſea-coaſt is the puerto, or ſea-port, of Orotava, where is carried on a conſiderable degree of commerce, principally for the exportation of wine. It is chiefly, as at Madeira, in the hands of a few Britiſh commercial houſes, which import, in return, the manufactures of Great Britain. Within a mile is a collection of living plants from Mexico, and other parts of the Spaniſh dominions in America. From hence they are to be tranſplanted into Spain. It is an eſtabliſhment of ſome expence; and, whatever may be its ſucceſs, it ſhews a laudable attention, on the part of that government, to the promotion of natural knowledge.

OROTCHYS and BITCHYS, two tribes of Tartars, who were viſited by La Perouſe in 1787, and of whoſe manners he gives ſuch an account as renders it difficult to ſay whether they have the beſt claim to be called a ſavage or a civilized people. He fell in with a ſmall village of them on the eaſt coaſt of Tartary, in a bay to which he gave the name of *Baie de Caſtrie*, in Lat. 51° 29′ North, and Lon. 139° 39′ Eaſt from Paris.

Their village, their employment, their dreſs, and their apparent ignorance of all religion, beſpoke them ſavages. Their village was compoſed of four cabins, built in a ſolid manner, of the trunks of fir-trees, and covered with bark. A wooden bench compaſſed the apartment round about; and the hearth was placed in the middle, under an opening large enough to give vent to the ſmoke.

This village was built upon a tongue of low marſhy land, which appeared to be uninhabitable during the winter; but on the oppoſite ſide of the gulf, on a more elevated ſituation, and expoſed to the ſouth, there was, at the entrance of a wood, another village, conſiſting of eight cabins, much larger and better built than the firſt. Above this, and at a very ſmall diſtance, were three yourts, or ſubterraneous houſes, perfectly ſimilar to thoſe of the Kamtſchadales, deſcribed in the third volume of Captain Cook's laſt voyage; they were extenſive enough to contain the inhabitants of the eight cabins during the rigour of the cold ſeaſon; beſides, on ſome of the ſkirts of this village were ſeen ſeveral tombs, which were larger and better built than the houſes; each of them encloſed three, four, or five biers, of a neat workmanſhip, ornamented with Chineſe ſtuffs, ſome pieces of which were brocade. Bows, arrows, lines, and, in general, the moſt valuable articles of theſe people, were ſuſpended in the interior of theſe monuments, the wooden door of which was cloſed by a bar, ſupported at its extremities by two props.

Their ſole employment ſeemed to be the killing and curing of ſalmon, of which they eat raw, the ſnout, the gills, the ſmall bones, and ſometimes the entire ſkin, which they ſtript off with infinite dexterity. When the ſtript ſalmon were carried to the huts, the women, in the moſt diſguſting manner, devoured the mucilaginous part of them, and ſeemed to think it the moſt exquiſite food. Every cabin was ſurrounded with a drying place for ſalmon, which remain upon poles, expoſed to the heat of the ſun, after having been during three or four days ſmoked round the fire, which is in the middle of their cabin; the women, who are charged with this operation, take care, as ſoon as the ſmoke has penetrated them, to carry them into the open air, where they acquire the hardneſs of wood.

The bones of the ſalmon ſo cured were ſcattered, and the blood ſpread round the hearth; greedy dogs, though gentle and familiar enough, licked and devoured the remainder. The naſtineſs and ſtench of this people are diſguſting. There is not perhaps anywhere a race of people more feebly conſtituted, or whoſe features are more different from thoſe forms to which we attach the idea of beauty; their middle ſtature is below four feet ten inches, their bodies are lank, their voices thin and feeble, like that of children; they have high cheek bones, ſmall blear eyes, placed diagonally; a large mouth, flat noſe, ſhort chin, almoſt beardleſs, and an olive-coloured ſkin, varniſhed with oil and ſmoke. They ſuffer their hair to grow, and tie it up nearly the ſame as we do; that of the women falls looſe about their ſhoulders, and the portrait which has juſt been drawn agrees equally well with their countenances as thoſe of the men, from whom it would be difficult to diſtinguiſh them, were it not for a ſlight difference in the dreſs, and a bare neck; they are not, however, ſubjected to any labour, which might, like the American Indians, change the elegance of their features, if nature had furniſhed them with this advantage. Their whole cares are limited to the cutting and ſewing their clothes, diſpoſing of their fiſh to be dried, and taking care of their children, to whom they give the breaſt till they are three or four years of age.

With reſpect to dreſs, the men and little boys are clothed with a waiſtcoat of nankeen, or the ſkin of a dog or a fiſh, cut in the ſhape of a waggoner's frock. If it reach below the knee, they wear no drawers; if it do not, they wear ſome in the Chineſe ſtyle, which fall as low as the calf of the leg. All of them have boots of ſeal's ſkin, but they keep them for the winter; and they at all times, and of every age, even at the breaſt, wear a leather girdle, to which are attached a knife in a ſheath, a ſteel to ſtrike a light with, a pipe, and a ſmall bag to contain tobacco. The dreſs of the women is ſomewhat different; they are wrapped up in a large nankeen robe, or ſalmon's ſkin, which they have the art of perfectly tanning, and rendering extremely ſupple. This dreſs reaches as low as the ankle-bone, and is ſometimes bordered with a fringe of ſmall copper ornaments, which make a noiſe ſimilar to that of ſmall bells. Thoſe ſalmon, the ſkins of which ſerve for clothing, are never caught in ſummer, and weigh thirty or forty pounds.

Though they had neither prieſts nor temples, they ſeemed to be believers in ſorcery, and took the motion of the Frenchmens hands, when writing, for ſigus of magic. Thus far they appeared ſavages.

Their ſacred regard of property, their attention to their women, and the delicacy of their politeneſs to ſtrangers, would, on the other hand, do honour to the moſt civilized nation. While Perouſe and his people were in the bay, one of the families took its departure on a voyage of ſome length, and did not return during their ſtay. When he went away, the maſter of the family put ſome planks before the door of his houſe, to prevent the dogs from entering it, and in this ſtate left it full of their effects. "We were ſoon (ſays our author) ſo perfectly convinced of the inviolable fidelity of theſe people, and their almoſt religious reſpect for property, that we left our ſacks full of ſtuffs, beads, iron tools, and, in general, every thing we uſed as articles of barter, in the middle of their cabins, and under no other ſeal of ſecurity than their own probity, without a ſingle inſtance of their abuſing our extreme confidence; and on our departure from this bay, we firmly entertained the opinion, that they did not even ſuſpect the exiſtence of ſuch a crime as theft."

Their attention to their women, ſo uncommon among ſavages, was diſplayed in their exempting them from hard labour; in their never concluding a bargain with the Frenchmen without previouſly conſulting their wives; and in their reſerving the pendent ſilver ear-rings and copper trinkets, which they purchaſed, for their wives and daughters. Of the delicacy of their manners to ſtrangers, we ſhall give the following intereſting inſtance in the words of Perouſe's tranſlator:

Obſerving with what repugnance they received preſents, and how often they refuſed them with obſtinacy, "I imagined (ſays Perouſe) I could perceive, that they were perhaps deſirous of more delicacy in the manner of offering them; and to try if this ſuſpicion were well founded, I ſat down in one of their houſes, and after having drawn towards me two little children, of three or four years old, and made them ſome trifling careſſes, I gave them a piece of roſe-coloured nankeen, which I had brought in my pocket. The moſt lively ſatisfaction was viſibly teſtified in the countenances of the whole family, and I am certain they would have refuſed this preſent, had it been directly offered to themſelves. The huſband went out of his cabin, and ſoon afterwards returning with his moſt beautiful dog, he entreated me to accept of it. I refuſed it, at the ſame time endeavouring to make him underſtand, that it was more uſeful to him than to me; but he inſiſted; and perceiving that it was without ſucceſs, he cauſed the two children, who had received the nankeen, to approach, and placing their little hands on the back of the dog, he gave me to underſtand, that I ought not to refuſe his children.

"The delicacy of ſuch manners cannot exiſt but among a very poliſhed people. It ſeems to me, that the civilization of a nation, which has neither flocks nor huſbandry, cannot go beyond it. It is neceſſary to obſerve, that dogs are their moſt valuable property; they yoke them to ſmall and very light ſledges, extremely well made, and exactly ſimilar to thoſe of the Kamtſchadales. Theſe dogs, of the ſpecies of wolf dogs, and very ſtrong, though of a middle ſize, are extremely docile, and very gentle, and ſeem to have imbibed the character of their maſters."

ORTHODROMICS, in navigation, is great-circle ſailing, or the art of ſailing in the arch of a great circle, which is the ſhorteſt courſe: For the arch of a great circle is *orthodromia*, or the ſhorteſt diſtance between two points or places.

ORYCTEROPUS, the name given by M. Geoffroy, profeſſor of zoology in the French muſeum of natural hiſtory, to the animal called by other zoologiſts *Myrmecophaga Capenſis*. (See MYRMECOPHAGA, *Encycl.*) He conſiders it as a diſtinct genus, and ſeems indeed to have proved, by a compariſon of the organs of the orycteropus with thoſe of the *tatous daſipus* of Linnæus, and of the *myrmecophagi*, that this genus is intermediate, by its forms and habits, between thoſe two families. It approaches to the *tatous* in its organs of maſtication, and the form of the toes and nails, and in having a ſhort and ſingle cæcum, whilſt that of the myrmecophagi is double, as in birds, by the reuniting of the bones of the os pubis, which are not articulated together in the myrmecophagi. The orycteropus, however, bears a relation to the laſt, ſince it has, like them, a very ſmall mouth, whence its tongue, covered with hair, may be protruded to a conſiderable length. Finally, the habits of the orycteropus reſemble thoſe of the animals to which it approaches the moſt; it does not climb trees, but lives under the earth like the tatous;

ctero pus ‖ delim.

tous; it feeds like them on roots, but alſo it hunts after anthills, like the myrmecophagi. Its ſnout terminates in a blunt callous; a character which is peculiar to it. It may be diſtinguiſhed in the works of naturaliſts by the following deſcription:

Oryćteropus. Molar teeth (ſix) with flat vertices; the body covered with hair.

The orycteropus, as appears from the preceding, connects the tatous with the myrmecophagi and with the *pangolin manis* of Linnæus. The large foſſile ſpecies found in Paraguay, for which Citizen Cuvier has eſtabliſhed a new genus, under the name of *megaterium*, is intermediate between the ſloth and the myrmecophagus; and, laſtly, the aſtoniſhing animal of New Holland, covered with briſtles like the porcupine, ſupported by very ſhort legs, and of very ſingular conformation, and with a head round at the occiput, terminating in a ſnout, without teeth, very ſlender, long, and cylindrical, and deſcribed by Mr George Shaw under the name of myrmecophaga aculeata, appears to have very ſtriking relations to the pangolin and the orycteropus: from hence it follows, that in conſequence of theſe important acquiſitions, we ought for the future to count, in the number of our natural orders, that of the *edentated*, or *edented*, conſiſting of the following genera: *Daſipus*, *orycteropus myrmecophaga*, and *aculeata*, *manis*, *myrmecophaga*, *megaterium* et *bradypus*.

OSCILLATION, in mechanics, vibration, or the reciprocal aſcent and deſcent of a pendulum.

Axis of Oscillation, is a line parallel to the horizon, ſuppoſed to paſs through the centre or fixed point about which the pendulum oſcillates, and perpendicular to the plane in which the oſcillation is made.

Centre of Oscillation, in a ſuſpended body, is a certain point in it, ſuch that the oſcillations of the body will be made in the ſame time as if that point alone were ſuſpended at that diſtance from the point of ſuſpenſion. Or it is the point into which, if the whole weight of the body be collected, the ſeveral oſcillations will be performed in the ſame time as before: the oſcillations being made only by the force of gravity of the oſcillating body.

OSCULATION, in geometry, denotes the contact between any curve and its oſculatory circle; that is, the circle of the ſame curvature with the given curve, at the point of contact or of oſculation. See Involution in this *Suppl.*

Osculation alſo means the point of concourſe of two branches of a curve which touch each other. For example, if the equation of a curve be $y = \sqrt{x} + \sqrt[4]{x^3}$, it is eaſy to ſee that the curve has two branches touching one another at the point where $x = 0$, becauſe the roots have each the ſigns + and —.

OUADELIM and Labdesseba, two tribes of Arabs inhabiting the *Sahara* or Great Deſart of Africa, of whom almoſt nothing was known to Europeans till the publication of Briſſon's narrative of his ſhipwreck and captivity among the latter tribe. He deſcribes the Ouadelim and Labdeſſeba as the moſt formidable of all the interior tribes of Arabs, and as often extending their ravages to the very gates of Morocco. "Their hordes (he ſays) are frequently intermingled with thoſe of the Rouſege, Rathidium, Chelus, Tucanois, and Ouadeli tribes, as they have no diſtinct boundaries, and change their habitations as the deſart affords paſturage and water. They are tall, handſome, ſtout, and vigorous men. Their hair is briſtled, and their nails, which they often uſe in battle, as long as claws; large hanging ears and a long beard give them a ſtern ferocious air. The Ouadelim in particular are fierce, arrogant, and warlike, but ſoon diſpirited by obſtinate reſiſtance, eſpecially when they have not a decided ſuperiority in numbers. In their hordes they lodge by families, in tents which are covered with a thick cloth of camels hair, which the women ſpin and weave upon a loom ſo ſmall, that they work ſitting on the ground. The furniture of their tents conſiſt of two large ſacks of leather, in which they keep old clothes and pieces of old iron, three or four goat ſkins for holding milk and water, two large ſtones for grinding their barley, a ſmaller one for driving the pins of their tents, an ozier matting which ſerves for a bed, a thick carpet for a covering, a ſmall kettle, and ſome wooden diſhes, with pack-ſaddles for their camels. The perſon who, beſides theſe articles, poſſeſſes a few horſes, camels, ſheep, and goats, is reckoned wealthy, as there are many Arabs who only poſſeſs ſheep and goats. Except ſore eyes and the cholic, they are ſubject to few endemic diſeaſes. The firſt diſorder is cauſed by the reflection of light from the burning ſands of the deſart, the other proceeds from the verdigreaſe which contaminates all their victuals. Their kettles are not tinned, and never waſhed, ſo that they are quite cruſted over with verdigreaſe, the virulence of which is probably diminiſhed by the quantity of milk they uſe. When they reſide long in one place, they ſometimes plough the ſpots which are moiſtened by the rain, and ſprinkle them with ſeed in a careleſs manner. Plentiful crops are often thus produced; but inſtead of waiting till the grain attains maturity, they cut it down, and dry it over hot cinders. Treachery and perfidy are the innate vices of the Arabs; aſſaſſinations are frequent; no man truſts the promiſe of another; no man makes a written agreement, as the poignard cancels all bonds and obligations. The men often relate their exploits to each other; the embelliſhing of a ſtory is ſucceeded by a charge of falſehood, and the poignard ſolves every difficulty. The ancient rites of hoſpitality, however, are practiſed among theſe tribes in their utmoſt extent. The Arab, who in the field is a rapacious plunderer, becomes liberal and generous as ſoon as he enters his tent. War is only a ſpecies of rapine, and the victory is decided at the firſt ſhock. The Arab is devoid of ſanguinary courage; he attacks only to plunder, and never thinks that booty is to be put in competition with his life. When the battle is ended, each party makes graves for the ſlain, and encloſe the tombs with mounds of ſtones. The ages of the warriors are denoted by the ſpace of ground which the grave occupies, and the funeral proceſſion is cloſed by the howls of the females.

Ouadelim.

"The women never aſſume the name of their huſbands, and never eat with them at meals. They are faithful to their huſbands, and cannot be divorced except by the decree of the ſeniors of the horde. The Arabs diſplay their opulence by the ornaments of their women, whoſe ears, arms, and legs, are generally adorned with rings of gold and ſilver. An Arab beauty muſt have long teeth ſhooting out of her mouth, a body extremely thick, and limbs of the longeſt ſize. At the birth of a ſon, every woman, to teſtify her joy, blackens

Ouadelim.

ens her face for 40 days. At the birth of a daughter, ſhe only daubs the half of her face during the ſpace of 20 days. A mother treats her ſon with the ſame reſpect as her huſband, almoſt as ſoon as he is able to walk; ſhe prepares his food, ſerves him, and eats when he has finiſhed his repaſt. In the education of their young men, the moſt important acquiſitions are, dexterity in the uſe of the poignard, ſkill in embowelling their enemies with their long nails, and a plauſible air in uttering a falſehood. More rude and ferocious than the tribes whoſe territories lie upon the ſhore of the ſea, the Labdeſſeba and Ouadelim Arabs are alſo more confined and illiberal in their ideas, not only believing that they are the firſt nation in the world, but fancying that the ſun riſes only for them. Briſſon relates, that ſome of them expreſſed this idea in unequivocal terms. 'Behold (ſaid they) that luminary, which is unknown in thy country. During the night, thou art not enlightened, as we are, by that heavenly body, which regulates our days and our faſts. His children (the ſtars) point out to us the hours of prayer. You have neither trees nor camels, ſheep, goats, nor dogs. Are your women ſimilar to ours?' 'How long didſt thou remain in the womb of thy mother (ſaid another)?' 'As long (replied Briſſon) as thou in that of thine.' 'Indeed (ſaid a third, counting the fingers and toes of the Frenchman) he is made like us; he differs only in his colour and language.' 'Do you ſow barley in your houſes?' ſaid the Arabs, alluding to the ſhips of the Europeans. 'No (ſaid Briſſon), we ſow our fields almoſt in the ſame ſeaſon as you.' 'How! (cried ſeveral) do you inhabit the earth? we believed that you were born and lived upon the ſea.' Theſe Arabs, according to the Turkiſh proverb, believe that all the world is like their father's houſe: unacquainted with the manners of other nations, and unaccuſtomed to reflect upon the cauſes of national character, every variation from their own cuſtoms appears not only ridiculous, but monſtrous; every difference of opinion not only abſurd, but criminal. This ignorance of the Arabs, conjoined with their local and religious prejudices, enables us to account for the inſulting treatment which Briſſon and his companions received, without having recourſe to inherent depravity of nature." That treatment was indeed ſhocking.

Briſſon had ſurrendered himſelf, on his ſhipwreck, to Sidi Mahomet, a *Talbe* or prieſt of the tribe of Labdeſſeba. During the abſence of the prieſt, the Labdeſſeba, who guarded the captives, were attacked and maltreated by a party of the Ouadelims, and during the battle which enſued, Briſſon had almoſt loſt his life. Inſtead of compaſſionating his forlorn ſituation, the women threw ſand into his eyes, as they ſaid, to dry his eye-lids. The Arabs, into whoſe hands he had fallen, had only come down to the ſea-coaſt to gather wild grain, three days before the ſhipwreck; and to preſerve their booty, they immediately retreated to the interior part of the deſart. A guide preceded the horde, to place at intervals ſmall pyramids of ſtone, to direct their courſe, at a diſtance from every hoſtile tribe. After paſſing ſome very high mountains, wholly covered with ſmall greyiſh pebbles as ſharp as flints, they deſcended into a ſandy plain overſpread with thorns and thiſtles. When Briſſon was unable to walk, on account of the bleeding of his feet, he was mounted on a camel; the briſtly hair and hard trot of which ſoon excoriated him ſo much, that the blood run copiouſly down its flanks. By throwing heated ſtones into a wooden veſſel, filled with barley meal, diluted with water procured on the ſea-ſhore, preſerved in a goat's ſkin, and mixed with pitch to prevent putrefaction, the Arabs prepared a kind of ſoup, which they kneaded with their hands, and ate unchewed. They roaſted a goat in heated ſand, ate its fat raw, and, after having devoured the fleſh, gnawed the bones, and ſcraped them with their nails, threw them to Briſſon and his companions, deſiring them to eat quickly, and load the camels, that the journey might not be impeded. Proceeding eaſtward, they croſſed a vaſt plain, covered with ſmall ſtones white as ſnow, round and flat as a lentil, where not a ſingle plant was produced. The earth beneath their feet reſounded dull and hollow, and the ſmall ſtones pricked them like ſparks of fire. The reflection of the rays of the ſun from the ſand was ſcorching; the atmoſphere was loaded with a red vapour, and the country appeared as if filled with flaming volcanoes. Neither birds nor inſects could be ſeen in the air. The profound ſilence was frightful. If a gentle breeze ever aroſe, it produced extreme languor, chopping of the lips, burning heat of the ſkin, with ſmall ſmarting pimples. This plain was even ſhunned by wild beaſts. After traverſing this plain, they entered another, where the wind had thrown up in furrows the ſand, which was of a reddiſh colour. On the tops of the furrows grew a few ſweet-ſcented plants, which were devoured by the camels. On quitting this ſandy plain, they entered a valley ſurrounded by mountains, where the ſoil was white and ſlimy, and where they found water of a noxious ſmell, covered with green moſs, and ſoon after diſcovered a horde of the friendly tribe Rouſſye.

After another journey of ſixteen days, they arrived at the tents of the Labdeſſeba horde, to which Sidi Mahomet belonged. The tents pitched among thick buſhy trees, and the numerous flocks feeding along the ſides of the hills, preſented at a diſtance an aſpect of happineſs and paſtoral ſimplicity. On approaching near, the trees of beautiful green foliage proved to be only old gummy ſtumps, almoſt void of branches, ſo encircled with thorns that their ſhade was inacceſſible. The women approached, with loud cries and the moſt fawning ſervility, to welcome their tyrants, to throw ſtones at the Chriſtians, and ſpit in their faces, while the children imitated the example of their mothers. Briſſon, who endeavoured to ingratiate himſelf with his maſter's favourite, not only failed in this, but incurred her implacable reſentment, through his irritability, which to the Arab women ſeemed extremely to reſemble petulance. During his reſidence with Sidi Mahomet, the hardſhips he endured were almoſt incredible. With the exceſſive heat, the milk of the ſheep, goats, and camels, diminiſhed, and then the dogs fared better than the Chriſtians, who were forced to ſubſiſt on wild herbs and raw ſnails. When the rains fell, and the leaſt preſſure made the water to ſpring up through the ſandy ſoil, the Chriſtians ſlept behind a buſh, unſheltered, on the bare ground. Briſſon and his maſter ſometimes reaſoned about religion; when the latter always anſwered the harangues of the former by declaring, that he preferred a bowl of churned milk to ſuch abſurdities. Several of his companions periſhed, and were left by the Arabs to be devoured by the ravens, while in the ſtruggles of death. One of them was ſuppoſed to be murdered by his maſter for milking his camels clandeſtinely. An application made by Briſſon to the conſul at Mogador, by a letter entruſted to a Jewiſh merchant, was fruſtrated through the negligence of the vice-conſul; and the Labdeſſeba Arabs thought the journey too dangerous to be encountered for the ranſom of their ſlaves. He was, however, at laſt relieved, through the humanity of his maſter's brother-in-law, who carried him to Morocco, where his ranſom was paid by the Emperor, and whence he returned to France. For a fuller account of theſe two ſavage tribes, ſee *Saugnier's and Briſſon's Narratives*; or a very pleaſing *Hiſtorical and Philoſophical Sketch of the Diſcoveries, &c. of the Europeans in Northern and Weſtern Africa*, publiſhed 1799 by *Symington* Edinburgh, and *Vernor* and *Hood* London.

OXYGLYCUS CERASUS, the name given by the editor of Dalzel's Hiſtory of Dahomy to a very ſingular fruit produced in that country, as well as in ſome other parts of Africa. It reſembles a ſmall olive in every reſpect but the colour; being of a duſky reddiſh hue, changing at the end next the ſtalk to a faint yellow. The pulp is firm, and almoſt inſipid; the ſtone is hard like that of the olive. After having chewed one or more of ſuch berries, and ſpit out or ſwallowed the pulp at pleaſure, a glaſs of vinegar will taſte, to the perſon trying the experiment, like ſweet wine; a lime will ſeem to have the flavour of a very ripe China orange; and the ſame change is produced on other acids, the ordinary effects of which upon the palate is deſtroyed in a very unaccountable manner, without effervеſcence or any ſenſible motion. Indeed, the effect is very different from neutralization, ariſing from the mixture of acid and alkali; ſuch combination producing a neutral ſaline liquor, whilſt this miraculous berry ſeems to convert acids to ſweets. Food or drink, not containing any acid, ſuffer no change by the previous uſe of this fruit; its effect upon acids continues, even after a meal, though in a much ſmaller degree. The natives uſe it to render palatable a kind of gruel called *guddoe*, which is made of bread after it becomes too ſtale for any other purpoſe. They deſcribe it as the fruit of a large tree.

Plants ſix or ſeven inches high were raiſed from this fruit by Mr Dalzel, who tried to carry them from Angola to the botanic garden at St Vincent's; but they died on the paſſage. He preſerved the berries in ſpirits, in ſyrup, and in a dry form; but they loſt their ſingular quality in all thoſe preparations. The plant is an evergreen, and the leaves in this infant ſtate are like thoſe of the olive.

OXY-MURIATIC ACID (See CHEMISTRY-*Index* in this *Suppl.*), is the principal agent in the new proceſs of bleaching (ſee BLEACHING, *Suppl.*); but, till very lately, at leaſt, if not even at preſent, the bleachers were in the practice of adding ſome alkali to the acid, notwithſtanding the ſtrong objections which M. Bertholet made to that addition, and notwithſtanding the proofs urged by Mr Rupp, that it increaſes the expence of bleaching about 40 *per cent.* The chief reaſon for perſiſting in a practice to which ſuch objections were urged was, that the addition of the alkali deprives the liquor of its ſuffocating effects without deſtroying its bleaching powers. Mr Rupp, however, has contrived the following apparatus, in which may be ſafely uſed the pure oxy muriatic acid ſimply diſſolved in water, which is at once its cheapeſt and beſt vehicle.

Figure 1. (Plate XLI.) is a ſection of the apparatus. It conſiſts of an oblong deal ciſtern ABCD, made water-tight. A rib EE of aſh or beech wood is firmly fixed to the middle of the bottom CD, being mortiſed into the ends of the ciſtern. This rib is provided with holes at FF, in which two perpendicular axes are to turn. The lid AB has a rim GG, which ſinks and fits into the ciſtern. Two tubes HH are fixed into the lid, their centres being perpendicularly over the centres of the ſockets FF when the lid is upon the ciſtern. At I, is a tube by which the liquor is introduced into the apparatus. As it is neceſſary that the ſpace within the rim GG be air tight, its joints to the lid, and the joints of the tubes, muſt be very cloſe; and, if neceſſary, ſecured with pitch. Two perpendicular axes KL, made of aſh or beech wood, paſs thro' the tubes HH, and reſt in the ſockets FF. A piece of ſtrong canvas M is ſewed very tight round the axis K, one end of it projecting from the axis. The other axis is provided with a ſimilar piece of canvas. N are pieces of cloth rolled upon the axis L. Two plain pulleys OO are fixed to the axes, in order to prevent the cloth from ſlipping down. The ſhafts are turned by a moveable handle P. Q is a moveable pulley, round which paſſes the cord R. This cord, which is faſtened on the oppoſite ſide of the lid (ſee fig. 2.), and paſſes over the ſmall pulley S, produces friction by means of the weight T. By the ſpigot and fauſſet V, the liquor is let off when exhauſted.

The dimenſions of this apparatus are calculated for the purpoſe of bleaching twelve or fifteen pieces of $\frac{4}{3}$ calicoes, or any other ſtuffs of equal breadth and ſubſtance. When the goods are ready for bleaching, the axis L is placed on a frame in an horizontal poſition, and one of the pieces N being faſtened to the canvas M by means of wooden ſkewers, in the manner repreſented in fig. 1. it is rolled upon the axis by turning it with the handle P. This operation muſt be performed by two perſons; the one turning the axis and the other directing the piece, which muſt be rolled on very tight and very even. When the firſt piece is on the axis, the next piece is faſtened to the end of it by ſkewers, and wound on in the ſame manner as the firſt. The ſame method is purſued till all the pieces are wound upon the axis. The end of the laſt piece is then faſtened to the canvas of the axis K. Both axes are afterwards placed into the ciſtern, with their ends in the ſockets FF, and the lid is put on the ciſtern by paſſing the axes through the tubes HH. The handle P is put upon the empty axis, and the pulley Q upon the axis on which the cloth is rolled, and the cord R, with the weight T, is put round it and over the pulley S. The uſe of the friction, produced by this weight, is to make the cloth wind tight upon the other axis. But as the effect of the weight will increaſe as one cylinder increaſes and the other leſſens, Mr Rupp recommends that three or four weights be ſuſpended on the cord, which may be taken off gradually as the perſon who works the machine may find it convenient. As the weights hang in open hooks, which are faſtened to the

Oxy-Muriatic Acid.

the cord, it will be little or no trouble to put them on and to remove them.

Things being thus diſpoſed, the bleaching liquor is to be transferred from the veſſels in which it has been prepared into the apparatus, by a moveable tube paſſing through the tube I, and deſcending to the bottom of the ciſtern. This tube being connected with the veſſels, by means of leaden or wooden pipes provided with cocks, hardly any vapours will eſcape in the transfer. When the apparatus is filled up to the line *a*, the moveable tube is to be withdrawn, and the tube I cloſed. As the liquor riſes above the edge of the rim G, and above the tubes HH, it is evident that no evaporation can take place, except where the rim does not apply cloſely to the ſides of the box; which will, however, form a very trifling ſurface if the carpenter's work be decently done. The cloth is now to be wound from the axis L upon the axis K, by turning this; and when this is accompliſhed, the handle P and pulley Q are to be changed, and the cloth is to be wound back upon the axis L. This operation is, of courſe, to be repeated as often as neceſſary It is plain, that by this proceſs of winding the cloth from one axis upon the other, every part of it is expoſed, in the moſt complete manner, to the action of the liquor in which it is immerſed. It will be neceſſary to turn, at firſt, very briſkly, not only becauſe the liquor is then the ſtrongeſt, but alſo becauſe it requires a number of revolutions, when the axis is bare, to move a certain length of cloth in a given time, though this may be performed by a ſingle revolution when the axis is filled. Experience muſt teach how long the goods are to be worked; nor can any rule be given reſpecting the quantity and ſtrength of the liquor, in order to bleach a certain number of pieces. An intelligent workman will ſoon attain a ſufficient knowledge of theſe points. It is hardly neceſſary to obſerve, that, if the liquor ſhould retain any ſtrength after a ſet of pieces are bleached with it, it may again be employed for another ſet.

With a few alterations, this apparatus might be made applicable to the bleaching of yarn. If, for inſtance, the pulley O were removed from the end of the axis K, and fixed immediately under the tube H;—if it were perforated in all directions, and tapes or ſtrings paſſed through the holes, ſkains of yarn might be tied to theſe tapes underneath the pulley, ſo as to hang down towards the bottom of the box. The apparatus being afterwards filled with bleaching liquor, and the axis turned, the motion would cauſe every thread to be acted upon by the liquor. Several axes might thus be turned in the ſame box, and being connected with each other by pulleys, they might all be worked by one perſon at the ſame time; and as all would turn the ſame way and with the ſame ſpeed, the ſkains could not poſſibly entangle each other.

P.

Painting.

ENCAUSTIC PAINTING is an art of very high antiquity, which, after being loſt for many ages, was reſtored, as is commonly believed, by the celebrated Count Caylus, whoſe method was greatly improved, firſt by Mr Joſiah Colebrooke, and afterwards by Miſs Greenland, who brought the rudiments of her knowledge from Italy (See ENCAUSTIC, *Encycl.*). In that country encauſtic painting had employed the attention of various artiſts and men of learning, ſuch as Requeno, Lorgna, and Aſtori, &c.; but the beſt account of it that has fallen under our notice, is in that valuable miſcellany called the *Philoſophical Magazine*, taken from a work of Giov. Fabbroni, publiſhed at Rome in the year 1797.

According to this author, "the knowledge and uſe of encauſtic painting is certainly older than the time of the Greeks and the Romans, to whom the learned Requeno ſeems to aſſign the excluſive poſſeſſion of this art; becauſe the Egyptians, who, with the Etruſcans, were the parents of the greater part of the inventions known among mankind, and from whom the Greeks learned ſo much, were acquainted with and employed encauſtic painting in the ancient ages of their greatneſs and ſplendour, as is proved by the valuable fragments of the bandages and coverings of ſome mummies which he had examined. No oil-painting (he ſays), of only two or three hundred years old, exhibits a white paint which has kept ſo well as that ſeen on theſe fragments; and this circumſtance ſufficiently proves the ſuperiority of the encauſtic method over the common oil-painting, which, notwithſtanding the general opinion, cannot, he thinks, have been unknown to the ancients.

"It is impoſſible (ſays he) that in Egypt and Phœnicia, where ſo much uſe was made of flax, the oil procured in abundance from that plant ſhould have been unknown. Thoſe who have kept oil, or who have ſpilt any of it, whether nut or lintſeed oil, muſt have remarked that it poſſeſſes the property of ſoon drying by the effects of the atmoſphere; and therefore it may be eaſily believed that mankind muſt ſoon have conceived the idea of employing it, particularly for ſhips, which, as Herodotus ſays, were painted with red ochre in the earlieſt periods, and adorned with figures and ornaments. The uſe of oil afforded painting a much ſimpler and eaſier method than that of wax; it muſt therefore have been firſt adopted, and the tranſition from oil to wax muſt be conſidered as a ſtep towards bringing the art to perfection; becauſe encauſtic painting is not expoſed to the irremediable inconveniences that ariſe in oil-painting, the value of which we extolled through ignorance, and praiſed as a new invention.

"Oil in general, and in particular drying oil which the painters uſe, has naturally a ſtrong inclination to combine itſelf with the vital air or oxygen of the atmoſphere, and by imbibing oxygen it becomes dry, and aſſumes the character of reſin; but the colour then becomes darker, as is the caſe with tranſparent turpentine, which gradually becomes a black pitch.

"Accord-

“ According to the new and more accurate method of decompoſing bodies, oil conſiſts principally of hydrogen and carbon. By coming into contact with the atmoſphere, and abſorbing its oxygen and light, it undergoes a ſlow and imperceptible combuſtion, which is not eſſentially different from the ſpeedy and violent one which it would undergo in the common mode of burning. It firſt paſſes, by imbibing oxygen, into the ſtate of a more or leſs dark reſin ; loſes gradually its eſſential hydrogen, which makes a new combination, and afterwards the oxygen itſelf which has attracted the carbon ; and at length leaves behind a thin layer of actual carbon, which in the end becomes black in the courſe of time, and conſiderably obſcures the oil painting. By a continuance of the before-mentioned ſlow combuſtion, the carbon itſelf, as it were, burns alſo : if it be ſtrongly acted upon by the light, it attracts the oxygen of the atmoſphere, and again brings forward the carbonic acid or fixed air, which gradually flies off. By this, which I may call the ſecond degree of combuſtion, the painting muſt become duſty and friable, like crayon *painting*.

“ Hence it appears (ſays our author) that one can hope only for a tranſient or deceitful effect from the refreſhing of oil-paintings with oil; becauſe the harmony of the tones, which the painter eſtabliſhes as ſuited for the moment, does not proceed with equal ſteps, and cannot preſerve itſelf in the like meaſure for the courſe of a few years, as each tint, as they ſay, ought to increaſe, or, to ſpeak more properly, to burn in proportion to its antiquity. It thence follows, that mere waſhing may be prejudicial to an old painting ; and that the method of refreſhing paintings, as it is called, by daubing over the ſurface, from time to time, with new drying oil, is highly prejudicial and ill calculated for the intended purpoſe, ſince the oil when it becomes dry contracts in its whole ſurface, carries with it the paint under it, and occaſions cracks in the painting. New oil of this kind gives occaſion to mineral paints to be reſtored ; but covers the picture with a new coat of reſin, and then of carbon, which ariſes from the gradual combuſtion, and always cauſes more blackneſs, and the decay of the painting which one wiſhes to preſerve.

“ Wax, on the other hand, undergoes a change which is very different from that of drying oil. The wax, inſtead of becoming black by the contact of the atmoſphere, increaſes in whiteneſs, and, according to its natural quality, is not decompoſed in the air, and it does not ſtrongly attract the oxygen of the calces or metallic aſhes which are commonly uſed in painting. Moreover, the ſo called earths, which are in themſelves white, and are never variable either by the preſence or abſence of oxygen, cannot be employed in oil-painting, becauſe that fluid makes them almoſt tranſparent, and cauſes them to remain as it were without body, and not to produce the wiſhed-for effect. That beautiful white, which may be obſerved on the before-mentioned Egyptian encauſtic, is nothing elſe than a ſimple earth, and according to our author's chemical experiments, a chalk which is alſo unalterable.”

That the ancients were once acquainted with the uſe of oil-painting, and neglected it on account of the great ſuperiority of the encauſtic method, our author thinks farther evident from the different accounts which we have of the ancient paintings. “ Thus Petronius praiſes the freſh appearance which the valuable works of Zeuxis and Apelles had, even in his time ; but Cicero, on the other hand, ſpeaks of the paintings of the ancients having ſuffered from blackneſs. The former ſpeaks of wax-painting, and the latter certainly alludes to paintings in oil. It is well known that paintings with wet chalks or water colours do not become black by age, and that this is the caſe alſo with encauſtic. Of this any one may be convinced, not only by the expreſſions of the above quoted authors, but by one's own eyes on ſurveying the Egyptian fragment alluded to. Galland proves, on various grounds, that a painting was made with oil ſo early as the reign of Marcus Aurelius ; and if no ſpecimens of that period have reached us, this is perhaps to be aſcribed to the frail and periſhable nature of this ſpecies of painting.”

Sign. Fabbroni, after ſome farther obſervations, calculated to prove that metallic oxyds or calces could not have been employed as pigments on ſuch mummies as ſtill retain their colours freſh, proceeds thus : “ Thoſe who are acquainted with the accuracy and certainty of the method not long ſince introduced into chemical operations, will be convinced, that in 24 grains of the encauſtic painting, which I ventured to detach from the above-mentioned Egyptian fragment, in order to ſubject it to examination, the mixture of an hundredth part of a foreign ſubſtance would have been diſcovered with the greateſt certainty ; that the reſin of Requeno muſt undoubtedly have been perceptible to me, and that the alkali of Bachelier and Lorgna could not have eſcaped the counteracting medium. But in this Egyptian encauſtic I found nothing except very pure wax, though I varied my analyſis in every known method. I muſt therefore conclude, that modern learned writers, at leaſt in reſpect to this Egyptian mode of painting, were as far from the truth as the accounts of ancient authors appear to me preciſe and ſatisfactory ; and that the encauſtum with which formerly the fore part of ſhips and the walls of houſes and temples were painted, was ſomething different from ſoap or reſinous crayons.

“ I am well aware that it will be aſked, In what manner can wax at preſent be rendered ſufficiently liquid for the ſtrokes of the pencil, if it be not converted into powder or ſoap ? This queſtion, in my opinion, can be fully anſwered from the words of an ancient author, and, in the next place, by experience.

“ Vitruvius in particular, book vii. chap. ix. expreſſes himſelf in the following clear manner :

‘ Thoſe (ſays he) who wiſh to retain cinnabar on walls, cover it, when it has been well laid on and dried, with Punic wax diluted in a little oil (let this be well remarked) ; and after they have ſpread out the wax with a hair bruſh, they heat the wall by means of a brazier filled with burning coals (hence it is called encauſtic painting), and then make it ſmooth and level by rubbing it with wax tapers and clean cloths, as is done when marble ſtatues are covered with wax. The effect of this wax cruſt is, that the colour is not deſtroyed by the light of the ſun or the moon (A).’

(A) The reader will find the original of this paſſage, with a tranſlation ſomewhat different, in the article Encaustic, *Encycl.*

“ It here appears, that the Romans, who copied the Grecian proceſs, which the latter borrowed from the Egyptians, mixed the wax with an oil to make it pliable under the bruſh ; but no maſtic, alkali, or honey, as has been ingeniouſly imagined, and which ſome have thought might be employed with ſucceſs. The difficulty now will be confined to point out in what manner this oil was employed. It does not appear that they uſed thoſe fat oils which are commonly called drying oils; becauſe they could have employed theſe as we do, without the addition of wax, which, in ſuch a caſe, would have been entirely ſuperfluous. Fat oils which do not dry would not have been proper for that purpoſe, as they would have kept the wax continually in the ſtate of a ſoft pomade or ſalve. Beſides, my experiments (continues the author) would without doubt have ſhewn me the exiſtence of any oily matter.

“ With regard to eſſential or volatile oils, a knowledge of them is not allowed to the ancients, as the invention of diſtilling is not older than the eighth or ninth century, and therefore falls in with the period of Geber or Avicenna.” Yet it is certain, that, in order to uſe wax in their encauſtic painting, they muſt have combined it with an ethereal volatile oil, of which no traces ſhould afterwards remain ; becauſe this was neceſſary for the ſolidity of the work, and becauſe no oil was found in the fragment that was examined. But naphtha is ſuch an oil, much lighter (ſays our author) than ether of vitriol itſelf. It is exceedingly volatile, and evaporates without leaving a trace of it behind. On this account it is uſed when ſignatures and manuſcripts are to be copied ; becauſe the paper, which is moiſtened by it, and ſo rendered tranſparent, quickly becomes white and opaque as before by the complete evaporation of the naphtha. That the Aſſyrians, Chaldeans, and Perſians, were well acquainted with the properties of naphtha is known to every ſcholar ; and hence our author thinks it highly probable that it was uſed by thoſe nations to render wax fit for painting. “ It appears to me (ſays he) that the Greeks, as was the caſe with many other things, learned encauſtic from the Egyptians, who probably derived it from the Aſſyrians or Chaldeans ; and if ſo, we have diſcovered the real mixture uſed for ancient encauſtic painting.”

To put the matter, however, beyond a doubt, Sign. Fabbroni prepared, for an eminent Saxon painter, a ſolution of Venetian wax in highly purified naphtha, deſiring him to mix up with it the colours neceſſary for a painting. The artiſt complied ; and both he and our author were aſtoniſhed, as well as all their friends, at the high tone which the colours aſſumed, and the agreeable luſtre which the painting afterwards acquired when it had been rubbed over with a ſoft cloth. A ſimilar ſolution of wax was made for another artiſt, in which the ſpirit of turpentine was uſed inſtead of naphtha with equal ſucceſs. Our author therefore concludes, we think with reaſon, that if he has not diſcovered the real compoſition employed by the ancients in their encauſtic paintings, he has at leaſt approached much nearer to that diſcovery than any of his predeceſſors who have employed their learned labours in the ſame field of inveſtigation.

PAINTINGS, or PICTURES, are often done upon objects from which, when they are valuable, it would be deſirable to tranſfer them. Thus, a connoiſſeur in painting might naturally wiſh to tranſfer an old and valuable picture from the ceiling or walls of his room to ſtretched canvas ; and ſuch a man would conſider himſelf as deeply indebted to the artiſt who ſhould perform ſo arduous a taſk. This taſk has actually been performed by Mr *Robert Salmon* of Woburn, Bedfordſhire, who was honoured by the *Society for the Encouragement of Arts, &c.* with the greater ſilver pallet, for communicating the method by which he accompliſhed it.

“ The firſt thing (ſays Mr Salmon) to be attended to with reſpect to paintings, either on plaſtered walls or ceilings, or on boards, is, that the place in which they are be ſecure from wet or damp. If the paintings are on old walls in large buildings, or other places where this cannot be attained by art, then the ſummer ſeaſon ſhould be taken for the purpoſe, as the picture will rarely eſcape damage, if wet or damp gets at it while under the proceſs. At the ſame time, care ſhould be taken that the room, or other place, be not overheated ; as that would produce equally bad effects.

“ Theſe precautions being taken, the next thing is to examine the ſurface of the painting. If there are any holes in the ſame, they muſt be carefully filled up with a paſte or putty, made of glue and whiting : this, if the holes are large, ſhould be twice or thrice done, ſo as entirely to fill them up, and leave the ſurface even and ſmooth ; but if there are any bruiſed places, with paint ſtill remaining on the ſurface of the bruiſed parts, then this ſtopping muſt not be applied, but the ſecuring-canvas, hereafter deſcribed, muſt be preſſed down into theſe places. In the places that are ſtopped, there will of courſe appear blemiſhes when the picture is transferred ; but the proceſs is rendered much more certain and ſure by being ſo done. Attention muſt next be paid to lay down any bliſters, or places where the paint is leaving the ground : this is done by introducing, between the paint and the ground. ſome very ſtrong paſte of flour and water ; and the ſurface of the bliſtered paint being damped with a wet ſponge or bruſh, it may be preſſed with the hand home to the ground, to which it will then adhere.

“ All the unſound places being thus ſecured, care muſt be taken to clear the ſurface of any greaſe or dirt, as alſo of any particles of the paſte that may happen to be left on it. The next thing is, to determine the ſize of the painting meant to be taken off : If it is on a plain ſurface, a board of the ſize of the picture muſt be procured, not leſs than an inch in thickneſs, and framed together with well-ſeaſoned wood, in ſmall pannels, ſmooth and fluſh on one ſide. This done, a piece of fine open canvas muſt be provided, ſuch as the fineſt ſort uſed for hanging paper on ; which canvas is to be ſomewhat larger than the picture, and ſo ſewed together, and the ſeam ſo preſſed, that it be perfectly ſmooth and even. This is what Mr Salmon calls the ſecuring canvas ; which, being ſo prepared, is to be ſtuck on the ſurface of the picture with a paſte made of ſtrong beer, boiled till it is half reduced, and then mixed with a ſufficient quantity of flour to give it a very ſtrong conſiſtence. To large pictures on walls or ceilings, the canvas muſt for ſome time be preſſed, and rubbed with the hand as ſmooth as poſſible, working it from the middle to the outſide, ſo as to make it tolerably tight ; obſerving, as it dries, to preſs it, with the hand or a cloth, into any hollow or bruiſed places, ſo that it may adhere to every part of the painting: this done, it is left to dry; which it will generally do in a day or two. When dry, a ſecond canvaſs, of a ſtronger and cloſer ſort, and of the ſame ſize as the other, is in like manner to be attached on the top of the firſt. This laſt will want very little attention, as it will readily adhere to the firſt; and, being dry, attention muſt be paid to take off any ſmall knots or unevenneſs that may be upon the ſurface of it; which done, the whole ſhould be again covered with a thin paſte of ſize and whiting; which is to be pumiced over when dry, ſo as to make the whole perfectly ſmooth and even.

“ The painting being thus ſecured, the board, already prepared to the ſize of the picture, is to be put with the ſmooth ſide againſt the ſurface thereof, ſo as exactly to cover as much as is intended to be transferred. The edges of the canvas, which, as before directed, is to be larger than the painting, are then to be pulled tight over, and cloſely nailed to the edge of the board. If the painting is large, and either on a ceiling or wall, the board muſt, by proper ſupports, be firmly fixed againſt it, ſo that it can readily be lowered down when the plaſter and painting are detached.

“ The canvas and board being fixed, the painting is to be freed from the wall or ceiling, together with a certain portion of the plaſtering: this, with proper care and attention, may be readily done. If on a ceiling, the firſt thing is to make ſome holes through the plaſtering, round the outſide of the board and painting; and, with a ſmall ſaw, to ſaw the plaſtering from one hole to another, till the whole is diſunited from the other parts of the ceiling: this done, the workman muſt get at the upper ſide of the ceiling, where he muſt free the plaſtering from the laths, by breaking off the keys thereof, and with a chiſel cut out the laths; whereby the plaſtering, together with the picture, will be left reſting on the board and ſupports.

“ If the painting is on a brick or ſtone wall, the wall muſt be cut away at top, and down the ſides of the painting; and then, by means of chiſels or ſaws in wooden handles, of different lengths, the wall muſt be cut away quite behind the painting; leaving the ſame, together with the plaſtering, reſting on the board. This operation may ſometimes be done with a ſaw; or, if the wall be not thick, nor the other ſide of much conſequence, the bricks or ſtones may be taken out from that ſide, leaving the plaſtering and painting as before. This laſt method (ſays the author) I have not practiſed: the other, of cutting away ſome part of the wall, I have, and ſee no difficulty, or very great labour, in the operation; but that, of courſe, muſt be various, according to the texture of the wall and mortar.

“ If the paintings are on curved ſurfaces, ſuch as the coves of ceilings, then the only difference of operation is, that ſome ribs of wood muſt be cut out, and boarded ſmooth to the curve of the ſurface of the painting, and then fixed up thereto, in place of the before deſcribed bearing-board; the painting is then to be freed, and left with the plaſtering, reſting on the bearers.

“ For paintings on wainſcot or boards, the ſame ſecuring and proceſs is to be exactly followed; only that, as the wainſcot or board can always be cut to the ſize wanted, and laid horizontal, the ſecuring-canvas is to be ſtretched thereon, and turned over the edges of the ſame, till it is dry; after which, the edges are again to be turned up, and nailed to the board, in the ſame manner as with reſpect to paintings from walls.

“ Having, as before deſcribed, in any of the aforementioned caſes, freed the paintings from their original places, you have got them ſecured to two thickneſſes of canvas, with their ſurfaces on the board prepared for that purpoſe; this being the caſe, they can readily be removed to any room or ſhop, to be finiſhed as follows: Having carried the painting into the ſhop or room, which ſhould be moderately warm and dry, but by no means overheated, lay the board on a bench or treſſels, ſo that the back of the picture be uppermoſt: the plaſtering or wood, as may happen, is then to be cleared away, leaving nothing but the body of paint, which will be firmly attached to the ſecuring-canvaſs. To perform this, a large raſp, a narrow plane, and chiſels, will be requiſite. This operation, though difficult to be deſcribed, would ſoon be learned by any one who ſhould make the attempt; nor is it very tedious; and being performed, the picture is ready to be attached to its new canvas, as follows.

“ The painting being cleared, and lying on the board, the back thereof is to be painted three or four times over ſucceſſively, with any good ſtrong-bodied paint; leaving one coat to dry before another comes on: a day or two between each will generally be found ſufficient. Each of theſe coats, and particularly the firſt, ſhould be laid on with great care, taking but a ſmall quantity in the bruſh at a time, and laying it very thin. This precaution is neceſſary, to prevent any of the oil or paint from paſſing through any ſmall cracks or holes in the ſurface of the picture; as ſuch oil or paint would run into the paſte, and ſo attach the ſecuring-canvas to the picture, as to prevent its being afterwards got off. If any ſuch holes or cracks are obſerved, they ſhould be ſtopped up with the glue and whiting paſte, and the painting then repeated, till a complete coat is formed on the back of the picture. It is then ready for attaching to its canvas, which is done by ſpreading all over the picture a paſte made of copal varniſh, mixed with ſtiff white lead, and a ſmall quantity of any other old fat paint; all which being ſpread equally over with a pallet-knife, ſuch a canvas as the firſt ſecuring-canvas is laid thereon, and ſtrained and nailed round the edges of the board; in which ſtate it is left till it becomes tolerably dry: then a ſecond canvas, of a ſtronger ſort, muſt be in like manner attached on the firſt, and left till it is perfectly dry and hard. This generally takes about two months; and the longer the painting is left, the more ſecurely it will be attached to its canvas, and leſs liable to crack or fly therefrom. When ſufficiently dry, all the four canvaſſes are to be unnailed from the board, and the edges turned up the reverſe way, and nailed to a proper ſtretching-frame. This is done by unnailing from the board a part on each ſide at a time, and immediately nailing it to the ſtretching-frame, ſo as never to leave the canvas to crack or partially ſtretch, which would damage the picture. In this manner, by degrees, the cloths are entirely detached from the board, and firmly fixed on the ſtretching-frame. The ſuperfluous canvas, left larger than the frame, may then be cut off, and the wedges put in the frame, and moderately tightened up. There remains then only to clear the ſurface of the painting from the ſecuring-canvaſs; which is done by repeatedly waſhing the ſurface with a ſponge and moderately warm water. In doing this, no violence or force muſt be uſed; and, by frequent and gentle waſhings, the paſte will all be worked out with the ſponge. The edges of the outer canvas are then to be cut round, and ſtripped off: the other, next the ſurface of the picture, is to be ſerved in like manner; which done, nothing remains but to take the paſte clean off, and repair any defects: the picture will then be as ſtrong as if painted on the canvas.

“ For taking pictures off walls, without taking the walls down, or cutting away more thereof than the plaſtering, the following proceſs is propoſed:

“ The ſurface of the picture is to be firſt ſecured, in the manner before deſcribed; but inſtead of the plain board, a bearer ſhould be prepared with a convex ſurface, compoſed of ribs, boarded over, ſo as to form part of a cylinder, of not leſs than five feet radius, and as long as the height of the picture. This bearer being prepared, in order to apply it, a floor or platform ſhould be erected, and placed horizontally, with its ſurface level, and its edge immediately in contact with the bottom of the picture meant to be transferred. The uſe of this platform is for the above deſcribed bearer to reſt and move upon; which bearer ſhould be ſet on its end, with one edge in contact with the wall, at one ſide of the picture; conſequently the other edge will be at ſome diſtance from the wall, according to the ſize of the picture and convexity of the bearer. Being thus placed, the ſuperfluous edge of the ſecuring-canvas ſhould be turned over, and nailed to that edge of the bearer that is next the wall: This done, the operation of cutting away the plaſtering ſhould be begun; which may he done with the corner and end of a ſhort ſaw; ſawing between the brick-work and plaſtering, and leaving the thickneſs, or part of the thickneſs, of the plaſtering on the painting faſtened to the bearer. When this edge of the picture is freed, the whole height, for nine or ten inches under the edge of the bearer that is fartheſt from the wall, muſt then be gently forced nearer; conſequently the other edge, together with the painting and plaſter that is freed, will leave the wall, and give an opportunity of introducing the ſaw behind, and cutting away the ſame to a certain diſtance farther under; and, by repeating this, the whole of the picture will at length be freed, and left on the bearer. Each time the bearer is removed, and, as it were, rolled on the vertical ſurface of the wall, care muſt be taken to turn and nail the ſecuring-canvas on the top and bottom edges of the bearer, ſo as to ſecure the freed plaſtering and picture from moving about; and, laſtly, before the bearer and plaſtering be moved, to nail the other edge of the picture in the ſame way, which will ſecure the whole to the bearer. This done, the picture and bearer are at liberty to be moved to a proper place, in order to be freed from the remaining plaſter. The edges may then be unnailed; the painting and canvas ſlipped from this bearer on to a plain board; and the new canvas may be then put on; which is to remain till dry, as in other caſes.

“ It may appear, that the bending of the canvas and plaſtering to the convex bearer will crack the plaſter, and damage the painting; but, from experience (ſays Mr Salmon) I have obſerved, that, to a curve of ſuch or even leſs radius, plaſtering will bend, without any viſible crack, even on the exterior part thereof; and that part next the bearer, not having occaſion, in bending, to extend its parts, will conſequently be much leſs liable to be diſturbed by ſuch bending.”

In clearing the wood from the paintings, our author never made uſe of aquafortis, or any other liquid; the uſe of which he conceives would be very tedious, and attended with danger, leſt it ſhould get through the paint, and wet or damp the paſte by which the ſecuring canvaſs is fixed. In working off the wood, he generally made uſe of ſuch planes as by the joiners are called the *levelled rabbit-plane*, and *ſmall rounds*. By the corners of the former, and proper handling of the latter, the wood is cleared off without force or violence: even the ſmalleſt particles may, in general, be got off; although in ſome paintings, and in particular parts of others, he has met with places on which he thought it beſt to leave ſome particles, or fine ſplinters, of wood, but nothing more. Raſps, and ſometimes a fine chiſel, are uſeful, to clear off ſuch parts as may be in hollow places, or where particles of wood are left, as above. The time required will be various, according to the manner in which the painting was originally done; ſome being painted on boards previouſly prepared with a water colour; others immediately painted with oil on the wood. This laſt ſort is by much the moſt difficult; the other is more eaſy, as the previous preparation prevents the wood from imbibing the oil, and conſequently admits it to be more eaſily ſeparated.

PALILICUM, the ſame as Aldebaran, a fixed ſtar of the firſt magnitude, in the eye of the bull, or ſign Taurus.

PALLIFICATION, or Piling, in architecture, denotes the piling of the ground-work, or the ſtrengthening it with piles, or timber driven into the ground; which is practiſed when buildings are erected upon a moiſt or marſhy ſoil.

PALM, an ancient long meaſure, taken from the extent of the hand. See Palmus, *Encycl.*

PALMÆ, palms. See *Encyclopædia*. The ſubject is introduced here to notice a kind of palm, the product of North America, of which we have the following account by Dr Barton.

“ There grows upon the river Mobile a ſpecies of palm, which is but little known to naturaliſts, but which promiſes to be an important article of food to man. It has no ſtalk or ſtem above ground. The leaves ſpread regularly all round, and when fully expanded are flabelliform. In the centre of theſe leaves is produced the receptacle of the fruit, which is of the form and ſize of a common ſugar-loaf. This receptacle conſiſts of a vaſt number of drupes, or berries, of the ſize and ſhape of common plums: each is covered with a fibrous, farinaceous, pulpy coating, of conſiderable thickneſs. This ſubſtance is ſaid to reſemble manna in texture, colour, and taſte; or, perhaps, it ſtill more reſembles moiſt brown ſugar, with particles of loaf ſugar mixed with it. It is a moſt delicious and nouriſhing food, and is diligently ſought after in the places where it grows. Upon firſt taſting it, it is ſomewhat bitter and pungent.

PANORAMA, a word derived from παν and οραμα; and therefore employed of late to denote a painting, whether in oil or water colours, which repreſents an entire view of any country, city, or other natural objects, as they appear to a perſon ſtanding in any ſituation, and turning quite round. To produce this effect, the

the painter or drawer muſt fix his ſtation, and delineate correctly and connectedly every object which preſents itſelf to his view as he turns round, concluding his drawing by a connection with where he began. He muſt obſerve the lights and ſhadows, how they fall, and perfect his piece to the beſt of his abilities. There muſt be a circular building or framing erected, on which this drawing or painting may be performed; or the ſame may be done on canvas, or other materials, and fixed or ſuſpended on the ſame building or framing, to anſwer the purpoſe complete. It muſt be lighted entirely from the top, either by a glazed dome, or otherwiſe as the artiſt may think proper. There muſt be an incloſure within the ſaid circular building or framing, which ſhall prevent an obſerver going too near the drawing or painting, ſo as it may, from all parts it can be viewed, have its proper effect. This incloſure may repreſent a room, or platform, or any other ſituation, and may be of any form thought moſt convenient; but the circular form is particularly recommended. Of whatever extent this inſide incloſure may be, there muſt be over it (ſupported from the bottom, or ſuſpended from the top) a ſhade or roof; which, in all directions, ſhould project ſo far beyond this incloſure, as to prevent an obſerver from ſeeing above the drawing or painting when looking up; and there muſt be without this incloſure another interception, to repreſent a wall, paling, or other interception, as the natural objects repreſented, or fancy, may direct, ſo as effectually to prevent the obſerver from ſeeing below the bottom of the drawing or painting; by means of which interception, nothing can be ſeen on the outer circle but the drawing or painting intended to repreſent nature. The entrance to the inner incloſure muſt be from below, a proper building or framing being erected for that purpoſe, ſo that no door or other interruption may diſturb the circle on which the view is to be repreſented. And there ſhould be, below the painting or drawing, proper ventilators fixed, ſo as to render a current circulation of air through the whole; and the inner incloſure may be elevated, at the will of an artiſt, ſo as to make obſervers, on whatever ſituation he may wiſh they ſhould imagine themſelves, feel as if really on the very ſpot.

1800.

PAPER is an article of ſuch importance, and at preſent* of ſo enormous a price, that no improvement in its manufacture ſhould paſs unnoticed in a work of this nature. The diſcovery made in France by M. Bertholet of the efficacy of oxy-muriatic acid in expediting the proceſs of BLEACHING (ſee that article in this *Suppl.*), has contributed eſſentially to facilitate the manufactures, not only of cotton and linen cloths, but alſo of paper, of which it has even increaſed the materials. Formerly writing paper could be made of *unprinted* linen alone; but by means of the proceſs of M. Bertholet even printed linen may be made into the fineſt and whiteſt paper. In the year 1795 a patent was granted to Mr Elias Carpenter of Bermondſay, Surrey, for a method of bleaching paper of ſuch materials in the *water-leaf* or *ſheet*, and ſizing it without drying:

In the preparation of the pulp, the coarſer rags are to be macerated for two or three days in a cauſtic alkaline ley, and wrought into ſheets of paper in the uſual way; a ſtrong wooden box or trough is then to be procured, of a ſize proportioned to that of the paper, lined on the inſide with white paint, and furniſhed with ſeveral ſtages of croſs bars of glaſs: the bottom of the box is to be covered with a ſtratum about one inch deep of cauſtic ley, and the paper laid by quarter reams, or leſs, acroſs the glaſs bar. A hole muſt be made in the box to admit the beak of an earthen-ware retort, into which muſt be put manganeſe and ſea ſalt, in powder, ſulphuric acid, and an equal quantity of water impregnated with the ſteams of burning ſulphur (ſulphureous acid). The cover of the box is to be made air-tight by luting or ſlips of paper dipped in paſte. The apparatus being thus prepared, the belly of the retort is to be plunged in water, kept boiling, and in a ſhort time the oxy-muriatic gas will be driven into the box, will penetrate the paper, and render it of a dazzling whiteneſs, while the alkaline ley at the bottom will, by gradually abſorbing it, prevent its becoming ſo concentrated as to deſtroy or injure the texture of the paper. From three to four pounds of ſulphuric acid will ſuffice for one hundred weight of paper, and the operation will be completed in about eight hours. The ſheets as they are taken out of the box are to be ſized with the following mixture:

To 1 cwt. of clippings of ſkin add 14lb. of alum, 7 of calcined vitriol, and 1 lb. of gum arabic, with a ſufficient quantity of water to ſize 50 reams of fools-cap.

The ſame method will ſerve equally well to clean engravings or printing; for though the oxy-muriatic acid diſcharges all ſtains, dirt, &c. yet it is incapable of acting on printers ink.

This, however, is not the only improvement in the manufacture of paper derived from modern chemiſtry. In Crell's *Chemical Annals* for the year 1797, we have an account of ſome curious experiments made by M. L. Brugnatelli, with the view of rendering

Paper.

PAPER incombuſtible, and the writing on it, of courſe, indeſtructible by fire. Of all the ſubſtances which he tried, he found the liquor of flints the moſt proper to ſecure paper from deſtruction by fire. He dipped a ſheet of paper ſeveral times in the above liquor freſh made, or daubed it ſeveral times over the whole paper with a hair bruſh, and dried it in the ſun or in an oven. Paper prepared in this manner loſt ſome of its ſoftneſs, became a little rougher than before, and acquired a lixivious cauſtic taſte. In other reſpects it was not different from common white paper. When this paper was laid upon glowing coals, it did not burn like common paper, but became red, and was converted to a coal, which however did not fall into aſhes like the coal of common paper, ſo that it might therefore be conſidered as petrified paper. This coal, however, is exceedingly friable; for when it is taken between the fingers, or preſſed together in any manner whatever, it drops to pieces. Still the diſcovery muſt be a valuable one, if there be any kind of ink of ſuch a nature as that the characters written with it continue viſible on this coal. Such an ink M. Brugnatelli made by combining diſſolved nitrite of zinc with common ink; and found, that the colour of this mixture, though it appeared ſomewhat pale on common paper, became ſo dark on prepared paper, that words written with it appeared more conſpicuous than words written with common ink. When the paper was burnt, or reduced to a coal, thoſe characters were ſo viſible, in a clear *white* colour on a *dark* ground, that they could be read with as much eaſe as characters written with the beſt ink on white

white paper. If the ingenious author ſucceed in his attempts to diſcover a method of rendering his prepared paper leſs friable when burnt, his diſcovery will be one of the moſt important of the preſent age.

PARABOLIC Conoid, is a ſolid generated by the rotation of a parabola about its axis. This ſolid is equal to half its circumſcribed cylinder; and therefore if the baſe be multiplied by the height, half the product will be the ſolid content.

Parabolic Pyramidoid, is a ſolid figure, thus named by Dr Wallis from its geneſis or formation, which is thus: Let all the ſquares of the ordinates of a parabola be conceived to be ſo placed, that the axis ſhall paſs perpendicularly through all their centres; then the aggregate of all theſe planes will form the parabolic pyramidoid. This figure is equal to half its circumſcribed parallelopipedon. And therefore the ſolid content is found by multiplying the baſe by the altitude, and taking half the product; or the one of theſe by half the other.

Parabolic Space, is the ſpace or area included by the curve line and baſe or double ordinate of the parabola.

Parabolic Spindle, is a ſolid figure conceived to be formed by the rotation of a parabola about its baſe or double ordinate.

Parabolic Spiral, is a curve ariſing from the ſuppoſition that the common or Apollonian parabola is bent or twiſted till the axis come into the periphery of a circle, the ordinates ſtill retaining their places and perpendicular poſitions with reſpect to the circle, all theſe lines ſtill remaining in the ſame place. This figure is ſometimes called the *Helicoid parabola*.

PARABOLOIDES, parabolas of the higher orders. The equation for all curves of this kind being $a^{m-n}x^{n}=y^{m}$, the proportion of the area of any one to the complement of it to the circumſcribing parallelogram, will be as *m* to *n*.

PARACENTRIC Motion, denotes the ſpace by which a revolving planet approaches nearer to, or recedes farther from, the ſun, or centre of attraction.

Paracentric Solicitation of Gravity, is the ſame as the vis centripeta.

PARACHUTE, a kind of large and ſtrong umbrella, contrived to break a perſon's fall from an air-balloon, ſhould any accident happen to the balloon at a high elevation. This contrivance was firſt thought of by Blanchard, who at different times, by means of the parachute, let fall from his balloon dogs and other animals. He ventured even to deſcend in this manner himſelf; but, whether from the bad conſtruction of his parachute, or from falling among trees, he had the misfortune to break one of his legs. Citizen Garnerin, as he chooſes to be called, was more ſucceſsful. On the 21ſt of October 1797, he aſcended from the garden de Mauſſeux at half paſt five in the evening; between the balloon and the car, in which he ſat, was placed the parachute, half opened, and forming a kind of tent over the aërial traveller; and when the whole apparatus was at a conſiderable height, he ſeparated the parachute and car from the balloon. The parachute unfolding itſelf, was, by his weight and that of the car, drawn of courſe towards the earth. Its fall was at firſt ſlow and vertical; but ſoon afterwards it exhibited a kind of balancing or vibration, and a rotation gradually increaſing, which might be compared with that of a leaf falling from a tree. The aëronaut, however, reached the ground unhurt.

This parachute was of cloth, and its diameter, when unfolded, about twenty-five feet. To uſe ſuch inſtruments with ſucceſs, it is neceſſary that the car be ſuſpended at a conſiderable diſtance from the parachute, ſo as that the centre of gravity of the whole ſhall be vertically below the centre of reſiſtance made by the air to the deſcent of the parachute; for if the car be otherwiſe placed, it is evident that the parachute will incline to one ſide, deſcend obliquely, oſcillate, and the ſmalleſt irregularity in its figure will cauſe it to turn round its vertical axis.

PARAGUATAN, a kind of wood which grows in Guiana, and promiſes to be of great utility as a dye ſtuff. We have ſeen no botanical deſcription of the tree; but from the report made to the Council of Trade and Mines, by D. Dominique Garcia Fernandez, inſpector of coinage, we learn that its bark, boiled in water, affords a coloured extract which reſiſts the agency of acids for a longer time than brazil or logwood; that the colour may be revived by means of alkalies, after it has been deſtroyed by combination with acids; that vinegar, lemon-juice, and tartar, render this colour more brilliant, while they entirely deſtroy the colours of brazil and logwood; that the fecula of the bark of paraguatan fixes and attaches itſelf to wool, cotton, and ſilk; and that the colour is brighter on ſilk than on wool, and brighter on wool than on cotton. The ſame fecula dried is afterwards ſoluble in alcohol, to which it communicates a tinge ſimilar to that afforded by cochineal; but it muſt be confeſſed, that the colour obtained from paraguatan has not the force of that of cochineal, though it is ſuperior to thoſe of madder, brazil wood, and logwood. From theſe facts D. Fernandez conſiders the paraguatan as one of the moſt valuable productions which America furniſhes to Spain.

PARALLAX (ſee *Encycl.*) is uſed, not only in aſtronomy, but alſo in levelling. for the angle contained between the line of true level, and that of apparent level. And, in other branches of ſcience, for the difference between the true and apparent places.

PARALLEL Ruler, is a mathematical inſtrument, conſiſting of two equal rulers, either of wood or metal, connected together by two ſlender croſs bars or blades of equal length, moveable about the points of junction with the rulers. There are other forms of the inſtrument; ſome, for inſtance, having the two blades croſſing in the middle, and fixed only at one end of them, the other two ends ſliding in grooves along the two rulers, &c.

The uſe of this inſtrument is obvious. For the edge of one of the rulers being applied to any line, the other opened to any extent will be always parallel to the former; and conſequently any parallels to this may be drawn by the edge of the ruler, opened to any extent.

PARALLELS, or Places of Arms, in a ſiege, are deep trenches, 15 or 18 feet wide, joining the ſeveral attacks together; and ſerving to place the guard of the trenches in, to be at hand to ſupport the workmen when attacked. There are uſually three in an attack: the firſt is about 600 yards from the covert-way, the ſecond between 3 and 400, and the third near or on ralleliſm ‖ Paramaribo

Paramaribo.

the glacis. It is ſaid they were firſt invented or uſed by Vauban.

PARALLELISM of the Earth's Axis, is that invariable ſituation of the axis, in the progreſs of the earth thro' the annual orbit, by which it always keeps parallel to itſelf; ſo that if a line be drawn parallel to its axis, while in any one poſition, the axis, in all other poſitions or parts of the orbit, will always be parallel to the ſame line.

PARAMETER, a certain conſtant right line in each of the three conic ſections; otherwiſe called alſo *latus rectum*.

PARAMARIBO, the capital of the Dutch ſettlement at Surinam, is ſituated on the right ſide of the beautiful river Surinam, at about 16 or 18 miles diſtance from its mouth. It is built upon a kind of gravelly rock, which is level with the reſt of the country, in the form of an oblong ſquare; its length is about a mile and a half, and its breadth about half as much. All the ſtreets, which are perfectly ſtraight, are lined with orange, ſhaddock, tamarind, and lemon trees, which appear in everlaſting bloom; while, at the ſame time, their branches are weighed down with the richeſt cluſters of odoriferous fruit. Neither ſtone nor brick is made uſe of here for pavement; the whole being one continued gravel, not inferior to the fineſt garden walks in England, and ſtrewed on the ſurface with ſea ſhells. The houſes, which are moſtly of two and ſome of three ſtories high, are all built of fine timber, a very few excepted; moſt of the foundations are of brick, and they are roofed with thin ſplit boards, called *ſhingles*, inſtead of ſlates or tiles. Windows are very ſeldom ſeen in this country, glaſs being inconvenient on account of the heat; inſtead of which they uſe gauze frames: ſome have only the ſhutters, which are kept open from ſix o'clock in the morning until ſix at night. As for chimneys, there are none in the colony; no fires being lighted except in the kitchens, which are always built at ſome diſtance from the dwelling houſe, where the victuals are dreſſed upon the floor, and the ſmoke let out by a hole made in the roof: theſe timber houſes are, however, very dear in Surinam, one of them having coſt above L. 15,000 ſterling. There is no ſpring water to be met with in Paramaribo; moſt houſes have wells dug in the rock, which afford but a brackiſh kind of beverage, only uſed for the negroes, cattle, &c. and the Europeans have reſervoirs or ciſterns, in which they preſerve rain-water for their own conſumption; thoſe of nicer taſte let it firſt drop through a filtering-ſtone into large jars or earthen pots, made by the native Indians on purpoſe, which they barter at Paramaribo for other commodities. The inhabitants of this country, of every denomination, ſleep in hammocks, the negro ſlaves excepted, who moſtly lie on the ground: the hammocks uſed by thoſe in ſuperior ſtations are made of cotton, ornamented with rich fringe; theſe are alſo made by the Indians, and ſometimes worth above twenty guineas; neither bedding nor covering is neceſſary, except an awning to keep off the muſquitoes. Some people indeed lie on bedſteads; in that caſe they are ſurrounded, inſtead of curtains, with gauze pavilions, which admit the air freely, and at the ſame time keep off the ſmalleſt inſect. The houſes in general at Paramaribo are elegantly furniſhed with paintings, gilding, cryſtal chandeliers, china jars, &c.; the rooms are never papered or plaſtered, but beautifully wainſcotted with cedar, and Brazil, and mahogany wood.

The number of buildings in Paramaribo is computed at about 1400, of which the principal is the governor's palace, whence there is a private paſſage through the garden which communicates with Fort Zelandia. This houſe, and that of the commandant, which has lately been burnt, were the only brick buildings in the colony. The town-hall is an elegant new building, and covered with tiles; here the different courts are held, and underneath are the priſons for European delinquents, the military excepted, who are confined in the citadel of Fort Zelandia. The Proteſtant church, where divine worſhip is performed both in French and Low Dutch, has a ſmall ſpire with a clock; beſides which there is a Lutheran chapel, and two elegant Jewiſh ſynagogues, one German the other Portugueſe. Here is alſo a large hoſpital for the garriſon, and this manſion is never empty. The military ſtores are kept in the fortreſs, where the ſociety ſoldiers are alſo lodged in barracks, with proper apartments for ſome officers. The town of Paramaribo has a noble road for ſhipping, the river before the town being above a mile in breadth, and containing ſometimes above 100 veſſels of burden, moored within a piſtol-ſhot of the ſhore. Before Holland became a province of France, and thereby loſt her trade, there were ſeldom fewer than 80 ſhips at Paramaribo, loading coffee, ſugar, cocao, cotton, and indigo, for the mother country, including alſo the Guinea-men that bring ſlaves from Africa, and the North American and Leeward Iſland veſſels, which bring flour, beef, pork, ſpirits, herrings, and mackarel ſalted, ſpermaceti candles, horſes, and lumber; for which they receive chiefly molaſſes to be diſtilled into rum. This town is not fortified, but is bounded by the river on the ſouth-eaſt; by a large ſavannah on the weſt; by an impenetrable wood on the north-eaſt; and is protected by Fort Zelandia on the eaſt. This citadel is only ſeparated from the town by a large eſplanade, where the troops parade occaſionally. The fort is a regular pentagon, with one gate fronting Paramaribo, and two baſtions which command the river; it is very ſmall but ſtrong, being made of rock or hewn ſtone, ſurrounded by a broad foſſe well ſupplied with water, beſides ſome outworks. On the eaſt ſide, fronting the river, is a battery of 21 pieces of cannon. On one of the baſtions is a bell, which is ſtruck with a hammer by the centinel, who is directed by an hour-glaſs. On the other is planted a large enſign-ſtaff, upon which a flag is hoiſted upon the approach of ſhips of war, or on public rejoicing days. The walls are ſix feet thick, with embraſures, but no parapet.

Paramaribo is a very lively place, the ſtreets being generally crowded with planters, ſailors, ſoldiers, Jews, Indians, and Negroes, while the river is covered with canoes, barges, &c. conſtantly paſſing and repaſſing like the wherries on the Thames, often accompanied with bands of muſic; the ſhipping alſo in the road adorned with their different flags, guns firing, &c not to mention the many groupes of boys and girls playing in the water, altogether form a pleaſing appearance; and ſuch gaiety and variety of objects ſerve, in ſome meaſure, to compenſate for the many inconveniences of the climate. Their carriages and dreſs are truly magnificent; ſilk embroidery, Genoa velvets, diamonds, gold and ſilver

Paramaribo, Paris.

lace, being daily worn, and even the maſters of trading ſhips appears with buttons and buckles of ſolid gold. They are equally expenſive at their tables, where every thing that can be called delicate is produced at any price, and ſerved up in plate and china of the neweſt faſhion, and moſt exquiſite workmanſhip. But nothing diſplays the luxury of the inhabitants of Surinam more than the number of ſlaves by whom they are attended, often twenty or thirty in one family. White ſervants are ſeldom to be met with in this colony.

The current money are ſtamped cards of different value, from five ſhillings to fifty pounds: gold and ſilver is ſo ſcarce, that the exchange premium for ſpecie is often above 10 *per cent.* A baſe Dantzic coin called a *bit*, value ſomething leſs than ſixpence, is alſo current in Surinam. Engliſh and Portugueſe coin are ſometimes met with, but moſtly uſed as ornaments by the Mulatto, Samboe, Quaderoon, and Negro girls. The Negro ſlaves never receive any paper money; for as they cannot read, they do not underſtand its value; beſides, in their hands it would be liable to many accidents, from fire or children, and particularly from the rats, when it becomes a little greaſy.

This town is well ſupplied with proviſions, *viz.* butchers meat, fowls, fiſh, and veniſon. Vegetables in particular the country abounds with; beſides the luxuries peculiar to this climate, they import whatever Europe, Africa, and Aſia can afford. Proviſions, however, are exceſſively dear in general, eſpecially thoſe imported, which are moſtly ſold by the Jews and maſters of ſhips. The firſt enjoy extraordinary privileges in this colony; the latter erect temporary warehouſes for the purpoſe of trade, during the time their ſhips are loading with the productions of the climate. Wheat flour is ſold from four-pence to one ſhilling per pound; butter, two ſhillings; butcher's meat never under one ſhilling, and often at one ſhilling and ſixpence; ducks and fowls from three to four ſhillings a couple. A ſingle turkey has ſometimes coſt one guinea and a half; eggs are ſold at the rate of five, and European potatoes twelve, for ſixpence. Wine three ſhillings a bottle. Jamaica rum a crown a gallon. Fiſh and vegetables are cheap, and fruit almoſt for nothing.

PARIS (Francis), a man more famous after his death than during his life, by the miracles which were ſaid to be performed at his tomb. He is generally known by the name of Abbé Paris; and his pretended miracles, with others of like manufacture, have furniſhed deiſtical writers, and Mr Hume in particular, with a kind of argument againſt the reality of the miracles of which we have an account in the Goſpel. It is merely that we may ſtate his pretenſions fairly, that we have introduced him to the notice of our readers; for in every other reſpect he is wholly unworthy of their regard. He was the ſon of a counſellor in Parliament, and had the proſpect, if he had choſen it, of ſucceeding to his father's appointment; but he choſe rather to become an eccleſiaſtic, and he became a very zealous one. He gave up all his poſſeſſions to his brother, refuſed preferment intended for him by the cardinal de Noailles, devoted himſelf entirely to retirement, and made ſtockings for his own ſupport, and for the aſſiſtance of the poor. He died, perhaps in conſequence of his rigorous mode of life, May 1. 1727, at the age of only 37. His brother raiſed a monument to him in the ſmall churchyard of St Medard, to which the poor and the pious ſoon began to flock; and after a time it was reported, that, in conſequence of their prayers at that tomb, ſome ſick perſons had received cures. As Paris had been a rigorous Janſeniſt, this was a fine opportunity for that ſect to gain credit to their cauſe; the miracles were therefore multiplied, and a variety of perſons affected the moſt ſingular convulſions.

Paris.

The minds of the people becoming inflamed by theſe extravagancies, the court found it neceſſary to ſhut up the churchyard, which was done on the 27th of January 1732. On this occaſion, ſome profane wit wrote upon the wall of the place,

> De par le Roy, defenſe a Dieu,
> De faire miracles en ce lieu.

The convulſions were continued, for a little while, in private houſes, but by degrees the matter ſubſided, and the Abbé Paris was forgotten.

The diſtinction between miracles exhibited to ſerve a party, and atteſted only by thoſe who are zealous in its ſupport, and miracles performed in the ſight of unbelievers, who, in ſpite of their deep-rooted prejudices, were converted by them, is too ſtriking to be overlooked by any, but thoſe who are deſirous of drawing a falſe and impious parallel; yet has Mr Hume dared to repreſent the miracles performed at the tomb of this ſaint as outvying in number, nature, and evidence, the miracles of Chriſt and his apoſtles—with what truth, the following obſervations will ſhew:

1*ſt*, It was often objected by the enemies of the ſaint, and the objection was never confuted by his friends, that the *proſtrations* at his ſepulchre, like animal magnetiſm more lately, *produced* more diſeaſes than they *cured*. Such, ſurely, was not the nature of our Saviour's miracles.

2*dly*, Though the crowds of ſick and infirm perſons who flocked to the tomb for relief were, by all accounts, innumerable; yet all the cures, of which the zealous hiſtorian of the Miracles could procure vouchers, amounted only to NINE! Now, were thouſands, and ten thouſands of diſeaſed perſons to apply to ſome circumforaneous quack, in full aſſurance of his extraordinary abilities and ſkill in phyſic, could it ſurpriſe any perſon, if the diſtempers of *eight* or *nine* of them ſhould take a favourable turn while they were under a courſe of his uſeleſs medicines?

3*dly*, We do not read that of thoſe nine who were cured by the dead Abbé, the greater part were Jeſuits and enemies to the Janſeniſts; whereas the greater part of our Saviour's miracles were performed upon unconverted Jews, and one of them upon the ſervant of the high prieſt, who was thirſting for his blood.

4*thly*, The cures reported to have been performed at the grave of Paris were all ſuch as might have been accompliſhed by natural means. Thus, a Spaniard who had loſt one eye, and was diſtreſſed with an inflammation in the other, had the inflamed eye gradually cured, but not the loſt eye reſtored. Another perſon having pricked his eye with an awl, loſt the ſight of it in conſequence of the aqueous humour dropping out; but his ſight was reſtored *whilſt* he was paying his devotions to the Abbé—and ſo it would have been while he was curſing the Abbé, had he continued his execrations for a ſufficient length of time.

5*thly*,

5thly, None of the cures ſaid to have been performed were *inſtantaneous*. *All* the worſhippers at the tomb perſiſted for *days*, ſeveral of them for *weeks*, and ſome for *months*, daily imploring the interceſſion of the Abbé *before* they received relief from their complaints.

6thly, Moſt of the devotees had been uſing *medicines* before they applied to the ſaint, and continued to uſe them *during the whole time* of their application; whilſt it is confeſſed that the diſtempers of others had *abated* before they determined to ſolicit his help.

7thly, Some of the cures atteſted were *incomplete*, and only of a temporary duration. Thus, the Spaniard was relieved only from the moſt inconſiderable part of his complaint, and that too but for a very ſhort period; for ſoon after his return home he relapſed into his former malady, as was fully atteſted by certificates and letters from Madrid. All this has been completely proved by the Archbiſhop of Sens; who in his *Paſtoral Inſtruction*, publiſhed at the time the miracles were making a noiſe, has,

8thly, Clearly detected the deceit and little artifices by which theſe pretended miracles were ſo long ſupported. To that work we refer our readers; requeſting them, after they have read it, to compare the evidence for the miracles of Paris with the evidence which in the article MIRACLE (*Encycl.*) we have ſtated for the reality of the Goſpel miracles, and to judge for themſelves with the impartiality of philoſophers.

Paris wrote a few very indifferent books of annotations on the Epiſtles to the Romans, to the Galatians, and the Hebrews; but few have ever read them, nor would they have reſcued the author from oblivion, without the aid of his lying wonders.

PARKHURST (the Rev. John), was the ſecond ſon of John Parkhurſt, Eſq; of Cateſby in Northamptonſhire. His mother was Ricarda Dormer, daughter of Judge Dormer. He was born in June 1728, was educated at the ſchool of Rugby in Warwickſhire, and was afterwards of Clare-hall, Cambridge; B. A. 1748, M. A. 1752; and many years fellow of his college.

Being a younger brother, he was intended for the church; but not long after his entering into holy orders his elder brother died. This event made him the heir of a very conſiderable eſtate; though, as his father was ſtill living, it was ſome time before he came into the full poſſeſſion of it; and when he did come into the poſſeſſion of it, the acquiſition of fortune produced no change on his manners or his purſuits. He continued to cultivate the ſtudies becoming a clergyman; and from his family connections, as well as from his learning and piety, he certainly had a good right to look forward to preferment in his profeſſion; but betaking himſelf to retirement, and to a life of cloſe and intenſe ſtudy, he ſought for no preferment; and, according to the author of the biographical ſketch of him publiſhed in the Gentleman's Magazine, he lived not in an age when merit was urged forward. Yet, in the capacity of a curate, but without any ſalary, he long did the duty, with exemplary diligence and zeal, in his own chapel at Cateſby, which, after the demolition of the church of the nunnery there, ſerved as a pariſh-church, of which alſo he was the patron.

When, ſeveral years after, it fell to his lot to exerciſe the right of preſentation, he was ſo unfaſhionable as to conſider church-patronage as a truſt rather than a property; and, accordingly, reſiſting the influence of intereſt, favour, and affection, preſented to the vicarage of Epſom, in Surrey, the Rev. Jonathan Boucher, who ſtill holds it. This gentleman was then known to him only by character; but having diſtinguiſhed himſelf in America, during the revolution, for his loyalty, and by teaching the unſophiſticated doctrines of the church of England to a ſet of rebellious ſchiſmatics at the peril of his life, Mr Parkhurſt thought, and juſtly thought, that he could not preſent to the vacant living a man who had given better proofs of his having a due ſenſe of the duties of his office.

In the year 1754, Mr Parkhurſt married Suſanna Myſter, daughter, and, we believe, heireſs of John Myſter, Eſq; of Epſom. It was thus that he became patron of the living which he beſtowed on Mr Boucher. This lady died in 1759, leaving him a daughter and two ſons; both the ſons are now dead. In the year 1761, he married again Millicent Northey, daughter of Thomas Northey, Eſq; by whom he had one daughter, now married to the Rev. Joſeph Thomas.

In the year 1753, he began his career of authorſhip, by publiſhing, in 8vo, "A friendly Addreſs to the Rev. Mr John Weſley, in relation to a principal Doctrine maintained by him and his Aſſiſtants." This work we have not ſeen; but though we have no doubt of its value, we may ſafely ſay that it was of very little importance, when compared with his next publication, which was "An Hebrew and Engliſh Lexicon, without Points; to which is added, a methodical Hebrew Grammar, without Points, adapted to the uſe of Learners, 1762," 4to. To attempt a vindication of all the etymological and philoſophical diſquiſitions which are ſcattered through this dictionary, would be very fruitleſs; but it is not perhaps too much to ſay, that we have nothing of the kind equal to it in the Engliſh language. He continued, however, to correct and improve it; and in 1778 another edition of it came out much enlarged, and a third in 1792.

His philological ſtudies were not confined to the Hebrew language; for he publiſhed a Greek and Engliſh Lexicon to the New Teſtament; to which is prefixed, a plain and eaſy Greek Grammar, 1769, 4to; a ſecond edition, 1794: and at his death there was in the preſs a new edition of both theſe lexicons, in a large 8vo, with his laſt corrections; for he continued to reviſe, correct, add to, and improve, theſe works, till within a few weeks of his death. As, from their nature, there cannot be ſuppoſed to be any thing in dictionaries that is particularly attractive and alluring, this continued increaſing demand for theſe two ſeems to be a ſufficient proof of their merit.

He publiſhed, "The Divinity and Pre-exiſtence of our Lord and Saviour Jeſus Chriſt, demonſtrated from Scripture; in Anſwer to the firſt Section of Dr Prieſtley's Introduction to the Hiſtory of early Opinions concerning Jeſus Chriſt; together with Strictures on ſome other Parts of the Work, and a Poſtſcript relating to a late Publication of Mr Gilbert Wakefield, 1787," 8vo. This work was very generally regarded as completely performing all that its title-page promiſed; and accordingly the whole edition was ſoon ſold off. The brief, evaſive, and very unſatisfactory notice taken of this able pamphlet by Dr Prieſtley, in "A

Parkhurſt.

Letter to Dr Horne," &c. ſhewed only that he was unable to anſwer it.

Mr Parkhurſt was a man of very extraordinary independency of mind and firmneſs of principle. In early life, along with many other men of diſtinguiſhed learning, it was alſo objected to him, that he was an Hutchinſonian; and on this account alone, in common with them, it has been ſaid that he was neglected and ſhunned.

There is not, in the hiſtory of the times, ſays the biographer already quoted, a circumſtance more difficult to be accounted for than the unmerited, but increaſing, diſcountenance ſhewn to thoſe perſons to whom Hutchinſonianiſm was then objected. Methodiſts, Papiſts, and ſectaries of any and of every name, all ſtood a better chance of being noticed and eſteemed than Hutchinſonians. Had it even been proved that the few peculiar tenets by which they were diſtinguiſhed from other Chriſtians were erroneous, the oppoſition they experienced might have been deemed *hard meaſure*, becauſe even their opponents allowed their principles to be inoffenſive, and themſelves to be learned.

Is this a fair ſtate of the caſe? We think not. The early Hutchinſonians had imbibed all the peculiar notions of their maſter, and maintained them with a degree of acrimony which would have diſgraced any cauſe. Being in general very little acquainted with the higher mathematics, as Mr Hutchinſon himſelf ſeems likewiſe to have been, they cenſured dogmatically works which, without that knowledge, they could not fully underſtand; whilſt they maintained, with equal dogmatiſm, as matters of fact, hypotheſes, which a moderate ſhare of mathematical ſcience would have ſhewn them to be impoſſible. Had they ſtopt here, no harm would have been done; they might have enjoyed their favourite notions in peace: but unfortunately they accuſed of Atheiſm, Deiſm, or Socinianiſm, all who thought not exactly as *they* thought, both in natural philoſophy and in theology. Becauſe Newton and Clarke had demonſtrated that the motions of the planets cannot be the effect of the impulſion of any material fluid, Hutchinſon, with ſome of his followers, affirmed, that theſe two illuſtrious men had entered into a ſerious deſign to overturn the Chriſtian religion, and eſtabliſh in England the worſhip of the Heathen Jupiter, or the Stoical *anima mundi*. Becauſe the Biſhops Pearſon, Bull, and others, who had uniformly been conſidered as the ableſt defenders of the Catholic faith, thought not exactly as Hutchinſon thought of the filiation of the Son of God, they were condemned by the pupils of his ſchool as *Arians*, or at leaſt *Semi-arians;* and the writer of this ſketch has heard a living Hutchinſonian pronounce the ſame cenſure, and for the ſame reaſon, on the preſent illuſtrious Biſhop of Rocheſter, and the no leſs illuſtrious Whitaker.

That men, who thus condemned all that before them had been deemed great and good in phyſical ſcience and Chriſtian theology, ſhould meet with ſome diſcountenance while they continued of ſuch a ſpirit, needs not ſurely excite much wonder; but that the diſcountenance is increaſing, we believe not to be true. The Hutchinſonians, as ſoon as they became leſs violent againſt thoſe who differed from them, had their ſhare of preferment, in proportion to their number, with others; and we doubt not they will continue to have it, while they allow that a man may be no heretic, though he believe not Mr Hutchinſon to have been infallible. The late excellent Biſhop Horne was an avowed Hutchinſonian, though not an outrageous one like Julius Bate; and we have been told, and have reaſon to believe, that the Biſhop of St Aſaph is likewiſe a moderate favourer of the ſame ſyſtem. There may be others on the epiſcopal bench; but perhaps two out of twenty-ſix is the full proportions of Hutchinſonian divines of eminence in England. It is true that Mr Parkhurſt was a man of great learning and great worth; but before we attribute his want of preferment in the church to his Hutchinſonianiſm, it is incumbent upon us to ſay why Mr Whitaker, who is no Hutchinſonian, is ſtill nothing more than the rector of Ruan-Lanyhorne.

Mr Parkhurſt, however, was not, if his biographer deſerves credit, a thorough-paced Hutchinſonian; for though he continued to read Hutchinſon's writings as long as he read at all, he was ever ready to allow, that he was oftentimes a confuſed and bad writer, and ſometimes unbecomingly violent. To have been deterred from reading the works of an author, who, with all his faults, certainly throws out many uſeful hints, for fear of being thought a Hutchinſonian, would have betrayed a puſillanimity of which Mr Parkhurſt was incapable. What he believed he was not afraid to profeſs; and never profeſſed to believe any thing which he did not very ſincerely believe. An earneſt lover of truth, he ſought it where only it is to be found—in the Scriptures (A) The ſtudy of theſe was at once the buſineſs and the pleaſure of his life; from his earlieſt to his lateſt years, he was an hard ſtudent; and had the daily occupations of every 24 hours of his life been portioned out, as it is ſaid thoſe of king Alfred were, into three equal parts, there is reaſon to believe that a deficiency would rarely have been found in the eight hours allotted to ſtudy. What the fruits have been of a life ſo conducted, few theologians, it is preſumed, need to be informed, it being hardly within the ſcope of a ſuppoſition, that any man will now ſit down to the ſtudy of the Scriptures without availing himſelf of the aſſiſtance to be obtained from his learned labours. Theſe labours ceaſed at Epſom in Surrey, where this great and good man died, on March the 21ſt, 1797. Beſides the works which we have mentioned, there is in the Gentleman's Magazine, for Auguſt 1797, a curious letter of his on the Confuſion of Tongues at Babel.

Mr Parkhurſt's character may be collected with tolerable accuracy even from this imperfect ſketch of his life. His notions of church patronage do him honour; and as a farther inſtance of the high ſenſe he entertained

---

(A) This is vague language, which is the ſource of much uſeleſs controverſy, and therefore ought to be avoided. If by *truth*, in this paſſage, be meant *religious* truth, we admit the aſſertion in the only ſenſe in which we think it can have been made. If the author means *all* truth, he writes nonſenſe; for the Scriptures treat not of *geometry* or *algebra*, where truth is certainly to be found; and *we think* that they have a higher object than even *mechanics* and *aſtronomy*.

ed of ſtrict juſtice, and the ſteady reſolution with which he practiſed it on all occaſions, an incident which occurred between him and one of his tenants, within theſe ten years, may here be mentioned. This man falling behind hand in the payment of his rent, which was L. 500 *per annum*, it was repreſented to his landlord that it was owing to his being over rented. This being believed to be the caſe, a new valuation was made; and it was then agreed that, for the future, the rent ſhould not be more than L. 450. Juſtly inferring, moreover, that if the farm was *then* too dear, it muſt neceſſarily have been *always* too dear, unaſked, and of his own accord, he immediately ſtruck off L. 50 from the commencement of the leaſe; and inſtantly refunded all that he had received more than L. 450 *per annum*.

Mr Parkhurſt was in his perſon rather below the middle ſize, but remarkably upright, and firm in his gait. He was all his life of a ſickly habit: and his leading ſo remarkably ſtudious and ſedentary a life (it having, for many years, been his conſtant practice to riſe at five, and, in winter, to light his own fire) to the very verge of David's limits of the life of man, is a conſolatory proof to men of ſimilar habits, how much, under many diſadvantages, may ſtill be effected by ſtrict temperance and a careful regimen. He alſo gave leſs of his time to the ordinary interruptions of life than is common. In an hoſpitable, friendly, and pleaſant neighbourhood, he viſited little; alleging, that ſuch a courſe of life neither ſuited his temper, his health, nor his ſtudies. Yet he was of ſociable manners; and his converſation always inſtructive, often delightful: for his ſtores of knowledge were ſo large, that he too has often been called a walking library. He belonged to no clubs; he frequented no public places; and there are few men who, towards the cloſe of life, may not, on a retroſpect, reflect with ſhame and ſorrow, how much of their precious time has thus been thrown away, or, perhaps, worſe than thrown away.

Like many other men of infirm and ſickly frames, Mr Parkhurſt was alſo irritable, and quick, warm, and earneſt, in his reſentments, though never unforgiving. But whether it be or be not a matter of reproach to poſſeſs a mind ſo conſtituted, it certainly is much to any man's credit to counteract and ſubdue it by an attention to the injunctions of religion. This Mr Parkhurſt effectually did: and few men have paſſed through a long life more at peace with his neighbours, more reſpected by men of learning, more beloved by his friends, or more honoured by his family.

PARKINSON (John). Of this ingenious Engliſh botaniſt, one of the firſt and moſt induſtrious cultivators of that ſcience among us, the memorials that remain are very ſcanty. He was born in 1567, was bred an apothecary, and reſided in London. He roſe to ſuch reputation in his profeſſion as to be appointed apothecary to King James I.; and, on the publication of his Theatre of Plants, he obtained from the unfortunate ſucceſſor of that prince the title of *Botanicus Regis primarius*. The time of his death cannot be exactly aſcertained; but, as his Herbal was publiſhed in 1640, and it appears that he was living at that time, he muſt have attained his 73d year.

Parkinſon's firſt publication was, his 1. *Paradiſi in Sole Paradiſus terreſtris*, or, A Garden of all Sorts of Pleaſant Flowers which our Engliſh Ayre will permit to be nurſed up: with a Kitchen-garden of all manner of Herbes, Roots, and Fruits, for Meat or Sauſe, &c. &c. Collected by John Parkinſon apothecary, of London, 1629, folio, 612 pages. In this work the plants are arranged without any exact order: nearly 1000 plants are ſeparately deſcribed, of which 780 are figured on 129 tables, which appear to have been cut expreſsly for this work. Parkinſon was, it is conceived, the firſt Engliſh author who ſeparately deſcribed and figured the ſubjects of the flower garden; and this book is therefore a valuable curioſity, as exhibiting a complete view of the extent of the Engliſh garden at the beginning of the laſt century. It may, perhaps, be neceſſary to inform the reader, that Paradiſus in Sole, is meant to expreſs the author's name, *Park in-ſun*. 2. In 1640 he publiſhed his *Theatrum Botanicum*; or Theatre of Plants, or an Herbal of a large extent: containing therein, a more ample and exact Hiſtory and declaration of the Phyſical Herbs and Plants than are in other Authors, &c. &c. London, folio, 1746 pages. This work had been the labour of the author's life; and he tells us that, owing to "the diſaſtrous times," and other impediments, the printing of it was long retarded. Dr Pulteney is of opinion, that, allowing for the defects common to the age, Parkinſon will appear "more of an original author than Gerard or Johnſon, independent of the advantages he might derive from being poſterior to them. His theatre was carried on through a long ſeries of years, and he profited by the works of ſome late authors, which Johnſon, though they were equally in his power, had neglected to uſe. Parkinſon's deſcriptions, in many inſtances, appear to be new. He is more particular in pointing out the places of growth. Johnſon had deſcribed about 2850 plants, Parkinſon has near 3800. Theſe accumulations rendered the *Theatrum Botanicum* the moſt copious book on the ſubject in the Engliſh language; and it may be preſumed, that it gained equally the approbation of medical people, and of all thoſe who were curious and inquiſitive in this kind of knowledge."

PARSONS (James), an excellent phyſician and polite ſcholar, was born at Barnſtaple, in Devonſhire, in March 1705. His father, who was the youngeſt of nine ſons of Colonel Parſons, and nearly related to the baronet of that name, being appointed barrack-maſter at Bolton in Ireland, removed with his family into that kingdom ſoon after the birth of his then only ſon James, who received at Dublin the early part of his education, and, by the aſſiſtance of proper maſters, laid a conſiderable foundation of claſſical and other uſeful learning, which enabled him to become tutor to Lord Kingſton. Turning his attention to the ſtudy of medicine, he went afterwards to Paris, where (to uſe his own words) "he followed the moſt eminent profeſſors in the ſeveral ſchools, as Aſtruc, Dubois, Lemery, and others; attended the anatomical lectures of the moſt famous [Hunaud and De Cat]; and chemicals at the King's Garden at St Come. He followed the phyſicians in both hoſpitals of the Hotel Dieu and La Charité, and the chemical lectures and demonſtrations of Lemery and Bouldoc; and in botany Juſſieu. Having finiſhed theſe ſtudies, his profeſſors gave him honourable atteſtations of his having followed them with diligence

Biog. Dict.

gence and induſtry, which intitled him to take the degrees of doctor and profeſſor of the art of medicine, in any univerſity in the dominions of France. Intending to return to England, he judged it unneceſſary to take degrees in Paris, unleſs he had reſolved to reſide there; and as it was more expenſive, he therefore went to the univerſity of Rheims, in Champaign, where, by virtue of his atteſtations, he was immediately admitted to three examinations, as if he had finiſhed his ſtudies in that academy; and there was honoured with his degrees June 11. 1736, In the July following he came to London, and was ſoon employed by Dr James Douglas to aſſiſt him in his anatomical works, where in ſome time he began to practiſe. He was elected a member of the Royal Society in 1740; and, after due examination, was admitted a licentiate of the college of phyſicians April 1. 1751; paying college fees and bond ſtamps of different denominations to the amount of L. 41 : 2 : 8, ſubject alſo to quarterage of L. 2 *per annum*. In 1755 he paid a farther ſum of L. 7, which, with the quarterage money already paid, made up the ſum of L. 16, in lieu of all future payments." On his arrival in London, by the recommendation of his Paris friends, he was introduced to the acquaintance of Dr Mead, Sir Hans Sloane, and Dr James Douglas. This great anatomiſt made uſe of his aſſiſtance, not only in his anatomical preparations, but alſo in his repreſentations of morbid and other appearances; a liſt of ſeveral of which was in the hands of his friend Dr Maty, who had prepared an *eloge* on Dr Parſons, which was never uſed, but which, by the favour of Mrs Parſons, Mr Nichols has preſerved at large. Though Dr Parſons cultivated the ſeveral branches of the profeſſion of phyſic, he was principally employed in the obſtetrical line. In 1738, by the intereſt of his friend Dr Douglas, he was appointed phyſician to the public infirmary in St Giles's. In 1739 he married Miſs Elizabeth Reynolds, by whom he had two ſons and a daughter, who all died young. Dr Parſons reſided for many years in Red Lion Square, where he frequently enjoyed the company and converſation of Dr Stukely, Biſhop Lyttleton, Mr Henry Baker, Dr Knight, and many other of the moſt diſtinguiſhed members of the Royal and Antiquarian Societies, and that of Arts, Manufactures, and Commerce; giving weekly an elegant dinner to a large but ſelect party. He enjoyed alſo the literary correſpondence of D'Argenville, Buffon, Le Cat, Beccaria, Amb. Bertrand, Valltravers, Aſcanius, Turberville Needham, Dr Garden, and others of the moſt diſtinguiſhed rank in ſcience. As a practitioner, he was judicious, careful, honeſt, and remarkably humane to the poor; as a friend, obliging and communicative; chearful and decent in converſation, ſevere and ſtrict in his morals, and attentive to fill with propriety all the various duties of life. In 1769, finding his health impaired, he propoſed to retire from buſineſs and from London; and with that view diſpoſed of a conſiderable number of his books and foſſils, and went to Briſtol. But he returned ſoon after to his old houſe, and died in it after a week's illneſs, on the 4th of April, 1770. By his laſt will, dated in October 1766, he gave his whole property to Mrs Parſons; and in caſe of her death before him, to Miſs Mary Reynolds her only ſiſter, "in recompence for her affectionate attention to him and to his wife, for a long courſe of years, in ſickneſs and in health." It was his particular requeſt, that he ſhould not be buried till ſome change ſhould appear in his corpſe; a requeſt which occaſioned him to be kept unburied 17 days, and even then ſcarce the ſlighteſt alteration was perceivable. He was buried at Hendon, in a vault which he had cauſed to be built on the ground purchaſed on the death of his ſon James, where his tomb had a very commendatory inſcription.

It would carry us beyond our uſual limits to enter into an enumeration of the many curious articles at various times communicated to the public by Dr Parſons, which may be ſeen in the Anecdotes of Bowyer. We ſhall therefore cloſe this article with an extract from Dr Maty's eulogium: "The ſurpriſing variety of branches which Dr Parſons embraced, and the ſeveral living as well as dead languages he had a knowledge of, qualified him abundantly for the place of aſſiſtant ſecretary for foreign correſpondences, which the council of the Royal Society beſtowed upon him about the year 1750. He acquitted himſelf to the utmoſt of his power of the functions of this place, till a few years before his death, when he reſigned in favour of his friend, who now gratefully pays this laſt tribute to his memory. Dr Parſons joined to his academical honours thoſe which the Royal College of Phyſicians of London beſtowed upon him, by admitting him, after due examination, licentiate, on the firſt day of April 1751. The diffuſive ſpirit of our friend was only equalled by his deſire of information To both theſe principles he owed the intimacies which he formed with ſome of the greateſt men of his time. The names of Folkes, Hales, Mead, Stukely, Needham, Baker, Collinſon, and Garden, may be mentioned on this occaſion, and many more might be added. Weekly meetings were formed, where the earlieſt intelligence was received and communicated of any diſcovery both here and abroad; and new trials were made, to bring to the teſt of experience the reality or uſefulneſs of theſe diſcoveries. Here it was that the microſcopical animals found in ſeveral infuſions were firſt produced; the propagation of ſeveral inſects by ſection aſcertained; the conſtancy of Nature amidſt theſe wonderful changes eſtabliſhed. His Remains of Japhet, being Hiſtorical Enquiries into the Affinity and Origin of the European Languages, are a moſt laborious performance, tending to prove the antiquity of the firſt inhabitants of theſe iſlands as being originally deſcended from Gomer and Magog, above 1000 years before Chriſt, their primitive and ſtill ſubſiſting language, and its affinity with ſome others. It cannot be denied but that there is much ingenuity, as well as true learning, in this work, which helps conviction, and often ſupplies the want of it. But we cannot help thinking that our friend's warm feelings now and then miſlead his judgment, and that ſome at leaſt of his conjectures, reſting upon partial traditions, and poetical ſcraps of Iriſh filids and Welſh bards, are leſs ſatisfactory than his tables of affinity between the ſeveral northern languages, as deduced from one common ſtock. Literature, however, is much obliged to him for having in this, as well as in many of his other works, opened a new field of obſervations and diſcoveries. In enumerating our learned friend's diſſertations, we find ourſelves at a loſs whether we ſhould follow the order of ſubjects or of time; neither is it eaſy to account

account for their ſurpriſing variety and quick ſucceſſion. The truth is, that his eagerneſs after knowledge was ſuch, as to embrace almoſt with equal facility all its branches, and with equal zeal to aſcertain the merit of inventions, and aſcribe to their reſpective, and ſometimes unknown, authors, the glory of the diſcovery. Many operations, which the ancients have tranſmitted to us, have been thought fabulous, merely from our ignorance of the art by which they were performed. Thus the burning of the ſhips of the Romans at a conſiderable diſtance, during the ſiege of Syracuſe, by Archimedes, would perhaps ſtill continue to be exploded, had not the celebrated M. Buffon in France ſhewn the poſſibility of it, by preſenting and deſcribing a model of a ſpeculum, or rather aſſemblage of mirrors, by which he could ſet fire at the diſtance of ſeveral hundred feet. In the contriving, indeed, though not in the executing of ſuch an apparatus, he had in ſome meaſure been foreſtalled by a writer now very little known or read. This Dr Parſons proved in a very ſatisfactory manner; and he had the pleaſure to find the French philoſopher did not refuſe to the Jeſuit his ſhare in the invention, and was not at all offended by the liberty he had taken. Another French diſcovery, I mean a new kind of painting fathered upon the ancients, was reduced to its real value, in a paper which ſhewed our author was poſſeſſed of a good taſte for the fine arts: and I am informed that his ſkill in muſic was by no means inferior, and that his favourite amuſement was the flute. Richly, it appears from theſe performances, did our author merit the honour of being a member of the Antiquarian Society, which long ago had aſſociated him to its labours. To another ſociety, founded upon the great principles of humanity, patriotiſm, and natural emulation, he undoubtedly was greatly uſeful (A). He aſſiſted at moſt of their general meetings and committees, and was for many years chairman to that of agriculture; always equally ready to point out and to promote uſeful improvements, and to oppoſe the intereſted views of fraud and ignorance, ſo inſeparable from very extenſive aſſociations. No ſooner was *this* ſociety (B) formed, than Dr Parſons became a member of it. Intimately convinced of the nobleneſs of its views, though from his ſtation in life little concerned in its ſucceſs, he grudged neither attendance nor expence. Neither ambitious of taking the lead, nor fond of oppoſition, he joined in any meaſure he thought right; and ſubmitted cheerfully to the ſentiments of the majority, though againſt his own private opinion. The juſt ideas he had of the dignity of our profeſſion, as well as of the common links which ought to unite all its members, notwithſtanding the differences of country, religion, or places of education, made him bear impatiently the ſhackles laid upon a great number of reſpectable practitioners: he wiſhed, fondly wiſhed, to ſee theſe broken; not with a view of empty honour and dangerous power, but as the only means of ſerving mankind more effectually, checking the progreſs of deſigning men and illiterate practitioners, and diffuſing through the whole body a ſpirit of emulation. Though by frequent diſappointments he foreſaw, as well as we, the little chance of a ſpeedy redreſs, he nobly perſiſted in the attempt; and had he lived to the final event, would undoubtedly, like Cato, ſtill have preferred the conquered cauſe to that ſupported by the gods. After having tried to retire from buſineſs and from London, for the ſake of his health, and having diſpoſed of moſt of his books with that view, he found it inconſiſtent with his happineſs to forſake all the advantages which a long reſidence in the capital, and the many connections he had formed, had rendered habitual to him. He therefore returned to his old houſe, and died in it, after a ſhort illneſs, April 4. 1770. The ſtyle of our friend's compoſition was ſufficiently clear in deſcription, tho' in argument not ſo cloſe as could have been wiſhed. Full of his ideas, he did not always ſo diſpoſe and connect them together, as to produce in the minds of his readers that conviction which was in his own. He too much deſpiſed thoſe additional graces which command attention when joined to learning, obſervation, and ſound reaſoning. Let us hope that his example and ſpirit will animate all his colleagues; and that thoſe practitioners who are in the ſame circumſtances will be induced to join their brethren, ſure to find amongſt them thoſe great bleſſings of life, freedom, equality, information, and friendſhip. As long as theſe great principles ſhall ſubſiſt in this ſociety, and I truſt they will outlaſt the longeſt liver, there is no doubt but the members will meet with the reward honeſt men are ambitious of, the approbation of their conſcience, the eſteem of the virtuous, the remembrance of poſterity."

PARODICAL DEGREES, in an equation, a term that has been ſometimes uſed to denote the ſeveral regular terms in a quadratic, cubic, biquadratic, &c. equation, when the indices of the powers aſcend or deſcend orderly in an arithmetical progreſſion. Thus, $x^3 + mx^2 + nx = p$ is a cubic equation where no term is wanting, but having all its parodic degrees; the indices of the terms regularly deſcending thus, 3, 2, 1, 0.

PARTY ARCHES, in architecture, are arches built between ſeparate tenures, where the property is intermixed, and apartments over each other do not belong to the ſame eſtate.

Party Walls, are partitions of brick made between buildings in ſeparate occupations, for preventing the ſpread of fire. Theſe are made thicker than the external walls: and their thickneſs in London is regulated by act of Parliament of the 14th of George III.

PASSIGRAPHY, the art of writing on any ſubject ſo as to be underſtood by all nations (See *Univerſal Characters* in this *Supplement*). In France, where every thing is admired that is new, and every vagary of the imagination of a pretended philoſopher thought practicable, a propoſal has lately been made to introduce one univerſal language into the world, conſtructed by a few metaphyſicians on the laws of human thought. And to this language, in its written form, is to be given the name of *paſſigraphy*. Such readers as think this idle dream

(c) A Medical Society inſtituted by Dr Fothergill, and other reſpectable phyſicians, licentiates, in vindication of their privileges; where, it ſhould ſeem, this eulogy was intended to be pronounced.

Path, Pearl.

dream worthy their attention (which is far from being the caſe with us), will find ſome ingenious thoughts on the hiſtory of a philoſophical language, in the 2d volume of *Nicholſon's Journal of Natural Philoſophy, &c.*

PATH of the vertex, a term frequently uſed by Mr Flamſteed, in his Doctrine of the Sphere, denoting a circle, deſcribed by any point of the earth's ſurface as the earth turns round its axis. This point is conſidered as vertical to the earth's centre; and is the ſame with what is called the vertex or zenith in the Ptolomaic projection.

PEARL Fish, is commonly conſidered as an *aſcidia* (ſee Mytilus, *Encycl.*); but this is denied by a late author, who ſeems to have paid great attention to the pearl-fiſhery at Ceylon. It has never, he ſays, been accurately deſcribed. It does not reſemble the *aſcidia* of Linnæus; and as he thinks it may form a new genus, he gives the following account of it:

"The fiſh is faſtened to the upper and lower ſhells by two white flat pieces of muſcular ſubſtance, which have been called ears, and extend about two inches from the thick part of the body, growing gradually thinner. The extremity of each ear lies looſe, and is ſurrounded by a double brown fringed line. Theſe lie almoſt the third part of an inch from the outer part of the ſhell, and are continually moved by the animal. Next to theſe, above and below, are ſituated two other double fringed moveable ſubſtances, like the bronchiæ of a fiſh. Theſe ears and fringes are joined to a cylindrical piece of fleſh of the ſize of a man's thumb, which is harder and of a more muſcular nature than the reſt of the body. It lies about the centre of the ſhells, and is firmly attached to the middle of each. This, in fact, is that part of the pearl-fiſh which ſerves to open and ſhut the ſhells. Where this column is faſtened, we find on the fleſh deep impreſſions, and on the ſhell various nodes of round or oblong forms, like imperfect pearls. Between this part and the hinge (*cardo*) lies the principal body of the animal, ſeparated from the reſt, and ſhaped like a bag. The mouth is near the hinge of the ſhell, enveloped in a veil, and has a double flap or lip on each ſide; from thence we obſerve the throat (*œſophagus*) deſcending like a thread to the ſtomach. Cloſe to the mouth there is a curved browniſh tongue, half an inch in length, with an obtuſe point; on the concave ſide of this deſcends a furrow, which the animal opens and ſhuts, and probably uſes to convey food to its mouth. Near its middle are two bluiſh ſpots, which ſeem to be the eyes. In a pretty deep hole, near the baſe of the tongue, lies the beard (*byſſus*), faſtened by two fleſhy roots, and conſiſting of almoſt 100 fibres, each an inch long, of a dark green colour, with a metallic luſtre; they are undivided, parallel, and flattened. In general, the *byſſus* is more than three quarters of an inch without the cleſt (*rima*); but if the animal is diſturbed, it contracts it conſiderably. The top of each of theſe threads terminates in a circular gland or head, like the *ſtigma* of many plants. With this *byſſus* they faſten themſelves to rocks, corals, and other ſolid bodies; by it the young pearl-fiſh cling to the old ones, and with it the animal procures its food, by extending and contracting it at pleaſure. Small ſhell fiſh, on which they partly live, are often found clinging to the former. The ſtomach lies cloſe to the root of the beard, and has, on its lower ſide, a protracted obtuſe point. Above the ſtomach are two ſmall red bodies, like lungs; and from the ſtomach goes a long channel or gut, which takes a circuit round the muſcular column above-mentioned, and ends in the anus, which lies oppoſite to the mouth, and is covered with a ſmall thin leaf, like a flap. Though the natives pretend to diſtinguiſh the ſexes by the appearance of the ſhell, calling the flat ones males, and thoſe which are thick, concave, and vaulted, females, our author, on a cloſe inſpection, could not perceive any viſible ſexual difference."

Pearl, Pedom

The pearls are only in the ſofter part of the animal, and never in the firm muſcular column above-mentioned. They are found, in general, near the earth, and on both ſides of the mouth. From the appearance of the ſhell a judgment may be formed, with greater or leſs probability, whether it contains pearls or not. Thoſe which have a thick calcareous cruſt upon them, to which *ſerpulæ* (ſea tubes) *Tubuli marini irregulariter intorti, Criſta-gali Chamar lazuras, Lepas tintinabulum, Madreporee, Millipore, Cellipore, Gorgontæ, Spongiæ*, and other Zoophytes, are faſtened, have arrived at their full growth, and commonly contain the beſt pearls; but thoſe that appear ſmooth, contain either none, or ſmall ones only.

In the article (*Encycl.*) intitled, *Manner of Fiſhing for Pearls in the Eaſt Indies*, we have moſt unaccountably ſaid, that "the beſt divers will keep under water near *half an hour*, and the reſt not leſs than a quarter!" This is a very great miſtake; for M. *Le Beck* aſſures us, that the time during which a diver is able to remain under water ſeldom exceeds two minutes; and that, even after that ſhort period, he diſcharges, on emerging from the ſea, a quantity of water, and ſometimes a little blood, from his mouth and noſe. We have mentioned the danger which the divers run of becoming a prey to monſtrous fiſhes. Theſe fiſhes are ſharks; of which ſuch a dread is juſtly entertained, that the moſt expert divers will not, on any account, deſcend, till the conjurer has performed his ceremonies of inchantment. Theſe conſiſt in a number of prayers, learned by heart, that nobody, probably not even the conjurer himſelf, underſtands, which he, ſtanding on the ſhore, continues muttering and grumbling from ſun riſe until the boats return. During this period, he is obliged to abſtain from food and ſleep, otherwiſe his prayers would have no avail: he is, however, allowed to drink; which privilege he indulges in a high degree, and is frequently ſo giddy, as to be rendered very unfit for devotion. Some of the conjurers accompany the divers in their boats; which pleaſes them very much, as they have their protectors near at hand.

PEDOMETER (ſee *Encycl.*), is the name given by Mr Lewin Thugwell to an inſtrument, which is rather an improved perambulator than the inſtrument which we have noticed by the name of Pedometer. The chief improvement made by him on the perambulator (ſee that article, *Encycl.*) is in the ſize of the wheel, of which the circumference meaſures 16½ feet, or one pole, adapted to Gunter's conciſe method of arithmetic, and divided into 25 equal parts, correſponding to the links of his chain for land meaſuring. There is likewiſe a contrivance in Mr Thugwell's pedometer, for compelling the attention of the traveller to the inſtrument at the end of every mile. It is very ingenious, and abundantly ſimple; but we hardly think it of ſufficient

cient importance to fill the ſpace which a complete deſcription of it would occupy in this Work. It is fully deſcribed in the *Letters and Papers of the Bath and Weſt of England Society, for the Encouragement of Agriculture*, and likewiſe in the 6th volume of the *Repertory of Arts and Manufactures*.

PEGUE, the ancient capital of the kingdom of the ſame name (ſee Pegu, *Encycl.*), appears to have been a quadrangle, each ſide meaſuring about a mile and a half. It was ſurrounded by a ditch and wall; which, before the latter tumbled down, and the former was filled up, muſt have furniſhed no contemptible defence. The breadth of the ditch appears to be about 60 yards; its depth, where not choked up, about ten or twelve feet; and there is ſtill in it water enough to impede an eaſtern ſiege. The wall has been at leaſt 25 feet high, and its breadth at the baſe not leſs than 40. It is compoſed of brick, badly cemented together with clay mortar, and has had on it ſmall equidiſtant baſtions, about 300 yards aſunder.

Nothing can exhibit a more ſtriking picture of deſolation than the inſide of this wall. We have elſewhere given an account of the almoſt inceſſant wars between the kings of Pegue and Birma or Barma. In the year 1757, the Birman ſovereign carried the city of Pegue by aſſault, razed every dwelling to the ground, and diſperſed, or led into captivity, all the inhabitants. The pagodas, which are very numerous, were the only buildings that eſcaped the fury of the conqueror; and of theſe the great pagoda of Shoemadoo has alone been attended to, and repaired.

This extraordinary edifice is built on a double terrace, one raiſed upon another. The lower and greater terrace is about ten feet above the natural level of the ground. It is quadrangular. The upper and leſſer terrace is of a like ſhape, raiſed about 20 feet above the lower terrace, or 30 above the level of the country. Theſe terraces are aſcended by flights of ſtone ſteps, broken and neglected. On each ſide are dwellings of the *Rahaans* or prieſts, raiſed on timbers four or five feet from the ground. Their houſes conſiſt only of a ſingle hall. The wooden pillars that ſupport them are turned with neatneſs. The roof is of tile, and the ſides of ſheathing-boards. There are a number of bare benches in every houſe, on which the *Rahaans* ſleep. They appear to have no furniture.

Shoemadoo is a pyramid, compoſed of brick and plaſter, with fine ſhell mortar, without excavation or aperture of any ſort; octagonal at the baſe, and ſpiral at the top. Six feet from the ground there is a wide ledge, which ſurrounds the baſe of the building; on the plane of which are 57 ſmall ſpires, of equal ſize, and equidiſtant. One of them meaſured 27 feet in height, and 40 in circumference at the bottom. On a higher ledge there is another row, conſiſting of 53 ſpires, of ſimilar ſhape and meaſurement. A great variety of mouldings encircles the building; and ornaments, ſomewhat reſembling the *fleur de lys*, ſurround what may be called the baſe of the ſpire. Circular mouldings likewiſe gird this part to a conſiderable height; above which there are ornaments in ſtucco, not unlike the leaves of a Corinthian capital; and the whole is crowned by a *tee*, or umbrella of open iron-work, from which riſes an iron rod with a gilded penant.

The extreme height of the building, from the level of the country, is 361 feet; and above the interior terrace, 331 feet. On the ſouth-eaſt angle of the upper terrace there are two handſome ſaloons, or *keouns*, lately erected. The roof is compoſed of different ſtages, ſupported by pillars. Captain Symes, from whoſe memoir in the Aſiatic Reſearches this account is taken, judged the length of each ſaloon to be about 60 feet, and the breadth 30. The ceiling of one of them was already embelliſhed with gold leaf, and the pillars lacquered; the other, when he ſaw it, was not completed. They are made entirely of wood. The carving on the outſide is very curious. He ſaw ſeveral unfiniſhed figures, intended to be fixed on different parts of the building; ſome of them not ill ſhapen, and many exceedingly groteſque. Splendid images of Gaudma (the *Birman* object of adoration) were preparing, which he underſtood were deſigned to occupy the inſide of theſe *keouns*.

At each angle of the interior terrace is a pyramidical pagoda, 67 feet in height, reſembling, in miniature, the great pagoda. In front of the one in the ſouth-weſt corner are four gigantic repreſentations in maſonry of Palloo, or the *man deſtroyer*, half beaſt, half human, ſeated on their hams, each with a large club on the right ſhoulder.

Nearly in the centre of the eaſt face of the area are two human figures in ſtucco beneath a gilded umbrella. One ſtanding, repreſents a man with a book before him, and a pen in his hand. He is called *Thagiamee*, the recorder of mortal merits and mortal miſdeeds. The other, a female figure kneeling, is *Maha Sumdere*, the protectreſs of the univerſe, as long as the univerſe is doomed to laſt: but when the time of general diſſolution arrives, by her hand the world is to be overwhelmed, and deſtroyed everlaſtingly.

On the north ſide of the great pagoda are three large bells, of good workmanſhip, ſuſpended near the ground between pillars. Several deers horns are ſtrewed around. Thoſe who come to pay their devotions firſt take up one of the horns, and ſtrike the bell three times, giving an alternate ſtroke to the ground. This act is to announce to the ſpirit of Gaudma the approach of a ſuppliant. There are ſeveral low benches near the bottom of the pagoda, on which the perſon who comes to pray places his offering; which generally conſiſts of boiled rice, a plate of ſweetmeats, or cocoa-nut fried in oil. When it is given, the devotee cares not what becomes of it. The crows and dogs commonly eat it up in the preſence of the donor, who never attempts to prevent or moleſt the animals.

There are many ſmall pagodas on the areas of both terraces, which are neglected, and ſuffered to fall into decay. Numberleſs images of Gaudma lie indiſcriminately ſcattered. A pious Birman who purchaſes an idol, firſt procures the ceremony of conſecration to be performed by the *Rahaans*, then takes his purchaſe to whatever ſacred building is moſt convenient, and there places it either in the ſhelter of a *keoun*, or on the open ground before the temple: nor does he ever after ſeem to have any anxiety about its preſervation, but leaves the divinity to ſhift for itſelf.

From the upper ledge that ſurrounds the baſe of Shoemadoo, the proſpect of the country is extenſive and pictureſque; but it is a proſpect of Nature in her rudeſt ſtate. There are few inhabitants, and ſcarcely any cultivation. The hills of *Martaban* riſe to the eaſtward; and the *Sitang* river, winding along the plains, gives here and there an interrupted view of its waters. To the north-north weſt, above 40 miles, are the *Galladzet* hills, whence the Pegue river takes its riſe; hills remarkable only for the noiſome effects of their atmoſphere. In every other direction the eye looks over a boundleſs plain, chequered by a wild intermixture of wood and water.

The preſent king of the Birmans has entirely altered the ſyſtem of his predeceſſors. He has turned his attention to the population and improvement, rather than the extenſion, of his dominions; and ſeems more deſirous to conciliate his new ſubjects by mildneſs, than to rule them through terror. He has abrogated ſeveral ſevere penal laws impoſed upon the *Taliens* or Peguers: juſtice is now diſtributed impartially; and the only diſtinction at preſent between a Birman and Talien conſiſts in the excluſion of the latter from all public offices of truſt and power.

No act of the Birman government is more likely to reconcile the Taliens to the Birman yoke than the reſtoration of their ancient place of abode. and the preſervation and embelliſhment of the pagoda of Shoemadoo. So ſenſible was the king of this, as well as of the advantages that muſt accrue to the ſtate from an increaſe of culture and population, that ſome years ago he iſſued orders to rebuild Pegue, encouraged new ſettlers by liberal grants, and invited the ſcattered families of former inhabitants to return and repeople their deſerted city.

Pegue, in its renovated ſtate, ſeems to be built on the plan of the former city. It is a ſquare, each ſide meaſuring about half a mile. It is fenced round by a ſtockade, from 10 to 12 feet high. There is one main ſtreet running eaſt and weſt, which is interſected at right angles by two ſmaller ſtreets, not yet finiſhed. At each extremity of the principal ſtreet there is a gate in the ſtockade, which is ſhut early in the evening. After that hour, entrance during the night is confined to a wicket. Each of theſe gates is defended by a ſorry piece of ordnance, and a few muſqueteers, who never poſt centinels, and are uſually aſleep. There are alſo two other gates on the north and ſouth ſides of the ſtockade.

The houſes of the inhabitants of Pegue are far from commodious, agreeably to European notions of accommodation; but they are at leaſt as much ſo as the houſes of other Indian towns. There are no brick buildings in Pegue, except ſuch as belong to the king, or are dedicated to Gaudma. The king has prohibited the uſe of brick or ſtone in private buildings, from the apprehenſion, that if people got leave to build brick houſes, they might erect brick fortifications, dangerous to the ſecurity of the ſtate. The houſes, therefore, are all made of mats or ſheathing boards, ſupported on bamboos or poſts. Being compoſed of ſuch combuſtible materials, the inhabitants are under continual dread of fire, againſt which they take every precaution. The roofs are lightly covered; and at each door ſtands a long bamboo, with a hook at the end, to pull down the thatch: alſo another pole, with a grating of ſplit bamboo at the extremity, about three feet ſquare, to ſuppreſs flame by preſſure. Almoſt every houſe has earthen pots of water on the roof. And there is a particular claſs of people, whoſe buſineſs it is to prevent and extinguiſh fires.

PEISHCAR, in Bengal, principal in office.

PEISHCUSH, a fine, tribute, or preſent.

PELL (Dr John), an eminent Engliſh mathematician, deſcended from an ancient family in Lincolnſhire, was born at Southwick in Suſſex, March 1. 1610, where his father was miniſter. He received his grammar education at the free ſchool at Stenning in that county. At the age of 13 he was ſent to Trinity college in Cambridge, being then as good a ſcholar as moſt maſters of arts in that univerſity; but though he was eminently ſkilled in the Greek and Hebrew languages, he never offered himſelf a candidate at the election of ſcholars or fellows of his college. His perſon was handſome; and being of a ſtrong conſtitution, uſing little or no recreations, he proſecuted his ſtudies with the more application and intenſeneſs.

In 1629 he drew up the "Deſcription and Uſe of the Quadrant, written for the Uſe of a Friend," in two books; the original manuſcript of which is ſtill extant among his papers in the Royal Society. And the ſame year he held a correſpondence with Mr Briggs on the ſubject of logarithms.

In 1630, he wrote *Modus ſupputandi Ephemerides Aſtronomicas, &c. ad an.* 1630 *accommodatus*; and, A Key to unlock the meaning of Johannes Trithemius, in his Diſcourſe on Steganography: which Key he imparted to Mr Samuel Hartlib and Mr Jacob Homedæ. The ſame year he took the degree of Maſter of Arts at Cambridge. And the year following he was incorporated in the univerſity of Oxford. June the 7th, he wrote A Letter to Mr Edmond Wingate on Logarithms: and, Oct. 5. 1631, *Commentationes in Coſmographiam Alſtedii.*

In 1632 he married Ithamaria, ſecond daughter of Mr Henry Reginolles of London, by whom he had four ſons and four daughters.—March 6. 1634, he finiſhed his "Aſtronomical Hiſtory of Obſervations of Heavenly Motions and Appearances;" and April the 10th, his *Ecliptica Prognoſtica*, or Foreknower of the Eclipſes, &c. In 1634 he tranſlated "The Everlaſting Tables of Heavenly Motions," grounded upon the Obſervations of all Times, and agreeing with them all, by Philip Lanſberg, of Ghent in Flanders. And June the 12th, the ſame year, he committed to writing "The Manner of Deducing his Aſtronomical Tables out of the Tables and Axioms of Philip Lanſberg."—March the 9th, 1625, he wrote "A Letter of Remarks on Gellibrand's Mathematical Diſcourſe on the Variation of the Magnetic Needle." And the 3d of June following, another on the ſame ſubject.

His eminence in mathematical knowledge was now ſo great, that he was thought worthy of a Profeſſor's chair in that ſcience; and, upon the vacancy of one at Amſterdam in 1639, Sir William Boſwell, the Engliſh Reſident with the States General, uſed his intereſt, that he might ſucceed in that Profeſſorſhip. It was not filled up, however, till 1642, when Pell was choſen to it; and he read with great applauſe public lectures upon Diophantus.—In 1644 he printed at Amſterdam, in two pages 4to, "A Refutation of Longomontanus's Diſcourſe," *De Vera Circuli Menſura.*

In 1646, on the invitation of the Prince of Orange, he removed to the new college at Breda, as Profeſſor of Mathematics, with a ſalary of 1000 guilders a year. His *Idea Matheſeos*, which he had addreſſed to Mr Hartlib, who in 1639 had ſent it to Des Cartes and Merſenne, was printed 1650 at London, in 12mo, in Engliſh, with the title of *An Idea of Mathematics*, at the end of Mr John Durie's Reformed Library keeper. It is alſo printed by Mr Hook, in his Philoſophical Collections, N° 5. p. 127.; and is eſteemed our author's principal work.

In 1652 Pell returned to England; and in 1654 he was ſent by the protector Cromwell agent to the Proteſtant Cantons in Switzerland; where he continued till June 23. 1658, when he ſet out for England, where he arrived about the time of Cromwell's death. His negociations abroad gave afterwards a general ſatisfaction, as it appeared he had done no ſmall ſervice to the intereſt of King Charles II. and of the church of England; ſo that he was encouraged to enter into holy orders: and in the year 1661 he was inſtituted to the rectory of Fobbing in Eſſex, given him by the king. In December that year, he brought into the upper houſe of convocation the calendar reformed by him, aſſiſted by Sancroft, afterwards archbiſhop of Canterbury. In 1673 he was preſented by Sheldon, biſhop of London, to the rectory of Laingdon in Eſſex; and, upon the promotion of that biſhop to the ſee of Canterbury ſoon after, became one of his domeſtic chaplains. He was then doctor of divinity, and expected to be made a dean; but his improvement in the philoſophical and mathematical ſciences was ſo much the bent of his genius, that he did not much purſue his private advantage. The truth is, he was a helpleſs man, as to worldly affairs; and his tenants and relations impoſed upon him, cozened him of the profits of his parſonage, and kept him ſo indigent, that he wanted neceſſaries, even ink and paper, to his dying day. He was for ſome time confined to the King's bench priſon for debt; but, in March 1682, was invited by Dr Whitler to live in the college of phyſicians. Here he continued till June following; when he was obliged, by his ill ſtate of health, to remove to the houſe of a grandchild of his in St Margaret's church-yard, Weſtminſter. But he died at the houſe of Mr Cothorne, reader of the church of St Giles's in the Fields, December the 12th, 1685, in the 74th year of his age, and was interred at the expence of Dr Buſby, maſter of Weſtminſter ſchool, and Mr Sharp, rector of St Giles's, in the rector's vault under that church.—Dr Pell publiſhed ſome other things not yet mentioned; a liſt of which is as follows, *viz.*

1. An Exercitation concerning Eaſter; 1644, in 4to. 2. A Table of 10,000 ſquare numbers, &c.; 1672, folio. 3. An Inaugural Oration at his entering upon the Profeſſorſhip at Breda. 4. He made great alterations and additions to Rhonius's Algebra, printed at London 1668, 4to, under the title of An Introduction to Algebra, tranſlated out of the High Dutch into Engliſh by Thomas Branker, much altered and augmented by D. P. (Dr Pell). Alſo a Table of Odd Numbers, leſs than 100,000, ſhewing thoſe that are incompoſite, &c. ſupputated by the ſame Thomas Branker. 5. His Controverſy with Longomontanus concerning the Quadrature of the Circle; Amſterdam, 1646, 4to.

He likewiſe wrote a Demonſtration of the 2d and 10th books of Euclid; which piece was in MS. in the library of Lord Brereton in Cheſhire: as alſo Archimedes's Arenarius, and the greateſt part of Diophantus's ſix books of Arithmetic; of which author he was preparing, Auguſt 1644, a new edition, in which he intended to correct the tranſlation, and make new illuſtrations. He deſigned likewiſe to publiſh an edition of Apollonius; but laid it aſide, in May 1645, at the deſire of Golius, who was engaged in an edition of that author from an Arabic manuſcript, given him at Aleppo 18 years before. Letters of Dr Pell to Sir Charles Cavendiſh, in the Royal Society.

Some of his manuſcripts he left at Brereton in Cheſhire, where he reſided ſome years, being the ſeat of William Lord Brereton, who had been his pupil at Breda. A great many others came into the hands of Dr Buſby; which Mr Hook was deſired to uſe his endeavours to obtain for the Society. But they continued buried under duſt, and mixed with the papers and pamphlets of Dr Buſby, in four large boxes, till 1755; when Dr Birch, ſecretary to the Royal Society, procured them for that body, from the truſtees of Dr Buſby. The collection contains, not only Pell's mathematical papers, letters to him, and copies of thoſe from him, &c. but alſo ſeveral manuſcripts of Walter Warner, the mathematician and philoſopher, who lived in the reigns of James I. and Charles I.

Dr Pell invented the method of ranging the ſeveral ſteps of an algebraical calculus, in a proper order, in ſo many diſtinct lines, with the number affixed to each ſtep, and a ſhort deſcription of the operation or proceſs in the line. He alſo invented the character ÷ for diviſion, ⊚ for involution, ɯ for evolution *.

PELLETIER (Bertrand), was born at Bayonne in 1761, and very ſoon began to diſplay an inſatiable thirſt of ſcience. It frequently happens, however, that young men, ſincerely deſirous of inſtruction, have no means or place where they can be aſſiſted in the developement of their natural talents, no maſter who may point out the direct road to ſcience, and that order and method, without which the efforts of the individual too often lead him from the object of his purſuit, inſtead of bringing him nearer to it. This was not the caſe with young Pelletier. He found every advantage in his father's houſe, where he received the firſt elements of the art of which he was afterwards the ornament; and his ſubſequent progreſs was made under Darcet, who having remarked in him that ſagacity which may be called the inſtinct of ſcience, admitted him among the pupils attached to the chemical laboratory of the college of France. Five years of conſtant application and ſtudy under ſuch a maſter, who was himſelf formed by nature, perfected by experience, and affectionately diſpoſed towards his pupil, afforded this young man a ſtock of knowledge very unuſual at his age. He ſoon gave a convincing proof of this, by publiſhing, at the age of 21, a ſet of very excellent obſervations on the arſenical acid. Macquer, by mixing nitre with the oxyd of arſenic, had diſcovered in the reſidue of this operation a ſalt ſoluble in water, ſuſceptible of cryſtallization in tetrahedral priſms, which he denominated the neutral

---

* *Hutton's Mathematical Dictionary.*

arſenical ſalt. It is the arſeniat of potaſh. He was of opinion that no acid could decompoſe it; but Pelletier ſhewed, that the ſulphuric acid diſtilled from it does diſengage the acid of arſenic. He ſhewed the true cauſe why the neutral arſenical ſalt is not decompoſable in cloſed veſſels; and particularly the order of affinity by which the ſalt itſelf is formed in the diſtillation of the nitrate of potaſh, and the white oxyd of arſenic. He explains in what reſpects this ſalt differs from what Macquer called the liver of arſenic. Pelletier had been anticipated in this work by Scheele, by Bergman, by the academicians of Dijon, and by Berthollet; but he poſſeſſed at leaſt the merit, in the firſt eſſay of his powers, of having clearly developed all the phenomena of this operation, by retaining and even determining the quantity of gas it was capable of affording. After the ſame principles it was that he decompoſed the arſenico-ammoniacal ſalt, by ſhewing how, in the decompoſition of this laſt, the pure arſenical acid is obtained in the form of a deliqueſcent glaſs. In this work we may obſerve the ſagacity with which he was enabled to develope all the phenomena of theſe compoſitions and decompoſitions, by tracing thoſe delicate threads of ſcientific relation which connect the ſeries of facts, and are imperceptible to ordinary minds.

Encouraged by the ſucceſs of theſe firſt works, which he preſented with the ſenſibility of grateful attachment to his inſtructor, he communicated his obſervations on the cryſtallization of ſulphur, cinnabar, and the deliqueſcent ſalts; the examination of zeolites, particularly the falſe zeolite of Fribourg in Briſgaw, which he found to be merely an ore of zinc; obſervations on the dephlogiſticated or oxygenated muriatic acid, relative to the abſorption of oxygen; on the formation of ethers, particularly the muriatic and the acetous; and ſeveral memoirs on the operation of phoſphorus made in the large way; its converſion into phoſphoric acid, and its combination with ſulphur and moſt metallic ſubſtances.

It was by his operations on that moſt aſtoniſhing production of chemiſtry, phoſphorus, that he burned himſelf ſo dangerouſly as nearly to have loſt his life. After the cure of his wound, which confined him to his bed for ſix months, he immediately began the analyſis of the various plumbagos of France, England, Germany, Spain, and America, and found means to give novelty and intereſt to his work, even after the publication of Scheele on the ſame object. The analyſis of the carbonat of barytes led him to make experiments on animals; which prove that this earth is a true poiſon, whether it be adminiſtered in the form of the native carbonat of barytes, or whether it be taken from the decompoſition of the ſulphat, even though again combined with another acid.

Chemiſts have given the name of *ſtrontian* to a newly diſcovered earth, from the name of the place where it was firſt found. Pelletier analyſed it, and diſcovered it in the ſulphat of barytes. He likewiſe analyſed the verditer of England, of which painters and paper-hangers make ſo much uſe. He diſcovered a proceſs for preparing it in the large way, by treating with lime the precipitate obtained from the decompoſition of nitrat of copper by lime. By his proceſs, verditer is afforded equal in beauty to that which comes from England. He was likewiſe one of the firſt chemiſts who ſhewed the poſſibility of refining bell metal, and ſeparating the tin. His firſt experiments were made at Paris; after which he repaired to the foundry at Romilly, to verify them in the large way. The following year he was received a member of the Academy of Sciences at Paris, and ſhortly afterwards went to La Fere, with Borda and General Daboville, to aſſiſt in experiments upon a new gunpowder. Being obliged, in order to render his experiments more deciſive, to paſs great part of the day in the open air during a cold and humid ſeaſon. his health, which was naturally delicate, became conſiderably impaired. He began to recover his health, when he again became the victim of his zeal for the ſcience he ſo ſucceſsfully cultivated. He had nearly periſhed by reſpiring the oxygenated muriatic acid gas. A violent attack of convulſive aſthma, which returned during ſeveral days, was the firſt conſequence of this unhappy accident. The diſorder then ſeemed to abate; but it was incurable. The aſſiſtance of art was inſufficient to ſave him; and he died in Paris, on the 21ſt of July 1797, of a pulmonary conſumption, in the flower of his age.

PENDULUM (See *Encycl.*). Beſides the effects of heat and cold on the length of the pendulum rod, and of courſe on its iſochroniſm, it may certainly be worth while, in the conſtruction of clocks intended to meaſure time with the utmoſt poſſible exactneſs, to take into conſideration the reſiſtance of the air, which, by its unequal denſity, varying the weight of the pendulum, muſt in a ſmall degree accelerate or retard its motion. The celebrated David Rittenhouſe, who paid particular attention to this ſubject, eſtimates the extreme difference of velocity, ariſing from this cauſe, at half a ſecond a day; and he obſerves, that a remedy dependent on the barometer will not be ſtrictly accurate, as the weight of the entire column of air does not preciſely correſpond with the denſity of its baſe. He propoſes, therefore, as a very ſimple and eaſy remedy, that the pendulum ſhall, as uſual, conſiſts of an inflexible rod carrying the ball beneath, and continued above the centre of ſuſpenſion to an equal (or an unequal) diſtance upwards. At this extremity is to be fixed another ball of the ſame dimenſions (or greater or leſs, according as the continuation is ſhorter or longer), but made as light as poſſible. The oſcillations of this upper ball will be accelerated by its buoyancy by the ſame quantity as thoſe of the lower would be retarded; and thus, by a proper adjuſtment, the two effects might be made to balance and correct each other.

Our author made a compound pendulum on theſe principles, of about one foot in its whole length. This pendulum, on many trials, made in the air 57 vibrations in a minute. On immerſing the whole in water, it made 59 vibrations in the ſame time; ſhewing evidently, that its returns were quicker in ſo denſe a medium as water than in the air. (This is contrary to what takes place with the common pendulum). When the lower bob or pendulum only was plunged in water, it made no more than 44 vibrations in a minute.

PENNANT (Thomas, Eſq.), ſo well known in the republic of letters as a writer of travels and of natural hiſtory, was an ancient Briton by birth, having drawn his firſt breath in Flintſhire, in 1726. His family has been ſettled in that county for many centuries; we learn from himſelf that he received the rudiments of his education at Wrexham, whence he was removed to Fulham. Soon after this he was ſent to Oxford; and having

ving made a conſiderable proficiency in the claſſics, he applied himſelf within the walls of that univerſity to attain a knowledge of juriſprudence; but we do not find that he ever entered himſelf of any of the inns of court, or followed the law as a profeſſion.

The ruling paſſions of mankind are excited, and the future current of their lives frequently directed, by trivial circumſtances. One of the greateſt painters of our age was attracted with an irreſiſtible impulſe towards his art by the peruſal of a treatiſe on it; and we have the authority of the ſubject of this memoir for aſſerting, that a preſent of Willughby's Ornithology, at an early period, firſt gave him a turn for natural hiſtory, which has never once abandoned him through the courſe of a very long life.

Mr Pennant commenced his travels with great propriety at home, where he made himſelf acquainted with the manners, productions, and curioſities, of his native country, before he ſallied forth to inſpect thoſe of other nations. He then repaired to the continent; and not only acquired conſiderable additional knowledge relative to his favourite ſtudies, but became acquainted, and eſtabliſhed a correſpondence, with ſome of the greateſt men of the age.

On his return he married, and had two children, but did not come into the family fortune until he was thirty-ſeven years of age, at which time he was ſettled at Downing.

Having loſt his wife, he appears to have ſet out once more for the continent, and to have formed an acquaintance with Voltaire, Buffon, Haller, Pallas, &c. He had by this time acquired conſiderable reputation as a ſcientific man, having commenced his career as an author ſo early as 1750. His Britiſh Zoology * eſtabliſhed his reputation as a naturaliſt; and this received a freſh acceſſion of celebrity in conſequence of his acquaintance with Linnæus, and his intercourſe by letters with all the celebrated naturaliſts in Europe.

Early in life he had undertaken a moſt intereſting tour to Cornwall; and he now entertained an ardent deſire to ſurvey the works of nature in the northern extremities of the iſland. He accordingly ſet out for Scotland, and in 1771 favoured the public with an entertaining account of his Tour †, which was ſo well received as to paſs through ſeveral editions. Not content with the main land of Great Britain, he was ambitious to ſurvey the iſlands in the vicinity, and accordingly penetrated to the Hebrides, and viſited Man.

It is not to be ſuppoſed that he would leave his own country unexplored; on the contrary, he minutely deſcribed all its wonders. He did not fail on this occaſion to preſent the world with the reſult of his enquiries, for in 1778 he commenced the publication of his Welch Tour §.

In four years after this (1782) appeared the account of the Journey from Cheſter to London ‡, in which he refutes the vulgar opinion that it is unintereſting; and in two years more his Arctic Zoology, an admirable work, greatly prized both here and in other countries.

In 1790 appeared a quarto volume, ſimply entitled Of London; in which he obſerves that this work is compoſed from obſervations, originally made without any view of publication. "Let me requeſt (ſays he in the preface) the good inhabitants of London and Weſtminſter not to be offended at my having ſtuffed their Iliad into a nutſhell; the account of the city of London and liberties of Weſtminſter into a quarto volume. I have condenſed into it all I could; omitted nothing that ſuggeſted itſelf; nor amplified any thing to make it a guinea book. In a word, it is done in my own manner, from which I am grown too old to depart.

"I feel within myſelf a certain monitor that warns me (adds he) to hang up my pen in time, before its powers are weakened, and rendered viſibly impaired. I wait not for the admonition of friends. I have the Archbiſhop of Grenada in my eye; and fear the imbecility of human nature might produce in long-worn age the ſame treatment of my kind adviſers as poor Gil Blas had from his moſt reverend patron. My literary bequeſts to future times, and more ſerious concerns, muſt occupy the remnant of my days. This cloſes my public labours."

Notwithſtanding his parting addreſs, the example of the Archbiſhop of Grenada, and the concluding ſentence of "*Valete & Plaudite*," we find Mr Pennant adventuring once more in the ocean of literature, at a late period of his life, and trying his fortune again with all the eagerneſs of a young author.

He accordingly publiſhed the Natural Hiſtory of the pariſhes of Holywell and Downing *, within the precincts of the latter of which he had reſided about half a century.

He alſo preſented the public, a very ſhort time before his death, with a ſplendid work, conſiſting of 2 vols. 4to. entitled The View of Hindooſtan; in the preface to which he candidly ſtates his motives for this new attempt. "I had many ſolicitations from private friends (ſays he), and a few wiſhes from perſons unknown, delivered in the public prints, to commit to the preſs a part, in the form in which the poſthumous volumes might hereafter make their appearance. I might have pleaded the imprudence of the attempt at my time of life, of beginning ſo arduous an undertaking in my 71ſt year.

"I happily, till very lately, had ſcarcely any admonition of the advanced ſeaſon. I plunged into the ſea of trouble, and with my papers in one hand, made my way through the waves with the other, and brought them ſecure to land. This, alas! is finite boaſting. I muſt ſubmit to the judgment of the public, and learn from thence how far I am to be cenſured for ſo grievous an offence againſt the maxim of Ariſtotle, who fixes the decline of human abilities to the 49th year.

"I ought to ſhudder, when I conſider the wear and tear of 22 years; and feel ſhocked at the remark of the elegant Delanty, who obſerves, 'that it is generally agreed among wiſe men, that few attempts, at leaſt in a learned way, have ever been wiſely undertaken and happily executed after that period!'

"I cannot defend the wiſdom: yet from the good fortune of my life I will attempt the execution."

Theſe valuable volumes are drawn up by Mr Pennant in the manner of his introduction to the Arctic Zoology. The plates, 23 in number, are admirably engraved, and one (the Napaul pheaſant) is beautifully coloured.

In addition to the liſt of literary labours already enumerated, is a letter on an earthquake felt at Downing, in Flintſhire, in 1753; another inſerted in the ſame publi-

publication *, in 1756, on coralloid bodies (κοραλλοειδης) collected by him: his Synopſis of Quadrupeds, publiſhed in 1771; a pamphlet on the Militia; a paper on the Turkey; and a volume of Miſcellanies.

Mr Pennant attained academical honours of all kinds, having had the degree of LL. D. conferred on him by the univerſity in which he was educated, he was a Fellow of the Royal Society, and a member of the Society of Antiquaries, a Fellow of the Royal Society of Upſal in Sweden, a member of the American Philoſophical Society, an honorary member of the Anglo-Linnæan Society, &c.

The ample fortune left him by his father enabled Mr Pennant to keep an hoſpitable table, and alſo to preſent the profits of ſeveral of his works to public inſtitutions, particularly the Welſh charity-ſchool in Gray's-inn-lane. He encouraged ſeveral engravers by his patronage, and was not a little ſerviceable to the advancement of the fine arts.

In 1776 he married a ſecond time; on which occaſion he became united to Miſs Moſtyn, ſiſter of his neighbour, the late Sir Roger Moſtyn, in Flintſhire. The latter part of his life was chearful, and he ſcarcely felt the approaches of old age. He died at his ſeat at Downing in his 72d year.

He has left ſeveral works behind him in MS. under the title of Outlines of the Globe; and as a proof that it will be a very voluminous and intereſting publication, it is only neceſſary to obſerve, that The View of Hindooſtan compoſed the xivth and xvth volumes.

Mr Pennant poſſeſſed a well-compacted frame of body, an open and intelligent aſpect, an active and chearful diſpoſition, and a vivacity which rendered him always entertaining, as well in converſation as in writing. Though not without a ſhare of iraſcibility, his heart was kind and benevolent. He was exemplary in the relations of domeſtic life, and ſenſibly felt for the diſtreſſes of his poor neighbours, whoſe relief in ſeaſons of hardſhip he promoted with great zeal and liberality. His candour and freedom from ordinary prejudices, are ſufficiently diſplayed in his writings; and Scotland was forward to confeſs, that he was the firſt traveller from this ſide the Tweed, who had viſited the country with no unfriendly ſpirit, and had fairly preſented it under its favourable as well as its leſs pleaſing aſpects. As a writer, his ſtyle is lively and expreſſive, but not perfectly correct. His principles of arrangement in zoology are judicious, and his deſcriptions characteriſtic. If in ſome of his later works a little vanity appears, and a propenſity to think that important to the world which was ſo to himſelf, it may readily be pardoned to one who has afforded ſuch copious and valuable entertainment to the public. His name will live with honour in the literary hiſtory of his country, and his memory will be cheriſhed with reſpect and affection by his ſurviving friends.

PENNATULA (See *Encycl.*). A ſpecies of this animal, hitherto undeſcribed, was diſcovered by La Martiniere near Nootka. Its body is of a cartilaginous ſubſtance, and a cylindrical form; its head, armed with two little horns of the ſame ſubſtance, preſents a ſpherical figure flatted at its anterior extremity. This part is covered with ſmall papillæ, ſome of which are viſible at D, and which ſerve the purpoſe of ſmall mouths, by means of which this animal ſucks the blood of fiſhes, making its way as far as poſſible into the fleſh: the extremity of its body, which always projects from the fiſh, appears like the feathers of a pen; theſe feather-like ſubſtances ſerve as excretory veſſels; for on making a ſlight preſſure on the animal, from the greater part of theſe cartilaginous barbs iſſued ſmall drops of a very limpid liquor: at the baſe of theſe barbs, and beneath the body, are placed two large cartilaginous threads, of which our author could not imagine the uſe, for they are not univerſally met with in each individual. The circulation of its blood is readily obſerved, it forms a complete revolution about once in a minute. It is probable that this animal is only able to make its way into the bodies of different fiſh when it is very young; and when it has once buried itſelf there, having abundance of nouriſhment, its head increaſes conſiderably, and the two horns with which it is furniſhed neceſſarily form an obſtacle to its regreſs, which is a remarkable inſtance of the foreſight of Nature, ſince it is deſtined to be nouriſhed at the expence of another. The pennatula, of which we have given from Martiniere a figure, was found by him at the depth of more than an inch and an half in the body of a *diodon*.

Plate XLI.

PEPUSCH (John Chriſtopher), one of the greateſt theoretic muſicians of modern times, as we are told, was born at Berlin about 1667; and became ſo early a proficient on the harpſichord, that at the age of 14 he was ſent for to court, and appointed to teach the prince, father of the late King of Pruſſia. About 1700, he came over to England, and was retained as a performer at Drury Lane: it is ſuppoſed that he aſſiſted in compoſing the operas which were performed there. While he was thus employed, he forebore not to proſecute his private ſtudies; and theſe led him to enquire into the muſic of the ancients, and the peruſal of the Greek authors upon that ſubject. The abilities of Pepuſch, as a practical compoſer, were not likely to become a ſource of wealth to him: his muſic was correct, but it wanted variety of modulation. Beſides, Handel had got poſſeſſion of the public ear, in the opinion of whoſe ſuperior merit he readily acquieſced; and choſe a track for himſelf, in which he was almoſt ſure to meet with no obſtruction. He became a teacher of muſic, not the practice of any particular inſtrument, but muſic in the abſolute ſenſe of the word, that is to ſay, the principles of harmony and the ſcience of practical compoſition; and this, not to children or novices, but in very many inſtances to profeſſors of muſic themſelves.

In 1713, he was admitted to the degree of Doctor in Muſic at Oxford, and continued to proſecute his ſtudies with great aſſiduity. In 1724, he accepted an offer from Dr Berkeley to accompany him to the Bermudas, and to ſettle as profeſſor of muſic in his intended college there; but the ſhip in which they ſailed being wrecked, he returned to London, and married Franceſca Margarita de l'Epine. This perſon was a native of Tuſcany, and a celebrated ſinger, who performed in ſome of the firſt of the Italian operas that were repreſented in England. She came hither with one Greber, a German, and from this connection became diſtinguiſhed by the invidious appellation of *Greber's Peg*. Afterwards ſhe commenced a new connection with Daniel Earl of Nottingham, who had defended the orthodox notion of the Trinity againſt the heretic Whiſton; and to this connection Rowe, in imitation of

Horace's,

---

* *Phil. Tranſ.*

Horace's, "Ne ſit ancillæ tibi amor pudori," thus alludes :

Did not baſe Greber's Peg inflame
The ſober Earl of Nottingham,
  Of ſober ſire deſcended ?
That, careleſs of his ſoul and fame,
To play-houſes he nightly came,
  And left church undefended.

She continued to ſing on the ſtage till about 1718 ; when having, at a modeſt computation, acquired above ten thouſand guineas, ſhe retired from the theatre, and afterwards married Dr Pepuſch. She was remarkably tall, and remarkably ſwarthy ; and, in general, ſo deſtitute of perſonal charms, that Pepuſch ſeldom called her by any other name than Hecate, to which ſhe is ſaid to have anſwered very readily.

The change in Pepuſch's circumſtances by Margarita's fortune was no interruption to his ſtudies : he loved muſic, and he purſued the knowledge of it with ardour. At the inſtance of Gay and Rich, he undertook to compoſe, or rather to correct, the muſic for the Beggar's Opera. His reputation was now at a great height He had peruſed with great attention thoſe ſeveral ancient treatiſes on Harmonics, publiſhed by Meibomius, and that of Ptolemy by Dr Wallis ; and the difficulties which occurred to him on the peruſal, were in a great meaſure removed by his friend De Moivre the mathematician, who aſſiſted him in making calculations for demonſtrating thoſe principles on which the harmonic ſcience is founded. In conſequence of theſe ſtudies, he was eſteemed, in matters of theory, one of the beſt muſicians of his time. In 1737, he was choſen organiſt of the Charter-houſe, and retired, with his wife, to that venerable manſion. The wife died in 1740, before which he loſt a ſon, his only child ; ſo that he had no ſource of delight left, but the proſecution of his ſtudies, and the teaching of a few favourite pupils, who attended him at his apartments. Here he drew up that account of the ancient genera which was read before the Royal Society, and is publiſhed in the Philoſophical Tranſactions for October, November, and December, 1746 ; and, ſoon after the publication of that account, he was choſen a Fellow of the Royal Society.

He died the 20th of July, 1752, aged 85 ; and was buried in the chapel of the Charter-houſe, where a tablet with an inſcription is placed over him *

PERCUSSION, Force of Percussion, is the name by which mechanicians diſtinguiſh that faculty of producing motion, or making other ſenſible mechanical impreſſions on bodies, by means of the ſtroke of a body in motion. It is nearly the ſame with *impulſe* ; only, it would ſeem that the very ſcrupulous and refined affect to limit the attention to the *immediate* cauſe of the motion, or other effect produced ; to the ſomething that is different, both from the force ſuppoſed to be inherent in the moving body (a hammer for example), and the ſubſequent motion and penetration of the nail which is driven by it. We may venture to ſay that it is needleſs to attempt any inveſtigation of this object. It is hid, with all other cauſes of all other effects in the univerſe, in impenetrable darkneſs. If we reflect on the conſtitution of our own mind, ſo far as we can know it by experience and obſervation, and on the manner in which we draw concluſions, we muſt ſee that the knowledge of the efficient cauſe of any effect is unattainable ; for were the intervening ſomething pointed out to us, and clearly conceived by us, we ſhould find it juſt as neceſſary to find out why and how this ſomething is connected with each of the events which we obſerve it invariably to connect.

But a knowledge of the force of percuſſion, in as far as it may or may not be diſtinguiſhable from other forces, is not unattainable. We can learn as much, and no more, concerning this, as concerning any other force ; and we can contemplate that circumſtance which, in our opinion, is common to it with all other forces, and may perhaps diſcover other circumſtances in which it differs from them. But in all this diſquiſition, it is plain that it is only events, which we conceive to be the characteriſtic effects of the cauſe, that we contemplate.

Percuſſion, conſidered as an effect, characteriſtic of a particular faculty of moving bodies, became an object of anxious reſearch, almoſt as ſoon as philoſophers began to think of motion and moving forces at all. The ancients (as has been obſerved in the article Impulsion, *Suppl.*) contented themſelves with very vague ſpeculations on the ſubject. Galileo was the firſt who conſidered it as a meaſurable thing, the object of mathematical diſcuſſion ; being encouraged by his precious diſcovery of the laws of accelerated motion, and the very refined meaſure which theſe gave him of the power of gravity. It was a meaſure of the heavineſs, not of the weight, of the body ; and this was meaſured by its acceleration, and not by its preſſure. Encouraged by this, he hoped to find ſome ſuch meaſure of the force of percuſſion, which he ſaw ſo intimately connected with motion ; whereas its connection with preſſure was far from being obvious. He therefore tried to convert the terms ; and as he had found a meaſure of the preſſure of gravity in the acceleration of motion, he endeavoured to find in preſſure a meaſure of the force of percuſſion ariſing from this acceleration. He endeavoured to find the number of pounds, whoſe preſſure is equal to the blow of a given body, moving with a given velocity. The velocity was known to him with great preciſion, by means of the height from which the ball muſt fall in order to acquire it. It ſeems pretty clear that percuſſion may be meaſured in this way ; for a body falling from a height will pierce an uniformly tenacious body to a certain degree, and no further ; and experiment ſhews that this degree of penetration is very preciſe and conſtant. The ſame body, being merely laid on the tenacious body, will penetrate to a ſmall depth by its weight. Laying more weight on it, will make it penetrate deeper ; and a certain weight will make it penetrate as deep as the fall did, and no deeper. Thus, percuſſion ſeems very eaſily meaſurable by weight, or by any preſſure ſimilar to that of weight. It appears that Galileo made experiments with this view, and that he was diſappointed, and obliged to acquieſce in the opinion of Ariſtotle, that percuſſion and weight are incomparable. He propoſes, therefore, another experiment, namely, to drop a body into the ſcale of a balance from greater and greater heights, till at laſt the blow on the ſcale raiſes a weight that lies in the other ſcale. This offers itſelf ſo plauſibly, that we are perſuaded that Galileo tried it : but as he makes no mention

tion of the reſults, we preſume that they were unſatisfactory.

Neither of theſe experiments *could* give us a meaſure of the force of percuſſion, if this force be any thing different from the forces which are excited or brought into action by percuſſion, in the manner deſcribed in the article Impulsion, *Suppl.* When the ball comes into phyſical contact with the ſcale, it begins to compreſs it. This compreſſion begins to ſtretch the ſtrings by which the ſcale is ſupported. Theſe pull at the arm of the balance, and cauſe it to preſs the centre-pin a little harder on its ſupport, and to bend the balance a little, and cauſe it to pull at the cords which ſupport the other ſcale. That ſcale is pulled upwards, diminiſhing a little its preſſure on the ground, and preſſing it harder to the incumbent weight. Theſe forces are excited *in ſucceſſion* from the one ſcale to the other, and a ſmall moment of time elapſes. The reaction of the ſcale diminiſhes, but does not inſtantaneouſly annihilate, the velocity of the falling ball. It therefore compreſſes the ſcale ſtill more, ſtretches the threads, preſſes the fulcrum, and bends the balance ſtill more (becauſe the weight in the other ſcale keeps it down). The velocity of the falling ball is rapidly diminiſhed; the balance is more bent, and pulls more ſtrongly upwards at the threads of the other ſcale; and thus preſſes that ſcale more ſtrongly againſt the incumbent weight, gradually communicating more and more motion to it, removing it farther from the ground, till, at laſt, the motion becomes ſenſible, or ſo conſiderable as to diſengage ſome delicate catch as a ſignal. The experiment is now finiſhed; and the mechanician fondly thinks that, at this inſtant, the preſſure excited by the percuſſion, between the oppoſite ſcale and the under ſide of the incumbent weight, is juſt equal, or but a very little ſuperior, to the preſſure of the incumbent weight: and, ſince the arms of the balance are equal, and therefore the preſſures on the two ſcales are equal, he imagines that that weight exerts a preſſure equal to the percuſſion of the falling ball.

But all this is miſconception, and alſo falſe reaſoning. It is not percuſſion that we are meaſuring, but the preſſures, excited by percuſſion, on the two ſcales. And theſe preſſures are the forces of elaſticity or expanſiveneſs, belonging to, or inherent in, the particles of the balls and the ſcales; forces which are brought into action by the approach of thoſe bodies to each other. This reaſoning is alſo erroneous; and we ſhould be miſtaken if we think that the preſſure actually exerted is equal to that of the weight in the oppoſite ſcale. It is greater than the mere preſſure of that weight. The reaction of the oppoſite ſcale on its load was preciſely equal to that weight before the ball was dropped from the hand; and, had the ball been equal to that weight, and ſimply laid into the ſcale on which it falls, it would have made no change on the mutual preſſures of the ſcale and the other weight; it would only have relieved the ground from the preſſure of that weight, and would have brought it on the threads which ſupport its ſcale. The preſſure of this ſcale upwards muſt be increaſed, before it can ſtart the weight ſenſibly from the ground. How much it muſt be increaſed depends on the ſpringineſs of the ſcales, cords, and beam. By a proper adjuſtment of theſe particulars, the apparatus will give us almoſt any meaſure of percuſſion that we chooſe. For this reaſon, the improvements made on it by Graveſande are of no value. The ſame reaſoning, nearly, may be applied to the meaſurements of the force of percuſſion by means of the penetration of ſoft bodies.

Galileo mentions another very curious experiment, by which he thought that he had obtained a juſt meaſure of percuſſion. A veſſel, filled with water, was ſuſpended on the arm of a balance, with another veſſel hanging from it, a great way below. All was exactly balanced by a weight in the oppoſite ſcale. By means of a ſuitable contrivance, a hole was opened in the bottom of the upper veſſel, without diſturbing the equilibrium. As ſoon as the water iſſued, and while it was falling through the air, that end of the balance roſe; but when the water ſtruck the lower veſſel, the equilibrium was reſtored, and continued during the whole time of the efflux. Hence Galileo concluded, that the force of the ſtroke was equal to the weight of the falling water. But we apprehend that the obſervations made on this in the article Impulsion, *Suppl.* will convince the reader that this concluſion is far from being legitimate. Beſides, the ſtroke, in any one inſtant, is made by thoſe particles only which ſtrike in that inſtant, while the whole vein of water between the veſſels is neither acting by its weight on the upper veſſel, nor by its ſtroke on the lower; and we ſhould conclude from the experiment, that the force of percuſſion is infinitely greater than the weight of the ſtriking body. Indeed this is the inference made by Galileo. But if we have recourſe to the experiments and reaſonings of Daniel Bernoulli, in the article *Resistance of Fluids*, *Encycl.* we ſhall find that the ſeeming impulſe on the lower veſſel is really a moſt complicated pure preſſure, and of moſt uncertain determination. The experiment is valuable, and gives room for curious reflections. We have repeated it, in a great variety of forms, and with great changes of impulſe, and ſometimes in ſuch a manner that no impulſe whatever can obtain, while at the ſame time a quantity of water was falling, unſupported by either veſſel. In all the trials the equilibrium remained undiſturbed. We were obliged to conclude, therefore, that the experiment afforded no meaſure of percuſſion. Indeed we were of this opinion before making the trial, for the reaſons juſt now given.

We cannot ſay that the ſubſequent labours of philoſophers have added much to our knowledge of this matter. Mr Leibnitz had contrived his whimſical doctrine of *living* and *dead* forces. The action of gravity, or of a ſpring, is a *vis viva*, when it actually produces motion in the body on which it acts: but when a ſtone lies on a table, and preſſes on it, this preſſure is a *vis mortua*. Its exertion is made, and in the ſame inſtant deſtroyed, by an oppoſite *vis mortua*. Each of theſe exertions would have produced *a beginning* of motion (ſomething different from any the ſmalleſt local motion); and the ſum of all would, after a certain time, have amounted to a ſenſible motion and velocity. There ſeems no diſtinct conception to accompany, or that can accompany, this language. And, as a proof that Leibnitz had no diſtinct conceptions of the matter, he has recourſe to this very experiment of Galileo in ſupport of his geneſis of a ſenſible motion from the continual exertions of the *vis mortua*; and he concludes that the force of percuſſion is infinitely, or incomparably, greater than preſſure, becauſe it is the ſum total of an infinity of individual

dual exertions of *vis mortua*. Nothing but the authority which Leibnitz has acquired on the continent, by the zealous efforts of his partizans, could excuſe our taking up any time in conſidering this unintelligible diſcourſe. Surely, if there is ſuch a thing as a *vis viva*, it exiſts in the moving water, and its impulſions are not continual exertions of a *vis mortua*. Nor is it poſſible to conceive continual impulſe, nor a beginning of motion that is not motion, &c. &c. It is paradoxical (and Leibnitz loved to raiſe the wonder of his followers by paradoxes) to ſay that percuſſion is infinitely greater than preſſure, when we ſee that preſſure can do every thing that can be done by percuſſion. Nay, Euler, by far the moſt able ſupporter of the doctrines of Leibnitz about the force of bodies in motion, actually compares theſe two forces; and, in his Commentary on Robins's Artillery, demonſtrates, in his way, that when a muſket ball, moving with the velocity of 1700 feet per ſecond, penetrates five inches into a block of elm, the force of its percuſſion is 107,760 times its weight. John Bernoulli reſtricts the infinite magnitude of percuſſion to the caſe of perfectly hard bodies; and, for this reaſon alone, ſays, that there can be none ſuch in the univerſe. But, as this juſtly celebrated mathematician ſcouts with ſcorn the notion of attractions and repulſions, he muſt allow, that an ultimate atom of matter is unchangeable in its form; which we take to be ſynonymous with ſaying that it is perfectly hard. What muſt be the reſult of one atom in motion hitting another at reſt? Here muſt be an inſtantaneous production of a finite velocity, and an infinite percuſſion. A doctrine which reduces its abetters to ſuch ſubterfuges, and engages the mind in ſuch puzzling contemplations, cannot (to ſay the beſt of it) be ſtyled an EXPLANATION of the laws of Nature. The whole language on the ſubject is full of paradoxes and obſcurities. In order to reconcile this infinite magnitude of percuſſion with the obſerved finite magnitude of its effects, they ſay that the preſſure, or inſtantaneous effort, has the ſame relation to the force of percuſſion that an element has to its integral; and in maintaining this aſſertion, they continually conſider this integral under the expreſs denomination of a *ſum total*, robbing Leibnitz's great diſcovery of the infiniteſimal calculus of every ſuperiority that it poſſeſſed over Wallis's Arithmetic of Infinites, and really employing all the erroneous practices of the method of indiviſibles. We look upon the ſtrange things which have been inculcated, with pertinacious zeal, in this doctrine of percuſſion and *vires vivæ*, as the moſt remarkable example of the errors into which the unguarded uſe of Cavalerius's Indiviſibles, and of the Leibnitzian notion of the infiniteſimal calculus, have led eminent mathematicians. It is not true that the preſſure, and the ultimate force of percuſſion, have this relation; nor has the preſſure and the reſulting motion, which is miſtaken for the meaſure of this ultimate force, any mathematical relation whatever. The relation is purely phyſical; it is the relation of pure cauſe and effect; and all that we know of it is their conſtant conjunction. The relation of fluxion and fluent is not a mathematical or meaſurable relation, but a connection in thought; which is ſufficient for making the one an indication of the other, and the meaſures of the proportions of the one a mean for obtaining a meaſure of the proportions of the other. In this point of view, the relation of preſſure to motion, as the meaſure of the force of percuſſion, *reſembles* that of fluxion and fluent, but is not the ſame.

Much has been ſaid by the partizans of Mr Leibnitz about the incomparableneſs of preſſure and percuſſion, and many experimental proofs have been adduced of the incomparable ſuperiority of the latter. Bulfinger ſays, that the preſſure of many tons will not cauſe a ſpike to penetrate a block of hard oak half ſo far as it may be driven by a weak man with one blow of a mallet; and that a moderate blow with a ſmall hammer will ſhiver to powder a diamond, which would carry a mountain without being hurt by its preſſure. Nay, even Mr Camus, of the Academy of Paris, a ſtaunch Carteſian, and an eminent mechanician, ſays that he beat a leaden bullet quite flat with a hammer of one pound weight, without much force; and that he found that 200 pounds weight would not have flattened it more than this blow: and he concludes from thence, that the force of the blow exceeded 200 pounds. Theſe, to be ſure, are remarkable facts, and juſtify a more minute conſideration of a power of producing certain effects, which is ſo frequently and ſo uſefully employed. But, at the ſame time, theſe are all very vague expreſſions, and they do not authoriſe any preciſe concluſions from them. Mr Camus ſaying "without much force," makes his pound weight, and his 200 pound weight, of no uſe for determining the force of the blow. He would have given more preciſe and applicable data for his deciſion, had he told us from what height the hammer ſhould fall in order to flatten the bullet to this degree. But even then we ſhould not have obtained any notion of the force in actual exertion during the flattening of the bullet; for the blow which could flatten the bullet in a longer or a ſhorter time, would unqueſtionably have been leſs or greater.

All the paradoxes, obſcurities, and puzzling difficulties, in this ſubject diſappear, if we leave out of our conſideration that unintelligible force, which is ſuppoſed to preſerve a body in motion or at reſt; and if we conſider both of theſe ſtates of body as conditions which will continue, unleſs ſome adequate cauſe operate a change; and if we farther grant, that ſuch cauſes do really exiſt in the univerſe, however unknown their nature may be by us; and, laſtly, if we acknowledge, that the phenomena of elaſticity, expanſiveneſs, coheſion, gravity, magnetiſm, electricity, are indications of the agency of ſuch cauſes, and that their actual exertions, and the motions and changes conſequent on theſe exertions, are ſo invariably connected with particular bodies, that they always accompany their appearance in certain mutual relations of diſtance and poſition:—if we proceed thus, all the phenomena of colliſion will be explained by theſe cauſes alone, without ſuppoſing the exiſtence and agency of a cauſe diſtinct from them all, and incomparable with them, called the FORCE OF PERCUSSION.

For it has been ſufficiently demonſtrated in the article IMPULSION (*Suppl.*), that that property of tangible coherent matter, which we call *perfect elaſticity*, operates as a preſſure during a certain ſmall portion of time on both bodies, diminiſhing more and more the motion of the one, and augmenting that of the other, as the compreſſion of one or both increaſes, till at laſt they ſeparate with ſenſible velocities. In ſome very ſimple or perſpicuous

Plate XLI.

ſpicuous caſes, we know what this preſſure is in every inſtant of the action. We can tell how many pounds weight, at reſt, will exert the ſame preſſure. We can tell the whole duration of this preſſure, and the ſpace along which it is exerted; and, in ſuch a caſe, we can ſay with preciſion what motion will be generated by this continued and varied preſſure on the body which was at reſt, and what diminution will be made in the motion of the other. All this can be done in the caſe of a ball A (fig. 1.), moving like a pendulum with a ſmall velocity, and ſtriking a ſlender elaſtic hoop B, alſo ſuſpended like a pendulum. We can aſcertain by experiment, before the colliſion, what preſſure is neceſſary for compreſſing it one inch, one-half, one-fourth, &c. Knowing this, and the weight of the hoop, and the weight and velocity of the ball, we can tell every circumſtance of the colliſion—how long the compreſſion continues—what is the greateſt compreſſion—how far the bodies have moved while they were acting on each other—and what will be the final motion of each:—in ſhort, every thing that affords any mark or meaſure of a force of percuſſion. And we know that all this is produced by a force, familiarly known to us by the name of elaſticity. Which of all theſe circumſtances ſhall be called the percuſſion, or the force of percuſſion? Is it the ultimate or greateſt preſſure occaſioned by the compreſſion? This cannot be, becauſe this *alone* will not be proportional to the final change of motion, which is generally taken as a meaſure of the percuſſion when a change of motion is its only obſerved effect.

We know that another perfectly elaſtic body, of the ſame weight, and ſtruck by the ſame blow, and acquiring the ſame final velocity by the ſtroke, may not have ſuſtained the tenth part of the preſſure, in any one inſtant of the colliſion, if it has only been much more compreſſible. The greateſt mutual preſſure in the colliſion of a billiard ball is perhaps 1000 times greater than it is in a ſimilar colliſion of a foot-ball of the ſame weight.

We alſo know what degree of compreſſion will break this hoop, and what preſſure will produce this compreſſion. Therefore, ſhould the fracture of the body be conſidered as the mark and meaſure of the percuſſion, we know what blow will juſt produce it, and be exhauſted by ſo doing. In ſhort, we know every mark and meaſure of percuſſion which this hoop can exhibit.

We can increaſe the ſtrength of this hoop till it becomes a ſolid diſk; and we ſee clearly, that in all theſe forms the mode of acting is the ſame. We ſee clearly that it is the ſame when, inſtead of the ſolid diſk, it is an elaſtic ball; therefore every thing that can indicate or meaſure the percuſſion of an elaſtic ball, is explained without the operation of a peculiar force of percuſſion, even when the ball is ſhivered to pieces by the blow.

Nor is the caſe materially different when the bodies are ſoft, or imperfectly elaſtic. When the ſtruck body is uniformly tenacious, it oppoſes a uniform reſiſtance to penetration, and its motion will be uniformly accelerated by the action of its own tenacity during the whole time of mutual action, except a trifling variation occaſioned by the mere motion of the internal parts, independent of their tenacity. If we knew the weight neceſſary for merely penetrating this maſs, and the weight and velocity of the penetrating body, we can tell how long it muſt be reſiſted by this force before its initial velocity will be annihilated, and therefore how far it will penetrate. We have tried this with deal, birch, willow, and other ſoft woods of uniform texture, and with nails having the body ſomewhat ſlenderer than the end, that there might not be an irregularity occaſioned by a friction on the ſides of the nail, continually increaſing as the penetration advanced. We made the hammer fall from a conſiderable height, and hit the nail with great accuracy in the direction of its length, by fixing it to the end of a long lath, moveable round an axis. The reſults correſponded with the calculation with all the preciſion that could be deſired.

But it does not reſult from all this agreement, that the force, exertion, or effect, of a blow with a hammer is equal to the preſſure of any number of pounds whatever. They are things that cannot be compared; and yet the force operating in the penetration by a blow is no way different from a preſſure. It is a phyſical blunder to compare the area of the curve, whoſe abſciſſa is the depth of penetration, and the ordinates are as the reſiſtances, with any preſſure whatever. This area expreſſes the ſquare of a velocity, and its ſlips, bounded by parallel ordinates indefinitely near each other, are as the decrements of this ſquare of a velocity, occaſioned by a preſſure, acting almoſt uniformly along a very ſmall ſpace, or during a very ſmall time. It is an abſurdity therefore to ſum up theſe ſlips as ſo many preſſures, and to conſider the ſum total as capable of expreſſing any weight whatever. Such a parallogiſm is peculiar to Leibnitz's way of conceiving his infiniteſimal method, and it could have no place in the genuine method of fluxions. It is this miſconception that has made Mr Leibnitz and his followers ſuppoſe that a body, accelerated by gravity, retains in it a ſum total of all the preſſures of gravity accumulated during its fall, and now forming a *vis viva*. Suppoſing that it requires a preſſure of twenty pounds to preſs a ſix pound ſhot ſlowly through a maſs of uniformly reſiſting clay; this preſſure would carry it from the top to the bottom of a mountain of ſuch clay. Yet this ball, if diſcharged horizontally from a cannon, would penetrate only a few yards, even though the clay ſhould reſiſt by tenacity only, independent of the motion loſt by giving *motion* to its internal parts. In this experiment, the utmoſt preſſure exerted during the motion of the ball did not much exceed the preſſure of twenty pounds. In this compariſon, therefore, percuſſion, ſo far from appearing infinitely greater than preſſure, would appear much leſs. But there is perhaps no body that reſiſts penetration with perfect uniformity, even though uniformly tenacious. When the ball has penetrated to ſome depth, the particles which are before it cannot be ſo eaſily diſplaced, even although they had no tenacity, becauſe the particles adjoining are more hemmed in by thoſe beyond them. We have always obſerved, that a ball impelled by gunpowder through water riſes toward the ſurface (having entered horizontally through the ſide of the veſſel at ſome depth), and this ſo much the more rapidly as it entered nearer to the ſurface. The reaſon is plain. The particles which muſt be diſplaced before the ball, eſcape more eaſily upwards than in any other direction. It is for this reaſon chiefly that a greater weight laid on the head of a nail will cauſe it ſink deeper into the wood; and thus a great weight appears to to be commenſurable with a great force of percuſſion. Alſo, while a bullet is flattening more and more under a hammer during the progreſs of a blow, it is ſpreading under the hammer; more particles are reſiſting at once, and they find more difficulty in effecting their eſcape, being harder ſqueezed between the hammer and the anvil. The ſame increaſed reſiſtance muſt obtain while it is flattening more and more under the quiet preſſure of a weight; and thus, too, a greater weight appears to be commenſurable with a greater blow.

After all, however, a blow given by a falling body muſt excite a preſſure greater than its mere weight can do, and this in any degree. Thus, ſuppoſe AB (fig. 2.) to repreſent a ſpiral ſpring in its natural unconſtrained dimenſions, ſtanding upright on a table. Let ab be the abſciſſa of a line $adhk$, whoſe ordinates cd, gh, ik, &c. are as the elaſtic reaction of the ſpring when it is compreſſed into the lengths cb, gb, ib, &c. Suppoſe that, when it is compreſſed into the form CD, it will juſt ſupport the weight of a ball lying on C. Then cd will be a reaction equal to the weight of the ball, and the rectangle $acdf$ will expreſs the ſquare of the velocity which this ball would acquire by falling freely through ac. If therefore the ball be gently laid on the top of the ſpring at A, and then let go, it will deſcend, compreſſing the ſpring. It will not ſtop when the ſpring has acquired the form CD, which enabled it to carry the weight of the ball gently laid on it. For in this ſituation it has acquired a velocity, of which the ſquare is repreſented by the figure adf (See DYNAMICS, *Suppl.* n° 95.). It will compreſs the ſpring into the length gb, ſuch that the area $cghd$ is equal to the area adf If the ball, inſtead of being gently laid on A, be dropped from M, it will compreſs the ſpring into ſuch a length ib, that the area aik is equal to the rectangle $mcdn$; and, if the ſpring cannot bear ſo great compreſſion, it will be broken by this very moderate fall.

Thus we ſee that a blow may do things which a conſiderable preſſure cannot accompliſh. The accounts which are given of theſe remarkable effects of percuſſion, with the view of impreſſing notions of its great efficacy, are generally in very indefinite terms, and often without mentioning circumſtances which are acceſſory to the effect. It would be very unfair to conclude an almoſt infinite power of percuſſion, from obſerving, that a particle of ſand, dropped into a thick glaſs bottle which has not been annealed, will ſhiver it to pieces. When Mr Bulfinger ſays that a moderate blow will break a diamond which could carry a mountain, he not only ſays a thing of which he cannot demonſtrate the truth, and which, in all probability, is not true; but he omits noticing a circumſtance which he was mechanician enough to know would have a conſiderable ſhare in the effect. We mean the rapidity with which the excited preſſure increaſes to its maximum in the caſe of a blow. In the experiment in queſtion, this happens in leſs than the millionth part of a ſecond, if the velocity of the hammer has been ſuch as a man would generate in it by a very moderate exertion. For the blow which will drive a good lath nail to the head in a piece of ſoft deal with an ordinary carpenter's hammer, muſt be accounted moderate. This we have learned by experiment to be above 25 feet per ſecond. The connecting forces exerted between the particles of the diamond may not have time ſufficient for their excitation in the remote parts, ſo as to ſhare the derangement among them all, in ſuch a manner that it may be ſo moderate in each as not to amount to a diſunion in any part of the diamond. We ſee many inſtances of this in the abrupt handling of bodies of tender and friable texture. It is partly owing to this that a ball diſcharged from a piſtol will go through a ſheet of paper ſtanding on edge without throwing it down, which it would certainly do if thrown at it by the hand. The connecting forces, having time to act in this laſt caſe, drag the other parts of the paper along with them, and their union is preſerved. Alſo, when a great weight is laid on the diamond, it is gradually dimpled by it; and thus incloſing many parts together in the dimple, it obliges them to act in concert, and the derangement of each is thus diminiſhed.

We flatter ourſelves that the preceding obſervations and reflections will contribute ſomewhat towards removing the paradoxes and myſteries which diſcredit, in ſome degree, our mechanical ſcience. If we will not pertinaciouſly conjure up ideal phantoms, which, perhaps, *cannot* exiſt, but content ourſelves with the ſtudy of that tangible matter which the Author of Nature has preſented to our view, we ſhall have abundant employment, and ſhall perceive a beautiful harmony thro' the whole of natural operations; and we ſhall gradually diſcover more and more of thoſe mutual adaptations which enable an atom of matter, although of the ſame preciſe nature wherever it is found, to act ſuch an unſpeakable variety of parts, according to the diverſity of its ſituations and the ſcene on which it is placed. If a mind be "not captivated by the harmony of ſuch ſweet ſounds," we may pronounce it "dark as Erebus, and not to be truſted"

PERFECT NUMBER, is one that is equal to the ſum of all its aliquot parts when added together. Eucl. lib. 7, def. 22. As the number 6, which is $= 1 + 2 + 3$, the ſum of all its aliquot parts; alſo 28, for $28 = 1 + 2 + 4 + 7 + 14$, the ſum of all its aliquot parts. It is proved by Euclid, in the laſt prop. of book the 9th, that if the common geometrical ſeries of numbers 1, 2, 4, 8, 16, 32, &c. be continued to ſuch a number of terms, as that the ſum of the ſaid ſeries of terms ſhall be a prime number, then the product of this ſum by the laſt term of the ſeries will be a perfect number.

PERGUNNA, in Bengal, the ſubdiviſion of a diſtrict.

PERKINISM, the proper name of what we muſt think an impoſition attempted to be put upon the world by Dr Perkins of North America.

Though the phenomena of electricity had been long familiar to the philoſophers of Europe, it is well known that a philoſophical theory of theſe phenomena was firſt formed by a tranſatlantic philoſopher. In like manner, though the diſcovery of Galvani, under the name of *animal electricity* (ſee GALVANISM in this *Supplement*), had occupied the attention of many of the firſt phyſicians and philoſophers of the old world, it was reſerved for a phyſician of the new, to apply it to the cure of a number of diſeaſes. Every philoſopher of America, however, has not the ſagacity of the Philadelphian ſage; nor muſt Dr Perkins or his admirers be ſurpriſed, if we treat not incomprehenſible myſticiſm with the reſpect due to a theory founded on facts.

Perkiniſm.

We are told by the ſon (A) of this rival of Franklin, that before the news of Galvani's diſcovery had reached America, he had obſerved ſeveral phenomena pointing out the influence of metals in caſes of pain. The firſt remarkable incident that preſented itſelf to his notice was the ſudden contraction of a muſcle when he was performing a chirurgical operation. This, he obſerved, regularly took place whenever the point of the metallic inſtrument was put in contact with the muſcle. Struck with the *novelty* of the appearance (Is Mr Perkins ſure that the appearance was new?), he was induced to try the points of wood and other ſubſtances; and no contraction taking place on theſe experiments, he thence inferred that the phenomena could be aſcribed only to the influence of the metal. About the ſame time, he obſerved that, in one or two caſes (and if his practice had been great he might have obſerved that in a thouſand caſes), a ceſſation of pain had enſued when a knife or lancet was applied to ſeparate the gum from a tooth previous to extracting it; and in the ſame year he diſcovered, that *momentary* eaſe was given, in a few inſtances, by the accidental application of a metallic inſtrument to inflamed and painful tumors previous to any inciſion.

Theſe are the judicious reaſonings and aſſertions of a dutiful child, who, having probably heard of Leibnitz's claims to ſome of Newton's diſcoveries, was determined to put in a ſimilar claim for his father, to a *ſhare*, at leaſt, of the diſcovery made by the celebrated profeſſor at Bologna. He has not, however, copied with ſervility the conduct of the Leibnitzians. We do not remember an inſtance where any of them attempted to elevate the fame or the merits of their maſter *above* the fame and merits of Newton; but, according to our author, the purſuits of Galvani and his European pupils ſink into inſignificance, when compared with thoſe of the tranſatlantic phyſician.

This is evident; for when the phyſiologiſts of Europe were engaged in experimenting on the denuded nerves and muſcles of the ſmaller animals, with a view to aſcertain the agency of this incomprehenſible property in them, Dr Perkins was proſecuting a ſeries of experiments, which conſiſted in applying externally, to parts affected with diſeaſe, metals, and compounds of metals of every deſcription which occurred to him, and conſtructed into various forms and ſizes. The reſult proved, that on drawing lightly over the parts affected certain inſtruments, termed *tractors*, which he formed from metallic ſubſtances into pointed ſhapes, he could remove moſt of thoſe topical diſeaſes of the human body, where an extra degree of nervous energy or vital heat was preſent; unleſs ſuch diſeaſe was ſituated in ſome of the internal viſcera, too remote from the part where the inſtruments could be applied.

The diſeaſes which have been found moſt ſuſceptible of the influence of the tractors are, rheumatiſm, ſome gouty affections, pleuriſy, ophthalmias, eryſipelas, violent ſpaſmodic convulſions, as epileptic fits and the locked jaw, the pain and ſwelling attending contuſions, inflammatory tumors, the pains from a recent ſprain, the painful effects of a burn or ſcald, pains in the head, teeth, and indeed moſt kinds of painful topical affections, excepting where the organic ſtructure of the part is deſtroyed, as in wounds, ulcers, &c. and excepting alſo where oils or ſome other non conducting ſubſtances are preſent.

But we have other teſtimonies than thoſe of Dr Perkins and his ſon for the influence of the tractors. Mr Meigs, profeſſor of natural philoſophy at Newhaven, in a letter on Dr Perkins's diſcovery, conceives the principles of metallic irritability as ſo little underſtood, that he will not pretend to explain how the tractors produce their effects; but ſeems ſatisfied in finding that the effects are produced. After ſtating an experiment on his own child, eight years of age, very dangerouſly ill with a peripneumonic complaint, and to which the tractors gave almoſt inſtantaneous relief, he ſays, "I have uſed the tractors with ſucceſs in ſeveral other caſes in my own family; and although, like Naaman the Syrian, I cannot tell why the waters of Jordan ſhould be better than Abana and Pharpar, rivers of Damaſcus; yet, ſince *experience* has proved them ſo, no reaſoning can change the opinion. Indeed, the cauſes of all common facts are, *we think*, perfectly well known to us; and it is very probable, fifty or an hundred years hence, we ſhall as well know why the metallic tractors ſhould in a few minutes remove violent pains, as we now know why cantharides and opium will produce oppoſite effects: viz. we ſhall know but *very little* about either, excepting *facts*."

Mr Woodward, profeſſor of natural philoſophy at Dartmouth, in a letter alſo on the ſame ſubject, has ſtated a number of ſucceſsful experiments in pains of the head, face, teeth, and in one caſe of a ſprain.

Dr Vaughan, a member of the Philadelphia medical ſociety, has lately publiſhed an ingenious tract on Galvaniſm, the object of which is to account for the influence of the tractors in removing diſeaſes. After a citation of numerous experiments made on the nerves and muſcles of animals, he obſerves, "If we only take an impartial view of the operations of Nature herſelf, and attend diligently to the analytical inveſtigations of the aforementioned experimentaliſts on this ſublime ſubject, I think the ſceptic muſt admit that the principle of nervous energy is a modification of electricity. As ſenſation is dependant on this energy, a pleaſurable ſenſation, or what may be termed a natural or healthy degree thereof; then certainly pain, or ſuperſenſation, can only depend on an accumulation of the electric fluid, or extra degree of energy in the part affected. On this principle the problem admits of eaſy ſolution; namely, that the metals, being ſuſceptible of this fluid, conduct the extra degree of energy to parts where it is diminiſhed, or out of the ſyſtem altogether, reſtoring the native law of electric equilibrium."

We truſt we are not ſceptics; and yet we feel not ourſelves inclined to admit any part of this theory. We have ſeen no proof that nervous energy is a modification of electricity; and we think that we have ourſelves proved, that *galvaniſm* and *electricity* are in many reſpects different; but we ſhall not be much ſurpriſed if we ſoon ſee a *demonſtration* by ſome American or German philoſopher,

---

(A) See a pamphlet, entitled The Influence of Metallic Tractors on the Human Body, &c. by Benjamin Douglas Perkins, A. M. ſon to the diſcoverer; or a very good abridgement of it in the firſt volume of the Philoſophical Magazine.

philosopher, that the ſoul of man is a compoſition of ſilver and zinc. One of theſe ſages has lately diſcovered, that the ſymptoms of *putrefaction* do not conſtitute an *infallible* evidence of death, but that the application of *metals* will in all caſes aſcertain it beyond the poſſibility of doubt! A proper application certainly will; for when the Perkiniſt is doubtful whether his patient be dead or alive, he has only to apply the muzzle of a loaded piſtol to his temple, and blow out his brains; after which he may ſafely ſwear that the man is dead.

From the *Philoſophical Magazine*, we learn that Profeſſor Schumacher at Copenhagen made experiments with tractors of braſs and iron on ten patients in Frederick's hoſpital at Copenhagen. He tried alſo tractors of ebony and ivory, which are ſaid to have cured a pain in the knee; with others of ſilver and zinc; and ſome of copper and lead. By the two laſt, pains in the knee, arm, and face, are ſaid to have been mitigated. According to M. Klingberg's experiments, this remedy was of uſe in *malum iſchiaticum*; and according to thoſe of M. Steffens, in *malum iſchiaticum* and megrim. According to M. Bang, the pains in ſome caſes were increaſed, and in others allayed. According to M. Blech, the tractors were of uſe in *hemicrania* and gouty pains in the head; and, according to M. Hahn, in rheumatic pains in both ſhoulders. The principal document in the Daniſh collection relating to Perkiniſm, appears to be a letter of Profeſſor Abilgaard, in whoſe opinion Perkins's tractors will never acquire much value in medicine, and ſcarcely even have the merit of being a palliative; but, in a phyſical point of view, he thinks they deſerve the attention of phyſicians, and particularly of phyſiologiſts. Mankind (he ſays) hitherto have paid too little attention to the influence which electricity has on the human body; otherwiſe they would know that the effects produced on it by our beds is no matter of indifference. If the feather beds and hair mattreſſes, &c. are perfectly dry, the perſon who ſleeps on them is in an inſulated ſtate; but the contrary is the caſe if they are moiſt. He three times removed a pain in the knee, by ſticking the tractors, one on each ſide of the knee, ſo deep through the ſtockings that the points touched the ſkin. He removed a rheumatic pain in the head from a lady by the ſame means. M. Kafn, by the tractors, relieved, in others, gouty pains of the head and megrim; and in himſelf, a rheumatic pain of the back, which, according to his ſenſations, was like a conſtriction in the cellular tiſſue. M. Herholdt, from his experiments, conſiders the effect of the tractors as indefinite and relative as that of other remedies. He, however, ſaw relief given by them in the ſtrangury in a caſe of ſyphilis. M. Bang alſo, at Soroe, freed a man from a violent gouty pain in the thigh, by drawing the tractors 200 times over the affected part. M. Jacobſen likewiſe found benefit derived from theſe tractors ſeveral times in the common hoſpital at Copenhagen. M. Tode tried them alſo in rheumatic pains, tooth-ache, and inflammation of the eyes; and obſerved that they neither did good nor harm.

On ſome of the atteſted cures mentioned in Mr Perkins's pamphlet, an able writer in the Monthly Review has made remarks ſo very pertinent, that we cannot refuſe ourſelves the pleaſure of tranſcribing them.

"At page 54 of the pamphlet, we meet (ſays the reviewer) with a ſtrong proof of the confidence placed in this remedy by ſeveral tranſatlantic philoſophers. Dr Willard, it ſeems, applied a red-hot piece of iron to a wart on his finger, and burnt himſelf very ſeverely, in order that he might be relieved by the tractors; which are ſaid to have given him eaſe in two ſucceſſive experiments. The author adds, 'many have ſubmitted to ſimilar meaſures, in order to *experience* the effects. I once formed one of five, who burned ourſelves ſo that bliſters were raiſed, to make the experiment; we all obtained relief in a few minutes.'

"This zeal for knowledge is truly edifying; eſpecially as the tractors are generouſly preſented to the public at *only* five guineas a pair; and it is clear that one pair would ſuffice to cure all the burns and ſcalds of a large pariſh. Why are not ſuch luculent experiments repeated here? If Mr Perkins, or any admirer of the diſcovery, would ſubmit to have a red hot poker run into ſome part of his body not neceſſary to life (into *that part where honour's lodged*, according to Butler, for example), in any public coffee houſe within the bills of mortality, and would afterward heal the wound in preſence of the company, in ten minutes, or in half as many hours, by means of the tractors, the moſt ſtony-hearted infidel could not reſiſt ſuch a demonſtration. Why trifle with internal inflammations, when ſuch an outward and viſible ſign might be afforded?

"Mr Perkins has taken ſome pains, in the firſt part of his pamphlet, to ſhew that the operation of his rods is not derived from animal magnetiſm. In our opinion, this is an unneceſſary piece of trouble in England, where there is a conſtant ſucceſſion of ſimilar pretenſions. The *virgula divinatoria*, and the *baguette* of the juggler, are the genuine prototypes of this myſtery. We were, indeed, rejoiced, on Dr Perkins's account, to find that the Connecticut Society had only denounced him as a Meſmeriſt: we trembled leſt he ſhould have been put into the inquiſitorial hands of the old women as a white witch."

This may be thought too ludicrous a treatment of a diſcovery which profeſſes to benefit mankind; but to have treated this diſcovery with ſeriouſneſs, would have degraded the profeſſion of a ſcientific critic. As if the very cures pretended to have been performed did not of themſelves throw ſufficient ridicule over the diſcovery, Mr Perkins informs us, "that in ſome inſtances the metallic influence, when excited by different perſons, produces different effects. Experiments made to aſcertain the point, proved that there were perſons who might uſe the tractors for any length of time, in diſeaſes which were ſuitable for the operation, and produce no perceptible effect; when by placing them in the hands of another perſon, who ſhould perform the operation preciſely in the ſame manner as before, the pain or inflammation would be removed directly." Hence he endeavours to prove that the influence of the tractors is Galvanic, by an argument as abſurd as the pretended fact on which it is founded.

"On the application (ſays he) of zinc and ſilver to the tongue, the ſenſation of taſte is very ſlight to ſome, while with others it is very ſtrong:—when the experiment is applied to the ſenſe of ſight, ſome are hardly ſenſible of it, while others obſerve a ſtrong flaſh." But, not to mention that neither ebony nor ivory can form part of the excitatory arc in *Galvaniſm*, though we have ſeen them both employed *ſucceſsfully* as tractors by a Daniſh Perkiniſt, it is enough to obſerve, that the different effects of the Galvanic metals on different perſons depend upon the difference of ſtructure of the organs of ſenſation in the *patients ;* whereas the different effects of the metallic tractors reſult, according to this account, from the difference of ſtructure in the organs of ſenſe of the various *operators !* Nay, what is ſtill more extraordinary, if any thing can be more extraordinary than this, is, that the value of the tractors depends, not upon the *materials* of which they are made, or the *ſkill* of the manufacturer, but upon ſome inconceivable virtue conveyed by Mr Perkins to the *perſon* of him by whom they are *ſold.* This we learn from a pamphlet publiſhed by Charles Cunningham Longworthy, ſurgeon in Bath ; who informs us, that he ſells tractors by *commiſſion* from Mr Perkins the original manufacturer in London."

After this article was ſent to the preſs, and thus much of it printed, we received, from a friend in London, a copy of Mr Perkins's laſt publication on the ſubject * ; in which he endeavours to repel the objections urged by Dr Haygarth and others againſt the influence of the metallic tractors. Had we not been previouſly convinced of the falſity of Perkiniſm, the peruſal of this pamphlet would have removed from our minds every doubt ; for we will venture to ſay, that it is not in the power of Dr Haygarth, and the whole faculty united, to bring more complete proof than Mr Perkins has here brought, that what he calls his father's *diſcovery* has no claim to rank otherwiſe than with the diſcovery of Meſmer. See *Animal* MAGNETISM, Encycl.

He gives indeed 250 caſes, which are atteſted to have been ſucceſsfully treated by the tractors ; but at leaſt an equal number of caſes were atteſted to have been ſucceſsfully treated by Meſmer and his partiſans ; and ſix times that number of cures were ſaid to have been miraculouſly performed at the tomb of the Abbé Paris (See PARIS in this *Suppl.)* We would willingly allow, however, that theſe atteſtations ought to draw the attention of men of ſcience to the ſubject, did not the author himſelf betray a want of confidence in the tractors, by his own arguments in their favour, and by his caution to the public againſt *counterfeits.* He ſeems indeed to conſider their ſanative influence as reſulting entirely from his *patent.*

Dr Haygarth having ſaid that he performed cures of the ſame kind with thoſe of which Mr Perkins boaſts, by the proper application of tractors made of *wood ;* and having added, that "if any perſon would repeat theſe experiments, it ſhould be done with due ſolemnity," in order to work upon the imagination ; our author replies, by putting the following queſtion: "Is there a ſingle poſſeſſor of the *patent metallic* tractors in England, who has frequently uſed them, and will ſay that this fraud is neceſſary to make *them* perform *cures ?"* Inſtead of anſwering for the Engliſh poſſeſſors of theſe valuable inſtruments, we beg leave, in our turn, to aſk, if there be a ſingle expert chemiſt in Great Britain who can underſtand this queſtion in any other ſenſe, than as implying that the virtue of the tractors reſides in the *patent ?* This, however, appears ſtill more palpable in the caution to the public.

"Among the various artifices (ſays Mr Perkins) which have been employed by certain intereſted perſons, I have to mention the mean attempt to circulate *falſe tractors*, and from the failure of theſe to throw diſcredit upon the diſcovery. Three inſtances of this kind have occurred lately. Complaints having been made to me that my tractors would not cure the diſeaſes for which they are recommended, I was led to make inquiry reſpecting the caſes alluded to ; and conceiving them fit ſubjects for the tractors, I called on the patients to apply them myſelf. In *both* inſtances (it was juſt now in *three* inſtances) I found they had been uſing *counterfeit* tractors. Had not this been diſcovered, the *merit* of the *patent* tractors muſt have ſuffered extremely !"

This is very extraordinary. The *character* or *fame* of any thing may indeed be injured by a counterfeit ; but we believe this is the firſt inſtance of the *merit* or *demerit* of one inanimate ſubſtance being increaſed or diminiſhed by another at a diſtance from it,—of the hardneſs of ſteel, for inſtance, being diminiſhed by the ſoftneſs of lead ! But we beg Mr Perkins's pardon. The *merit* of his tractors conſiſts in their putting money into his pocket ; and *that* merit might certainly be injured by the uſe of *counterfeits.* Hence, with great propriety, he informs the public, that every *genuine ſet* is ſtamped with the words PERKINS'S PATENT TRACTORS, accompanied with a receipt for the five guineas, numbered and ſigned in the handwriting of the patentee. From theſe facts we infer (and he muſt acknowledge the inference to be juſt), that the virtue of the tractors reſides in the *patent*, reſtricting the making of them to *Benjamin Douglas Perkins*, and not to the *metal* of which they are made. This is indeed moſt obvious ; for he cannot be ſuch a ſtranger to the ſtate of chemical ſcience in this country, as to ſuppoſe that his tractors may not be analyſed into their component principles, and, of courſe, that others may not be made poſſeſſing all their virtues except ſuch as reſult from the patent.

We ſhall conclude this article in the words of the reviewer already quoted : "To trace the relations and dependencies of projects ſimilar to that of Dr Perkins, would now be a work of more labour than utility. The fund of public credulity is an inexhauſtible reſource for thoſe who can reſolve to levy contributions on it. In vain is the ſpirit of quackery exorciſed in one form ; it riſes again immediately, 'with twenty ghaſtly murders on its head, to puſh us from our ſtools.' We, who have contemplated the progreſs of real knowledge during a long courſe of years, have ſeen many bubbles like this glitter for a moment, and then diſappear for ever. People may talk of Meſmeriſm, or Perkiniſm, but we conſider all ſuch varieties as belonging to the old and extenſive claſs of Charlataniſm."

PEROUSE (John Francis Galoup de la), the celebrated, though unfortunate, French navigator, was born at Albi in 1741. Of the rank or condition of his father, M. *Milet-Marsau* has given us no information in that meagre eulogy of Perouſe which he has inſerted in the introduction to his laſt voyage. It appears, however, that he intended to make his ſon a ſeaman, and ſent him, at a very early period of life, to the marine ſchool, where the young man became enthuſiaſtically fond of his profeſſion, and laudably ambitious to emulate the fame of the moſt celebrated navigators.

Being

---

* *The Efficacy of Perkins's Patent Metallic Tractors, &c.* 1800.

Perpendicular
||
Peterſburgh.

Being appointed a midſhipman on the 19th of November 1756, he behaved, we are told, with great bravery in that ſtation, and was ſeverely wounded in the engagement between the admirals Hawke and Conflans, on the 20th of November 1759. The Formidable, in which he ſerved, was taken, after a vigorous reſiſtance; and it is probable that Perouſe reaped ſome advantage from his acquaintance with Britiſh officers.

On the 1ſt of October 1764 he was promoted to the rank of lieutenant; and deſpiſing a life of eaſe and idleneſs, he contrived to be employed in ſix different ſhips of war during the peace that ſubſiſted between Great Britain and France. In 1767 he was promoted to the rank of what, in our navy, is called *maſter* and *commander*. In 1779 he commanded the *Amazone*, belonging to the ſquadron of Vice-admiral Count d'Eſtaing; and when that officer engaged Admiral Byron, the poſt of La Perouſe was to carry his Admiral's orders to the whole of the line. He afterwards took the ſloop *Ariel*, and contributed to the capture of the *Experiment*—exploits which his eulogiſt ſeems to conſider as inſtances of very uncommon heroiſm; but he ſoon after performed a greater.

Being, on the 4th of April 1780, appointed captain of the frigate *Aſtrea*, and being on a cruiſe with the *Hermione*, theſe two frigates attacked ſix Engliſh veſſels of war, of from 28 to 14 guns each, and took two of them. The French certainly reaped more laurels about that period than they have been accuſtomed to do in naval wars with Great Britain; but as we have completely forgotten the particulars of this fight, we ſuſpect that it was not altogether ſo very brilliant a buſineſs as M. Milet-Mureau is pleaſed to repreſent it.

In the year 1782, La Perouſe was diſpatched with the Sceptre of 74 guns, and two frigates of 36 guns each, having ſome troops and field pieces on board, to deſtroy the Engliſh ſettlements in Hudſon's Bay. This taſk was eaſily accompliſhed; for when he had ſurmounted the difficulties of navigation in a frozen ſea, he found nothing on ſhore to oppoſe the ſmalleſt force. Having deſtroyed the ſettlements, he learned that ſome of the Engliſh had fled at his approach into the woods; and his eulogiſt conſiders it (ſuch are the diſpoſitions of French republicans) as a moſt wonderful inſtance of humanity, that he left to theſe unfortunate men proviſions to preſerve them from periſhing by hunger, and arms to protect them from the fury of the ſavages! Perouſe, we dare anſwer for him, was conſcious of nothing heroic or extraordinary in this act of beneficence, which he certainly could not have omitted, without incurring both infamy and guilt.

In the year 1785, he was appointed to the command of a voyage round the world; which was unfortunately deſtined to be his laſt. Of this voyage, as far as it was accompliſhed, there is a full account in the hands of every French and Engliſh reader; and from that account it appears, that Perouſe was admirably qualified to diſcharge ſuch a truſt. He ſeems to have been an experienced and ſkilful ſeaman; a man of conſiderable mathematical and phyſical ſcience, uncorrupted by that philoſophiſm which diſgraced many of his attendants; and capable of the utmoſt perſeverance in every laudable purſuit. To theſe qualities he united a proper combination of caution and courage, with a diſpoſition truly benevolent to the various tribes of ſavages whom he viſited. The diſaſters which occurred on the voyage were all, except the laſt, of which nothing is known, occaſioned by the diſobedience of his officers, or their neglecting to follow his advice.

The laſt diſpatches of this great and good man were dated from Botany Bay, February the 7th 1788; and ſince that period, no account of him has been received which is intitled to the ſmalleſt confidence. *M. Milet-Mureau* has indeed given us, at ſome length, the childiſh conjectures of the Society of Natural Hiſtory reſpecting his fate, which, in language equally childiſh, were delivered at the bar of the National Aſſembly; and he has added the ridiculous decree which that body of legiſlative ſcioliſts paſſed in conſequence of ſo extraordinary a ſpeech. We will not diſgrace our pages, or inſult the memory of Perouſe, by contributing to the circulation of nonſenſe, which, we are perſuaded, would have made him bluſh for his country.

PERPENDICULAR, in gunnery, is a ſmall inſtrument, uſed for finding the centre line of a piece in the operation of pointing it to a given object.

PERSIAN or PERSIC, in architecture, a name common to all ſtatues of men, ſerving inſtead of columns to ſupport entablatures.

PERWANNAH, in the language of Bengal, an order of government, or a letter from a perſon in authority.

PETERSBURGH (St), the capital of Ruſſia, is a city, of which a pretty full hiſtorical detail has been given in the *Encyclopædia*. It is introduced here merely on account of its police, which, according to the anonymous author of the life of Catharine II. has a very ſimple and competent organization, and deſerves to be adopted in other great capitals. Excepting the governor, whoſe office naturally extends to all objects of public welfare, the head police-maſter is the proper chief of the whole ſyſtem of police. His office takes in the great compaſs of this department, but confined to the general objects of public ſecurity and order. He is not here, as in ſome large towns, the formidable copartner of family ſecrets, and the inviſible witneſs of the actions of the private man. Under the head police-maſter is the police office, where ſit a police-maſter, two preſidents, the one for criminal, the other for civil caſes, and two conſulters, choſen from the burgher claſs. To this is committed the care to maintain decorum, good order, and morals: alſo it is its buſineſs to ſee to the obſervance of the laws, that the orders iſſued by government, and the deciſions of the courts of juſtice, are put in force. The attainment of theſe purpoſes is effected by the following mechaniſm:

The reſidence is divided into ten departments Each of theſe has a preſident, appointed to watch over the laws, the ſecurity, and the order of his diſtrict. The duties and rights of this office are not leſs extenſive than important. A preſident muſt have exact knowledge of the inhabitants of his department, over which a ſort of parental authority is committed to him; he is the *cenſor morum* of his department; his houſe muſt not be bolted or barred by night or day, but muſt be a place of refuge, continually open to all that are in danger or diſtreſs; he himſelf may not quit the town for the ſpace of two hours, without committing the diſcharge of his office to ſome other perſon. The police-commando (conſtables), and the watchmen of his department, are

under

Peterſburgh.

under his orders ; and he is attended on all affairs of his office by two ſerjeants. Complaints againſt unjuſt behaviour in the preſident may be brought to the police office.

Each department is again divided into three, four, or five ſubdiviſions, called quarters, of which, in the whole reſidence, are 42. Each of theſe has a quarter-inſpector, in ſubordination to whom is a quarter-lieutenant. The duty of theſe police-officers is in harmony with that of the preſident, only that their activity is confined to a ſmaller circle. They ſettle low affairs and ſlight altercations on the ſpot, and keep a watchful eye on all that paſſes.

The number of the nightly watch in the city amounts to 500. They have their ſtations aſſigned them in watch-houſes at the corners of ſtreets; and, beſides their proper deſtination, are to aſſiſt in the taking up of offenders, and in any ſervice, by day or night, as their commanders ſhall require. Beſides theſe, for the execution of the police orders, and to act as patroles, there is alſo a commando of 120 men, who, in caſes of emergency, are ſupported by a company of koſaks, or a regiment of huſſars.

This machine, conſiſting of ſo many ſubordinate parts, preſerves in its orderly courſe that ſecurity and peace which excite the admiration of all foreigners. The activity of every individual member is unobſerved in the operation of the whole ; and by ſuch a diſtribution alone is the attainment of ſo complicated an aim practicable.—All the quarter-inſpectors of a department repair every morning, at ſeven o'clock, to their inſpector's houſe, to lay before him the report of all that has happened in their quarters during the laſt 24 hours ; and at eight o'clock, all the inſpectors bring together theſe ſeveral reports into the police-office, whereupon they firſt and immediately take into examination the caſes of perſons taken into cuſtody during the night. On urgent occaſions, the police-office aſſembles at all hours.

This organization, and the extraordinary vigilance of the police, which is found competent to the buſineſs of a numerous and reſtleſs people, render all ſecret inquiſitions unneceſſary. The police has knowledge of all perſons in the reſidence ; travellers who come and go are ſubject to certain formalities, which render it extremely difficult to conceal their place of abode, or their departure from the city. To this end, every houſeholder and innkeeper is obliged to declare to the police, who lodges with him, or what ſtrangers have put up at his houſe. If a ſtranger or lodger ſtays out all night, the landlord muſt inform the police of it at lateſt on the third day of his abſence from his houſe. The cautionary rules, in regard to travellers quitting the town, are ſtill more ſtrict. Theſe muſt publiſh in the newſpapers their name, their quality, and their place of abode, three ſeveral times, and produce the newſpapers containing the advertiſement, as a credential in the government from which they then receive their paſſport ; without which, it is next to impoſſible to get out of the empire. This regulation not only ſecures the creditor of the perſon about to depart, but alſo enables the police to keep a cloſer inſpection over all ſuſpected inhabitants.

If individuals may be ſuſpected by the government, becauſe their means of ſupport, the company they keep, and their whole courſe of action, are cloſely wrapped up in myſtery ; ſo likewiſe may whole ſocieties be leſs indifferent to it, if they carefully conceal the object of their connection, or their very exiſtence, from the eye of the public. The police watches here, with laudable attention, over ſecret ſocieties of all kinds ; and frequently as the fanatical ſpirit of religious or political ſectaries, or the enthuſiaſm of pretended myſtagogues, have attempted to neſtle here, they have never been able to proceed, or only for a very ſhort time. Animal magnetiſm, Martiniſm, Roſycrutianiſm, and by whatever other name the conceits of diſtempered imaginations may be called, have always been attended with the ſame bad ſucceſs on this ſtage.

From this ſketch it will be readily imagined, that the number of impoſtors and diſturbers of the public peace can be but ſmall. Quarrels and affrays in the ſtreet or in the cabaks but ſeldom happen. The perſon attacked calls the neareſt watchman ; and in a moment both the aggreſſor and the aggrieved are taken into cuſtody, and led to the next ſieja (police-watch-houſe), where the cauſe of their quarrel is inquired into, and the aggreſſor is puniſhed. For matters of ſome deſcriptions, there is a peculiar tribunal, under the denomination of the oral court, which, on account of its ſingularity, deſerves to be briefly noticed.

In each quarter of the town are one or more judges of the oral court, who are choſen from the claſs of burghers, and with whom are aſſociated a few jurats. This court ſits daily in the forenoon, and proceeds orally in all the differences that come before it. It, however, keeps a day-book, in which are entered all the cauſes and deciſions of the court, and which muſt be every week laid before the magiſtrate. When a charge is brought, the court declares it orally to the preſident of the quarter : whereupon the accuſed muſt not delay his appearance before the police longer than one day after he has received the ſummons. Every cauſe muſt be determined in one day, or, if the examinations require more time in collecting, in three days. The oral court communicates the deciſion to the preſident of the quarter by means of his day-book, in order to its ratification. If either party is not ſatisfied with the ſentence, he may appeal to the court as appointed in the regulations.

This is a very favourable account of the police of St Peterſburgh ; but it is differently repreſented in *Beaujolin's Travels of two Frenchmen through Ruſſia*, in 1790—1792. According to him, the police of the capital of that empire is far from being on the moſt reſpectable footing. There happen, indeed, but few accidents in the night ; yet ſometimes murders are committed, and eſpecially thefts ; for which, according to our author, it is exceedingly rare to obtain juſtice. When a perſon has been aſſaſſinated in ſome place of bad repute, the police-officer is engaged to ſecrecy by means of a few rubles ; ſo that the affair is ſoon huſhed up, unleſs the deceaſed belonged to ſome powerful family, whoſe intereſt makes it neceſſary that inquiries ſhould be inſtituted. When two perſons quarrel, either in the ſtreet or in a public-houſe, he who *pays* the inquirer is always in the right : the inferior police-officers are never proof againſt money ; and the *poor* individual, whether he be in the right or wrong, is almoſt ſure of a beating.

PETIVER (James), a famous Engliſh botaniſt, was con-

tiver,
ſianus.

contemporary with Plukenet; but the exact time of his birth is not known, nor is much intelligence concerning him at preſent to be obtained. His profeſſion was that of an apothecary, to which he was apprenticed under Mr Feltham, then apothecary to St Bartholomew's hoſpital *. When he entered into buſineſs for himſelf, he ſettled in Alderſgate-ſtreet, and there continued for the remainder of his life. He obtained conſiderable buſineſs, and after a time became apothecary to the charter houſe. After the Tradeſcants, he appears to have been the only perſon, except Mr Courten and Sir Hans Sloane, who made any conſiderable collection in natural hiſtory, previous to thoſe of the preſent day. He engaged the captains and ſurgeons of ſhips to bring him home ſpecimens, and enabled them to ſelect proper objects, by printed directions which he diſtributed among them. By theſe means his collection became ſo valuable, that ſome time before his death, Sir Hans Sloane offered him L. 4000 for it. After his death, it was purchaſed by the ſome collector. His muſeum extended his fame both at home and abroad. He was elected into the Royal Society; and becoming acquainted with Ray, aſſiſted him in arranging the ſecond volume of his Hiſtory of Plants. He died April 20. 1718; and much honour was ſhewn to him at his funeral, by the attendance of Sir Hans Sloane, and other eminent men, as pall bearers, &c. By future botaniſts, his name was given to a plant. See PETIVERIA, *Encycl.*

* ult- s Sket- of Bo- in E and.

He gave the world ſeveral publications on various ſubjects of natural hiſtory: 1. *Muſei Petiveriani Centuriæ decem*, 1692—1703, 8vo. 2. *Gazophylacii Naturæ et Artis, Decades decem*, folio, 1702, with 100 plates. 3. A Catalogue of Mr Ray's Engliſh Herbal, illuſtrated with figures, folio, 1713, and continued in 1715. 4. Many ſmall publications, which may be found enumerated in Dr Pultney's book. 5. Many papers in the Philoſophical Tranſactions, and a material article in the third volume of Ray's work, entitled, *Plantæ Rariores Chinenſes Madraſpatanæ, et Africanæ, a Jacobo Petivero ad opus Conſummandum Collatæ*, &c. Many of his ſmaller tracts having become very ſcarce, his works were collected and publiſhed, excluſive of his papers in the Tranſactions, in 2 vols folio, and one 8vo, in the year 1764.

PHASIANUS (See *Encycl.*). A ſpecies of this genus of birds, formerly not deſcribed, was ſent from Batavia to England by Lord Macartney, or ſome of his attendants, when they were on their voyage to China. The ſpecies to which it ſeemed to be moſt nearly allied, in point of general habit or appearance, was the *phaſianus curviroſtris*, or Impeyan pheaſant; an Eaſt Indian bird, deſcribed and figured both in Mr Latham's Ornithology, and in the Muſeum Leverianum. From that bird, however, it differs very conſiderably. The tail of the latter being in a mutilated ſtate, it was ſcarce poſſible to determine, with abſolute preciſion, whether it ſhould be referred to that ſubdiviſion of pheaſants, which contains thoſe with long or cuneiform tails, or thoſe with rounded ones, as in the Impeyan pheaſant. The general colour of this moſt elegant bird was black, with a gloſs of blue, or what, in the language of natural hiſtory, may be termed chalybean black, or black accompanied by a ſteel blue luſtre. The lower part of the back was of a peculiarly rich colour, which, according to the different directions of the light, appeared either of a deep ferruginous or of the brighteſt fiery orange-red. This beautiful colour paſſed in the manner of a broad zone round the whole body; but on the abdomen was of a much more obſcure appearance than on the back, as well as ſomewhat broken or irregular, eſpecially on the ſides. The throat was furniſhed with a large, and ſomewhat angular, pair of wattles, uniting with the bare ſpaces on the cheeks. The feathers on the top of the head, which was of a lengthened form, ran a little backward, ſo as to give the appearance of an indiſtinct occipital creſt. The beak was remarkable for a more lengthened and curved aſpect than in any other bird of this genus, except the Impeyan pheaſant. The feathers on the neck, back, and breaſt, were rounded, and of the ſame ſhell-like or ſcaly habit as thoſe of the turkey. The legs very ſtout, and were armed with a pair of extremely ſtrong, large, and ſharp ſpurs. Both legs and beak were of a pale colour. Whether this bird be really new or not to the ornithologiſts of Europe, it may at leaſt be affirmed with ſafety, that it had never been properly deſcribed; nor can the character of any ſpecies, hitherto introduced into the books of any ſyſtematic naturaliſt, be conſidered as a juſt or competent ſpecific character of the preſent bird. . It may be called the *fire-backed pheaſant*; and its eſſential character may be delineated in the following terms: Black pheaſant with a ſteel-blue gloſs; the ſides of the body rufous; the lower part of the back fiery ferruginous; the tail rounded; the two middle feathers pale yellow brown.—*Sir George Staunton's Account of an Embaſſy to China, &c.*

Phaſianus, Philoſophiſt.

PHILOSOPHIST, a lover of ſophiſtry or falſe reaſoning, in contradiſtinction to *philoſopher*, who is a lover of ſound reaſoning, true ſcience, and practical wiſdom.

CRITICAL PHILOSOPHY.

1
in of
ſcience.

CRITICAL PHILOSOPHY, is the appellation given to a ſyſtem of ſcience, of which the founder is *Immanuel Kant*, regius profeſſor of logic and metaphyſics in the univerſity of Koenigſberg. Of this ſyſtem, which is very generally admired in Germany, we promiſed, in our Proſpectus, to gratify our ſpeculative readers with a ſhort view; and that promiſe we are enabled to fulfil, by the kind communication of an illuſtrious foreigner, who, after acting a conſpicuous part on the theatre of the world, and ſtriving in vain to ſtem the torrent of democratic innovation, is now living an exile from his wretched country, and cultivating the ſciences and the arts of peace.

2
Obſcurity of its language.

"To explain (ſays he) the philoſophy of Kant in all its details, would require a long and a painful ſtudy, without producing any real advantage to the reader. The language of the author is equally obſcure, and his reaſonings equally ſubtle, with thoſe of the commentators of Ariſtotle in the 15th century."

The truth of this aſſertion will be denied by none, who have endeavoured to make themſelves maſters of the works of *Willich* and *Nitſch* on the critical philoſophy; and the ſource of this obſcurity ſeems to be ſufficiently obvious. Beſides employing a vaſt number of words of his own invention, derived from the Greek language, Kant uſes expreſſions, which have long been familiar to metaphyſicians, in a ſenſe different from that in which they are generally received; and hence a large portion of time is requiſite to enable the moſt ſagacious mind to aſcertain with preciſion the import of his phraſeology.

The difficulty of comprehending this philoſophy has contributed, we believe, more than any thing elſe, to bring it into vogue, and to raiſe the fame of its author. Men are aſhamed, after ſo laborious and fatiguing a ſtudy, to acknowledge that all their labour has been thrown away; and vanity prompts almoſt every man to raiſe the importance of that branch of ſcience which is underſtood but by a few, and in which he is conſcious that his own attainments have been great. "We acknowledge, however, that in the ſyſtem of Kant there is diſplayed much genius, combination, and ſyſtematic arrangement; but this only affords one of the many reaſons which it preſents, for our regretting that the author has not directed his mind to more uſeful reſearches, and that he has waſted the ſtrength of his genius in rendering uncertain the moſt comfortable truths, and in giving the appearance of novelty to opinions for the moſt part taught long before his day.

The following analyſis, we believe, will ſufficiently enable any one, at all converſant with metaphyſical ſcience, to form a judgment of this celebrated ſyſtem; and our correſpondent, on whoſe word the reader may rely, aſſures us, that, in detailing the principles of Kant, he has taken ſpecial care to exhibit them with the utmoſt poſſible exactneſs, having ſeveral times preferred the obſcurity of the author's reaſonings and language, to the danger of a falſe, though more perſpicuous, interpretation.

3 Diviſion of human knowledge. "Kant divides all our knowledge into that which is *a priori*, and that which is *a poſteriori*. Knowledge *a priori* is conferred upon us by our nature. Knowledge *a poſteriori* is derived from our ſenſations, or from experience; and is by our author denominated *empyric.* One would at firſt be induced, by this account of the origin of human knowledge, to believe that Kant intended to revive the ſyſtem of *innate ideas;* but we very quickly diſcover that ſuch is not his ſyſtem. He conſiders all our knowledge as acquired. He maintains, that experience is the *occaſional cauſe* or *productrice* of all our knowledge; and that without it we could not have a ſingle idea. Our ideas *a priori*, he ſays, are produced *with* experience, and could not be produced *without* it; but they are not produced *by* it, or do not proceed *from* it. They exiſt in the mind; they are the *forms* of the mind. They are diſtinguiſhed from other ideas by two marks, which are eaſily diſcerned; *i. e.* they appear *univerſal* and *neceſſary*; or, in other words, they admit of no exception, and their *converſe* is impoſſible. Ideas which we derive from experience have no ſuch characters. We can ſuppoſe, that what we have ſeen, or felt, or heard once, we may ſee, or feel, or hear again; but we do not perceive any impoſſibility in its being otherwiſe. For inſtance, a houſe is on fire in my view: I am certain of this fact; but it affords me no *general* or *neceſſary* knowledge. It is altogether *a poſteriori*; the materials are furniſhed by the individual impreſſion which I have received; and that impreſſion might have been very different.

"But if I take twice two ſmall balls, and learn to call twice two *four*, I ſhall be immediately convinced, that any two bodies whatever, when added to any two other bodies, will conſtantly make the ſum of bodies *four*. Experience has indeed afforded me the *opportunity* of acquiring this knowledge; but it has not given it to me; for how could experience prove to me that this truth ſhall never vary? Experience muſt always be *limited*; and therefore cannot teach us that which is *neceſſary* and *univerſal*. It is not experience which diſcovers to us, that we ſhall always have the ſurface of the whole pyramid by multiplying its baſe by the third part of its height; or that two parallel lines, extended *in infinitum*, ſhall never meet.

"All the truths of pure mathematics are, in the language of Kant, *a priori*. Thus, that a ſtraight line is the ſhorteſt of all poſſible lines between two fixed points; that the three angles of a triangle are always equal to two right angles; that we have the ſame ſum, whether we add 5 to 7 or 7 to 5; and that we have the ſame remainder when we ſubtract 5 from 10 as when we ſubtract 10 from 15—are ſo many propoſitions, which are true *a priori*.

4 Pure knowledge *a priori*. "Pure *knowledge a priori*, is that which is abſolutely without any mixture of experience. *Two and two men* make *four men*, is a truth, of which the knowledge is *a priori*; but it is not PURE knowledge, becauſe the truth is particular. The ideas of *ſubſtance*, and of *cauſe* and *effect*, are *a priori*; and when they are ſeparated from the objects to which they refer (we ſuppoſe from this or that *particular* object), they form, in the language of Kant, *void ideas* (A). It is our knowledge *a priori*, *i. e.* that knowledge which precedes experience as to its origin, which renders experience poſſible (B). Our faculty of knowledge has an effect on our ideas of ſenſation analogous to that of a veſſel, which gives its own form to the liquor with which it is filled. Thus, in all our knowledge *a poſteriori*, there is ſomething *a priori* derived from our faculty of knowledge. All the operations of our minds; all the impreſſions which our external and internal ſenſes receive and retain, are brought into effect by the *conditions*, the *forms*, which exiſt in us by the pure ideas *a priori*, which alone render all our other knowledge certain.

5 Time and ſpace. "*Time* and *ſpace* are the two eſſential forms of the mind:

(A) In the language of Locke *abſtract ideas*.

(B) In our correſpondent's manuſcript, this ſentence runs thus: "It is our knowledge *a priori*, or that knowledge which *entirely precedes experience* as to its origin, which experience renders poſſible;" but here muſt be ſome miſtake, either by the tranſlator or by the amanuenſis. Kant's philoſophy is abundantly obſcure and paradoxical; but it ſurely never entered into his head to repreſent the effect as prior in its origin to the very cauſe which alone renders it poſſible. The context, too, ſeems to us to agree better with the meaning of the ſentence as we have printed it in the text.

mind : the former for impreſſions received by the internal ſenſe ; the ſecond for thoſe received by our external ſenſes. Time is neceſſary in all the *immediate* (perhaps *intuitive*) perceptions of objects ; and ſpace in all *external* perceptions.

6 xtenſion. “ *Extenſion* is nothing real but as the form of our ſenſations. If extenſion were known to us only by experience, it would then be poſſible to conceive that there might be ſenſible objects without ſpace.

7 mpenetrability, &c “ It is by means of the form *ſpace* that we are enabled, *a priori*, to attribute to external objects *impenetrability, diviſibility, mobility*, &c. ; and it is by means of the form *time* that we attribute to any thing *duration, ſucceſſion, ſimultaneity, permanence*, &c.

8 Origin of rithmetic nd geometry. “ *Arithmetic* is derived from the form of our internal ſenſe, and *geometry* from that of our external.

9 Unifying power of the mind. “ Our underſtanding collects the ideas received by the impreſſions made on our organs of ſenſe, confers on theſe ideas *unity* by a particular *force* (we ſuppoſe energy) *a priori* ; and thereby forms the repreſentation of each object. Thus, a man is ſucceſſively ſtruck with the impreſſions of all the parts which form a particular garden. His underſtanding unites theſe impreſſions, or the ideas reſulting from them ; and in the unity produced by that unifying act, it acquires the idea of the garden. If the objects which produce the impreſſions afford alſo the *matter* of the ideas (c), then the ideas are *empyric* ; but if the objects only unfold the *forms of the thought*, the ideas are *a priori*. The act of the underſtanding which unites the perceptions of the various parts of an object into the perception of one whole, is the ſame with that which unites the attribute with its ſubject.

10 Analytic judgments. “ Judgments are divided into two ſpecies ; *analytic* and *ſynthetic*. An analytic judgment is that in which the attribute is the mere developement of the ſubject, and is found by the ſimple analyſis of the perception ; as *bodies are extended* ; *a triangle has three ſides*.

11 Synthetic judgments. “ A ſynthetical judgment is that where the attribute is connected with the ſubject by a cauſe (or baſis) taken from the faculty of knowledge, which renders this connection neceſſary : as, *a body is heavy* ; *wood is combuſtible* ; *the three angles of a triangle are equal to two right angles*. There are ſyntheſes *a priori* and *a poſteriori* ; and the former being formed by experience, we have the ſure means of avoiding deception.

“ It is a problem, however, of the utmoſt importance, to diſcover how ſynthetic judgments *a priori* are poſſible. How comes it, for example, that we can affirm that all the radii of a circle are equal, and that two parallel lines will never meet ? It is by ſtudying the *forms* of our mind that we diſcover the poſſibility of making theſe affirmations. In all objects there are things which muſt neceſſarily be THOUGHT (be ſupplied by thought) ; as, for example, that there is *a ſubſtance*, an *accident*, a *cauſe*, and certain *effects*.

12 Forms of the underſtanding. “ The *forms* of the underſtanding are, *quantity, quality, relation, modality*.

“ Quantity, Kant diſtinguiſhes into *general, particular*, and *individual* ; quality, into *affirmation, negation, infinite* ; relation, into *categoric, hypothetic*, and *disjunctive* ; and modality, into *problematic, certain*, and *neceſſary*. He adds alſo to theſe properties of the four principal forms of the underſtanding, a table of *categories*, or fundamental ideas *a priori*.

13 Categories. “ Quantity, gives *unity, plurality, totality*. Quality, gives *reality, negation, limitation*. Relation, gives *inherence, ſubſtance, cauſe, dependence, community, reciprocity*. Modality, gives *poſſibility, impoſſibility, exiſtence, nothing, neceſſity, accident*. Theſe categories can only be applied to experience. When, in the conſideration of an object, we abſtract all that regards ſenſation, there remain only the pure ideas of the underſtanding, or the *categories*, by which a *thing* is conceived as a *thing*.

“ Pure reaſon is the faculty of tracing our knowledge *a priori*, to ſubject it to principles, to trace it from its neceſſary conditions, till it be entirely without condition, and in complete unity. This pure reaſon has certain fundamental rules, after which the neceſſary connection of our ideas is taken for the determination of the objects in themſelves ;—an illuſion which we cannot avoid, even when we are acquainted with it. We can conclude from what we know to what we do not know ; and we give an *objective* reality to theſe concluſions from *an appearance* which leads us on.

14 Critique of pure reaſon. “ The writings of Kant are multifarious ; but it is in his work entitled the *Critique of Pure Reaſon* that he has chiefly expounded his ſyſtem. This work is a treatiſe on a pretended ſcience, of which Kant's ſcholars conſider him as the founder, and which has for its objects the *natural forces*, the *limits of our reaſon*, as the ſource of our pure knowledge *a priori*, the *principles of all truth*. Kant does not propoſe to give even an expoſition of theſe branches of knowledge, but merely to examine their origin ; not to extend them, but to prevent the bad uſe of them, and to guard us againſt error. He denominates this ſcience *tranſcendental criticiſm* ; becauſe he calls all knowledge, of which the object is not furniſhed by the ſenſes, and which concerns the kind and origin of our ideas, *tranſcendental knowledge*. The Criticiſm of Pure Reaſon, which gives only the fundamental ideas and maxims *a priori*, without explaining the ideas which are derived from them, can lead (ſays Kant) to a complete ſyſtem of pure knowledge, which ought to be denominated *tranſcendental philoſophy*, of which it (the *Criticiſm*, &c.) preſents the *architectonic* plan, *i. e.* the plan regular and well diſpoſed.

“ The work entitled *The Critique of Pure Reaſon*, is divided into ſeveral parts or ſections, under the ridiculous titles of *Æſthetic tranſcendental* ; of *tranſcendental logic* ; of *the pure ideas of the underſtanding* ; of *the tranſcendental judgment* ; of *the paralogiſm of pure reaſon* ; of *the ideal tranſcendental* ; of *the criticiſm of ſpeculative theologies* ; of *the diſcipline of pure reaſon*, &c.

15 We cannot know objects as they are in themſelves. “ But to proceed with our abſtract of the ſyſtem. We know objects only by the manner in which they affect us ; and as the impreſſions which they make upon us are only certain *apparitions* or *phenomena*, it is impoſſible for us to know what an *object is in itſelf*. In conſequence of this aſſertion, ſome have ſuppoſed that Kant is an *idealiſt* like Berkeley and ſo many others, who have thought that ſenſations are only *appearances*, and

---

(c) This is wonderful jargon ; but the reader will reflect that it is not ours.

and that there is no truth but in our reaſon; but ſuch is not the opinion of Kant (D). According to him, our underſtanding, when it conſiders the apparitions or phenomena, acknowledges the *exiſtence* of the objects in themſelves, inaſmuch as they ſerve for the baſes of thoſe apparitions; though we know nothing of their *reality*, and though we can have no certitude but in experience.

“When we apply the *forms* of our underſtanding, ſuch as *unity*, *totality*, *ſubſtance*, *caſuality*, *exiſtence*, to certain ideas which have no object in *ſpace* and *time*, we make a fallacious and arbitrary application. All theſe forms can bear only on ſenſible objects, and not on the *world of things in itſelf*, of which we can THINK, but which we CAN NEVER KNOW. Beyond things ſenſible we can only have *opinions* or a *belief* of our reaſon.

16 Objective and ſubjective truths.

“The motives to conſider a propoſition as true, are either *objective*, *i. e.* taken from an *external* object, ſo that each man ſhall be obliged to acknowledge them; and then there is a truth *evident* and ſuſceptible of *demonſtration*, and it may be ſaid that we are *convinced;* or the motives are *ſubjective*, *i. e.* they exiſt only in the mind of him who judges, and he is *perſuaded*.

“TRUTH, then, conſiſts in the agreement of our *notions* with the *objects*, in ſuch a manner as that all men are obliged to form the ſame judgment; BELIEF conſiſts in holding a thing for true in a *ſubjective manner*, in conſequence of a perſuaſion which is entirely perſonal, and has not its baſis in an object ſubmitted to experience.

17 Belief.

“There is a *belief of doctrine*, of which Kant gives, as an example, this aſſertion—‘there are inhabitants in the planets.’ We muſt acknowledge (he adds) that the ordinary mode of teaching the exiſtence of God belongs to *the belief of doctrine*, and that it is the ſame with *the immortality of the ſoul*. *The belief of doctrine* (he continues) has in itſelf ſomething *ſtaggering;* but it is not the ſame with *moral belief*. In moral belief there is ſomething *neceſſary;* it is (ſays he), that I ſhould obey the law of morality in all its parts. The end is ſtrongly eſtabliſhed; and I can perceive only one condition, by means of which this end may be in accord with all the other ends, *i. e.* that *there is a God*. I am certain that no man knows any other condition which can conduct to the ſame unity of end under the moral law; which law is a law of my reaſon. I will conſequently believe certainly the *exiſtence of God*, and a *future life;* becauſe this perſuaſion renders immoveable my moral principles—principles which I cannot reject without rendering myſelf contemptible in my own eyes. I wiſh for happineſs, but I do not wiſh for it without morality; and as it depends on *nature*, I cannot wiſh it with this condition, except by believing that nature depends on a Being who cauſes this connection between morality and happineſs. This ſuppoſition is founded on the *want* (or *neceſſity*) of my reaſon, and not on my duty.

18 Proof of the exiſtence of God, &c.

“We have, however, no *certainty* (ſays Kant) in our knowledge of God, becauſe certainty cannot exiſt except when it is founded on an object of experience. The philoſopher acknowledges, that *pure reaſon* is too weak to prove the exiſtence of a being beyond the reach of our ſenſes. The neceſſity of believing in God is therefore only *ſubjective*, although neceſſary and general for all thoſe beings who conform to their duty. This is not *knowledge*, but only a *belief* of reaſon, which ſupplies the place of a knowledge which is impoſſible (E).

“The proofs of natural theology (ſays our philoſopher) taken from the order and beauty of the univerſe, &c. are proofs only in *appearance*. They reſolve themſelves into a bias of our reaſon to *ſuppoſe* an Infinite Intelligence as the author of all that is poſſible; but from this bias it does not follow that there really is ſuch an Author. To ſay, that whatever exiſts muſt have a cauſe, is indeed a maxim *a priori;* but it is a maxim applicable only to experience, for one knows not how to ſubject to the laws of our perceptions that which is abſolutely independent of them. It is as if we were to ſay, that whatever exiſts in experience muſt have an experience; but the world, taken as a whole, is without experience as well as its cauſe. It is much better to draw the proof of the exiſtence of God from morality, than to weaken it by ſuch reaſoning. This proof is relative. It is impoſſible to *know* that God exiſts; but we can comprehend how it is poſſible to act morally on the *ſuppoſition* of the exiſtence (although incomprehenſible) of an intelligent Creator—an exiſtence which PRACTICAL REASON forces THEORETICAL *reaſon* to adopt. This proof not only *perſuades*, but even acts on the CONVICTION, in proportion as the motives of our actions are conformable to the law of morality.

“Religion ought to be the *means* of virtue and not its object. Man has not in himſelf the idea of religion as he has that of virtue. The latter has its principle in the mind; it exiſts in itſelf, and not as the means of happineſs; and it may be taught without the idea of a God, for the pure law of morality is *a priori*.

19 Morality.

“He who does good by inclination does not act *morally*. The converſe of the principle of morality is to make perſonal happineſs the baſis (F) of the will. There are compaſſionate minds which feel an internal pleaſure in communicating joy around them, and who thus enjoy the ſatisfaction of others; but their actions, however juſt, however good, have no moral merit, and may be compared to other inclinations; to that of honour

---

(D) We muſt requeſt the reader to obſerve that this is the language of our correſpondent. We have ſhewn elſewhere, that Berkeley did not deny the reality of ſenſations; and we hope to ſhew by and bye, that Kant is as much an *idealiſt* as he was, if this be a fair view of the Critical Philoſophy.

(E) We have here again taken the liberty to alter the language of our correſpondent. He makes Kant ſay, “It is not this knowledge, but a *belief* of reaſon, &c.;” but this is ſurely not the author's meaning. From the context, it is apparent that Kant means to ſay, that we have not, and cannot have, what can be properly called a *knowledge* of the exiſtence of God, but only ſuch a belief of his exiſtence as ſupplies the place of this impoſſible knowledge.

(F) This is a very abſurd phraſe. We ſuppoſe Kant's meaning to be, that the principles of him whoſe actions and volitions are influenced by the proſpect of perſonal happineſs, are the reverſe of the pure principles of morality.

honour (for example), which, whilſt it meets with that which is juſt and uſeful, is worthy of praiſe and encouragement, but not of any high degree of eſteem. According to Kant, we ought not even to *do good*, either for the pleaſure we feel in doing it, or in order to be happy, or to render others happy; for any one of theſe additions (perhaps motives) would be *empyric*, and injure the purity of our morals. A reaſonable being ought to deſire to be exempted from all *inclinations*, and never to do his duty but for his duty's ſake.

"We ought to act after the maxims derived *a priori* from the faculty of knowledge, which carry with them the idea of neceſſity, and are independent of all experience; after the maxims which, it is to be wiſhed, could be erected into GENERAL LAWS for all beings endowed with reaſon."

20 lity of ſyſtem

If this be a correct view of the object and the reſults of the critical philoſophy, and the character of him from whom we received it permits us not to doubt of its being nearly correct, we confeſs ourſelves unable to diſcover any motive which ſhould induce our countrymen, in their reſearches after truth, to prefer the dark lantern of Kant to the luminous torch of Bacon. The metaphyſical reader will perceive, that, in this abſtract, there is little which is new except the phraſeology; and that what is new is either unintelligible or untenable.

21 which funda- ral ciples not

The diſtinction between knowledge *a priori* and knowledge *a poſteriori*, is as old as ſpeculation itſelf; and the mode in which Kant illuſtrates that diſtinction differs not from the illuſtrations of Ariſtotle on the ſame ſubject. The Stagyrite talked of *general forms*, or *formal cauſes*, in the mind, as well as the profeſſor at Koenigſberg; and he or his diſciples (for we quote from memory) compared them to the form of the ſtatue in the rough block of marble. As that form is brought into the view of the ſpectator by the chiſſel of the ſtatuary, ſo, ſaid the peripatetics, are the general *forms* in the mind brought into the view of conſciouſneſs by ſenſation and experience.

Such was the doctrine of Ariſtotle and his diſciples, and ſuch ſeems to be the doctrine of Kant and his followers; but it is either a falſe doctrine, or, if it be true, a doctrine fooliſhly expreſſed. A block of marble is capable of being cut into any form that the ſtatuary pleaſes; into the form of a man, a horſe, an ox, an aſs, a fiſh, or a ſerpent. Not one of theſe forms therefore can be inherent in it, or eſſential to it, in oppoſition to the reſt; and a general form, including all the animals under it, is inconceivable and impoſſible. In like manner, the human mind is capable of having the ideas of a circle, a triangle, a ſquare, of black, white, red, of four, ſweet, bitter, of the odour of a roſe, and the ſtench of a dunghill, of proportion, of muſical ſounds, and of a thouſand other things. None of theſe ideas therefore can be eſſential to the mind in oppoſition to the reſt; and every man, who is not an abſolute ſtranger to the operations of his own intellect, knows well that he cannot think of a thouſand things at once; or, to uſe the language of philoſophers, have in his mind a general idea, comprehending under it a thouſand things ſo diſcordant as colours and ſounds, figures, and ſmells. If therefore Kant means to affirm, with Plato, that, previous to all experience, there are *actually* in the mind *general forms*, or *general ideas*, to which ſenſation, or experience, gives an opportunity of coming into view, he affirms what all men of reflection know to be falſe. If he means only to affirm, what ſeems to have been the meaning of Ariſtotle, that particular ſenſations give occaſion to the intellect to form general ideas, he expreſſes himſelf indeed very ſtrangely; but his doctrine on this ſubject differs not eſſentially from that of Locke and Reid, and many other eminent metaphyſicians of modern times. Of abſtraction and general ideas we have given our own opinion elſewhere (See METAPHYSICS, *Encycl.* Part I. Chap. iv.), and ſhall not here reſume the ſubject.

22 Improper uſe of terms;

But when Kant ſays that his ideas *a priori* are *univerſal*, and *neceſſary*, and that their converſe is *impoſſible*, he ſeems by the word *idea* to mean what more accurate writers expreſs by the term *propoſition*. There are indeed two kinds of propoſitions, of which both may be true, though the one kind expreſſes neceſſary and univerſal truths, and the other ſuch truths as are contingent and particular. (See METAPHYSICS, *Encycl.* Part I. Chapter vii.) Propoſitions directly contrary to thoſe which expreſs particular and contingent truths may be eaſily conceived; whilſt ſuch as are contrary to neceſſary and univerſal truths are inconceivable and impoſſible; but we doubt whether *any idea*, in the proper ſenſe of the word, has a *contrary* or, as he expreſſes it, a *converſe*. *Nothing* is not contrary to *ſubſtance*, nor *black* contrary to *white*, nor *four* contrary to *ſweet*, nor an *inch* contrary to an *ell*. Nothing is the negation of ſubſtance, and black the negation of white; four is different from ſweet, and an inch is leſs than an ell; but between theſe different ideas we perceive no contradiction.

That Kant uſes the term *idea* inſtead of *propoſition*, or ſome word of ſimilar import, is farther evident from his inſtances of *the houſe on fire*, and the manner in which we learn that any two bodies added to any two other bodies will conſtantly make the ſum of *four bodies*. If it be his will to uſe the terms *a priori* and *a poſteriori* in the ſenſe in which other metaphyſicians uſe the terms *neceſſary* and *contingent*, we can make no other objection to his diſtinction between theſe two propoſitions, but that it is expreſſed in very improper language. The houſe might certainly be *on fire* or *not* on fire; but twice two bodies *muſt* always make the ſum of four bodies, and cannot poſſibly make any other ſum.

The truth of this laſt propoſition (he ſays) we cannot have learned from *experience*, becauſe experience, being always limited, cannot poſſibly teach us what is *neceſſary* and *univerſal*. But this is egregious trifling. The experience employed here is not limited A child unqueſtionably learns the import of the terms of numeration, as he learns the import of all other terms, by experience. By putting two little balls to two little balls, he learns to call the ſum *four* balls. After two or three leſſons of this kind with different bodies, his own reflection ſuggeſts to him, that the ſum four has no dependance upon the ſhape or conſiſtence of the bodies, but merely upon the *individuality* of each or their numerical difference; and individuality, or numerical difference, is as completely exemplified in two bodies of any kind as in two thouſand.

23 With its conſequences.

All the truths of pure mathematics (ſays Kant) are *a priori*. If he means that they are all *neceſſary*, and that the contrary of any one of them is *inconceivable*, he affirms nothing but what is true, and has been known

to

to all mathematicians theſe two thouſand years. But, if he means that they are *innate* truths, not diſcovered by induction or ideal meaſurement, his meaning is demonſtrably falſe. (See INDUCTION in this *Supplement.*) When he ſays, that it is not *experience* which diſcovers to us that we ſhall always have the ſurface of the pyramid, by multiplying its baſe by the third part of its height, he is right, if by experience he means the actual meaſurement of all poſſible pyramids; but ſurely he cannot mean that the truth of this meaſurement is innate in the mind, for it is in fact not a true but a falſe meaſurement (G). The baſe of a pyramid multiplied by the third part of its height gives, not the ſurface, but the ſolid contents of the pyramid; and he who underſtands the propoſition on which this truth is immediately built, knows perfectly that Euclid proved it by a ſeries of ideal meaſurements of thoſe particulars in which all pyramids neceſſarily agree.

Kant ſeems often to confound ſenſation with experience; and if by experience he means *ſenſation*, when he ſays that *pure knowledge, a priori*, is that which is abſolutely without any mixture of experience, he talks nonſenſe; for the moſt ſpiritual notions which men can form are derived from the operations of the mind on ideas of ſenſation. To the reſt of the paragraph, reſpecting pure knowledge, we have hardly any objection to make. Locke, the great enemy of innate ideas, taught, before Kant was born, that our knowledge depends upon our organization and the faculties of our minds, as much as upon impreſſions made on the ſenſes *ab extra;* that if our organs of ſenſe were different from what they are, the taſte of ſugar might be bitter, and that of wormwood ſweet; and that if we had not memory, and could not modify and arrange our ideas, all progreſs in knowledge would be impoſſible.

24 Groundleſs or falſe aſſertions.

When our author talks of *time* and *ſpace* as the two eſſential *forms* of the mind, we are not ſure that we underſtand him. We have ſhewn elſewhere, that a conſcious intelligence may be conceived which has no ideas either of ſpace or of time (ſee METAPHYSICS, *Encycl.* n° 182, &c. and 209, &c.); and he who can affirm, that if extenſion were known to us only by *experience*, it would be poſſible to conceive ſenſible objects *without ſpace*, has never attended to the force of what philoſophers call *the aſſociation of ideas in the mind.* But what is here meant by ſenſible objects? Are they objects of touch, taſte, or ſmell? Objects of touch cannot indeed be conceived without ſpace; but what extent of ſpace is ſuggeſted by the taſte of ſugar or the odour of a roſe?

When Kant talks of the *form* ſpace enabling us to attribute to external objects *impenetrability, mobility*, &c. he talks at random; and another man may, with as much propriety, and perhaps more truth, affirm the converſe of his propoſitions, and ſay, that it is the impenetrability and mobility, &c. of external objects that enable us to form the idea called *ſpace*, and the ſucceſſion of ſome objects, compared with the permanence of others, that enables us to form the notion or mode called *time*.

25 Bad logic

On the two or three next paragraphs it is not worth while to detain the reader with many remarks. They abound with the ſame uncouth and obſcure phraſeology, and the ſame idle diſtinctions between ideas *a priori* and *a poſteriori*. In n° 11. he affirms, that the three following propoſitions (*a body is heavy, wood is combuſtible*, and *the three angles of a triangle are equal to two right angles*) are all neceſſary judgments. In one ſenſe this affirmation is true, and in another it is falſe. We cannot, without ſpeaking unintelligibly, give the name *body* to any ſubſtance which is not heavy; and we are not acquainted with any kind of *wood* which is not combuſtible; but ſurely it is not impoſſible to conceive a ſubſtance extended and diviſible, and yet *not* heavy, to which the name *body* might be given without abſurdity, or to conceive wood as incombuſtible as the mineral called *aſbeſtos*. That the three angles, however, of a plane triangle can be either more or leſs than equal to two right angles, is obviouſly impoſſible, and muſt be perceived to be ſo by every intelligence from the Supreme down to the human. The three propoſitions, therefore, are not of the ſame kind, and ſhould not have been claſſed under the ſame genus of *neceſſary* ſynthetic judgments.

In the critique of pure reaſon, Kant ſeems to teach that all demonſtrative ſcience muſt proceed from general principles to particular truths. Hence his *forms* of the underſtanding, and his *categories*, which, according to one of his pupils*, "lie in our underſtanding as pure notions *a priori*, or the foundation of all our knowledge. They are *neceſſary forms, radical* notions, of which all our knowledge *muſt* be compounded." But this is directly contrary to the progreſs of the human mind, which, as we have ſhewn in the article INDUCTION, already referred to, proceeds, in the acquiſition of every kind of knowledge, from particular truths to general principles. This *tranſcendental philoſophy* of Kant's, therefore, inverts the order of nature, and is as little calculated to promote the progreſs of ſcience as the ſyllogiſtic ſyſtem of Ariſtotle, which was likewiſe built on *categories* or *general forms*. His *tranſcendental æſthetic*, which, according to Dr Willich, is the knowledge *a priori* of the *rules of ſenſation*, ſeems to be a contradictory expreſſion, as it implies that a man may know the laws of ſenſation, without paying the ſmalleſt attention to the organs of ſenſe.

That we know objects only by the manner in which they affect us, and not as they are in themſelves, is a truth admitted, we believe, by all philoſophers, and certainly by Locke and Reid; but when Kant ſays that we know nothing of the *reality* of the objects which affect our ſenſes, he ſeems to be ſingularly paradoxical. Berkeley himſelf, the moſt ingenious idealiſt perhaps that ever wrote, contends ſtrenuouſly for the exiſtence of a *cauſe* of our ſenſations diſtinct from our own minds; and becauſe he thinks inert matter a cauſe inadequate

---

* *Dr W lich.*

(G) This may look like cavilling, as the blunder may be either Kant's or our correſpondent's, though neither of them can be ſuppoſed ignorant of the method of meaſuring the ſurface of a pyramid. We aſſure the reader, however, that we do not mean to cavil. We admit that both Kant and our correſpondent know perfectly well how to meaſure the ſurface of a pyramid; but had that knowledge been *innate* in their minds, we cannot conceive the poſſibility of their falling into the blunder. The blunder, therefore, though the offspring of mere inadvertence, ſeems to be a complete confutation of the doctrine.

inadequate to this effect, he concludes, that every ſenſation of which we are conſcious is a proof of the immediate agency of the Deity. But Kant, as we ſhall perceive by and bye, makes the exiſtence of God and of matter equally problematical. Indeed he ſays expreſsly, that beyond things ſenſible we can only have *opinions* or *belief;* but things ſenſible, as every one knows, are nothing more than the *qualities* of objects.

Ten cy of th yſ- tem ward the- iſm.

It ſhould ſeem that the greater number of wonders which Kant has found in our primitive knowledge and in the faculties of our mind, the greater number of proofs ought he to have found of the exiſtence and attributes of one Firſt Cauſe: but ſo far is this from being the caſe, that we have ſeen him reſting the evidence of this moſt important of all truths, either upon the *moral ſenſe,* which our paſſions and appetites ſo eaſily alter, or upon the intuitive perception of *abſtract moral rectitude;* a perception which thouſands, as virtuous and as profound as he, have conſidered as impoſſible. Our philoſopher's proof of a God is nothing more than his perſuaſion that happineſs is connected with virtue by a Being upon whom nature depends; and he ſays expreſsly, that this proof carries conviction to the mind in proportion as the motives of a man's actions are conformable to the law of morality. This being the caſe, the reader cannot be much ſurpriſed, when he is informed that ſeveral of Kant's diſciples on the continent have avowed themſelves Atheiſts or Spinoziſts. We have elſewhere (ſee ILLUMINATI, n° 37.) mentioned one of thoſe gentlemen who was lately diſmiſſed from his profeſſorial chair in the univerſity of Jena, for making GOD nothing more than an *abſtract idea,* derived from our relations with the moral world. His ſucceſſor, a Kantiſt likewiſe, when it was told in his preſence, that, during one of the maſſacres in Paris, David the Painter ſat with his pencil in his hand, enjoying the ſufferings of the unfortunate wretches, and trying to paint the expreſſions of their agonies, exclaimed—"What force of character! What ſublimity of ſoul!" That this wretch muſt be an Atheiſt, likewiſe, follows of courſe from Kant's principles; for it is not conceivable that he perceives any connection between happineſs and virtue.

That Kant is an atheiſt himſelf, we have not learned, though his doctrine leads thus naturally to atheiſm, and though in his work called TUGEND LEHRE, page 180, he makes the following ſtrange obſervation upon oaths: "As it would be abſurd to ſwear that God exiſts, it is ſtill a queſtion to be determined, whether an oath would be poſſible and obligatory if one were to make it thus—*I ſwear on the ſuppoſition that God exiſts.* It is extremely probable (ſays he), that all *ſincere* oaths, taken with *reflection,* have been taken in no other ſenſe!"

It is not our intention to plunge deeper into this mire of atheiſm, or to enter into a formal confutation of the deteſtable doctrines which have been dragged from its bottom. Enough has been ſaid elſewhere to convince the *theoretical* reaſon of the ſound minds of our countrymen of the exiſtence of one omnipotent, infinitely wiſe, and perfectly good Being, the author and upholder of all things (See *Encycl.* METAPHYSICS, Part III. Chap. vi. and THEOLOGY, Part I. Sect. 1.). It may not, however, be altogether uſeleſs to point out to the reader how completely Kant confutes himſelf, even in the ſhort abſtract that we have given of his ſyſtem.

27 Kant confutes himſelf.

Among his *categories,* or fundamental ideas, which are *neceſſarily* formed in the mind, he expreſsly reckons *cauſe* and *effect:* but in various articles of this work, it has been proved beyond the poſſibility of contradiction, that no *ſenſible* object is the *true metaphyſical cauſe* of any one event in nature; and indeed Kant himſelf is at much pains to ſhew that his *categories* or ideas *a priori* are not ideas of ſenſation. There muſt therefore, upon his own principles, be cauſes which are *not* the objects of *ſenſe* or *experience;* and by tracing theſe cauſes backward, if there be a ſucceſſion of them, we muſt arrive at one ſelf-exiſtent cauſe, by a demonſtration as complete as that by which Euclid proves the equality of the three angles of a plane triangle to two right angles. We have no other evidence for the truth of geometrical axioms than the laws of human thought, which compel us to perceive the impoſſibility of ſuch propoſitions being falſe. According to our philoſopher, we have the very ſame evidence for the reality of cauſes and effects which are not the objects of ſenſe. The conſequence is obvious.

28 His morality is extravagant.

Kant's *political* opinions are ſaid to be tolerably moderate, though he betrays, what we muſt think, an abſurd confidence in the *unlimited perfectibility* of the human mind. On his morality our valued correſpondent has beſtowed a much larger ſhare of his approbation than we can allow it of ours. Kant ſeems to contend, that the actions of men ſhould be directed to no end whatever; for he expreſsly condemns, as an end of action, the purſuit either of our own happineſs or of the happineſs of others, whether temporal or eternal; but actions performed for no purpoſe are ſurely indications of the very eſſence of folly. Such actions are indeed impoſſible to beings endowed with reaſon, paſſions, and appetites; for if there be that beauty in abſtract virtue, for which Kant and the Stoics contend, it cannot be but that the virtuous man muſt feel an internal pleaſure when he performs a virtuous action, or reflects upon his paſt conduct. He who makes his temporal intereſt the ſole rule of his conduct, has indeed no pretenſions to the character of a virtuous man; but as the morality of the goſpel has always appeared to us ſufficiently pure and diſintereſted, we think a man may, without deviating into vice, have reſpect unto "the recompence of future reward."

Pho-

PHOSPHORUS (See CHEMISTRY-*Index, Supplement.*) has lately been employed as a medicine by Alphonſus Leroi, profeſſor at the Medical School of Paris. Its effects, in a variety of caſes, are thus deſcribed in the *Bulletin de la Societé Philomatique,* 1798.

Phoſphorus.

1. Phoſphorus adminiſtered internally in conſumptive diſeaſes appears to give a certain degree of activity to life, and to revive the patients, without raiſing their pulſe in the ſame proportion. The author relates ſeveral inſtances that occurred to him in the courſe of his

practice; one of which is as follows: Being called to attend a woman, at the point of death, who was quite worn out by a conſumptive diſorder, with which ſhe had been afflicted for three years, in compliance with the earneſt deſire of her huſband, who requeſted him to give her ſome medicine, he compoſed one of a portion of ſyrup diluted with water, in which a few ſticks of phoſphorus had been kept. Next day the woman found herſelf much better. She was revived for a few days; and did not die till about a fortnight after.

2. He himſelf, as he acknowledges, was ſo imprudent as to take two or three grains of ſolid phoſphorus combined only with treacle, and experienced the moſt dreadful ſymptoms. At firſt he felt a burning heat in the whole region of the ſtomach. That organ ſeemed to be filled with gas which eſcaped by the mouth. Being dreadfully tormented, he tried to vomit, but in vain; and found relief only by drinking cold water from time to time. His uneaſy ſenſations were at length allayed; but next morning he ſeemed to be endowed with an aſtoniſhing muſcular force, and to be urged with an almoſt irreſiſtible impulſe to try its energy. The effect of this medicine at length ceaſed, adds the author, *à la ſuite d'un priapiſme violent*.

3. In many caſes the author employed, and ſtill employs, phoſphorus internally, with great benefit, to reſtore and revive young perſons exhauſted by exceſſes. He divides the phoſphorus into very ſmall particles, by ſhaking it in a glaſs filled with boiling water. He continues to ſhake the bottle, plunging it into cold water, and thus obtains a kind of precipitate of phoſphorus, exceedingly fine, which he bruiſes ſlowly with a little oil and ſugar, or afterwards employs as liquid electuary, by diluting the whole in the yolk of an egg. By means of this medicine he has effected aſtoniſhing cures, and reſtored the ſtrength of his patients in a very ſhort time.

4. In malignant fevers the uſe of phoſphorus internally, to check the progreſs of gangrene, has ſucceeded beyond expectation. The author relates ſeveral inſtances.

5. Pelletier told him, that having left, through negligence, ſome phoſphorus in a copper baſon, that metal was oxydated, and remained ſuſpended in the water. Having thoughtleſsly thrown out the water in a ſmall court in which ducks were kept, theſe animals drank of it, and all died. *Mais le male* (ſays the author) *couvrit toutes ſes femelles juſque au dernier inſtant de ſa vie.* An obſervation which accords with the effect experienced by the author.

6. The author relates a fact which proves the aſtoniſhing diviſibility of phoſphorus. Having adminiſtered to a patient ſome pills, in the compoſition of which there was not more than a quarter of a grain of phoſphorus, and having had occaſion afterwards to open the body, he found all the internal parts luminous; and even the hands of the perſon who had performed the operation, though waſhed and well dried, retained a phoſphoric ſplendor for a long time after.

7. The phoſphoric acid, employed as lemonade, has been ſerviceable to the author in the cure of a great number of diſeaſes.

8. Leroi aſſures us that he oxydated iron with phoſphorus, and obtained, by the common means, a white oxyd, almoſt irreducible, which he thinks may be employed with advantage in the arts, and particularly in painting with oil, and in enamel, inſtead of the white oxyd of lead. This white oxyd of iron occaſioned violent retchings to the author, who ventured to place a very ſmall particle of it on his tongue. He does not heſitate, therefore, to conſider this oxyd as a terrible poiſon. He was not able to reduce it but by fixed alkali and the glaſs of phoſphorus.

9. The author aſſerts that, by means of phoſphorus, he decompoſed and ſeparated from their baſes the ſulphuric, muriatic, and nitric acids; that by help of the phoſphoric acid he tranſmuted earths; and that with calcareous earth he can make, at pleaſure, conſiderable quantities of magneſia. He declares, that to his labours on phoſphorus he is indebted for proceſſes by which he effects the diſſipation (*opère la frite*) of rubies, the fuſion of emeralds, and the vitrification of mercury.

We agree with the editor of the reſpectable Miſcellany *, from which we have immediately taken this article, that Britiſh practitioners will do well to uſe their wonted caution in the application of ſo powerful a remedy. Indeed we conſider it as ſo very *hazardous* a remedy, that we had reſolved to make no mention of it, till we found it tranſcribed into various journals, both foreign and domeſtic, and thence began to ſuſpect that we might be accuſed of culpable negligence, were we to paſs unnoticed what had attracted the attention of ſo many of our fellow-labourers in the field of ſcience.

PHOSPHORUS, in aſtronomy, is the morning ſtar, or the planet Venus, when ſhe riſes before the ſun. The Latins call it *Lucifer*, the French *Etoile de berger*, and the Greeks *Phoſphorus*.

PHOTOMETER, an apparatus for meaſuring the intenſity of light, and likewiſe the tranſparency of the medium through which it paſſes. Inſtruments for this purpoſe have been invented by Count Rumford, M. de Sauſſure, that eminent mathematician and philoſopher Mr John Leſlie, and others. We ſhall content ourſelves with deſcribing in this place the photometer of Count Rumford, and the inſtrument to which Sauſſure gives the name of *diaphanometer*. Mr Leſlie's is indeed the ſimpleſt inſtrument of the kind of which we have anywhere met with a deſcription; but it meaſures only the momentary intenſities of light; and he who wiſhes to be informed of its conſtruction, will find that information in the third volume of Nicholſon's Philoſophical Journal.

Count Rumford, when making the experiments which we have noticed in the article LAMP (*Suppl.*), was led, ſtep by ſtep, to the conſtruction of a very accurate *photometer*, in which the ſhadows, inſtead of being thrown upon a paper ſpread out upon the wainſcot, or ſide of the room (See page 64 of this volume), are projected upon the inſide of the back part of a wooden box $7\frac{1}{4}$ inches wide, $10\frac{1}{2}$ inches long, and $3\frac{1}{4}$ inches deep, in the clear. The light is admitted into it through two horizontal tubes in the front, placed ſo as to form an angle of 60°; their axes meeting at the centre of the field of the inſtrument. In the middle of the front of the box, between theſe two tubes, is an opening thro' which is viewed the field of the photometer (See fig. 1.). This field is formed of a piece of white paper, which is not faſtened immediately upon the inſide of the back of the box, but is paſted upon a ſmall pane of very fine ground glaſs; and this glaſs, thus covered, is

Plate X

---

* Philoſophical Magazine, vol. ii.

P tome-er.

is let down into a groove, made to receive it, in the back of the box. The whole inſide of the box, except the field of the inſtrument, is painted of a deep black dead colour. To the under part of the box is fitted a ball and ſocket, by which it is attached to a ſtand which ſupports it; and the top or lid of it is fitted with hinges, in order that the box may be laid quite open, as often as it is neceſſary to alter any part of the machinery it contains.

The Count had found it very inconvenient to compare two ſhadows projected by the ſame cylinder, as theſe were either neceſſarily too far from each other to be compared with certainty, or, when they were nearer, were in part hid from the eye by the cylinder. To remedy this inconvenience, he now makes uſe of two cylinders, which are placed perpendicularly in the bottom of the box juſt deſcribed, in a line parallel to the back part of it, diſtant from this back $2\frac{2}{10}$ inches, and from each other 3 inches, meaſuring from the centres of the cylinders; when the two lights made uſe of in the experiment are properly placed, theſe two cylinders project four ſhadows upon the white paper upon the inſide of the back part of the box, or the *field* of the inſtrument; two of which ſhadows are in contact, preciſely in the middle of that field, and it is theſe two alone that are to be attended to. To prevent the attention being diſtracted by the preſence of unneceſſary objects, the two outſide ſhadows are made to diſappear; which is done by rendering the field of the inſtrument ſo narrow, that they fall without it, upon a blackened ſurface, upon which they are not viſible. If the cylinders be each $\frac{4}{10}$ of an inch in diameter, and $2\frac{2}{10}$ inches in height, it will be quite ſufficient that the field be $2\frac{7}{10}$ inches wide; and as an unneceſſary height of the field is not only uſeleſs, but diſadvantageous, as a large ſurface of white paper not covered by the ſhadows produces too ſtrong a glare of light, the field ought not to be more than $\frac{3}{10}$ of an inch higher than the tops of the cylinders. That its dimenſions, however, may be occaſionally augmented, the covered glaſs ſhould be made $5\frac{1}{2}$ inches long, and as wide as the box is deep, viz. $3\frac{1}{4}$ inches; ſince the field of the inſtrument can be reduced to its proper ſize by a ſcreen of black paſteboard, interpoſed before the anterior ſurface of this covered glaſs, and reſting immediately upon it. A hole in this paſteboard, in the form of an oblong ſquare, $1\frac{7}{10}$ inch wide, and two inches high, determines the dimenſions, and forms the boundaries of the field. This ſcreen ſhould be large enough to cover the whole inſide of the back of the box, and it may be fixed in its place by means of grooves in the ſides of the box, into which it may be made to enter. The poſition of the opening above-mentioned is determined by the height of the cylinders; the top of it being $\frac{3}{10}$ of an inch higher than the tops of the cylinders; and as the height of it is only two inches, while the height of the cylinders is $2\frac{2}{10}$ inches, it is evident that the ſhadows of the lower parts of the cylinders do not enter the field. No inconvenience ariſes from that circumſtance; on the contrary, ſeveral advantages are derived from that arrangement.

That the lights may be placed with facility and preciſion, a fine black line is drawn through the middle of the field, from the top to the bottom of it, and another (horizontal) line at right angles to it, at the height of the top of the cylinders. When the tops of the ſhadows touch this laſt mentioned line, the lights are at a proper height; and farther, when the two ſhadows are in contact with each other in the middle of the field, the lights are then in their proper directions.

Photometer.

We have ſaid that the cylinders, by which the ſhadows are projected, are placed perpendicularly in the bottom of the box; but as the diameters of the ſhadows of theſe cylinders vary in ſome degree, in proportion as the lights are broader or narrower, and as they are brought nearer to or removed farther from the photometer, in order to be able in all caſes to bring theſe ſhadows to be of the ſame diameter, which is very advantageous, in order to judge with greater facility and certainty when they are of the ſame denſity, the Count renders the cylinders moveable about their axes, and adds to each a vertical wing $\frac{11}{20}$ of an inch wide, $\frac{1}{10}$ of an inch thick, and of equal height with the cylinder itſelf, and firmly fixed to it from the top to the bottom. This wing commonly lies in the middle of the ſhadow of the cylinder, and as long as it remains in that ſituation it has no effect whatever; but when it is neceſſary that the diameter of one of the ſhadows be increaſed, the correſponding cylinder is moved about its axis, till the wing juſt deſcribed, emerging out of the ſhadow, and intercepting a portion of light, brings the ſhadow projected upon the field of the inſtrument to be of the width or diameter required. In this operation it is always neceſſary to turn the cylinder outwards, or in ſuch a manner that the augmentation of the width of the ſhadow may take place on that ſide of it which is oppoſite to the ſhadow correſponding to the other light. The neceſſity for that precaution will appear evident to any one who has a juſt idea of the inſtrument in queſtion, and of the manner of making uſe of it. They are turned likewiſe without opening the box, by taking hold of the ends of their axes, which project below its bottom.

As it is abſolutely neceſſary that the cylinders ſhould conſtantly remain preciſely perpendicular to the bottom of the box, or parallel to each other, it will be beſt to conſtruct them of braſs; and, inſtead of fixing them immediately to the bottom of the box (which, being of wood, may warp), to fix them to a ſtrong thick piece of well-hammered plate braſs; which plate of braſs may be afterwards faſtened to the bottom of the box by means of one ſtrong ſcrew. In this manner two of the Count's beſt inſtruments are conſtructed; and, in order to ſecure the cylinders ſtill more firmly in their vertical poſitions, they are furniſhed with broad flat rings, or projections, where they reſt upon the braſs plate; which rings are $\frac{1}{10}$ of an inch thick, and equal in diameter to the projection of the wing of the cylinder, to the bottom of which they afford a firm ſupport. Theſe cylinders are likewiſe forcibly puſhed, or rather pulled, againſt the braſs plate upon which they reſt, by means of compreſſed ſpiral ſprings placed between the under ſide of that plate and the lower ends of the cylinders. Of whatever material the cylinders be conſtructed, and whatever be their forms or dimenſions, it is abſolutely neceſſary that they, as well as every other part of the photometer, except the field, ſhould be well painted of a deep black dead colour.

In order to move the lights to and from the photometer with greater eaſe and preciſion, the obſerver ſhould provide two long and narrow, but very ſtrong and ſteady, tables; in the middle of each of which there

there is a ſtraight groove, in which a ſliding carriage, upon which the light is placed, is drawn along by means of a cord which is faſtened to it before and behind, and which, paſſing over pulleys at each end of the table, goes round a cylinder; which cylinder is furniſhed with a winch, and is ſo placed, near the end of the table adjoining the photometer, that the obſerver can turn it about, without taking his eye from the field of the inſtrument.

Many advantages are derived from this arrangement: Firſt, the obſerver can move the lights as he finds neceſſary, without the help of an aſſiſtant, and even without removing his eye from the ſhadows; ſecondly, each light is always preciſely in the line of direction in which it ought to be, in order that the ſhadows may be in contact in the middle of the vertical plane of the photometer; and, thirdly, the ſliding motion of the lights being perfectly ſoft and gentle, that motion produces little or no effect upon the lights themſelves, either to increaſe or diminiſh their brilliancy.

Theſe tables muſt be placed at an angle of 60 degrees from each other, and in ſuch a ſituation, with reſpect to the photometer, that lines drawn through their middles, in the direction of their lengths, meet in a point exactly under the middle of the vertical plane or field of the photometer, and from that point the diſtances of the lights are meaſured; the ſides of the tables being divided into Engliſh inches, and a vernier, ſhewing tenths of inches, being fixed to each of the ſliding carriages upon which the lights are placed, and which are ſo contrived that they may be raiſed or lowered at pleaſure; ſo that the lights may be always in a horizontal line with the tops of the cylinders of the photometer.

In order that the two long and narrow tables or platforms, juſt deſcribed, may remain immoveable in their proper poſitions, they are both firmly fixed to the ſtand which ſupports the photometer; and, in order that the motion of the carriages which carry the lights may be as ſoft and gentle as poſſible, they are made to ſlide upon parallel braſs wires, 9 inches aſunder, about $\frac{1}{10}$ of an inch in diameter, and well poliſhed, which are ſtretched out upon the tables from one end to the other.

The ſtructure of the apparatus will be clearly underſtood by a bare inſpection of Plate XLI. where fig. 1. is a plan of the inſide of the box, and the adjoining parts of the photometer. Fig. 2. Plan of the two tables belonging to the photometer. Fig. 3. The box of the photometer on its ſtand. Fig. 4. Elevation of the photometer, with one of the tables and carriages.

Having ſufficiently explained all the eſſential parts of this photometer, it remains for us to give ſome account of the precautions neceſſary to be obſerved in uſing it. And, firſt, with reſpect to the diſtance at which lights, whoſe intenſities are to be compared, ſhould be placed from the field of the inſtrument, the ingenious and accurate inventor found, that when the weakeſt of the lights in queſtion is about as ſtrong as a common wax-candle, that light may moſt advantageouſly be placed from 30 to 36 inches from the centre of the field; and when it is weaker or ſtronger, proportionally nearer or farther off. When the lights are too near, the ſhadows will not be well defined; and when they are too far off, they will be too weak.

It will greatly facilitate the calculations neceſſary in drawing concluſions from experiments of this kind, if ſome ſteady light, of a proper degree of ſtrength for that purpoſe, be aſſumed as a ſtandard by which all others may be compared. Our author found a good Argand's lamp much preferable for this purpoſe to any other lamp or candle whatever. As it appears, he ſays, from a number of experiments, that the quantity of light emitted by a lamp, which burns in the ſame manner with a clear flame, and *without ſmoke*, is in all caſes as the quantity of oil conſumed, there is much reaſon to ſuppoſe, that, if the Argand's lamp be ſo adjuſted as always to conſume a given quantity of oil in a given time, it may then be depended on as a juſt ſtandard of light.

In order to abridge the calculations neceſſary in theſe inquiries, it will always be advantageous to place the ſtandard-lamp at the diſtance of 100 inches from the photometer, and to aſſume the intenſity of its light at its ſource equal to unity; in this caſe (calling this ſtandard light A, the intenſity of the light at its ſource $= x = 1$, and the diſtance of the lamp from the field of the photometer $= m = 100$), the intenſity of the illumination at the field of the photometer ($= \frac{x}{m^2}$) (See Lamp, p. 67. of this volume) will be expreſſed by the fraction $\frac{1}{100^2} = \frac{1}{10000}$; and the relative intenſity of any other light which is compared with it, may be found by the following proportion: Calling this light B, putting $y =$ its intenſity at its ſource, and $n =$ its diſtance from the field of the photometer, expreſſed in Engliſh inches, as it is $\frac{y}{n^2} = \frac{x}{m^2}$, as was ſhewn in the article Lamp referred to; or, inſtead of $\frac{x}{m^2}$, writing its value $= \frac{1}{10000}$, it will be $\frac{y}{n^2} = \frac{1}{10000}$; and conſequently y is to 1 as n^2 is to 10000; or the intenſity of the light B at its ſource, is to the intenſity of the ſtandard light A at its ſource, as the ſquare of the diſtance of the light B from the middle of the field of the inſtrument, expreſſed in inches, is to 10000; and hence it is $y = \frac{n^2}{10000}$.

Or, if the light of the ſun, or that of the moon, be compared with the light of a given lamp or candle C, the reſult of ſuch compariſon may beſt be expreſſed in words, by ſaying, that the light of the celeſtial luminary in queſtion, *at the ſurface of the earth*, or, which is the ſame thing, at the field of the photometer, is equal to the light of the given lamp or candle, *at the diſtance found by the experiment*; or, putting $a =$ the intenſity of the light of this lamp C at its ſource, and $p =$ its diſtance, in inches, from the field, when the ſhadows correſponding to this light, and that correſponding to the celeſtial luminary in queſtion, are found to be of equal denſities, and putting $z =$ the intenſity of the rays of the luminary at the ſurface of the earth, the reſult of the experiment may be expreſſed thus, $z = \frac{a}{p^2}$; or the real value of a being determined by a particular experiment, made expreſsly for that purpoſe with the ſtandard lamp, that value may be written inſtead of it. When the ſtandard-lamp itſelf is made uſe of, inſtead of the lamp C, then the value of A will be 1.

The Count's firſt attempts with his photometer were to determine how far it might be poſſible to aſcertain, by direct experiments, the certainty of the aſſumed law of the diminution of the intenſity of the light emitted by luminous bodies; namely, that the intenſity of the light is everywhere as the ſquares of the diſtances from the luminous body inverſely. As it is obvious that this law can hold good only when the light is propagated through perfectly tranſparent ſpaces, ſo that its intenſity is weakened merely by the divergency of its rays, he inſtituted a ſet of experiments to aſcertain the tranſparency of the air and other mediums.

With this view, two equal wax candles, well trimmed, and which were found, by a previous experiment, to burn with exactly the ſame degree of brightneſs, were placed *together*, on one ſide, before the photometer, and their united light was counterbalanced by the light of an Argand's lamp, well trimmed, and burning very equally, placed on the other ſide over againſt them. The lamp was placed at the diſtance of 100 inches from the field of the photometer, and it was found that the two burning candles (which were placed as near together as poſſible, without their flames affecting each other by the currents of air they produced) were juſt able to counterbalance the light of the lamp at the field of the photometer, when they were placed at the diſtance of 60,8 inches from that field. One of the candles being now taken away and extinguiſhed, the other was brought nearer to the field of the inſtrument, till its light was found to be juſt able, ſingly, to counterbalance the light of the lamp; and this was found to happen when it had arrived at the diſtance of 43,4 inches. In this experiment, as the candles burnt with equal brightneſs, it is evident that the intenſities of their united and ſingle lights were as 2 to 1, and in that proportion ought, according to the aſſumed theory, the ſquares of the diſtances, 60,8 and 43,4, to be; and, in fact, $\overline{60{,}8}^2 = 3696{,}64$ is to $\overline{43{,}4}^2 = 1883{,}56$ as 2 is to 1 very nearly.

Again, in another experiment, the diſtances were,

With two candles = 54 inches. Square = 2916
With one candle = 38,6 - - = 1489,96

Upon another trial,

With two candles = 54,6 inches. Square = 2981,16
With one candle = 39,7 - - = 1576,09

And, in the fourth experiment,

With two candles = 58,4 inches. Square = 3410,56
With one candle = 42,2 - - = 1780,84

And, taking the mean of the reſults of theſe four experiments,

	Squares of the Diſtances		
	With two Candles.		With one Candle
In the Experiment Nº 1.	3696,64	—	1883,56
Nº 2.	2916	—	1489,96
Nº 3.	2981,16	—	1576,09
Nº 4.	3410,56	—	1780,84
	4) 13004,36		4) 6730,45
Means	3251,09	and	1682,61

which again are very nearly as 2 to 1.

With regard to theſe experiments, it may be obſerved, that were the reſiſtance of the air to light, or the diminution of the light from the imperfect tranſparency of air, ſenſible within the limits of the inconſiderable diſtances at which the candles were placed from the photometer, in that caſe the diſtance of the two equal lights united ought to be, to the diſtance of one of them ſingle, in a ratio leſs than that of the ſquare root of 2 to the ſquare root of 1. For if the intenſity of a light emitted by a luminous body, *in a ſpace void of all reſiſtance*, be diminiſhed in the proportion of the ſquares of the diſtances, it muſt of neceſſity be diminiſhed in a ſtill higher ratio when the light paſſes thro' a reſiſting medium, or one which is not perfectly tranſparent; and from the difference of thoſe ratios, namely, that of the ſquares of the diſtances, and that other higher ratio found by the experiment, the reſiſtance of the medium might be aſcertained. This he took much pains to do with reſpect to air, but did not ſucceed; the tranſparency of air being ſo great, that the diminution which light ſuffers in paſſing through a few inches, or even through ſeveral feet of it, is not ſenſible.

Photometer.

Having found, upon repeated trials, that the light of a lamp, properly trimmed, is incomparably more equal than that of a candle, whoſe wick, continually growing longer, renders its light extremely fluctuating, he ſubſtituted lamps to candles in theſe experiments, and made ſuch other variations in the manner of conducting them as he thought bid fair to lead to a diſcovery of the reſiſtance of the air to light, were it poſſible to render that reſiſtance ſenſible within the confined limits of his machinery. But the reſults of them, ſo far from affording means for aſcertaining the reſiſtance of the air to light, do not even indicate any reſiſtance at all; on the contrary, it might almoſt be inferred, from ſome of them, that the intenſity of the light emitted by a luminous body in air is diminiſhed in a ratio *leſs* than that of the ſquares of the diſtances; but as ſuch a concluſion would involve an evident abſurdity, namely, that light moving in air, its abſolute quantity, inſtead of being diminiſhed, actually goes on to *increaſe*, that concluſion can by no means be admitted.

Why not? Theories muſt give place to facts; and if this fact can be fairly aſcertained, inſtead of rejecting the concluſion, we ought certainly to rectify our notions of light, the nature of which we believe no man fully comprehends. Who can take it upon him to ſay, that the ſubſtance of light is not latent in the atmoſphere, as heat or caloric is now acknowledged to be latent, and that the agency of the former is not called forth by the paſſage of a ray through a portion of air, as the agency of the latter is known to be excited by the combination of oxygen with any combuſtible ſubſtance? See CHEMISTRY, nº 293, *Suppl.*

The ingenious author's experiments all conſpired to ſhew that the reſiſtance of the air to light is too inconſiderable to be perceptible, and that the aſſumed law of the diminution of the intenſity of light may be depended upon with ſafety. He admits, however, that means may be found for rendering the air's reſiſtance to light apparent; and he ſeems to have thought of the very means which occurred for this purpoſe to M. de Sauſſure.

That eminent philoſopher, wiſhing to aſcertain the tranſparency of the atmoſphere, by meaſuring the diſtances at which determined objects ceaſe to be viſible, perceived at once that his end would be attained, if he ſhould find objects of which the diſappearance might be accurately determined. Accordingly, after many trials, he found that the moment of diſappearance can be obſerved with much greater accuracy when a black object is placed on a white ground, than when a white object is placed on a black ground; that the accuracy was ſtill greater when the obſervation was made in the ſun than in the ſhade; and that even a ſtill greater degree of accuracy was obtained, when the white ſpace ſurrounding a black circle, was itſelf ſurrounded by a circle or ground of a dark colour. This laſt circumſtance was particularly remarkable, and an obſervation quite new.

If a circle totally black, of about two lines in diameter, be faſtened on the middle of a large ſheet of paper or paſteboard, and if this paper or paſteboard be placed in ſuch a manner as to be expoſed fully to the light of the ſun, if you then approach it at the diſtance of three or four feet, and afterwards gradually recede from it, keeping your eye conſtantly directed towards the black circle, it will appear always to decreaſe in ſize the farther you retire from it, and at the diſtance of 33 or 34 feet will have the appearance of a point. If you continue ſtill to recede, you will ſee it again enlarge itſelf; and it will ſeem to form a kind of cloud, the darkneſs of which decreaſes more and more according as the circumference becomes enlarged. The cloud will appear ſtill to increaſe in ſize the farther you remove from it; but at length it will totally diſappear. The moment of the diſappearance, however, cannot be accurately aſcertained; and the more experiments were repeated the more were the reſults different.

M. de Sauſſure, having reflected for a long time on the means of remedying this inconveniency, ſaw clearly, that, as long as this cloud took place, no accuracy could be obtained; and he diſcovered that it appeared in conſequence of the contraſt formed by the white parts which were at the greateſt diſtance from the black circle. He thence concluded, that if the ground was left white near this circle, and the parts of the paſteboard at the greateſt diſtance from it were covered with a dark colour, the cloud would no longer be viſible, or at leaſt almoſt totally diſappear.

This conjecture was confirmed by experiment. M. de Sauſſure left a white ſpace around the black circle equal in breadth to its diameter, by placing a circle of black paper a line in diameter on the middle of a white circle three lines in diameter, ſo that the black circle was only ſurrounded by a white ring a line in breadth. The whole was paſted upon a green ground. A green colour was choſen, becauſe it was dark enough to make the cloud diſappear, and the eaſieſt to be procured.

The black circle, ſurrounded in this manner with white on a green ground, diſappeared at a much leſs diſtance than when it was on a white ground of a large ſize.

If a perfectly black circle, a line in diameter, be paſted on the middle of a white ground expoſed to the open light, it may be obſerved at the diſtance of from 44 to 45 feet; but if this circle be ſurrounded by a white ring a line in breadth, while the reſt of the ground is green, all ſight of it is loſt at the diſtance of only 15½ feet.

According to theſe principles M. de Sauſſure delineated ſeveral black circles, the diameters of which increaſed in a geometrical progreſſion, the exponent of which was $\frac{3}{2}$. His ſmalleſt circle was $\frac{1}{5}$ or 0·2 of a line in diameter; the ſecond 0·3; the third, 0·45; and ſo on to the ſixteenth, which was 87·527, or about 7 inches 3½ lines. Each of theſe circles was ſurrounded by a white ring, the breadth of which was equal to the diameter of the circle, and the whole was paſted on a green ground.

M. de Sauſſure, for his experiments, ſelected a ſtraight road or plain of about 1200 or 1500 feet in circumference, which towards the north was bounded by trees or an aſcent. Thoſe who repeat them, however, muſt pay attention to the following remarks: When a perſon retires backwards, keeping his eye conſtantly fixed on the paſteboard, the eye becomes fatigued, and ſoon ceaſes to perceive the circle; as ſoon therefore as it ceaſes to be diſtinguiſhable, you muſt ſuffer your eyes to reſt; not, however, by ſhutting them, for they would when again opened be dazzled by the light, but by turning them gradually to ſome leſs illuminated object in the horizon. When you have done this for about half a minute, and again directed your eyes to the paſteboard, the circle will be again viſible, and you muſt continue to recede till it diſappear once more. You muſt then let your eyes reſt a ſecond time in order to look at the circle again, and continue in this manner till the circle becomes actually inviſible.

If you wiſh to find an accurate expreſſion for the want of tranſparency, you muſt employ a number of circles, the diameters of which increaſe according to a certain progreſſion; and a compariſon of the diſtances at which they diſappear will give the law according to which the tranſparency of the atmoſphere decreaſes at different diſtances. If you wiſh to compare the tranſparency of the atmoſphere on two days, or in two different places, two circles will be ſufficient for the experiment.

According to theſe principles, M. de Sauſſure cauſed to be prepared a piece of white linen cloth eight feet ſquare. In the middle of this ſquare he ſewed a perfect circle, two feet in diameter, of beautiful black wool; around this circle he left a white ring two feet in breadth, and the reſt of the ſquare was covered with pale green. In the like manner, and of the ſame materials, he prepared another ſquare; which was, however, equal to only $\frac{1}{12}$ of the ſize of the former, ſo that each ſide of it was 8 inches; the black circle in the middle was two inches in diameter, and the white ſpace around the circle was 2 inches alſo.

If two ſquares of this kind be ſuſpended vertically and parallel to each other, ſo that they may be both illuminated in an equal degree by the ſun; and if the atmoſphere, at the moment when the experiment is made, be perfectly tranſparent, the circle of the large ſquare, which is twelve times the ſize of the other, muſt be ſeen at twelve times the diſtance. In M. de Sauſſure's experiments the ſmall circle diſappeared at the diſtance of 314 feet, and the large one at the diſtance of 3588 feet, whereas it ſhould have diſappeared at the diſtance of 3768. The atmoſphere, therefore, was not perfectly tranſparent. This aroſe from the thin vapours which at that time were floating in it. M. de Sauſſure, as we have obſerved, calls his inſtrument a *diaphanometer*; but as it anſwers one of the purpoſes of a photometer, we truſt our readers will not conſider this account of it as a digreſſion.

To return to Count Rumford. From a number of experiments made with his *photometer*, he found that, by paſſing through a pane of fine, clear, well poliſhed glaſs, ſuch as is commonly made uſe of in the conſtruction of looking-glaſſes, light loſes ,1973 of its whole quantity,

ano
rte.

quantity, *i. e.* of the quantity which impinged on the glaſs; that when light is made to paſs through two panes of ſuch glaſs ſtanding parallel, but not touching each other, the loſs is ,3184 of the whole; and that in paſſing through a very thin, clear, colourleſs pane of window-glaſs, the loſs is only ,1263. Hence he infers, that this apparatus might be very uſefully employed by the optician, to determine the degree of tranſparency of glaſs, and direct his choice in the proviſion of that important article of his trade. The loſs of light when reflected from the very beſt plain glaſs mirror, the author aſcertained, by five experiments, to be $\frac{1}{3}$d of the whole which fell upon the mirror.

PIANO FORTE, otherwiſe called FORTE PIANO, a well-known muſical inſtrument, of which we need make no apology for conſidering the peculiarities with ſome attention. If we look on muſic from no higher point of view than as the *laborum dulce lenimen*, the innocent, the ſoothing, the chearing ſweetener of toil, we muſt acknowledge that it is far from being the meaneſt of thoſe enjoyments with which the Bountiful Father of Men has embelliſhed this ſcene of our exiſtence. But there is a *ſcience* in muſic, independent of that artificial half mathematical doctrine which we have contrived to unite with it, and which really enables us to improve pure muſical pleaſure. Hence in the Engliſh univerſities degrees are conferred in muſic.

The voice is the original muſical inſtrument, and all others are but imitations. The voice of man obeys the impulſe of the heart with wonderful promptitude, and ſtill more wonderful accuracy. A very coarſe ear is hurt by an error in its tone, amounting to what is called a *comma*. A very limited voice can execute melodies extending to 12 notes, or an octave and a fifth. The motion of the glottis between theſe extremes does not amount to $\frac{1}{11}$th of an inch. This muſt therefore be divided, by the moſt ordinary finger, into more than a thouſand parts; and this muſt be done in an inſtant, and repeated with rapidity, without ever miſtaking one of theſe diviſions; and this is done everywhere, and without any ſeeming effort or thought. The mechaniſm of the human organ for effecting this with eaſe and preciſion is very remarkable, and ſeems to prove that the Author of our Being meant to give us this pleaſure.

When, in the cultivation of this fruit of our own ſoil, the moderns diſcovered the beauties of harmony or conſonance, and inſtruments of fixed ſounds were employed, by means of which theſe beauties could be exhibited in their utmoſt richneſs and variety; and particularly when the organ, that "magic world of ſound," was invented, the immenſe advantages of the ingenious ſpeculations of the ancient Greeks about the diviſion of the monochord were now perceived, and muſic became a deep intellectual ſtudy. It fell into the hands of men of letters, and, for a long while, counterpoint occupied all their attention. Inſtruments of fixed ſounds were now made, not only with pipes, but with ſtrings, bells, rings, and every thing that could make a noiſe in tune.

But all theſe inſtruments were far inferior to the voice, the ſpontaneous gift of Nature, in promptitude, and in the power of obeying every call of ſentiment, every degree, as well as every kind of emotion, with which the heart was agitated. The pleaſures of harmony, though great, were monotonous, and could not expreſs the momentary variations of ſentiment, which are as fleeting as the light and ſhade of a proſpect while the dappled clouds ſail acroſs the ſky. The violin, and a ſmall number of the ſimple wind inſtruments, were found to be the only ones which could fully expreſs thoſe momentary gradations of ſentiment that give muſic its pathos, and enable it to thrill the very ſoul.

Piano
Forte.

Attempts were made to remove this defect of the harmonic inſtruments, and the SWELL was added to the organ. The effect was great, and encouraged the artiſts to attempt ſimilar improvements on other inſtruments of the ſame kind. This was firſt done in the ſame way as in the organ. The harpſichord was ſhut up, like the ſwell organ, and was opened by means of pedals when the performer wiſhed to enforce the ſound. But the effect was far inferior to that of the ſwell organ; for this was (at leaſt in all great organs) a real addition of another properly ſelected ſound. But the effect of the pedal on the harpſichord could not be miſtaken; it was juſt like opening the door of a room where muſic was performing. Other methods were tried with better effect. Uniſons were added to each note, which were brought on either by means of pedals or by another ſet of keys.

This method ſucceeded perfectly well, and the power of the harpſichord was greatly improved. But ſtill it was imperfect, becauſe it was only the more conſiderable changes of force which could be exhibited, and this only in one or two degrees. Other artiſts, therefore, attempted to conſtruct the inſtrument, ſo that the jacks (the moveable upright pieces which carry the quills) can be made to approach nearer to the wires, ſo that the quills ſhall give them a ſtronger twang. The mechaniſm was ſuch, that a very conſiderable motion of the pedal produced but a moſt minute motion of the quill; ſo that the performer was not reſtricted to the utmoſt preciſion in the degree of preſſure. Some of thoſe inſtruments, when freſh from the hand of the artiſt, gave full ſatisfaction. But, though made in the moſt accurate manner, at an enormous expence, they very ſoon become unfit for the purpoſe. The hundredth part of an inch, more or leſs, in the place of the quill, will make a great odds in the force of the ſound. Nor does the ſame change of diſtance produce an equal alteration of ſound on different quills. Other inſtrument makers have therefore tried baked or prepared leather (buffalo hide) in place of quills; and it is found much more uniform in the tone which it produces, and alſo remains longer in the ſame ſtate; but the tone is not ſo powerful, nor in general ſo much reliſhed.

But all theſe contrivances, both in the organ and harpſichord, were ſtill very deficient. Whatever change they could produce in the ſtrength of the ſound, was produced through the whole inſtrument, or at leaſt through two or three octaves. But the captivating expreſſion of muſic frequently reſults from the momentary ſwelling or ſoftening of a ſingle phraſe, or a ſingle note, in one of the parts. Hence ariſe the unrivalled powers of the harp, and the acknowledged ſuperiority of the theorbo, the lute, and even the guitar, over all keyed inſtruments, notwithſtanding their great limitations in harmony and in practicable melodies. Theſe inſtruments ſpeak, while the harpſichord only plays.

Many attempts have been made to enable the performer to produce, by the intervention of the key, all the gradations of ſtrength, and even the varieties of ſound,

ſound, which the ſinger can bring forth by the different manner of pinching, bruſhing, or, as it were, careſſing the ſtring; but we have no diſtinct account of any attempt that has ſucceeded. Such a thing would quickly ſpread over Europe. The compiler of the article LUTHIER, in the *Encyclopedie Methodique*, ſays a great deal about a harpſichord fitted with prepared buffalo leather inſtead of crow quills; and aſſerts expreſsly, that, by the mere preſſure on the key, without the aſſiſtance of pedals or ſtops of any kind, the leather is made to act with greater or leſs force on the ſtring. But he gives no account by which we can comprehend how this is brought about; and indeed he writes in terms which ſhew plainly that he has not ſeen the inſtrument, and is merely puffing ſomething that he does not underſtand.

The attempt has been made with more ſucceſs on keyed inſtruments, when the ſtrings are not pinched, but are rubbed by a wheel or band, in the manner of the vielle (hurdygurdy), or ſtruck with a plectrum, like the dulcimer. The CELESTINA (deſcribed by Merſennus by the name of ARCHIVIOLA) is of this kind. A fine band of horſe hair or ſilk, filled with roſin, is extended under the ſtrings, and drawn ſmoothly along by a wheel. By a particular mechaniſm of the keys, this band is made to preſs or rub on any ſtring tranſverſely, as the ſtrings of a violin are touched by the bow. The preſſure on the key regulates the ſtrength of the tone. This inſtrument is not without conſiderable beauties, and will execute ſoft *cantabile* muſic in eaſy modulation, with great expreſſion and juſtneſs. But the artiſts have not yet been able to give it either clearneſs or brilliancy of tone, nor ſufficient force for concert muſic, nor that promptitude of touch that is indiſpenſably neceſſary for figurative muſic or quick movements.

The ſame improvements have been made on the pulſatile inſtruments; and indeed they are here the moſt obvious and eaſy. When the key is employed merely as the means of cauſing a plectrum to give a blow to the ſtring, the performer will hardly fail to give that degree of force which he feels proper for his intended expreſſion. Accordingly, many inſtruments of this kind have been made in Germany, where the artiſts have long been eminent for mechanical knacks. But all their inſtruments of the dulcimer kind are feeble and ſpiritleſs, and none of them have been brought into general uſe, if we except the CLAVICHORD. This is indeed an inſtrument of feeble, and not the moſt pleaſing ſound; but is well fitted for giving every momentary gradation of ſtrength by the preſſure of the finger. Is is therefore a good inſtrument for forming the muſical taſte by chamber practice, and was much uſed by compoſitors in their ſtudies. It is alſo an ingenious, though ſeemingly an obvious and ſimple contrivance, and is capable of much more force, and even brilliancy of ſound, than has generally been given to it.

The conſtruction is ſhortly this. The inner end of the key is furniſhed with an upright piece, which terminates in an edge of braſs, ſomewhat like the end of a narrow blunt chiſel, whoſe line of direction is athwart the ſtrings. When the key is preſſed down, this edge ſtrikes the ſtring, and forces it out of the ſtraight line in which it is ſtretched between its pins. Thus the ſtring is ſhaken or jogged into vibration, in the ſame manner as we obſerve a tight rope ſet a vibrating by a ſudden jerk given to any part of it. The ſtring, thus agitated, gives a ſound, which will continue for ſome little time if the key be held down. As the tone depends on the length of the vibrating ſtring, as well as on its tenſion, it is of importance that the ſtroke be made on the preciſe point of the ſtring which terminates the proper length. The ſtring does not give the note correſponding to its whole length, but that which is produced by the part between the edge and the pin. And becauſe the parts of the ſtring on each ſide of the edge are equally thrown into vibration, the ſhorter portion of it muſt be wrapped up in a liſt of cloth, to prevent it from diſturbing the ear by its ſonorous vibrations. This, however, greatly diminiſhes the ſweetneſs of the ſound given by the other part.

The clavichord gives a fretful waſpiſh kind of ſound, not at all ſuited to tender expreſſion. If the bridge (for the end of the key is really a bridge during the ſound) were placed at an exact third of the length of the ſtring. and if both parts were free, and if the ſtroke be of a proper ſtrength, the ſtring would ſound its twelfth with great ſweetneſs, and with much more force and brilliancy than it does by the preſent conſtruction, and the clavichord would be a charming inſtrument for a leſſon and for private ſtudy. We ſay this from experience of the power of one conſtructed under the direction of the great mathematician Euler, who was alſo an excellent judge of muſic and muſical compoſition. The tones of the upper part of that inſtrument had a ſort of pipe or vocal ſound, and were ſuperior in clearneſs and ſweetneſs to any ſtringed inſtrument we ever heard. But as this conſtruction required every ſtring to be one half longer than a harpſichord wire of the ſame pitch, and as this would have made the inſtrument of a moſt inconvenient ſize, the baſſes were made ſhorter, by placing the bridge at one ſixth of the length, and loading the ſhorter portion of the ſtring with wire twiſted round it. But although this was executed by a moſt dexterous artiſt, the tones were far inferior to thoſe of the trebles, and the inſtrument was like the junction of a very fine one and a very bad one, and made but hobbling muſic. This was probably owing to the impoſſibility of connecting the metal wire and its covering with ſufficient cloſeneſs and ſolidity. An upright clavichord, where the length would be no inconvenience, would be indeed a capital inſtrument for muſical ſtudy. It is worthy of remark, that Mr Euler tried other diviſions of the ſtring by the bridge. When it is ſtruck preciſely in the middle, it ſhould ſound its octave; when it is ſtruck at one-fourth, it ſhould give the double octave, &c. But the maker found that theſe diviſions gave very indifferent, and even uncertain tones; ſometimes not ſounding at all, and ſometimes ſounding beautifully. Our readers will find this well explained in a future article of this *Supplement*, (TRUMPET, *Marine*). They may pleaſe to reflect on the very different tone of the violin as it is bowed on different parts of the ſtring, and on the very different tones of the fore and back uniſons, and particularly of the Cornet ſtop of the harpſichord. The harpſichords of Rucker are noted for the grand fulneſs of their tone; thoſe of Haſſe of Dreſden for their mellow ſweetneſs, and thoſe of Kirkmann of London for their unequalled brilliancy. Theſe makers differed greatly in the placing of their quills.

But the Engliſh PIANO FORTE, by its ſuperior force of tone, its adequate ſweetneſs, and the great variety of voice of which our artiſts have made it ſuſceptible, has with-

withdrawn all farther attention from the clavichord, ſo that it is no longer probable that the learned contribution of the great Euler to public amuſement will be followed up. The Piano forte correſponds to its name with great preciſion: For, without any other attention or effort than what ſentiment ſpontaneouſly dictates, and what we practiſe (without knowing it) on the harpſichord, where it is ineffectual, we make the Pianoforte give every gradation of ſtrength to the ſound of the ſtring, and give it every expreſſion that an inſtrument, purely pulſatile, is capable of. It is alſo ſuſceptible of a very conſiderable variety of tone by the clothing of the mallets, which may be acute or obtuſe, hard or ſoft. And we ſee, by the effect of what are called the grand Piano fortes, that they are fully equal to the harpſichord in fulneſs or body of tone. Nothing ſeems to be wanting to it but that ſliding, or (as the French call it) *careſſing* touch of the ſtring, by which a delicate finger, guided by fine taſte, cauſes the harp or lute to melt the heart, and excite its fineſt emotions. We truſt that the ingenuity of our Britiſh artiſts will accompliſh even this, and make this national inſtrument rival even the violin of Italy.

We call it a *national inſtrument*, not doubting but that this is a recommendation to a Britiſh heart, and becauſe we are very well aſſured that it is an Engliſh contrivance; the invention of a moſt excellent man and celebrated poet, Mr William Maſon. His Caractacus and Elfrida may convince any perſon who is a judge of muſic, that he had a mind exquiſitely ſenſible of all its charms; and we cannot be ſurpriſed that it was one of his chief delights. No man enjoyed the pleaſures of muſic with more rapture; and he uſed to ſay, that his ſpeedieſt recruit from the fatigue of a long walk was to ſit down for a few minutes to the harpſichord. He had ſeen ſeveral of the German attempts to make keyed dulcimers, which were, in ſome meaſure, ſuſceptible of the *forte* and *piano*: But they were all on one principle, and required a particular touch of the finger, of difficult acquiſition, and which ſpoiled it for harpſichord practice. We have alſo ſeen of thoſe inſtruments, ſome of very old date, and others of modern improvement. Some had very agreeable tones; but all were deficient in delicacy and juſtneſs. The performer was by no means certain of producing the very ſtrength of ſound that he intended. And, as Mr Maſon obſerved, they all required an artificial peculiarity of fingering; without which, either the intended ſtrength of tone was not brought out, or the tone was deſtroyed by repeated rattling of the mallet on the wire.

Mr Maſon removed all thoſe imperfections by detaching the mallet entirely from the key, and giving them a connection quite momentary. The ſketch in Plate XL. will give the reader a clear view of Mr Maſon's general principle by which the Engliſh piano forte is diſtinguiſhed from all others. The parts are repreſented in their ſtate of inaction. The key ABK turns, as uſual, on the round edge of the bar B, and a pin *b*, driven into the bar, keeps it in its place. The dot F repreſents a ſection of the ſtring. ED is the mallet, having a hinge of vellum, by which it is attached to the upper ſurface of the bar E. At the other end is the head D, of wood, covered with ſome folds of prepared leather. The mallet lies in the poſition repreſented in the figure, its lower end reſting on a cuſhion-bar K, which lies horizontally under the whole row of mallets. The key AR has a pin C, tipt with a bit of the ſofteſt cork or buckſkin. This reaches to within $\frac{1}{20}$th of an inch of the ſhank of the mallet, but muſt not touch it. The diſtance E *e* is about $\frac{1}{3}$d or $\frac{1}{4}$th of the length of the ſhank. When the end A of the key is preſſed down on the ſtuffing (two or three thickneſſes of the moſt elaſtic woollen liſt) it raiſes the mallet, by means of the pin C, to the horizontal poſition E *d*, within $\frac{1}{8}$th or $\frac{1}{10}$th of an inch of the wire F; but it cannot be ſo much preſſed down as to make the mallet touch the wire. At the ſame time that the key raiſes the mallet by means of the pin C, it alſo lifts off the damper G (a bit of ſpunge) from the wire. This damper is fixed on the end of a little wooden pin G *g*, connected with the lever *g* H, which has a vellum hinge at H. This motion of the damper is cauſed by the pin I, which is fixed into the key near to R. Theſe pieces are ſo adjuſted, that the firſt touch of the key lifts the damper, and, immediately after, the pin C acts on the ſhank of the mallet. As it acts ſo near to its centre of motion, it cauſes the head D to move briſkly through a conſiderable arch D *d*. Being made extremely moveable, and very light, it is thus *toſſed* beyond the horizontal poſition E *d*, and it ſtrikes the wire F, which is now at liberty to vibrate up and down, by the previous removal of the damper G. Having made its ſtroke, the mallet falls down again, and reſts on the ſoft ſubſtance on the pin C. It is of eſſential importance that this mallet be extremely light. Were it heavy, it would have ſo much force, after rebounding from the wire, that it would rebound again from the pin C, and again ſtrike the wire. For it will be recollected, that the key is, at this time, down, and the pin C raiſed as high as poſſible, ſo that there is very little room for this rebound. Leſſening the momentum of the mallet by making it very light, making the cuſhion on the top of the pin C very ſoft, and great preciſion in the ſhape and figure of all the parts, are the only ſecurities againſt the diſagreeable rattling which theſe rebounds would occaſion. In reſpect to the ſolidity and preciſion of workmanſhip, the Britiſh inſtruments are unrivalled, and vaſt numbers of them are ſent to all parts of the continent.

As the blow of ſo light a mallet cannot bring much ſound from a wire, it has always been found neceſſary to have two ſtrings for each note. Another circumſtance contributes to enfeeble the ſound. The mechaniſm neceſſary for producing it makes it almoſt impoſſible to give any conſiderable extent to the belly or ſound board of the inſtrument. There is ſeldom any more of it than what occupies the ſpace between the tuning pins and the bridge. This is the more to be regretted, becauſe the baſſes are commonly covered ſtrings, that they may be of a moderate length. The baſs notes are alſo of braſs, which has a conſiderably lower tone than a ſteel wire of the ſame diameter and tenſion. Yet even this ſubſtitution for ſteel in the baſs ſtrings is not enough. The higheſt of them are much too ſlack, and the loweſt ones muſt be loaded, to compenſate for want of length. This greatly diminiſhes the fulneſs, and ſtill more the mellowneſs and diſtinctneſs of the tone, and frequently makes the very loweſt notes hardly appreciable. This inequality of tone about the middle of the inſtrument is ſomewhat diminiſhed by conſtructing the inſtrument with two bridges; one for the ſteel, and the other for the braſs wires. But ſtill the baſs notes are very much inferior to the treble. It would ſurely be worth while to conſtruct ſome piano fortes, of full ſize, with naked baſſes. If theſe were made with all the other advantages of the grand piano forte, they would ſurpaſs all other inſtruments for the regulating power of their thorough baſs. We wiſh that the artiſts would alſo try to conſtruct them with the mechaniſm of mallets, &c. above the ſound board. This would allow to it the full extent of the inſtrument, and greatly improve the tone. It does not ſeem impoſſible, nor (we think) very difficult.

For directions how to tune this pleaſing inſtrument, ſee Temperament in this *Supplement.*

PIGMENTS, or Paints, are furniſhed by both the mineral and vegetable kingdoms. The former are the moſt durable, and are generally prepared from the Oxyds of metals (ſee Chemistry *Index* in this *Suppl.* and *Colour-Making*, Encycl.); but Fourcroy thinks that chemiſtry furniſhes a method of fixing vegetable colours completely. From a number of experiments, which we need not detail, as they will be noticed in the article *Vegetable Substances*, he draws the following concluſions:

1. That oxygen, when combined with vegetable ſubſtances, changes their colour.

2. That different proportions of this principle produce different ſhades in coloured vegetable matter.

3. That theſe ſhades paſs, by a ſort of degradation, from the darkeſt colours to the lighteſt; and that the extreme point of the latter may be conſidered as a complete deprivation of colour.

4. That in many vegetable ſubſtances this degradation does not take place, as M. Berthollet has obſerved.

5. That many red, violet, purple, cheſnut, and blue vegetable colours, are produced by different proportions of oxygen; but that none of theſe are completely ſaturated with this principle.

6. That the complete ſaturation here ſpoken of generally produces yellow colours, which are the leaſt changeable of all.

7. That vegetable ſubſtances coloured by oxygen, not only change their colour according to the proportion of oxygen they have imbibed, but that they alſo change their nature in the ſame proportion, and approach more to a reſinous ſtate as they become nearer to a yellow colour.

Laſtly, that the cauſe of the changeability of the red, brown, and violet colours, procured from vegetables, is ſuch as has been ſtated above; that there exiſts a method of fixing them, or rendering them permanent, by impregnating them with a certain quantity of oxygen, by means of the oxygenated muriatic acid; imitating, by this proceſs, the method purſued by nature, who never forms fixed and permanent colours, except in ſubſtances which have been long expoſed to the open air.

PITCH. See *Encycl.*—The beſt black pitch is made of the refuſe of roſin and turpentine, ſuch as will not paſs through the ſtraw filter, and the cuttings around the inciſion on the tree. Theſe materials are put into a boiler ſix or ſeven feet in circumference, and eight or ten high. Fuel is laid around the top, and the materials as they melt flow through a channel cut in the fire-place into a tub half filled with water. It is at that time very red, and almoſt liquid. To give this a proper conſiſtence, it is put in a cauldron placed in a furnace, and boiled down in the ſame manner as roſin, but it requires much leſs precaution and double the time. It is then poured into moulds of earth, and forms the beſt kind of black pitch. See Rosin and Turpentine in this *Suppl.*

Bastard PITCH, is a mixture of colophony, black pitch, and tar. They are boiled down together, and put into barrels of pine wood, forming, when the ingredients are mixed in equal portions, a ſubſtance of a very liquid conſiſtence, called in France *bray gras.* If, on the contrary, it is deſired of a thicker conſiſtence, a greater proportion of colophony is added, and it is caſt in moulds. It is then called *baſtard pitch.*

PLAGUE (ſee Medicine-*Index*, Encycl.), is a diſeaſe which has been lately aſſerted by Dr Moſeley to be not contagious. In ſupport of this opinion, he quotes many paſſages from medical writers, ancient and modern; but he ſeems to place the greateſt confidence (as is indeed natural) in his own obſervations on peſtilential fevers in the Weſt Indies, and on what is ſaid of the plague in Berthier's account of Buonaparte's expedition into Syria.

"At the time of our entry into Syria (ſays this Frenchman), all the towns were infected by the plague; a malady which ignorance and barbarity render ſo fatal in the Eaſt. Thoſe who are affected by it give themſelves up for dead: they are immediately abandoned by every body (A), and are left to die, when they might have been ſaved by medicine and attention.

"Citizen Degenettes, principal phyſician to the army, diſplayed a courage and character which entitle him to the national gratitude. When our ſoldiers were attacked by the leaſt fever, it was ſuppoſed that they had caught the plague, and theſe maladies were confounded. The fever hoſpitals were abandoned by the officers of health and their attendants. Citizen Degenettes repaired in perſon to the hoſpitals, viſited all the patients, felt the glandular ſwellings, dreſſed them, declared and maintained that the diſtemper was not the plague, but a malignant fever with glandular ſwellings, which might eaſily be cured by attention, and keeping the patient's mind eaſy."

Degenette's views in making this diſtinction were highly commendable; but certainly, ſays Dr Moſeley, this fever was the plague. The phyſician, however, carried his courage ſo far, as to make two inciſions, and to inoculate the ſuppurated matter from one of theſe buboes above his breaſt and under his arm-pits, but was not affected with the malady. He thus eaſed the minds of the ſoldiers, the firſt ſtep to a cure; and, by his aſſiduity and conſtant attendance in the hoſpitals, a number of men attacked with the plague were cured. His example was followed by other officers of health.

The lives of a number of men Citizen Degenettes was

(A) This can hardly be true. Every one knows that Mahometans are fataliſts in the ſtricteſt ſenſe of the word; and Mr Browne, whoſe knowledge of Syria and its inhabitants muſt be at leaſt equal to that of Berthier, aſſures us, that, far from abandoning his friend in the plague, "the Moſlem, awe-ſtruck, and reſigned to the unalterable decrees of fate, hangs over the couch of his expiring relative."

was thus inſtrumental of ſaving. He diſmiſſed thoſe who had been ill with the fever and buboes, without the leaſt contagion being communicated to the army.

"There are (ſays Dr Moſeley) annual or ſeaſonal diſorders, more or leſs ſevere, in all countries; but the plague, and other great depopulating epidemics, do not always obey the ſeaſons of the year. Like comets, their courſe is eccentric. They have their revolutions; but from whence they come, or whither they go after they have made their revolutions, no mortal can tell.

"To look for the cauſe of an epidemic in the preſent ſtate of the air, or weather, when it makes its appearance, is a very narrow contracted method of ſcrutiny. The cauſe of peſtilential epidemics cannnot be confined, and local. It muſt lie in the atmoſphere, which ſurrounds, and is in contact with every part of us; and in which we are immerſed, as bodies in fluids.

"Theſe diſeaſes not appearing in villages and thinly inhabited places, and generally attacking only great towns and cities, may be, that the atmoſphere, which I conceive to be the univerſal propagator of peſtilence, wants a commixture, or union, with ſome compounded and peculiar air, ſuch as is generated in populous communities, to releaſe its impriſoned virulence, and give it force. Like the divided ſeminal principles of many plants, concealed in winds and rains until they find ſuitable materials and ſoil to unite their ſeparated atoms, they then aſſume viſible forms in their own proper vegetation.

"Diſeaſes originating in the atmoſphere ſeize ſome, and paſs by others; and act excluſively on bodies graduated to receive their impreſſions; otherwiſe whole nations would be deſtroyed. In ſome conſtitutions of the body the acceſs is eaſy, in ſome difficult, and in others impoſſible.

"The air of confined places may be ſo vitiated as to be unfit for the purpoſes of the healthy exiſtence of any perſon. Hence gaol, hoſpital, and ſhip fevers. But as theſe diſtempers are the offspring of a local cauſe, that local cauſe, and not the diſtempered people, communicate the diſeaſe.

"Plagues and peſtilences, the produce of the great atmoſphere, are conveyed in the ſame manner, by the body being in contact with the cauſe; and not by its being in contact with the effect. If peſtilences were propagated by contagion, from infected perſons, the infection muſt iſſue from their breath or excrements, or from the exhalations of the bodies of the diſeaſed. The infection, if it were not in the atmoſphere, would be confined within very narrow limits; have a determinate ſphere of action; and none but phyſicians and attendants on the ſick would ſuffer; and theſe muſt ſuffer; and the cauſe and the effects would be palpable to our ſenſes. Upon this ground the precaution of quarantine would be rational. But who then would viſit and attend the ſick, or could live in hoſpitals, priſons, and lazarettos?"

From theſe reaſonings and facts, the author is convinced, that the bubo and carbuncle, of which we hear ſo much in Turkey, and read ſo much in our own hiſtory of plagues, ariſe from heating food and improper treatment; that they contain no infection; and conſequently that they are not the natural depoſit of the morbific virus ſeparated from the contagion.

He is equally confident that no peſtilential or pandemic fever was ever imported or exported; and hence he conſiders the fumigating of ſhip-letters, and ſhutting up the crews and paſſengers of veſſels, on their arrival from foreign places, ſeveral weeks, for fear they ſhould give diſeaſes to others which they have not themſelves, as an ignorant barbarous cuſtom. Whence was the importation of the plague at Naples in 1656; by which 20,000 people died in one day? Can any perſon, for a moment reflecting, believe, that the great plague of London in 1665, which imagination traced from the Levant to Holland, and from Holland to England, was cauſed by opening a bag of cotton in the city, or in Long Acre; or a package of hemp in St Giles's pariſh? Quarantine, always expenſive to commerce, and often ruinous to individuals, is a reflection on the good ſenſe of countries.

That Dr Moſeley is a man of learning, and a lively writer, is known to every one who has looked into his works, and is not himſelf a ſtranger to letters. On this account, and ſtill more on account of the opportunities which he has poſſeſſed of making accurate obſervations on various kinds of peſtilential diſeaſes, we have detailed at ſome length his notions of the plague; but as it does not appear that he ever *ſaw* the diſeaſe which is *known* by the name of *the plague*, juſtice requires that we give ſome account of it from a man who had the beſt poſſible opportunities of obtaining correct information on the ſubject.

"The facts that appear to be chiefly aſcertained relative to the plague (ſays Mr Browne), are, 1. That the infection is not received but by actual contact. In this particular, it would ſeem leſs formidable than ſeveral other diſorders. 2. That it is communicated by certain ſubſtances, by others not; as by a woollen cloth, or rope of hemp, but not by a piece of ivory, wood, or a rope made of the date tree; nor by any thing that has been completely immerſed in water. It would appear from the report of the Kahirines*, that no animal but man is affected with this diſorder; though, it is ſaid, a cat paſſing from an infected houſe has carried the contagion. 3. That perſons have often remained together in the ſame houſe, and entirely under the ſame circumſtances, of whom one has been attacked and died, and the others never felt the ſmalleſt inconvenience. 4. That a perſon may be affected any number of times. 5. That it is more fatal to the young than the old. 6. That no climate appears to be exempt from it; yet, 7. That the extremes of heat and cold both appear to be adverſe to it. In Conſtantinople it is often, but far from being always, terminated by the cold of winter, and in Kahira by the heat of ſummer; both circumſtances being, as may be conjectured, the effect of indiſpoſition for abſorption in the ſkin, unleſs it be ſuppoſed that in the latter caſe it may be attributed to the change the air undergoes from the increaſe of the Nile.

"The firſt ſymptoms are ſaid to be thirſt; 2. cephalalgia; 3. a ſtiff and uneaſy ſenſation, with redneſs and tumor about the eyes; 4. watering of the eyes; 5. White puſtules on the tongue. The more advanced ſymptoms of buboes, fœtor of the breath, &c. &c. are well known; and I have nothing authentic to add to them. Not uncommonly, all theſe have ſucceſſively ſhewn themſelves, yet the patient has recovered; in which caſe, where ſuppuration has had place, the ſkin always remains diſcoloured, commonly of a purple hue. Many who have been bleeded in an early ſtage of the

---

* The inhabitants of *Cairo*, which Mr Brown uniformly calls *Kahira*.

diſorder, have recovered without any fatal ſymptoms; but whether from that or any other cauſe, does not appear certain (B). The ſame operation is reported to have been commonly fatal in a late ſtage. It is ſaid that embrocating the buboes continually with oil has ſometimes wrought a cure; but this remedy is ſo difficult and dangerous for the operator, that it would appear experiments muſt yet be very defective."

They are not, perhaps, ſo defective as Mr Browne ſuppoſes. In the hoſpital of St Anthony at Smyrna, it has been the practice for many years paſt to rub over with warm olive oil the bodies of perſons infected by the plague; and that practice has been attended with wonderful ſucceſs. It was firſt ſuggeſted by Mr Baldwin the Engliſh conſul; and from him adopted by *P. Luigi di Pavia*, who for upwards of 27 years has expoſed himſelf to infection by his unremitting attendance on thoſe who are labouring under this dreadful diſtreſs. This excellent man, whoſe philanthropy equals that even of "Marſeilles' good biſhop," declares, that during the long period mentioned, he has found no remedy comparable to that of rubbing olive oil, with the ſtrongeſt friction, into the whole body of the infected perſon. When the body is thus rubbed, the pores being opened, imbibe the oil, and a profuſe perſpiration takes place, by which the poiſonous infection is again thrown out. This operation muſt be performed the firſt day of the infection; and if only a weak perſpiration enſues, it muſt be repeated till it is obſerved that every particle of infection is removed, and that the whole body of the patient is covered with a profuſe ſweat. Neither the patient's ſhirt nor bed-clothes muſt be changed till the perſpiration has entirely ceaſed. The operation muſt be performed in a very cloſe apartment; and at every ſeaſon of the year there muſt be kept in it a fire-pan, over which ſugar and juniper muſt be thrown from time to time, that the vapour which thence ariſes may promote the perſpiration. The whole body of the patient, the eyes alone excepted, muſt in this manner be anointed, or rather rubbed over with the greateſt care.

This practice of the pious monk is mentioned by Mr Howard in his work on Lazarettos; but a more ſatisfactory account of it is given by Count *Leopold von Berchtold*, who adds the following remarks by way of illuſtration: 1. The operation of rubbing in the oil muſt be performed by means of a ſponge, and ſo ſpeedily as not to laſt more than about three minutes. 2. The interval between the firſt and the ſecond rubbing, if a ſecond be neceſſary, muſt be determined by circumſtances, as the ſecond muſt not be performed till the firſt perſpiration is over, and this will depend on the conſtitution of the patient. If any ſweat remains upon the ſkin, it muſt be wiped off with a warm cloth before the ſecond rubbing takes place. This ſtrong friction with oil may be continued, for ſeveral days ſucceſſively, until a favourable change is remarked in the diſeaſe; after which the rubbing may be performed in a more gentle manner. The quantity of oil requiſite each time cannot be determined with accuracy; but, in general, a pound may be ſufficient. The pureſt and freſheſt oil is the beſt for this operation: it muſt not be hot, but only lukewarm. The breaſt and privities muſt be rubbed ſoftly. In a cold climate ſuch as ours, thoſe parts only into which the oil is rubbed muſt be expoſed naked. The other parts muſt be covered with warm clothing. In this manner each part of the body muſt be rubbed with oil in ſucceſſion, as quickly as poſſible, and be then inſtantly covered. If the patient has boils or buboes, they muſt be rubbed over gently with the oil till they can be brought to ſuppurate by means of emollient plaſters. The perſons who attend the patients to rub in the oil muſt take the precaution to rub themſelves over in the like manner, before they engage in the operation. They muſt, if poſſible, avoid the breath of the patient, and not be under any apprehenſions of catching the infection.

P. Luigi then ſays: "In order to prevent the patients from loſing their ſtrength, I preſcribed for them, during four or five days, ſoup made of vermicelli boiled in vinegar without ſalt. I gave them ſix or ſeven times a-day a ſmall ſpoonful of preſerved ſour cherries; preſerved not with honey, but with ſugar, as the former might have occaſioned a diarrhœa. When convinced that the patients were getting better, I uſually gave them the fifth morning a cup of good Mocha coffee, with a piece of toaſted biſcuit *(biſcotto)* prepared with ſugar; and I doubled the latter according to the ſtrength and improvement of my patients."

In the courſe of five years, during which friction with oil was employed in the hoſpital at Smyrna, of 250 perſons attacked by the plague the greater part were

---

(B) Dr Moſeley, we think, has aſſigned a very ſufficient reaſon why bleeding ſhould generally prove effectual, if recourſe be had to it at the commencement of the diſeaſe. "In the common order of peſtilential fevers (ſays he), they commence with coldneſs and ſhivering; ſimply demonſtrating, that ſomething unuſual has been in contact with the ſkin, agonizing cutaneous ſenſibility. Sickneſs at the ſtomach, and an immoveable preſſure about the præcordia, follow. Theſe demonſtrate, that the blood cannot pervade the extremities of the body, and that the quantity which ought to dilate through the whole machine is confined to the larger organs, and is crowding and diſtending the heart and central veſſels.

"The reſtraining power of the remoter blood-veſſels being deſtroyed, the thinner parts of the blood eſcape their boundaries; hence ariſes yellowneſs in the ſkin in ſome climates; in others, the extravaſated groſſer parts of the blood ſtagnate, forming black lodgements, bubo, anthrax, and exanthemata.

"The object in theſe fevers is, to decide the conteſt between the ſolids and the fluids; and this appears to me to be only practicable, when ſpontaneous ſweats do not happily appear, or cannot be raiſed by a cooling regimen; and by draining the vital parts, by bleeding and purging, before the fluids have burſt their confines, and diſſolved their bond of union with the ſolids. The next ſtep is to regain the loſt energy of the ſurface of the body, by exciting perſpiration; and then of the whole ſyſtem, by tonics.

"When theſe things are not done in the firſt hours of attack, in peſtilential fevers, and the conflict is not *extinguiſhed* at once attempting to extort ſweats from the body, by heating alexapharmics, will do miſchief; and bark, wine, ſtimulants, and cordials, may be called on, like undertakers, to perform an uſeleſs ceremony."

were cured; and this would have been the caſe with the reſt had they not neglected the operation, or had it not been employed too late after their nervous ſyſtem had been weakened by the diſeaſe ſo as to render them incurable. Immenſe numbers of people have been preſerved from the effects of this malady by the above means; and of all thoſe who have anointed themſelves with oil, and rubbed it well into their bodies, not one has been attacked by the plague, even though they approached perſons already infected, provided they abſtained from heavy and indigeſtible food.

Thus we ſee, if this account may be depended on, that oil rubbed into the ſkin acts as a preventative, as well as a cure. When the operation is performed to prevent infection, and it is ſucceſsfully performed with that view at Smyrna, as often as the plague makes its appearance in the city, as it is not done for the purpoſe of promoting perſpiration, it is not requiſite that it ſhould be performed with the ſame ſpeed as when for curing the diſorder; nor is it neceſſary to abſtain from fleſh and to uſe ſoups; but it will be proper to uſe only fowls or veal for ten or twelve days, boiled or roaſted, without any addition or ſeaſoning *(condimento)*. In the laſt place, it will be neceſſary to guard againſt fat and indigeſtible food, and ſuch liquors as might put in motion or inflame the maſs of the blood.

This important diſcovery deſerves the ſerious conſideration of all medical men; for if olive oil has been found efficacious in curing or preſerving againſt one ſpecies of infection, it is not abſurd to ſuppoſe that the ſame or other kinds of oil might be productive of much benefit in other malignant infectious diſeaſes. We hope ſoon to hear of ſome trial being made with it in this country. Would it be of any ſervice in the yellow fever, ſo prevalent in the weſtern world? See the *Philoſophical Magazine*, Vol. II.

PLANETARY hours, are twelfth parts of the artificial day and night; being each double in length to the hour uſed in civil computation in Europe. They are ſtill uſed by the Jews as they were among their forefathers; and hence are called *Jewiſh* hours. The reaſon of their being called *planetary* hours, is, that, according to the aſtrologers, a new planet comes to predominate every hour, and that the day takes its denomination from that which predominates the firſt hour of it; as Monday from the moon, &c.

PLANTS, organiſed bodies, of which a full account has been given in the *Encycl.* under the title BOTANY, PLANT, SEXES, *&c.* The eſtabliſhment of the ſexual ſyſtem in vegetables, and the acknowledged analogy between vegetable and animal bodies, has ſuggeſted a method of improving plants, as animals are confeſſedly improved, by what is called *croſſing the breed*. This thought occurred firſt, we believe, to Andrew Knight, Eſq; and in the Tranſactions of the Royal Society for 1799, we have an account of ſome very curious experiments made by him, with the view of aſcertaining whether the improvement which he had conceived be actually practicable. Thoſe were chiefly made on the garden pea, of which he had a kind growing in his yard; which having been long cultivated in the ſame ſoil, had ceaſed to be productive, and did not appear to recover the whole of its former vigour when removed to a ſoil of a ſomewhat different quality. On this his firſt experiment in 1787 was made. Having opened a dozen of its immature bloſſoms, he deſtroyed the male parts, taking great care not to injure the female ones; and a few days afterwards, when the bloſſoms appeared mature, he introduced the farina of a very large and luxuriant grey pea into one half of the bloſſoms, leaving the other half as they were. The pods of each grew equally well; but he ſoon perceived that of thoſe into whoſe bloſſoms the farina had not been introduced, the ſeed remained nearly as they were before the bloſſom expanded, and in that ſtate they withered. Thoſe in the other pods attained maturity, but were not in any ſenſible degree different from thoſe afforded by other plants of the ſame variety; owing, he imagines, to the external covering of the ſeed (as he had found in other plants) being furniſhed entirely by the female. In the ſucceeding ſpring, the difference, however, became extremely obvious; for the plants from them aroſe with exceſſive luxuriance, and the colour of their leaves and ſtems clearly indicated that they had all exchanged their whiteneſs for the colour of the male parent: the ſeeds produced in autumn were dark grey. By introducing the farina of another white variety (or in ſome inſtances by ſimple culture), he found this colour was eaſily diſcharged, and a numerous variety of new kinds produced; many of which were in ſize and every other reſpect much ſuperior to the original white kind, and grew with exceſſive luxuriance, ſome of them attaining the height of more than twelve feet.

The diſſimilarity he obſerved in the offspring, afforded by different kinds of farina in theſe experiments, pointed out to him an eaſy method of aſcertaining whether ſuperfœtation (the exiſtence of which has been admitted among animals) could alſo take place in the vegetable world. For as the offspring of a white pea is always white, unleſs the farina of a coloured kind be introduced into the bloſſom, and as the colour of the grey one is always transferred to its offspring, though the female be white, it readily occurred to Mr Knight, that if the farina of both were mingled or applied at the ſame moment, the offspring of each could be eaſily diſtinguiſhed.

His firſt experiment was not altogether ſucceſsful; for the offspring of five pods (the whole which eſcaped the birds) received their colour from the coloured male. There was, however, a ſtrong reſemblance to the other male in the growth and character of more than one of the plants; and the ſeeds of ſeveral in the autumn very cloſely reſembled it in every thing but colour. In this experiment he uſed the farina of a white pea, which poſſeſſed the remarkable property of ſhrivelling exceſſively when ripe; and in the ſecond year he obtained white ſeeds from the grey ones above mentioned, perfectly ſimilar to it. He is therefore ſtrongly diſpoſed to believe that the ſeeds were here of common parentage; but doth not conceive himſelf to be in poſſeſſion of facts ſufficient to enable him to ſpeak with deciſion on this queſtion. We have no right to form a decided opinion on this part of the ſubject, having paid to it very little attention; but at preſent we are inclined to think differently from the author. We admit, indeed, that if the female afford the firſt organized atom, and the male act only as a ſtimulus, it is by no means impoſſible that the exploſion of two veſicles of farina, at the ſame moment (taken from different plants), may afford ſeeds of common parentage; but whether the female or the male affords the firſt organized atom, is the queſtion which to us appears not yet decided.

Another ſpecies, however, of ſuperfœtation, in which one ſeed appears to have been the offspring of two males, has occurred to Mr Knight ſo often, as to remove, he ſays, all poſſibility of doubt as to its exiſtence. In 1797, the year after he had ſeen the reſult of the laſt mentioned experiment, having prepared a great many white bloſſoms, he introduced the farina of a white and that of a grey nearly at the ſame moment into each; and as in the laſt year the character of the coloured male had prevailed, he uſed its farina more ſparingly than that of the white one; and now almoſt every pod afforded plants of different colours. The majority, however, were white; but the characters of the two kinds were not ſufficiently diſtinct to allow him to judge with preciſion whether any of the ſeeds were produced of common parentage or not. In the year 1798 he was more fortunate; having prepared bloſſoms of the little early frame pea, he introduced its own farina, and immediately afterwards that of a very large and late grey kind, and ſowed the ſeeds thus obtained in the end of ſummer. Many of them retained the colour and character of the ſmall early pea, not in the ſlighteſt degree altered, and bloſſomed before they were eighteen inches high; whilſt others (taken from the ſame pods), whoſe colour was changed, grew to the height of more than four feet, and were killed by the froſt before any bloſſoms appeared.

It is evident, that in theſe inſtances ſuperfœtation took place; and it is equally evident that the ſeeds were not all of common parentage. Should ſubſequent experience evince, that a ſingle plant may be the offſpring of two males, the analogy between animal and vegetable nature may induce ſome curious conjectures relative to the proceſs of generation in the animal world.—It certainly may; but either we do not perfectly underſtand the author's meaning, or this experiment is not concluſive. There were here ſeeds of different colours produced by the farina of different males, operating on the ſame female plant; and there are well atteſted inſtances of twin children being born of different colours, in conſequence of the coition of different males, a negro and a white man, with the ſame woman. Had Mr Knight diſcovered, not that the ſame pod, but that the ſame individual *pea*, was the offspring of two males, his diſcovery would indeed have led to ſome curious conjectures reſpecting animal generation. But to proceed with his experiments:

By introducing the farina of the largeſt and moſt luxuriant kinds into the bloſſoms of the moſt diminutive, and by reverſing this proceſs, he found that the powers of the male and female, in their effects on the offspring, are exactly equal. The vigour of the growth, the ſize of the ſeeds produced, and the ſeaſon of maturity, were the ſame, though the one was a very early and the other a late variety. He had in this experiment a ſtriking inſtance of the ſtimulative effects of croſſing the breeds; for the ſmalleſt variety, whoſe height rarely exceeded two feet, was increaſed to ſix feet; whilſt the height of the large and luxuriant kind was very little diminiſhed. By this proceſs it is evident, that any number of new varieties may be obtained; and it is highly probable, that many of theſe will be found better calculated to correct the defects of different ſoils and ſituations than any we have at preſent.

The ſucceſs of Mr Knight's experiments on the pea induced him to make ſimilar experiments on wheat; but theſe did not anſwer his expectations. The varieties indeed which he obtained, eſcaped the blights of 1795 and 1796; but their qualities were not otherwiſe good, nor were they permanent. His experiments on the apple, the improvement of which was the firſt object of his attention, have, as far as he could judge from the cultivated appearance of trees which had not borne fruit when he wrote his memoir, been fully equal to his hopes. The plants which he obtained from his efforts to unite the good qualities of two kinds of apple, ſeem to poſſeſs the greateſt health and luxuriance of growth, as well as the moſt promiſing appearance in other reſpects. In ſome of theſe the character of the male appears to prevail; in others that of the female; and in others both appear blended, or neither is diſtinguiſhable. Theſe variations, which were often obſervable in the ſeeds taken from a ſingle apple, evidently ariſe from the want of permanence in the character of this fruit, when raiſed from ſeed. Many experiments of the ſame kind were tried on other plants; but it is ſufficient to ſay, that all tended to evince, that improved varieties of every fruit and of eſculent plants may be obtained by this proceſs, and that Nature intended that a ſexual intercourſe ſhould take place between neighbouring plants of the ſame ſpecies.

Plants, Nutrition of. This is a ſubject on which a variety of opinions has been entertained by modern chemiſts. Haſſenfratz conſiders carbon as the ſubſtance which nouriſhes vegetables. Ingenhouz, in his work on the nutrition of plants, publiſhed in 1797, endeavours to prove, that if carbon has any influence in this reſpect, it can be only in the ſtate of carbonic acid, as that acid is abſorbed and decompoſed by vegetables; while the ligneous carbon, furniſhed by Nature, produces no effect on the expanſion of plants. Mr A. Young has endeavoured to demonſtrate the ſame thing by experiments. M. Rafn, a Daniſh chemiſt, deſirous of diſcovering the truth amidſt theſe contradictory opinions, made, for three years, a ſeries of experiments; from which he concludes, by the expanſion, ſize, and colour of the plants employed, that carbon, either vegetable or animal, has a decided influence in the nouriſhment of vegetables. What is new, and particularly worthy of remark in theſe reſearches, is, that, according to M. Rafn, the carbonic acid produces exactly the ſame effect as charcoal of wood.

According to Mr Rafn, coal aſhes, on which the German and Engliſh farmers beſtow ſuch praiſe, deſtroy the plants if the ſoil contains an eighth part of that admixture. The leaves become faded, as if ſcorched, at the end of from fifteen to twenty days, and the plants themſelves die at the end of four or five weeks.

No ſeed germinates in oil. A ſingle grain of common ſalt, in 200 grains of water, is ſufficient to retard the vegetation of plants, and may even kill them if they are watered with that ſaline liquor.

Shavings of horn, next to infuſion animals, are the moſt favourable to vegetation: charcoal holds the third rank. For the truth of theſe opinions, ſee *Vegetable* SUBSTANCES in this *Suppl.*

PLATINUM, or PLATINA (See CHEMISTRY, *Suppl.* Part I. Chap. iii. Sect. 3.), is a metal, of which every chemiſt regrets the difficulty of making it malleable. Of the different proceſſes adopted to accompliſh this end, we have reaſon to believe that of Mr Richard Knight the moſt ſucceſsful; and, with the ſpirit

Pl ium, Po rds.

ſpirit of a true philoſopher, he wiſhes to make that proceſs as generally known as poſſible. We ſhall give it in his own words:

"To a given quantity of crude platinum, I add (ſays he) 15 times its weight of nitro-muriatic acid (compoſed of equal parts of nitric and muriatic acids) in a tubulated glaſs retort, with a tubulated receiver adapted to it. It is then boiled, by means of an Argand's lamp, till the acid has aſſumed a deep ſaffron colour: it is then poured off; and if any platina remains undiſſolved, more acid is added, and it is again boiled until the whole is taken up. The liquor, being ſuffered to reſt till quite clear, is again decanted: a ſolution of ſal-ammoniac is then added, by little and little, till it no longer gives a cloudineſs. By this means the platina is thrown down in the form of a lemon-coloured precipitate, which having ſubſided, the liquor is poured off, and the precipitate repeatedly waſhed with diſtilled water till it ceaſes to give an acid taſte (too much water is injurious, the precipitate being in a certain degree ſoluble in that liquid); the water is then poured off, and the precipitate evaporated to dryneſs."

Thus far our author's method, as he candidly obſerves himſelf, differs not from that which has been followed by many others; but the remainder of the proceſs is his own. "A ſtrong, hollow, inverted cone of crucible earth being procured, with a correſponding ſtopper to fit it, made of the ſame materials, the point of the latter is cut off about three-fourths from the baſe. The platina, now in the ſtate of a light yellow powder, is preſſed tight into the cone, and, a cover being fixed ſlightly on, it is placed in an air-furnace, and the fire raiſed gradually to a ſtrong white heat. (The furnace uſed by Mr Knight is portable, with a chamber for the fire only eight inches in diameter.) In the mean time the conical ſtopper, fixed in a pair of iron tongs ſuitable for the purpoſe, is brought to a red, or to a bright red, heat. The cover being then removed from the cone, the tongs with the heated ſtopper is introduced through a hole in the cover of the furnace, and preſſed at firſt gently on the platina, at this time in a ſtate nearly as ſoft as dough, till it at length acquires a more ſolid conſiſtence. It is then repeatedly ſtruck with the ſtopper, as hard as the nature of the materials will admit, till it appears to receive no farther impreſſion. The cone is then removed from the furnace; and being ſtruck lightly with a hammer, the platina falls out in a metallic button, from which ſtate it may be drawn, by repeatedly heating and gently hammering, into a bar fit for flatting, drawing into wire, planiſhing, &c.

"Beſides the comparative facility of this proceſs, it has the farther advantage of rendering the platina much purer than when red-hot iron is obliged to be had recourſe to; for platina, when of a white heat, has a ſtrong affinity for iron, and, with whatever care it may have been previouſly ſeparated from that metal, will be found to have taken up a portion of it, when it is employed of a red heat, to ſerve to unite the particles of the platina."

PLATONIC Bodies, ſee *Regular Bodies*, *Suppl.*

PLUVIAMETER, a machine for meaſuring the quantity of rain that falls, otherwiſe called Ombrometer; which ſee, *Encycl.*

POLLARDS, the name of a coarſe kind of wheaten flour. When the flour of wheat is ſeparated into three degrees of fineneſs, the third is the pollards. There is nothing between it and the bran.

Porcelain, Poſition.

PORCELAIN, a kind of earthen or ſtone ware, of the manufacture of which a full account is given in the *Encyclopædia* from Groſier and Reaumur. It may be proper, however, to add here, from Sir George Staunton, that one of the principal ingredients in the Chineſe porcelain called *pe-tun-tſe*, is a ſpecies of fine granite, or compound of quartz, feldſpath, and mica, in which the quartz bears the largeſt proportion. "It appears (ſays Sir George) from ſeveral experiments, that *pe-tun-tſe* is the ſame as the growan-ſtone of the Corniſh miners. The micaceous part in ſome of this granite from both countries, often contains ſome particles of iron; in which caſe it will not anſwer the potter's purpoſe. This material can be calcined and ground much finer by the improved mills of England, than by the very imperfect machinery of the Chineſe, and at a cheaper rate, than the prepared *pe-tun-tſe* of their own country, notwithſtanding the cheapneſs of labour there. The *kao-lin*, or principal matter mixed with the *pe-tun-tſe*, is the growan clay alſo of the Corniſh miners. The *wha-ſhe* of the Chineſe is the Engliſh ſoap rock; and the *ſhe kan* is aſſerted to be gypſum.

"The manufacture of porcelain is ſaid to be precarious, from the want of ſome preciſe method of aſcertaining and regulating the heat within the furnaces, in conſequence of which, their whole contents are baked ſometimes into one ſolid and uſeleſs maſs." If this be ſo, Wedgewood's thermometer would be a preſent highly valuable to the Chineſe potter, if that arrogant and conceited people would condeſcend to be taught by a native of Europe.

POSITION, Centre of, is a point of any body, or ſyſtem of bodies, ſo ſelected, that we can eſtimate with propriety the ſituation and motion of the body or ſyſtem by the ſituation and motion of this point. It is very plain that, in all our attempts to accurate diſcuſſion of mechanical queſtions, eſpecially in the preſent extended ſenſe of the word *mechaniſm*, ſuch a ſelection is neceſſary. Even in common converſation, we frequently find it neceſſary to aſcertain the diſtance of objects with a certain preciſion, and we then perceive that we muſt make ſome ſuch ſelection. We conceive the diſtance to be mentioned, neither with reſpect to the neareſt nor the remoteſt point of the object, but as a ſort of average diſtance; and we conceive the point ſo aſcertained to be ſomewhere about the middle of the object. The more we reflect on this, we find it the more neceſſary to attend to many circumſtances which we had overlooked. Were it the queſtion, to decide in what preciſe part of a country pariſh the church ſhould be placed, we find that the geometrical middle is not always the moſt proper. We muſt conſider the populouſneſs of the different quarters of the pariſh, and ſelect a point ſuch, that the diſtances of the inhabitants on each ſide, in every direction, ſhall be as equally balanced as poſſible.

In mechanical diſcuſſions, the point by whoſe poſition and diſtance we eſtimate the poſition and diſtance of the whole, muſt be ſo ſelected, that its poſition and diſtance, eſtimated in any direction whatever, ſhall be the average of the poſitions and diſtances of every particle of the aſſemblage, eſtimated in that direction.

This will be the caſe, if the point be ſo ſelected that, when a plane is made to paſs through it *in any direc-*

tion whatever, and perpendiculars are drawn to this plane from every particle in the body or ſyſtem, the ſum of all the perpendiculars on one ſide of this plane is equal to the ſum of all the perpendiculars on the other ſide. If there be ſuch a point in a body, the poſition and motion of this point is the average of the poſitions and motions of all the particles.

Plate XL.

For if P (fig. 1.) be a point ſo ſituated, and if QR be a plane (perpendicular to the paper) at any diſtance from it, the diſtance Pp of the point from this plane is the average of the diſtances of all the particles from it. For let the plane APB be paſſed through P, parallel to QR. The diſtance CS of any particle C from the plane QR is equal to DS—DC, or to Pp—DC. And the diſtance GT of any particle G, lying on the other ſide of APB, is equal to HT+GH, or to Pp+GH. Let n be the number of particles on that ſide of AB which is neareſt to QR, and let o be the number of thoſe on the remote ſide of AB, and let m be the number of particles in the whole body, and therefore equal to $n+o$. It is evident that the ſum of the diſtances of all the particles, ſuch as C, is n times Pp, after deducting all the diſtances, ſuch as DC. Alſo the ſum of all the diſtances of the particles, ſuch as G, is o times Pp, together with the ſum of all the diſtances, ſuch as GH. Therefore the ſum of both ſets is $\overline{n+o}\times \mathrm{P}p$ + ſum of GH — ſum of DC, or $m\times \mathrm{P}p$ + ſum of GH — ſum of DC. But the ſum of GH, wanting the ſum of DC, is nothing, by the ſuppoſed property of the point P. Therefore $m\times \mathrm{P}p$ is the ſum of all the diſtances, and Pp is the mth part of this ſum, or the average diſtance.

Now ſuppoſe that the body has changed both its place and its poſition with reſpect to the plane QR, and that P (fig. 2.) is ſtill the ſame point of the body, and $\alpha \mathrm{P} \beta$ a plane parallel to QR. Make $p\pi$ equal to pP of fig. 1. It is plain that Pp is ſtill the average diſtance, and that $m\times \mathrm{P}p$ is the ſum of all the preſent diſtances of the particles from QR, and that $m\times \pi p$ is the ſum of all the former diſtances. Therefore $m\times \mathrm{P}\pi$ is the ſum of all the changes of diſtance, or the whole quantity of motion eſtimated in the direction πP. Pπ is the mth part of this ſum, and is therefore the average motion in this direction. The point P has therefore been properly ſelected; and its poſition, and diſtance, and motion, in reſpect of any plane, is a proper repreſentation of the ſituation and motion of the whole.

It follows from the preceding diſcuſſion, that if any particle C (fig. 1.) moves from C to N, in the line CS, the centre of the whole will be transferred from P to Q, ſo that PQ is the mth part of CN; for the ſum of all the diſtances has been diminiſhed by the quantity CN, and therefore the average diſtance muſt be diminiſhed by the mth part of CN, or PQ is $=\frac{\mathrm{CN}}{m}$.

But it may be doubted whether there is in every body a point, and but one point, ſuch that if a plane paſs through it, *in any direction whatever*, the ſum of all the diſtances of the particles on one ſide of this plane is equal to the ſum of all the diſtances on the other.

It is eaſy to ſhew that ſuch a point may be found, with reſpect to a plane parallel to QR. For if the ſum of all the diſtances DC exceed the ſum of all the diſtances GH, we have only to paſs the plane AB a little nearer to QR, but ſtill parallel to it. This will diminiſh the ſum of the lines DC, and increaſe the ſum of the lines GH. We may do this till the ſums are equal.

In like manner we can do this with reſpect to a plane LM (alſo perpendicular to the paper), perpendicular to the plane AB. The point wanted is ſomewhere in the plane AB, and ſomewhere in the plane LM. Therefore it is ſomewhere in the line in which theſe two planes interſect each other. This line paſſes through the point P of the paper where the two lines AB and LM cut each other. Theſe two lines repreſent planes, but are, in fact, only the interſection of thoſe planes with the plane of the paper. Part of the body muſt be conceived as being above the paper, and part of it behind or below the paper. The plane of the paper therefore divides the body into two parts. It may be ſo ſituated, therefore, that the ſum of all the diſtances from it to the particles lying above it ſhall be equal to the ſum of all the diſtances of thoſe which are below it. Therefore the ſituation of the point P is now determined, namely, at the common interſection of three planes perpendicular to each other. It is evident that this point alone can have the condition required in reſpect of theſe three planes.

But it ſtill remains to be determined whether the ſame condition will hold true for the point thus found, in reſpect to *any other* plane paſſing through it; that is, whether the ſum of all the perpendiculars on one ſide of *this fourth* plane is equal to the ſum of all the perpendiculars on the other ſide. Therefore

Let AGHB (fig. 3.), AXYB, and CDFE, be three planes interſecting each other perpendicularly in the point C; and let CIKL be any other plane, interſecting the firſt in the line CI, and the ſecond in the line CL. Let P be any particle of matter in the body or ſyſtem. Draw PM, PO, PR, perpendicular to the firſt three planes reſpectively, and let PR, when produced, meet the oblique plane in V; draw MN, ON, perpendicular to CB. They will meet in one point N. Then PMNO is a rectangular parallelogram. Alſo draw MQ perpendicular to CE, and therefore parallel to AB, and meeting CI in S. Draw SV; alſo draw ST perpendicular to VP. It is evident that SV is parallel to CL, and that STRQ and STPM are rectangles.

All the perpendiculars, ſuch as PR, on one ſide of the plane CDFE, being equal to all thoſe on the other ſide, they may be conſidered as compenſating each other; the one being conſidered as poſitive or additive quantities, the other are negative or ſubtractive. There is no difference between their ſums, and the ſum of both ſets may be called 0 or nothing. The ſame muſt be affirmed of all the perpendiculars PM, and of all the perpendiculars PO.

Every line, ſuch as RT, or its equal QS, is in a certain invariable ratio to its correſponding QC, or its equal PO. Therefore the poſitive lines RT are compenſated by the negative, and the ſum total is nothing.

Every line, ſuch as TV, is in a certain invariable ratio to its correſponding ST, or its equal PM, and therefore their ſum total is nothing.

Therefore the ſum of all the lines PV is nothing; but each is in an invariable ratio to a correſponding perpendicular from P on the oblique plane CIKL. Therefore the ſum of all the poſitive perpendiculars on this plane is equal to the ſum of all the negative perpendiculars, and the propoſition is demonſtrated, *viz.* that in every body, or ſyſtem of bodies, there is a point ſuch, that if a plane be paſſed through it *in any direction whatever*, the ſum of all the perpendiculars on one ſide of the plane is equal to the ſum of all the perpendiculars on the other ſide.

The point P, thus ſelected, may, with great propriety, be called the CENTRE OF POSITION of the body or ſyſtem.

If A and B (fig. 4.) be the centres of poſition of two bodies, whoſe quantities of matter (or numbers of equal particles) are a and b, the centre C lies in the ſtraight line joining A and B, and $AC : CB = b : a$, or its diſtance from the centres of each are inverſely as their quantities of matter. For let $\alpha C \beta$ be any plane paſſing through C. Draw $A\alpha$, $B\beta$, perpendicular to this plane. Then we have $a \times A\alpha = b \times B\beta$, and $A\alpha : B\beta = b : a$, and, by ſimilarity of triangles, $CA : CB = b : a$.

If a third body D, whoſe quantity of matter is d, be added, the common centre of poſition E of the three bodies is in the ſtraight line DC, joining the centre D of the third body with the centre C of the other two, and $DE : EC = a + b : d$. For, paſſing the plane $\delta E \kappa$ through E, and drawing the perpendiculars $D\delta$, $C\kappa$, the ſum of the perpendiculars from D is $d \times D\delta$; and the ſum of the perpendiculars from A and B is $\overline{a+b} \times C\kappa$, and we have $d \times D\delta = \overline{a+b} \times C\kappa$; and therefore $DE : EC = a + b : d$.

In like manner, if a fourth body be added, the common centre is in the line joining the fourth with the centre of the other three, and its diſtance from this centre and from the fourth is inverſely as the quantities of matter; and ſo on for any number of bodies.

If all the particles of any ſyſtem be moving uniformly, in ſtraight lines, in any directions, and with any velocities whatever, the centre of the ſyſtem is either moving uniformly in a ſtraight line, or is at reſt.

For, let m be the number of particles in the ſyſtem. Suppoſe any particle to move uniformly in any direction. It is evident from the reaſoning in a former paragraph, that the motion of the common centre is the mth part of this motion, and is in the ſame direction. The ſame muſt be ſaid of every particle. Therefore the motion of the centre is the motion which is compounded of the mth part of the motion of each particle. And becauſe each of theſe was ſuppoſed to be uniform and rectilineal, the motion compounded of them all is alſo uniform and rectilineal; or it may happen that they will ſo compenſate each other that there will be no diagonal, and the common centre will remain at reſt.

Cor. 1. If the centres of any number of bodies move uniformly in ſtraight lines, whatever may have been the motions of each particle of each body, by rotation or otherwiſe, the motion of the common centre will be uniform and rectilineal.

Cor. 2. The quantity of motion of ſuch a ſyſtem is the ſum of the quantities of motion of each body, reduced to the direction of the centre's motion. And it is had by multiplying the quantity of matter in the ſyſtem by the velocity of the centre.

The velocity of the centre is had by reducing the motion of each particle to the direction of the centre's motion and then dividing the ſum of thoſe reduced motions by the quantity of matter in the ſyſtem.

By the ſelection of this point, we render the inveſtigation of the motions and actions of bodies incomparably more ſimple and eaſy, freeing our diſcuſſions from numberleſs intricate complications of motion, which would frequently make our progreſs almoſt impoſſible.

POSITION, in arithmetic, called alſo *Falſe Poſition*, or *Suppoſition*, or *Rule of Falſe*, is a rule ſo called, becauſe it conſiſts in calculating by falſe numbers ſuppoſed or taken at random, according to the proceſs deſcribed in any queſtion or problem propoſed, as if they were the true numbers, and then from the reſults, compared with that given in the queſtion, the true numbers are found.

Thus, take or aſſume any number at pleaſure for the number ſought, and proceed with it as if it were the true number, that is, perform the ſame operations with it as, in the queſtion, are deſcribed to be performed with the number required: then if the reſult of thoſe operations be the ſame with that mentioned or given in the queſtion, the ſuppoſed number is the ſame as the true one that was required; but if it be not, make this proportion, *viz.* as your reſult is to that in the queſtion, ſo is your ſuppoſed falſe number to the true one required.

Example. What number is that, to which if we add $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, and $\frac{1}{6}$ of itſelf, the ſum will be 240?

Suppoſe 99

$$\begin{array}{r l}
49.5 & = \frac{1}{2} \\
33. & = \frac{1}{3} \\
24.75 & = \frac{1}{4} \\
16\ 5 & = \frac{1}{6} \\
\hline
222.75 & = \text{reſult}
\end{array}$$

Then, as $222.75 : 240 :: 99 : 106.\dot{6}$ = Anſwer.

$$\begin{array}{r l}
53.\dot{3} & = \frac{1}{2} \\
35.5 & = \frac{1}{3} \\
26.\dot{6} & = \frac{1}{4} \\
17.\dot{7} & = \frac{1}{6} \\
\hline
240. & = \text{proof.}
\end{array}$$

This is *ſingle* poſition.

Sometimes it is neceſſary to make two different ſuppoſitions or aſſumptions, when the ſame operations muſt be performed with each as in the ſingle rule. If neither of the ſuppoſed numbers ſolve the queſtion, find the differences between the reſults and the given number; multiply each of theſe differences into the other's poſition; and if the errors in both ſuppoſitions be of the ſame kind, *i. e.* if both ſuppoſitions be either leſs or greater than the given number, divide the differences of the products by the differences of the errors. If the errors be not of the ſame kind, *i. e.* if the one be greater and the other leſs than the given number, divide the ſum of the products by the ſum of the errors. The quotient, in either caſe, will be the anſwer.

Example. Three partners, A, B, and C, bought a ſugar-work which coſt them L. 2000; of which A paid a certain ſum unknown; B paid as much as A, and L. 50 over; C paid as much as them both, and L. 25 over: What ſum did each pay?

(1.) Suppoſe A paid L. 500
B —— 550
C —— 1075

2125
2000

125 = error of exceſs.

(2.) Sup-

Pottery.

```

This is called double poſition.

POTTERY is an art of very conſiderable importance; and in addition to what has been ſaid on it in the *Encyclopædia*, the following reflections, by that eminent chemiſt Vauquelin, will probably be acceptable to many of our readers.

Four things (ſays he) may occaſion difference in the qualities of earthen-ware: *1ſt*, The nature or compoſition of the matter; *2d*, The mode of preparation; *3d*, The dimenſions given to the veſſels; *4th*, The baking to which they are ſubjected. By compoſition of the matter, the author underſtands the nature and proportions of the elements of which it is formed. Theſe elements, in the greater part of earthen-ware, either valuable or common, are ſilex, argil, lime, and ſometimes a little oxyd of iron. Hence it is evident that it is not ſo much by the diverſity of the elements that good earthen-ware differs from bad, as by the proportion in which they are united. Silex or quartz makes always two-thirds at leaſt of earthen-ware; argil or pure clay, from a fifth to a third; lime, from 5 to 20 parts in the hundred; and iron, from 0 to 12 or 15 parts in the hundred. Silex gives hardneſs, infuſibility, and unalterability; argil makes the paſte pliable, and renders it fit to be kneaded, moulded, and turned at pleaſure. It poſſeſſes at the ſame time the property of being partially fuſed by the heat which unites its parts with thoſe of the ſilex; but it muſt not be too abundant, as it would render the earthen-ware too fuſible and too brittle to be uſed over the fire.

Hitherto it has not been proved by experience that lime is neceſſary in the compoſition of pottery: and if traces of it are conſtantly found in that ſubſtance, it is becauſe it is always mixed with the other earths, from which the waſhings and other manipulations have not been able to ſeparate it. When this earth, however, does not exceed five or ſix parts in a hundred, it appears that it is not hurtful to the quality of the pottery; but if more abundant, it renders it too fuſible.

The oxyd of iron, beſides the inconvenience of communicating a red or brown colour, according to the degree of baking, to the veſſels in which it forms a part, has the property of rendering them fuſible, and even in a greater degree than lime.

As ſome kinds of pottery are deſtined to melt very penetrating ſubſtances, ſuch as ſalts, metallic oxyds, glaſs, &c. they require a fine kind of paſte, which is obtained only by reducing the earths employed to very minute particles. Others deſtined for melting metals, and ſubſtances not very penetrating, and which muſt be able to ſupport, without breaking, a ſudden tranſition from great heat to great cold, require for their fabrication a mixture of calcined argil with raw argil. By theſe means you obtain pottery, the coarſe paſte of which reſembles *breche*, or ſmall-grained pudding-ſtone, and which can endure ſudden changes of temperature.

The baking of pottery is alſo an object of great importance. The heat muſt be capable of expelling humidity, and agglutinating the parts which enter into the compoſition of the paſte, but not ſtrong enough to produce fuſion; which, if too far advanced, gives to pottery a homogenuouſneſs that renders it brittle. The ſame effect takes place in regard to the fine pottery, becauſe the very minute diviſion given to the earths reduces them nearly to the ſame ſtate as if this matter had been fuſed. This is the reaſon why porcelain ſtrongly baked is more or leſs brittle, and cannot eaſily endure alternations of temperature. Hence coarſe porcelain, in the compoſition of which a certain quantity of calcined argil is employed, porcelain retorts, crucibles, tubes, and common pottery, the paſte of which is coarſe, are much leſs brittle than diſhes and ſaucers formed of the ſame ſubſtance, ground with more labour.

The general and reſpective dimenſions of the different parts of veſſels of earthen-ware have alſo conſiderable influence on their capability to ſtand the fire.

In ſome caſes the glazing or covering, eſpecially when too thick, and of a nature different from the body of the pottery, alſo renders them liable to break. Thus, in making ſome kinds of pottery, it is always eſſential, *1ſt*, To follow the beſt proportion in the principles; *2d*, To give to the particles of the paſte, by grinding, a minuteneſs ſuited to the purpoſe for which it is intended, and to all the parts the ſame dimenſions as far as poſſible; *3d*, To carry the baking to the higheſt degree that the matter can bear without being fuſed; *4th*, To apply the glazing in thin layers, the fuſibility of which ought to approach as near as poſſible to that of the matter, in order that it may be more intimately united.

C. Vauquelin, being perſuaded that the quality of good pottery depends chiefly on uſing proper proportions of the earthy matters, thought it might be of importance, to thoſe engaged in this branch of manufacture, to make known the analyſis of different natural clays employed for this purpoſe, and of pottery produced by ſome of them, in order that, when a new earth is diſcovered, it may be known by a ſimple analyſis whether it will be proper for the ſame object, and to what kind of pottery already known it bears the greateſt reſemblance.

	Heſſian Crucibles.	Argil of Dieux.	Porcelain Capſules.	Wedgewood's Pyrometers.
Silex	69	43·5	61	64·2
Argil	21·5	33·2	28	25
Lime	1	3·5	6	6
Oxyd of iron	8	1	0·5	0·2
Water		18		6·2

elain,
ules.

Raw kaolin 100 parts.—Silex 74, argil 16·5, lime 2, water 7. A hundred parts of this earth gave eight of alum, after being treated with the ſulphuric acid.

Waſhed kaolin 100 parts —Silex 55, argil 27, lime 2, iron 0·5, water 14. This kaolin, treated with the ſulphuric acid, gave about 45 or 50 *per cent.* of alum.

Petuntzé.—Silex 74, argil 14·5, lime 5·5, loſs 6. A hundred parts of this ſubſtance, treated with the ſulphuric acid, gave ſeven or eight parts of alum. But this quantity does not equal the loſs ſuſtained.

Porcelain of retorts.—Silex 64, argil 28·8, lime 4·55, iron 0·50, loſs 2·77. Treated with the ſulphuric acid, this porcelain gave no alum.

There is a kind of earthen veſſels, called *Alcarrezes*, uſed in Spain for cooling the water intended to be drunk. Theſe veſſels conſiſt of 60 parts of calcareous earth, mixed with alumina and a little oxyd of iron, and 36½ of ſiliceous earth, alſo mixed with alumina and the ſame oxyd. The quantity of iron may be eſtimated at almoſt one hundredth part of the whole. This earth is firſt kneaded into a tough paſte, being for that purpoſe previouſly diluted with water; formed into a cake of about ſix inches in thickneſs, and left in that ſtate till it begin to crack. It is then kneaded with the feet, the workman gradually adding to it a quantity of ſea-ſalt, in the proportion of ſeven pounds to a hundred and fifty; after which it is applied to the lath, and baked in any kind of furnace uſed by potters. The alcarrezes, however, are only about half as much baked as the better kinds of common earthen ware; and being exceedingly porous, water oozes through them on all ſides. Hence the air, which comes in contact with it by making it evaporate, carries off the caloric contained in the water in the veſſel, which is thus rendered remarkably cool.

POULES, or FOULQUES, one of the principal nations which inhabit the banks of the Senegal. They poſſeſs an extent of more than ſixty leagues along the river, and exact heavy cuſtoms from the Senegal traders with the interior of the country. They are not ſo black as the other negroes, but of a copper colour, much inclining to red. It is remarkable, however, that their children who are ſent to Senegal, and reſide there for ſome years, become much blacker. The females are very handſome, and the whites of Senegal generally take care to procure ſome of them. But they are of a bad diſpoſition, and utterly incapable of attachment. When a man has a miſtreſs of this nation, he muſt watch her conduct very narrowly, and even chaſtiſe her, that ſhe may not be guilty of infidelity to him whom ſhe honours with her favours. The dread of the baſtinado will, in ſuch caſe, effect what attention and complaiſance can never bring about.

Although the Poules inhabit one of the fineſt ſpots in Africa, they are nevertheleſs a wretched people; they are baſe, cruel, thieviſh, and fanatic in the extreme. They are commanded by a chief of their religion, which is a contemptible mixture of Mahometaniſm and idolatry. This chief is called the *Almamy;* he is always choſen from among the Tampſirs, who are twelve in number. The Tampſirs are the interpreters of the law, and are the moſt learned, or rather the moſt fanatical among them. The Almamy has the power of life and death over his ſubjects; yet he may be depoſed by an aſſembly of Tampſirs: it is therefore his intereſt to keep on good terms with them. The payment of cuſtoms is made to the Almamy, and is afterwards diſtributed among the Tampſirs; and although a part belongs to the former, he nevertheleſs requires a ſeparate preſent for himſelf.

Printing.

PRINTING. (See that article, *Encycl.* and TYPOGRAPHY in this *Supplement.*) We ſhall here only deſcribe a *PRINTING-Preſs*, for the invention of which a patent was granted, in 1790, to Mr William Nicholſon of New North-ſtreet, Red Lion Square, London. This machine, with ſome ſlight varieties, is adapted for printing on *paper*, *linen*, *cotton*, *woollen*, and other articles, in a more neat, cheap, and accurate method, the author thinks, than the printing preſſes now in uſe.

The invention conſiſts in three particulars, 1*ſt*, The manner of preparing and placing the types, engravings, or carvings, from which the impreſſion is to be made; 2*dly*, In applying the ink or colouring matter to types or engravings; and, 3*dly*, In taking off the impreſſion.

1*ſt*, Mr Nicholſon makes his moulds, punches, and matrices, for caſting letters, in the ſame manner, and with the ſame materials, as other letter-founders do, excepting that, inſtead of leaving a ſpace in the mould for the ſtem of one letter only, he leaves ſpaces for two, three, or more letters, to be caſt at one pouring of the metal; and at the lower extremity of each of thoſe ſpaces (which communicate by a common groove at top) he places a matrix, or piece of copper, with the letter punched upon its face in the uſual way. And moreover, he brings the ſtem of his letters to a due form and finiſh, not only by rubbing it upon a ſtone, and ſcraping it when arranged in the finiſhing-ſtick, but likewiſe by ſcraping it, on one or more ſides, in a finiſhing-ſtick whoſe hollowed part is leſs deep at the inner than the outer ſide. He calls that ſide of the groove which is neareſt the face of the diſpoſed letter, the outer ſide; and the purpoſe accompliſhed by this method of ſcraping is, that of rendering the tail of the letter gradually ſmaller the more remote it is, or farther from the face. Such letters may be firmly impoſed upon a cylindrical ſurface, in the ſame manner as common letters are impoſed upon a flat ſtone.

2*dly*, He applies the ink or colouring matter to the types, forms, or plates, by cauſing the ſurface of a cylinder, ſmeared or wetted with the colouring matter, to roll over the ſurfaces of the ſaid forms or plates, or by cauſing the forms or plates apply themſelves ſucceſſively to the ſurface of the cylinder. The ſurface of this colouring cylinder is covered with leather, or with woollen, linen, or cotton-cloth. When the colour to be uſed is thin, as in calico-printing, and in almoſt every caſe, the covering is ſupported by a firm elaſtic ſtuffing, conſiſting of hair, or wool, or woollen cloth wrapped one or more folds round the cylinder. When the covering conſiſts of woollen cloth, the ſtuffing muſt be defended by leather, or oilſkin, to prevent its imbibing too much colour, and by that means loſing its elaſticity. It is abſolutely neceſſary that the colouring matter be evenly diſtributed over the ſurface of the cylinder; and for this purpoſe, when the colour is thick and ſtiff, as in letter-preſs printing, he applies two, three, or more ſmall cylinders, called diſtributing-rollers, longitudinally againſt the colouring cylinders, ſo that they may be turned by the motion of the latter; and the effect of this application is, that every lump or maſs of colour which may be redundant, or irregularly placed upon the face of the colouring cylinder, will be preſſed, ſpread, and partly taken up, and carried by the ſmall rollers to the other parts of the colouring cylinder; ſo that this laſt will very ſpeedily acquire and preſerve an even face of colour. But if the colouring matter be thinner, he does not apply more than one or two of theſe diſtributing-rollers; and, if it be very thin, he applies an even blunt edge of metal, or wood, or a ſtraight bruſh, or both of theſe laſt, againſt the colouring cylinder, for the purpoſe of rendering its colour uniform. When he applies colour to an engraved plate, or cylinder, or through the interſtices of a perforated pattern, as in the manufacturing of ſome kinds of paper-hangings, he uſes a cylinder entirely covered with hair or briſtles in the manner of a bruſh.

3*dly*, He performs all his impreſſions, even in letter-preſs printing, by the action of a cylinder or cylindrical ſurface. The conſtruction of this machine, and the manner of uſing it, will be intelligible to every reader, who ſhall attentively conſider Plate XL; where fig. 1. repreſents a printing-preſs, more eſpecially applicable to the printing of books. A and E are two cylinders, running or turning in a ſtrong frame of wood, or metal, or both. The cylinder A is faced with woollen cloth, and is capable of being preſſed with more or leſs force upon HI, by means of the lever M. HI is a long table, which is capable of moving endwiſe, backwards and forwards, upon the rollers E and K. The roller A acts upon this table by means of a cog-wheel, or by ſtraps, ſo as to draw it backwards and forwards by the motion of its handle L. The table is kept in the ſame line by grooves on its ſides, which contain the cylinder A. D is a chaſe, containing letter ſet up and impoſed. B is a box, containing a colouring-roller, with its diſtributing-rollers CC; it is ſupported by the arm N. O is a cylinder faced with leather, and lying acroſs an ink-block; this cylinder is fixed by the middle to a bended lever moveable on the joint Q.

The action. When D, or the letter, is drawn beneath the cylinder B, it receives ink; and when it has paſſed into the poſition R, a workman places or turns down a tympan with paper upon it (this tympan differs in no reſpect from the uſual one, except that its hinge opens ſidewiſe); it then proceeds to paſs under the cylinder A, which preſſes it ſucceſſively through its whole ſurface. On the other ſide, at S, the workman takes off the paper, and leaves the tympan up. This motion cauſes the cylinder B to revolve continually, and conſequently renders its inked ſurface very uniform, by the action of its diſtributing-rollers CC; and, when the table has paſſed to its extreme diſtance in the direction now ſpoken of, the arm G touches the lever P, and raiſes the cylinder O off the ink block, by which means it dabs againſt one of the diſtributing-rollers, and gives it a ſmall quantity of ink. The returning motion of the table carries the letter again under the roller B, which again inks it, and the proceſs of printing another ſheet goes on as before.

Fig. 2. is another printing-preſs. In this, B is the inking-roller; A is a cylinder, having the letter impoſed upon its ſurface; and E is a cylinder, having its uniform ſurface covered with woollen cloth: theſe three cylinders are connected, either by cogs or ſtraps at the edges of each. The machine is uniformly turned in one direction by the handle L. The workman applies a ſheet of paper to the ſurface of E, where it is retained, either by points in the uſual manner, or by the apparatus to be deſcribed in treating of fig. 4. The paper paſſes between E and A, and receives an impreſſion; after which the workman takes it off, and applies another ſheet; and in the mean time the letter on the ſurface of A paſſes round againſt the ſurface of B, and receives ink during the rotation of B. The diſtributing-rollers CC do their office as in the machine fig. 1.; and once in every revolution the tail F, affixed to B, raiſes the inking-piece G, ſo as to cauſe it to touch one of the diſtributing-rollers, and ſupply it with ink. In this way therefore the repeated printing of ſheet after ſheet goes on.

Fig. 3. is a printing-preſs, more particularly adapted to print cottons, ſilks, paper-hangings, or other articles which run of a conſiderable length. A is a cylinder covered with woollen cloth, or other ſoft ſubſtance. The web or piece of cotton, or other goods, is paſſed round this cylinder, from the carrying-roller F to the receiving-rollers GH; which are connected by a piece of linen, woollen, or hair-cloth, in the manner of a jack-towel ſewed round them; the rotation of this towel carries away the printed ſtuff or goods, and depoſits them at I. KL is a moveable box, containing three rollers, which move againſt each other in rotation. The loweſt roller C revolves in a maſs of colour, contained in a trough or veſſel in the bottom part of the box KL; the ſurface of this colour is repreſented by the line MN. The next roller B is ſtuffed and covered as deſcribed in ſection 2. The preſſure of B againſt C prevents the cylinder B from receiving too much colour. D is a cut or carved cylinder, which receives colour, during the rotation, from the roller B, and impreſſes it upon the web as it paſſes round the cylinder A; in this way the conſtant and effectual action of the machine is ſufficiently obvious. It muſt be obſerved, that the cylinders ADB and G are connected together by cog-wheels, ſtraps, or other well-known equivalent contrivances; ſo that the handle P drives the whole, without their neceſſarily depending on any adheſion or friction at their ſurfaces. The preſſure of B againſt D is governed by an adjuſtment of the axis of D, whoſe ſockets are capable of a ſmall motion; and the preſſure of D againſt A is governed by the poſition of the whole box KL. When it is required to print more than one colour upon a piece, Mr Nicholſon cauſes it to paſs two or more times through the machine; or, in thoſe caſes where the materials are liable to change their dimenſions, he applies, at one and the ſame time, two or more ſuch boxes as KL, with their reſpective cylinders, ſo that the pattern cylinder of each may make its impreſſion upon the web or material to be printed on.

Fig. 4. is a printing-preſs, chiefly of uſe for books and papers. 1, 2, 3, 4, repreſents a long table, with ledges on each ſide; ſo that the two cylinders A and B can run backwards and forwards without any ſide ſhake. In one of theſe ledges is placed a ſtrip or plate of metal cut into teeth, which lock into correſpondent teeth in each cylinder; by which means the two cylinders roll along, without the poſſibility of changing the relative poſitions of their ſurfaces at any determinate part of the table. This may alſo be effected by ſtraps, and may indeed be accompliſhed, with tolerable accuracy, by the mere rolling of the cylinders on the ſmooth or flat ledges without any proviſion A is the printing-cylinder, covered with woollen cloth, and B is the inking-cylinder, with its diſtributing rollers. The table

may be divided into four compartments, marked with a thicker bounding line than the reſt, and numbered 1, 2, 3, 4. At 1 is placed a ſheet of paper; at 2 is the form or chaſe, containing letter ſet and impoſed; at 3 is an apparatus for receiving the printed ſheet; and 4 is employed in no other uſe than as a place of ſtanding for the carriage E, after it has paſſed through one operation, and when it takes ink at F. Its action is as follows: the carriage is thruſt forward by the workman, and as the roller A paſſes over the ſpace numbered 1, it takes up the ſheet of paper previouſly laid there, while the roller B runs over the form and inks the letter. The ſheet of paper, being wrapped round the cylinder A, is preſſed againſt the form as that cylinder proceeds, and conſequently it receives an impreſſion. When A arrives at the ſpace numbered 3, it lets go the ſheet of paper, while the prominent part of the carriage G ſtrikes the lever P, and raiſes the inking-piece, which applies itſelf againſt one of the diſtributing-rollers. In this manner therefore the cylinder A returns empty, and the cylinder B inked, and in the mean time the workman places another ſheet of paper ready in the ſpace numbered 1. Thus it is that the operation proceeds in the printing of one ſheet after another.

The preceding deſcription is not incumbered with an account of the apparatus by which the paper is taken up and laid down. This may be done in ſeveral ways: Fig. 9. and 10. repreſent one of the methods. DE is a lever, moving on the centre pin C, and having its end D preſſed upwards by the action of the ſpring G. The ſhoulder which contains the pin C is fixed in another piece F, which is inſerted in a groove in the ſurface of the cylinder A (fig. 4.), ſo that it is capable of moving in and out, in a direction parallel to the axis of that cylinder. As that cylinder proceeds, it meets a pin in the table; which (letter P, fig. 9.) acting on the inclined plane at the other end of the lever, throws the whole inwards, in the poſition repreſented in fig. 10.; in which caſe the extremity D ſhoots inwards, and applies itſelf againſt the ſide of the cylinder.

In fig. 11. is a repreſentation of part of the table; the dotted ſquare repreſents a ſheet of paper, and the four ſmall ſhaded ſquares denote holes in the board, with pins ſtanding beſide them. When the lever DE (fig. 10.) ſhoots forward, it is ſituated in one of theſe holes, and advances under the edge of the paper, which conſequently it preſſes and retains againſt the cylinder with its extremity D. Nothing more remains to be ſaid reſpecting the taking up, but that the cylinder is provided with two pair of theſe claſps or levers, which are ſo fixed as to correſpond with the four holes repreſented in fig. 11. It will be eaſy to underſtand how the paper is depoſited in the compartment n° 3. (fig. 4.) A pin P (fig. 10.) riſing out of the platform or table, acts againſt a pin E, projecting ſidewiſe out of the lever, and muſt of courſe draw the ſlider and its lever to the original poſition; the paper conſequently will be let go, and its diſengagement is rendered certain by an apparatus fixed in the compartment numbered 3. (fig. 4.) of exactly the ſame kind as that upon the cylinder, and which, by the action of a pin duly placed in the ſurface of the cylinder A, takes the paper from the cylinder in preciſely the ſame manner as that cylinder originally took it up in the compartment numbered 1 (fig. 4.)

Figs. 5, 6, and 7, repreſent a ſimpler apparatus for accompliſhing the ſame purpoſe. If A *a* B *b* (fig. 7.) be ſuppoſed to repreſent a thick plate of metal of a circular form, with two pins, A and B, proceeding ſidewiſe or perpendicularly out of its plane, and diametrically oppoſite to each other, and G another pin proceeding in the direction of that plane, then it is obvious that any force applied to the pin A, ſo as to preſs it into the poſition *a* (by turning the plate on its axis or centre X), will at the ſame time cauſe the pin G to acquire the poſition *g*; and, on the other hand, when B is at *b*, or the dotted repreſentation of the ſide-pin, if any preſſure be applied to reſtore its original poſition at B, the pin *g* will return back to G. Now the figures 5 and 6 exhibit an apparatus of this kind, applied to the cylinder A; and that cylinder, by rolling over the pins P and *p*, properly fixed in the table to re-act upon the apparatus, will cauſe its prominent part G either to apply to the cylinder and claſp the paper, or to riſe up and let it go. The compartment numbered 3 (fig. 4.) muſt of courſe have an apparatus of the ſame kind to be acted upon by pins from A, in order that it may take the paper from that cylinder.

There is one other circumſtance belonging to this machine which remains to be explained. When the carriage E (fig. 4.) goes out in the direction of the numbers 1, 2, 3, 4, both rollers, A and B, preſs the form of letter in their paſſage; but in their return back again the roller A, having no paper upon it, would itſelf become ſoiled, by taking a faint impreſſion from the letter, if it were not prevented from touching it: the manner of effecting this may be underſtood from fig. 12. The apparatus there repreſented is fixed upon the outſide of the carriage E, near the lower corner, in the vicinity of the roller A; the whole of this projects ſidewiſe beyond the ledge of the table, except the ſmall truck or wheel B. The irregularly-triangular piece, which is ſhaded by the ſtroke of the pen, carries this wheel, and alſo a catch moveable on the axis or pin E. The whole piece is moveable on the pin A, which connects it to the carriage. CD, or the part which is ſhaded by dotting, is a detent, which ſerves to hold the piece down in a certain poſition. It may be obſerved, that both the detent and the triangular piece are furniſhed each with a claw, which holds in one direction, but trips or yields in the other, like the jacks of a harpſichord, or reſembling certain pieces uſed in clock and watch making, as is clearly repreſented in the figure. Theſe claws overhang the ſide of the table, and their effect is as follows: There is a pin C (fig. 4.) between the compartments of the table numbered 2 and 3, but which is marked F in fig. 12. where GH repreſents the table. In the outward run of the carriage theſe claws ſtrike that pin, but with no other effect than that they yield for an inſtant, and as inſtantly reſume their original poſition by the action of their reſpective ſlender back-ſprings. When the carriage returns, the claw of the detent indeed ſtrikes the pin, but with as little effect as before, becauſe its derangement is inſtantly removed by the action of the back ſpring of the detent itſelf; but, when the claw of the triangular piece takes the pin, the whole piece is made to revolve on its axis or pin A, the wheel B is forced down, ſo as to lift that end of the carriage, and the detent, catching on the piece at C, prevents the former poſition from being recovered. The conſequence of this is, that the carriage runs upon the truck B (and its correſpondent truck on the oppoſite ſide) inſtead of the cylinder A, which is too much raiſed to take the letter, and ſoil itſelf; but as ſoon as the end of the carriage has paſſed clear of the letter, another pin R (fig. 4.) takes the claw of the detent, and draws it off the triangular piece; at which inſtant the cylinder A ſubſides to its uſual place, and performs its functions as before. This laſt pin R does not affect the claw of the triangular piece, becauſe it is placed too low; and the claw of the detent is made the longeſt, on purpoſe that it may ſtrike this pin.

Fig. 8. repreſents an inſtrument for printing floor-cloths, paper-hangings, and the like, with ſtiff paint and a bruſh. D is a copper or metallic cylinder fixed in a frame A, like a garden roller; its carved part is thin, and is cut through in various places, according to the deſired pattern. A ſtrong axis paſſes through the cylinder, and its extremities are firmly attached to the frame A. To this axis is fixed a veſſel or box of the ſame kind, and anſwering the ſame purpoſe as the box KL in fig. 3. It carries a cylinder P, which revolves in the colour; another cylinder E, which revolves in contact with P; and a third cylinder B, whoſe exterior ſurface is covered with hair, after the manner of a bruſh, and revolves in contact with E. This cylinder B is adjuſted by its axis, in ſuch a manner that its bruſh-part ſweeps in the perforated parts of the metallic cylinder D. The circle C repreſents a cog-wheel, fixed concentric to the cylinder D, and revolving with it; this wheel takes another wheel concentric to, and fixed to, B; hence the action is as follows: When the metallic cylinder is wheeled or rolled along any ſurface, its cog-wheel C drives the bruſh B in the contrary direction; and this bruſh-cylinder, being connected by cogs or otherwiſe with E and P, cauſes thoſe alſo to revolve and ſupply it with colour. As the ſucceſſive openings of the cylinder D, therefore, come in contact with the ground, the ſeveral parts of the bruſh will traverſe the uncovered part of that ground, and paint the pattern upon it. The wheel G, being kept lightly on the ground, ſerves to determine the line of contact, that it ſhall be the part oppoſite to B, and no other.

PRINTS (ſee *Encycl.*) are valuable on many accounts; but they are liable to be ſoiled by ſmoke, vapour, and the excrements of inſects. Different methods have, of courſe, been practiſed to clean them. Some have propoſed ſimple waſhing with clear water, or a ley made of the aſhes of reeds, and then expoſing the prints to the dew. Others have cleaned prints with *aqua fortis* (ſulphuric acid); but both theſe methods are attended with a degree of riſk at leſt equal to their advantages. The following method of cleaning prints is recommended in the ſecond volume of Nicholſon's Journal of Natural Philoſophy, &c. as at once ſafe and efficacious:

“ Provide a certain quantity of the common muriatic acid, for example three ounces, in a glaſs bottle, with a ground ſtopper, of ſuch a capacity that it may be only half full. Half an ounce of minium muſt then be added; immediately after which the ſtopper is to be put in, and the bottle ſet in a cold and dark place. The heat, which ſoon becomes perceptible, ſhews the beginning of the new combination. The minium abandons the greateſt part of its oxygen with which the fluid remains impregnated, at the ſame time that it acquires a fine golden yellow, and emits the deteſtable ſmell of oxygenated muriatic acid. It contains a ſmall portion of muriat of lead; but this is not at all noxious in the ſubſequent proceſs. It is alſo neceſſary to be obſerved, that the bottle muſt be ſtrong, and the ſtopper not too firmly fixed, otherwiſe the active elaſtic vapour might burſt it. The method of uſing this prepared acid is as follows:

“ Provide a ſufficiently large plate of glaſs, upon which one or more prints may be ſeparately ſpread out. Near the edges let there be raiſed a border of ſoft white wax half an inch high, adhering well to the glaſs and flat at top. In this kind of trough the print is to be placed in a bath of freſh urine, or water containing a ſmall quantity of ox-gall, and kept in this ſituation for three or four hours. The fluid is then to be decanted off, and pure warm water poured on, which muſt be changed every three or four hours until it paſſes limpid and clear. The impurities are ſometimes of a reſinous nature, and reſiſt the action of pure water. When this is the caſe, the waſhed print muſt be left to dry, and alcohol is then to be poured on and left for a time. After the print is thus cleaned, and all the moiſture drained off, the muriatic acid prepared with minium is to be poured on in ſufficient quantity to cover the print; immediately after which another plate of glaſs is to be laid in contact with the rim of wax, in order to prevent the inconvenient exhalation of the oxygenated acid. In this ſituation the yelloweſt print will be ſeen to recover its original whiteneſs in a very ſhort time. One or two hours are ſufficient to produce the deſired effect; but the print will receive no injury if it be left in the acid for a whole night. Nothing more is neceſſary to complete the work, than to decant off the remaining acid, and waſh away every trace of acidity by repeated affuſions of pure water. The print being then left to dry (in the ſun if poſſible) will be found white, clear, firm, and in no reſpect damaged either in the texture of the paper or the tone and appearance of the impreſſion.”

The judicious editor of the Journal ſubjoins the following note, to which collectors of prints will do well to pay attention: “ As I have not repeated this proceſs, I cannot eſtimate how far the preſence of the lead may weaken the corroſive action of the acid on the paper; but I ſhould be diſpoſed to recommend a previous dilution of the acid with water. Whoever uſes this proceſs will of courſe make himſelf maſter of the proportion of water required to dilute the acid, by making his firſt trials with an old print of no value.”

PRISM, in geometry, is a body or a ſolid, whoſe two ends are any plane figures which are parallel, equal, and ſimilar; and its ſides, connecting thoſe ends, are parallelograms. The definition of this figure in the *Encyclopædia* we muſt, in candour, acknowledge to be unaccountably indiſtinct, if not unintelligible.

PRISMOID, is a ſolid or body, ſomewhat reſembling a priſm, but that its ends are any diſſimilar parallel plane figures of the ſame number of ſides; the upright ſides being trapezoids.—If the ends of the priſmoid be bounded by diſſimilar curves, it is ſometimes called a *cylindroid*.

PRISON is ſaid, in the *Encyclopædia*, to be only a place of ſafe cuſtody, not a place of puniſhment. Such was,

was, no doubt, the original intention of Engliſh priſons; but now temporary confinement is, in England as well as elſewhere, inflicted as a puniſhment for certain crimes. Perhaps it would be expedient to ſubſtitute this puniſhment more frequently than is yet done in Great Britain, for tranſportation and death; proportioning the length of the confinement, as well as its cloſeneſs, to the heinouſneſs of the crime. In no country, we believe, is this more accurately done, or to better purpoſe, than in Pennſylvania; and ſurely in no country has impriſonment been more abuſed than in Venice under the old government.

By the laws of Pennſylvania, puniſhment by impriſonment is impoſed, not only as an expiation of paſt offences, and an example to the guilty part of ſociety, but alſo for another important purpoſe—the reformation of the criminal's morals. The regulations of the gaol are calculated to promote this effect as ſoon as poſſible; ſo that the building deſerves the name of a *penitentiary houſe* more than that of a *gaol* (ſee PHILADELPHIA, *Encycl.*) As ſoon as a criminal is committed to the priſon, he is made to waſh; his hair is ſhorn; and, if not decently clothed, he is furniſhed with clean apparel. He is then thrown into a ſolitary cell, about nine feet long and four wide, where he remains debarred from the ſight of every living being except his gaoler, whoſe duty is to attend to his bare neceſſities, but who is forbidden on any account to hold converſation with him. If a priſoner be at all refractory, or if the offence for which he is committed be of a very atrocious nature, he is then confined to a cell ſecluded even from the light of heaven. The treatment of each priſoner, during his confinement, is varied according to his crime and his ſubſequent repentance. Solitary confinement in a dark cell is looked upon as the ſevereſt uſage; next, ſolitary confinement in a cell with the admiſſion of light; next, ſolitary confinement in a cell, where the priſoner is allowed to do ſome ſort of work; and, laſtly, labour in company with others. The longeſt period of confinement is for a rape, which is not to be leſs than ten years, nor more than twenty-one; for high treaſon, it is not to exceed twelve, nor fall ſhort of ſix years.

The priſoners are obliged to bathe twice every week, proper conveniences for that purpoſe being provided within the walls of the priſon, and alſo to change their linen, with which they are regularly ſupplied. Thoſe in ſolitary confinement are kept upon bread and water; but thoſe who labour are allowed broth, porridge, puddings, and the like. Meat is diſpenſed only in ſmall quantities, twice in the week; and on no pretence whatever is any other beverage than water ſuffered to be brought into the priſon. Thoſe who labour are employed in the trade to which they have been accuſtomed; and for thoſe acquainted with no particular trade, ſome kind of work is deviſed which they can perform. One room is ſet apart for ſhoemakers, another for tailors, a third for carpenters, and ſo on. In the yards are ſtone cutters, ſmiths, nailers, &c. In a word, this priſon has all the advantages of the raſping houſe of Amſterdam, without any of its enormous defects. See CORRECTION-*Houſe* in this *Suppl.*

The priſon of Venice is of a very different deſcription, and is worthy of notice here only as a curioſity in the annals of tyranny, which has, we hope, paſſed away with the government which contrived it. Dr Moſeley, in conſequence of his being an Engliſh phyſician (a character then highly reſpected in Venice), was permitted, on the 16th of September 1787, to viſit the common priſon, but was abſolutely refuſed admittance into the *Sotto Piombi*, where the ſtate priſoners were kept. As the Doctor believes that no foreigner beſides himſelf ever witneſſed the ſcenes, even in the common priſon, which he relates, we ſhall give his relation in his own words.

"I was conducted (ſays he) through the priſon by one of its inferior dependants. We had a torch with us. We crept along narrow paſſages as dark as pitch. In ſome of them two people could ſcarcely paſs each other. The cells are made of maſſy marble; the architecture of the celebrated Sanſovini.

"The cells are not only dark, and black as ink, but being ſurrounded and confined with huge walls, the ſmalleſt breath of air can ſcarcely find circulation in them. They are about nine feet ſquare on the floor, arched at the top, and between ſix and ſeven feet high in the higheſt part. There is to each cell a round hole of eight inches diameter, through which the priſoner's daily allowance of twelve ounces of bread and a pot of water is delivered. There is a ſmall iron door to the cell. The furniture of the cell is a little ſtraw and a ſmall tub; nothing elſe. The ſtraw is renewed and the tub emptied through the iron door occaſionally.

"The diet is ingeniouſly contrived for the perduration of puniſhment. Animal food, or a cordial nutritious regimen, in ſuch a ſituation, would bring on diſeaſe, and defeat the end of this Venetian juſtice. Neither can the ſoul, if ſo inclined, ſteal away, wrapt up in ſlumbering deluſion, or ſink to reſt; from the admonition of her ſad exiſtence, by the gaoler's daily return.

"I ſaw one man who had been in a cell thirty years; two who had been twelve years; and ſeveral who had been eight and nine years in their reſpective cells.

"By my taper's light I could diſcover the priſoners horrid countenances. They were all naked The man who had been there thirty years, in face and body was covered with long hair. He had loſt the arrangement of words and order of language. When I ſpoke to him, he made an unintelligible noiſe, and expreſſed fear and ſurpriſe; and, like ſome wild animals in deſarts, which have ſuffered by the treachery of the human race, or have an inſtinctive abhorrence of it, he would have fled like lightning from me if he could.

"One whoſe faculties were not ſo obliterated; who ſtill recollected the difference between day and night; whoſe eyes and ears, though long cloſed with a ſilent blank, ſtill languiſhed to perform their natural functions—implored, in the moſt piercing manner, that I would prevail on the gaoler to murder him, or to give him ſome inſtrument to deſtroy himſelf. I told him I had no power to ſerve him in this requeſt. He then entreated I would uſe my endeavours with the inquiſitors to get him hanged, or drowned in the Canal' Orfano. But even in this I could not ſerve him: death was a favour I had not intereſt enough to procure for him.

"This kindneſs of death, however, was, during my ſtay in Venice, granted to one man, who had been ‘ from the cheerful ways of man cut off’ thirteen years.

“ Before he left his dungeon I had ſome converſation with him; this was ſix days previous to his execution. His tranſport at the proſpect of death was ſurpriſing. He longed for the happy moment. No ſaint ever exhibited more fervour in anticipating the joys of a future ſtate, than this man did at the thoughts of being releaſed from life, during the four days mockery of his trial.

“ It is in the Canal' Orfano where veſſels from Turkey and the Levant perform quarantine. This place is the watery grave of many who have committed political or perſonal offences againſt the ſtate or ſenate, and of many who have committed no offences at all. They are carried out of the city in the middle of the night, tied up in a ſack with a large ſtone faſtened to it, and thrown into the water. Fiſhermen are prohibited, on forfeiture of their lives, againſt fiſhing in this diſtrict. The pretence is the plague. This is the ſecret hiſtory of people being loſt in Venice.

“ The government, with age, grew feeble; was afraid of the diſcuſſion of legal proceſs and of public executions; and navigated this rotten Bucentaur of the Adriatic by ſpies, priſons, aſſaſſination, and the Canal' Orfano.”

This is indeed a frightful narrative, and, we doubt not, true as well as frightful; but when, from the ſtate of the Venetian priſons, the author inſinuates, that Howard was not actuated by genuine benevolence, and infers, or wiſhes his reader to infer, that the propoſal of that celebrated philanthropiſt for ſubſtituting ſolitary confinement, in many caſes, for capital puniſhment, muſt have reſulted from his not taking into conſideration the *mind* of the criminal—the inſinuation, to ſay the leaſt of it, is ungenerous, and the concluſion is at war with the premiſes. That there was ſomething romantic and ſuperfluous in Howard's wanderings, we readily admit; but it ſeems impoſſible to doubt of the reality of his benevolence; and though the horrid priſon of Venice, into which, as the Doctor aſſures us, Mr Howard never entered, was calculated to injure the body without improving the mind of the criminal, it does not follow but that ſolitary confinement, under ſuch regulations as at Philadelphia, is the beſt means that have yet been thought of for obtaining the object neareſt Howard's heart, the reformation of the morals of the criminal.

PROCYON, in aſtronomy, a fixed ſtar of the ſecond magnitude, in Canis Minor, or the Little Dog.

PROSTHAPHERESIS, in aſtronomy, the difference between the true and mean motion, or between the true and mean place, of a planet, or between the true and equated anomaly; called alſo *equation of the orbit*, or *equation of the centre*, or ſimply the *equation*; and it is equal to the angle formed at the planet, and ſubtended by the eccentricity of its orbit.

PROTRACTING, or PROTRACTION, in ſurveying, the act of plotting or laying down the dimenſions taken in the field, by means of a protractor, &c. Protracting makes one part of ſurveying.

PROTRACTING-Pin, a fine pointed pin or needle, fitted into a handle, uſed to prick off degrees and minutes from the limb of the protractor.

PRUNING. Under this title (*Encycl.*) it is obſerved, that when large branches of trees bearing ſtone-fruit are taken off, the trees are ſubject to gum and decay. For this a remedy has been invented by *Thomas Skip Dyot Bucknall*, Eſq; of Conduit-ſtreet, which, notwithſtanding many objections made to it at firſt, experience has proved to be ſucceſsful, and for the diſcovery of which the Society for the Encouragement of Arts, &c. voted the ſilver medal to the diſcoverer. It is as follows:

Cut every branch which ſhould be taken away cloſe to the place of its ſeparation from the trunk; ſmooth it well with a knife; and then with a painter's bruſh ſmear the wound over with what Mr Bucknall calls *medicated tar*. This medicated tar is compoſed of one quarter of an ounce of corroſive ſublimate, reduced to fine powder by beating with a wooden hammer, and then put into a three-pint earthen pipkin, with about a glaſs full of gin or other ſpirit, ſtirred well together, and the ſublimate thus diſſolved. The pipkin is then filled by degrees with vegetable or common tar, and conſtantly ſtirred, till the mixture be blended together as intimately as poſſible; and this quantity will at any time be ſufficient for two hundred trees. To prevent danger, let the corroſive ſublimate be mixed with the tar as quickly as poſſible after it is purchaſed; for, being of a very poiſonous nature to all animals, it ſhould not be ſuffered to lie about a houſe, for fear of miſchief to ſome part of the family.

By the application of this compoſition, Mr Bucknall can, without the ſmalleſt danger, uſe the pruning hook on all kinds of trees much more freely than we have recommended its uſe in the article referred to. “ I give no attention (ſays he) to fruit-branches, and wood-branches; but beg, once for all, that no branch ſhall ever be ſhortened, unleſs for the figure of the tree, and then conſtantly taken off cloſe to the ſeparation, by which means the wound ſoon heals. The more the range of the branches ſhoots circularly, a little inclining upwards, the more equally will the ſap be diſtributed, and the better will the tree bear; for, from that circumſtance, the ſap is more evenly impelled to every part. Do not let the ranges of branches be too near each other; for remember all the fruit and the leaves ſhould have their full ſhare of the ſun; and where it ſuits let the middle of the tree be free from wood, ſo that no branch ſhall ever croſs another, but all the extreme ends point outwards.”

PULO, the name of ſeveral iſlands of Aſia, in the Indian Ocean; the principal of which alone, according to Dr Brooke's, is inhabited. This is the iſland

PULO-Condore, which, being viſited by Lord Macartney as he ſailed to China, is thus deſcribed by Sir George Staunton. “ It has the advantage of convenient anchoring places in either monſoon. The ſquadron accordingly ſtopped on the 17th of May, in a ſpacious bay on the eaſtern ſide of the iſland; and came to anchor at the entrance of its ſouthern extremity, as the water ſhoaled there to five fathoms and a half, occaſioned by a bank which ſtretches acroſs two-thirds of the entrance. It was found afterwards, that beyond the bank there is a ſafe paſſage to the inner part of the bay, the north of which is ſheltered by a ſmall iſland lying to the eaſtward. The whole of the bay is formed by four ſmall iſlands, which approach ſo nearly to each other, as to appear, from ſeveral points, to join.

Pulo.

Pulo, Punctuation.

They all ſeem to be the rude fragments of primitive mountains, ſeparated from the great continent in the lapſe of time. The principal iſland is eleven or twelve miles in length, and about three in breadth. It is in the form of a creſcent, and conſiſts of a ridge of peaked hills. Its latitude, as calculated from a meridional obſervation, is 8° 40′ north from the equator; and its longitude, according to a good chronometer, is 105° 55′ eaſt from Greenwich.

"The Engliſh had a ſettlement on Condore until the beginning of the preſent century, when ſome Malay ſoldiers in their pay, in reſentment for ſome unjuſtifiable treatment, murdered their ſuperiors, with the exception of a very few who eſcaped off the iſland, where no Europeans have ſince reſided. At the bottom of the bay was a village ſituated cloſe to a fine ſandy beach, with a long range of cocoa-nut trees before it, and it was defended from the north-eaſt ſea by a reef of coral rocks, within which was good anchorage for ſmall veſſels, and an eaſy landing for boats. A party went on ſhore from Lord Macartney's ſquadron, with the precaution, however, of being armed, as large canoes were eſpied within the reef, which might have been Malay pirates. Several of the inhabitants came to the beach, and with the appearance of much urbanity of manners welcomed them on ſhore, and conducted them to the houſe of their chief. It was a neat bamboo cabin, larger than the reſt. The floor was elevated a few feet above the ground, and ſtrewed with mats, on which were aſſembled as many men as the place could hold. It was apparently on the occaſion of ſome feſtival, or pleaſurable meeting. There was in one of the apartments an altar decorated with images, and the partitions hung with figures of monſtrous deities; but the countenances and deportment of the people conveyed no idea of religious awe, and no perſon was ſeen in the poſture of prayer or adoration. A few ſpears ſtood againſt the wall with their points downwards, together with ſome matchlocks and a ſwivel gun. The dreſs of thoſe people was compoſed chiefly of blue cotton worn looſely about them; and their flat faces and little eyes denoted a Chineſe origin or relation. Several long ſlips of paper, hanging from the ceiling, were covered with columns of Chineſe writing. One of the miſſionaries, who was of the party, could not, however, in any degree, underſtand their converſation; but when the words were written, they inſtantly became intelligible to him. Though their colloquial language was altogether different from what is ſpoken in China, yet the characters were all Chineſe; and the fact was clearly aſcertained on this occaſion, that thoſe characters have an equal advantage with Arabic numbers, of which the figures convey the ſame meaning wherever known; whereas the letters of other languages denote not things, but elementary ſounds, which combined variouſly together, form words, or more complicated ſounds, conveying different ideas in different languages, though the form of their alphabet be the ſame.

"The inhabitants of Pulo Condore were, it ſeems, Cochin-Chineſe, with their deſcendants, who fled from their own country, in conſequence of their attachment to one of its ſovereigns, dethroned by ſeveral of his own ſubjects. It was propoſed to purchaſe proviſions here; and the people promiſed to have the ſpecified quantity ready, if poſſible, the next day, when it was intended, if the weather ſhould be favourable, to land the invalids. The next morning was fair in the beginning; and a party of pleaſure was made from the Hindoſtan to a ſmall iſland cloſe to Pulo Condore. They were ſcarcely arrived upon it when the weather began to lower; and the boat ſet off on its return, in order to reach the ſhip before the impending ſtorm ſhould begin.

"With difficulty it reached the ſhip; and as ſoon as the weather became fair, meſſengers were diſpatched on ſhore to receive and pay for the proviſions promiſed. When they arrived at the village, they were aſtoniſhed to find it abandoned. The houſes were left open, and none of the effects, except ſome arms, that had on the firſt viſit been perceived within them, or even of the poultry feeding about the doors, were taken away. In the principal cabin a paper was found, in the Chineſe language, of which the literal tranſlation purported, as nearly as it could be made, that 'the people of the iſland were few in number, and very poor, yet honeſt, and incapable of doing miſchief; but felt much terror at the arrival of ſuch great ſhips and powerful perſons, eſpecially as not being able to ſatisfy their wants in regard to the quantity of cattle and other proviſions, of which the poor inhabitants of Pulo Condore had ſcarcely any to ſupply, and conſequently could not give the expected ſatisfaction. They therefore, through dread and apprehenſion, reſolved to fly to preſerve their lives. That they ſupplicate the great people to have pity on them; that they left all they had behind them, and only requeſted that their cabins might not be burnt; and conclude by proſtrating themſelves to the great people a hundred times.'

"The writers of this letter had probably received ill treatment from other ſtrangers. It was determined that they ſhould not continue to think ill of all who came to viſit them. On their return they were perhaps as much ſurpriſed to find their houſes ſtill entire, as their viſitors had been who found they were deſerted. Nothing was diſturbed; and a ſmall preſent, likely to be acceptable to the chief, was left for him in the principal dwelling, with a Chineſe letter, ſignifying that 'the ſhips and people were Engliſh, who called merely for refreſhment, and on fair terms of purchaſe, without any ill intention; being a civilized nation, endowed with principles of humanity, which did not allow them to plunder or injure others who happened to be weaker or fewer than themſelves."

Pulo Lingen, another of this cluſter, is likewiſe a conſiderable iſland, remarkable for a mountain in its centre, terminating in a fork like Parnaſſus; but to which the unpoetical ſeamen beſtow the name of *aſſes ears*. Every day preſented new iſlands to the view, diſplaying a vaſt variety in form, ſize, and colour. Some iſolated, and ſome collected in cluſters. Many were clothed with verdure; ſome had tall trees growing on them; others were mere rocks, the reſort of innumerable birds, and whitened with their dung.

PUNCTUATION, in grammar, is an art with which we have ſaid, in the *Encyclopædia*, that the ancients were entirely unacquainted. Candour obliges us to confeſs that this was ſaid raſhly. A learned writer, in the Monthly Magazine for September 1798, who ſubſcribes J. WARBURTON, has proved, we think completely, that the art is not wholly modern; and we ſhall lay his proofs, in his own words, before our readers.

" Some ſpecies of pauſes and diviſions of ſentences in ſpeaking and writing muſt have been coeval with the knowledge of communicating ideas by ſound or by ſymbols. Suidas * ſays, that the *period* and the *colon* were diſcovered and explained by Thraſymacus, about 380 years before the Chriſtian æra. Cicero † ſays, that Thraſymacus was the firſt who ſtudied oratorical numbers, which entirely conſiſted in the artificial ſtructure of periods and colons. It appears from a paſſage in Ariſtotle ‡, that punctuation was known in his time. The learned Dr Edward Bernard § refers the knowledge of pointing to the time of that philoſopher, and ſays, that it conſiſted in the different poſitions of one ſingle point. At the bottom of a letter, thus, (A.) it was equivalent to a comma; in the middle (A·) it was equal to a colon; at the top (A˙) it denoted a period, or the concluſion of a ſentence.

" This mode was eaſily practiſed in Greek manuſcripts, while they were written in capitals. But when the ſmall letters were adopted, that is, about the 9th century, this diſtinction could not be obſerved; a change was therefore made in the ſcheme of punctuation. *Unciales literas hodierno uſu dicimus eas in vetuſtis codicibus, quæ priſcam formam ſervant, ac ſolutæ ſunt; nec mutuò colligantur. Hujus modi literæ unciales obſervantur in libris omnibus ad nonum uſque ſæculum*—Montf. Palæog. Recens. p. xii.

" According to Cicero, the ancient Romans, as well as the Greeks, made uſe of points. He mentions them under the appellation of *librariorum notæ*; and in ſeveral parts of his works he ſpeaks of '*interpunctæ clauſulæ in orationibus*,' of '*clauſulæ atque interpuncta verborum*,' of '*interpunctiones verborum*,' &c *.

" Seneca, who died A. D. 65, expreſsly ſays, that Latin writers, in his time, had been uſed to punctuation. '*Nos* †, *cum ſcribimus interpungere conſuevimus*.' Muretus and Lipſius imagined that theſe words alluded to the inſertion of a point after each word: but they certainly were miſtaken; for they muſt neceſſarily refer to marks of punctuation in the diviſion of ſentences, becauſe in the paſſage in which theſe words occur, Seneca is ſpeaking of one Q. Haterius, who made no pauſes in his orations.

" According to Suetonius, in his *Illuſt. Gram.* Valerius Probus procured copies of many old books, and employed himſelf in correcting, pointing, and illuſtrating them; devoting his time to this and no other part of grammar. *Multa exemplaria contracta emendare, ac diſtinguere et adnotare curavit; ſoli huic, nec ulli præterea, grammatices parti deditus.*

" It appears from hence, that in the time of Probus, or about the year 68, Latin manuſcripts had not been uſually pointed, and that grammarians made it their buſineſs to ſupply this deficiency.

" Quintilian, who wrote his celebrated treatiſe on Oratory, about the year 88, ſpeaks of commas, colons, and periods; but it muſt be obſerved, that by theſe terms he means clauſes, members, and complete ſentences, and not the marks of punctuation ‡.

" Ælius Donatus § publiſhed a treatiſe on Grammar in the 4th century, in which he explains the *diſtinctio*, the *media diſtinctio*, and the *ſubdiſtinctio*; that is, the uſe of a ſingle point in the various poſitions already mentioned.

" Jerom *, who had been the pupil of Donatus, in his Latin Verſion of the Scriptures, made uſe of certain diſtinctions or diviſions, which he calls *cola* and *commata*. It has, however, been thought probable, that theſe diviſions were not made by the addition of any points or ſtops; but were formed by writing, in one line, as many words as conſtituted a clauſe, equivalent to what we diſtinguiſh by a comma or a colon. Theſe diviſions were called στιχοι or ρηματα; and had the appearance of ſhort irregular verſes in poetry. There are ſome Greek manuſcripts ſtill extant, which are written in this manner †."

Mr Warburton ſays, that the beſt treatiſe upon punctuation that he has ſeen, was publiſhed ſome years ſince by an anonymous author, and dedicated to Sir Clifton Wintringham, Bart. With that treatiſe we are not acquainted; but we do not think that the art of punctuation can be taught by rules. The only way to acquire it is to obſerve attentively how the moſt perſpicuous writers diſpoſe of their periods, colons, ſemicolons, and commas. This will make us acquainted with the importance of each; and then every writer, who knows his own meaning, muſt be capable of pointing his own pages more correctly than any other man.

PYRAMIDOID, is ſometimes uſed for the parabolic ſpindle, or the ſolid formed by the rotation of a ſemiparabola about its baſe or greateſt ordinate. See Parabolic *Spindle*.

PYRITES. See Mineralogy in this *Suppl.*—In the third volume of Mr Nicholſon's Philoſophical Journal, we have a method of making artificial pyrites, which we ſhall give in the words of the author.

" I impregnated water (ſays he) very ſtrongly with carbonic acid, and introducing ſome iron filings, I continued the impregnation for a day or two, and afterwards allowed the water to ſtand in a well corked bottle for ſome days, till the acid had taken up as much iron as poſſible. I then poured it into an aerating apparatus; threw up the hepatic gas from ſulphuret of potaſh and ſulphuric acid; and after having agitated the water till it had got a good doſe of the gas, I poured the water into a large baſon: this was in the evening, and next morning when I looked at it I found it covered with a pretty thick film of a moſt beautiful variegated pyrites. I had ſo little of it, that the only proof I had of its being this ſubſtance was, that it was ignited on its being placed on a hot poker."

Q.

QUADRATURE, in geometry (ſee that article, and likewiſe **Fluxions**, *Encycl.*), has employed the time and ingenuity of ſome of the moſt eminent mathematicians both of ancient and of modern times. Dr Halley's method of computing the ratio of the diameter of the circle to its circumference, was conſidered by himſelf, and other learned mathematicians, as the eaſieſt the problem admits of. And although, in the courſe of a century, much eaſier methods have been diſcovered, ſtill a celebrated mathematician of our own times has expreſſed an opinion, that no other aliquot part of the circumference of a circle can be ſo eaſily computed by means of its tangent as that which was choſen by Dr Halley, viz. the arch of 30 degrees. Without taking upon him to determine whether this opinion be juſt or not, the Rev. John Hellins has ſhewn how the ſeries by which Dr Halley computed the ratio of the diameter to the circumference of the circle may be transformed into others of ſwifter convergency, and which, on account of the ſucceſſive powers of $\frac{1}{10}$ which occur in them, admit of an eaſy ſummation. We ſhall give the memoir in the author's own words.

"1. The propoſed transformation is obtained by means of different forms in which the fluents of ſome fluxions may be expreſſed; and to proceed with greater clearneſs, "I will here (ſays Mr Hellins) ſet down the fluxion in a general form, and its fluent, in the two ſeries which are uſed in the following particular inſtance, and may be applied with advantage in ſimilar caſes.

"2. The fluent of $\frac{x^{m-1}\dot{x}}{1-x^n}$ is $= \frac{x^m}{m} + \frac{x^{m+n}}{m+n} + \frac{x^{m+2n}}{m+2n} + \frac{x^{m+3n}}{m+3n}$, &c. which ſeries, being of the ſimpleſt form which the fluent ſeems to admit, was firſt diſcovered, and probably is the moſt generally uſeful. But it has alſo been found, that the fluent of the ſame fluxion may be expreſſed in ſeries of other forms, which, though leſs ſimple than that above written, yet have their particular advantages. Amongſt thoſe other forms of ſeries which the fluent admits of, that which ſuits my preſent purpoſe is $\frac{x^m}{m.\overline{1-x^n}} - \frac{nx^{m+n}}{m.\overline{m+n}.\overline{1-x^n}|^2} + \frac{n.2n.x^{m+2n}}{m.\overline{m+n}.\overline{m+2n}.\overline{1-x^n}|^3} - \frac{n.2n.3n.x^{m+3n}}{m.\overline{m+n}.\overline{m+2n}.\overline{m+3n}.\overline{1-x^n}|^4}$ + &c. which, to ſay nothing of other methods, may eaſily be inveſtigated by the rule given in p. 64. of the third edition of *Emerſon's Fluxions*; or its equality with the former ſeries may be proved by algebra.

"3. On account of the ſign — before x^n, in the laſt ſeries, it may be proper to remark, that its convergency, by a geometrical progreſſion, will not ceaſe till $\frac{x^n}{1-x^n}$ becomes $= 1$, or x becomes $= \sqrt[n]{\frac{1}{2}}$; and that when x is a ſmall quantity, and n a large number, this ſeries will converge almoſt as ſwiftly as the former. For inſtance, if x be $= \sqrt{\frac{1}{3}}$, and $n = 8$, which are the values in the following caſe, the former ſeries will converge by the quantity $x^n = \sqrt{\overline{\tfrac{1}{3}}}|^8 = \frac{1}{81}$, and this ſeries by the quantity $\frac{x^n}{1-x^n} = \frac{\frac{1}{81}}{1-\frac{1}{81}} = \frac{1}{80}$; where the difference in convergency will be but little, and the diviſions by 80 eaſier than thoſe by 81.

"4. With reſpect to the indices m and n, as they are here ſuppoſed to be affirmative whole numbers, and will be ſo in the uſe I am about to make of them, the reader need not be detained with any obſervations on the caſes in which theſe fluents will fail, when the indices have contrary ſigns.

"5. It may be proper further to remark, that by putting $\frac{x^n}{1-x^n} = z$, and calling the firſt, ſecond, third, &c. terms of the ſeries $\frac{x^m}{m.\overline{1-x^n}} - \frac{nx^{m+n}}{m.\overline{m+n}.\overline{1-x^n}|^2} + \frac{n.2nx^{m+2n}}{m.\overline{m+n}.\overline{m+2n}.\overline{1-x^n}|^3}$ + &c. A, B, C, &c. reſpectively, the ſeries will be expreſſed in the conciſe and elegant notation of Sir Iſaac Newton, viz. $\frac{x^m}{m.\overline{1-x^n}} - \frac{nzA}{m+n} + \frac{2nzB}{m+2n} - \frac{3nzC}{m+3n}$ + &c. which is well adapted to arithmetical calculation.

"6. I come now to the transformation propoſed, which will appear very eaſy, as ſoon as the common ſeries, expreſſing the length of an arch in terms of its tangent, is properly arranged.

"If the radius of a circle be 1, and the tangent of an arch of it be called t, it is well known that the length of that arch will be $= t - \frac{t^3}{3} + \frac{t^5}{5} - \frac{t^7}{7} + \frac{t^9}{9} - \frac{t^{11}}{11}$ + &c. Now, if the affirmative terms of this ſeries be written in one line, and the negative ones in another, the arch will be

$$= \begin{cases} t + \frac{t^5}{5} + \frac{t^9}{9} + \frac{t^{13}}{13} + \frac{t^{17}}{17} + \&c. \\ -\frac{t^3}{3} - \frac{t^7}{7} - \frac{t^{11}}{11} - \frac{t^{15}}{15} - \frac{t^{19}}{19} - \&c. \end{cases}$$

And if, again, the firſt, third, fifth, &c. term of each of theſe ſeries be written in one line, and the ſecond, fourth, ſixth, &c. in another, the ſame arch will be expreſſed thus:

$$= \begin{cases} + \begin{cases} t + \frac{t^9}{9} + \frac{t^{17}}{17} + \frac{t^{25}}{25} + \frac{t^{33}}{33} + \&c. \\ \frac{t^5}{5} + \frac{t^{13}}{13} + \frac{t^{21}}{21} + \frac{t^{29}}{29} + \frac{t^{37}}{37.} + \&c. \end{cases} \\ \hline - \begin{cases} \frac{t^3}{3} + \frac{t^{11}}{11} + \frac{t^{19}}{19} + \frac{t^{27}}{27} + \frac{t^{35}}{35} + \&c. \\ \frac{t^7}{7} + \frac{t^{15}}{15} + \frac{t^{23}}{23} + \frac{t^{31}}{31} + \frac{t^{39}}{39} + \&c. \end{cases} \end{cases}$$

All which ſeries are evidently of the firſt form in article 2. and therefore their values may be expreſſed in the ſecond form there given, or more neatly the Newtonian notation mentioned in art. 5. In each of theſe ſeries the value of n is 8:

$$\text{And the value of } m, \begin{cases} \text{in the firſt ſeries, is 1;} \\ \text{in the ſecond ſeries, is 5;} \\ \text{in the third ſeries, is 3;} \\ \text{in the fourth ſeries, is 7.} \end{cases}$$

"If now we take $t = \sqrt{\frac{1}{3}}$, the tangent of 30°, which was choſen by Dr Halley, we ſhall have the arch of 30°

$$=\left\{\begin{array}{l} +\left\{\begin{array}{l} \frac{1}{\sqrt{3}}\times:1+\frac{1}{9.81}+\frac{1}{17.81^2}+\frac{1}{25.81^3}+\frac{1}{33.81^4}, \text{\&c.} \\ \frac{1}{9\sqrt{3}}\times:\frac{1}{5}+\frac{1}{13.81}+\frac{1}{21.81^2}+\frac{1}{29.81^3}+\frac{1}{37.81^4}, \text{\&c.} \end{array}\right. \\ \hline -\left\{\begin{array}{l} \frac{1}{3\sqrt{3}}\times:\frac{1}{3}+\frac{1}{11.81}+\frac{1}{19.81^2}+\frac{1}{27.81^3}+\frac{1}{35.81^4}, \text{\&c.} \\ \frac{1}{27\sqrt{3}}\times:\frac{1}{7}+\frac{1}{15.81}+\frac{1}{23.81^2}+\frac{1}{31.81^3}+\frac{1}{39.81^4}, \text{\&c.} \end{array}\right. \end{array}\right.$$

Six timees this quantity will be = the ſemicircumference when radius is 1, and = the whole circumference when the diameter is 1. If therefore we multiply the laſt ſeries by 6, and write $\sqrt{12}$ for $\frac{6}{\sqrt{3}}$, and expreſs their value in the form given in art. 5. we ſhall have the circumference of a circle whoſe diameter is 1,

$$=\left\{\begin{array}{l} +\left\{\begin{array}{l} \frac{81\sqrt{12}}{80}-\frac{8A}{9.80}+\frac{16B}{17.80}-\frac{24C}{25.80}+\frac{32D}{33.80}, \text{\&c.} \\ \frac{81\sqrt{12}}{5.9.80}-\frac{8A}{13.80}+\frac{16B}{21.80}-\frac{24C}{29.80}+\frac{32D}{37.80}, \text{\&c.} \end{array}\right. \\ \hline -\left\{\begin{array}{l} \frac{81\sqrt{12}}{3.3.80}-\frac{8A}{11.80}+\frac{16B}{19.80}-\frac{24C}{27.80}+\frac{32D}{35.80}, \text{\&c.} \\ \frac{81\sqrt{12}}{7.27.80}-\frac{8A}{15.80}+\frac{16B}{23.80}-\frac{24C}{31.80}+\frac{32D}{39.80}, \text{\&c.} \end{array}\right. \end{array}\right.$$

"7. All theſe new ſeries, it is evident, converge ſomewhat ſwifter than by the powers of 80. For in the firſt ſeries, which has the ſloweſt convergency, the coefficients $\frac{8}{9}$, $\frac{16}{17}$, $\frac{24}{25}$, &c. are each of them leſs than 1; ſo that its convergency is ſomewhat ſwifter than by the powers of 80.

"8. But another advantage of theſe new ſeries is, that the numerator and denominator of every term except the firſt, in each of them, is diviſible by 8; in conſequence of which, the arithmetical operation by them is much facilitated, the diviſion by 80 being exchanged for a diviſion by 10, which is no more than removing the decimal point. Theſe ſeries, then, when the factors which are common to both numerators and denominators are expunged, will ſtand as below (each of which ſtill converging ſomewhat quicker than by the powers of 80), and we ſhall have the circumference of a circle whoſe diameter is 1,

$$=\left\{\begin{array}{l} +\left\{\begin{array}{l} \frac{81\sqrt{12}}{80}-\frac{A}{9.10}+\frac{2B}{17.10}-\frac{3C}{25.10}+\frac{4D}{33.10}, \text{\&c.} \\ \frac{9\sqrt{12}}{400}-\frac{A}{13.10}+\frac{2B}{21.10}-\frac{3C}{29.10}+\frac{4D}{37.10}, \text{\&c.} \end{array}\right. \\ \hline -\left\{\begin{array}{l} \frac{9\sqrt{12}}{80}-\frac{A}{11.10}+\frac{2B}{19.10}-\frac{3C}{27.10}+\frac{4D}{35.10}, \text{\&c.} \\ \frac{3\sqrt{12}}{7.80}-\frac{A}{15.10}+\frac{2B}{23.10}-\frac{3C}{31.10}+\frac{4D}{39.10}, \text{\&c.} \end{array}\right. \end{array}\right.$$

"By which ſeries the arithmetical computation will be much more eaſy than by the original ſeries."

Quadrature Lines, or *Lines of Quadrature*, are two lines often placed on Gunter's ſector. They are marked with the letter Q, and the figures 5, 6, 7, 8, 9, 10; of which Q denotes the ſide of a ſquare, and the figures denote the ſides of polygons of 5, 6, 7, &c. ſides. Alſo S denotes the ſemidiameter of a circle, and 90 a line equal to the quadrant or 90° in circumference.

QUADRIPARTITION, is the dividing by 4, or into four equal parts. Hence *quadripartite*, &c. the 4th part, or ſomething parted into four.

QUADRUPLE, is four-fold, or ſomething taken four times, or multiplied by 4; and ſo is the converſe of quadripartition.

QUART, a meaſure of capacity, being the quarter or 4th part of ſome other meaſure. The Engliſh quart is the 4th part of the gallon, and contains two pints. The Roman quart, or quartarius, was the 4th part of their congius. The French, beſides their quart or pot of two pints, have various other quarts, diſtinguiſhed by the whole of which they are quarters; as *quart de muid*, and *quart de boiſſeau*.

QUARTILE, an aſpect of the planets when they are at the diſtance of three ſigns or 90° from each other; and is denoted by the character □.

QUELPAERT, an iſland lying in the mouth of the channel of Japan, and ſubject to the king of COREA (See that article *Encycl.*) Till the laſt voyage of La Perouſe, this iſland was known to Europeans only by the wreck of the Dutch ſhip Sparrow-hawk in 1635. On the 21ſt of May 1787, the French Commodore made this iſland, and determined the ſouth point of it to be in Lat. 33° 14′ north, and in Lon. 124° 15′ eaſt from Paris. He ran along the whole ſouth eaſt ſide, at ſix leagues diſtance, and ſays that it is ſcarcely poſſible to find an iſland which affords a finer aſpect; a peak of about a thouſand toiſes, which is viſible at the diſtance of eighteen or twenty leagues, occupies the middle of the iſland, of which it is doubtleſs the reſervoir; the land gradually ſlopes towards the ſea, whence the habitations appear as an amphitheatre. The ſoil ſeemed to be cultivated to a very great height. By the aſſiſtance of glaſſes was perceived the diviſion of fields; they were very much parcelled out, which is the ſtrongeſt proof of a great population. The very varied gradation of colours, from the different ſtates of cultivation, rendered the view of this iſland ſtill more agreeable. Unfortunately, it belongs to a people who are prohibited from all communication with ſtrangers, and who detain in ſlavery thoſe who have the misfortune to be ſhipwrecked on theſe coaſts. Some of the Dutchmen of the ſhip Sparrow-hawk, after a captivity of eighteen years there, during which they received many baſtinadoes, found means to take away a bark, and to croſs to Japan, from which they arrived at Batavia, and afterwards at Amſterdam.

QUEUE D'ARONDE, or *Swallow's Tail*, in fortification, is a detached or outwork, whoſe ſides ſpread or open towards the campaign, or draw narrower and cloſer towards the gorge. Of this kind are either ſingle or double tenailles, and ſome horn-works, whoſe ſides are not parallel, but are narrow at the gorge, and open at the head, like the figure of a ſwallow's tail. On the contrary, when the ſides are leſs than the gorge, the work is called *contre queue d'aronde*.

Queue, Quintal

Queue d'aronde, in carpentry, a method of jointing, called alſo *dove-tailing*.

QUINTAL, the weight of a hundred pounds, in moſt countries: but in England it is the hundred weight, or 112 pounds. Quintal was alſo formerly uſed for a weight of lead, iron, or other common metal, uſually equal to a hundred pounds, at 6 ſcore to the hundred.

Quintile.

QUINTILE, in aſtronomy, an aſpect of the planets when they are diſtant the 5th part of the zodiac, or 72 degrees; and is marked thus, C, or O.

R.

Rachitis.

RACHITIS, Rickets (See Medicine-*Index*, *Encycl.*), is a diſeaſe ſo formidable to children, that we believe no parent will think the following abſtract of *Bonhomme*'s memoir on the nature and treatment of it too long even for this *Supplement*.

The change which the bones undergo in this diſorder, has long been attributed to the action of an acid on their ſubſtance; but this ſuppoſition was grounded on mere conjecture and remote analogy. Bonhomme holds the ſame opinion on better grounds; and the principal notions which conſtitute the baſis of his memoir are the following:

1. According to him, the nature of the rachitic diſorder ariſes, on the one hand, from the developement of an acid approaching in its properties to the vegetable acids, particularly the oxalic; and, on the other, from the defect of phoſphoric acid, of which the combination with the animal calcareous earth forms the natural baſis of the bones, and gives them their ſolidity. Whence it follows, that the indication reſulting from this propoſition, if once adopted, would be, that the treatment of rachitis muſt depend on two principal points, namely, to prevent the developement of the oxalic acid, and to re eſtabliſh the combination of the phoſphoric acid with the baſis of the bones to which they owe their ſolidity.

2. The author proves, by experiments and obſervations, in the firſt place, that alkaline lotions of the parts affected with rachitis contribute to their cure; next, that the calcareous phoſphate taken internally is really tranſmitted by the lymphatic paſſages, and contributes to oſſification; and, laſtly, that the internal uſe of calcareous phoſphate, whether alone or combined with the phoſphate of ſoda, powerfully contributes to reſtore the natural proportions in the ſubſtance of the bones, and accelerate the cure of rachitis.

With regard to the author's endeavours to prove that the calcareous acid is wanting in the bones of thoſe who are diſordered with rachitis, and that the developement of oxalic acid contributes to the diſeaſe, we muſt not conceal that his memoir contains views rather than abſolute proofs of theſe two poſitions. He declares, himſelf, he was not provided with the neceſſary means to eſtabliſh an exact and complete analyſis. He therefore preſents his ideas, in this reſpect, merely as conjectures approaching to the truth.

The effect of the action of acids upon bones was before known; that is to ſay, that when deprived of calcareous phoſphate, and reduced to the gelatinous parenchyma which forms one of their elements, they loſe their conſiſtence, and become flexible. Hence it was already conjectured by various phyſicians, that the rachitis was the effect of a peculiar acid.

Rachitis.

A diſpoſition to aceſcence in the firſt paſſages is obſervable in all infants. The odour which characterizes this aceſcence is often manifeſt in their breath, and even their perſpiration. The bile corrects this diſpoſition; but in general the bile is wanting in rachitic infants. It does not colour their excrements, and the acids accordingly are developed in a very decided manner. They diſturb the circulation, and attack and ſoften the bones. As it is by defect of animalization that theſe acids develope themſelves, it follows that their character is analogous to the fermenteſcible vegetable acids, and more or leſs to the oxalic acid; and that, on the contrary, the animal acid or phoſphoric acid ceaſes to be formed, and to unite with the animal calcareous earth; whence they are deprived of the principle of their ſolidity. This is the theory of Citizen Bonhomme.

In order to eſtabliſh this doctrine upon preciſe experiments, it was requiſite to analyſe rachitic bones comparatively with thoſe of healthy individuals of the ſame age; and as it is known that the urine of rachitic ſubjects depoſites a great quantity of a ſubſtance of ſparing ſolubility and earthy appearance, it would have been advantageous to have joined a complete analyſis of this urine and its ſediment. Citizen Bonhomme, not being provided with the means ſufficient to make theſe analyſes, and being beſides of opinion that ſuch rachitic bones as are deſtroyed by this malady exiſt in a progreſſive ſtate of change, which might render their analyſis ſcarcely ſuſceptible of compariſon, limited himſelf to a collection of ſome of the moſt remarkable phenomena of the urine, of the aged, the adult, and infants in the healthy ſtate, of infants in the rachitic ſtate, and of patients after the perfect cure of this diſorder. From theſe obſervations he has deduced ſeveral important reſults.

It is known, that when the urine contains diſengaged phoſphoric acid, as happens to aged individuals, and in ſome peculiar circumſtances of the ſyſtem, if lime water be poured in, there is a ſpeedy depoſition of calcareous phoſphate. It is alſo known, that when a ſolution of the nitrate of mercury is poured to the freſh urine of adults, a roſe-coloured precipitate is formed, which is a phoſphate of mercury produced by the decompoſition of the phoſphates contained in the urine. Theſe two proofs are therefore extremely proper to aſcertain the preſence of phoſphoric acid, whether free or combined, in a fluid which in its natural ſtate contains a remarkable proportion. Beſides this principle, the urine depoſits more or leſs of ſediment, either gelatinous or of an earthy appearance; and, laſtly, by evaporation, a ſaponaceous and ſaline extract, in greater or leſs abundance, is obtained by evaporation. By means of theſe four methods of examination, the author has aſcertained the following facts:

1. In the healthy ſtate, the ſediment naturally depoſited by urine is almoſt totally gelatinous in the infant and the adult, and in the aged individual it is ſurcharged with an abundant ſediment of an earthy appearance ſimilar to the earth of bones, which conſequently is calcareous phoſphate. 2. The quantity of brown ſaponaceous ſaline extract afforded by evaporation is greater in proportion to the age. 3. The preſence of diſengaged phoſphoric acid, as ſhewn by lime water, is none in the urine of infants, ſcarcely perceptible in that of adults, but very remarkable in that of old men. For two ounces of this laſt urine afforded by this means ten grains of phoſphate of lime. 4. The decompoſition of the phoſphates by nitrate of mercury is not ſeen in the urine of infants; an abundant precipitate of a light roſe-colour is produced in this way from the urine of adults; and in that of old men this precipitate is always of a grey colour, and very abundant. Hence Citizen Bonhomme concludes, that the phoſphoric acid, whether at liberty or combined, does exiſt in the urine of healthy individuals in proportion to the deſtruction of the ſolids by age, and that it increaſes with the age.

With regard to the urine of rachitic ſubjects, the moſt remarkable facts are, 1. The abundant and apparently earthy ſediment it depoſits (ſpontaneouſly) is different from that of old men, by its colour, which is grey, and does not reſemble phoſphate of lime, and alſo by its much greater quantity. For a pound of this urine let fall two gros, whereas the ſame quantity of the urine of old men depoſited only 45 grains. 2. The extract left by evaporation is likewiſe much more conſiderable than in other urine. It is one-third more in quantity than the extract afforded even by the urine of aged perſons.

From theſe two firſt obſervations it follows, that the ſolids in rachitic ſubjects are deſtroyed with much more rapidity than even in old men; and that they afford a much more abundant portion of waſte to the urine.

3. The light depoſition occaſioned by lime water in the urine of rachitic ſubjects is very ſmall in quantity, brown, gelatinous when freſh, and pulverulent when dry. It does not at all reſemble calcareous phoſphate. 4. The depoſition formed by the ſolution of mercurial nitrate is not abundant, neither of a roſe colour as in the urine of adults, nor grey like that of old men. It is always white, and conſequently has no external reſemblance to the phoſphate of mercury. The author affirms that it reſembles a mercurial oxalate. Laſtly, the urine of the ſame rachitic ſubjects when cured, exhibits again all the characters obſerved in the urine of healthy children. We ſhall not add to the reflections of the author. In effect, though theſe firſt obſervations are curious, they are incomplete. We offer them to phyſicians ſimply as the elements of an inveſtigation which it is of importance to continue and bring to perfection. We ſhall therefore proceed to the curative and experimental parts of the memoir.

One of the facts which it was of the utmoſt importance to eſtabliſh, was the tranſition of the calcareous phoſphate from the inteſtinal paſſages, into thoſe of circulation and ſecretion. Fourcroy had already well aſcertained that the ſerum of milk contains this ſalt naturally. Vauquelin had proved its exiſtence, as well as that of pure ſoda, in the ſeminal fluid; but was it poſſible that it could paſs unaltered from the ſtomach and inteſtines into the veſſels which contain the blood and lymph? Could it by this means apply itſelf to the bones? This was to be aſcertained by experiments; and the following are the experiments made by Bonhomme for that purpoſe. We give them in a tranſlation of his own words.

"I cauſed (ſays he) ſeveral young fowls of the ſame incubation to be fed in different manners. Some received the uſual food without any mixture; others received daily a certain quantity of calcareous phoſphate mixed in the ſame paſte as formed the ſupport of the others; and, laſtly, one of them was fed with variations in the uſe of the mixture: the calcareous phoſphate was ſometimes given and ſometimes ſuſpended. When theſe fowls, after two months, had acquired their ordinary growth, I examined and carefully compared the ſtate of their bones. The progreſs of the oſſification in the epiphyſes was various according to the nature of the food the animal had received. The bones of the laſt fowl, which had received the phoſphate only from time to time, were rather more advanced than the bones of thoſe which had been fed without mixture. The bones of thoſe fowls which had been habitually fed with the mixture were evidently more ſolid, and their epiphyſes were much leſs perceptible. Simple inſpection was ſufficient to ſhew theſe differences when the bones were mixed together.

"I had fed ſeveral young fowls of the ſame incubation according to another plan. Some were fed on a ſimple paſte, without mixture; for others it was mixed with pulveriſed madder-root; and a third compoſition was made of this laſt paſte and calcareous phoſphate. This was alſo given habitually to other fowls. When after two months I examined the progreſs of oſſification in the bones of theſe different animals, I eaſily perceived the red traces of the madder in the oſſified parts of all thoſe which had uſed it; but I obſerved, that the oſſification was not more advanced by the ſimple mixture of this root than by the ordinary food: on the contrary, the bones of thoſe fowls which had ſwallowed the phoſphate mixed with madder were much more ſolid than the others. The red colour ſerved admirably to diſtinguiſh the extremities of the long bones from their epiphyſes. After an exact compariſon, there could be no doubt of the efficacy of calcareous phoſphate in favour of the progreſs of oſſification. The virtue of the madder ſeemed confined to that of giving colour to the oſſified parts."

From theſe experiments, it was natural to make the trial of calcareous phoſphate in addition to the remedies made uſe of in the treatment of rachitic ſubjects. Here follows what the author himſelf ſays of two remarkable inſtances in which the calcareous phoſphate was adminiſtered with ſucceſs:

"The daughter of Mr Ranchon watch-maker, aged two years and a half, walked with a feeble and tottering pace, and the extremities of all her bones preſented epiphyſes very

Rachitis.

very prominent. In this ſituation ſhe exhibited the appearance of imperfect rachitis, or the firſt period of this diſorder. Alkaline lotions, which I immediately adviſed, were attended with a good effect. Her ſleep became more firm; and as the firſt paſſages were in a good ſtate, I gave, without internal preparation, one ſcruple of a mixture of equal parts of phoſphate of lime and phoſphate of ſoda twice a day. In the courſe of three weeks her legs were perfectly reſtored; and this amiable infant has ever ſince had the ſatisfaction to run with ſpirit and agility.

" A female infant, of the name of Boiard, aged four years had experienced from her birth the moſt decided ſymptoms of rachitis. The protuberance of the epiphyſes and tumefaction of the abdomen firſt indicated the diſeaſe. The impoſſibility of ſupporting herſelf and walking at the uſual age confirmed theſe unfortunate ſymptoms. By degrees the glands of the neck and of the meſentery became ſwelled; the teeth were blackened, became carious, and were not replaced. This ſituation became ſtill more afflicting by criſes almoſt periodical at an interval of three or four weeks. At theſe afflicting periods, a fever of conſiderable ſtrength, cardialgia, and even convulſions, particularly in the night, were obſerved. The termination of each paroxyſm was announced or aſcertained by abundant ſtools, and the evacuation of urine ſtrongly charged with an earthy ſediment. The imprudent exhibition of a purge at the beginning of one of theſe criſes had nearly deprived the patient of her life. In this ſtate it was that I beheld her for the firſt time in the month of January 1791. The alkaline lotion was the only remedy the mother adopted in the firſt inſtance, and it produced a remarkable effect. After eight days the infant was ſo much better as to be able to ſupport herſelf. The remedy was then laid aſide, and eight days aftewards the child was incapable of ſtanding without ſupport. The uſe of the alkaline ſolution being renewed, was attended with the ſame ſucceſs, and its diſcontinuance was again followed by the complete return of all the ſymptoms. In the firſt days of March, the other remedies I had adviſed were exhibited. The conſtipation which had always exiſted became leſs, and the following criſis was effected without pain. And at length the convulſions, the pains, and the criſes diſappeared; but the impoſſibility of walking ſtill remained. At this time, namely on the ſecond of May, I gave the child the phoſphate of ſoda and calcareous phoſphate mixed together, in the doſe of half a dram twice a-day. At the end of the month ſhe was able to ſtand upright, leaning againſt a chair, and the ſwellings began to diminiſh. She continued for a long time afterwards to take the mixture of the phoſphates. I likewiſe gave her occaſionally one grain of the extract of bile, prepared with ſpirit of wine; and at length in the month of July I had the pleaſure to ſee the patient run and play in the middle of the ſtreet with the other children of her own age, &c."

The author gives other inſtances of this medicine being adminiſtered with complete ſucceſs to rachitic children, and one in which it was attended with the beſt effects in a caſe of incurvated ſpine. Theſe it is needleſs to inſert, becauſe we truſt that none of our leſs learned readers will have recourſe to the medicine without the advice of a phyſician; and to him an enumeration of caſes could ſerve no purpoſe. It may be proper, however, as alkaline lotions and their beneficial effects are mentioned, to give here the author's account of the lotion which he uſed.

Rachitis, Raja.

" In ordinary caſes of rachitis, particularly at the commencement of the diſorder, it is of advantage to uſe a ſimple ſolution of pot-aſh to waſh the parts affected. This ſolution is made by diſſolving from half an ounce to an ounce of purified pot-aſh in a pound of diſtilled or very pure ſpring water. When it is to be uſed, the ſkin muſt firſt be rubbed with a dry cloth or a piece of fine flannel. After this precaution, the diſeaſed extremities are to be waſhed carefully with the warm ſolution, and at length wiped, ſo as to leave no trace of moiſture. This practice and waſhing muſt be repeated at leaſt twice a-day. I can affirm, from repeated trials, that it will ſoon be attended with ſucceſs."

In a note on this paſſage, M. Hallé, who analyſed the memoir at the deſire of the Society of Medicine at Paris, juſtly obſerves, that as pure potaſs, or the vegetable alkali, is a moſt powerful cauſtic, it cannot be uſed in theſe proportions; adding, that he found one-eighth part of the ſalt here indicated to form too ſtrong a lotion for the ſkin of an infant. M. Bonhomme, upon enquiry being made, informed him, that the potaſs which he uſed was that of the ſhops, which is very far from being pure; and Mr Nicholſon conjectures that it was the common ſalt of tartar of our ſhops. This, we think, extremely probable, eſpecially as M. Bonhomme aſſures us that even a lixium of wood-aſhes, ſuch as is uſed for waſhing fine linen, may anſwer the purpoſe extremely well.

For a fuller account of this intereſting memoir our readers are referred to the 17th volume of the *Annals de Chimie*, or to the firſt volume of *Nicholſon's Philoſophical Journal.*

RAJA, the *ray fiſh*. See *Encyclopædia*, where it is ſaid that the *oxyrinchus* or ſharp noſed ray, is ſuppoſed to be the *bos* of the ancients; but if there be any truth in the following narrative, which we confeſs has much the air of fiction, this is probably a miſtake. It is the narrative of Vaillant, and we ſhall give it in his own words.

" In the latitude 10° 15′ north, and longitude 355°, an enormous flat fiſh of the ray genus (ſays he), came and ſwam round our veſſel. It differed from the common ray, however, in the ſhape of its head, which, inſtead of being pointed, formed a creſcent, and from the extremities of the ſemicircle iſſued two arms as it were, which the ſailors called horns. They were two feet wide at the baſe, and only five inches at the extremity. This monſter they told me was called the *ſea-devil*.

" A few hours after, we ſaw two others with this, one of which was ſo extremely large, that it was computed by the crew to be *fifty* or *ſixty* feet wide. Each ſwam ſeparately, and was ſurrounded by thoſe ſmall fiſh which uſually precede the ſhark, and which are therefore called by ſeamen *pilot-fiſh*. Laſtly, all three carried on each of their horns a white fiſh, about the ſize of a man's arm, and half a yard long, which appeared to be ſtationed there on duty.

" You would have ſaid they were two ſentinels placed to keep watch for the ſafety of the animal, to inform him of any approaching danger, and to guide his movements. If he approached too near the veſſel, they quitted their poſts, and, ſwimming briſkly before, led him

him away. If he roſe too high above the water, they paſſed backward and forward over his back till he had deſcended deeper. If, on the contrary, he ſwam too low, they diſappeared, and we ſaw no more of them, becauſe, no doubt, they were paſſing underneath, as in the preceding inſtance they had paſſed above him. Accordingly we found him re-aſcend towards the ſurface, and then the two ſentinels reaſſumed their poſts, each on his horn."

Theſe manœuvres continued three days; and to give our author the better opportunity of obſerving them, the ſhip moſt fortunately was becalmed the whole time. He was naturally very deſirous of catching one of them that he might examine it at leiſure; and, by bribing the ſeamen with a dozen of bottles of wine, he accompliſhed his object. One of the fiſh was ſtruck with twelve or fifteen harpoons; ſeveral halſers were paſſed round his body, and he was hoiſted on board.

" This (ſays our author) was the leaſt of the three, being only *eight-and-twenty* feet in its extreme breadth, and *one-and-twenty* in length from the extremity of the horns to that of the tail. The tail, which was thick in proportion to the body, was *twenty-two inches* long. The mouth, placed exactly like that of the ray, was wide enough to ſwallow a man with eaſe. The ſkin was white under the belly, and brown on the back, like that of the ray. We reckoned the animal to weigh not leſs, certainly, than a ton."

We think it was fortunate that they chanced to ſtrike the ſmalleſt fiſh; for an addition of eight or ten ton weight, which the largeſt ray muſt have weighed, as certainly as the ſmalleſt weighed one ton, might have been very inconvenient on board a ſhip already loaded. We do not remember to have anywhere met with a deſcription of this ray before, and we think it ſhould be conſidered as a new ſpecies; but we ſhall not give it a name till its exiſtence be better aſcertained, when we ſubmit to the pupils of Linnæus, whether it may not be proper to give it the ancient name *bos*.

RAJAH. (See *Encyclopædia*.) We learn from Sir Charles Rouſe Boughton's *Diſſertation concerning the Landed Property of Bengal*, that this title is conferred upon Hindoos by the emperor, and frequently given out of courteſy to the greater zemindars. It would appear therefore that the Rajahs can never be independent of the Mogul but by a ſucceſsful rebellion.

RAYEI-UL-MULK, in the language of Bengal, the uſage of the country, the common law.

RATIO (See *Encyclopædia*) has been defined by Euclid, in the 5th book of his Elements, in terms to which many mathematicians have objected; and his definition of proportion, which is ſo ultimately connected with it, is ſtill more objectionable. The Rev. Abraham Robertſon of Oxford, in a ſmall tract publiſhed in 1789, demonſtrates the truth of the two definitions in queſtion in ſeven propoſitions, of which the ſubſtance is as follows. He firſt lays down theſe four definitions:

" 1. Ratio is the relation which one magnitude has to another, of the ſame kind, with reſpect to quantity.

" 2. If the firſt of four magnitudes be exactly as great when compared to the ſecond, as the third is when compared to the fourth, the firſt is ſaid to have to the ſecond the ſame ratio that the third has to the fourth.

" 3. If the firſt of four magnitudes be greater, when compared to the ſecond, than the third is when compared to the fourth, the firſt is ſaid to have to the ſecond a greater ratio than the third has to the fourth.

" 4. If the firſt of four magnitudes be leſs, when compared to the ſecond, than the third is when compared to the fourth, the firſt is ſaid to have to the ſecond a leſs ratio than the third has to the fourth."

He then demonſtrates, by reaſoning ſtrictly geometrical, the following propoſitions:

Prop. 1. If the firſt of four magnitudes have to the ſecond, the ſame ratio which the third has to the fourth; then, if the firſt be equal to the ſecond, the third is equal to the fourth; if greater, greater; if leſs, leſs.

Prop. 2. If the firſt of four magnitudes be to the ſecond as the third to the fourth, and if any equimultiples whatever of the firſt and third be taken, and alſo any equimultiples of the ſecond and fourth; the multiple of the firſt will be to the multiple of the ſecond as the multiple of the third to the multiple of the fourth.

Prop. 3. If the firſt of four magnitudes be to the ſecond as the third to the fourth, and if any like aliquot parts whatever be taken of the firſt and third, and any like aliquot parts whatever of the ſecond and fourth, the part of the firſt will be to the part of the ſecond as the part of the third to the part of the fourth.

Prop. 4. If the firſt of four magnitudes be to the ſecond as the third to the fourth, and if any equimultiples whatever be taken of the firſt and third, and any whatever of the ſecond and fourth; if the multiple of the firſt be equal to the multiple of the ſecond, the multiple of the third will be equal to the multiple of the fourth; if greater, greater; if leſs, leſs.

Prop. 5. If the firſt of four magnitudes be to the ſecond as the third is to a magnitude leſs than the fourth, then it is poſſible to take certain equimultiples of the firſt and third, and certain equimultiples of the ſecond and fourth, ſuch, that the multiple of the firſt ſhall be greater than the multiple of the ſecond, but the multiple of the third not greater than the multiple of the fourth.

Prop. 6. If the firſt of four magnitudes be to the ſecond as the third is to a magnitude greater than the fourth, then certain equimultiples can be taken of the firſt and third, and certain equimultiples of the ſecond and fourth, ſuch, that the multiple of the firſt ſhall be leſs than the multiple of the ſecond, but the multiple of the third not leſs than the multiple of the fourth.

Prop. 7. If any equimultiples whatever be taken of the firſt and third of four magnitudes, and any equimultiples whatever of the ſecond and fourth; and if when the multiple of the firſt is leſs than that of the ſecond, the multiple of the third is alſo leſs than that of the fourth; or if when the multiple of the firſt is equal to that of the ſecond, the multiple of the third is alſo equal to that of the fourth; or if when the multiple of the firſt is greater than that of the ſecond, the multiple of the third is alſo greater than that of the fourth: then, the firſt of the four magnitudes ſhall be to the ſecond as the third to the fourth.

RATIONAL, in arithmetic, &c. the quality of numbers, fractions, quantities, &c. when they can be expreſſed by common numbers; in contradiſtinction to irrational or ſurd ones, which cannot be expreſſed in common numbers.

RAYNAL (William Thomas), commonly called the Abbé Raynal, was educated among the Jeſuits, and had become one of the order. The learning of that Society is univerſally known, as well as the happy talents which its ſuperiors poſſeſſed, of aſſigning to each member his proper employment. Raynal, however, after having acquired among them a taſte for literature and ſcience, had probably become refractory, for he was expelled from the order; and the cauſe of his expulſion, according to the Abbé Barruel, was his impiety.

With the real cauſe of his expulſion M. Barruel is ſurely much better acquainted than we can pretend to be; but we have a ſtrong ſuſpicion that his impieties had not then reached farther than to call in queſtion the ſupreme authority of the church; for our author himſelf aſſures us, that he did not utter his atrocious declarations againſt Chriſtianity till he had ceaſed to be a member of the order of Jeſuits. He then aſſociated himſelf with Voltaire, D'Alembert, and Diderot, and was by them employed to furniſh the theological articles for the *Encyclopédie*. But though his religious opinions were certainly lax, and his moral principles very exceptionable, he could not even then be what, in a Proteſtant country, would be deemed a man remarkable for impiety; for he employed the Abbé Yvon, whom M. Barruel calls an odd metaphyſician, but an inoffenſive and upright man, to write the articles which he was engaged to furniſh. In the conducting of this tranſaction, he ſhewed, indeed, that he poſſeſſed not a proper ſenſe of honour; for he paid poor Yvon with twenty-five louis d'ors for writing theological articles, for which he received himſelf ſix times that ſum. This trick was diſcovered, Raynal was diſgraced, and compelled to pay up the balance to Abbé Yvon; but tho' he had thus ſhewn himſelf to be without honour, it is difficult to believe that he had yet proceeded ſo far as to blaſpheme Chriſt, ſince he had employed a Chriſtian divine to ſupply his place in the *Encyclopédie*.

His firſt work of eminence, and that indeed upon which his fame is chiefly built, is his "Political and Philoſophical Hiſtory of the European Settlements in the Eaſt and Weſt Indies." That this hiſtory is written in an animated ſtyle, and that it contains many juſt reflections, both political and philoſophical, is known to all Europe; for it has been tranſlated into every European language. Its beauties, however, are deformed by many ſentiments that are irreligious, and by ſome that are impure. It was followed, we think, in 1780, by a ſmall tract entitled "The Revolution of America;" in which the author pleads the cauſe of the revolted coloniſts with a degree of zeal, cenſures the conduct of the Britiſh government with a keenneſs of aſperity, and diſplays a knowledge of the principles and intrigues of the different factions which at that period divided the Engliſh nation, that ſurely was not natural to the impartial pen of a philoſophic foreigner. Hence he has been ſuppoſed to have been incited to the undertaking, and to have been furniſhed with part of his materials, by that deſperate faction which uniformly oppoſed the meaſures of Lord North, and ſecretly fomented the rebellion in America. Be this as it may, he propagated, both in this tract and in his hiſtory, a number of licentions opinions reſpecting government and religion, of which he lived to regret the conſequences.

A proſecution was inſtitnted againſt him by the French government on account of his hiſtory of the Eaſt and Weſt Indies; but it was conducted with ſo little ſeverity, that he had ſufficient time to retire to the dominions of the King of Pruſſia, who afforded him the protection he ſolicited, although his Majeſty's character was treated by the author in his book with no great degree of veneration. Raynal alſo experienced the kindneſs of the Empreſs of Ruſſia; and it is not a little remarkable of this ſingular perſonage, that, although he was always ſevere in diſcuſſing the characters of princes, yet the moſt deſpotic among theſe heaped upon him many marks of favour and generoſity. The Abbé alſo received a very unuſual mark of reſpect from a Britiſh Houſe of Commons. It was once intimated to the ſpeaker that Raynal was a ſpectator in the gallery. The buſineſs was immediately ſuſpended, and the ſtranger conducted to a more convenient and honourable ſituation. How different was the conduct of Dr Johnſon, who, when a friend advanced to him with our author, ſaying, "Will you give me leave, Doctor, to introduce to you the Abbé Raynal?" turned on his heel, and vociferated, "No, Sir!" We are far from wiſhing to vindicate the rudeneſs of the ſage; but it was perhaps as proper as the politeneſs of the Houſe of Commons.

The great trait of Raynal's character was a love of liberty, which, in his earlier writings, he did not properly define; but when he lived to ſee ſome of the conſequences of this, in the progreſs of the French Revolution, he made one glorious effort to retrieve his errors. In the month of May 1791, he addreſſed to the conſtituent aſſembly one of the moſt eloquent, argumentative, and impreſſive letters that ever was written on any ſubject; a letter which, if the majority of them had not been intoxicated with their newly acquired conſequence, muſt have given ſome check to their mad career. After complimenting them upon what they had done, he proceeds thus: "I have long dared to ſpeak to kings of their duty; ſuffer me now to ſpeak to the people of their errors, and to their repreſentatives of the dangers which threaten us. I am, I own to you, deeply afflicted at the crimes which plunge this empire into mourning. Is it true that I am to look back with horror at myſelf for being one of thoſe who, by feeling a noble indignation againſt arbitrary power, may perhaps have furniſhed arms to licentiouſneſs? Do then religion, the laws, the royal authority, and public order, demand back from philoſophy and reaſon the ties which united them to the grand ſociety of the French nation, as if, by expoſing abuſes, and teaching the rights of the people and the duties of princes, our criminal efforts had broken thoſe ties? But, no!—never have the bold conceptions of philoſophy been repreſented by us as the ſtrict rule for acts of legiſlation.

"You cannot juſtly attribute to us what could only be the reſult of a falſe interpretation of our principles. Alas! now that I ſtand on the brink of the grave; now that I am about to quit this immenſe family, whoſe happineſs I have ardently deſired, what do I ſee around me? Religious troubles, civil diſſenſions, conſternation on the one hand, tyranny and audacity on the other; a government the ſlave of popular tyranny; the ſanctuary of the laws ſurrounded by unruly men, who alternately dictate or deſpiſe thoſe laws; ſoldiers without diſcipline; leaders without authority; miniſters without means; a king, the firſt friend of his people, plunged into bitterneſs, inſulted, menaced, ſtripped of all authority; and the public power no longer exiſting but in clubs, in which ignorant and rude men dare to decide all political queſtions."

He then proceeds to prove, which he does very completely, that it was not the buſineſs of the aſſembly to aboliſh every ancient inſtitution; that the genius of the French people is ſuch, that they never can be happy or proſperous but under a well-regulated monarchical government; and that, if they wiſhed not the nation to fall under the worſt kind of deſpotiſm—the deſpotiſm of a low faction, they muſt increaſe the power of the king. "Alas! (continues he) what are my ſufferings, when in the heart of the capital, in the centre of knowledge, I ſee this miſguided people welcome, with a ferocious joy, the moſt criminal propoſitions, ſmile at the recital of murder, and celebrate their crimes as conqueſts!"

He had then ſeen comparatively but little; but he lived to ſee more—to ſee his countrymen celebrate, as virtues, crimes, compared with which the atrocities of 1790 appear almoſt as harmleſs. Being ſtripped of all his property, which was large, by the robbers of the revolution, he died in poverty in March 1796, and in the 84th year of his age.

Beſides the works which we have already mentioned, he wrote "A Hiſtory of the Parliament of England," and a "Hiſtory of the Stadholderate;" but theſe are both of them more remarkable for a ſpecious ſtyle and loftineſs of invention than for uſeful obſervation or ſolid argument. He wrote likewiſe "The Hiſtory of the Divorce of Catharine of Arragon by Henry the Eighth," which is not ſo much a recital of, and commentary upon, the fact from which he takes the title, as it is an able picture of univerſal Europe at that period, of the views, intereſts, and power, of all the different potentates. At the time of his death he was preparing a new edition of all his works, in which were to be made many alterations; and he is ſaid to have left among his manuſcripts a "Hiſtory of the Revocation of the Edict of Nantes," in four volumes; but it is alſo very certain, that, during the ſanguinary reign of Robeſpierre, he burnt a great part of his papers.

REAPING, the well known operation of cutting corn either by the ſickle or by the ſcythe. Reaping by the ſickle is by much the moſt common practice, and that which, we believe, prevails univerſally in Scotland; yet the other method, where it is practicable, is certainly the leaſt laborious, and by much the moſt expeditious. To the ſcythe, as an inſtrument of reaping, many objections are urged.

It is ſaid that it ſhakes the ear, ſo that many of the grains are loſt; that it lets the corn fall, after cutting it, in a confuſed and ſcattered ſtate, ſo that either much of it is loſt, or a great deal of time is conſumed in gathering it together; that it can only be made uſe of in land which is very even and free from ſtones; that it does not leave ſufficient length of ſtubble in the ground to lay the corn on when cut; that it mixes bad weeds with the corn, the ſeeds of which are ſown the next year; and, laſtly, that the uſe of the ſcythe is prejudicial to the health of the reaper.

Theſe objections, however, are either of no weight, or they are made by thoſe who are not acquainted with the ſcythes which have been adapted to this purpoſe, and with the proper manner of uſing them. With a good ſcythe, properly managed, the corn, after being cut, remains at firſt upright, and then falls very gently upon the rake fixed to the ſcythe, without any ſhake or jolt; or at leaſt with leſs than that which it receives when reaped with a ſickle. With reſpect to the loſs of grain, that proceeds chiefly from the corn being too dry; conſequently it ſhould be reaped only upon proper days, and proper times of the day, which is much more eaſily done with the ſcythe than with the ſickle, becauſe the work is ſo much ſhorter. The ſtalks, kept together by the rake, may be laid upon the ground, or rather againſt the corn not yet cut, in ſo regular and collected a ſtate, that thoſe who gather and tie the ſheaves, whether they are women or children, have nothing but their own negligence to accuſe if any thing is left behind. When land is properly ploughed and harrowed, it is ſufficiently even; and in ſuch as is ſtony, the only precaution neceſſary is to keep the ſcythe a little higher in uſing it, that it may not ſtrike againſt the ſtones. If the ſtubble left in the ground be ſhort, the ſtraw which is cut off will be the longer; and the latter is certainly of more value than the former, which only ſerves to incommode the cattle which afterwards go to feed in the field.

Theſe conſiderations, and others of a like nature, induced the patriotic ſociety of Milan to ſend, ſome years ago, to thoſe parts in which ſcythes are made uſe of for reaping; and having procured a model of a ſcythe from Sileſia, they cauſed one to be made of a proper ſize. It was firſt tried upon corn, and afterwards upon millet; and although the firſt ſcythe was not accurately made, and the reaper had never before made uſe of ſuch an inſtrument, yet it was found that nearly half the uſual time was ſaved, and that the labour and fatigue were much diminiſhed; the corn alſo was cut without receiving any ſhock that could be hurtful to it, and fell in an even and regular ſtate, ſo that it was afterwards eaſily bound up in compact ſheaves. They were afterwards preſented with a ſcythe ſomewhat different from the Sileſian, which is very generally uſed in Auſtria.

Plate XLII.

Theſe inſtruments are ſo ſimple, that the figure of one of them renders the deſcription of either almoſt unneceſſary. In fig. 1. is ſhewn the Sileſian ſcythe tried by the Society; the difference between that and the Auſtrian one we ſhall mention in our deſcription. The firſt, or Sileſian ſcythe, differs very little from the ſcythe we commonly uſe for mowing graſs, except that the blade is rather ſmaller; to it are added four teeth of wood, parallel to the blade, fixed and ſecured in a proper manner, and intended to keep the corn together after being cut, ſo that inſtead of its falling in a confuſed ſtate, the reaper may lay it down in a regular and compact one. The ſecond, or Auſtrian ſcythe, is ſimilar to the former, except that the blade is larger; conſequently the wooden teeth, of which there are five, are longer; the handle alſo is more flat, and rather crooked.

In the *firſt*, the handle *a b* (ſee fig. 1.) is two Milaneſe braſſes (A), and nine inches and a half in length; the

---

(A) One hundred Milaneſe *braſſes* are equal to fifty-eight Engliſh yards and a half.

the blade *b c* is one braſs three inches and a half; the piece of wood in which the teeth are fixed, one braſs one inch and a half. In the *ſecond*, the handle is two braſſes, and ſeven inches long; the blade, one braſs eleven inches; the piece in which the teeth are fixed, eleven inches and a quarter. The proportions of the other parts may be conceived from the figure.

The difference in the conſtruction of theſe two ſcythes makes it requiſite to uſe them in a different manner; but that will be better acquired in practice than by precept. Such of our countrymen as are accuſtomed to the uſe of the common ſcythe will very ſoon find out the moſt convenient and advantageous manner of uſing theſe new kinds of ſcythe, and of laying down the corn properly when cut.

It ſhould, however, be obſerved, that in mowing graſs the feet are kept almoſt parallel to each other, whereas in reaping corn they ſhould be kept upon a line, one behind the other, thruſting the right foot forward, and drawing the left towards it. This is neceſſary, becauſe when graſs is mowed it is left to fall juſt where it is cut; but when corn is cut, it is to be carried and laid in a proper manner againſt that which is not yet cut, and which is at the left hand of the reaper; and if the feet were kept parallel to each other, the reaper would be obliged to extend and turn his body in a very inconvenient manner.

After having made public theſe obſervations, the ſociety made farther experiments upon the ſubject; in which it was found, that when, on account of very wet weather, the ſtalks of the corn are bent down, the wooden teeth of the forementioned ſcythes are apt to lay hold of ſome ears, to the ſtalks of which the iron does not reach, and conſequently not being cut below, they are pulled ſo that the grain is ſcattered. This happens chiefly when the reapers, not being yet ſufficiently accuſtomed to that kind of ſcythe, do not know how to adapt it to particular circumſtances.

To remedy this inconvenience, it occurred to an ingenious blackſmith to add to the common ſcythe a *gatherer* or *collector* made of cloth, as may be ſeen at fig. 2. where *a b c* is a common ſcythe; *c d m l o f n e* is the gatherer; which at *c d e* is compoſed of a thin plate of iron, having at its extremity a hollow for receiving the point of the blade. At *e d* are holes for ſewing in the cloth, which is coarſe, light, and of low price; it is alſo fixed to two thick iron wires, of which the upper one is continued to *f*, where it terminates in a hole in the handle; the other is fixed to the back of the blade. The manner of fixing this gatherer to the blade of the ſcythe will be better underſtood by referring to fig. 3. which repreſents one of the irons which, by means of a ſcrew, are faſtened to the back of the ſcythe. Theſe irons proceed from, and make part of, the upright irons *m n*, *l o*, which ſerve to keep the gatherer extended.

This is a very ſimple and cheap contrivance; but an attempt was made to render it ſtill more ſimple, by ſubſtituting for the gatherer two iron hoops, which are ſhown in fig. 2. by the dotted lines *h g*, *k i*, with a croſs piece *p* which connects them. Experience, however, has ſhewn, that the gatherer is in general preferable to theſe hoops, as it does not leave an ear of corn behind.

RECTIFICATION of ether, a proceſs for depriving ether of its ſulphureous acid (See CHEMISTRY, *Index* in this *Suppl.*) It has been uſual to add an alkali for this purpoſe; but Dizé has found it much more advantageous to add a ſubſtance which might afford the requiſite quantity of oxygen to convert the ſulphureous into the ſulphuric acid; in which ſtate it is not diſpoſed to riſe and come over. Various metallic oxyds were tried, among which the black oxyd of manganeſe proved the beſt and the cheapeſt. His proceſs is as follows:

The ſulphureous acid contained in unrectified ether being neutralized with oxyd of manganeſe, the fluid is decanted into a pewter veſſel of the capacity of fifty ounces, which is placed on a water bath. To this veſſel a head and worm are adapted, the latter of which paſſes through a refrigeratory conſtantly ſupplied with water in a ſtream from below, which cauſes the heated water to flow off above. The diſtillation is then performed by raiſing the bath to a temperature of 36° (113° Fahrenheit, if the decimal thermometer be here meant). The rectification by this treatment uſually requires a day to complete it. The flavour of the ether is of the beſt kind, and the product about one-ſixth more than in the uſual method with retort and receiver. Dizé has practiſed this method with ſucceſs for three years.—*Journal de Phyſique, April*, 1798.

RECTIFICATION, in geometry, is the finding of a right line equal to a curve. The rectification of curves is a branch of the higher geometry, a branch in which the uſe of the inverſe method of fluxions is eſpecially uſeful.

TURKEY-RED, *Levant-Red*, and *Adrianople-Red*, the names indifferently given to that beautiful red dye which diſtinguiſhes the cotton manufactured in the Ottoman empire, and at *Aſtracan* in the dominions of Ruſſia. We have two accounts of the proceſs of communicating this dye to the ſtuffs; one by Profeſſor Pallas as he ſaw it practiſed at Aſtracan; the other in the 92d number of the *Annales de Chimie* by Citizen Felix. As every thing relating to uſeful manufactures is of general importance, we ſhall give pretty copious extracts from both papers.

According to Dr Pallas, the dye-ſtuffs employed at Aſtracan are, madder, ſumach, gall-nuts, alum, an inferior kind of ſoda, and fiſh-oil. The proceſs of dyeing is as follows:

The roots of the madder, when freſh gathered, are placed above each other in a ſtove, or in a pit dug in viſcous earth which has been ſtrongly heated. Earth is then thrown over the madder, and it muſt ſweat until the ſtove or pit becomes cold; when the roots, the ſecond or third day, are taken from it, and either ſpread out or hung up to dry. When it is thoroughly dried in the ſun, the madder is ground to a very fine powder, as are likewiſe the round leaves of the ſumach (*rhus cotinus*). The fiſh oil is boiled from the entrails of the ſturgeon and other large fiſhes; and the proof of its being proper for dyeing is, that when mixed with a lixivium of ſoda, it muſt immediately aſſume a milky appearance. Should that not be the caſe, it cannot be uſed by the dyers.

The cotton to be dyed red is firſt waſhed exceedingly clean in running water; and when the weather is clear, hung up on poles to dry. If it does not dry before the evening, it is taken into the houſe, on account

Turkey-Red.

of the ſaline dews ſo remarkable in the country around Aſtracan, and again expoſed to the air next morning. When it is thoroughly dry it is laid in a tub, and fiſh-oil is poured over it till it is entirely covered. In this ſtate it muſt ſtand all night; but in the morning it is hung up on poles, and left there the whole day; and this proceſs is repeated for a week, ſo that the cotton lies ſeven nights in oil, and is expoſed ſeven days to the atmoſphere, that it may imbibe the oil, and free itſelf from all air. The yarn is then again carried to a ſtream, cleaned as much as poſſible, and hung up on poles to dry.

After this preparation a mordant is made of three materials, which muſt give the grounds of the red colour. The pulveriſed leaves of the ſumach are firſt boiled in copper kettles; and when their colouring matter has been ſufficiently extracted, ſome powdered galls are added, with which the liquor muſt be again boiled; and by theſe means it acquires a dark dirty colour. After it has been ſufficiently boiled the fire is taken from under the kettle, and alum put into the ſtill hot liquor, where it is ſoon diſſolved. The proportion of theſe three ingredients cannot be aſcertained, as the dyers vary that proportion at pleaſure. The powder of the ſumach leaves is meaſured into the kettle with ladles; the water is poured in according to a gauge, on which marks are made to ſhew how high the water muſt ſtand in the kettle to ſoak ſix, eight, ten, &c. puds of cotton yarn. The galls and alum are added in the quantity of five pounds to each pud of cotton. In a word, the whole mordant muſt be ſufficiently yellow, ſtrong, and of an aſtringent taſte.

As ſoon as the alum is diſſolved, no time muſt be loſt in order that the mordant may not be ſuffered to cool. The yarn is then put into hollow blocks of wood ſhaped like a mortar, into each of which ſuch a quantity of the mordant has been poured as may be ſufficient to moiſten the yarn without any of it being left. As ſoon as the workman throws the mordant into the mortar, he puts a quantity of the yarn into it, and preſſes it down with his hand till it becomes uniformly moiſtened, and the whole cotton yarn has ſtruck. By this it acquires only a pale yellow colour, which, however, is durable. It is then hung up on poles in the ſun to dry; again waſhed in the ſtream, and afterwards dried once more.

The next part of the proceſs is to prepare the madder dye. The madder, ground to a fine powder, is ſpread out in large troughs, and into each trough is poured a large cupful of ſheep's blood, which is the kind that can be procured with the greateſt facility by the dyers. The madder muſt be ſtrongly mixed in it by means of the hand, and then ſtand ſome hours in order to be thoroughly ſoaked by it The liquor then aſſumes a dark red appearance, and the madder in boiling yields more dye.

After this proceſs water is made hot in large kettles, fixed in brickwork; and as ſoon as it is warm, the prepared red dye is put into it, in the proportion of a pound to every pound of cotton. The dye is then ſuffered to boil ſtrongly; and when it is enough, which may be tried on cotton threads, the fire is removed from under the kettle, and the prepared cotton is depoſited near it. The dyer places himſelf on the edge of the brickwork that incloſes the kettle; dips the cotton yarn, piece by piece, into the dye; turns it round backwards and forwards; preſſes it a little with his hands; and lays each piece, one after the other, in pails ſtanding ready for the purpoſe. As ſoon as all the cotton has received the firſt tint, it is hung up to dry; as the red, however, is ſtill too dull, the yarn, which has been already dyed once, and become dry, is put once more into the dyeing-kettle, and muſt be left there to ſeethe for three hours over a ſtrong fire; by which it acquires that beautiful dark red colour which is ſo much eſteemed in the Turkey yarn. The yarn is now taken from the dye with ſticks; the ſuperfluous dye which adheres to it is ſhaken off; the hanks are put in order, and hung up, one after another, to dry. When it is thoroughly dry, it is waſhed in the pure ſtream, and again dried.

Turkey-Red.

In the laſt place, the above-mentioned ſoda is diſſolved with boiling water in tubs deſtined for that purpoſe, and it is uſual at Aſtracan to allow 20 pounds of ſoda to 40 pounds of cotton, or half the weight. Large earthen jars, which are made in Perſia of very ſtrong clay, a yard and a half in height, almoſt five ſpans wide in the belly, and ending in a neck a ſpan and a half in diameter, incloſed by means of cement in brickwork over a fire-place, in ſuch a manner that the necks only appear, are filled with the dyed cotton yarn. The ley of diſſolved ſoda, which is blackiſh and very ſharp, is then poured over it till the jars be filled; and ſome clean rags are preſſed into their mouths, that the uppermoſt ſkains of yarn may not lie uncovered. A fire is then made in the fire place below, and continued for 24 hours; and in the mean time the ſteam which ariſes from the jars is ſeen collected among the rags in red drops. By this boiling the dye is ſtill more heightened, and is made to ſtrike completely; every thing ſuperfluous is removed, and all the fat matter which ſtill adheres to the yarn is waſhed out. Nothing more is then neceſſary for completing the dye of the yarn but to rinſe it well ſeveral times in running water, and then to dry it.

Cotton cloth is dyed with madder at Aſtracan in the ſame manner; but many purſue a fraudulent proceſs, by dyeing with red wood, and then ſell their cloth as that which has been dyed in the proper manner.

The proceſſes followed in the Grecian manufactories in the Levant, as deſcribed by M. Felix, varies in ſome particulars from this. The firſt proceſs is that of cleaning the cotton: for which purpoſe three leys are employed; one of ſoda, another of aſhes, and a third of lime. The cotton is thrown into a tub, and moiſtened with the liquor of the three leys in equal quantities: it is then boiled in pure water, and waſhed in running water.

The ſecond bath given to the cotton is compoſed of ſoda and ſheep's dung diſſolved in water. To facilitate the ſolution, the ſoda and dung are pounded in a mortar. The proportions of theſe ingredients employed, are one occa of dung, ſix of ſoda, and forty of water; each occa being equal to about fifty ounces. When the ingredients are well mixed, the liquor expreſſed from them is ſtrained; and being poured into a tub, ſix occas of olive oil are added to it, and the whole is well ſtirred till it becomes of a whitiſh colour like milk. The cotton is then beſprinkled with this water; and when the ſkains are thoroughly moiſtened, they are wrung,

wrung, preſſed, and expoſed to dry. The ſame bath muſt be repeated three or four times, becauſe it is this liquor which renders the cotton more or leſs fit for receiving the dye. Each bath is given with the ſame liquor, and ought to continue five or ſix hours. It is to be obſerved that the cotton, after each bath, muſt be dried without being waſhed, as it ought not to be rinſed till after the laſt bath. The cotton is then as white as if it had been bleached in the fields.

It may be ſuppoſed that the dung is of no utility for fixing the colours: but this ſuppoſition would be raſh; for, as M. Felix obſerves, it is well known that this ſubſtance contains a great quantity of volatile alkali in a diſengaged ſtate, which has the property of giving a roſy hue to the red. It is therefore probable that it is to this ingredient that the red dyes of the Levant are indebted for their ſplendour and vivacity. This much, at any rate, is certain, that the Morocco leather of the Levant is prepared with dog's dung; becauſe it has been found that this dung is proper for heightening the colour of the lack.

The proceſs of galling, which follows the bath of dung, is performed by immerſing the cotton in a bath of warm water, in which five occas of pulveriſed gall-nuts have been boiled. This operation renders the cotton more fit for being ſaturated with the colour, and gives to the dye more body and ſtrength. After the galling comes aluming, which is performed twice, with an interval of two days, and which conſiſts in dipping the cotton into a bath of water in which five occas of alum have been infuſed, mixed with five occas of water alkaliſed by a ley of ſoda. The aluming muſt be performed with care, as it is this operation which makes the colouring particles combine beſt with the cotton, and which ſecures them in part from the deſtructive action of the air. When the ſecond aluming is finiſhed, the cotton is wrung; it is then preſſed, and put to ſoak in running water, after being incloſed in a bag of thin cloth.

The workmen then proceed to the dyeing. To compoſe the colours, they put in a kettle five occas of water, and 35 occas of a root which the Greeks call *ali-zari*, or painting colour, and which in Europe is known under the name of *madder*. The madder, after being pulveriſed, is moiſtened with one occa of ox or ſheep's blood. The blood ſtrengthens the colour, and the doſe is increaſed or leſſened according to the ſhade of colour required. An equal heat is maintained below the kettle, but not too violent; and when the liquor ferments, and begins to grow warm, the ſkains are then gradually immerſed before the liquor becomes too hot. They are then tied with packthread to ſmall rods placed croſſwiſe above the kettle for that purpoſe; and when the liquor boils well, and in an uniform manner, the rods from which the ſkains were ſuſpended are removed, and the cotton is ſuffered to fall into the kettle, where it muſt remain till two-thirds of the water is evaporated. When one third only of the liquor remains, the cotton is taken out and waſhed in pure water.

The dye is afterwards brought to perfection by means of a bath alkaliſed with ſoda. This manipulation is the moſt difficult and the moſt delicate of the whole, becauſe it is that which gives the colour its tone. The cotton is thrown into this new bath, and made to boil over a ſteady fire till the colour aſſumes the required tint. The whole art conſiſts in catching the proper degree: a careful workman, therefore, muſt watch with the utmoſt attention for the moment when it is neceſſary to take out the cotton; and he will rather burn his hand than miſs that opportunity.

It appears that this bath, which the Greeks think of ſo much importance, might be ſupplied by a ley of ſoap; and it is probable that ſaponaceous water would give the colour more brightneſs and purity.

M. Felix ſeems doubtful whether the ali-zari of the Greeks be the ſame plant with the European madder. If it be, its ſuperiority muſt ariſe from the mode in which it is cultivated, and the method employed to dry it. The ali-zari is not collected till the fifth or ſixth year of its growth, when it has acquired its full ſtrength; and as it is the woody part of the roots which affords the greateſt quantity of colouring particles, this muſt give it an obvious ſuperiority over madder, which is collected before it has arrived at maturity. The mode of deſiccation contributes alſo, in the opinion of our author, to improve the quality of the ali-zari. The Levantines dry it in the open air; and this operation is eaſy in a country where great dryneſs prevails in the atmoſphere, while in our damp climates we are obliged to dry the madder by ſtoves. Hence it happens that the ſmoke, which mixes itſelf with the cold air, and penetrates the roots, impregnates them with fuliginous particles, which alter the colouring ſubſtance; an accident which does not take place when the madder is dried without the aſſiſtance of fire.

For the philoſophical principles of theſe proceſſes of dyeing, ſee *Animal and Vegetable* SUBSTANCES in this *Supplement*.

REDINTEGRATION, is the taking or finding the integral or fluent again from the fluxion. See FLUXIONS, *Encycl.*

REFLECTOR FOR A LIGHT-HOUSE, is compoſed of a number of ſquare plane glaſs mirrors, ſimilar to thoſe with which Archimedes is ſaid to have ſet fire to the Roman fleet at the ſiege of Syracuſe (See BURNING, *Encycl.*) Each of theſe mirrors is about an inch ſquare; and they are all diſpoſed cloſe to each other in the concave of a parabolic ſegment, formed of ſtucco or any other proper bed. Stucco has been found to anſwer the purpoſe beſt; and is accordingly employed in all the reflectors of the light-houſes erected by Mr Thomas Smith tinplate worker, Edinburgh, at the expence, and by the authority, of government. This ingenious and modeſt man ſeems to have conceived the idea of illuminating light-houſes by means of lamps and reflectors inſtead of coal-fires, without knowing that ſomething of the ſame kind had been long uſed in France; he has therefore all the merit of an inventor, and what he invented he has carried to a high degree of perfection.

His parabolic moulds are from three to five or ſix feet in diameter; and in the centre or apex of each is placed a long ſhallow lamp of tin-plate, filled with whale oil. In each lamp are ſix cotton wicks, almoſt contiguous to each other, which are ſo diſpoſed as to burn without trimming for about ſix hours. The light of theſe is reflected from each mirror ſpread over the concave ſurface, and is thus multiplied, as it were, by the number of mirrors. The ſtucco moulding is covered on the back with tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the

Reflector, Reflexity.

light room, and ſerves as a funnel, through which the ſmoke eſcapes without ſullying the faces of the mirrors. The light-room is a cupola or lantern of from eight to twelve ſides, compoſed entirely of glaſs, fixed in caſt-iron frames or ſaſhes, and roofed with copper. On circular benches paſſing round the inſide of this lantern, at about eighteen inches from the glaſs frames, are placed the reflectors with their lamps, ſo as that the concave ſurfaces of two or three of the reflectors front every point of the compaſs, and throw a blaze of light in all directions. In the roof immediately over the centre of the room is a hole, through which paſs all the funnels already mentioned, and which ſerves likewiſe to admit freſh air to the lamps. This light-room is firmly fixed on the top of a round tower ſo as to be immoveable by the weather; and the number of the reflectors, and the height of the tower, are leſs or greater according as it is the intention that the light ſhould be ſeen at a leſs or a greater diſtance.

A man judging from mere theory would be very apt to condemn light-houſes of this kind; becauſe the firmeſt building ſhakes in a violent ſtorm, and becauſe ſuch ſhaking, he might think, would ſometimes throw the whole rays of light into the air, and thus miſlead the bewildered ſeaman. This opinion, we know, was actually entertained of them by one of the profoundeſt philoſophers and moſt ſcientific mechanicians of the age. Experience, however, has convinced him, as well as the public at large, that ſuch apprehenſions are groundleſs, and that light-houſes with lamps and reflectors are, in every point of view, preferable to thoſe with fires burning in the open air. They are ſupported at much leſs expence; their light is more brilliant, and ſeen at a greater diſtance, whilſt it can never be obſcured by ſmoke, or beaten down on the lee-ſide by a violent guſt of wind; and what is perhaps of ſtill greater importance, the reflectors with their lamps may be ſo variouſly placed, that, as Mr Smith obſerves, one light-houſe cannot be miſtaken for another. If we add to all this, that the lamps do not ſtand in need of trimming ſo often as open fires require fuel, and that the light man is never expoſed either to cold or to wet by attending to his duty, we muſt be convinced that light-houſes with reflectors are much leſs liable to be neglected in ſtormy weather than thoſe with open fires, and that this circumſtance alone would be enough to give the former a preference, almoſt incalculable, over the latter.

It has been propoſed to make the concave ſurface of the parabola one ſpeculum of metal, inſtead of covering it over with a multitude of plain glaſs mirrors; or to diminiſh the ſize of each mirror, if they are to be retained in preference to the metallic ſpeculum. To every man who has but dipped into the ſcience of optics, it muſt be obvious, that either of theſe alterations would be wrong. The brighteſt metal does not reflect ſuch a quantity of light as well foliated clear glaſs; and were the ſize of the mirrors to be diminiſhed, the number of joinings would be increaſed, in each of which ſome light is loſt, not merely in the ſeam, but from its being almoſt impoſſible to foliate glaſs perfectly at its edge.

REFLEXITY, a word employed by Mr Brougham to denote a property of light which cauſes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, inflected, and deflected, at different diſtances. This property follows the ſame law that the other optical properties of light follow: the red ray having moſt reflexity, and the violet leaſt (See *Philoſophical Tranſactions*, 1797, p. 360.) Mr Brougham has denoted this property by the three words, *refrangity*, *reflexity*, and *flexity*; but as the power is the ſame, there is no occaſion for different names. Some philoſophers have refuſed to admit this as a new property; we have not verified it by experiment.

Refraction

REFRACTION OF ALTITUDE, is the arc or portion of a vertical circle, by which the altitude of a ſtar is increaſed by the refraction of light.

REFRACTION of Aſcenſion and Deſcenſion, is an arc of the equator, by which the aſcenſion and deſcenſion of a ſtar, whether right or oblique, is increaſed or diminiſhed by the refraction.

REFRACTION of Declination, is an arc of a circle of declination, by which the declination of a ſtar is increaſed or diminiſhed by refraction.

REFRACTION of Latitude, is an arc of a circle of latitude, by which the latitude of a ſtar is increaſed or diminiſhed by the refraction.

REFRACTION of Longitude, is an arc of the ecliptic, by which the longitude of a ſtar is increaſed or diminiſhed by means of the refraction.

Terreſtrial REFRACTION, is that by which terreſtrial objects appear to be raiſed higher than they really are, in obſerving their altitudes. The quantity of this refraction is eſtimated by Dr Maſkelyne at one tenth; by Le Gendre at one-fourteenth; by De Lambre at one-eleventh; and by others at a twelfth of the diſtance of the object obſerved, expreſſed in degrees of a great circle. But it is obvious that there can be no fixed quantity of this refraction, ſince it depends upon the ſtate of the atmoſphere, which is extremely variable. Hence ſome very ſingular effects of it are related, of which the following is worthy of notice. It is taken from the Philoſophical Tranſactions of London 1798; being an extract of a letter, dated Haſtings, Auguſt 1. 1797.

"On Wedneſday, July 26, about five o'clock in the afternoon, while I was ſitting in my dining room at this place, which is ſituated upon the Parade, cloſe to the ſea ſhore, nearly fronting the ſouth, my attention was excited by a number of people running down to the ſea-ſide. Upon enquiring the reaſon, I was informed that the coaſt of France was plainly to be diſtinguiſhed by the naked eye. I immediately went down to the ſhore, and was ſurpriſed to find that, even without the aſſiſtance of a teleſcope, I could very plainly ſee the cliffs on the oppoſite coaſt; which, at the neareſt part, are between 40 and 50 miles diſtant, and are not to be diſcerned, from that low ſituation, by the aid of the beſt glaſſes. They appeared to be only a few miles off, and ſeemed to extend for ſome leagues along the coaſt. I purſued my walk along the ſhore eaſtward, cloſe to the water's edge, converſing with the ſailors and fiſhermen upon the ſubject. They at firſt could not be perſuaded of the reality of the appearance; but they ſoon became ſo thoroughly convinced, by the cliffs gradually appearing more elevated, and approaching nearer, as it were, that they pointed out and named to me the different places they had been accuſtomed to viſit; ſuch as the Bay, the Old Head or Man, the Windmill, &c. at Boulogne; St Vallery, and other places on the coaſt of Picardy; which they aftewards confirmed when they viewed them through their teleſcopes. Their obſervations were, that the places appeared as near as if they were ſailing, at a ſmall diſtance, into the harbours."

The writer of this extract was W. Latham, Eſq; F. R. S. and A. S. who adds, that the day was extremely hot, that it was high water at Haſtings about two o'clock P. M. and that not a breath of wind was ſtirring the whole day.

REGIS (Peter Sylvain), a French philoſopher, and great propagator of Carteſianiſm, was born in Agenois 1632. He cultivated the languages and philoſophy under the Jeſuits at Cahors, and afterwards divinity in the univerſity of that town, being deſigned for the church. He made ſo uncommon a progreſs, that at the end of four years he was offered a doctor's degree without the uſual charges; but he did not think it became him to accept of it till he had ſtudied alſo in the Sorbonne at Paris. He went thither, but was ſoon diſguſted with theology; and as the philoſophy of Des Cartes began at that time to make a noiſe through the lectures of Rohault, he conceived a taſte for it, and gave himſelf up entirely to it. He frequented theſe lectures; and becoming an adept, went to Toulouſe in 1665, and read lectures in it himſelf. Having fine parts, a clear and fluent manner, and a happy way of making himſelf underſtood, he drew all ſorts of people; the magiſtrates, the learned, the eccleſiaſtics, and the very women, who now all affected to abjure the ancient philoſophy. In 1680 he returned to Paris; where the concourſe about him was ſuch, that the ſticklers for Peripateticiſm began to be alarmed. They applied to the archbiſhop of Paris, who thought it expedient, in the name of the king, to put a ſtop to the lectures; which accordingly were diſcontinued for ſeveral months. The whole life of Regis was ſpent in propagating the new philoſophy. In 1690 he publiſhed a formal ſyſtem of it, containing logic, metaphyſics, phyſics, and morals, in 3 vols 4to, and written in French. It was reprinted the year after at Amſterdam, with the addition of a diſcourſe upon ancient and modern philoſophy. He wrote afterwards ſeveral pieces in defence of his ſyſtem; in which he had diſputes with M. Huet, Du Hamel, Malebranche, and others. His works, though abounding with ingenuity and learning, have been diſregarded, in conſequence of the great diſcoveries and advancement in philoſophic knowledge that have been ſince made. He died in 1707. He had been choſen member of the academy of ſciences in 1699*.

REGULAR BODY, called alſo *Platonic Body*, is a body or ſolid comprehended by like, equal, and regular plane figures, and whoſe ſolid angles are all equal.

The plane figures by which the ſolid is contained are the faces of the ſolid; and the ſides of the plane figures are the edges, or linear ſides of the ſolid.

There are only five regular ſolids, viz.

The tetrahedron, or regular triangular pyramid, having four triangular faces;
The hexahedron, or cube, having ſix ſquare faces;
The octahedron, having eight triangular faces;
The dodecahedron, having twelve pentagonal faces;
The icoſahedron, having twenty triangular faces.

Beſides theſe five, there can be no other regular bodies in nature. See PLATONIC *Body*, Suppl.

REGULUS, in aſtronomy, a ſtar of the firſt magnitude, in the conſtellation Leo; called alſo, from its ſituation, *Cor Leonis*, or the *Lion's Heart*; by the Arabs, *Alhabor*; and by the Chaldeans, *Kalbeleced*, or *Karbeleceid*; from an opinion of its influencing the affairs of the heavens.

Reid.

REID (Thomas, D. D.), ſo well known to the public by his moral and metaphyſical writings, was the ſon of the Rev. Lewis Reid, miniſter of the pariſh of Strachan, in the county of Kincardine, North Britain. His mother was the daughter of David Gregory, Eſq; of Kinardie, of whom ſome account has been given in this *Supplement*, and ſiſter to David, James, and Charles Gregories, who were at the ſame time profeſſors of aſtronomy, or mathematics, in the univerſities of Oxford, Edinburgh, and St Andrews.

He was born at the parſonage-houſe of Strachan in April 1710, and received the rudiments of his education at the pariſh ſchool of Kincardine-oniel. At that period the parochial ſchools of Scotland were very ſuperior to what they are now; and young men went from them to the univerſity well furniſhed with philological learning. The progreſs of young Reid muſt have been rapid; for he was removed from ſchool to the Mariſchal College, Aberdeen, when not more than twelve years of age; and we have never heard that he was admitted into the univerſity before he was qualified to profit by the lectures of the profeſſors. On the contrary, he ſoon diſplayed the genius of his mother's family, and ſhone conſpicuous among the ſtudents of mathematics in a college where that ſcience has been at all times cultivated with ardour and ſucceſs.

After the uſual courſe of four years employed in the ſtudy of Latin, Greek, Mathematics, and Philoſophy, he probably took his degree of M. A. which at that period, and for a long time ſubſequent to it, was the univerſal practice in the univerſity of Aberdeen, and then commenced the ſtudy of theology. In due time he was licenſed to preach the goſpel according to the forms of the church of Scotland; but continued to reſide for ſome years in Aberdeen, cultivating his favourite ſcience, mathematics.

The mathematical chair in Mariſchal College was then filled by Mr John Stuart, a man of great eminence in his profeſſion; but who, like many other profound mathematicians, was not happy in his mode of communicating ſcience, at leaſt to the duller part of his pupils. Mr Reid occaſionally read lectures for the profeſſor; and a friend of our's, by no means dull, has often been heard to expreſs great ſatisfaction that Mr Stuart was kept a whole winter from the ſchools, when he was a ſtudent, and that the claſs was taught by Mr Reid. "Had it not been for this circumſtance (ſaid he) I ſhould never have underſtood more of mathematics than the firſt ſix books of Euclid's elements; but Mr Reid had the faculty of making every thing intelligible to the ſtudents which he clearly apprehended himſelf."

He could not, however, ſpend his life in the ſtudy of mathematics, and in reading barren lectures for other men. He had been educated for the church; and it was in the church only that he had the proſpect of gaining a livelihood. He was accordingly preſented, we know not in what year, to the church of *New-Machar* in Aberdeenſhire, at a time when the good people of Scotland were very far from being reconciled to the rights of patronage; and the conſequence was,

that

that his ſettlement met with much popular oppoſition. Even a little riot took place in the church at his ordination; but he ſoon gained the affections of his flock by his good ſenſe, his acknowledged worth, and his unwearied attention to all their wants, which he was ever ready to relieve to the utmoſt extent of his abilities. So deeply rooted indeed was their regard for him at laſt, that, though it is now almoſt half a century ſince his relation to the pariſh of New Machar ceaſed, his memory continues to be revered in that pariſh even at the preſent day; and the following anecdote evinces that it is not revered without reaſon.

A man who, from being in decent circumſtances, and a member of the kirk ſeſſion (See PRESBYTERIANS, *Encycl.*), when Dr Reid was miniſter, had become, in his old age, poor and infirm, obſerved to the then miniſter of the pariſh, that if he were able to go to Glaſgow, and make his caſe known to his old friend and paſtor, he was ſure that he would get ſomething done for him. This obſervation was reported to the Doctor, who inſtantly recollected the man, though, in all probability, he had not thought of him for thirty years; and he ſettled upon him an annual penſion of ten pounds, which was punctually paid as long as they both lived. The pride of ſcience had not from the mind of this great man eradicated the amiable ſympathies of humanity, nor had his philoſophic fame made him overlook the unaſpiring duties of the Chriſtian paſtor.

In the year 1751, about the beginning of the ſeſſion or annual term, one of the profeſſors of philoſophy in King's College, Aberdeen, died; and his death being unexpected, preſented to the other members of that learned body ſome difficulty in carrying on the uſual courſe of education for that year. At this our readers will not be ſurpriſed, when they reflect on the mode in which ſcience was taught in that univerſity; for he who could with propriety be placed in the vacant chair, muſt have been qualified, without much previous preparation, to read lectures on LOGIC, ONTOLOGY, PNEUMATICS, MORALS, POLITICS, MATHEMATICS, and NATURAL PHILOSOPHY (See GERARD, in this *Suppl.*). In ſuch a place as Aberdeen, it is hardly to be ſuppoſed that there was a ſingle man unemployed, ſo completely maſter of all theſe branches of ſcience, as to take up the claſs where it was dropt by the deceaſed profeſſor, and carry it ſucceſsfully through that ſcience, whatever it might be, in which, at his death, he chanced to be lecturing. It occurred, however, to the principal, and ſome of the profeſſors, that the miniſter of New Machar was fully equal to the taſk; and the late Dr John Gregory, then profeſſor of medicine, and the Rev. Dr Macleod, the preſent ſubprincipal of King's College, were deputed to viſit Mr Reid, and requeſt his immediate acceptance of the vacant profeſſorſhip. He yielded to the requeſt not without ſome heſitation, and was admitted profeſſor of philoſophy on the 22d of November.

He was now in the very ſituation for which Nature ſeemed to have intended him. He had not only an opportunity, but it was his duty to cultivate the ſcience to which his attachment was ſo ſtrong; and the duties of his office made him turn his attention more cloſely than he had hitherto done to another ſcience, in which he was deſtined to make a more conſpicuous figure than he ever made even in his favourite mathematics.

It was during his profeſſorſhip in the univerſity of Aberdeen that he wrote his "Eſſay on Quantity," which was publiſhed in the 45th volume of the Philoſophical Tranſactions, and is perhaps the fineſt ſpecimen of metaphyſical mathematics, if we may uſe ſuch an expreſſion, that is extant in our own or in any other language (See QUANTITY, *Encycl.*). It was during the ſame period that he publiſhed his "Inquiry into the Human Mind on the Principles of Common Senſe;" a work of unqueſtionable merit, which has contributed more than any other work whatever to give a rational turn to metaphyſical ſpeculations. It was about this period that the degree of D. D. was conferred upon him by his mother-college.

The well-earned fame of Dr Reid attracted the attention of the univerſity of Glaſgow to him as the fitteſt perſon to ſucceed the celebrated Dr Adam Smith; and he was admitted profeſſor of moral philoſophy in that univerſity on the 11th of June 1764. There his attention was not diſtracted by a multitude of ſciences, which it was his duty to teach; and he had leiſure to improve his metaphyſical ſyſtem, though he continued through life to amuſe himſelf occaſionally with mathematical ſpeculations.

In the year 1773 appeared, in Lord Kames's "Sketches of the Hiſtory of Man, a brief Account of Ariſtotle's Logic; with remarks by Dr Reid." It would ſeem that he had entered upon this taſk rather reluctantly, and merely in compliance with the ſolicitations of his friend, the author of the Sketches. "In attempting (ſays he) to give ſome account of the analytics, and of the topics of Ariſtotle, ingenuity requires me to confeſs, that though I have often purpoſed to read the whole with care, and to underſtand what is intelligible, yet my courage and patience always failed before I had done. Why ſhould I throw away ſo much time and painful attention upon a thing of ſo little uſe? If I had lived in thoſe ages when the knowledge of Ariſtotle's Organon intitled a man to the higheſt rank in philoſophy, ambition might have induced me to employ upon it ſome years of painful ſtudy; and leſs, I conceive, would not be ſufficient. Such reflections as theſe always got the better of my reſolution, when the firſt ardour began to cool. All I can ſay is, that I have read ſome parts of the different books with care, ſome ſlightly, and ſome perhaps not at all. I have glanced over the whole often; and when any thing attracted my attention, have dipped into it till my appetite was ſatisfied."

Notwithſtanding this modeſt acknowledgment, we are not ſure that any one of Dr Reid's publications does him greater honour than his very perſpicuous view of this ſtupendous ſyſtem. Having ourſelves occaſionally looked into the writings of Ariſtotle, we ſhould not heſitate to ſay, that it is by much the beſt analyſis of theſe writings that we have anywhere met with, even though we could not corroborate our own opinion by that of other men much more converſant than we are with the oracular language of the Stagyrite. But when it is known that the late Dr Doig of Stirling, to whom Greek was as familiar as his mother tongue, and an equally learned Doctor of Oxford, who has been reading Ariſtotle ever ſince he was fourteen years of age, agreed in opinion, that a more accurate view of his logic could not be given in the ſame compaſs than had been given by Dr Reid, we may ſurely affirm, with ſome degree of confidence, that this ſmall work adds much to the fame of our celebrated countryman.

Though Dr Reid's health continued good, and his mental faculties unimpaired, till a very ſhort time before his death, he ceaſed for ſome years to read lectures from his profeſſorial chair, employing that time in preparations for eternity, and in fitting his lectures for the preſs. Theſe were publiſhed in two volumes 4to: the the firſt in 1785, under the title of "Eſſays on the Intellectual Powers of Man," dedicated to his friends Dr Gregory and Profeſſor Stewart, both of the univerſity of Edinburgh; and the ſecond in 1788, under the title of "Eſſays on the Active Powers of Man," without any dedication or preface. He continued to enjoy the fame acquired by this work, as well as the affection of his friends and the reverence of the public, for eight years, dying at Glaſgow in the end of September, or the beginning of October 1796, in the 87th year of his age. He had been married, and he left behind him one daughter.

To do juſtice to the biography of ſuch a man as this, we ſhould here attempt to draw his intellectual character, and to appreciate the merits of his works; but to perform this taſk in a manner at all worthy of him, or we hope of ourſelves, would require more room than our limits permit us to allot to any article of the kind; and our readers will be pleaſed to learn, that they may confidently expect an account of his life, with a critique on his works, by a man better qualified to do juſtice to both, than the writer of this ſhort ſketch pretends to be. His works are in the hands of the ſpeculative public; and by that public will be duly valued, as long as ſound ſenſe ſhall be preferred to impious jargon. How long that may be, God only knows; but if any thing can guard the minds of our youth againſt that ſophiſtry of which the object is to attribute real agency to material fluids, and to repreſent the elective attractions of chemiſtry as perfectly ſimilar to human volitions, it will be the unbiaſſed ſtudy of Dr Reid's "Eſſays on the Intellectual and Active Powers of Man." They will there find metaphyſics diveſted of myſtery, and the profoundeſt ſpeculations rendered intelligible by the conſtant uſe of words in one determined ſenſe. We think, indeed, that in this conſiſts the Doctor's chief merit; for, except when treating of our notions of power, he ſeems not to have added much to what certainly *may be* found in the writings of Locke.

Let not our readers ſuppoſe, that by this obſervation we wiſh to detract in the ſmalleſt degree from our author's fame, or to leſſen him by compariſon with the Engliſh philoſopher. If on mere topics of ſpeculative ſcience, he appears to us to have thought as Locke thought, it is on the other hand certain, that the greater part of Locke's doctrines may be gleaned from the logical and metaphyſical writings of Bacon, Hobbes, and Des Cartes. Nor need this ſurpriſe any one; for he who reflects a moment on the ſubject, muſt perceive that ſuch a coincidence of thought in metaphyſical ſcience is among men of eminence almoſt inevitable. Of mind and its powers—the ſubject of that ſcience—we neither know, nor can know any thing, but by patiently attending to the operations of our own minds, when we ſee, hear, feel, think, reaſon, and will, &c.: and it is obvious, that every man who is capable of ſuch patient attention, and does not labour under the bias of ſome prejudice, muſt view theſe operations in the ſame way. The great ſuperiority of Dr Reid over his predeceſſors, in this department of ſcience, appears to have been this, that he apprehended the operations of his own mind with a clearneſs, which gave to his language a preciſion and perſpicuity which the language of Locke certainly does not poſſeſs.

In the Eſſay on the Human Underſtanding, the term *idea* ſometimes ſignifies a material ſubſtance, ſometimes the qualities of that ſubſtance, ſometimes the conception of theſe qualities, ſometimes the power or faculty of the mind by which we conceive a thing, ſometimes a perception of ſenſe, and ſometimes an intellectual notion. Hence the ambiguity of terms which runs thro' the whole of that immortal work, has furniſhed both the author's friends and his enemies with an opportunity of attributing to him pernicious doctrines, which we are perſuaded he did not maintain, and which, we think, a patient analyſis of the eſſay muſt *convince every man* that he did not maintain. From this ambiguity the writings of Dr Reid are perfectly free. His doctrines, whether well or ill-founded, can never be miſunderſtood by him who is deſirous to underſtand them; and he who knows how much perſpicuity of ſtyle depends upon accuracy of thinking, will not deem us enemies to his fame for having ſaid that his chief merit conſiſts in the preciſion of his language.

He has been much cenſured by ſome, and much applauded by others, for introducing the phraſe *common ſenſe* into ſpeculative philoſophy, as the proper name of that faculty of the mind by which we apprehend firſt truths; but he is on this account entitled neither to praiſe nor to cenſure. He adopted the phraſe from others; and has proved, by the moſt unexceptionable authorities, both ancient and modern, that it may with great propriety be uſed as he has uſed it. Whether the adopting of it into works of ſcience was neceſſary, is another queſtion, on which we have given our opinion elſewhere; it is ſufficient in this place to vindicate his uſe of it, eſpecially in his latter works, from ambiguity.

Candour obliges us to acknowledge, that he has advanced ſome doctrines which we cannot admit as true. Though not in general partial to Locke, he has adopted his notions reſpecting our power of abſtraction, with hardly any other variation than the ſubſtituting of the term *conceptions* for Locke's favourite phraſe *ideas*. He has likewiſe endeavoured to prove, that we may diſtinctly conceive what cannot poſſibly exiſt. Theſe miſtakes, for ſuch they appear to us, we have pointed out elſewhere (See METAPHYSICS, Part I. Chap. iii. and iv. *Encycl.*); but they are infinitely more than counterbalanced by his clear, accurate, and ſatisfactory diſquiſitions on our notions of active power. Had Dr Reid never written a ſentence but the eſſay which treats of this delicate and important ſubject, he would have been entitled to a place in the very firſt rank of uſeful metaphyſicians; for, previous to the appearance of his works, we had nothing written directly on *power* but contradictory and unintelligible jargon. We recommend the ſerious peruſal of this eſſay, the firſt in his ſecond volume, to ſuch of our readers as fancy that they diſtinctly conceive the powers of chemical agents, and that intelligence and volition may reſult from any mechanical organization, or any combination whatever of matter and motion.

REISKE (John James), a moſt profound ſcholar and ſagacious critic, was born in 1706 at a ſmall town of the duchy of Anhalt. After ſtruggling with ſome difficulties in his ſchool education, in which, however, he, by perſeverance, obtained conſiderable advantages, he went, in 1733, to Leipſic; where he continued, for the ſake of ſtudy, five years. Here he accompliſhed himſelf in Arabic, and tranſlated and publiſhed a book from that language. In order to proſecute his ſtudy of Arabic with greater effect, he travelled on foot, and with many difficulties, to Leyden. Here he was employed in arranging the Arabic manuſcripts, for which, however, he received a very ſcanty compenſation; and here alſo he tranſlated from the German and French, into Latin, various eſſays ſent him by Dorville, whom he had viſited in his journey, and who afterwards inſerted theſe papers in the *Miſcellanea Critica*. Dorville was ſo well pleaſed with his ſkill and diligence, that he employed him in more important concerns. At his deſire, Reiſke tranſlated the whole of the Chariton from the Greek, and the Geography of Abulfeda from the Arabic, into Latin. At Leyden he continued for the ſpace of eight years; where a ſtorm of jealouſy and calumny, excited againſt him by the younger Burman, finally induced him to change his reſidence. This was principally owing to the freedom he uſed with reſpect to the edition of Petronius, edited by the younger Burman at Leyden; however, before he quitted it, he took the degree of doctor of phyſic, which was given him in a manner which did him the higheſt honour. He then viſited different parts of Germany, till he at length ſettled at Leipſic a ſecond time. Here, for twelve years, notwithſtanding he was made profeſſor of Arabic, he experienced all the inconveniences of poverty, and was obliged to undergo a great deal of drudgery for bookſellers, and the editors of periodical publications, to procure a ſubſiſtence; at this period, in particular, the *Acta Eruditorum* were greatly indebted to him. Amidſt all theſe hardſhips, however, he found opportunity to write, and to publiſh, his *Animadverſiones in Auctores Græcos*, in five volumes; a work of extraordinary learning and merit. In 1758, by the death of Haltauſius, he obtained a ſituation at once honourable and lucrative, which placed him above want, and enabled him to follow his favourite purſuits at eaſe. He was made rector of the academy at Leipſic, in which office he continued till the time of his death. In 1764, he married Erneſtina Chriſtina Muller, a woman of wonderful attainments, whoſe knowledge was hardly inferior to his own, and particularly in Greek literature. She aſſiſted him in all his literary labours, and eſpecially in his immortal work of the "Edition of the Greek Orators." Thus, in the manner moſt grateful to himſelf, Reiſke conſumed the remainder of his life, which continued till 1774, when he died poſſeſſed of the higheſt reputation. The number of works which he ſuperintended and publiſhed is very great; but it will be ſufficient to name thoſe which are moſt ſought after and eſteemed. Theſe are, the "Remarks upon Greek Authors," before mentioned. An "Edition of the Greek Orators," in 12 vols 8vo, which was finiſhed by his widow. "Dionyſius Halicarnaſſenſis," in 7 vols. "Plutarch's Works," in 9 vols. "Theocritus, &c. &c." This John James Reiſke muſt not be confounded with *John Reiſke*, rector of the college of Wolfenbuttel, who was alſo a learned man, and publiſhed various works*.

REMONSTRANTS, in church hiſtory, a title given to the ARMINIANS (See that article, *Encycl.*) by reaſon of the remonſtrance which, in 1610, they made to the States of Holland, againſt the ſentence of the ſynod of Dort, which condemned them as heretics. Epiſcopius and Grotius were at the head of the *Remonſtrants*, whoſe principles were firſt openly patroniſed in England by Archbiſhop Laud. In Holland, the patrons of Calviniſm preſented an addreſs in oppoſition to the remonſtrance of the Arminians, and called it a counter-remonſtrance. Hence the Dutch Calviniſts were termed *Counter remonſtrants*. Much controverſy was carried on by theſe rival ſects, which, on the ſide of the Calviniſts, was extremely illiberal.

REMORA, or SUCKING FISH, a ſpecies of ECHENEIS (See *Encycl.*), M. Vaillant found, upon different parts of his enormous *ray* (See RAJA in this *Suppl.*) about twenty ſmall ſucking fiſh, or *remoras*, faſtened ſo firmly, that they did not drop off when he was hoiſted on board. Some naturaliſts have ſaid, that the head of the ſucking fiſh is viſcous on the lower part, and furniſhed with rough points ſimilar to the teeth of a file; and, according to them, it is by means of theſe two qualities, its roughneſs and viſcoſity, that it is enabled to adhere to other fiſh.

"Figure to yourſelf (ſays one of them) a row of nineteen ſharp-edged and dentated laminæ, placed croſſwiſe, and iſſuing immediately from the rim of the lower jaw, and you will have a juſt idea of the part with which the remora makes itſelf faſt."

This deſcription (ſays Vaillant) is exact as far as relates to the figure and number of the dentated laminæ; but it places them on the lower part of the head, whereas they are, in reality, on the upper. Accordingly, when the remora fixes itſelf, it is obliged to turn upon its back, with its belly upward.

If the two white fiſh, however, that poſted themſelves on the arms of the *ray*, and ſerved him as pilots, be of the remora ſpecies, as he is inclined to think, the laminæ by which that variety adheres to other fiſhes muſt be on the lower part of the body, ſince the two pilots continued in their natural poſition, and had no occaſion to turn over to fix themſelves at their poſt.

REPETEND, in arithmetic, denotes that part of an infinite decimal fraction, which is continually repeated *ad infinitum*. Thus in the numbers 2·13 13 13 &c. the figures 13 are the repetend, and marked thus $\dot{1}\dot{3}$.

REPUBLICANS, the name given by Vaillant, with ſome propriety, to a kind of birds which were obſerved in South Africa, both by him and Paterſon, to inhabit apparently the ſame enormous neſt. Cutting one of theſe neſts in pieces with a hatchet, he perceived that the principal and fundamental piece conſiſted of a maſs of ſtrong coarſe graſs (called by the Hottentots *Boſhmen's graſs*), without any mixture, but ſo compact and firmly knit together as to be impenetrable to the rain. This nucleus is the commencement of the ſtructure; and each bird builds and applies to it its particular neſt. But theſe cells are formed only beneath and around the maſs; the upper ſurface remains void, without, however, being uſeleſs; for, as it has a pro-

---

* *Biog. Dict.* new edit.

jecting rim, and is a little inclined, it ſerves to let the water run off, and preſerves each dwelling from the rain. Figure to yourſelf a huge irregular maſs, the ſummit forming a kind of roof, and all the other parts of the ſurface completely covered with cells ſqueezed one againſt another, and you will have a tolerably accurate idea of theſe ſingular edifices.

Each cell is three or four inches in diameter, which is ſufficient for the bird. But as they are all in contact with one another through the greater part of the ſurface of the maſs, they appear to the eye to form but one building, and are diſtinguiſhable from each other only by a little external aperture, which ſerves as an entrance to the neſt; and even this is ſometimes common to three different neſts, one of which is ſituated at the bottom, and the other two at the ſides.

The neſt which he examined contained 320 inhabited cells, which, ſuppoſing a male and female to each, announce a ſociety of 640 individuals. Such a calculation, however, would not be exact; for whenever our author fired at a flock of theſe birds, he always killed four times as many females as males. "For the reſt (ſays he), theſe birds have nothing very remarkable in their plumage. It is an uniform brown grey, diverſified by a few black ſpots on the ſides, and a large patch of the ſame colour on the throat. The male is a little larger than the female; in other reſpects they exactly reſemble each other."

RESIDUAL ANALYSIS, a calculus propoſed by the inventor, Mr Landen, as a ſubſtitute for the method of fluxions. The object of this ſubſtitution was to avoid introducing the idea of motion, and of quantities infinitely or indefinitely ſmall, into mathematical inveſtigation. The reſidual analyſis accordingly proceeds, by taking the difference of the ſame function of a variable quantity in two different ſtates of that quantity, and expreſſing the relation of this difference to the difference between the two ſtates of the ſaid variable quantity itſelf. This relation being firſt expreſſed generally, is then conſidered in the caſe when the difference of the two ſtates of the variable quantity is $= 0$; and by that means it is evident, that the ſame thing is done as when the fluxion of a function of a variable quantity is aſſigned by the ordinary methods.

The evolution of the functions, conſidered in this very general view, requires the aſſiſtance of a new theorem, diſcovered by Mr Landen, and remarkable for its ſimplicity, as well as its great extent. It is, that if x and v are any two variable quantities, $\frac{x^{\frac{m}{n}} - v^{\frac{m}{n}}}{x - v}$

$$= x^{\frac{m}{n} - 1} \times \frac{1 + \frac{v}{x} + \frac{v^2}{x^2} + \frac{v^3}{x^3} + \cdots (m)}{1 + \left(\frac{v}{x}\right)^{\frac{m}{n}} + \left(\frac{v}{x}\right)^{\frac{2m}{n}} + \left(\frac{v}{x}\right)^{\frac{3m}{n}} \cdots (n)}$$

where m and n are any integer numbers.

This theorem is the baſis of the calculus; and from the expreſſions $x^{\frac{m}{n}} - v^{\frac{m}{n}}$, and $x - v$ having the form of what algebraiſts call *reſiduals*, the ingenious inventor gave to his whole method the name of the *reſidual analyſis*.

The firſt account of this method was publiſhed by Mr Landen in 1758, under the title of a *Diſcourſe concerning the Reſidual Analyſis*. The firſt book of the Reſidual Analyſis itſelf was publiſhed in 1764; and contained an explanation of the principles of the new calculus, with its application to ſeveral of the moſt conſiderable problems belonging to the direct method of fluxions. The ſecond book was intended to give the ſolution of many of the moſt difficult problems that belong to the inverſe method of fluxions, or to the integral calculus; but it has never been publiſhed: a circumſtance which every one, who has taken the trouble to ſtudy the firſt part of the work, will very much regret.

If we eſtimate the value of the reſidual analyſis from the genius, profound knowledge, and extenſive views required to the diſcovery of it, it will rank high among works of invention: but if, on the other hand, we eſtimate its value by its real practical utility, as an inſtrument of inveſtigation, we muſt rate it much lower. When compared with the fluxionary calculus, which it was intended to ſuperſede, its principles, though in appearance more rigorous, are much leſs eaſily apprehended, much leſs luminous, and leſs direct in their application; and therefore, as a means of extending the bounds of mathematical ſcience, it muſt ever be regarded as vaſtly inferior to the latter (A).

RETICULA, or RETICULE, in aſtronomy, a contrivance for meaſuring very nicely the quantity of eclipſes, &c. This inſtrument, introduced ſome years ſince by the Paris Academy of Sciences, is a little frame, conſiſting of 13 fine ſilken threads, parallel to, and equidiſtant from, each other, placed in the focus of object-glaſſes of teleſcopes; that is, in the place where the image of the luminary is painted in its full extent. Conſequently the diameter of the ſun or moon is thus ſeen divided into 12 equal parts or digits: ſo that, to find the quantity of the eclipſe, there is nothing to do but to number the parts that are dark, or that are luminous. As a ſquare reticule is only proper for the diameter of the luminary, not for the circumference of it, it is ſometimes made circular, by drawing ſix concentric equidiſtant circles, which repreſents the phaſes of the eclipſe perfectly. But it is evident that the reticule, whether ſquare or circular, ought to be perfectly equal to the diameter or circumference of the ſun or ſtar, ſuch as it appears in the focus of the glaſs; otherwiſe the diviſion cannot be juſt. Now this is no eaſy matter to effect, becauſe the apparent diameter of the ſun and moon differs in each eclipſe; nay, that of the moon differs from itſelf in the progreſs of the ſame eclipſe. Another imperfection in the reticule is, that its magnitude is determined by that of the image in the focus; and of conſequence it will only fit one certain magnitude. See MICROMETER, *Encycl.*

REVETEMENT, in fortification, a ſtrong wall built on the outſide of the rampart and parapet, to ſupport the earth, and prevent its rolling into the ditch.

REVIVIFICATION, in phyſiology, the recalling

(A) For this view of the *Reſidual Analyſis*, we are obliged to Mr Playfair profeſſor of Mathematics in the Univerſity of Edinburgh.

to life of animals apparently dead. There are many kinds of inſects which may be revivified, after all the powers of animation have been ſuſpended for a conſiderable time. Common flies, ſmall beetles, ſpiders, moths, bugs, &c. after being drowned in ſpirit of wine, and continuing apparently dead for more than a quarter of an hour, have been reſtored to life merely by being thrown among wood-aſhes ſlightly warm.

While Dr Franklin reſided in France, he received from America a quantity of Madeira wine which had been bottled in Virginia. In ſome of the bottles he found a few dead flies, which he expoſed to the warm ſun, it being then the month of July; and in leſs than three hours theſe apparently dead animals recovered life which had been ſo long ſuſpended. At firſt they appeared as if convulſed; they then raiſed themſelves on their legs, waſhed their eyes with their fore feet, dreſſed their wings with thoſe behind, and began in a little time to fly about.

But the moſt extraordinary inſtance of revivification that we ever heard of, is the following: In the warmer parts of France there is an inſect very deſtructive to rye, which ſeems to begin its operations at the root of the plant, and gradually to proceed upwards to the ear. If the plant be completely dried while the inſect is in the root or ſtem, the animal is irrecoverably killed; but after it has reached the grain, the caſe is very different. There have been inſtances, which are noticed in the Academy of Sciences, of theſe inſects being brought to life in a quarter of an hour, by a little warm water, after the grains, in which they were lodged, had been kept dry for 30 years.

What is the metaphyſician to think of theſe phænomena, or what concluſion is he to draw from them with reſpect to the mind or ſentient principle? If he be a ſober man, he will draw no concluſion; and for this very good reaſon, that of the ſentient principle of inſects, and indeed of every animal but man, he knows nothing. He is conſcious that it is the ſame individual being, which, in himſelf, thinks, and wills, and feels; he knows, that part of his thought is not in one place and part of it in another; and therefore he rationally concludes that this thinking being is not matter, whilſt experience teaches him that it quits the material ſyſtem as ſoon as that ſyſtem becomes completely unfit to diſcharge its functions, and that when it has once taken its flight, it cannot be recalled. Experience teaches him, on the other hand, that the ſentient principle of theſe inſects does not quit the material ſyſtem as ſoon as that ſyſtem ſeems unfit for its functions; and hence he ought to infer, that the minds of men and of inſects (if we may uſe ſuch language), though probably both immaterial, are very different ſubſtances; and that the bond which unites the material and immaterial parts of an inſect, is certainly different from that which unites the mind and body of man. This is the only inference which can be legitimately drawn from theſe phenomena; and he who makes them the baſis of materialiſm, muſt have his judgment warped by ſome paſſion or prejudice.

216 Narrative continued

REVOLUTION OF FRANCE. We formerly preſented to our readers a conciſe ſtatement of the commencement and progreſs of this extraordinary event (See REVOLUTION *Encycl.*). The ſingularity of its nature, and the important place which it muſt hereafter occupy in the moral and political hiſtory of mankind, require that we ſhould now reſume and continue the detail of its wide-waſting career. We left the ſubject towards the commencement of the year 1795, at the cloſe of that wonderful campaign, during which the armies of the Republic had exerted themſelves with ſuch unparalleled ſucceſs in every direction. On the one ſide they had croſſed the Pyrennees, and ſhaken the Spaniſh monarchy to its centre; while on the other they had driven the united forces of Auſtria, Pruſſia, and Britain, from the walls of Landrecies acroſs the Rhine, at all points from Hageneau to the ſea, and had finally cloſed their efforts by the conqueſt of Holland. At that period, though a prolongation of hoſtilities was threatened, we ſcarcely expected that Europe was ſo ſoon to witneſs, or we to record, a ſucceſſion of military enterpriſes of a ſtill more romantic and extraordinary nature, the ſcene of which was even to extend into barbarous countries, where the opinions and the quarrels of the European nations had hitherto remained unknown.

217 Diminiſhed energy of the Convention,

The campaign of 1794, however, was not immediately followed by any important military exertions. The Britiſh troops were recalled home, Pruſſia had been gradually withdrawing from the coalition, and the Auſtrian armies remained upon the defenſive. Neither was the French government in a ſituation which could enable it to renew its enterpriſes with vigour, or to give much trouble to the allies. The Convention ſtill exiſted; but it was no longer that terrible aſſembly which, under Robeſpierre and his aſſociates, had, in the ſhort period of fifteen months, reduced two thirds of France under its dominion, and ſent forth armies which the combined ſtrength of the reſt of Europe ſeemed unable to reſiſt. While its authority remained almoſt concentrated in one man, and while the fear of foreign invaſion, and the new born enthuſiaſm for freedom, induced the people to ſubmit to every meaſure of government, however oppreſſive or arbitrary, the power of the Convention, and the number of its armies, were unbounded. The dreadful price, however, which they had paid for liberty, and the facility with which they ſaw it might be loſt, had now diminiſhed the political zeal of all claſſes of citizens. The removal of the foreign armies had diſpelled the dread of invaſion, and the death of Robeſpierre, by diſſolving the unity of its efforts, and ſuffering it to fall into contending factions, had greatly weakened the authority of the Convention, and diminiſhed its efficiency as a government.

218 And diſcredit of the Jacobins,

The fall of Robeſpierre had been accompliſhed by two ſeparate conſpiracies. At the head of one of theſe were, Barrere, Billaud Varennes, and Collot d'Herbois, who had been members of the Committee of public ſafety. The other conſpiracy conſiſted of members of the Convention who did not belong to the committees, and had no immediate ſhare in the adminiſtration. Among theſe, Tallien, Bourdon de l'Oiſe, and Lecointre of Verſailles, were conſpicuous. After the deſtruction of their mutual tyrant, a conteſt for power took place between theſe parties. The popularity of Robeſpierre had once been ſo conſiderable, and all men had ſubmitted ſo tamely to his dominion, that both parties accounted it neceſſary, in their ſpeeches and writings, to juſtify to the nation the ſhare they had taken in accompliſhing his ruin. It was eaſy to be eloquent upon ſuch a topic; but its diſcuſſion naturally operated to the diſcredit of the members of the committee, and of the

the more violent Jacobins, who had been the immediate inſtruments for carrying into effect his ſanguinary meaſures. They nevertheleſs retained poſſeſſion, for ſome time, of a conſiderable portion of power. The current of public opinion, however, ran ſo ſtrongly againſt them, and the reſtoration to their ſeats in the Convention of the ſeventy one impriſoned members of the Girondiſt party, added ſo much to the ſtrength of their antagoniſts, that they gradually loſt their influence, and were threatened to be brought to trial for their conduct.

As early as Auguſt 1794, Lecointre of Verſailles had denounced the members of the old committee of ſafety; but his accuſation at that time produced little effect. Towards the end of that year, however, their approaching fall became evident. On the 26th of December the Convention ordered, on the motion of Clauzel, that the committees ſhould immediately report upon the conduct of the repreſentatives denounced by Lecointre and all France. Accordingly, on the following day, Merlin of Douay reported, in the name of the committees, that there was no cauſe for inquiry into the conduct of Vouland, Amar, and David; but that there was room for examining the conduct of Barrere, Billaud Varennes, Collot d'Herbois, and Vadier.

219
hoſe
aders
ere accu-
d,

In conſequence of this report, a committee of twenty-one members was appointed to make the enquiry. On the 2d of March this year (1795), Saladin preſented the report of the commiſſion; in which theſe four deputies were accuſed of having participated, as members of the governing committee, in the tyranny and atrocious meaſures of Robeſpierre. Their trial commenced before the Convention on the 22d of March; but previous to that period, Vadier had made his eſcape. The others remained, and reſted their defence upon this ground, that although members of the committee of ſafety, they had no power to reſiſt Robeſpierre, and that they were not more culpable in having acquieſced in his tyranny than the other members of the Convention, who had all been overpowered for the time by the knowledge that inſtant deſtruction awaited every man who ſhould dare to oppoſe his meaſures. Except in the caſe of the cruelties committed by Collot d'Herbois at Lyons, this defence was probably by no means deſtitute of foundation. It had much weight with the nation at large; in whoſe eyes it tended, not to exculpate the three perſons now accuſed, but to criminate and degrade the character of the whole Convention.

Carnot, Lindet, Cambon, Duhem, and the other members of what was now called the *Jacobin party*, defended their leaders with conſiderable ability, and with much vehemence. Nor was the party leſs active without doors than within the hall of the Convention. For ſome time they had drawn their friends to the capital from all quarters of the country; and in the morning ſitting of the firſt of April, they commenced their operations by an open inſurrection. An immenſe multitude having aſſembled in the ſuburbs, proceeded to the hall of the Convention. A real or factitious ſcarcity exiſted at the time. Taking advantage of this circumſtance, they pretended they were going to petition for bread; and this pretence drew numbers along with them who had no ſhare in their deſigns.

220
nd de-

n inſurrec-
on;

Boiſſy d'Anglas, a conſpicuous member of the moderate party, was addreſſing the Convention upon the means of removing the preſent ſcarcity when the inſurgents arrived, drove the centinels from their poſts, and ſuddenly filled the hall. They tumultuouſly demanded "Bread, and the Conſtitution." The Jacobin party ſupported the inſurgents; and one of the multitude, in a vehement harangue, exclaimed, "We are men of the 14th of July, of the 10th of Auguſt, and of the 31ſt of May." He demanded, that the Convention ſhould change its late meaſures, that the people ſhould no longer be the victims of mercantile rapacity, and that the accuſed patriots ſhould not be ſacrificed to the paſſions of their antagoniſts. The Convention ordered the tocſin to be rung, and the people of Paris to be called to arms. General Pichegru was in Paris at the time; and, upon the motion of Barras, he was appointed to the command of the military force.

221
Which is quelled by Pichegru.

The citizens of Paris, who remembered with horror the domination of Robeſpierre and his adherents, and now ſaw themſelves menaced with its return, inſtantly called each other to arms, and aſſembled, by ſix in the evening, for the protection of the Convention, to the amount of 20,000 men. Till that time the aſſembly had remained under no ſmall diſquietude, ſurrounded by the inſurgents, and liſtening to the addreſſes of their orators, and the ſpeeches of the Jacobin minority in their favour. The majority was now reſcued from this ſtate of conſtraint; and, on the motion of Dumont, without proceeding farther in the trial, it was decreed that Barrere, Collot d'Herbois, and Billaud Varennes, ſhould immediately be tranſported to Guiana.

During the following day the inſurgents were completely ſubdued; and the majority of the Convention, taking advantage of their victory, decreed the arreſt and confinement, in the caſtle of Ham in Picardy, of ſeveral of the moſt obnoxious of their antagoniſts. Among theſe were Leonard Bourdon, Duhem, Chaſles, Choudieu, Ruamps, Fouſſedoire, Huguet, Bayle, Lecointre, Cambon, Thuriot Maignet, Heutz, Craſſous, and Levaſſeur. By departing from the puniſhment of death, and adopting that of baniſhment on this occaſion, the Convention expected to diminiſh the ferocity of the contending factions in the ſtate, by rendering the reſult of a political defeat leſs fatal than formerly. The deſign was good; but in attempting to accompliſh it, they eſtabliſhed the pernicious precedent of inflicting puniſhment without a trial, which could ſcarcely fail to prove highly dangerous, if not ultimately fatal, to all their proſpects of a free and juſt government.

222
Victory of the Convention.

223
Propoſal for a new conſtitution.

The Convention now followed up its victory with the popular meaſure of preparing for its own diſſolution, by endeavouring to frame a fixed conſtitution for the Republic. The conſtitution which had been decreed in 1793, under the auſpices of Robeſpierre, was conſidered as impracticable, and a committee was appointed to report upon the meaſures which ought now to be adopted. It conſiſted of Sieyes, Cambaceres, Merlin of Douay, Thibaudeau, Mathieu, Le Sage of Eure and Loire, and Latouche. On the 19th of April, Cambaceres reported, that it was the opinion of this committee that a commiſſion ſhould be appointed to frame an entirely new conſtitution. The Convention accordingly appointed the following perſons to this important office, Le Sage, Louvet, Boiſſy d'Anglas, Creuze, Latouche, Bertier, Daunow, Baudin, Durand, Maillane, Languinais, La Reveillere Lepaux, and Thibaudeau. All other citizens of every deſcription were at

French Revolution, 1795.

at the ſame time invited to communicate projects upon the ſubject, and the committee was required to order the beſt conceived of theſe to be printed.

The Convention farther gratified the feelings of the great majority of the nation, by bringing to trial Fouquier Jenville the preſident, and fifteen judges and jurors of the late revolutionary tribunal. They were convicted on the 8th of May, and executed on the following day, amidſt the execrations of a multitude of ſpectators.

224 New inſurrection of the Jacobins,

In the mean time, though defeated on the 1ſt and 2d of April, the Jacobins by no means conſidered themſelves as ſubdued. On the contrary, they were preparing a new and more extenſive inſurrection, which ſhould not, like the former, be confined to the capital. They fixed upon the 20th of May as the day of revolt. Thuriot, and Robeſpierre's financier Cambon, had found means to eſcape from the caſtle of Ham in Picardy, and to come to Paris. They concealed themſelves in the ſuburb St Antoine, and from thence gave counſel to their party, and urged them to action. The ſcarcity of bread had increaſed, and advantage was again taken of this circumſtance. For ſome days the walls were covered in various places of Paris with printed accuſations againſt the Convention of withholding bread from the people, and attempts were made to excite the troops in the city to join the diſaffected party. On the evening of the 19th, a paper was openly diſtributed in the different ſections, explaining the object of the approaching inſurrection. It declared inſurrection to be the moſt ſacred duty of the people, and called upon the citizens of Paris to proceed in a maſs to the Convention, to demand from it bread and the eſtabliſhment of Robeſpierre's conſtitution, together with a new election of national repreſentatives.

On the morning of the 20th, the tocſin was rung, and drums beat to arms in the ſuburb St Antoine, which had always been the quarter of the city in which the Jacobins poſſeſſed the greateſt ſtrength. Upon this alarm the Convention aſſembled; but although the intended inſurrection was no ſecret, and though the committee of public and general ſafety now made a report, in which they confeſſed their previous knowledge of it, yet it does not appear that any vigorous meaſures of precaution had been taken; for it was only at the inſtant when the inſurgents were actually approaching, that General Hoche was appointed to command the armed force, and was ſent forth to aſſemble the military and the citizens for the defence of the Convention. In the mean time, the multitude ſurrounded the hall. They ſoon overpowered the guards, and burſt into the midſt of the aſſembly. In all the turbulent days of the revolution, the women of Paris have never failed to act a conſpicuous part. On this occaſion they greatly augmented the crowd by their numbers, and the tumult by their cries of "Bread, and the conſtitution of 1793," which was the rallying exclamation of the party. After ſome fruitleſs efforts to reſtore tranquillity, Vernier the preſident, an old man, reſigned the chair to Boiſſy D'Anglas, who remained in it with much firmneſs during the day. The whole ſtrength of the inſurgents had not arrived at once; for the firſt party that approached, although they forced their way into the hall, were ſoon repulſed by the aid of a few ſoldiers and citizens, who came to the aſſiſtance of the Convention. A ſhort interval of tranquillity was thus obtained; but the attack was ſpeedily renewed with double fury by armed men, who ſubdued all oppoſition, and entered the hall with cockades, on which was written the inſcription, "Bread, and the conſtitution of 1793."

225 Who murder ſome the Convention, and drive from its hall.

While things were in this ſtate, a citizen of the party of the Convention raſhly tore off the hat of one of the inſurgents, and was immediately aſſaulted with ſwords by the multitude. He fled towards the preſident's chair, and was killed at the ſide of it by a muſket ſhot. Ferand, one of the members, having attempted to reſcue him, was alſo attacked. He eſcaped into one of the paſſages, where he was alſo killed, and his head was brought into the Convention upon a pike. The greater number of the members now gradually departed, and left the hall in poſſeſſion of the inſurgents, who acted with ſome regularity, and propoſed a variety of laws favourable to their party, which were inſtantly decreed. Duroi, Duqueſnoi, Bombotte, and Goujon, were the members who ſtood moſt openly forward on this occaſion, and appeared as chiefs of the inſurrection. But their triumph only laſted a few hours. Towards the evening a large body of citizens joined the military, and marched to the aid of the Convention. Having overcome the inſurgents, they entered the hall in great force, and reſtored the powers of the majority. The decrees that had been forced upon them were repealed as ſpeedily as they had been enacted, and the deputies who had propoſed or ſupported them were arreſted.

The citizens of Paris, and even the members of the Convention, appear now to have fancied their victory complete; for they adopted no adequate meaſures to prevent a new diſturbance. But the Jacobins did not ſo eaſily give up their own cauſe. On the following day they once more aſſembled in the ſuburbs, and in the afternoon they returned to the attack. They took poſſeſſion of the Carouſal without oppoſition, and pointed ſome pieces of cannon againſt the hall of the Convention. This aſſembly was now unprotected, and attempted not to ſubdue, but to flatter, the inſurgents.

226 Meanneſs of the Convention.

A deputation of the members was ſent forth to fraterniſe with them, and to carry forth two decrees paſſed at that inſtant, which ordained that bread ſhould abound, and that Robeſpierre's conſtitution of 1793 ſhould immediately be put in force. The inſurgents, in return, ſent a deputation to the Convention, to expreſs their ſatisfaction with the decrees, to demand the releaſe of the impriſoned patriots, and the puniſhment of thoſe who preferred money to aſſignats. The Convention pretended to agree to all their demands, and the preſident was ordered to give to the deputation the fraternal embrace.

The 22d, which was the third day of the inſurrection, appears to have been paſſed by both parties in a ſtrange degree of inaction. The Convention proceeded in its ordinary buſineſs; and the Jacobins, at their head quarters in the ſuburb St Antoine, were occupied in conſultations and preparations for new movements. But on the following day the citizens aſſembled at their ſections, and haſtened from thence to the Thuilleries to defend the Convention. Conſiderable bodies of the military were alſo collected, and the aſſembly at laſt reſolved to act upon the offenſive. A decree was paſſed, declaring, that if the ſuburb St Antoine did not inſtantly ſurrender its arms and cannon, together with

the

ench olution, 795.

227 ictory the Jacobins;

the murderer of Ferand, it ſhould be conſidered as in a ſtate of rebellion. The conventional generals were at the ſame time ordered to reduce it by force. The inſurgents now found themſelves unequal to the conteſt, and were compelled to ſurrender without conditions by the inhabitants of the ſuburb, who dreaded the deſtruction of their property by military operations. Several ſoldiers being found among the priſoners, were put to death: and ſix members of the Convention were tried and condemned on this occaſion by a military commiſſion. Three of theſe periſhed by ſelf ſlaughter, and three were executed. The majority of the Convention, elated by their victory, ordered back Collot D'Herbois, Billaud Varennes, and Barrere to take their trial; but the two former had ſailed before the arrival of the courier. Barrere only remained, and he was brought back and impriſoned.

In the mean time, the Jacobins in the ſouth were not leſs active than their brethren at Paris. On the 20th of May they formed a vigorous inſurrection at Toulon. They ſeized the gates, and mounted them with cannon; they liberated ſuch of their aſſociates as had been impriſoned, and detained the fleet, which was about to ſail. Having begun their operations in this ſucceſsful manner, they marched from Toulon towards Marſeilles. Their force amounted to three thouſand men and twelve pieces of cannon. They were encountered on their way, however, and defeated by Generals Charton and Pactod. Three hundred of them were carried priſoners to Marſeilles, and Toulon was ſpeedily retaken.

228 ho ſtill tain their irit;

The party of the *Mountain*, as it had been called, or of the violent Jacobins, who wiſhed to revive the reign of terror and the meaſures of Robeſpierre, was now reduced very low both in the Convention and out of it. Thoſe who adhered to it were even in many places, and more eſpecially in the ſouth, expoſed to very violent perſecution. Aſſociations were formed, called Companies of *Jeſus* and of the *Sun*, for the purpoſe of avenging the crimes committed by them during the period of their power. At Lyons ſeveral of them were maſſacred in priſon, and many of them in all places periſhed by aſſaſſination. On conſidering the mercileſs character of the government of Robeſpierre and his aſſociates, and the perſecution which was ſuffered under it, not merely by the nobles and the rich, but by every man who was diſtinguiſhed by integrity, talents, or literature, it may appear ſurpriſing that it ſhould have obtained admirers, or that any number of individuals ſhould have been found willing to hazard their lives to procure its reſtoration. Accordingly, from the period of the fall of its leader, the party had gradually been forſaken by its adherents; and the more cloſely its conduct was conſidered, it loſt ground the more rapidly in the eſtimation of the public. After the unſucceſsful inſurrections of the 20th of May, it was treated with the utmoſt contempt, and its unpopularity was extreme. Still, however, a party remained. It was ſmall, indeed, but its members compenſated the inferiority of their numbers by ſuperior enterpriſe and activity. They conſiſted of outrageous republicans, whoſe heated imaginations beheld royalty and ariſtocracy in every propoſal for ſober and regular government. In the conduct of Robeſpierre, they remembered only the energy of his meaſures, by which France was enabled to triumph over the combined efforts of the kings of Europe; and overlooked the atrocities by which he had brought diſgrace upon their cauſe, and rendered his party odious to their own countrymen, as well as to the neighbouring nations. Amidſt this univerſal odium, however, the Jacobins did not deſpair of riſing once more into power; and it is not a little ſingular, that we muſt date the revival of their ſtrength from the period of the unſucceſsful inſurrections which we have juſt recorded, and which ſeemed to have extinguiſhed their hopes for ever.

French Revolution, 1795.

The unpopularity under which the Jacobins laboured ſoon began to affect the Convention itſelf. The tame ſubmiſſion of that body to the government of Robeſpierre was now remembered. It was recollected, that the majority of its members had been the inſtruments of his power, and had applauded, or at leaſt acquieſced in, his crimes. As the preſs was now free, and the reins of government unſteadily held, their conduct was repreſented to the public in the moſt odious colours. A celebrated ſong, *Le Reveil du Peuple*, became extremely popular, as the means of marking diſlike both to the Convention and to the Jacobins; and their conduct was canvaſſed with the utmoſt bitterneſs in a great variety of publications, but more eſpecially in a journal that at this time attracted much notice, and which was conducted by Freron, who had himſelf been a Jacobin, but had now abandoned his party.

229 And terrify the Convention.

In this ſtate of things, the majority of the Convention ſpeedily began to repent of their late victory over the Jacobins. In the firſt efforts of their zeal, they had taken meaſures for the immediate formation and eſtabliſhment of a ſettled conſtitution to ſuperſede their own authority; but they now regretted their raſhneſs, when they perceived, from the temper the nation was in, that the men, the moſt avowedly hoſtile to their character and meaſures, would without doubt be elected as their ſucceſſors. They, and their friends, had ariſen to great diſtinction and wealth under the revolutionary government; and they now began to dread, not only the loſs of power, but alſo a ſevere inveſtigation of their conduct. Theſe conſiderations ſoon produced their natural effects. The decrees for forming and putting in force the conſtitution could not decently be recalled; but the majority of the Convention ſet about deviſing means for rendering them of little importance, ſo far as they themſelves were concerned.

230 New conſtitution, conſiſting of

On the 23d of June, Boiſſy D'Anglas preſented the report of the committee that had been appointed to prepare the plan of a conſtitution. It began, like the former conſtitutions, with a declaration of the rights of man; and in addition to this, conſiſted of fourteen chapters, upon the following ſubjects:—The extent of the territorial poſſeſſions of the Republic, the political ſtate of citizens, the primary aſſemblies, the electoral aſſemblies, the legiſlature, the executive power, the municipal bodies, the judicial authority, the public force, public inſtruction, the finances, foreign treaties, the mode of reviſing the conſtitution, and, laſtly, an enactment, that no rank or ſuperiority ſhould exiſt among citizens, excepting what might ariſe from the exerciſe of public functions.

The primary aſſemblies were to poſſeſs the right of electing the members of the electoral aſſemblies, and alſo the juſtices of the peace. The electoral aſſemblies were to nominate the judges and the legiſlators of the ſtate.

231 Two Councils and an

ſtate. The legiſlature was divided into two aſſemblies; the one of which conſiſted of 250 members, and was called the *Council of the Ancients*, as none but married men and widowers above 40 years of age could be members of it. The other aſſembly or council conſiſted of 500 members, and poſſeſſed the excluſive privilege of propoſing the laws; the Council of Ancients being only intitled to reject or approve, without power to alter the decrees preſented to it. To this rule there was one exception, which was afterwards employed as the means of overturning the whole fabric of the conſtitution; the Council of the Ancients might decree the removal of the legiſlature from its ordinary place of ſitting. To this decree the approbation of the Council of Five Hundred was not neceſſary; and when once enacted, it could not be reconſidered even by the Council of Ancients itſelf. One-third of the members of the two Councils was to be elected annually. A member might be once re-elected, but he could not be elected a third time till an interval of two years had elapſed.

232 Executive Directory.

The executive power was intruſted to five perſons of forty years of age at leaſt, to be ſtyled the *Executive Directory*. Its members were elected by the two Councils; the Council of Five Hundred electing ten times the number of candidates that might be neceſſary to fill up the vacancies, and the Council of Two Hundred and Fifty nominating the directors from this liſt of candidates. One member of the Directory was to go out annually; ſo that the whole might be changed every five years. The Executive Directory had no vote in the enactment of laws; but it ſuperintended their execution, regulated the coining of money, and diſpoſed of the armed force. Foreign treaties made by it were not binding till ratified by the legiſlative body, nor could it make war without the authority of a decree of the two aſſemblies. The public functionaries were to receive ſalaries, and to appear dreſſed in an appropriated habit.

Each article of this conſtitution was ſeparately diſcuſſed; and on the 23d of Auguſt the whole was declared to be complete, and ordained to be tranſmitted to the primary aſſemblies for their approbation. Previous to this reſolution, however (that is, on the 22d of the ſame month), the majority of the Convention had brought forward the grand meaſure by which they meant to provide for their own ſafety, and the ſafety of their friends and adherents, againſt the change which the public opinion had undergone concerning them They decreed, that at the approaching general election, the electoral bodies ſhould be bound to chooſe *two-thirds* of the new legiſlature from among the members of the preſent convention; and they afterwards decreed, that, in default of the election of two-thirds of the Convention, the Convention ſhould fill up the vacancies themſelves.

233 The Convention fetters the fredom of election.

Theſe decrees were tranſmitted, along with the Conſtitution, to the primary aſſemblies, to be accepted or rejected by them. Many of the primary aſſemblies underſtood, that they could not accept of the conſtitution without accepting along with it the law for the re-election of the *two-thirds*. The point had, in all probability, been purpoſely left under a certain degree of ambiguity; and as the people were now weary of this Convention, they acquieſced in any conditions that gave them the proſpect of one day getting quit of it. But at Paris, and in the neighbouring departments, where the ſubject was more accurately inveſtigated, the public diſapprobation of the Convention diſplayed itſelf with great vehemence.

234 Conſeque ces of thi conduct,

There was indeed ſomething extremely aukward in the decree about the re-election of two thirds of the Convention. That body might, if neceſſary, have continued its own exiſtence for ſome time longer, or it might have diſmiſſed one-third of its number by ballot or otherwiſe, and allowed a new election only to that extent; but a compulſory election was an abſurdity ſo new, and ſo obvious, that it gave their antagoniſts every advantage againſt them. Accordingly, at the meetings of the ſections of Paris, the laws for the re-election were rejected with contempt, and their abſurdity demonſtrated with much acrimony. In conſequence of the debates which took place at theſe meetings, the minds of men were gradually inflamed, and it became obvious that a political convulſion approached. On the one ſide, the Convention took care to publiſh daily the approbation of the decrees, along with the conſtitution, by the majority of the primary aſſemblies, by moſt of which the two had been confounded and accepted in the groſs. Its committees alſo called in the aid of the troops of the line for its protection. On the other hand, the language of the ſections became every day more violent. The whole Convention was repreſented as a band of tyrants and of murderers, the aſſociates of all the cruelty of Robeſpierre and the Mountain party. It was even propoſed to bring to trial every individual member of the aſſembly before a new revolutionary tribunal, and to puniſh him according to his demerits.

For ſome time much anxiety prevailed on both ſides. Numerous deputations were repeatedly ſent from the ſections to the Convention to remonſtrate againſt the obnoxious decrees. But the eagerneſs with which theſe remonſtrances were made, ſerved only to convince more ſtrongly the members of the Convention of the danger to themſelves as individuals which would attend a reſignation of their power, and confirmed the reſolution they had taken to retain it. The deputies of the ſections having obtained inſpection of the records of the convention, aſſerted, that the national majority, if rightly numbered, had rejected the decrees; as every aſſembly that voted in oppoſition to them was only numbered as one vote, however numerous its members might be; which enabled the primary aſſemblies of remote diſtricts to outvote the more populous ſections of Paris and other great towns. Whereas it was ſaid, that if the individual voters were counted, it would be found that the decrees were diſapproved of by a conſiderable majority. All this was diſregarded by the Convention, and the ſections prepared to decide the diſpute by arms. The firſt ſtep taken by them, however, was ill concerted. A notion was propagated, that as ſoon as the primary aſſemblies or ſections had choſen the electors who were to chooſe the members of the new legiſlature, the national ſovereignty became veſted in theſe electors, and that they had a right to aſſume the government in their various diſtricts. Accordingly, about 100 of the electors of Paris aſſembled in the hall of the French theatre in the ſuburb St Germain, previous to the day of meeting appointed by the Convention. Having choſen

De Nivernois (formerly the Duke de Nivernois) their preſident, they began their debates. The Convention was alarmed, and inſtantly ſent a body of the military to diſmiſs the meeting as illegal. This was eaſily accompliſhed, as the citizens had not been unanimous with regard to it, and no meaſures were taken for its protection.

435 Con- ion ts the bins.

Notwithſtanding this firſt advantage on the ſide of the Convention, the ſections regarded its power with contempt, and imagined themſelves ſecure of ultimate ſucceſs. In every political conteſt that had hitherto occurred ſince the commencement of the revolution, the immenſe population of the capital had given a deciſive ſuperiority to the faction whoſe ſide it eſpouſed. The citizens alſo regarded with indifference the armed force with which the Convention had ſurrounded itſelf, from a notion, which they fondly entertained, that the military would in no caſe be brought to act againſt the people. It would appear that the Convention itſelf entertained ſome jealouſy upon this head, and did not account itſelf entirely ſafe under the protection of the ſoldiers. On this occaſion, therefore, it had recourſe to a new ally, and beſought the aid of thoſe very Jacobins whom it had almoſt cruſhed on the 24th of May. The members of the Convention were odious to the ſections of Paris, on account of their participation in the revolutionary crimes and meaſures of Robeſpierre; but this very circumſtance endeared them to the Jacobins, whoſe character it was to imagine that they had never enough of war abroad or of revolution at home. It was eaſy therefore to bring about a reconciliation between the Convention and theſe men. Several hundreds of them were diſmiſſed from the priſons, where they had been confined ſince the two laſt inſurrections, and they were now put in requiſition to defend the legiſlative body.

When the ſections of Paris beheld the Convention ſurrounded by thoſe Jacobins who had been the unrelenting agents of the government of Robeſpierre, and who were now denominated *terroriſts* and *men of blood*, their ardour for action became unbounded. They aſſembled in arms at their different ſections on the 12th Vendemaire (October 4th); but they do not ſeem to have acted with much concert, or upon any well digeſted plan of operations. The general deſign of their leaders was to ſeize the members of the Convention, and impriſon them in the church of the Quatre Nations till they could be brought to trial. As this would occaſion a vacancy or interregnum in the government, it was reſolved that all affairs ſhould be conducted by committees of the ſections, till a new legiſlature could be elected. General Miranda, a Spaniard, a native of the Carraccas in South America, who had ſerved in the republican armies, was to be appointed to the chief command of the armed force after the overthrow of the Convention. This man, in his eagerneſs for preferment, had alternately courted all parties, and he now ſeems to have joined the Pariſians upon the ſuppoſition of their being the ſtrongeſt. As he entertained ſome doubts of their ſucceſs, however, he adopted the crooked and timid policy of avoiding the ſtorm by retiring from the city till the combat ſhould be finiſhed, reſolving to return immediately on its concluſion to ſhare the rewards and the triumph of victory.

The Convention, in the mean time, reſolved to ſtrike the firſt blow. For this purpoſe they ſent General Menou to the ſection of Le Pelletier to diſperſe the citizens, whoſe greateſt force was aſſembled there. But this officer, diſliking the ſervice which he was employed to perform, inſtead of proceeding to action, began to negociate with the leaders of the ſections, and ſpent the evening of this day in fruitleſs conferences. The ſections on their ſide appointed General Danican, who had diſtinguiſhed himſelf in the war againſt the Royaliſts in La Vendee to act as their military leader. It would appear, however, that this officer, from the moment that he aſſumed the command, began to deſpair of the cauſe of the ſections. He found them totally deſtitute of cannon, whereas the Convention was ſurrounded by regular troops and a numerous artillery. This inequality in point of weapons appears to have been conſidered by him as a ſufficient reaſon for avoiding an engagement. Occupied in viſiting and arranging the different poſts, he was unacquainted with the diſaffection of the conventional generals. He therefore thought he had done much when he had prevented bloodſhed for another day, and thus the favourable moment for attack was loſt. Whether the ſections would have been ſucceſsful had they been inſtantly led to battle on this important occaſion, cannot now be known. Though the ſuperior officers of the Convention were unfaithful, yet the ſubalterns and the troops in general might have ſtood firm, confirmed as they were by the perſuaſion of their Jacobin auxiliaries. Even in this caſe, however, the fate of a battle might have at leaſt been doubtful. The battalions of Paris were very numerous, their contempt of danger was great, and their ardour unbounded. The mere poſſeſſion of cannon might not in a conteſt againſt ſuch men have afforded ſecurity to the Convention. But the firſt moments of popular enthuſiaſm were ſuffered to paſs away, and that diſtruſt and diſſenſion, which delay never fails to introduce among great and irregular aſſemblages of men, ſoon began to render the conduct of the ſections undecided and weak.

The conventional committees, during the night of the 12th Vendemaire (October 4th), diſmiſſed Generals Menou, Raffet, and ſome others, from their ſtations, and gave the command of the troops to Barras. He immediately collected around him a variety of able officers, among whom we find the names of Generals Brune and Bonaparte. With their aſſiſtance he began to provide for a moſt vigorous defence. Troops with cannon were ſtationed in all the avenues leading to the Thuilleries. In caſe any of theſe poſts ſhould be forced, maſked batteries were planted in more retired ſituations. Nor was this all; meaſures were taken for conveying the public magazines of proviſions and military ſtores to St Cloud, whither the Convention prepared to retreat if they ſhould ſuffer a defeat at Paris.

On the 13th Vendemaire (October 5th) from which the inſurrection was afterwards named, both parties remained for many hours upon the defenſive. At laſt, about three o'clock in the afternoon, General Danican made advances to an accommodation by a letter to the committee of public ſafety; in which he ſtated, that the only cauſe on account of which the citizens had taken arms was the dread of a maſſacre being intended by the armed terroriſts who ſurrounded the Convention, and that if theſe men were removed, tranquillity would immediately be re-eſtabliſhed. A civil meſſage was returned;

236 Subdues the citizens of Paris.

turned; but the Jacobin party in the Convention, being now more confident of victory, and wiſhing to ſtrengthen themſelves by the defeat and puniſhment of their antagoniſts, it was reſolved that the diſpute ſhould be decided by arms. It is not correctly known how the conteſt commenced, but the armed Jacobins are moſt generally underſtood to have begun the attack. The citizens on the ſouthern ſide of the river attempted to reach the Convention by the Quay de Voltaire, but were ſpeedily repulſed by the conventional cannon; but on the northern ſide of the river, near the Convention, the combat was extremely obſtinate. The cannon were repeatedly ſeized by the citizens, and repeatedly retaken by the troops and the armed Jacobins. It was not till after a conteſt of four hours that the ſections were repulſed and driven to the poſt of St Roch. This poſt was alſo taken after great ſlaughter, and the ſections were driven to their head quarters at the ſection of Le Pelletier. After a ſhort interval they were purſued thither by the troops of the Convention, who by midnight were maſters of the whole city.

237 Mountain party, or the moſt violent Jacobins, again at the head of the ſtate.

This inſurrection was aſcribed by the victorious party to the exertions of the Royaliſts. It is no doubt true, that by this time Royalty was become leſs unpopular even among the rabble of France than the extreme of Republicaniſm, as it had appeared in the conduct of the Mountain party. It is alſo probable, that the Royaliſts mingled in a conteſt that had the overthrow of the preſent Convention for its object; but the inſurgents in general ſeem neither to have avowed nor entertained any farther view than the diſarming of the Jacobins, and the obtaining an immediate election of new repreſentatives. The failure of the attempt had the effect of placing the Mountain party once more at the head of the ſtate. This party at firſt thought of adjourning the new conſtitution, and of renewing all the terrors of the revolutionary government. This project, however, was oppoſed in the Convention with ſo much vehemence and ability by Thibaudeau, that it was renounced. Indeed it was become unneceſſary to the ſafety or aſcendency of the men who propoſed it, as the decrees for the re-election of two-thirds of the Convention enabled them to retain the full poſſeſſion of their power. A few members of the moderate party, ſuch as Boiſſy D'Anglas, Languinais, and Le Sage, were elected by almoſt every place in France, though they could only ſit for one place. Hence the Convention itſelf had the re-election of nearly two-thirds of its own members; and the Mountain party, which now commanded the majority, was thus enabled to fill the new legiſlature with its own leaders.

238 Firſt ſitting of the new legiſlature.

On the 27th of October the Convention terminated its ſittings, and was ſucceeded by the new legiſlature as appointed by the Conſtitution. By its laſt decrees, a general amneſty was granted for all revolutionary crimes and proceedings. From this amneſty, however, were excepted the emigrants, the tranſported prieſts, and all perſons concerned in the laſt inſurrection; ſo that in fact it was merely a pardon granted by the Mountain party to its own friends for all the exceſſes they had committed. The members of the Convention, who had been impriſoned in the caſtle of Ham ſince the Jacobin inſurrection in May, were now ſet at liberty. The members of the revolutionary committees, and other agents of Robeſpierre in Paris and the departments, were all diſmiſſed from their priſons, and advanced to the moſt important offices under the new government.

239 The Council of Five Hundred outwits the Council of Ancients.

As ſoon as the new legiſlature had divided itſelf into two councils, it proceeded to the election of an Executive Directory. Here the genius of the French nation for intrigue inſtantly diſplayed itſelf. The Council of Five Hundred was bound to preſent to the Council of Two Hundred and Fifty a liſt of ten times the number of candidates neceſſary for the office. It fulfilled this duty in the following manner. The majority of the Council of Five Hundred made out a liſt, conſiſting of the five following perſons, upon whom they wiſhed the election ultimately to fall: Sieyes, Barras, Rewbell, La Reveillere Lepaux, and Letourneur de la Manche. To complete the liſt, they added the names of 45 obſcure perſons, country juſtices, farmers, and even peaſants. Thus there was nothing left to the Council of Ancients but the mere form of an election; and from the want of other qualified candidates, they were under the neceſſity of nominating to the office of directors the five perſons at the head of the liſt preſented by the Council of Five Hundred. The crafty Sieyes, however, who had been the adviſer of all parties, but the oſtenſible agent of none, did not yet think fit to venture upon the poſſeſſion of power. He had diſapproved of the conſtitution which was now put in force, and had even framed one of his own in oppoſition to it, which, however, was rejected by the Convention. The moſt remarkable circumſtance in his plan of government was a national jury, upon which he propoſed to confer the power of diſmiſſing from their offices, without a cauſe being aſſigned, any of the public functionaries whom they might account dangerous to the ſtate. Sieyes having refuſed to accept the office of director, Carnot was elected in his ſtead. But on this occaſion the Council of Ancients was treated with a little, and but a little, more decency than formerly; as the name of Cambaceres, a man of conſiderable eminence, appeared along with that of Carnot in the liſt of candidates voted by the Council of Five Hundred.

240 New government not popular.

The republican government that was now attempted to be eſtabliſhed promiſed little tranquillity to the nation. This great misfortune attended it, that the chief offices in the ſtate were intruſted to men who were diſliked by the people. The members of the Executive Directory, with the exception of Reveillere Lepaux, had always belonged to the Mountain or moſt violent Jacobin party. As they now owed their power to that party, they employed its members in almoſt every official department. The goverment was therefore neceſſarily unpopular. Things might have been gradually altered, indeed, by ſucceſſive elections, which would in time bring other men into power: But, by the forms of the conſtitution, the executive power was more permanent than the legiſlative body, without poſſeſſing any influence over it. Hence it was to be feared that a conteſt for power might ſpeedily occur between a directory nominated by the Jacobin party and the new legiſlators appointed by the people, in which the Conſtitution might ſuffer ſhipwreck; an event which actually occurred.

While the poſſeſſion of power continued to fluctuate in the manner we have already ſtated, between the Moderate and the Jacobin or Mountain parties, the armies of the ſtate were ſuffered to languiſh; but upon the rench olution, 795.

4r atment e Republic by ign vers.

credit of its former military ſucceſs, the Republic was treated with reſpect by ſome of the neighbouring powers. On the 10th of April, a treaty of peace with Pruſſia, which had been negociated by the committees through the medium of Barthelemi the French reſident at Baſle, was preſented to the Convention for ratification. By this treaty, it was ſtipulated, that the French troops ſhould immediately evacuate the Pruſſian territory on the right bank of the Rhine, but ſhould retain the territory belonging to that power on the left bank till a general peace. Priſoners of war were to be mutually reſtored, and the commerce of the two countries was to be placed on its ancient footing. Meaſures were alſo to be taken to remove the theatre of war from the north of Germany by treaties between France and thoſe princes for whom the king of Pruſſia might interpoſe.

During the ſame month of April, the French Republic was acknowledged by the king of Sweden; and Baron Stael his ambaſſador was received at Paris with great ſolemnity. In the month of May a ſecond treaty with Pruſſia was concluded. It chiefly regarded the line of neutrality. It is worthy of remark, that theſe treaties contained ſecret articles which were to be revealed only to a ſelect committee. By authoriſing this mode of procedure, the Convention ſufficiently demonſtrated its reſolution, that no form of popular government to be adopted in France ſhould ſtand in the way of the national aggrandiſement. The Swiſs cantons now followed the example of Sweden, and acknowledged the French Republic. A treaty of peace with Spain was alſo concluded at Baſle on the 22d of July. France, on this occaſion, relinquiſhed all the conqueſts ſhe had made in the territory of that country, and reſtored the ancient frontier. She received in return all the Spaniſh part of the iſland of St Domingo. The Dutch Republic was included in this treaty; and France agreed to accept of the king of Spain's mediation in favour of Portugal and the Italian princes.

242 ath of uisXVII.

On the 9th of June, the Dauphin, ſon of the unfortunate Louis XVI. died in the priſon of the Temple, where he had been confined, along with his ſiſter, ſince the executions of his father, mother, and aunt. His death, which was probably produced by diſeaſes ariſing from long confinement, if not by more unjuſtifiable means, excited in the French nation ſuch a degree of intereſt in favour of his family, that the Convention found it neceſſary to liberate his ſiſter from impriſonment. The committee of public ſafety propoſed to the Emperor to exchange this princeſs for the members of the Convention whom Dumourier had delivered up to Auſtria, along with two ambaſſadors, Semonville and Maret, who had been ſeized on their way to Turkey. This propoſal was accepted, and the exchange took place at Baſle in Switzerland.

243 val ſupe. rity of tain.

On the ſide of Britain the war maintained its former character. The Britiſh retained their ſuperiority by ſea, and were unfortunate in their efforts on the continent. On the 14th of March the Britiſh fleet in the Mediterranean, under Admiral Hotham, engaged the French fleet, and took two ſail of the line, the Ca-Ira and the Cenſeur; but as the French fleet, four days before the engagement, had captured the Berwick, a Britiſh ſhip of the line, when detached from the fleet, and as the Illuſtrious, another Britiſh ſhip of the line, was ſo ſeverely injured in the action that ſhe run aſhore and was loſt at Avenza, the ſubſtantial loſs on both ſides was nearly equal. On the 23d of June another Britiſh fleet under Lord Bridport attacked the French off Port L'Orient, and took three ſhips of the line, the reſt of the fleet eſcaping into that port.

French Revolution, 1795.

This evident ſuperiority of the Britiſh fleet in every conteſt, induced the government to take advantage of the command which it had of the ſea, to give aſſiſtance to the French Royaliſts in the weſtern departments. Theſe Royaliſts, hitherto unaſſiſted by foreign powers, had, by repeated defeats, been reduced very low. The Convention had at laſt offered them a treaty, which was accepted and ſigned at Nantes on the 3d of March, on the one ſide by deputies from the Convention, and on the other by Charette, Sapineau, and other chiefs of the inſurgents of La Vendée, and by Cormartin, as repreſenting the party called *Chouans* or Night Owls. Stofflet, another chief, held out for ſome weeks longer; but at laſt, on the 20th of April, he too was under the neceſſity of ſubmitting by treaty to the Republic.

244 Expedition to Quiberon Bay.

In a ſhort time, however, the hopes of the Royaliſts were revived by the countenance of the Britiſh government, and theſe treaties were ill obſerved. In the beginning of June the Britiſh expedition was ready to ſail for the French coaſt. The troops to be employed conſiſted of emigrants in the pay of Great Britain, and many of them had been priſoners of war, who now agreed to join the royal cauſe. The command during the voyage, and the ſelection of the place of landing, were intruſted to the Count D'Hervilly. The command on ſhore was given to Puiſaye, who had been employed under the Girondiſts in the military ſervice of the Republic, but had now become a royaliſt. The Count de Sombreuil was afterwards ſent to join them with a ſmall reinforcement.

On the 25th of June the expedition arrived in the Bay of Quiberon, and on the 27th 2500 emigrants made good their landing, after diſperſing a ſmall party of republican troops. The emigrant army ſoon after diſtributed itſelf into cantonments along the ſhore, and gave arms to the inhabitants of the country, who appeared to receive them with joy. It was ſoon found, however, that the Chouans, though well qualified for a deſultory warfare, could not be of much uſe to regular troops. They had little ſubordination. They were eaſily diſperſed, and never fought unleſs every advantage was on their ſide. When it was found that their unſteady aid could not be depended on, a reſolution was taken to withdraw the emigrant army within the peninſula of Quiberon. The fort of that name was taken on the 3d of July. Its garriſon conſiſted of five or ſix hundred men, and it was now occupied by the emigrants. A republican army, in the mean time, under General Hoche, advanced, and attacked all the poſts that had been left without the peninſula. Theſe were ſpeedily taken. The emigrants and Chouans eſcaped into the boats of the Britiſh fleet, or fled under the cannon of the fort of Quiberon. The republicans then began to conſtruct formidable works on the heights of St Barbe, at the entrance of the peninſula. To prevent their operations, a ſally was made from the fort on the 7th of July; but without ſucceſs. On the 15th, another ſally was attempted in greater force. The whole troops in the peninſula amounted to about 12,000, including Chouans. Out of theſe a detachment of 5000 was ſent to attack the heights of St Barbe. The republicans were entrenched in three camps. The two firſt of theſe were eaſily taken, and the detachment preſſed eagerly forward to attack the third. But here a maſked battery opened upon them with grape ſhot. A dreadful carnage enſued; and very few of the detachment could have eſcaped, had not the fire of the Britiſh ſhips ſoon compelled the republicans to deſiſt from the purſuit.

245 Its failure.

It now became obvious that the expedition muſt ultimately fail. Deſertion became extremely common among the emigrants. Thoſe men in particular who had been priſoners of war, and received their liberty on condition of joining the expedition, ſeized every opportunity of going over to their countrymen; and a correſpondence ſeems even to have been eſtabliſhed between the republicans and the diſcontented troops in the fort of Quiberon. On the evening of the 20th of July, the weather was extremely tempeſtuous, which produced a fatal ſecurity in the emigrant army. Suſpicious patroles were remarked; but as they repeated the watchword for the night, they were allowed to paſs. The republican troops were conducted in ſilence along an unguarded quarter of the ſhore, till they were enabled to ſurpriſe one of the poſts of the garriſon, where they found the artillery men faſt aſleep. Their matches were ſeized, and the lanthorn intended to give the alarm to the Britiſh fleet was extinguiſhed. The fort was ſpeedily in confuſion. Some regiments threw away their arms, and went over to the republicans; others even maſſacred their own officers. A conſiderable number, however, maintained a violent conflict for ſome time before they ſurrendered. Puiſaye eſcaped on board the fleet. The Count de Sombreuil was taken; and this accompliſhed young man was ſoon after put to death, along with the other emigrant officers and all the Chouans that were found in the fort. The biſhop of Dol was alſo put to death, with his clergy who accompanied him; but many of the private ſoldiers of the emigrant army made their peace with the republicans, by pretending they had been compelled to engage in the expedition.

The Britiſh fleet, with tranſports and troops, ſtill hovered upon the French coaſt, and made an unſucceſsful attempt upon the iſland of Noirmontier. In conſequence of the ſeaſon of the year, however, it returned home in December, after evacuating a ſmall iſland called *L'Iſle Dieu*, which the troops had for ſome time occupied.

246 Succeſſes of the French in Germany.

On the ſide of Germany the fortreſs of Luxembourg ſurrendered on the 7th of June, after having been in a ſtate of blockade ſince the preceding campaign. The French were now in poſſeſſion of the whole left bank of the Rhine excepting the city of Mentz, which they attacked in vain, becauſe the Auſtrians could at all times throw ſuccours into it from Fort Caſſel on the oppoſite bank of the river. Finding the capture of Mentz impoſſible in theſe circumſtances, the French reſolved to croſs the Rhine, to inveſt the city on all ſides. The enterpriſe, however, was delayed for ſome time, till the reſult of the Britiſh expedition to Quiberon ſhould appear. In the month of Auguſt, General Jourdan forced the paſſage of the Rhine at Duſſeldorf, at the head of what was called the army of the Sambre and Meuſe. After driving before him three Auſtrian poſts upon the Lahn, he croſſed the Mein, and completely inveſted Mentz and Caſſel. Pichegru, in the mean time, croſſed the river, with the army of the Rhine and Moſelle, near Manheim, of which city he immediately took poſſeſſion.

247 They receive a check.

But the French generals ſoon found their forces inadequate to the undertaking in which they were engaged. A conſiderable detachment of Pichegru's army, after driving the Auſtrians under General Wurmſer from a poſt of ſome importance, began to plunder, and went into confuſion. The Auſtrians being informed of this circumſtance, returned to the charge, and defeated the French. General Clairfait alſo, having violated the line of neutrality, came upon the rear of Jourdan's army, and took a conſiderable part of his artillery. Both the French generals now retreated. Jourdan was rapidly purſued by Clairfait till he returned to Duſſeldorf, where he maintained his ground. Pichegru recroſſed the Rhine near Manheim, leaving a garriſon of 8000 men in that city. The Auſtrians advanced in all directions. Manheim was taken after a vigorous ſiege. The French were driven from the neighbourhood of Mentz. The Palatinate became the theatre of war, and the Auſtrians ſeized the country called the *Hundſruck*, ſouth of the Rhine as far as Landau and Treves. After various engagements, in which little more ground was loſt or won, the two parties entered into an armiſtice for three months.

248 Treaties with German princes.

On the 28th of Auguſt a treaty of peace was concluded between the French Republic and the Landgrave of Heſſe Caſſel, on condition that he ſhould lend no more troops to Great Britain for the proſecution of the war. It is not a little ſingular, that peace was concluded with the Elector of Hanover, at this period upon ſimilar terms. The Duke of Wirtemberg, and ſome other princes of the empire, alſo began to treat; but the negociations were broken off in conſequence of the reverſe of fortune now experienced by the French.

1796.

The Directory, however, reſolved to continue the war with vigour, and vaſt preparations for the approaching campaign were made during the winter. The Mountain party being once more poſſeſſed of power, its members exerted themſelves with their uſual energy. Such, however, was the turbulent character of theſe men, that they could not long ſubmit peaceably to any government, and ſoon became weary of that Directory whom they themſelves had eſtabliſhed. They held clubs in all quarters, and were continually diſturbing the public tranquillity. For ſome time the government ſupported them. The Pariſians, after the 5th October, no longer dared to avow openly their diſlike to the Jacobins; but they were underſtood to expreſs this ſentiment by wearing green ſilk cravats, and by applauding with much vehemence at the public ſpectacles the air called *Le Reveil du Peuple*.

249 Ridicul conduct the Direc tory.

The Directory now prohibited, by an edict, as tokens of royaliſm, the wearing of green cravats, or the performing at any of the theatres the air now mentioned, though the ſentiments it contained were entirely republican. The Directory alſo ordered in its ſtead, that the Marſeillois hymn, and other popular ſongs, ſhould be performed every evening at all the theatres. The Pariſians ſhewed their diſapprobation of the Directory by maintaining a profound ſilence during the performance of theſe ſongs.

ſongs, which had never failed till that period to excite burſts of applauſe. The Directory ſoon became aſhamed of this ridiculous conteſt, and in a few weeks recalled their edict. Indeed they found it impoſſible to give countenance for any long period to the reſtleſs and innovating ſpirit of the Jacobins, who continually wiſhed and attempted to return to revolutionary, that is, to violent meaſures againſt their antagoniſts. In the ſouth, in particular, the preſent ſupremacy of the Jacobins produced very pernicious effects. Freron, who had deſerted them after the death of Robeſpierre, and became one of their moſt violent adverſaries, thought fit to return to their party before the 5th October, and was ſent to Toulon with full powers of adminiſtration. Here he diſmiſſed the municipality that had been elected by the people, reſtored the Jacobin clubs, and proceeded to impriſon all ſuſpected perſons as in the days of Robeſpierre. Theſe meaſures produced a violent reaction on the part of the enemies of the Jacobins. Aſſaſſinations became frequent, and many perſons began to leave the country. The Directory was alarmed by the many complaints againſt the Jacobins or terroriſts that came from all quarters, and reſolved to aim at popularity by deſerting a ſet of men who could not be prevailed upon to act with moderation. Freron was recalled from Toulon, and more manageable men were ſought out to replace the more violent Jacobins, who were in general diſmiſſed from the ſervice of government.

250 leaſures ken a- inſt the cobins.

The Directory proceeded farther, and acknowledged, by a public reſolution, that its confidence had been abuſed. The miniſter of police was ordered to remove from Paris the members of former revolutionary tribunals, and others who now acted as leaders of the Jacobins, or *anarchiſts* as they were called. A body of troops, amounting to 10,000 men, called the *legion of police*, that had acted againſt the Pariſians on the 5th October, and was now devoted to the Jacobins, was ordered by the Directory, with the authority of the legiſlature, to join the armies on the frontiers. Theſe men refuſed to obey the order; but they were reduced to ſubmiſſion by ſome troops that had been brought to the neighbourhood to provide againſt ſuch an event. The more violent Jacobins were enraged, but not intimidated, by theſe meaſures, and began to organize a plot for the overthrow of the Directory and of the majority of the councils, who had now deſerted them. They were not prepared for action, however, before the month of May, and by that time their deſigns were diſcovered and counteracted. On the 10th of that month the guards were increaſed, and bodies of cavalry ſtationed around the Luxembourg and the Thuilleries. The Directory at the ſame time informed the Council of Five Hundred, by a meſſage, that a dreadful conſpiracy was prepared to burſt forth on the following morning. At the ſound of the morning bell, which is every day rung, the conſpirators were to proceed in ſmall parties of three or four men to the houſes of ſuch perſons as they had marked out for deſtruction. After aſſaſſinating thoſe perſons, the whole parties were to unite, and to act againſt the Directory, whoſe guard they apprehended they could eaſily overpower. The conſpirators had appointed a new Directory and a new legiſlature, to conſiſt of the moſt violent of their own party. Among the leaders of this conſpiracy, who were now arreſted by order of the Directory, was Drouet the poſtmaſter of Varennes, whom we formerly mentioned as having arreſted the unfortunate Louis XVI. when attempting to eſcape to the frontiers. Along with him were Babeuf, Antonelle, Pelletier, Gaudet, Julien, General Roſſignol, Germain, D'Arthe, Laignelot, and Amar, who had been a member of the committee of general ſafety along with Robeſpierre. Vadier and Robert Lindet were alſo engaged in the conſpiracy, but they made their eſcape. Drouet alſo eſcaped by the connivance of the Directory, as was generally underſtood; but the reſt of the conſpirators were removed for trial to the high national court at Vendome, where they were condemned. At the period of their removal thither, a new attempt was made by their party for their reſcue. About 600 men entered the camp at Grenelle near Paris, and endeavoured to prevail with the ſoldiers to join them in an inſurrection. This attempt was altogether unſucceſsful. A few of the inſurgents were killed, and the reſt fled.

251 Moderate party.

Theſe defeats of the Jacobins, and the diſcredit under which they were again brought, encouraged the moderate party in the two legiſlative councils to attempt to repeal the laſt decrees of the Convention, which had at once granted them an amneſty, and confirmed all the laws which, by confiſcating the property of emigrants, excluded their relations from the ſucceſſion. The diſcuſſion laſted many days; but the reſult was, that the law with regard to emigrants remained on the former footing; and the only point which the moderate party were yet able to carry was a modification of the decree to this extent, that thoſe terroriſts were declared incapable of holding public offices who owed their ſafety to the amneſty.

252 Diſtreſſed ſtate of the finances.

The ſtate of the finances now began to occupy the French government in a very ſerious manner. During the government of Robeſpierre, while the credit of the aſſignats was preſerved by the influence of terror, or by the ſale of the church lands, and the property of emigrants, little attention was beſtowed upon this ſubject. When money was wanted, more aſſignats were fabricated; and as few or no taxes were demanded from the people, no enquiry was made about the public expenditure. But when the boundleſs extravagance of the agents of government had loaded the circulation with aſſignats till they became of little or no value, it became a very difficult queſtion how the public ſervice was hereafter to be ſupported. A new paper currency, called *reſcripts*, was firſt adopted. Theſe were orders on the treaſury for caſh, payable at certain periods. But their credit ſoon paſſed away, as the treaſury had no means of fulfilling its engagements. The Directory complained very bitterly, in a meſſage to the Councils, of its diſtreſſes, and of the want of funds to carry on the approaching campaign. In conſequence of this meſſage, a law was paſſed, on the 25th of March, authoriſing the ſale of the remainder of the national domains for the price that had been fixed upon them at an early period of the revolution, amounting to about twenty-two years purchaſe. A new paper currency, called *mandats*, was to be received in payment. But the credit of government was now gone. The mandats inſtantly loſt in all private tranſactions one-fourth of their value, and they ſoon fell ſtill lower. This, however, produced a great demand for national property, which was thus about to be ſold far below its value. To prevent this effect, the legiſlature broke its engagements, and decreed, that one-fourth of every purchaſe ſhould be paid, not in mandats, but in caſh. This decree put a ſtop both to the ſale of national property and to the circulation of mandats.

253 Reaſons of the flouriſhing ſtate of agriculture.

Recourſe was next had to taxation; but this was attended with much difficulty. By the war, and the violent government of Robeſpierre, the French commerce had been in a great meaſure ruined. Induſtrious men, who poſſeſſed any capital, had therefore turned their attention to the cultivation of land. Many circumſtances led to this. By the emigration of the nobles, and the confiſcation of the church lands, the farmers were left with no landlord but the government; which, being ſupported by aſſignats, paid little attention to any other ſource of revenue. Hence they paid no rent, and ſpeedily roſe into opulence. The revolutionary government, which kept the inhabitants of the towns under dreadful bondage, was ſcarcely felt by the inhabitants of the country, who thus enjoyed the advantage of exciting no ſuſpicion in the rulers, and of paying neither rent nor taxes. The law which declared aſſignats to be a legal tender of payment, was a great ſource of profit to the cultivators of the ſoil. They contrived to ſell the produce of their farms only to ſuch as offered them ready ſpecie; while, at the ſame time, they paid their rents, where the landlord had not emigrated, in aſſignats, which they obtained at a trifling price. Hence it uſually happened, that while the tenant enjoyed affluence, his miſerable landlord was reduced to the neceſſity of ſelling his moveables to buy a portion of the grain that grew upon his own eſtate, or was tempted to ſell the eſtate itſelf, at an undervalue, to obtain the means of emigration. By theſe and other circumſtances, the whole induſtry of the French nation came to be directed towards agriculture. Their country was accordingly well cultivated; but as the riches of agricultural nations are not eaſily ſubjected to taxation, the French Directory now found it impoſſible to carry on the ſchemes of ambition and of conqueſt, which they had already formed, without relying for reſources upon the plunder of the neighbouring ſtates, which ſpeedily rendered their armies odious in all thoſe quarters of Europe to which they penetrated.

254 National Inſtitute.

Amidſt their preparations for the approaching campaign, the Directory attempted to increaſe their own reputation at home, by eſtabliſhing what is called the *National Inſtitute*; which is a ſociety of men of letters, under the protection of the government*. Into this body were collected the moſt celebrated literary characters in the nation that had eſcaped the fury of the Mountain Party. Among theſe were La Place, Lalande, Fourcroy, Bertholet, Volney, Dolomieu, and others, well known throughout Europe. The firſt public meeting of the Inſtitute was held, with great ſplendour, on the 4th of April, in the hall of the Louvre, called the *Hall of Antiques*. The ambaſſadors of Spain, Pruſſia, Sweden, Denmark, Holland, America, Tuſcany, Genoa, and Geneva, were preſent. The members of the Directory attended in their robes, and their preſident made a ſpeech of inſtallation, declaring the determination of the executive power to protect and encourage literature and the arts. Duſaulx, the preſident of the Inſtitute, replied, in a ſpeech in which he declared the reſolution of the members to labour to give luſtre to the republican government by their talents and productions. Fifteen hundred ſpectators applauded the ſpeeches with enthuſiaſm, and vainly imagined that all the evils of the revolution were terminated, and that their country was now entering upon a career of unexampled glory and proſperity.

255 Overtures of the Britiſh government.

At this period the Britiſh government made an approach towards a negociation with France. On the 8th of March Mr Wickham, the miniſter plenipotentiary to the Swiſs Cantons, tranſmitted to Barthelemy, ambaſſador from the French Republic to the Helvetic body, a note containing three queſtions. Whether France would be diſpoſed to ſend miniſters to a congreſs to negociate peace with his Britannic Majeſty and his allies? Whether France would be diſpoſed to communicate the general grounds on which ſhe would be willing to conclude peace, that his Majeſty and his allies might conſider them in concert? and, laſtly, Whether France would deſire to communicate any other mode of accompliſhing a peace? The note concluded with a promiſe to tranſmit to the Britiſh court whatever anſwer ſhould be returned; but declared, that Mr Wickham was not authoriſed to enter into any diſcuſſion upon theſe ſubjects.

256 Inſolently rejected by the Directory.

On the 26th of the ſame month Barthelemy returned an anſwer in name of the French Directory. This anſwer began by complaining of inſincerity in the propoſal made by the Britiſh court, ſeeing its ambaſſador was not authoriſed to negociate, and that a congreſs was propoſed, which muſt render negociation endleſs. It proceeded to ſtate the ardent deſire of the Directory for peace; but aſſerted, that it could liſten to no propoſal for giving up any territory that had been declared by the conſtitutional act to form a part of the Republic (alluding to the Auſtrian Netherlands); declaring, however, that other countries occupied by the French armies, and political or commercial intereſts, might become the ſubject of negociation. Upon theſe points the Directory declared its readineſs to receive reaſonable propoſals.

To this anſwer no reply was ſent; but the Britiſh court publiſhed a note, of which copies were preſented to the foreign miniſters reſiding at London; and in it the ſpirit of the Directors anſwer was complained of, and alſo the refuſal even to negociate about the retention of foreign territory, under pretence of an internal regulation. It was added, with truth, that while ſuch diſpoſitions were perſiſted in, nothing was left but to proſecute a war equally juſt and neceſſary; but that, when more pacific ſentiments ſhould be manifeſted, his Majeſty would be ready to concur with his allies in taking meaſures for eſtabliſhing a juſt, honourable, and permanent peace.

257 French armies.

The French Directory had ſucceeded, during the winter, in reducing the weſtern departments into ſubjection. The emigrant expedition from England had induced the royaliſts once more to try the fortune of war; but, after various defeats, their leaders, Charette and Stofflet, were taken, and put to death on the 29th of March, and the inſurgents were ſuppreſſed in all quarters. The French government being thus left without an enemy at home, was enabled to make great efforts on the frontiers. The military force of the Republic was divided into three armies. On the Lower Rhine, the army of the Sambre and Meuſe was chiefly ſtationed about Duſſel-

ench olution, 796.

Duſſeldorf and Coblentz, and was commanded by Jourdan. Moreau commanded the army of the Rhine and Moſelle, in the room of General Pichegru, who had been diſmiſſed from his command. This army was ſtationed on the Upper Rhine, and from Landau to Treves. The third and laſt army was ſtationed on the coaſt of Italy, from Nice towards Genoa, and now received Bonaparte as its commander. The name and the actions of this man muſt hereafter fill ſo large a ſpace in the detail of this eventful period, that it is neceſſary to pay ſome attention to his perſonal hiſtory.

58 aparte

A Corſican gentleman, a lawyer by profeſſion, but who had appeared in arms under the celebrated Paoli in defence of the independence of his native iſland, was the father of Napolone Bonaparte. Napolone was born at Ajaccio in 1767; and by the intereſt of M. de Marboeuf, the French governor of the iſland, he was placed for his education at the celebrated military academy of France (*Ecole Militaire*), which has produced ſo many accompliſhed men. At a very early period of life he preſented himſelf as candidate for a commiſſion in the artillery, and was ſucceſsful, being the 12th on the liſt out of 36 victorious candidates. In conſequence of this event he ſerved two or three years in the French army as a lieutenant in the regiment of La Fere. Bonaparte having riſen to the rank of captain of artillery, returned to Corſica after the revolution, and was there elected lieutenant-colonel of a corps of Corſican national guards. Here he formed a connection, which had nearly proved fatal to him, with General Paoli, the friend of his father. He reſented the treatment which Paoli received from Robeſpierre's government, and entered ſo far into his intereſts as to write the remonſtrance, which was tranſmitted by the municipality to the Convention, againſt the decree which declared the general an enemy to the Republic. In conſequence of this, a warrant was at one time iſſued for his arreſt by the commiſſioners of the Convention. He made his peace, however, on this occaſion; and reſolved to adhere to the intereſts of France, in oppoſition to Great Britain, which at this period formed the deſign of taking poſſeſſion of Corſica. He embarked with the other members of his family for France, and arrived there at the time when Lord Hood was in poſſeſſion of Toulon. Salicetti, a deputy from Corſica to the Convention, introduced him to Barras, who was now ſuperintending the ſiege of Toulon. Here Bonaparte was advanced to the rank of general of artillery; and, under Dugommier, directed the attack of the various fortified poſts around the city. He was afterwards employed for a ſhort time againſt the royaliſts in the weſt of France; and we have already mentioned, that he was at the capital, and aſſiſted Barras in the conteſt between the Convention and the Pariſians on the 5th October. Hence he was regarded with diſlike by the moderate party, and repreſented as an unprincipled adventurer, brought forward to ſupport the terroriſt faction. He had many enemies, therefore, at the commencement of his career, and his character was treated with much freedom. The ſcandal of the times went ſo far as to aſſert, that he owed his preſent preferment, not ſo much to any talents he had yet had an opportunity to diſplay, as to his marriage with Madame Beaucharnois, a beautiful French woman whom Barras had taken under his protection.

French Revolution, 1796.

259 Takes the command of the army of Italy.

The French army of Italy amounted at this time to 56,000 men. Bonaparte at his arrival found it ill equipped, and the troops mutinous for want of pay and neceſſaries. He addreſſed them, however, in the true ſtyle of military enterpriſe, "If we are to be vanquiſhed, we have already too much; and if we conquer, we ſhall want nothing;" and ordered them to prepare for immediate action. His opponents, however, anticipated him in the attack. The Auſtrians employed in the defence of Italy, under General Beaulieu, are ſaid to have more than equalled the French in numbers. To theſe were united the King of Sardinia's army, under Count Colli, of 60,000 regular troops, beſides the militia of the country, which was now embodied, and a ſmall body of Neapolitan cavalry, amounting to about 2500 men. General Beaulieu began the campaign, on the 9th of April, by attacking a poſt called Voltri, which the French poſſeſſed, within ſix leagues of Genoa. They defended themſelves till the evening, and then retreated to Savona. Next morning Beaulieu, at the head of 15,000 men, preſſing upon the centre of the French army, was completely ſucceſsful till one o'clock afternoon, when he reached a redoubt at Montenotte, which was the laſt of their entrenchments. This redoubt contained 1500 French. Their commander, Rampon, prevailed with them, in a moment of enthuſiaſm, to ſwear that they would not ſurrender; and the conſequence was, that they arreſted the progreſs of Beaulieu for the remainder of the day. During the night, Bonaparte ſtationed his right wing under La Harpe, a Swiſs exile, in the rear of the redoubt of Montenotte, which ſtill held out, while he himſelf, with Maſſena, Berthier, and Salicetti, advanced by Altara, to take the Auſtrians on their flank and rear. Beaulieu, in the mean time, had received powerful reinforcements, and on the morning of the 11th renewed the attack on the French under La Harpe; but Maſſena ſoon advancing upon the flank of the Auſtrians and Sardinians, they gave way on all ſides. Two of their generals, Roccavina and Argentau, were wounded. They loſt 2500 priſoners, and were purſued beyond Cairo, of which the French took poſſeſſion on the following day.

260 His ſucceſſes.

On the 13th at day-break, the defiles of Milleſimo were forced by the French General Augereau; and, by a ſudden movement, General Provera, a knight of the order of Maria Thereſa, at the head of 1500 Auſtrian grenadiers, was ſurrounded; a circumſtance which proved not a little embarraſſing to the French army. For this reſolute officer, inſtead of ſurrendering, inſtantly withdrew to a ruined caſtle on the top of the mountain, and there entrenched himſelf. Augereau brought up his artillery, and ſpent many hours in attempting to diſlodge him. At laſt he divided his troops into four columns, and endeavoured to carry Provera's entrenchments by ſtorm. The French loſt two generals, Banel and Quenin, and Joubert was wounded in this attempt, which proved unſucceſsful. Provera paſſed the night in the midſt of the French army, which had been prevented by his obſtinate reſiſtance from coming to battle. On the 14th the hoſtile armies faced each other, but a diviſion of the French troops was ſtill occupied in blockading General Provera. The Auſtrians attempted to force the centre of the French, but without ſucceſs. Maſſena, in the mean time, turned the left flank of their left wing near the village

village of Dego; while La Harpe, with his diviſion in three cloſe columns, turned the right flank of the ſame wing. One column kept in awe the centre of the Auſtrians, a ſecond attacked the flank of their left wing, while the third column gained its rear. Thus was the left wing of the combined army completely ſurrounded and thrown into confuſion. Eight thouſand men were, on this occaſion, taken priſoners, and General Provera at laſt alſo ſurrendered.

Theſe victories were not gained over a timid or an inactive adverſary. On the morning after his fatal defeat at Milleſimo, Beaulieu made one of thoſe ſpirited efforts which often retrieve and alter the fortune of war At the head of 7000 choſen Auſtrian troops he attacked, at day-break, the village of Dego, where the French repoſed in ſecurity after their ſucceſs. He took the village; but the French having rallied under General Maſſena, ſpent the greater part of the day in attempting to retake it. They were thrice repulſed, and one of their generals, Cauſſe, was killed. Towards evening, however, Bonaparte in perſon having brought up reinforcements, the poſt was retaken, and the Auſtrians retired with the loſs of 1400 made priſoners.

Bonaparte had now thrown himſelf between the Auſtrian and Sardinian armies. By the poſſeſſion of the ſtrong poſt of Dego, his right was ſecured againſt the efforts of Beaulieu, while he was enabled to act with the maſs of his force againſt the Piedmonteſe troops. His enterpriſes in this quarter were facilitated by the exertions of Augereau, who had opened a communication with the valley of the Tanaro, where Serrurier's diviſion was approaching the town of Ceva, near which the Piedmonteſe had an entrenched camp defended by 8000 men.

On the 16th Augereau attacked the redoubts which covered this camp, and took moſt of them; which induced the Piedmonteſe to evacuate it during the night, and on the 17th Ceva was entered by Serrurier. Count Colli now retreated to cover Turin; making choice, however, of the ſtrongeſt poſts, and fighting in them all. He was able, on the 20th, to repulſe Serrurier; but on the 22d Bonaparte, ſtill preſſing on the Piedmonteſe general, defeated him near Mondovi, and entered that place. The retreating army next endeavoured to make a ſtand, with its head quarters at Foſſano, and its wings at Coni and Cheraſco. On the 25th Maſſena advanced againſt Cheraſco, which was ſpeedily evacuated. Foſſano ſurrendered to Serrurier, and Alba to Augereau.

261 Armiſtice with Sardinia ſucceeded by

Previous to theſe laſt movements, however, Count Colli, on the 23d of April, had written to Bonaparte, requeſting an armiſtice, to allow the King of Sardinia an opportunity of negociating a peace. The French army was now within 26 miles of Turin; and that prince ſaw himſelf ſuddenly reduced to the neceſſity of ſtanding a ſiege in his capital, or of accepting ſuch terms as the conqueror might think fit to impoſe. Bonaparte granted an armiſtice, on condition that the three fortreſſes of Coni, Ceva, and Tortona, ſhould be delivered up to him, with their artillery and magazines, and that he ſhould be allowed to croſs the Po at Valentia. 262 A formal treaty. The armiſtice was ſigned on the 29th, and it was followed by a formal treaty with the French Republic, which was concluded at Paris on the 17th of May. The conditions impoſed by this treaty upon the King of Sardinia were humiliating and ſevere. He gave up to France for ever the duchy of Savoy, and the counties of Nice, Jenda, and Bretneil. He gave an amneſty to all his ſubjects that were proſecuted for political opinions. He agreed that the French troops ſhould have free acceſs to Italy through his territory; and, in addition to the fortreſſes ſurrendered by the armiſtice, he gave up thoſe of Exiles, Suſa, Brunette, Aſſiette, Chateau Dauphin, and Alexandria, to be poſſeſſed by the French during the war; and they were authoriſed to levy military contributions in the territory occupied by them. He agreed to erect no fortreſſes on the ſide of France, to demoliſh the fortreſſes of Brunette and Suſa, and to diſavow his diſreſpectful conduct towards the laſt French ambaſſador.

In the mean time the French army advanced towards the Po. Beaulieu was deceived by the article in the armiſtice; which ſtipulated, that the French ſhould be allowed to croſs that river at Valentia, and made all his preparations for reſiſtance in that quarter. Bonaparte laboured, by ſeveral evolutions, to confirm this error; and while the Auſtrian general waited for him near Valentia, in various well fortified poſitions, he advanced haſtily into Lombardy, and had proceeded ſixty miles down the river to Placentia, where he arrived on the 7th of May, before the direction of his march was diſcovered. He immediately ſeized whatever boats or other craft he could find, and effected his paſſage without difficulty, there being only a ſmall party of Auſtrian cavalry accidentally on the oppoſite bank, and they fled at his approach. Beaulieu in the meanwhile had ſent, when too late, a body of 6000 infantry and 2000 cavalry, to prevent if poſſible the French from paſſing the river; but Bonaparte, now on the ſame ſide of the river with themſelves, met and defeated them on the 8th at the village of Fombio. Another body of 5000 Imperialiſts, advancing to the aſſiſtance of thoſe at Fombio, was met at Codogno, and repulſed by General La Harpe; but this officer was killed on the occaſion. 263 Armiſtice with the Duke of Parma. On the 9th Bonaparte granted an armiſtice to the Duke of Parma, on condition of his paying a contribution of 2,000,000 of French money, and delivering 10,000 quintals of wheat, 5,000 quintals of oats, and 2,000 oxen, for the uſe of the army. This prince alſo agreed to deliver up 20 of his beſt paintings, to be choſen by the French. This laſt ſtipulation was no ſooner known in France, than many men of letters and artiſts remonſtrated againſt it as both impolitic and uſeleſs. They contended, that it would render the French Republic odious to all Italy, without producing any advantage to compenſate this evil, as the progreſs of the arts could not be promoted by removing their beſt productions from the ſcenes in which they originated. But the Directory was too much occupied by views of national aggrandiſement to liſten to conſiderations of this kind, and ſimilar ſtipulations were ordered to be inſerted in every future treaty; by which means the moſt valuable curioſities of Italy were gradually transferred to the French capital.

Beaulieu, now driven from the Po, croſſed the Adda at Lodi, Pizzighitone, and Cremona. He left ſome troops, however, to defend the approaches to Lodi. The advanced guard of the French attacked theſe on the 10th, and drove them into the town; which was entered in ſuch cloſe purſuit, that the Imperialiſts, on leaving ench R olution, 796. 64 V ory at L i.

ving it, had not leiſure to break down the bridge over the Adda. At the other end of the bridge the Imperial army was drawn up, and thirty pieces of cannon defended the paſſage. The French generals, after a conſultation, agreed that it could not be forced. But Bonaparte having demanded of his grenadiers if they were willing to make the attempt, they applauded the propoſal, and he formed them into a cloſe column. Taking advantage of a cloud of ſmoke which iſſued from the hoſtile artillery, they ruſhed along the bridge, which was about 100 yards in length, and were at the middle of it before they were diſcovered. Here a general diſcharge from the Auſtrians deſtroyed 700 men. The French column heſitated, and the carnage became terrible; but Maſſena, Berthier, Dallemagne, Cervoni, Laſneſs, Dupat, and other officers, flying to the head of the column, urged on the ſoldiers, and preſſing forward, broke into the ranks of the Imperial army, which immediately gave way, and fled in all directions. This exploit has been much celebrated. The intrepidity of the troops by whom it was accompliſhed is unqueſtionable; but how far the leader who urged them to ſuch an enterpriſe is entitled to approbation may well be doubted. He had paſſed the Po with ſcarcely the loſs of a man. The Adda is a very inferior ſtream, which has fords both above and below the town of Lodi. The river was actually croſſed at one of theſe by Augereau with the cavalry, during the attack upon the bridge. With the delay of one day therefore the paſſage might have been effected without difficulty by the whole army, and there was no adequate motive to juſtify the laviſh expenditure of blood which was here made; for the French army no longer preſſed forward in purſuit of Beaulieu, but, after the ſurrender of Pizzighitone and Cremona on the 12th, returned upon Pavia and Milan on its left (A). Theſe places opened their gates without reſiſtance, though the citadel of Milan held out for a ſhort time.

265 conſe- ences.

It would ſeem that, in the original plan of Bonaparte's campaign, the utmoſt expected from his efforts was to gain ſuch an aſcendancy in Italy as might induce the princes and ſtates of that country to deſert the coalition againſt France, which all of them aſſiſted with money and proviſions, if not with troops. To accompliſh this object, though he ſent Maſſena in purſuit of Beaulieu as far as Verona, yet he himſelf now turned aſide into Modena and the territories of the Pope. He took Ferrara, Bologna, and Urbino; and at laſt granted an armiſtice to his holineſs and the Duke of Modena, on the uſual conditions of large contributions of money, paintings, and curioſities. From the Pope he farther exacted the ceſſion of the legations of Bologna and Ferrara, and poſſeſſion of the citadel of Ancona. His march into the Roman territory ſo alarmed the Neapolitan cabinet, that it now ſolicited peace; and Bonaparte granted an armiſtice, without attempting to add to it the humiliating conditions to which the other Italian ſtates were ſubjected. From the territories of the Pope, Bonaparte haſtily advanced with a body of troops to Leghorn, in the neutral ſtate of Tuſcany, under pretence of driving out the Engliſh, whoſe property there he confiſcated. By theſe meaſures the taſk aſſigned to Bonaparte was completed by the time the campaign upon the Rhine was begun. Mantua was ſtill indeed in the hands of the Imperialiſts, but it was blockaded, and all Italy was now ſubmiſſive to France.

French Revolution, 1796.

266 Succeſſes of the French in Germany.

To diminiſh, if poſſible, the efforts of the French on the ſide of Italy, the Imperialiſts thought it neceſſary to renew the conteſt in Germany. An intimation was therefore ſent to General Jourdan, that the armiſtice would terminate and hoſtilities commence on the 31ſt of May. At this time General Wartenſleben oppoſed Jourdan; and the Archduke Charles commanded the army in the Hundſruck, which covered Mentz and Manheim, and was ſtationed againſt Moreau on the Upper Rhine. The French began their operations with a very artful ſtratagem, intended to draw the whole Auſtrian force to the Lower Rhine, that Moreau might have an opportunity of ſuddenly penetrating into Swabia, and conſequently of carrying the war towards the hereditary territories of Auſtria. For this purpoſe Moreau remained quiet, while Jourdan began to act vigorouſly. On the 31ſt of May his left wing, under Kleber, iſſued from the lines of Duſſeldorf, on the right bank of the Rhine, and, advancing towards the Sieg, defeated the Imperialiſts. Thereafter they were driven ſucceſſively from the ſtrong poſitions of Ukareth and Altenkirchen, and retreated acroſs the Lahn. Jourdan, in the mean time, having advanced with his centre and right wing, forced the Auſtrian poſts on the Nahe, croſſed the Rhine, formed the blockade of the fortreſs of Ehrenbreitſtein, and haſtened forward as if about to form the blockade or ſiege of Mentz. By theſe movements the Archduke found himſelf in the hazardous ſituation of having Moreau in his front, while Jourdan, with a victorious army, commanded his rear. He therefore haſtily croſſed the river, leaving the fortreſſes of Mentz and Manheim to keep Moreau in check. Having joined the retreating army, he encountered Jourdan's advanced guard, which he compelled to retire after an obſtinate conflict. Jourdan did not hazard a general engagement, but withdrew to his former poſitions, the Archduke preſſing hard upon him, till he raiſed the blockade of Ehrenbreitſtein, and croſſed the Rhine in its neighbourhood, till Kleber, on the 20th of June, entered the lines of Duſſeldorf, from which he had ſet out.

Theſe movements were foreſeen. For the inſtant that the Archduke withdrew from the Palatinate to drive Jourdan down the Rhine, Moreau aſcended rapidly towards Straſburg; ſo that theſe hoſtile armies ſeemed to be flying from each other with all poſſible ſpeed. On the 24th of June, Moreau effected the paſſage of the river oppoſite to fort Kehl. This was an enterpriſe of conſiderable difficulty; for a ſudden ſwell, by covering a part of the iſlands with which the river abounds, had prevented the Auſtrians from being taken by ſurpriſe, as was originally intended. The entrenchments on ſuch iſlands as were occupied by troops were ſpeedily carried by the bayonet, and 2600 French landed on the oppoſite ſhore, but without cavalry or artillery. Here they were expoſed to the attacks of the Auſtrian

---

(A) We think this conduct cannot be accounted for, but by the ſuppoſition of a very improper correſpondence between Bonaparte and the Auſtrian officers.

Auſtrian horſe from the camp of Wilſtedt, and to the fire of the cannon of the fort. They maintained their ground, however, and even acted on the offenſive, till the boats, which had been ſent back, returned with a reinforcement. The whole redoubts and the fort were then inſtantly taken by ſtorm, or with the aſſiſtance of ſuch cannon as had been found in the firſt redoubts at which the French arrived, and the Imperialiſts fled towards Offenburgh.

The departure of the Archduke to the Lower Rhine in purſuit of Jourdan, and the large detachments which had recently been ſent towards Italy to oppoſe Bonaparte, now enabled Moreau to enter Swabia with a great ſuperiority of force. The ſtrong military poſitions, however, which the country affords, preſented to him conſiderable difficulties. On the 26th of June he drove the Auſtrians from their camp of Wilſtedt; and on the 27th he advanced with his army, in three columns, againſt another camp of 15,000 men in front of Offenburg. General Wurmſer ſent a ſtrong reinforcement from Manheim to the aſſiſtance of theſe troops; but having encountered two of the French columns on its way, the reinforcement was defeated, and the camp at Offenburg was evacuated during the night. The Auſtrians made an obſtinate ſtand at Renchen, near Philipſburg, on the 29th, but were at laſt compelled to retire with the loſs of 1200 men taken priſoners, and ſeveral pieces of cannon. On the 2d of July a diviſion of the French army, under General Laroche, ſucceeded in ſeizing the mountain Knubis, which is the higheſt point of the ridge of mountains called the Black Foreſt. On the 3d, after an obſtinate conflict, the Auſtrians were driven from the paſs of Friedenſtadt; in conſequence of which they loſt all communication with the emigrant troops under the Prince of Condé, and other Imperial troops ſtationed on the Rhine towards Switzerland. On the 6th, the left wing of the French, under Deſaix, encountered the Imperialiſts at Raſtadt, where the Auſtrians, who had received ſome reinforcements from the Lower Rhine, made a very determined reſiſtance; but were at laſt compelled to give way, and to retire to Ettingen.

The Archduke Charles now arrived in perſon with his army from the Lower Rhine, where he had left Wartenſleben, but with inferior force, to oppoſe Jourdan. The French, under this general, had inſtantly reſumed the offenſive upon the departure of the Archduke. Kleber advanced from the lines of Duſſeldorf, as formerly; while the centre and right wing croſſed the Rhine near Coblentz. The poſts of Ukareth and Altenkirchen were forced, and on the 9th of July the whole of Jourdan's army croſſed the Lahn. On the 10th, Wartenſleben was defeated near this river, after great ſlaughter on both ſides, with the loſs of 500 priſoners; and the French on the 12th entered Franckfort. The ſituation of the hoſtile armies was now become extremely important. The two Imperial armies were at no great diſtance from each other, and were placed in the centre between the armies of Moreau and Jourdan. Could the Archduke, who was commander in chief, have reſiſted one of theſe armies for a ſhort time, at any ſtrong poſition, by a detachment of his troops, while he precipitated himſelf with the maſs of his force upon the other, it is probable that any farther invaſion of Germany might have been prevented. But the activity of the French generals, whoſe progreſs could nowhere be reſiſted by partial efforts, prevented the poſſibility of executing ſuch a plan. He was therefore under the neceſſity of making his final exertion for the preſent ſafety of Germany againſt Moreau at Ettingen, on the 9th of July, without having formed any junction with Wartenſleben. The battle was moſt obſtinately fought. The French were four times repulſed in their attempts to force the heights of Rollenſolhe; and it was not till they had experienced a dreadful ſlaughter that they at laſt carried the field by the bayonet.

The loſs of the battle of Ettingen compelled the two Imperial armies to retire eaſtward. After placing ſtrong garriſons in Mentz, Manheim, and Philipſburg, the Archduke retreated through Swabia towards Ulm, where his magazines were placed. At every ſtrong poſition, however, he made an obſtinate ſtand; thus endeavouring to render the progreſs of the French under Moreau as tardy as poſſible. Wartenſleben, with the other Imperial army, retired through Franconia, reſiſting Jourdan in the ſame manner. Many bloody battles were fought, of which it is here unneceſſary to give a minute deſcription. It is ſufficient to remark, that the French were long ſucceſsful in them all. They gradually preſſed forward till Moreau's army compelled the Archduke to croſs the Neckar, and afterwards the Danube, leaving the whole circle of Swabia in the rear of the French. Wartenſleben was in like manner driven through Aſchaffenburg, Wurtzburg, Schweinfurt, and found it neceſſary to croſs the Rednitz, on the 6th of Auguſt, at Bamberg, to avoid the preſſure of Jourdan's army in his rear. This army continued to advance till its right wing, under Bernadotte, was poſted at Neumarck, with his advanced poſts at Teining, while the body of the army had driven Wartenſleben beyond the Nab, and had reached Amberg on the 22d of Auguſt.

267 Alarm throughou Germany.

Excepting a part of the mountains of Tyrol, three French armies, under Jourdan, Moreau, and Bonaparte, now occupied the whole country reaching from the frontiers of Bohemia to the Adriatic Sea. The alarm throughout Germany was extreme. The Duke of Wirtemberg obtained peace from the French on condition of paying 4,000,000 of French money. The circle of Swabia did the ſame, on engaging to pay 12,000,000 of livres, and to deliver 8,400 horſes, 5,000 oxen, 100,000 quintals of wheat, 50,000 quintals of rye, 100,000 ſacks of oats, 100,000 pairs of ſhoes, and a large quantity of hay. The Margrave of Baden obtained peace on ſimilar terms. The elector of Bavaria and the circle of Franconia negociated, and offered large payments; and even the diet of Ratiſbon ſent a deputation to treat with the French generals for neutrality. The King of Pruſſia now entered into a new treaty with the French; the conditions of which were concealed, but its nature appeared in the advantage which he took of the progreſs of their arms to take poſſeſſion of certain territories in Germany, and particularly of the ſuburbs of Nuremberg, under pretence of ſome antiquated title. Spain alſo entered into a treaty offenſive and defenſive with France, which was afterwards followed up by a declaration of war againſt Britain.

268 Danger the houſ of Auſtri

The danger of the houſe of Auſtria was now very great; and had Bonaparte, inſtead of being detained in Italy, by events of which we ſhall immediately take notice, ench Re lution, 796.

tice, been able to croſs the Tyrol by Inſpruck, and to reach the banks of the Danube, there is little doubt that the Emperor muſt have ſubmitted to ſuch conditions as the French thought fit to impoſe. Deſerted in all quarters by the members of the coalition, he ſtill, however, retained an ally in Great Britain, whoſe riches, liberally beſtowed in the form of a loan, extricated him from the preſent difficulties. Having the command of abundance of money, he was enabled to ſend one army after another to oppoſe Bonaparte in Italy, while he recruited his armies in Germany by extenſive levies, and by taking into his pay the troops of thoſe ſtates that made peace with France.

69 erly uct of Arch- d.

The Archduke, having received powerful reinforcements, reſolved to make a ſtand, on the 11th of Auguſt, againſt Moreau at Umenheim. A ſevere battle was fought during ſeventeen hours, and one of the wings of the Auſtrian army, under General Rieſe, even ſucceeded in occupying four leagues of territory in the rear of the French army; but the Archduke having received intelligence, in the mean time, that Wartenſleben could not maintain his ground againſt Jourdan, he thought it neceſſary to continue his retreat, and to adopt new meaſures. On the 17th of Auguſt he left General La Tour, with a part of his numerous army, to oppoſe Moreau, and having croſſed the Danube at Neuburg and Ingolſtadt, he marched to Wartenſleben's aſſiſtance to fall upon Jourdan with united forces. On the 23d he attacked Bernadotte at Teining, and forced him to retire towards Nuremberg. The Archduke was thus upon the right of Jourdan, while Wartenſleben was ſtationed on his front. The French general, finding his poſition dangerous, began to retreat on the 24th. From the ſtate of the finances, the French armies, at the commencement of this campaign, had been extremely ill equipped and ill paid. Hence the two armies of Moreau and Jourdan plundered, without decency or mercy, every place into which they entered. In Jourdan's army, more eſpecially, the want of diſcipline was extreme (A). Hence, when they began to retreat, loaded as they were with ſpoil, they ſuffered not leſs from the enraged inhabitants of the countries through which they paſſed, than from the military efforts of the hoſtile army. The Archduke having joined Wartenſleben, was enabled to ſend off Nauendorf with reinforcements to La Tour, who oppoſed Moreau, and, in the mean time, he continued in perſon to purſue Jourdan towards Wurtzburg. Here the French made a ſtand, on the 3d of September, and a general engagement took place. Both parties ſuffered great loſs, but more eſpecially the French, who retreated during the night. Jourdan now fled by Fuldaw to Wetzlaer. Having croſſed the Lahn, where he made ſome reſiſtance, he deſcended along the banks of the Rhine, till his army, on the 17th, reached Coblentz and Duſſeldorf, from which it had originally departed.

French Revolution, 1796.

270 Critical ſituation of Moreau.

The ſituation of Moreau's army was now uncommonly dangerous. He maintained his poſition, however, till the 17th of September; but he was undecided in his movements, and was obviouſly at a loſs how he ought to proceed. He attempted, without ſucceſs, to withdraw the Archduke from the purſuit of Jourdan, by detaching a part of his troops towards Nuremberg. Many attacks were made upon him, but all of them without ſucceſs; and the Imperial generals at laſt gave way to him wherever he turned. Finding at laſt that Jourdan's defeat was irretrievable, and that Bonaparte did not arrive from Italy, he reſolved to retreat. He had recroſſed the Lech, to prepare for this event; but now ſuddenly paſſing it again, as if determined to advance farther into Auſtria, he drove back General La Tour as far as Landſperg. Having thus obtained freedom for his future movements, he ſet out in full retreat, proceeding between the Danube at Ulm and the lake of Conſtance. La Tour, however, ſoon preſſed upon his rear. He found the paſſes of the Black Foreſt occupied by large bodies of Auſtrians and armed peaſants, while Generals Nauendorf and Petrarſch haraſſed his right flank with 24,000 men. Once more therefore he turned upon La Tour, at Biberach, on the 3d of October, with great impetuoſity, and having defeated him, took no leſs than 5000 priſoners; whom he was able to carry to France. He now continued his retreat; his right wing, under General Deſaix, keeping Nauendorf and Petrarſch in check, while the reſt of the army cleared the paſſages in front till he arrived at what is called the Valley of Hell (*Val d'Enfer*), a narrow defile, running for ſome leagues between lofty mountains, and in ſome places only a few fathoms in breadth. The centre of his army, advancing in a maſs, forced this paſſage, while the wings reſiſted the Imperial troops under La Tour and Nauendorf. After this deſperate effort he reached Fribourg on the 13th of October, and was ſoon compelled by the Archduke Charles, who had now arrived from the purſuit of Jourdan, to evacuate all his poſitions on the Swabian ſide of the Rhine, with the exception of Kehl, and a temporary fortification erected at Huningen, called a

271 His ſkilful retreat.

(A) It would be improper to interrupt our military detail with the following information reſpecting the morals of Jourdan's army at this time; which, however, it is of importance for our readers to know. We have it from a German Count, who ſaw with his own eyes a conſiderable extent of the march and countermarch of the French through Franconia.

Almoſt every officer in Jourdan's army had a miſtreſs; and ſuch of them as by plunder could ſupport the expence, gave balls, acted plays, and exhibited every ſpecies of gaiety when the army was not in actual motion. In all this there was nothing wonderful. The ladies, however, were not unfrequently pregnant; and as nurſing would keep them from theſe aſſemblies, where their company could not be diſpenſed with by the ſoldiers of liberty, they drowned their new-born infants—*they drowned them publicly!* Our correſpondent (the Count) ſaw two of the little victims, and he heard, from unqueſtionable authority, of ſeveral more. At a place within ſix miles of Nuremberg, a Pruſſian pariſh-miniſter, who was alſo a ſort of juſtice, endeavoured to ſave one innocent, and was thrown into the river and fired at by the French, when his pariſhioners endeavoured to ſave him. He had the happineſs, however, to ſave the child, and was allowed to keep it, the mother never enquiring after it!

bridge-head (*tete de pont*), though there was no bridge at that place.

The Imperial troops, in the mean time, had taken advantage of the defenceleſs ſtate of the French frontier to croſs the Rhine at Manheim, and to advance in various detachments to Weiſſemburg, Seltz, Hagenau, and almoſt to the gates of Straſburg, levying contributions and taking hoſtages wherever they came. Theſe detachments being now recalled, the Archduke reſolved to terminate the campaign by the capture of Kehl, and of the fortification at Huningen. But this proved no eaſy taſk. As the communication with the French ſide of the river was open at both places, the diviſions of Moreau's army did duty at them by turns. A great part of the winter was ſpent in fruitleſs attempts, on the part of the Auſtrians, ſometimes to take them by ſtorm, and ſometimes to reduce them by the forms of regular ſiege. Different ſallies were made by the French, and immenſe numbers of men were loſt on both ſides by the ſword, and by the ſeverity of the ſeaſon. It was not till the 10th of January that the French agreed to evacuate Kehl, and the fortification at Huningen was not given up till the ſucceeding month.

272
Reflections on the different orders of battle.

273
The order adopted by Bonaparte.

274
His pompous proclamation.

During the invaſion of Germany that has been now mentioned, and the reverſes that were ſuffered by the French armies there, Bonaparte ſtill continued to gain victories in Italy. The ſucceſs and the wonderful fortune of this man, require that we ſhould give ſome account of the arts by which he was enabled, ſo unexpectedly, to triumph over the moſt experienced military commanders of the age in which he lived. In the military art three orders of battle, or forms of drawing up an army, have been chiefly adopted by thoſe nations whoſe force has principally conſiſted of foot ſoldiers. The firſt form or mode conſiſts of arranging the troops in a deep line; that is, with from 16 to 30 men placed cloſe behind each other. This is the moſt ancient and the ſimpleſt order of battle. It was carried to perfection by the Greeks, under the name of the *Phalanx*; and, when the ſoldiers were armed with the long ſpear, it was extremely formidable. It left little to the ſkill of the general, except the choice of the ground where he was to fight, and made all to depend upon the ſteadineſs of the troops. It was attended with theſe diſadvantages, however, that an army thus drawn up commanded very little territory, and that if its ranks happened to be broken by unequal ground, or an uncommon effort of the enemy at a particular quarter, its parts could not eaſily be re-united, and it infallibly went into confuſion. In modern times, this order of battle cannot be adopted with ſucceſs on account of the facility with which it is broken by artillery, and the ſlaughter to which it expoſes the troops from every kind of fire arms. The ſecond, or modern order of battle, conſiſts in forming a front of an immenſe extent, with only two or three men in depth, and uſually ſupporting theſe by another, and perhaps a third equally ſlender line, at a conſiderable diſtance in the rear. Troops thus drawn up derive the greateſt poſſible benefit from their own fire arms, and ſuffer the leaſt loſs from thoſe of the enemy. They provide for their own ſubſiſtence by covering an immenſe track of country. Their battles are not ſanguinary, as they are ſeldom very cloſely engaged; and in caſe of a defeat, little loſs is ſuffered, becauſe they can ſcatter themſelves over a wide ſpace, as the rear protects the advanced body; and as the troops in a long line can ſeldom all be engaged at once, they are ſupported by each other in a retreat. This order of battle, however, is eaſily broken; and the moment the flank of an army is turned, it is under the neceſſity of retreating, as troops cannot ſpeedily be brought from other quarters to face the enemy there. The laſt order of battle conſiſts of dividing an army into columns of a narrow front and very great depth, and of ſtationing the columns at ſome diſtance from each other, with a ſecond ſet of columns oppoſite to the intervals between the firſt. This arrangement is ſuperior to the phalanx, in this reſpect, that it does not expoſe an army to diſorder by inequalities of ground, by the turning of its flank, or even by the defeat of one of its parts. The celebrated Epaminondas won the battles of Leuctra and Mantinea, by forming a part of his troops, on each of theſe occaſions, into a ſtrong column, which, by its great depth, and the mechanical weight of its ſhock, broke through the Spartan phalanx. The Romans are known to have owed their military ſucceſs, in a great meaſure, to the arrangement of their legion. It was drawn up upon the principle now mentioned; and tho' the columns were only 16 men in depth, it was confeſſedly ſuperior to the phalanx. In modern times, however, this order of battle is attended with great difficulties. It muſt reduce an army to embarraſſment with regard to proviſions from the ſmallneſs of territory which is thus occupied, and it expoſes the troops in an engagement to dreadful deſtruction from the powerful miſſile weapons which are now employed. In every enterpriſe they muſt inſtantly carry their point or be undone, as the fire of a few guns from a ſingle battery or redoubt would exterminate them by thouſands. With all its imperfections, however, this laſt order of battle has at times been employed by enterpriſing men. It was the favourite arrangement of Guſtavus Adolphus; and his troops were drawn up according to it at the battle of Lutzen, where he himſelf was killed, while his army was victorious. The celebrated Marquis of Montroſe alſo uſed it on more than one occaſion, and it was now adopted in all important caſes by Bonaparte. Truſting to its ſucceſs, he puſhed his columns into the midſt of the Auſtrian army at Milleſimo, and fairly captured one of its wings. He ventured farther to throw himſelf into the centre, between the Auſtrian and Sardinian armies, and to vanquiſh the one, by acting againſt it with his whole troops while ſeparated from the other. Being careleſs about the ſhedding of blood, he never heſitated to expoſe his whole army to utter ruin in caſe of a failure. The ſucceſs of his battles, by enabling him to lay almoſt all Italy under contribution, gave him the means of maintaining the moſt ſteady and ſevere diſcipline over a well paid army. Filled with high notions of military glory, which he is ſaid to have derived from the writings of Plutarch, he laboured to inflame, with the ſame ſpirit, the minds of his ſoldiers by proclamations, expreſſed in a very different ſtyle from the formal and more modeſt language of modern times. "Soldiers (ſaid he, when he firſt entered Lombardy), you have ruſhed like a torrent from the ſummit of the Appenines, you have driven back and diſperſed all who oppoſed your march. Your fathers, your mothers, your wives, your ſiſters, your ſweethearts, rejoice in your ſucceſs, and boaſt with pride of being related to you.

But

But remains there nothing more for you to effect? Shall poſterity reproach us with having found a Capua in Lombardy? But I already ſee you ruſhing to arms; an unmanly repoſe fatigues you, and the days loſt to glory are loſt to your felicity. But let the people be tranquil; we are the friends of all nations, and more particularly of the deſcendants of the Brutuſes, the Scipios, and the illuſtrious perſonages whom we have choſen as models. To reſtore the Capitol, to replace with honour the ſtatues of the heroes who rendered it renowned, and to rouſe the Roman people, become torpid by ſo many ages of ſlavery, ſuch will be the fruit of your victories; they will form an epoch to poſterity, and you will have the immortal glory of renovating the faireſt portion of Europe. The French nation, free and reſpected by all the world, will give to Europe a glorious peace. You will then return to your homes and your fellow-citizens; who, when pointing to you, will ſay, *He was of the army of Italy*."

275 rſhal urmſer cked.

At the commencement of the French invaſion of Germany, Marſhal Wurmſer was ſent into Italy to replace Beaulieu, who was removed from his command. On his arrival, he collected the wrecks of the Auſtrian army, and prepared, till he ſhould receive re-inforcements, to confine the French within as narrow limits as poſſible, by lines drawn from the lake of Garda to the river Adige. At the end of June, however, theſe lines were attacked and carried by Maſſena's diviſion, which induced Wurmſer to avoid farther exertion till he ſhould receive an increaſe of force. In the mean time Bonaparte was not a little diſturbed by partial inſurrections of the Italians. Soon after his arrival in Lombardy, the inhabitants of Milan and of Pavia had riſen in concert againſt his troops; but they were reduced to ſubjection with little bloodſhed. In the beginning of July, farther inſurrections broke out in the Romagna. The inſurgents eſtabliſhed their head quarters at Lugo, and repulſed a party of French cavalry that was ſent againſt them. It was not till Augereau had overcome them, on the 6th, in a battle in which he loſt 200 men, that they could be ſubdued. The ſlaughter of theſe unhappy people was very great. Their town was given up to pillage, and all found in arms were deſtroyed.

276 antua ſieged.

The firſt part of the month of July was ſpent by Bonaparte in commencing the ſiege of Mantua in regular form; and towards the cloſe of that month he expected its capture. In this, however, he had ill calculated the immenſe military efforts which Auſtria, aided by the money of Britain, was capable of making. Twenty thouſand troops had been ſent from the Rhine, and other reinforcements were marching towards Italy from all quarters; ſo that Bonaparte, inſtead of being able to take Mantua, had ſpeedily to defend himſelf againſt the force of a ſuperior army to his own, that approached to raiſe the ſiege, and even threatened to drive him out of Italy.

277 rtial ſuc- ſſes of urmſer.

Wurmſer's army deſcended from the Tyrol in two diviſions. One half of it proceeded along the eaſt ſide of the lake of Garda, and the other came by the weſt to cut off the retreat of the French, who were thus encloſed by the Auſtrians. On the 29th of July, at three o'clock in the morning, Maſſena was driven from the ſtrong poſt of La Corona, on the eaſt of the lake, while, at the ſame time, 15,000 Auſtrians drove the French from Salo, and afterwards took Breſcia, with all the magazines and hoſpitals of Bonaparte's army. There was a fatal error, however, in the general plan of operations that had been formed by the Imperialiſts. Their army united was an overmatch for the French; but they had voluntarily divided it into two parts, placing Bonaparte between them. The error was inſtantly diſcerned, and taken advantage of by their antagoniſt. On the night of the 30th, he ſuddenly raiſed the ſiege of Mantua, and leaving a ſmall body of troops to keep in check the Imperialiſts on that ſide, he marched rapidly weſtward, and on the firſt of Auguſt retook Breſcia, with the magazines and hoſpitals. Having the maſs of his army united, Bonaparte ſurpaſſed his antagoniſts in numbers wherever he encountered them. He prepared to attack the Imperialiſts on the 3d at Salo, Lonado, and Caſtiglione, but was anticipated by them. Having formed a large body of his troops into cloſe columns, the Auſtrians, who were not yet aware of the nature of his mode of fighting, extended their line to ſurround them; a movement which enabled the columns to penetrate the Imperial army in all directions, and throw it into compleat diſorder.

278 He is defeated.

The French took 4000 priſoners, and 20 pieces of cannon. The Imperial troops were here ſo completely defeated, that a conſiderable diviſion of them having in vain attempted to retreat by Salo, which they found occupied by the French, wandered about in ſearch of a road by which to eſcape; and having next day come to Lonado, they ſummoned it to ſurrender, upon the ſuppoſition that the greater part of the French army had gone eaſtward to encounter Wurmſer. This was actually the caſe; but it ſo happened, that Bonaparte was in perſon at Lonado with only 1200 men. He was ſufficiently perplexed by this accident; but having ordered the meſſenger to be brought into his preſence, he threatened to deſtroy the whole diviſion for having dared to inſult the French army, by ſummoning its commander in chief to ſurrender. The ſtratagem was ſucceſsful. The Imperial officers imagined that the whole army was in the place, and immediately, with their troops, laid down their arms, to the number of 4000 men.

Such is the account of this tranſaction, which we have from the partial pen of the panegyriſt of Bonaparte, who writes the hiſtory of his campaigns in Italy; but we believe that the General has himſelf aſſigned the true reaſon of his ſucceſs on this occaſion, and others, where ſucceſs could not be reaſonably expected. In one of his intercepted letters, Bonaparte informs his correſpondent, that the Auſtrian armies in Italy coſt him more money than his own; and indeed it is not within the compaſs of ſuppoſition, that a body of veteran ſoldiers could have been intimidated to lay down their arms by ſo vain-glorious a threat as this, had not their officers been corrupted by French gold and French principles. The ſtratagem might have its effect upon the common ſoldiers, but it could not poſſibly impoſe upon their leaders, or upon the meſſenger who ſummoned Lonado to ſurrender.

279 Again defeated.

On the 5th and 6th, Bonaparte attacked Marſhal Wurmſer, and drove him from Peſchiera and the river Mincio. On the 7th, the Auſtrians were compelled to quit Verona, and to retire once more to the mountains of Tyrol. This conteſt, which had laſted more than ſix days, coſt the Imperialiſts more than 20,000 men, upwards of 15,000 of whom were made priſoners. A part of the Emperor's troops had been levied in Gallicia,

licia, the part of Poland which, in the partition of that country, had been allotted to Auſtria. Theſe men ſeized the moment of defeat to quit a ſervice which they diſliked, and to go over to the French; a circumſtance which greatly ſwelled the liſt of priſoners.

It was now neceſſary for the French to commence the ſiege of Mantua anew. The garriſon in their abſence had deſtroyed their works, and carried into the place 140 pieces of heavy cannon which they had left behind them, and procured a conſiderable quantity of proviſions. The blockade was renewed; but the French, by the loſs of their artillery, were unable to proceed to a regular ſiege; and by the beginning of the month of September, Marſhal Wurmſer, having received new reinforcements, was again enabled to attempt the relief of the place. Bonaparte having information of his intended approach, left ſufficient troops to keep up the blockade, while he advanced northward with his army; and on the 4th of September drove the Auſtrians from the paſſes of St Marco and the city of Roveredo to the paſs of Calliano, where they made their principal ſtand.

280 His maſterly conduct after a third defeat.

Here a battle enſued, in which the French took no leſs than 6000 priſoners, and entered Trent as conquerors. Upon ſuffering this defeat, Marſhal Wurmſer adopted a meaſure which cannot be ſufficiently approved of. Inſtead of retiring before the conqueror, who might have driven him to Inſpruck, and arrived at a critical moment at the Danube, where Moreau, after much heſitation, had only commenced his retreat, he ſuddenly threw himſelf with his vanquiſhed army into Baſſano, upon the flank and rear of Bonaparte, and then advanced by haſty marches towards Mantua. He attempted to make a ſtand at Baſſano on the 8th, but was defeated, and 5000 of his men were taken priſoners. He had ſtill a conſiderable body of troops however. With theſe he puſhed forward; and having fought different ſcattered diviſions of the French at Cerea, Caſtellano,

280 He enters Mantua.

and Due Caſtello, he effected the paſſage of the Adige at Porto Legnano, entered Mantua with the wreck of his army, amounting to about 4000 infantry and 4500 cavalry. In this enterpriſe the Imperialiſts loſt altogether 20,000 men; but the effect of it was, that it fixed Bonaparte in Italy, where he was obliged to remain watching and keeping under blockade the numerous garriſon of Mantua. He hoped that its numbers would ſoon reduce it by famine to the neceſſity of a capitulation; but in this he was deceived, as the fleſh of the horſes, carried into it by Wurmſer, afforded ſubſiſtence to the troops during a very long period.

281 Corſica revolts from Britain, and unites with France.

In the mean time, the fame which their countryman Bonaparte gained by theſe victories, produced in the Corſicans a deſire to change the Britiſh government for that of France. They accordingly diſplayed ſo mutinous a ſpirit, that the Britiſh Viceroy thought fit to evacute the iſland, which was no longer of any value to his government after all Italy had, in a great meaſure, ſubmitted to the French. The Imperial ſubjects in Italy alſo, along with the inhabitants of Bologna, Ferrara, and Modena, who were completely corrupted by the falſe philoſophy of the age, began now to republicaniſe themſelves under the patronage of the French general. They ſent deputies to a convention, levied troops, and aboliſhed all orders of nobility.

The Emperor ſoon ſent into the field a new army to attempt the relief of Mantua. In the beginning of November this army advanced under the command of Field Marſhal Alvinzi, who advanced towards Vizenza on the eaſt, ſeconded by General Davidovich, who deſcended with another diviſion from Tyrol. Alvinzi had already croſſed the Piava, when he was met by the French, and compelled to repaſs that river.

282 Partial ſucceſſes of the Auſtrians.

But Davidovich, in the mean time, after ſeveral engagements, having ſucceeded in driving the French down the Adige towards Verona, Bonaparte was under the neceſſity of concentrating his forces. He now adopted his uſual expedient of keeping one diviſion of the hoſtile army in check, while he contended with the maſs of his forces againſt the other. He left Vaubois with ſome troops to detain Davidovich, while he advanced in perſon againſt Alvinzi, who was now haſtening towards Verona. He was met, on his way, by the Auſtrians at the village of Arcole. To ſeize this village, which could not be ſpeedily turned on account of a canal, the French were under the neceſſity of paſſing a narrow bridge in the face of the fire of the Auſtrians. They made the attempt without ſucceſs. Their officers ruſhed to the head of the column, and in vain attempted to rally the troops. Generals Verdier, Bon, Verne, and Laſnes, were carried off the field. Augereau advanced with a ſtandard to the extremity of the bridge, but nobody followed him. At laſt Bonaparte, who in the mean time had ſent Guieux with 2000 men to turn the village at two miles diſtance, haſtened to the bridge of Arcole. Seizing a ſtandard, he advanced at the head of the grenadiers, crying, "Follow your general." They accordingly followed him to within 30 yards of the bridge, when they were intimidated by the terrible fire of the Auſtrians, and their leader found it neceſſary to retire. Attempting to mount his horſe to rally the column, leſt the Auſtrians ſhould advance to the purſuit, he was thrown into a moraſs, while ſtill under the fire of the troops in the village; but here he again eſcaped, as the Auſtrians did not attempt to follow up their advantage.

The village of Arcole was taken towards the evening by Guieux, and afterwards evacuated by the French. On the following day (the 16th of November) an obſtinate conflict enſued in its neighbourhood, in which nothing deciſive was accompliſhed.

283 They are defeated.

On the 17th the Auſtrians, having preſſed impetuouſly forward upon the centre of the French army, were taken by ſurpriſe upon their flank by the left wing of the French, which had been ſtationed for that purpoſe in ambuſcade. Their left wing, however, maintained its ground till Bonaparte ſent round a party of horſe with twenty-five trumpeters to their rear, who, by the noiſe they made, induced the Auſtrians to believe themſelves ſurrounded, and to fly on all ſides in confuſion.

Here again appear evidences of treachery among the Auſtrian officers, though the battle of Arcole was the moſt ſevere which the French had yet fought in Italy, and extremely fatal to their officers, as well as to a multitude of their troops. During its continuance, Davidovich had ſucceeded in defeating Vaubois, who was oppoſed to him and Rivoli, and the blockade of Mantua was actually uncovered for a time. But Bonaparte now returned, after having driven Alvinzi acroſs the Brenta, and the poſitions of Rivoli and La Corona were retaken, and Davidovich repulſed into Tyrol. General Wurmſer, however, ſtill held out in Mantua during 'rench volution, 1796.

during the remaining part of the year; and the only fruit hitherto derived from ſo many victories was, that the French nation was led to look towards Bonaparte as its only invincible commander, upon whom all its hopes of conqueſt were to depend.

284 gocia- i be- een Bri- n and ance.

During theſe military tranſactions, Great Britain had entered into a negociation with France. In conſequence of paſſports obtained from the Directory, Lord Malmeſbury arrived in Paris, and began the negociation with De la Croix the miniſter for foreign affairs. Tho' the Directory could not decently refuſe to negociate, yet they were unwilling ſeriouſly to conclude a peace with Britain. On the other hand, the Britiſh miniſtry have ſince declared that, as individuals, they actually diſapproved of a peace at this time, but that they thought it neceſſary both to negociate, and even to conclude a treaty, if proper terms could be obtained. In judging thus, they were certainly right; for the country at large, not ſeeing the danger of peace, was very deſirous of it, whilſt a deſperate faction was conſtantly aſcribing the continuance of the war to the criminal obſtinacy of the Britiſh government. The negociation which was now ſet on foot opened the eyes of all but thoſe who wiſhed to ſell their country to French regicides. Lord Malmeſbury propoſed, that the principle of mutual reſtitutions ſhould be agreed upon as the baſis of the treaty. After much uſeleſs altercation, and many notes had paſſed upon this ſubject, and alſo upon the queſtion, how far Lord Malmeſbury could negociate for the allies of Great Britain, from whom he had received no official powers, the Directory at laſt agreed to the general principle of mutual reſtitutions, and required that the objects of theſe ſhould be ſpecified. Accordingly, the Britiſh ambaſſador propoſed, in two memorials, that France ſhould relinquiſh the Auſtrian Netherlands, and offered to give up the French foreign ſettlements in return. An offer was alſo made to reſtore a great part of the Dutch foreign poſſeſſions, on condition that the Stadtholder's ancient authority ſhould be acknowledged in that country. The Directory now required Lord Malmeſbury to preſent the ultimatum of his conditions within twenty-four hours. On his complaining of this demand, he was informed, on the 19th of December, that the Directory would agree to no conditions contrary to the French conſtitution; and it was added, that his farther reſidence at Paris was unneceſſary!

285 uddenly roke off y the Di- ectory.

286 Cape of Good Hope, with a Dutch squadron, aken by he Briti*ſh*.

During this year, Great Britain retained her uſual ſuperiority by ſea. A Britiſh ſquadron, under Admiral Elphinſton, had taken poſſeſſion of the Dutch ſettlement at the Cape of Good Hope, on the 16th of September 1795. This ſettlement the Dutch wiſhed eagerly to recover; and for this purpoſe they advanced money to enable the French to fit out a ſquadron to co-operate with them in an attack upon it. The French government took the money, but the ſquadron was never equipped. The Dutch themſelves this year ſent a ſquadron of ſeven ſhips of war, under Admiral Lucas, to attempt to reconquer the Cape; but being no match for the Britiſh ſquadron, and being likewiſe caught between two fires, without the poſſibility of eſcaping, the Dutch fleet, without firing a gun, was delivered up to the Britiſh admiral.

Notwithſtanding the ſuperiority of Great Britain by ſea, the French, towards the cloſe of this year, attempted an invaſion of Ireland; but the plan was ill concerted, and, of courſe, unſucceſsful. The whole conduct of it was intruſted to one man, General Hoche, and no ſecond was prepared to occupy his place in caſe of any accident. The diſaffected faction with whom the French meant to co-operate was not warned of their approach, and the fleet was ſent towards a quarter of the country where the people were little diſpoſed, or, at leaſt, by no means prepared to receive them. Eighteen ſhips of the line, thirteen frigates, twelve ſloops, and ſome tranſports, having 25,000 land forces on board, were employed in this expedition. When about to ſail, it was detained for ſome time by a mutiny which aroſe in conſequence of the enliſtment of about 1,200 galley ſlaves. The fleet ſailed on the 10th of December; but a ſhip of the line was loſt in going out of Breſt, and ſome of the reſt were damaged. The frigate in which the commander in chief had embarked was ſeparated from the fleet in a gale of wind; and the conſequence was, that when the greater part of the fleet arrived at Bantry Bay, on the weſt coaſt of Ireland, nobody had inſtructions how to proceed. The troops and their officers wiſhed to land, but the admiral, Bouvet, refuſed to comply with their requeſt. Having remained ſeveral days upon the coaſt, he ſailed for France, and arrived at Breſt with a part of the fleet on the 31ſt of December. General Hoche did not reach Bantry Bay till it was too late. and therefore could not land. The fleet ſuffered great loſſes in its return. One ſhip of the line and two frigates foundered at ſea, a frigate was taken by the Britiſh, and a ſhip of the line, after an engagement with two Britiſh ſhips, was run aſhore to prevent her being captured.

French Revolution, 1796.

287 Unſucceſsful attempt by the French on Ireland.

1797.

At the commencement of the year 1797, the Archduke Charles was ſtill occupied in the reduction of Kehl, and of the French fortifications oppoſite to Huningen. Moreau ſtill commanded the army that oppoſed the Archduke; but General Hoche, after his return from the expedition to Ireland, was appointed to ſucceed Jourdan on the Lower Rhine. Bonaparte was ſtill engaged in the blockade of Mantua, while the Auſtrian government was making vaſt efforts to recruit the army of Alvinzi after its defeat at Arcole, and to enable that General to make a laſt and deſperate effort for the relief of Mantua. The young men of Vienna were urged to give their aſſiſtance on this important occaſion, and 6000 of them marched into Italy as volunteers. Alvinzi's army amounted now to nearly 50,000 men; and he commenced his operations on the 8th of January, by ſkirmiſhing along the whole of the French line from below Porto Legnago upwards, to La Corona near the Lake Garda. He continued for ſome days to alarm the French at all points, and thus to conceal the plan of his future efforts. On the 10th Bonaparte was ſtill at Bologna, on the other ſide of Mantua, taking precautions againſt the eſcape of Wurmſer by that quarter, which, from an intercepted letter, he had learned was in contemplation. Being now informed of the approach of the Auſtrian army, he haſtened to Mantua, and from thence to Verona, which was the centre of the line of his army that oppoſed Alvinzi. He arrived at Verona on the morning of the 12th; but as the Auſtrians continued to make their attacks upon all quarters at once, he was unable to penetrate the deſign of their leader. At laſt, on the 13th, the

288 Succeſſes of the Auſtrians.

the efforts of the Auſtrians began to aſſume a more formidable aſpect on the lower part of his line near Porto Legnago; but on the evening of the ſame day he received intelligence, that the upper extremity of his line, where Joubert commanded, had been attacked by ſuch an immenſe ſuperiority of numbers, that there could be no doubt that the greateſt number of the Imperial troops was concentrated there. The poſt of La Corona had even been forced, and Joubert compelled to withdraw to Rivoli, which he alſo abandoned.

298 They divide their army; The Auſtrians ſtill perſiſted in their unfortunate plan of dividing their army, that they might have two chances of ſucceſs. Ten thouſand choſen troops, among whom were the Vienna volunteers, were deſtined under General Provera to penetrate to Mantua by Porto Legnago, at the lower extremity of the French line; while Alvinzi in perſon advanced with the maſs of the army againſt Joubert at its other extremity. On the 13th all went well; Joubert was compelled to retreat; and he was ſo ſituated, that the eaſy capture of his whole diviſion on the following day appeared a very probable event.

Bonaparte, in the mean time, having learned the ſtate of affairs, left Verona in the evening of the 13th, having firſt ordered the whole centre of his army under Maſſena to follow him to the neighbourhood of Rivoli with all poſſible ſpeed. Here he ſpent the night with his officers in arranging the order of battle for next day, and in occupying proper poſitions. At day-break of the 14th the attack was begun by Joubert's diviſion, to the no ſmall ſurpriſe of the Imperialiſts, who were not aware of the arrival of Bonaparte with reinforcements. The battle, however, was long and obſtinate. The ſuperiority of numbers on the ſide of the Auſtrians enabled them to defeat all the efforts of the French to turn their diviſions. They at laſt ſucceeded in driving back upon the centre the two wings of the French army in conſiderable diſorder. Alvinzi now attacked the centre, which ſcarcely maintained its poſition; and the Auſtrian wings advancing on both ſides, completely ſurrounded the French army. The victory ſeemed already won; and it is ſaid that Alvinzi diſpatched a courier to Vienna to announce the approaching capture of Bonaparte and his army. Bonaparte indeed conſidered his own ſituation as very alarming; and is ſaid to have meditated his eſcape acroſs the Auſtrian right wing. From the nature of his order of battle, his troops had rather been concentrated than ſcattered by the repulſe they had received, and it was therefore ſtill in his power to make a deſperate effort. Having formed three ſtrong columns, he ſent them againſt the Auſtrian right wing. They ſucceeded in penetrating it at different points; and it fled in ſuch confuſion, that having encountered a party of French that had not arrived in time to join the body of the army, 4000 Auſtrians laid down their arms in a panic, and ſurrendered themſelves priſoners of war. 290 And are defeated. Night put an end to any farther conteſt; but Bonaparte conſidering this quarter of his line as no longer in danger, departed to oppoſe General Provera, leaving Joubert to proſecute the victory now gained. This ſervice he performed with great ſucceſs. A detachment under General Murat having marched all the night of the 14th after the battle, ſeized Montebaldo in the rear of the poſition at Corona, to which a conſiderable diviſion of the Auſtrians had retreated, while Joubert, next morning, attacked them in front. Finding themſelves ſurrounded, they ſoon fell into confuſion. Six thouſand men were made priſoners, many were drowned in attempting to croſs the Adige, and the remainder fled to Tyrol.

During this ſanguinary conteſt on the upper part of the Adige, General Provera had forced his paſſage acroſs the lower part of that river at Angiara near Porto Legnago, and compelled the French General Guieux to retire to Ronco. Augereau collected all the troops in the neighbourhood, and marched to attack Provera; but as he haſtened towards Mantua, Augereau could only come up with his rear; of which, after an engagement, he took 2000 priſoners. On the 15th, however, General Provera arrived in the vicinity of Mantua. The city, which ſtands in a lake, was blockaded at the two points, by which it has acceſs to the main-land called *St George* and *La Favorite*. Alvinzi was to have formed his junction with Provera at the poſt of St George. Receiving no intelligence of him, General Provera ſummoned the French commander here to ſurrender; and on his refuſal, endeavoured to carry the poſition by aſſault. 291 Mantua ſurrenders. Having failed in this attempt, he turned his attention towards the poſt of La Favorite, which he attacked on the morning of the 16th; while Wurmſer, who had perceived his arrival, advanced with the troops of the garriſon againſt the ſame point. But by this time Bonaparte had arrived with reinforcements. General Wurmſer was repulſed (B); and Provera being completely ſurrounded by the French, was under the neceſſity of ſurrendering himſelf with his troops priſoners of war. The reſult of all theſe battles at Rivoli and Mantua was the capture of 23,000 priſoners and 60 pieces of cannon; and thus four Imperial armies had periſhed in Italy in the attempt to preſerve Mantua. The capture of this city, however, was now inevitable, in conſequence of famine. It ſurrendered by capitulation on the 2d of February. Bonaparte on this occaſion endeavoured to acquire the reputation of humanity. To allow the French emigrants in the garriſon to eſcape, he conſented to an article in the capitulation that General Wurmſer ſhould be allowed to ſelect and carry out of the garriſon 700 men, who were not to be examined

---

(B) Marſhal Wurmſer had before this time begun to ſuſpect that his plans were betrayed to the enemy. When he reſolved to make his laſt ſally to co-operate with Alvinzi, he kept his plan to himſelf; and in the morning of that day on which the army was to march out, he gave to each of the generals commanding the diviſions (which we think were ſeven) his orders in a ſealed packet. The troops marched at the hour fixed on, in ſo many diviſions; and they were inſtantly attacked at all points by the enemy. Upon this, the old General ſaid to a Britiſh officer of high rank, who was with him in the fortreſs, We are betrayed, make your eſcape by any means that you can. This anecdote was communicated to us through a channel which leaves no doubt of its truth in our own minds; but not being authoriſed to give the *names* of our informers, we thought it not right to inſert it in the text. Its truth or falſehood may be eaſily aſcertained.

mined nor conſidered as priſoners; and the General himſelf was allowed to depart unconditionally.

29?
e Pope
ſeveres
oſti-
es;

In the meanwhile, the Pope, who of all the European princes had the beſt reaſon for diſliking the French cauſe, uncautiouſly perſevered in hoſtility, in the hope that ſome one of the Imperial armies might ſucceed in driving Bonaparte from Italy. Having recovered from the panic which induced him to ſolicit an armiſtice when the French firſt entered Lombardy, he had avoided concluding a treaty of peace, and attempted to enter into a cloſe alliance with the court of Vienna. He procured officers to be ſent from thence to take the command of his troops, and flattered himſelf with the vain hope of being able to make an important diverſion in favour of the Imperial troops.

As the Emperor and the French were both preparing with all poſſible ſpeed to renew their bloody conteſt on the frontiers of Germany, it was of importance to Bonaparte to leave all Italy in peace on his rear. On the 1ſt of February he ſent a diviſion of his troops under General Victor, along with what was called the *Lombard Legion*, conſiſting of Italians, to enter the territory of the Pope; and upon the ſurrender of Mantua Bonaparte followed in perſon. The troops of his Holineſs made feeble reſiſtance. The new raiſed Lombard legion was made to try its valour againſt them on the river Senis on the 2d. After ſtorming their entrenchments, it took their cannon and 1000 of themſelves priſoners. Urbino, Ancona, and Loretto, ſucceſſively fell an eaſy prey to the French. From the chapel at Loretto the papal General Colli had carried moſt of the treaſure; but the French ſtill found gold and ſilver articles worth 1,000,000 of livres, and the image of the virgin was conveyed as a curioſity to Paris. Bonaparte now proceeded through Macerata to Tolentino. He was here met by a meſſenger from the Pope with offers of peace, and concluded a treaty with his Holineſs on the 19th. By this treaty the conditions of the armiſtice were confirmed; and in addition to the payments then ſtipulated, the Pope promiſed to pay 15,000,000 of livres, and to deliver 800 cavalry horſes, with as many draught horſes and oxen. He alſo engaged to pay 300,000 livres to the family of the French envoy Baſſeville, who had been murdered at Rome, and to apologiſe by his miniſter at Paris for that event.

ered.

294
onaparte
inforced.

The French had been ſo unſucceſsful in their late irruption into Germany, through Swabia and Franconia, that they now reſolved to make their principal effort from Italy under Bonaparte. For this purpoſe, the Directory detached great bodies of the veteran troops that had fought under Moreau as ſecretly as poſſible through Savoy into Italy. The court of Vienna, however, was aware of the approaching danger, and gave the command on the ſide of Italy to the Archduke Charles, who of all their military leaders had alone of late been ſucceſsful againſt the French. He brought along with him his beſt troops from the Rhine, and numerous levies were endeavoured to be made in all the hereditary ſtates for his farther ſupport. The war was now about to be carried into new territories, on which the houſe of Auſtria had ſcarcely hitherto beheld a foe. It was neceſſary that Bonaparte ſhould once more attempt to ſcale the ſummit of the Alps. This immenſe chain of mountains, which takes its riſe in the vicinity of Toulon, at firſt ſtretches northward under the names of *Piedmont* and *Savoy*. It then runs towards the eaſt, forming the countries of Switzerland, Tyrol, Carinthia, and Carniola. The three laſt of theſe, paſſing along the head of the Adriatic, form the frontier in this quarter of the hereditary ſtates of Auſtria. Between the mountains and the ſea lies the level and fertile tract of territory which belonged to Venice. It is croſſed by many large ſtreams, which are fed by the melting ſnows of the Alps, and whoſe nature is this, that they are greateſt in ſummer, and that their waters diminiſh during the froſts of winter.

295
Blunder of
the Court
of Vienna.

The council of war at Vienna now committed an important error in the plan of defence which it adopted. Inſtead of making a ſtand in the defiles of the mountains, the Archduke was ſent down into the plain to defend the paſſages of the rivers. War is eſſentially an offenſive art. Whatever the general purpoſe of hoſtility may be, it is always conducted with moſt ſucceſs when the detail of its operations is ſo managed as to aſſume the form of enterpriſe and of vigorous attack. This ariſes not from any thing in the nature of the art of war, but from the immutable conſtitution of the human character. The ſtrength of men who are fixed without motion in a particular ſpot, is ſubdued by the depreſſing paſſion of fear, and by the deſpair of accompliſhing any important object; whereas, when urged to action and to enterpriſe, their energy is increaſed by hope, and by that preſumption of their own ſuperiority which all men readily entertain. Hence we have ſo few inſtances in hiſtory of nations ſucceſsfully defended by rivers or extenſive fortified lines; whereas mountainous countries have uſually ſet bounds to the progreſs of armies. In ſuch ſituations, the defending party can always act upon the offenſive. He finds his adverſaries divided, by their ſituation, into ſmall parties. He hopes to vanquiſh them in detail, and he acquires ſtrength and courage from the proſpect of ſucceſs.

While Bonaparte was advancing into the territory of the Pope, the Auſtrian army was arranging itſelf along the eaſtern bank of the Piava. The French were on the oppoſite bank, and Bonaparte haſtened to join them after he had concluded his treaty with the Pope. The beginning of March was ſpent in preparations; but at laſt the troops advanced, that the point of reſiſtance might be diſcovered. Having croſſed the Piava on the 12th of March, the Auſtrians retired, ſkirmiſhing for ſome days till they had croſſed the Tagliamento, where they made a ſtand with their whole force. Early on the 17th the French army arrived at Valvaſone, on the oppoſite bank; and after ſome heſitation, reſolved to force the paſſage of the river. To have accompliſhed this object very ſpeedily would have been difficult, had not a recent froſt diminiſhed the ſtream, by which means the French were enabled to croſs it in the face of the enemy in columns at various points. The army of Bonaparte was now in three diviſions. Joubert, with the left wing, advanced along the courſe of the Adige into Tyrol, and was ordered to croſs over from thence, and to deſcend along the valley of the river Drave, which is beyond the higheſt chain of what the Romans called the *Noric Alps*. Maſſena, with the centre, after croſſing the Tagliamento, advanced into the defiles of theſe mountains; while the right diviſion, which was attended by Bonaparte in perſon, proceeded along the coaſt of the Adriatic.

296
Progreſs of
the French
army.

After forcing the paſſage of the Tagliamento on the 17th, the French had eaſily defeated the Auſtrians on the oppoſite bank, and compelled them everywhere to retreat. The other rivers were eaſily paſſed; and on the 19th, the town of Gradiſca, on the river Liſonzo, ſurrendered to the right wing of the army, and its garriſon, amounting to 3000 men, were made priſoners of war. On the 21ſt Goritz was entered by the ſame diviſion, who found there the principal Auſtrian magazines and hoſpitals. Trieſte was entered on the 23d; and the French ſent off in waggons, from the quickſilver mines of Ydria, materials worth 2,000,000 of livres. In the mean time, the Auſtrians, in their haſty retreat, entangled themſelves and their baggage among the mountains. On the 24th, a large body of them was hemmed in between Maſſena, who had reached Tarvis, and a part of the French right wing under Guieux. 297 The Auſtrians defeated. Reinforcements, however, having found means to reach them from the Archduke's head quarters at Clagenfurt, they hazarded an enagement on the following day, but were defeated, with the loſs of 5000 taken priſoners, and 400 waggons loaded with baggage. The French left wing under Joubert, Baraguay D'Hilliers, and Delmas, was equally ſucceſsful. On the banks of the Lavis, after an obſtinate engagement, 4000 Auſtrians were taken; and thereafter at Clauzen they were again defeated, with the loſs of 1500 taken priſoners. Having entered Brixen, this diviſion turned eaſtward, and deſcended the valley of the Drave towards Clagenfurt. the capital of Carinthia, where it was met by General Maſſena; the Archduke, after a ſlight conteſt, having evacuated the place, and advanced farther towards the capital of the empire, which was now ſeriouſly menaced, and in which great conſternation prevailed. 298 Wonderful ſucceſs of Bonaparte. In 15 days Bonaparte had taken 20,000 priſoners, and croſſed the Alps; and though the country ſtill preſented ſome difficulties, there was no fortified place capable of reſiſting his progreſs towards Vienna. He did not, however, conſider his own ſituation as deſtitute of hazard, and ſeized the preſent moment of unbounded ſucceſs to make propoſals of peace. On the 31ſt of March he ſent a letter to the Archduke, in which he deprecated the uſeleſs prolongation of the war, and intreated him to interpoſe his good offices to put a ſtop to its farther ravages. But this prince, who ſeems to have doubted his own influence at the court of Vienna, returned a cold anſwer, ſtating, that it belonged not to him to inveſtigate the principles on which the war was carried on, and that he had no powers to negociate.

299 Partial ſucceſſes of the Auſtrians. The Auſtrian chiefs made a laſt effort, by raiſing the peaſants of the Tyrol in a maſs to embarraſs the rear of the French. They accordingly gained ſome ſucceſſes under General Laudohn, and drove out the French troops that had been left at Botzen and Brixen. The inhabitants of the Venetian ſtates alſo roſe againſt the troops that remained in their country; and being joined by ten regiments of Sclavonians, which had been in the pay of the government of Venice, they put the French to death wherever they were found, without excepting the ſick in the hoſpitals, of whom 500 were maſſacred at Verona. A party of Imperialiſts alſo drove the French garriſon out of Trieſte, and thus attempted to ſurround the invading army. Bonaparte, however, knew that the court of Vienna muſt be at leaſt as much embarraſſed as himſelf. His army amounted to 95,000 men. It had hitherto proved irreſiſtible; and the Auſtrians knew, that to ſurround was not to conquer it. He therefore perſiſted in advancing. On the 2d of April he ſucceeded in forcing the ſtrong defiles between Freiſach and Newmark, after a bloody battle, in which he took 600 priſoners. On the 4th, his advanced guard reached Hunſmark, where the Auſtrians were again defeated; and his army occupied Kintenfeld, Murau, and Judenbourg. 300 The Auſtrian cabinet treats for peace. Theſe advantages compelled the Auſtrian cabinet to treat for peace, as there was no longer any point at which the Archduke's army could hope to make a ſtand till it came to the mountains in the vicinity of Vienna. Meaſures were taken for removing the public treaſure and effects into Hungary, while Generals Bellegarde and Morveld were ſent to requeſt from Bonaparte a ſuſpenſion of hoſtilities. On being ſuffered to take poſſeſſion of Gratz and Leoben, within little more than 50 miles of Vienna, he conſented, on the 7th of April, to an armiſtice, which was only to endure till the night of the 13th, but was afterwards renewed for a longer period. It was followed on the 19th by a preliminary treaty, ſigned at Leoben; by which it was agreed that the Auſtrian Netherlands ſhould belong to France, and that the new republic in Lombardy ſhould continue under the name of the *Ciſalpine Republic*, and ſhould include the Milaneſe, the duchy of Mantua, and the territories of Modena, Ferrara, and Bologna. There is reaſon to ſuſpect that ſomething hoſtile to the independence of Venice was here alſo ſtipulated. 301 Unjuſt and cruel conduct of Bonaparte. Bonaparte agreed to withdraw without delay into Italy, on receiving ſubſiſtence for his army during its march; and it was reſolved, that all farther diſputes ſhould be afterwards ſettled by a definitive treaty of peace. On his return he accuſed the Venetian government of connivance at the inſurrection which had taken place againſt the French in his abſence; and having ſeized their city and whole territory, he diſſolved that ancient and ſingular, but now feeble, ariſtocracy.

While Bonaparte was advancing towards Vienna, the French armies on the Rhine had begun to preſs upon the Auſtrians, to prevent farther reinforcements from being ſent againſt him from that quarter. The Auſtrians offered an armiſtice; but as the French demanded the fortreſs of Ehrenbreitſtein as the price of it, both parties prepared for action. The left wing of the army of General Hoche advanced rapidly from Duſſeldorf, while the centre and right wing croſſed the Rhine near Coblentz. 302 Succeſſes of the French on the Rhine. The Auſtrians under General Wernecht retreated to the Lahn, where they waited the arrival of the French. Here a violent conteſt enſued on the 18th of April, in which 4000 Auſtrians were taken priſoners. The French took poſſeſſion of Wetzlaer, and drove their antagoniſts to the gates of Francfort. In the mean time, General Moreau, on the Upper Rhine, forced the paſſage of the river near Straſburg, and attacked the village of Dierſheim, of which he at laſt retained poſſeſſion, after having been more than once driven out, and the village nearly deſtroyed. The following day, however, the Auſtrians renewed the attack, and forced the French for ſome time to give way; but powerful reinforcements having croſſed the river, 03 e con- ed.

river, the French were at laſt enabled to renew the battle with ſuch vigour, that they took Fort Kehl, together with 5000 priſoners. The Imperialiſts in this quarter were now purſued towards the Danube; when all military operations were ſuddenly arreſted by meſſengers ſent through Germany by the Archduke Charles and Bonaparte, announcing that peace was concluded. Theſe meſſengers found the army of Hoche violently attacking Francfort on the Maine, which General Wernecht was endeavouring to defend. The news was diffuſed in an inſtant through both armies; and the contending troops, throwing aſide their weapons, congratulated each other upon the event.

04 ver of ce at period.

France now held a very elevated rank, and a formidable character, among the nations of Europe. Spain, Italy, and Holland, were held in dependence; while her victorious armies had compelled the laſt continental member of the coalition to accept of peace from an army that approached his capital. Had the Auſtrian officers been faithful, and the court of Vienna leſs ſelfiſh, ſubſequent events have indeed ſhewn that the affairs of the Emperor were not yet deſperate, and that Bonaparte was not that invincible hero which his rapid ſucceſſes gave ſome reaſon to ſuppoſe him. After the peruſal of his letters from Egypt, his victories loſe much of their brilliancy; nor does any action, or all the actions of his life, diſplay ſuch military ſkill, as the retreat of Moreau through Swabia, when preſſed on the rear by a victorious army, and ſurrounded on all hands by an incenſed populace. But Bonaparte had been ſucceſsful; the Archduke knew not whom to truſt: there is reaſon to believe that his plans were continually thwarted by a corrupt council at home; and the court of Vienna was bribed to make a peace. Of all the enemies of the French revolution, Britain alone remained in hoſtility. From her command of the ocean ſhe was enabled indeed to retain the feeble ſtate of Portugal, attached to her cauſe; but on land, ſuch was the terrible energy of France, that, with this exception, which ſeemed only to exiſt by tolerance, the Britiſh trading veſſels were excluded, by her influence, from all approach to the continent, from the Elbe to the Adriatic; and the Britiſh government was once more induced, in theſe circumſtances, to try the effect of a new negociation. All theſe external advantages, however, were ſpeedily loſt by the French nation; and it ſeemed the unhappy deſtiny of this people to be conſtantly deprived of the fruits of all their ſufferings, and their courage, by the turbulence of their domeſtic factions, and the profligacy and unprincipled conduct of their rulers.

05 tain con- es the r.

306 nteſt be- een the rectory l Coun-

A ſerious conteſt between the executive power and the legiſlature was now approaching. We already remarked, that the Directory was originally ſelected by thoſe men who had been the aſſociates of Robeſpierre; and though deſerted of late by ſome of the more violent ſpirits, who were termed *Anarchiſts*, it was ſtill conſidered as the head of the Mountain party. By the victory obtained over the ſections of Paris on the 5th of October, all oppoſition had been ſet at defiance for a time; but the nation at large had never been reconciled to theſe men. The period now arrived when a third of the legiſlative body was to be changed. On the 19th of May, Letourneur went out of the directory by lot. On the 20th, the new third took their ſeats in the Councils, a third of their predeceſſors having evacuated their ſeats by lot; and on the following day, Barthelemi, the ambaſſador to Switzerland, was choſen to ſucceed Letourneur in the Directory. The election of the members of the new third had almoſt entirely fallen upon men who were underſtood to be hoſtile to the Directory. Many Generals out of employment were choſen; ſuch as Pichegru, Jourdan, and Willot, and many repreſentatives of the families of the ancient nobility who had not emigrated (among whom was the prince of Conti) were now elected into the legiſlature. The moderate or oppoſition party in the two Councils now poſſeſſed a complete majority. Carnot and Barthelemi were underſtood to be favourable to them in the Directory; the former having made his peace with them, and the latter being eſtabliſhed by themſelves. The effect of this change in the ſtate of the Councils ſpeedily appeared in their adopting every meaſure that could embarraſs the Directory, or caſt odium upon the Mountain party, and alter the ſtate of things which it had eſtabliſhed.

307 Mild meaſures of the Councils.

On the 14th of June, Gilbert Deſmolieres brought forward a report from a committee upon the ſtate of the finances; in which he exhibited and reprobated in the ſtrongeſt terms the prodigality of the Directory, and the profuſion and rapacity of its agents. On the 18th the ſame committee propoſed a new plan of finance, the object of which was to deprive the Directory of any ſhare in the adminiſtration of the public money. In the mean time, on the 17th of the ſame month, Camille Jourdan had preſented a long report on the ſubject of religion; in which he endeavoured to demonſtrate the impropriety of prohibiting the public diſplay of its ceremonies, and the injuſtice of the perſecution which its miniſters had undergone for refuſing to take oaths preſcribed by the legiſlature. This report was afterwards, on the 15th of July, followed up in the Council of Five Hundred, by a decree, repealing all the laws againſt refractory prieſts, or which aſſimilated them to emigrants. On the following day, another decree, requiring from them a declaration of fidelity to the conſtitution, could only be carried by a majority of 210 againſt 204. A propoſal was now brought forward in the Council of Five Hundred by Emery, a new member, to repeal the laws which confiſcated the property of emigrants, and to allow their relations to ſucceed to them as if they had died at the period of their emigration. Thoſe who had fled into foreign countries from Toulon and other places, during the reign of terror, were alſo encouraged to return, and allowed to expect that their names would be crazed from the liſt of emigrants. The conduct of the Directory towards foreign powers was attacked on different occaſions; and Dumoullard propoſed the appointment of a committee to enquire into the external relations of the republic. This was a delicate ſubject; as it involved the character of the armies and their leaders, and as it might ſubvert the intereſts of the Directory with ſome of their friends of the Mountain party. The Venetian republic, though a neutral ſtate, had been overturned by Bonaparte on account of a popular inſurrection, for which the government apologiſed. Little account had been given of the immenſe ſums of money that had been levied in Italy. The armies in the preceding year had entered Germany in the character of plunderers;

plunderers; which had diſguſted all thoſe in that country who had once been friendly to their cauſe, and longed for their arrival. The Directory, at the ſame time, inſtead of encouraging the progreſs of revolution, which the Jacobins eagerly deſired, had ſuddenly made peace with the German princes, upon receiving pecuniary contributions, which were left to be exacted according to the ancient laws of the different ſtates (which exempt the nobles and the clergy), and thus fell heavieſt upon thoſe very perſons who had cheriſhed the new republican principles.

The diſcuſſion of theſe ſubjects brought the majority of the Directory and of the Councils into a ſtate of complete hoſtility. Both parties reſolved to violate the conſtitution, under the pretence of preſerving it. The one wiſhed to change the Directory before the time preſcribed by law, and the other to deprive of their ſeats a great number of the new legiſlators elected by the people. Barras was the moſt obnoxious of the directors; and an attempt was made to deprive him of his office, upon the footing that he was leſs than 40 years of age. But his colleagues aſſerted that he was born in the year 1755; and as no proof to the contrary could be brought, this abortive attempt ſerved only ſtill farther to irritate the contending parties, and they began to prepare for more effectual meaſures. Had not force been ſpeedily uſed on the ſide of the Directory, the Councils muſt naturally have prevailed. 308 Their popularity. The majority of the people confided in them. The national purſe was in their hands; and they hoped to ſubdue the Directory, as the conſtituent aſſembly had done the king, by avoiding to vote the neceſſary ſupplies. They could enact what laws they pleaſed. They had not indeed the command of the armies; but to remedy their weakneſs in this reſpect, General Pichegru, on the 20th of July, preſented a plan for reorganiſing the national guard, and placing it more at the diſpoſal of the Councils, by depriving the Directory of the nomination of the officers.

In the mean time the Directory was by no means deſtitute of adherents. The reſolutions of the Councils in favour of the prieſts, and the relations of emigrants, looked ſo like a deſertion of former maxims, that many perſons expected an immediate counter-revolution. The royaliſts gained courage, and a multitude of journals or newſpapers, favourable to their cauſe, began to be publiſhed. Emigrants obtained paſſports, and haſtened to Paris in the hope of being ſtruck off the liſt, upon alleging that they fled to avoid proſcription during the power of the Jacobins. The effect of all this was, that the purchaſers of national property, and thoſe who had become rich by the revolution, were alarmed. The whole Mountain party, and all thoſe who had been active in oppoſition to royalty, rallied round the Directory. The armies, whoſe chiefs found themſelves involved in ſome of the accuſations brought againſt that body, ſent addreſſes, in which they declared their reſolution to ſupport its power. The Councils declared theſe addreſſes, which the Directory had received from armed bodies, unconſtitutional, and procured counter addreſſes from different departments. At laſt the partizans of the two contending powers began to diſtinguiſh themſelves in Paris by their dreſs, and every thing preſaged an approaching appeal to force. On the 20th of July the Councils received intelligence that a diviſion of the army of General Hoche had advanced within a few leagues of Paris; whereas, by the conſtitution, the Directory incurred the penalty of ten years impriſonment if it authoriſed troops to approach nearer to the reſidence of the legiſlative body than twelve leagues, without its own conſent. An explanation of this event was immediately demanded. The Directory denied that they had ordered the march, and aſcribed it to a miſtake of the officer by whom it was conducted. Their explanation was treated with contempt, and much angry debate took place in the Councils concerning it; the Directory all the while conducting themſelves with much ſeeming moderation, and even ſubmiſſiveneſs. In the mean time their antagoniſts acted a very undecided part. 309 The Directory victorious. They long hoped to gain Lareveillere Lepaux to their ſide; in which caſe they would have had a majority in the Directory. This vain expectation rendered their conduct indeciſive. At length the majority of the Directory procured an addreſs of adherence from the ſuburb St Antoine, which in all the tempeſtuous days of the revolution had been the rallying point of the Mountain party. Encouraged by this addreſs they proceeded to immediate action. General Augereau had been ſent from Italy under pretence of preſenting ſome Auſtrian ſtandards to the Directory, and he was employed as their tool upon this occaſion. They commanded the garriſon of Paris, and they had managed to bring over to their party the ſoldiers compoſing the guard of the two councils. Before day-break on the morning of the 4th, Augereau ſurrounded the Thuilleries with a diviſion of the troops. The guard of the Councils refuſed to reſiſt, and their commander, Ramel, was taken priſoner. Having entered the hall, he found Pichegru and other twelve of the chiefs of the oppoſite party ſitting in conſultation, and immediately ſent them priſoners to the Temple. Some other obnoxious members of the Councils were alſo put under arreſt. The director Carnot had made his eſcape on the preceding evening, but Barthelemi remained, and was impriſoned.

All this was accompliſhed without noiſe, and in an inſtant. Many members of the Councils, when they came to the hall at the uſual hour, were ſurpriſed to find that ſeals were put upon the doors, and that they could not obtain admittance. They were invited, however, to go to the Surgeons Hall and the theatre of the Odeon, where they were told the Directory had appointed the Councils to aſſemble. At theſe places, about forty of the Council of Ancients, and double that number of the other Council, aſſembled about noon, and ſent to demand from the Directory an account of the proceedings of the morning. They received an anſwer, declaring, that what had been done was neceſſary to the ſalvation of the Republic, and congratulating the Councils *on their eſcape* from the machinations of royaliſts. 310 Pretended conſpiracy. Being ſtill at a loſs how to act, the Council of Five Hundred appointed a committee of four members (of whom Sieyes was one) to report upon the meaſures to be adopted. On the following day Boullay de la Meurth preſented a report from this committee, in which he announced, that a vaſt royaliſt conſpiracy, whoſe centre was in the boſom of the Councils, had been formed to overturn the conſtitution, but that it had been baffled by the wiſdom and activity of the Directory. The report concluded, by propoſing the immediate tranſportation of the conſpirators without a trial.

trial. Accordingly, theſe degraded repreſentative bodies proceeded, after ſome debate, on hearing the names of the accuſed perſons read over, to vote the tranſportation to Guiana in South America, of fifty-three of their own members, and twelve other perſons, among whom were the directors Carnot and Barthelemi. They annulled the elections in forty-nine departments, repealed the laws lately enacted in favour of the diſaffected clergy and the relations of emigrants; and even ſo far aboliſhed the liberty of the preſs, as to put all periodical publications under the inſpection of the police for one year. New taxes were voted without heſitation, Francis de Neufchateau and Merlin were elected to fill the vacancies in the Directory, and affairs were endeavoured to be conducted in their ordinary train.

the Di-
tory to
ify their
duct.

All this while the city of Paris remained tranquil. That turbulent capital, which had made ſo many ſanguinary efforts in favour of what it accounted the cauſe of freedom, had been ſo completely ſubdued ſince its unfortunate ſtruggle on the 5th of October, that it now permitted the national repreſentation to be violated, and the moſt obvious rules of practical liberty to be infringed, without an effort in their defence. The Directory, in the mean time, attempted to juſtify their conduct to the nation at large, by publiſhing various documents intended to prove the exiſtence of a royaliſt conſpiracy. The moſt remarkable of theſe was a paper, ſaid to be written by M. d'Antraigues, and found by Bonaparte at Venice; in which a detail was given of a correſpondence between General Pichegru and the Prince of Condé in the year 1795. The correſpondence itſelf was alſo, at the ſame time, ſaid to be found by General Moreau among papers taken by him at the late paſſage of the Rhine. It ſtated, that Pichegru had offered to the Prince of Condé to croſs the Rhine with his army, and having joined the Auſtrians under General Wurmſer, and the emigrants under the Prince of Condé, to return with the united armies and march to Paris, where they were to re-eſtabliſh royalty. The Prince is ſaid to have refuſed to accept of the offer, from jealouſy of the participation of the Auſtrians in the honour of the tranſaction. He therefore inſiſted that it ſhould be conducted without their aid; but Pichegru thought the attempt too hazardous in this form, and, being ſoon after removed from his command, the project failed. At the time of its publication, the genuineneſs of this correſpondence, and alſo of the paper found by Bonaparte, was denied; and nothing has appeared ſince to induce an unprejudiced man to think otherwiſe at preſent. Moreau, who was certainly involved in this conſpiracy, if real, has been intruſted ſince that period with the command of the armies of the republic; and though defeated by Marſhal Suwarrow, he is ſo far from being now conſidered as a royaliſt, that the revolutionary government ſeems inclined to intruſt to his military ſkill and fidelity its laſt efforts for the continuance of its exiſtence.

y all
werful.

From the violation of the repreſentative government that has been now ſtated, it became obvious to ſurrounding nations, that France had paſſed under the dominion of a ſmall faction at variance with the majority of the people. The Directory was all powerful. Its members, however, ſeem very ſoon to have become giddy by the elevated nature of their ſituation, and to have adopted a notion that there was no project of ambition or rapacity in which they might not venture to engage. During their conteſt with the Councils, they had protracted the negociations with Lord Malmeſbury at Liſle, and had ſuffered thoſe to relax which had been entered into between Bonaparte and the Imperial ambaſſadors at Campo Formio near Udine. Great Britain had offered to conſent to peace, on condition of being allowed to retain the Dutch ſettlements of the Cape of Good Hope, and the Spaniſh iſland of Trinidad, which had been taken in the month of February this year. The Directory now recalled their former negociators Letourneur and Maret, and ſent two others, Treilhard and Bonnier, in their ſtead; who immediately demanded whether Lord Malmeſbury had full power to reſtore all the ſettlements taken from France and her allies during the war? Upon his Lordſhip's declining to anſwer ſuch a queſtion, becauſe it implied an enquiry, not into his powers, which were in the uſual form, but into his inſtructions, which would preclude all negociation, he was required to return home to procure more ample powers. The negociations with the Emperor, however, were now ſpeedily brought to a concluſion. On the 17th of October, a definitive treaty was ſigned at Campo Formio. By it the Emperor gave up the Netherlands to France, the Milaneſe to the Ciſalpine republic, and his territories in the Briſgaw to the Duke of Modena, as an indemnification for the loſs of his duchy in Italy. The Emperor alſo conſented that the French ſhould poſſeſs the Venetian iſlands in the Levant of Corfu, Zante, Cephalonia, Santa Maura, Cerigo, and others. On the other hand, the French Republic conſented that the Emperor ſhould poſſeſs in full ſovereignty the city of Venice, and its whole other territory, from the extremity of Dalmatia round the Adriatic as far as the Adige and the lake Garda. The Ciſalpine Republic was to poſſeſs the remaining territory of Venice in this quarter, along with the city and duchy of Mantua, and the eccleſiaſtical ſtates of Ferrara and Bologna.

312
Treaty of
Campo
Formio.

Upon whatever principles the war might have hitherto been conducted, the terms of this treaty ſufficiently demonſtrated to all Europe, that its leſſer ſtates had no better reaſon to expect ſecurity from the houſe of Auſtria than from that of the new republic. This truth would have been ſtill more evident, had the articles of a convention, which was ſigned by theſe parties at the ſame period at Campo Formio, been publiſhed to the world. Fearing, however, to alarm too much the Germanic body, theſe articles were kept ſecret, and the parties agreed to prevail with the German princes, at a congreſs to be opened at Raſtadt, to conſent, in conſequence of an apparently fair negociation, to what France and Auſtria had determined ſhould take place. By the ſecret convention or treaty now alluded to, it was ſtipulated, that the Rhine, including the fortreſs of Mentz, ſhould be the boundary of the French Republic; that the princes, whoſe territories were alienated by this agreement, ſhould be indemnified by the ſecularization of church lands in Germany; that the Stadtholder of Holland ſhould be indemnified for the loſs of his eſtates in that country, by receiving German territory; that the Emperor ſhould receive the Archbiſhopric of Saltzburg, and the part of the circle of Bavaria ſituated between that archbiſhopric, the rivers Inn and Salzt, and the Tyrol; that the Imperial troops ſhould immediately withdraw to the confines of the hereditary ſtates beyond Ulm; and if the Germanic body ſhould refuſe peace on the above terms, it was ſtipulated, that the Emperor ſhould ſupply to it no more troops than his contingent as a co-eſtate amounted to, and that even theſe ſhould not be employed in any fortified place

313 Violent meaſures of the Directory.

Theſe treaties were immediately begun to be put in execution. The Auſtrians left the Rhine, which enabled the French to ſurround the fortreſſes of Mentz and Ehrenbreitſtein. Of the former, they ſpeedily obtained poſſeſſion; but the latter coſt them a very tedious blockade, before the garriſon, conſiſting of troops of the Palatinate, would agree to ſurrender. The Imperial troops, at the ſame time, entered Venice; the French having evacuated that city after carrying off or deſtroying its whole navy. The Ciſalpine Republic was eſtabliſhed, and Bonaparte left Italy; leaving, however, an army of 25,000 men to garriſon Mantua, Breſcia, Milan, and other places, and to retain this new republic in dependence upon France. Genoa was, at the ſame time, brought under a ſimilar dependence by means of popular commotions, inſtigated by the French, and a revolution in its government which took place at this period. And thus the French Directory, without the excuſe of hoſtility, as in the caſes of Holland and Spain, began a ſyſtem of interference in the affairs of weaker neighbouring ſtates, which was ſpeedily carried to an height that once more alarmed all Europe These men even attempted, at this time, to compel the ſtates of North America to purchaſe with money their forbearance from war. This was done through a circuitous channel, and in the form of an intrigue, by private perſons, who were inſtructed to inform the American miniſters at Paris, that a large loan on the part of America would be the beſt means of ſecuring peace; and it was hinted, that it would be rendered more acceptable if accompanied with a private preſent of L. 50,000 ſterling to the members of the Directory. This laſt propoſal was indeed denied by the French miniſter Tallyrand, who had given his countenance to this crooked negociation: but the general impreſſion produced by the tranſaction could not be removed; and its effect was to injure very deeply the character of the French government in the opinion of thoſe diſtant nations that were otherwiſe diſpoſed to regard it in the moſt favourable light. Nor was its reſpectability increaſed by a law which the two Councils, at the deſire of the Directory, thought fit to enact, declaring the ſhips of all neutral ſtates bound for Britain, or returning from thence, liable to capture. This law was not leſs impolitic than unjuſt. It placed the whole carrying trade of the weſtern world in the hands of the Britiſh, and thus enriched the very people whom it was intended to injure.

314 Invaſion of Wales.

For at this period Britain had acquired over the ocean a degree of uncontrouled dominion that was altogether unexampled in former times. During the whole year the French fleet lay blockaded in its own ports, and no enterpriſe was attempted by ſea, excepting in one ſolitary but ſingular inſtance. We have already mentioned that a number of galley ſlaves were ſent as ſoldiers with Hoche in his attempt upon Ireland. On the failure of that expedition, the Directory were at a loſs how to diſpoſe of theſe men. They could not now with propriety be ſent back to puniſhment, the troops would not ſerve along with them in the army; and as the new laws of France allow no remiſſion of crimes, they could not receive a pardon, nor was it ſafe to let looſe upon the country 1400 criminals. In this dilemma, the Directory reſolved to throw them into England. Accordingly, they were ſent in two frigates and ſome ſmall veſſels to the coaſt of Wales, and there landed with muſkets and ammunition, but without artillery. In the evening of the very day on which they landed, the 23d of February, they ſurrendered themſelves priſoners of war to a party of militia, yeomanry, cavalry, colliers and others, under the command of Lord Cawdor. The Directory boaſted that, by this enterpriſe, they had demonſtrated the poſſibility of landing troops on the Britiſh coaſt in ſpite of the vigilance of the navy; but this aſſertion was ill ſupported by the fate of the two frigates accompanying the expedition; both were captured in attempting to return to Breſt.

315 Brilliar victory Sir Joh Jervis the Spa fleet,

Though the French navy remained in port, and conſequently ſafe during the reſt of the year, their allies, the Spaniards and Dutch, ſuffered ſeverely. On the 14th of February, a Britiſh fleet of 15 ſail of the line, under the command of Sir John Jervis, engaged the Spaniſh fleet, amounting to 27 ſail of the line, off Cape St Vincent. In this action, the Spaniſh force, if it be eſtimated by the number of men, the number of guns, and the weight of metal, was more than double that of the Britiſh; but by the ſkilful manœuvres of its heroic commander, the Britiſh fleet twice croſſed through the line of the Spaniards, and ſucceeded in cutting off a part of their fleet from the reſt. Four ſhips of the line were taken, and the Spaniſh admiral's own ſhip eſcaped with difficulty. The fleet had been on its way to Breſt to join the French fleet there; but in conſequence of this action, it returned to Cadiz, where it was blockaded by the Britiſh.

For his gallant conduct in this engagement, which, when every circumſtance is taken into conſideration, is perhaps unparalleled in the annals of naval war, Sir John Jervis was immediately created Earl St Vincent, and received the thanks of both houſes of the Britiſh Parliament.

316 And of miral can ov the D

The Dutch were ſtill more unfortunate. The Texel, within which their fleet lay, was blockaded during the whole ſummer by Admiral Duncan. The French intended, by means of the Dutch fleet, to make another attempt upon Ireland. Troops were accordingly embarked, under the command of General Daendels; but a reſolution having at laſt been adopted of hazarding an engagement with the Britiſh, the Dutch admiral De Winter, in oppoſition to his own remonſtrances, was ordered to put to ſea. The Britiſh admiral had by this time left his ſtation near the Texel, and gone to Yarmouth to refit. On receiving intelligence, however, that the Dutch had ſailed, he inſtantly proceeded in queſt of them. On the 11th of October the Britiſh fleet, amounting to 16 ſail of the line, and 3 frigates, came in ſight of the Dutch fleet, which in force was nearly equal, within about nine miles of Camperdown in Holland. Admiral Duncan immediately run his fleet through the Dutch line, and, though on a lee ſhore, began the engagement between them and their own coaſt. A moſt bloody and obſtinate conflict enſued, which laſted nearly three hours. By that time, it is ſaid that almoſt the whole Dutch fleet had ſtruck. The ſhips could not all be approached and ſeized, however,

ench
olution
798.

ever, on account of the ſhallowneſs of the water upon the coaſt, to which the fleets were now very near. Eight ſhips of the line, with two of 56 guns, and one of 44, were taken, beſides a frigate, which was afterwards loſt near the Britiſh coaſt, and one of the ſhips of 56 guns foundered at ſea. Admiral de Winter was taken with his ſhip, and alſo the Vice-admiral Rentjies.

Similar honours were conferred upon Admiral Duncan as upon Sir John Jervis, and both admirals had each a penſion of L. 2000 *per annum* conferred upon him for life, with the full approbation, we may venture to ſay, of every well affected man in the kingdom.

in
ance.

The internal hiſtory of France now ceaſed to be very intereſting. Political freedom could not be ſaid to exiſt after ſo many of the repreſentatives choſen by the people had been driven from the legiſlature, and the departments reduced to the neceſſity of electing men more acceptable to their preſent rulers. Public ſpirit therefore rapidly declined. The high notions of the freedom and felicity it was about to enjoy, which had once been ſo eagerly cheriſhed by a great part of the nation, now gave way to a growing indifference about political queſtions, and the future deſtiny of the republic; for the people at large found themſelves little intereſted in a government which exiſted independent of their will, which conſiſted of a narrow circle of perſons, and whoſe conduct was ſurely not leſs crooked, intriguing, and unprincipled, than that of the ancient royalty, and its attending court, from which they had eſcaped; whilſt its ferocious cruelty, and total diſregard even of the forms of juſtice, were infinitely greater. But though the Directory was all-powerful, yet its power was limited by the preſent ſtate of things, which denied it the poſſeſſion of an abundant revenue. It had not yet been found poſſible to re-eſtabliſh a ſyſtem of productive taxation. The legiſlative councils, indeed, who now complied with every wiſh of the Directory, voted abundance of taxes: but theſe were ſcantily paid; partly on account of the total loſs of the national commerce, and partly becauſe the people were not diſpoſed to make great exertions in this way for the ſupport of government. By the conſtitution, they ſtill poſſeſſed the election of the judges and other magiſtrates; the country was filled with veteran ſoldiers, who at different times had returned from the armies after the lapſe of

318
Meaſure of
the Direc-
tory.

the uſual period of ſervice. The Directory, kept in awe by theſe circumſtances, turned its attention abroad, and found means to eſtabliſh an extenſive patronage, by dividing among its adherents the plunder of neighbouring ſtates, in whoſe welfare the people of France were little intereſted. The Girondiſt party had formerly propoſed to propagate their principles by eſtabliſhing a number of petty republics in the vicinity of France. The Directory now adopted the ſame project; that, under the pretence of diffuſing liberty, they might obtain new ſources of revenue and of power, by the dominion which they meant to exerciſe over theſe new governments. Holland and the Ciſalpine republic were already placed in dependence upon them; and Rome and Switzerland readily afforded them opportunities for extending their plan.

319
Embaſſy to
Rome.

After the treaty with the Emperor had been concluded at Campo Formio, Joſeph Bonaparte, brother of the General, had entered Rome as ambaſſador from the French Republic. The Pope, now deprived of all hope of foreign aid, and accuſtomed to humiliations, had ſubmitted to every demand made by him for reducing the number of his troops, and ſetting at liberty perſons impriſoned on account of political opinions. But an event

French
Revolution,
1798.

320
Inſurrec-
tion in that
city.

ſoon occurred to afford the Directory a pretence for accompliſhing the ruin of this decayed government. On the 26th of December 1797, three perſons had waited upon the French ambaſſador, and ſolicited the protection of his government to a revolution which a party at Rome meant to accompliſh. He rejected their propoſals, and diſſuaded them from the attempt; but did not, as was certainly his duty, communicate theſe propoſals to the papal government, to which he was ſent on a friendly embaſſy. On the following day, however, a tumult took place, in which the French cockade was worn by about 100 inſurgents. They were ſpeedily diſperſed, but two of the Pope's dragoons were killed. The ambaſſador, who probably knew the diſpoſition of the Directory towards the Pope, ſeems to have reſolved that his own perſonal conduct ſhould be blameleſs on the occaſion. He therefore went on the 28th of December to the ſecretary of ſtate, and preſented a liſt of the perſons under his protection who were entitled to wear the French cockade, conſenting that all others adopting it ſhould be puniſhed. He alſo agreed to ſurrender ſix of the inſurgents who had taken refuge in his palace. Towards the evening of this day, however, the popular tumult became more ſerious, particularly in the courts and neighbourhood of the French miniſter's palace. The Pope appears to have been perſonally unacquainted with the ſtate of affairs; but the governor of the city ſent parties of cavalry and infantry to diſperſe the inſurgents. About twenty perſons, having a Frenchman at their head, had, in the mean time, ruſhed into the palace, and demanded aid towards accompliſhing a revolution. A number of French officers, and others who were with the ambaſſador, propoſed to drive the whole inſurgents by force from the juriſdiction of the palace. This was certainly a ſalutary advice, and ſuch as could not have been rejected by the ambaſſador, had not his deſigns been hoſtile to the eſtabliſhed government. Rejected, however, it was; for, pretending to believe that his authority would be ſufficient to accompliſh the object in a peaceable manner, he went out into the court to addreſs the multitude. He was prevented from doing ſo by a diſcharge of muſquetry from the military, who were firing within the juriſdiction of the palace. He interpoſed with his friends between the military and the inſurgents; and while a part of the French officers in his train drove back the inſurgents with their ſabres, the ambaſſador advanced towards the ſoldiers, and demanded why they preſumed to violate his juriſdiction? as if the juriſdiction of a foreign ambaſſador were a legal aſylum for men in open rebellion againſt the government of the ſtate. It is not, therefore, ſurpriſing, that no attention was paid to this arrogant and abſurd demand; and the nature of the ground being ſuch, that the troops could fire over his head upon the multitude in the rear, they made a ſecond diſcharge, which killed ſeveral of the inſurgents. Upon this the ambaſſador advanced cloſe upon the ſoldiers, to prevail with them to depart; but they remained in a menacing attitude, and prepared for another diſcharge. Eager to prevent this, the French General Duphot, who was with the ambaſ-

321 A French general killed.

ambaſſador, and was next day to have married his ſiſter, ruſhed into the ranks of the military, intreating them to deſiſt. Here a petty officer of the Pope's troops diſcharged his muſket into the body of Duphot. Upon this, the ambaſſador and his other friends found it neceſſary to make their eſcape through a bye-way into the palace. The Spaniſh miniſter hearing of this event, ſent to the ſecretary of ſtate to proteſt againſt this violation of the privileges of ambaſſadors. But the government, equally alarmed and perplexed by the fear of a revolution, and of French vengeance, remained during many hours totally inactive. All this while the palace of the French ambaſſador remained cloſely beſet by the military, who occupied the whole of its juriſdiction, and all its courts and paſſages. He at laſt ſent to demand paſſports, to enable him to leave the territories of the Pope. They were granted; but with many proteſtations of the innocence of the government, and its regret on account of this unfortunate occurrence.

322 The papal government overturned.

Joſeph Bonaparte retired to Florence, and from thence to Paris. The Pope ſolicited the protection of the courts of Vienna, Naples, Tuſcany, and Spain; but they all ſtood aloof from his misfortunes: and this government, which had once poſſeſſed the moſt uncontrouled dominion over the minds of men, now fell without a ſtruggle. General Berthier, at the head of a body of French and Ciſalpine troops, encountered no oppoſition in his march to Rome, where he overturned the government of the Pope, and proclaimed the ſovereignty of the Roman people, with circumſtances of wanton inſult; which convey a ſtriking example of French humanity and French delicacy.

“ That the head of the church might be made to feel with more poignancy his humiliating ſituation, the day choſen for planting the tree of liberty on the Capitol was the anniverſary of his election to the ſovereignty. Whilſt he was, according to cuſtom, in the Siſtine chapel celebrating his acceſſion to the papal chair, and receiving the congratulations of the cardinals, Citizen Haller, the commiſſary general, and Cervoni, who then commanded the French troops within the city, gratified themſelves in a peculiar triumph over this unfortunate potentate. During that ceremony they both entered the chapel, and Haller announced to the ſovereign Pontiff on his throne, that his reign was at an end.

323 Cruel treatment of th Pope.

“ The poor old man ſeemed ſhocked at the abruptneſs of this unexpected notice, but ſoon recovered himſelf with becoming fortitude; and when General Cervoni, adding ridicule to oppreſſion, preſented him the national cockade, he rejected it with a dignity that ſhewed he was ſtill ſuperior to his misfortunes. At the ſame time that his Holineſs received this notice of the diſſolution of his power, his Swiſs guards were diſmiſſed, and republican ſoldiers put in their place.”

He was himſelf removed to the territory of Tuſcany, where he reſided in much obſcurity, till his enemies, driven from Rome in their turn, thought fit to carry him ſtill farther from his capital, to end his days beyond the Alps.

324 Roman re- public.

In the mean time, the Roman ſtates were converted into a republic after the French model; excepting that the ancient appellations of *conſuls*, *ſenators*, and *tribunes*, were adopted, inſtead of the new names of a *Directory* and *two Councils* (D). But this oſtentatious grant of freedom was rendered completely illuſory, by a condition

---

(D) The character of a nation, like that of an individual, will not perhaps admit of a ſudden and total change. This remark is exemplified in the French; who, even when they affect to aſſume the ſtern manners of Republicans, cannot diveſt themſelves of their frivolous and fantaſtical turn, and of that fondneſs for pomp and ſhow by which they were always diſtinguiſhed. The following account of the re-eſtabliſhment of the Roman Republic, by an author of reſpectability, who witneſſed the ſolemn farce, will amply confirm the truth of our aſſertion.

“ That the regenerated Roman people might be conſtitutionally confirmed in their newly-acquired rights, a day was ſet apart ſolemnly to renounce their old government, and ſwear fidelity to the new. For the celebration of this ſolemnity, which took place on the 20th of March, an altar was erected, in the middle of the piazza of St Peter's, with three ſtatues upon it, repreſenting the French, Ciſalpine, and Roman Republics. Behind the altar was a large tent, covered and decorated with ſilk of the Roman colours, ſurmounted with a red cap, to receive the deputies from the departments who had been ſummoned to aſſiſt. Before the altar was placed an open orcheſtra, filled with the ſame band that had before been employed to celebrate the funeral honours of Duphot. At the foot of the bridge of St Angelo, in the piazza di Ponte, was erected a triumphal arch, upon the general deſign of that of Conſtantine, in the Campo Vacino, on the top of which was alſo placed three coloſſal figures, repreſenting the three republics. As a ſubſtitute for baſs-reliefs, it was painted in compartments in *chiara ſcura*, repreſenting the moſt diſtinguiſhed actions of Bonaparte in Italy. Before this arch was another orcheſtra.

“ The ceremony in the piazza began by the marching in of the Roman legion, which was drawn up cloſe to the colonnade, forming a ſemicircular line; then came French infantry, and then cavalry, one regiment after another alternately, drawn up in ſeparate detachments round the piazza. When all was thus in order, the conſuls made their entrance, on foot, from the Vatican palace, where they had robed themſelves, preceded by a company of national troops and a band of muſic; and if the weather had permitted, a proceſſion of citizens, ſelected and dreſſed in *gala* for the occaſion, from the age of five years to fifty, were to have walked two and two carrying olive branches; but an exceſſively heavy rain prevented this part of the ceremony.

“ Before the high altar, on which were placed the ſtatues, there was another ſmaller one with fire upon it. Over this fire the conſuls, ſtretching out their hands, ſwore eternal hatred to monarchies, and fidelity to the republic; and at the concluſion, one of them committed to the flames a ſcroll of paper he held in his hand, containing a repreſentation of all the inſignia of royalty, as a crown, a ſceptre, a tiara, &c.; after which the French troops fired a round of muſketry; and, at a ſignal given, the Roman legion raiſed their hats in the air upon the points of their bayonets, as a demonſtration of attachment to the new government: but there was no ſhouting—no ench lution, 798.

tion annexed to it, that for ten years the French General ſhould poſſeſs a negative upon all laws and public acts. At firſt, however, the conquerors took care to place the government in the hands of the moſt reſpectable perſons in the ſtate favourable to democracy. But theſe men finding that they were merely to be employed as tools to plunder their fellow-citizens, for the emolument of their northern maſters, ſoon renounced their odious dignities, and were ſucceeded by men of more compliant characters, and leſs ſcrupulous integrity. The whole public property was ſeized by the invaders, and contributions were levied without end. The property of the cardinals and others who fled was confiſcated, and thoſe members of the ſacred college who remained were thrown into priſons, from which they could only eſcape by purchaſing their freedom at a high price.

325 erſeded military potiſm.

When this was done, and Generals and Commiſſaries had glutted themſelves with wealth, quarrelled about a *juſt* diviſion of the ſpoil, mutinied, and diſperſed, other unpaid, unclothed, unproviſioned armies from the north, with new appointments, ſucceeded; and when at length, even by theſe *conſtitutional* means, nothing more was to be obtained, and artifice had exhauſted every reſource, the maſk was put under the feet that had been long held in the hand; liberty was declared dangerous to the ſafety of the republic, the conſtituted authorities incapable of managing the affairs of the ſtate, and military law the only rational expedient to ſupply their place. Thus at once the mockery of conſular dignity was put an end to, the ſenators ſent home to take care of their families, and the tribunes to blend with the people whom they before repreſented. This new and preferable ſyſtem began its operations with nothing leſs important for the general welfare, than ſeizing the whole annual revenue of every eſtate productive of more than ten thouſand crowns; two-thirds of every eſtate that produced more than five, but leſs than ten; and one half of every inferior annual income.

Even the degenerated Romans could not have ſubmitted to all this, or at leaſt would not have aſſiſted in forging their own chains, had not the ſame means been employed to eradicate from their minds every moral and religious principle, which had been formerly employed for the ſame purpoſe in Paris. In order that the ſpirit of equality might be more extenſively diffuſed, a conſtitutional democratic club was inſtituted, and held in the hall of the Duke d'Altemp's palace. Here the new-born ſons of freedom harangued each other on the bleſſings of emancipation; talked loudly and boldly againſt all conſtituted authority; and even their own conſuls, when hardly inveſted with their robes, became the ſubjects of cenſure and abuſe. The Engliſh were held as particularly odious, and a conſtant theme of imprecation; and this farce was ſo ridiculouſly carried on, that a twopenny ſubſcription was ſet on foot to reduce what they were pleaſed to call the proud Carthage of the North.

French Revolution, 1798.

326 Methods employed to corrupt the Roman youth.

If this fooliſh ſociety had had no other object in view than ſpouting for each other's amuſement, bowing to and kiſſing a buſt of Brutus which was placed before the roſtrum (a ceremony conſtantly practiſed before the evening's debate), it would have been of little conſequence to any but the idle, who preferred that mode of ſpending their time; but it had other objects of a very different tendency, more baneful, and more deſtructive to the peace and morals of ſociety—that of intoxicating young minds with heterogeneous principles they could not underſtand, in order to ſuperſede the firſt laws of nature in all the ſocial duties; for there were not wanting men who knew how to direct the folly and enthuſiaſm of thoſe who did not know how to direct themſelves. Here they were taught, that their duty to the Republic ought ever to be paramount to every other obligation; that the illuſtrious Brutus, whoſe buſt they had before them, and whoſe patriotic virtue and juſtice ought never to be loſt ſight of, furniſhed them with the ſtrongeſt and moſt heroic example of the ſubordination of the deareſt ties of humanity to the public good; and that, however dear parental affection might be, yet, when put in competition with the general welfare of ſociety, there ought not to be a moment's heſitation which was to be preferred.

This ſort of reaſoning might perhaps have done no harm to the ſpeculative cloſet metaphyſician, who might have had neither father, nor mother, nor brother, nor ſiſter, nor a chance of ever being thrown in the way to reduce his theory to practice; but with a people who knew of no other ties but ſuch as depended on their religion and their natural feelings, without having been previouſly educated to diſcriminate, how far their reaſon might be deluded by ſophiſtry, or upon what cauſes

---

no voluntary ſigns of approbation; nor do I believe that there ever was a ſhow, in which the people were intended to act ſo principal a part, where ſo decided a tacit diſapprobation was given as on this occaſion.

"After the ceremony was concluded, the French officers, with the conſuls and deputies from the departments, dined together in the papal palace on Monte Cavallo, and in the evening gave a magnificent ball to the exnobles and others, their partizans, which was numerouſly attended, yet with an exception to the houſes Borgheſe, Santacroce, Altemp, and Ceſarini: I believe not one diſtinguiſhed family was preſent from deſire or inclination: but it was now no longer time to accumulate additional cauſes for oppreſſion; and he who hoped to ſave a remnant of his property, avoided giving occaſion for perſonal reſentment. At night the dome of St Peter's was illuminated, with the ſame ſplendour as was cuſtomary on the anniverſary of St Peter's day. This was the ſecond time of its illumination ſince the arrival of the French, having been before diſplayed on the evening of the ſolemn fete to honour the manes of Duphot, which, though not quite ſo opportune, was done to gratify the officers that were to leave Rome on the morrow.

"The day after this federation, the French publiſhed the Roman conſtitution in form, which was only a repetition of the one given to the unfortunate Venetians, conſiſting of 372 articles, and which I think unneceſſary to tranſcribe, as it would only be giving what we have already had from time to time in tranſlations made from their own."—*Duppa's Journal of the moſt remarkable Occurrences that took place in Rome,* upon the Subverſion of **the Eccleſiaſtical Government in 1798.**

cauſes the permanent good of ſociety depended, it had the moſt direct tendency to generate the worſt paſſions, and to annihilate the beſt.

Young men were thus initiated to loſe all reſpect for their parents and relations, and even encouraged to lodge information againſt them, with the hopeful proſpect of being conſidered as deſerving well, of what they were pleaſed to denominate, the republic; and by thus weakening or deſtroying the bonds of affection, the way was made ſmooth and eaſy to the deſtruction of every thing like what, in a ſtate of civilization, is called character; doubtleſs, in order to prepare them the better to become the faithful agents of thoſe whom they were thus educated to ſerve.

327 Monuments of ancient art expoſed to ſale.

The moſt remarkable curioſities of this celebrated city had already been conveyed to Paris; and as national vanity had now given place to avarice in the minds of the Directory, the remaining monuments of ancient or of modern art, with which Rome abounded, were ſold by public auction. Advertiſements (E) were ſent through Europe, offering paſſports to the natives of countries at war with France, if they ſhould wiſh to become purchaſers; and thus the wealthier inhabitants of the Roman territory not only ſaw themſelves ſubjected to ſevere exactions, but they beheld with cruel mortification thoſe objects now given up as a prey to vulgar ſpeculation, and diſperſed over the world, which had ſo long rendered their city the reſort of all nations.

Such was the progreſſive conduct of the *Great Nation* towards an injured and oppreſſed people, whoſe happineſs and deareſt intereſts were its firſt care, and to whom *freedom* and *liberty* had been reſtored, that they might know how to appreciate the virtue of their benefactors, and the ineſtimable bleſſings of independence.

328 French ingratitude to Switzerland.

More ſanguinary ſcenes were, in the meanwhile, taking place in Switzerland. That country had remained neutral during the conteſt in which France had lately been engaged; and had thus protected the weakeſt portion of her frontier, while the reſt of it was aſſailed by the combined forces of Europe. The merit of this ſervice was now forgotten, and the Directory reſolved to render Switzerland one of their tributary ſtates. Ambitious nations have in all ages found it an eaſy matter to deviſe apologies for invading the territory of their neighbours. The wealthier branches of the Swiſs confederacy were in general governed by hereditary ariſtocracies. Some of the cantons had no government within themſelves, but were the ſubjects of neighbouring cantons. In conſequence of this circumſtance, and of the contending privileges of different orders of men, popular inſurrections were more frequent in Switzerland than in any country in Europe, though none was more equitably governed. When an inſurrection took place in one canton, its government was frequently under the neceſſity of ſoliciting the aid of the government of an adjoining canton, or even of the neighbouring monarchs of France or Sardinia, to enable it to ſubdue its own rebellious ſubjects. A dangerous precedent was thus eſtabliſhed; and as the French kings had formerly interfered in favour of the rulers, the republican Directory now interfered in favour of the ſubjects. The canton of Berne was ſovereign of the territory called the *Pays de Vaud*. In this diſtrict diſcontents had always exiſted; and an inſurrection, under the countenance of the French Directory, broke out towards the end of the year 1797. The government of Berne ſaw the dangerous nature of its own ſituation; and on the 5th of January iſſued a proclamation, commanding the inhabitants of the Pays de Vaud to aſſemble in arms, to renew their oath of allegiance, and to reform every abuſe that might appear to exiſt in their government. A commiſſion was at the ſame time appointed by the Senate or Sovereign Council at Berne to examine all complaints, and to redreſs all grievances. The proceedings of this commiſſion, however, did not keep pace with the popular impatience; and the inſurgents began to ſeize the ſtrong places in their country. The government of Berne now reſolved to reduce them by force, and ſent troops againſt them; but their commander Weiſs appears to have acted with much heſitation, if not with treachery. In the mean time, a body of French approached under General Menard. He ſent an aide de camp with two huſſars, with a meſſage to General Weiſs. On the return of the meſſengers, an accidental affray took place, in which one of the huſſars was killed. This was magnified into an atrocious breach of the law of nations. The French advanced; and by the end of January obtained poſſeſſion of the whole Pays de Vaud. Still, however, the government of Berne attempted to preſerve peace, while it endeavoured to prepare for war. The ſoldiers who had killed the French huſſar were delivered up, negociations were begun, and a truce entered into with General Brune, who ſucceeded Menard in the command of the French troops in the Pays de Vaud. As internal commotions were breaking out in all quarters, an attempt was made to quiet the minds of the people, that they might be induced to unite againſt the threatened invaſion.

329 Undecided conduct of the magiſtrates of Berne.

Fifty-two deputies from the different diſtricts were allowed to ſit in the Supreme Council of Berne, and a ſimilar meaſure was adopted by the cantons of Zurich, Lucerne, Fribourg, Soleure, and Schaffhauſen. An army of 20,000 men was at the ſame time aſſembled, and intruſted to the command of M. d'Erlach, formerly field-marſhal in the French ſervice. But diſaffection greatly prevailed in this army, and the people could not be brought to any tolerable degree of union. The French knew all this, and demanded a total change of government. M. d'Erlach, dreading the increaſing tendency to deſertion among his troops, requeſted leave to diſſolve the armiſtice. It was granted by the government, and immediately recalled. But the French now refuſed to negociate; and on the 2d of March, General Schawenberg, at the head of 13,000 men, entered Soleure.

(E) A copy of an advertiſement, iſſued on this occaſion by what was called *The Adminiſtration of Finances and Contributions of the French Republic in Italy*, is to be found in *Nicholſon's Journal of Philoſophy, Chemiſtry, and the Arts, for May* 1798. The advertiſement is dated at Rome, 28th Feb. 1798. A copy of it was ſent by Hubert, the agent of the French adminiſtrators, to Mr Trevor the Britiſh miniſter at Turin, and by him was tranſmitted to England.

rench volution, 1798.

330 nſterna- n of the vern- nt, and itulation Berne.

Soleure. Friburg was afterwards reduced by Brune, and the Swiſs army retreated. The government of Berne was in conſternation, and decreed what was called the *landſthurm*, or riſing of the people; which, in caſes of emergency, was authoriſed by their ancient cuſtoms. The people accordingly aſſembled; and their firſt act was to diſſolve the government, and to offer to diſmiſs the army, on condition that the French troops ſhould proceed no farther. This offer was refuſed, unleſs a French garriſon ſhould be received into Berne, and the invaders continued to advance. The regular troops under M. d'Erlach were reduced by deſertion to 14,000. The riſing of the people had indeed ſupplied him with numbers, but there was no time for arranging them. On the 5th of March he was attacked, and driven from the poſts of Newenbeg and Favenbrun. He rallied his troops, however, at Uteren, where they made a ſtand for ſome time. They renewed the conteſt at Grauholtz without ſucceſs, and were driven from thence about four miles farther to the gates of their capital. Here the Swiſs army made a laſt and bloody effort. Being completely routed, they murdered many of their officers in deſpair, and among others their commander M. d'Erlach. The ſlaughter on both ſides is ſaid to have been nearly equal; but the French ſucceeded in obtaining poſſeſſion of Berne by capitulation on the evening of the day on which theſe battles were fought. Upon the capture of this city, the other more wealthy and populous ſtates ſubmitted to the French; but the poorer cantons, who had leaſt to loſe, made a terrible effort in defence of their ſmall poſſeſſions, and the independence of their country. They even at firſt compelled Schawenberg to retire with the loſs of 3000 men; but were at laſt overpowered by the ſuperior numbers and military ſkill of the French army. Switzerland was treated as a conquered country. Its public magazines were ſeized by the French, heavy contributions were levied, and a new conſtitution, in imitation of that of France, was impoſed.

331 itzer- d treat- as a con- ered intry.

332 ie Direc- y vio- es the nſtitu- n.

While the Directory continued to encroach upon the independence of other nations, they were not likely to reſpect the freedom of their countrymen at home. In the month of April, a third of the legiſlature was changed. Francis de Neufchateau went out of the Directory by ballot, and Treilhard was choſen in his ſtead. The Directory had made great efforts to influence the elections in favour of their friends, but with little ſucceſs. They prepared therefore to preſerve the legiſlature in ſubjection to them by a new violation of the conſtitution. On the 2d of May they complained to the Council of Five Hundred of the plots of anarchiſts and royaliſts; by which they alleged that the elections had in many places been made to fall on men hoſtile to the Republic. On the 7th a committee made a report upon this meſſage, and propoſed that the proceedings of many electoral aſſemblies ſhould be totally or partially annulled, according to the characters of the perſons they had choſen. General Jourdan, and ſome others, ventured to oppoſe this plan as utterly inconſiſtent with the freedom of election, and as proceeding upon alleged intrigues of conſpirators againſt the Republic, while no conſpiracy had been proved to exiſt. But the majority agreed to the propoſal of the committee, and arbitrarily annulled the whole elections in ſix or ſeven departments, beſides the particular elections of a great number of individuals.

French Revolution, 1798.

333 Plans an expedition to Egypt and India.

The Directory now carried into effect the moſt fatal of all their projects, that of ſending a powerful army to the eaſt to ſeize upon Egypt, and from thence to attack the empire which Britain has acquired in India. The treaty with Auſtria had no ſooner been ſigned at Campo Formio, than the Directory excited the expectation of France and of all Europe, by loudly proclaiming their determination to invade Great Britain. They ſent troops into their own weſtern departments, called them the *Army of England*, and appointed Bonaparte their commander in chief. This officer, in the mean time, had reſided during the winter at Paris. Here he ſeems to have endeavoured to guard againſt the jealouſy of government, and the envy of individuals, by paſſing his time in retirement, and aſſuming the character of a man of letters. He procured himſelf to be elected a member of the National Inſtitute; but ſo ſeldom did he appear abroad, that when he attended ſome of its public ſittings his perſon was altogether unknown to the ſpectators. Greedy of renown, but aware that it ultimately depends upon the labours and the approbation of the learned, he never failed, when called into military ſervice, to remind this order of men of his alliance with them, by adding to his name at all proclamations and diſpatches the deſignation of *Member of the National Inſtitute.*

Whether the expedition to Egypt was now ſuggeſted by Bonaparte himſelf, or whether it was not a ſnare by which the preſent rulers of France impoſed upon the vanity of an enterpriſing young man, to enable them to get quit of him and his veteran army, is not known. It is very poſſible, however, that Bonaparte might neither be the deviſer nor the unconſcious victim of this plan; but that he might account himſelf more ſafe abroad, upon the moſt hazardous expedition, than expoſed at home to the malice of a government that had become jealous of his reputation, and was by no means ſcrupulous in its conduct.

334 Preparations for it conducted with ſecrecy.

The projected invaſion of Egypt was conducted with much ſecrecy. The world was amuſed with tales of monſtrous rafts to be conſtructed to convey the army of England over into Britain. To favour the deception, Bonaparte made a journey to the weſtern coaſt. In the mean time, the fleet was preparing at Toulon, and troops aſſembling in its neighbourhood. When all was in readineſs, Bonaparte embarked with 40,000 of the troops that had fought in Italy. On the 9th of June he arrived at the iſland of Malta, and contrived to quarrel with the Grandmaſter, becauſe he refuſed to admit ſo large a fleet all at once into his ports to water. The French General immediately landed his troops in different quarters, and endeavoured to reduce the iſland. The knights were divided into factions. Many of them, as is now well known, were of the order of ILLUMINATI, and of courſe prepared to act the part of traitors. After making a very feeble reſiſtance, the Grandmaſter propoſed a capitulation; and thus was treacherouſly ſurrendered, in a few days, a fortreſs which, if defended by faithful troops, might have held out for as many weeks againſt all the forces of the French Republic. Bonaparte, after leaving a garriſon of 4000 men in the iſland, ſailed on the 21ſt of June for Alexandria.

335 Conqueſt of Malta.

336 Admiral Nelſon ſails in queſt of Bonaparte.

In the mean time, Rear-admiral Nelſon, who, in the ſtation of Commodore, had ſignalized himſelf in a very high degree under Lord St Vincent, had been diſpatched in queſt of him from the Britiſh fleet, which ſtill blockaded Cadiz. Not knowing the object of the French expedition, the Britiſh Admiral ſailed firſt to Naples; and having there been informed of the attack upon Malta, he directed his courſe to that iſland. By the time he arrived there, however, Bonaparte had departed. Conjecturing now that Alexandria might be the deſtination of the French troops, he ſailed thither; but they had not been ſeen in that quarter, and he therefore went eagerly in ſearch of them to other parts of the Mediterranean. Bonaparte, in the mean while, inſtead of ſteering in a direct line for Alexandria, had proceeded ſlowly, with his immenſe train of nearly 400 tranſports, along the coaſt of Greece, till he arrived at the eaſtern extremity of the iſland of Candia. Here he ſuddenly turned ſouthward; and in conſequence of his circuitous courſe, did not arrive at the coaſt of Egypt till Admiral Nelſon's fleet had left it. He landed his troops; and on the 5th of July took by ſtorm the city of Alexandria. The inhabitants defended themſelves very deſperately, but without ſkill; and for ſome time a ſcene of barbarous pillage and maſſacre enſued. The tranſports that had conveyed the army were now placed within the inner harbour of Alexandria, and the ſhips of war under Admiral Brueys caſt anchor in a line cloſe along the ſhore of what proved to them the fatal Bay of Aboukir.

337 Conqueſts of Bonaparte in Egypt.

The army proceeded to the Nile, and aſcended along the banks of that river, ſuffering great hardſhips from the heat of the climate. They were met and encountered by the Mamalukes, or military force that governed Egypt; but theſe barbarians could not reſiſt the art and order of European war. Cairo was taken on the 23d of July. On the 25th another battle was fought; and on the 26th the Mamalukes made a laſt effort in the neighbourhood of the celebrated pyramids for the preſervation of their empire. Two thouſand of them were killed on this occaſion, 400 camels laden with their baggage were taken, along with 50 pieces of cannon.

A proviſional government was now eſtabliſhed in Egypt. Proclamations were iſſued in the Arabian tongue, declaring that the French were friendly to the religion of Mahomet, that they acknowledged the authority of the Grand Signior, and had only come to puniſh the crimes committed by the Mamalukes againſt their countrymen trading to Egypt. Thus far all had gone well; but on the 1ſt of Auguſt the Britiſh fleet appeared at the mouth of the Nile; and the ſituation of the French fleet having been diſcovered, Admiral Nelſon prepared for an attack.

338 Admiral Nelſon attacks and deſtroys the French fleet.

In number of ſhips the fleets were equal; but in the number of guns and weight of metal the French ſquadron had the ſuperiority. It was drawn up, too, in a form which ſuggeſted to its ill fated commander the idea of its being invincible; but remaining at anchor, the Britiſh Admiral was enabled, by running ſome of his ſhips between thoſe of the enemy and the ſhore, to ſurround and engage one part of their fleet, while the reſt remained unemployed and of no ſervice. In executing this plan of attack, a Britiſh ſhip, the Culloden, run aground; but this accident only ſerved as a beacon to warn the others of the ſpot that ought to be avoided. The battle commenced at ſunſet, and was continued at intervals till daybreak. At laſt, nine ſail of the French line were taken; one ſhip of the line was burned by her own commander; a frigate was burned in the ſame manner, to prevent her being taken. The French Admiral's ſhip L'Orient took fire, and blew up during the action, and only a ſmall number of her crew of 1000 men eſcaped deſtruction. Two French ſhips of the line and two frigates were ſaved by a timely flight (F).

339 Conſequences of his victory.

No naval engagement has in modern times produced ſuch important conſequences as this. The unexampled military efforts made by France had gradually diſſolved the combination which the princes of Europe formed againſt her. By the train of victories which Bonaparte had gained, the houſe of Auſtria, her moſt powerful rival, had been humbled and intimidated. The whole continent looked towards the new Republic with conſternation; and when the Directory ſeized upon Rome and Switzerland, none were found hardy enough to interpoſe in their favour. The current of affairs was now almoſt inſtantaneouſly altered. Europe beheld Bonaparte, with his *invincible* army, exiled from its ſhores, and ſhut up in a barbarous country, from which the triumphant navy of Britain might for ever prevent his return. The enemies of France could not beforehand have conceived the poſſibility of the event which was now realiſed; and the hope was naturally excited of being able to form a new and more efficient coalition againſt a government which had ſo groſsly abuſed the temporary proſperity it had enjoyed. The northern powers began to liſten to the propoſals made to them by Great Britain for commencing hoſtilities anew, and the Italian ſtates prepared to make another effort for independence. The court of Naples in particular openly avowed its joy on account of the recent deſtruction of the French fleet. The king himſelf put to ſea to meet Admiral Nelſon on his return from the Nile. Illuminations took place in the capital, and vigorous preparations were made for war. The Grand Signior, who had poſſeſſed of late little authority in Egypt, and might perhaps have been induced to relinquiſh his claims on that province rather than engage his decaying empire in war, now entered into cloſe alliance with Britain, and engaged in hoſtilities againſt the French. Tippoo Sultan had ſtipulated for the aid of a French army againſt the Britiſh in India; but Bonaparte, on taking poſſeſſion of Suez and the other Egyptian ports on the Red Sea, found no ſhipping there fit to tranſport his army to the Indian peninſula. Inſtead of proceeding therefore upon any ſplendid ſcheme of farther conqueſt, he was compelled to remain in his preſent ſituation, and to contend for exiſtence againſt the whole force of the Ottoman empire.

340 Rebellio in Irelan

The French at this time did not venture to ſend forth any large fleet upon the ocean; but wherever their ſmaller ſquadrons appeared, the fortune of Britain overpowered them there no leſs than it had done in the Mediterranean. They had long promiſed aid to the diſaffected party in Ireland; but weary of fruitleſs expectation, the Iriſh had during this ſummer broken out into rebellion, without waiting the arrival of the troops whom the Directory had engaged to ſend to their aſſiſtance. While the rebellion was at its height, and although the inſurgents for ſome time occupied the ſea port of Wexford, the French did not arrive. Afterwards,

wards, however, when the rebellion had been totally ſubdued, they attempted to elude the vigilance of the Britiſh fleet, and to land men in ſmall parties. On the 22d of Auguſt, General Humbert came aſhore at Killala, at the head of about 1100 men. Even this ſmall party might have been dangerous had it arrived a month earlier; and it actually produced very ſerious alarm. It conſiſted of men ſelected with great care, and capable of enduring much fatigue. They were joined by a few of the moſt reſolute of the diſcontented Iriſh in the neighbourhood, and ſpeedily defeated General Lake, who advanced againſt them with a ſuperior force, taking from him ſix pieces of cannon. They next marched in different directions, for the purpoſe of raiſing the people, and maintained their ground in the country during three weeks. Finding, however, that he was not ſeconded by additional troops from France, that the rebellion in Ireland had been fully ſubdued, and that 25,000 men under Lord Cornwallis were cloſing round him, Humbert diſmiſſed his Iriſh aſſociates; and four days thereafter, having encountered one of the Britiſh columns in his march, he laid down his arms. Now, when it was too late, the Directory was very active in ſending troops towards Ireland; but all their efforts were defeated by the ſuperiority of the Britiſh navy. On the 12th of October, Sir John Borlaſe Warren took La Hoche, a ſhip of 84 guns, and four frigates, attempting to reach Ireland with nearly 3000 men on board. The other ſhips belonging to the French ſquadron, which conveyed 5000 men in all, contrived to make their eſcape by ſailing round by the north of the iſland. On the 20th of the ſame month another frigate bound for Ireland was taken; and the French finding that the ſea was completely occupied by the Britiſh fleet, were at laſt compelled to deſiſt from their enterpriſe.

Negociations at
Raſtadt.

Ever ſince the treaty of Campo Formio had been concluded, a congreſs of miniſters from the French Directory, and from the German princes, had been negociating at Raſtadt a treaty between France and the empire. As theſe negociations terminated in nothing, and were tedious and unintereſting during their progreſs, it is unneceſſary to enter into a detail of the ſteps by which they were conducted. The intended reſult of them had been previouſly arranged between the Emperor and the Directory in the ſecret convention of Campo Formio, which has been already mentioned. That the articles of this convention might be concealed, the French miniſters at Raſtadt formally brought forward their propoſals in ſucceſſion for the diſcuſſion of the German deputies. The French demanded that the Rhine ſhould be the boundary of their Republic. The Germans reſiſted this. References were made to the diet of Ratiſbone, and long diſcuſſions and negociations took place among the different princes. When it was found that little was to be expected from the protection of Auſtria, the German deputies at Raſtadt were inſtructed to offer one half of the territory demanded. This offer was refuſed, and new negociations took place. The other half was at laſt yielded up, and a long diſcuſſion commenced about the debts due by the ceded territory, which the French refuſed to pay. The tolls upon the river, and upon the rivers flowing into the Rhine, alſo gave riſe to much altercation. It was even a matter of no ſmall difficulty, after all, to determine the preciſe boundary of France; whether her territory ſhould extend to the left bank, the right bank, or the thalweg, that is, the middle of the navigable channel of the river. It became alſo a queſtion how thoſe princes ought to be indemnified who loſt their revenues or territories by the new acquiſitions of France; and it was at length agreed that they ſhould receive portions of the eccleſiaſtical eſtates in Germany.

344
Preparations for
war on the
Continent.

Theſe diſcuſſions, conducted with endleſs formality and procraſtination, ſtill occupied the congreſs at Raſtadt; but it now became gradually more probable that no treaty would be concluded at that place. Auſtria began to ſtrengthen her armies in all quarters. Ruſſia, that had hitherto avoided any active interference in the conteſt, placed a large body of troops in Britiſh pay, and ſent them towards the German frontiers. The king of Naples avowedly and eagerly prepared for war. This impatient monarch, reſolving to attack without delay the French troops who occupied the Roman territory, procured General Mack and other officers from the court of Vienna to aſſume the command of his army. Without waiting, however, till Auſtria ſhould commence the attack, he raſhly began the war alone and unaided, excepting by the Britiſh fleet, and thus drew upon himſelf the whole force of the French Republic. The Directory did not ſuſpect ſuch imprudent conduct on the part of this prince; and accordingly, when General Mack entered the Roman territory, at the head of 45,000 men, the French troops in that quarter were altogether unequal to the conteſt. A French ambaſſador ſtill reſided at Naples when this event took place, and war was not declared. When the French General Championnet complained of the attack made upon his poſts under theſe circumſtances, he was informed in a letter by General Mack, that the king of Naples had reſolved to take poſſeſſion of the Roman territory, having never acknowledged its exiſtence as a Republic; he therefore required the French quietly to depart into the Ciſalpine ſtates; declaring, that any act of hoſtility on their part, or their entrance into the territory of Tuſcany, would be regarded as a declaration of war. Championnet finding himſelf unable to reſiſt the force now brought againſt him, actually evacuated Rome. He left, however, a garriſon in the caſtle of St Angelo, and endeavoured to concentrate whatever troops he could haſtily collect in the northern extremity of the Roman ſtate. Towards the end of November, General Mack entered Rome without oppoſition.

345
The Neapolitans
take poſſeſſion of
Rome.

When theſe events came to be known at Paris, war was immediately declared againſt the king of Naples, and alſo againſt the king of Sardinia. This laſt prince had made no attack upon France; but he was accuſed by the Directory, in their meſſage to the Councils, of *diſaffection* to the Republic, and of *wiſhing* to join the king of Naples in his hoſtile efforts. This accuſation could not well be falſe. From the period of Bonaparte's ſucceſsful irruption into Italy, the king of Sardinia had felt himſelf placed in the moſt humiliating circumſtances; his moſt important fortreſſes were occupied by the French; they levied in his country what contributions they thought fit; and when they recently required him to receive a garriſon into his capital, he found himſelf unable to reſiſt the demand. Even now, when they performed the uſeleſs ceremony of declaring war, he could make no effort in his own defence, and

346
Hard fate
of the king
of Sardinia.

French Revolution, 1798.

quietly gave them a formal reſignation in writing of his whole continental dominions, conſenting to retire to the iſland of Sardinia.

In the mean time, the conteſt with Naples was ſoon decided. The French on their retreat were much haraſſed by the people of the country. The Neapolitan troops regarded them with ſuch animoſity, that they ſcarcely obſerved the modern rules of war towards the priſoners who fell into their hands. Even their leaders ſeemed in this reſpect to have forgotten the practice of nations; for when General Bouchard, by order of General Mack, ſummoned the caſtle of St Angelo to ſurrender, he declared, that he would conſider the priſoners of war and the ſick in the hoſpitals as hoſtages for the conduct of the garriſon; and that for every gun that ſhould be fired from the caſtle, a man ſhould be put to death. It cannot well be imagined that the Neapolitan officers would have acted in this vehement manner, had they not expected countenance and ſupport from the immediate co-operation of Auſtrian troops. 347 Naples conquered by by the French. In their hopes from this quarter, however, they were completely diſappointed. Mindful of her recent calamities, and attentive only to her own aggrandiſement, Auſtria ſeems ſtill to have expected more from negociation than from war, and the territory of Naples ſoon fell into the hands of the French. Such indeed was the terror of the French name in Italy, or ſuch was the diſaffection or cowardice of the Neapolitan troops themſelves, that they were beaten by one-fourth of their number in different engagements, at Terni, Porto Fermo, Civita Caſtellana, Otricoli, and Calvi. At the commencement of the conteſt, a body of Neapolitans, with the aſſiſtance of the Britiſh fleet, had been landed at Leghorn, for the purpoſe of taking the French in the rear: but they, diſregarding this attempt on the part of ſuch an enemy, preſſed on towards Naples. By degrees, General Mack's army being reduced by the reſult of the battles which it fought, and by deſertion, to 12,000 men, he found it neceſſary to adviſe the king and royal family of Naples to take refuge on board the Britiſh fleet. They did ſo; and arrived at Palermo, in Sicily, on the 27th of December, in the Britiſh Admiral Lord Nelſon's ſhip. General Mack, in the mean time, requeſted an armiſtice, to afford an opportunity for making peace; but this was refuſed. Being driven from Capua, which is the laſt military poſt of any ſtrength in the Neapolitan territory, and his life being in no ſmall danger from the diſaffection of his own troops, he at laſt found it neceſſary to ſeek for ſafety, by ſurrendering himſelf, along with the officers of his ſtaff, to the French General. The governor of Naples, in the mean time, offered to the French a contribution in money, if the commander in chief would conſent to avoid entering that city. The offer was accepted, and the invading army remained at Capua. General Serrurier, on the 28th of December, at the head of a column of French troops, expelled the Neapolitans from Leghorn, and took poſſeſſion of that place. So far as the efforts of regular armies are to be conſidered, the war might now therefore be regarded as brought to a termination; but the French had ſpeedily a new and unuſual enemy to contend againſt.

1799. From the mildneſs of the climate, and the fertility of the ſoil, human life can be ſuſtained in the ſouthern parts of Italy with fewer efforts of induſtry than in almoſt any other country in Europe. Hence ariſes a general propenſity to idleneſs, which is increaſed by the numerous charitable inſtitutions to which the Roman Catholic religion gives riſe. French Revolution 1799. 348 The Lazzaroni riſe againſt the French. In the city of Naples there had long exiſted a body of perſons under the denomination of *Lazzaroni* or Beggars, amounting to the incredible number of from thirty to forty thouſand men, who did nothing, and ſubſiſted merely by charity, or by ſuch ſhifts as occaſionally occurred to them. One of theſe frequently was the menacing the ſtate with an inſurrection, in caſe their wants were not inſtantly ſupplied; which uſually drew from a feeble adminiſtration very liberal diſtributions of money and proviſions. On the preſent occaſion they demonſtrated abundance of loyalty; but the king had thought fit to avoid entruſting his ſafety to ſuch defenders. During the confuſion which followed the flight of the court and the approach of the French army, the Lazzaroni became mutinous. They heard that the French aboliſhed, wherever they came, all thoſe monaſteries and other religious eſtabliſhments which are the great ſources of public charity. The Lazzaroni, therefore, conceived the moſt violent hatred againſt them, and againſt all who were ſuſpected of favouring opinions hoſtile to royal government. In the beginning of January they began to ſhew ſymptoms of diſcontent, and in a few days broke out into open inſurrection. The members of the government left by the king, overcome by habitual terror of the Lazzaroni, conſulted merely their own perſonal ſafety, and made no effort to preſerve the public tranquillity. Prince Militorni had gained conſiderable applauſe on account of his vigorous defence of Capua againſt the French. The Lazzaroni therefore elected him their commander in chief; but he attempted in vain to reſtrain their violence and love of plunder. They declared hoſtility againſt the French and all the adviſers of the armiſtice. They broke open the priſons, and put to death all thoſe who were confined on account of political offences againſt the royal government. 349 Their outrages. They next ſpread themſelves over the city in ſearch of thoſe perſons whom they conſidered as favourable to the invaders, and committed murder and robbery in all quarters, concluding by burning the houſes of thoſe accounted diſaffected. An attempt was made by a conſiderable body of the inhabitants, who thought themſelves in the greateſt danger, to reſiſt their fury, by fortifying the convent of the Celeſtins, and retiring thither; but the Lazzaroni, after encountering the fire of cannon and of muſketry, ſucceeded in ſtorming the place, and deſtroyed all who had taken refuge there. Their power and their fury were now equally boundleſs, and the city became in many quarters a ſcene of maſſacre and pillage. Prince Militorni, therefore, went to Capua, and requeſted Championnet to reſcue Naples from utter ruin by occupying it with his army. For this purpoſe it was arranged, that a column of French troops ſhould ſecretly advance by a circuitous march, and ſuddenly enter the city from the oppoſite quarter. Before this plan could be fully executed, the Lazzaroni had adopted the daring reſolution of attacking the French within the fortifications of Capua. Accordingly two-thirds of them marched out upon this enterpriſe, and ſpent the 19th and 20th of January in attempting to take Capua by aſſault. Multitudes of theſe men here periſhed by the artillery of the place; for the

French,

ench lution, 99.

French, to favour the capture of Naples by the party that had been ſent eaſtward for that purpoſe, avoided making any ſally, and remained upon the defenſive. The Lazzaroni at Capua, however, having learned on the 21ſt that a French column had marched to Naples, and approached the gates, ſuddenly returned to the aſſiſtance of their brethren in the capital. They were cloſely purſued by the French; but they had leiſure, nevertheleſs, to barricade the ſtreets, and to form themſelves into parties for the defence of different quarters. A dreadful and ſanguinary conteſt now enſued, which laſted from the morning of the 22d to the evening of the 23d of January. The Lazzaroni, with ſome peaſants who had joined them, diſputed obſtinately every ſpot of ground; and by the energy which they diſplayed, caſt a ſevere reproach upon the feeble and unſkilful government, which had not been able to direct in a better manner the courage of ſuch men. At length, after having been gradually driven from ſtreet to ſtreet, the Lazzaroni rallied for the laſt time at one of the gates of the city, where they were nearly exterminated. The inhabitants rejoiced on account of their own eſcape from immediate ruin; and while the French armies found themſelves become odious in all the other countries which they had entered, they here found themſelves, from the peculiar circumſtances of the caſe, received with unfeigned welcome, in a city which holds the third place in population and ſplendour among the capitals of Europe.

350 y are ly ex inated.

This may be regarded as the laſt triumph enjoyed by the Directory. The conſequences of their conduct were now gathering faſt around them. They were deſervedly unpopular at home; not only from the violations they had offered to the conſtitution of their country, but alſo from the manner in which they conducted public affairs in detail. They ſet no bounds to their profuſion, or to the exactions with which their agents vexed the conquered countries. Championnet, aſhamed of the extortions of which the commiſſaries of the Directory were guilty, attempted in Italy to reſtrain them; and the conſequence was, that, upon the complaint of the commiſſary Taypoult, he was deprived of his command, and thrown into priſon. Scherer, the miniſter of war, was appointed his ſucceſſor. Under him the rapacity of the agents of government, and the embezzlement of the public ſtores, was carried to its height. The numbers of the armies were ſuffered to decline, that the Directory, the commiſſaries, and the generals, might become rich. Thus the ſtate was left totally unprepared againſt the ſtorm which was now rapidly gathering from abroad. Still, however, France was feared by the neighbouring nations, to whom the preſent ſtate of her internal affairs was obſcurely known. Though an army of 45,000 Ruſſians had advanced to the aid of Auſtria, yet that Cabinet heſitated to declare war. Pruſſia was eagerly ſolicited by Britain to take up arms againſt France, and large pecuniary aid was offered; but Sieyes, the Directory's ambaſſador at Berlin, artfully contrived to defeat this negociation, and to counteract the unpopularity of his country in Germany, by publiſhing the ſecret convention at Campo Formio, which we have already mentioned. This treaty demonſtrated ſo clearly to the German princes the utter unconcern with which their independence and their intereſts were regarded by the head of the empire, that no ſteady co operation with Auſtria could henceforth be expected from them. The greater number of them, therefore, reſolved to maintain their neutrality under the protection of Pruſſia.

351 acity of Direc-

French Revolution, 1799.

On the 2d of January, the French miniſters at Raſtadt preſented a note to the congreſs, in which they intimated, that the entrance of Ruſſian troops into Germany, if not reſiſted, would be regarded by them as a declaration of war. Some negociation took place in conſequence of this note, but no ſatisfactory anſwer was returned. On the 26th of that month, the ſtrong fortreſs of Ehrenbreitſtein ſurrendered, after having remained under blockade ſince the concluſion of the treaty of Campo Formio. By the poſſeſſion of this place, and of Mentz and Duſſeldorf, France was now rendered very formidable on the Rhine. As ſhe poſſeſſed alſo the ſtrong country of Switzerland, and all the fortified places of Italy, ſhe was well prepared, not only for defence, but for active operation; for it is now known, that the conferences of Raſtadt were purpoſely protracted, by orders from the Directory, till the French armies ſhould be ready to take the field with advantage againſt an enemy whoſe conduct betrayed the moſt culpable tardineſs. At this time Jourdan commanded on the Upper Rhine from Mentz to Huningen; Maſſena occupied with an army the eaſtern frontier of Switzerland towards the Griſon country; Scherer was commander in chief in Italy; Moreau acted as general of a diviſion under him; and Macdonald commanded the troops that occupied the territory of Rome and Naples. But theſe armies that kept in ſubjection, and were now to defend ſo many countries, ſcarcely amounted to 170,000 men in all, and were far outnumbered by the armies which Auſtria alone, without the aid of Ruſſia, could bring into the field. The Directory, however, confiding in the unity of its own plans, in the undecided politics of the court of Vienna, and in the conſequent ſlow movements of the Imperial armies, was eager to renew the war; and the two Councils, on the 13th of March, declared France to be at war with the Emperor of Germany and the Grand Duke of Tuſcany. The war, however, had already been begun. On the 1ſt of March Jourdan croſſed the Rhine at Straſburg, and occupied ſeveral ſtrong poſitions in Swabia. Manheim was taken, and Philipſburg ſummoned to ſurrender by Bernadotte (G), while St Cyr entered Stutgard. On the 4th of March the Auſtrians croſſed the Lech, under the command of the Archduke Charles, to oppoſe this army. Maſſena advanced into the territory of

352 War renewed on the Rhine.

(G) This ſummons was conceived in very extraordinary terms, and cannot be accounted for but upon the ſuppoſition that Bernadotte believed the Auſtrian officers infected with French principles. He calls upon the commander of the fortreſs to ſurrender without reſiſtance, and thus violate the truſt repoſed in him by his ſovereign. He tells him, that a diſcharge of his duty would produce the *defection of his officers and men*. He warns him of the folly and danger of leading troops to action *againſt their will*; and, laſtly, he threatens him with *vengeance* if he ſhould *dare to reſiſt!*

of the Griſons ; and ſurpriſing a ſtrong body of Auſtrians, took them all priſoners, together with their General Auffenburgh, and the whole of his ſtaff, after a deſperate reſiſtance under the walls of *Coire*. The reduction of the Griſons was the conſequence of this victory.

353 And in Switzerland.

But in order to complete the plan of the French, which was to effect a junction with their two armies, that of Maſſena in Switzerland with that of Jourdan in Germany, it was neceſſary to carry the important poſt of Feldkirch, which was occupied by the Auſtrian General Hotze, whoſe line extended from the frontiers of the Griſons, to the north-eaſt by the Vorelberg, to the eaſtern extremity of the Lake Conſtance. Vigorouſly repulſed in his firſt attack, Maſſena renewed it, five different times, with freſh forces, and increaſed impetuoſity. But all could not avail againſt the ſteady bravery of the Auſtrians, who drove back the aſſailants with immenſe ſlaughter. The French, however, being in poſſeſſion of the Griſons, the invaſion of the Engadine, and the county of Bormio, by a diviſion of the army of Italy cantoned in the Valteline, under the orders of General Caſabianca, was facilitated. The Auſtrians, too weak in that quarter to reſiſt them, retreated into the Tyrol, whither they were purſued by the French, who forced ſome of the defiles by which the entrance of that country was defended, and extended their deſtructive incurſions as far as Glurenz and Nauders.

354 The French are defeated in Swabia,

Meanwhile the van-guard of the main army of the Imperialiſts puſhed forward to meet the enemy. On the 20th of March it was attacked by Jourdan, who drove in the outpoſts ; but on the following day that general was himſelf attacked in the centre of his army, driven from his poſition, and compelled to retire during the night to Stockach. Both parties now prepared for a deciſive engagement. On the 24th, the Archduke encamped before Stockach, with his right wing towards Nellenburg, and his left near Wallenweis. On the 25th, at day break, the French army began the attack. They directed their chief efforts againſt the right wing of the Auſtrians commanded by General Meerfeldt. The battle was long and obſtinate. From five o'clock in the morning till paſt one of the afternoon, its termination remained extremely doubtful. The French ſucceeded in their attempt againſt General Meerfeldt. His poſition was forced, and he retreated into a wood between Liptingen and Stockach. Here he renewed the combat without ſucceſs. He was gradually driven to the extremity of the wood, though it is a German mile in breadth. The left wing of the Auſtrians, however, had in the mean time maintained its ground, and reinforcements were ſent from it to General Meerfeldt. With the aſſiſtance of theſe he at laſt ſucceeded in making a ſtand, and even obliged the French to retire in their turn. At length, about two o'clock, the French found it neceſſary to withdraw from this quarter. The battle, however, was continued in different points till night came on. The French remained upon the ground where they had begun the attack, and they even retained 4000 priſoners whom they had taken during the various movements of the day. The reſult of the battle, upon the whole, however, was fatal to their affairs. Their loſs was ſo great, and the ſuperiority of the Auſtrians ſo manifeſt, that Jourdan dared not to hazard another engagement. On the following day he retired to Weiller near Dutlingen ; and finding his army altogether unequal to offenſive operations, he ſent back one part of it to cover Kehl and Straſburg, while he withdrew with the other towards Switzerland. This event compelled Maſſena, who was preſſing upon Tyrol and the Engadine, to return to the defence of Switzerland. He was immediately intruſted with the chief command of the troops in this quarter, in the room of Jourdan, who was removed. The Auſtrians continued to advance in every direction, and immediately occupied the whole of the right, or German ſide, of the Rhine, from the lake of Conſtance to Mentz.

355 And in Italy.

In Italy the ſucceſs of the Auſtrians was equally conſpicuous, notwithſtanding the treachery of the French in attacking them before the expiration of the truce. The attempt of the latter to force the advanced poſts of the former, on the 26th of March, at Santa Lucia and Buſſelango, was rendered abortive ; and at Legnago, the Auſtrian general, Kray, obtained a complete victory, and compelled them to ſeek protection under the walls of Mantua. On the 5th of April, the Auſtrians again attacked them in their poſition at Memiruolo, which lies on the road from Mantua to Peſchiera, and compelled them, after an obſtinate conflict, once more to retreat. The loſs of the French in theſe different actions was undoubtedly great; but it is probably overrated at 30,000 men killed, wounded, and taken.

The ſucceſs of the Auſtrians, however, was not cheaply purchaſed. Scherer, who commanded the French army, gained over them, at firſt, ſome advantages, which, had he known how to improve them, might have given a different turn to the tide of affairs. One diviſion of his army had actually forced the Auſtrian poſts on the 26th of March, and taken 4000 priſoners ; but the other diviſion being repulſed, he withdrew his troops from their advanced poſition, and thus relinquiſhed the advantage which he had gained. Even on the 5th of April, Moreau's diviſion performed prodigies of valour, and took, it has been ſaid, 3000 priſoners ; but from the injudicious diſpoſitions which had been made by Scherer, that general was not ſupported, and the victory of the Auſtrians was complete. Kray now quickly drove the French from the Mantuan, and compelled them, after having ſuſtained new loſſes, to relinquiſh their ſtrong holds on the Mincio and the Adige, and to retreat to the Adda.

356 Moreau fortifies h camp.

On the banks of this river, rendered remarkable for the dear bought victories which Bonaparte had obtained at the bridge of Lodi, the French general Moreau, to whom the Directory had given the chief command of their army, prepared to make a vigorous defence. The military talents of this man had been rendered unqueſtionable by his celebrated retreat through a hoſtile country, and before a victorious army ably commanded. On the preſent occaſion he did not belie his former character. Nothing that could give courage or confidence to his troops was neglected. Entrenchments were thrown up wherever the river was conſidered as paſſable ; and a ſituation, remarkably ſtrong by Nature, was ſtrengthened by every means which art could ſupply.

Before this period, a conſiderable body of Ruſſians had joined the Imperialiſts ; and the chief command of the allied army was now aſſumed by Field Marſhal Suwarrow Rimniſki. This celebrated leader, whoſe cha-

rench
olution
1799.

357
rſhal
varrow

racter every democrate labours to miſrepreſent, had entered into the army at the age of twelve, and riſen from the ranks to the ſtation which he now holds, of Generaliſſimo of the Ruſſian armies. Poſſeſſed of ſtrong natural talents, he had likewiſe the benefit of an excellent education, and is ſaid, by thoſe who are perſonally known to him, as well as acquainted with the ſtate of literature in Ruſſia, to be one of the beſt claſſical ſcholars of all the natives of that great empire. He had ſtudied, in early life, mathematics and natural philoſophy, as branches of ſcience abſolutely neceſſary to the man whoſe higheſt ambition is to become a great commander; and his knowledge of the learned, as well as of the faſhionable languages, has enabled him to avail himſelf of all that has been written either by the ancients or the moderns on the art of war. This art has indeed been his chief ſtudy from his youth; it has been at once his buſineſs and his amuſement.

Poſſeſſed with his countrymen, in general, of the moſt undaunted courage, and formed by Nature to endure the greateſt fatigue, it is not ſurpriſing, that with all theſe advantages Suwarrow ſhould have long ago acquired the character of one of the ableſt generals of his time. It is indeed true, that, till the opening of the campaign of 1799, he had diſtinguiſhed himſelf only againſt the Turks, whom we are too apt to deſpiſe, and againſt the Poles when divided among themſelves; but let it be remembered, that the enthuſiaſtic courage of thoſe ſame Turks had found employment for the talents of ſome of the ableſt generals in Europe, a Laudohn and a Cobourg; and that the Poliſh armies which Suwarrow ſubdued were united by the ſtrongeſt of all ties—the knowledge that they muſt conquer or periſh. All this was ſo well known to Frederic the Great, that he held the military talents of the Ruſſian hero in the higheſt eſteem; and the attention of all Europe was now turned towards the quarter where thoſe talents were to be exerted in the ſupport of ſocial order, and of every thing which ennobles man. His operations in Italy did not diſappoint the higheſt expectations which had been formed of them. At an age conſiderably above ſixty, he began a campaign not leſs remarkable for its activity than any which had gone before it ſince the commencement of the French revolution. We are by no means prepared, however, to do juſtice to the various military efforts which were now made, or to explain clearly the means employed to inſure ſucceſs. If the work entitled the *Hiſtory of Suwarrow's Campaigns* be deſerving of credit, the ſuperiority of that commander over his rivals and opponents ſeems to have at all times conſiſted principally in the promptitude with which he formed his plans, and the rapidity with which he carried them into execution. It is likewiſe ſaid to be a maxim of his, always to *commence* the attack when he ſees a battle inevitable, from the perſuaſion that the ardour of the attacking army more than counterbalances the advantage of ground, if that advantage be not very great. Such was certainly the principle upon which he acted at preſent.

358
Attacks
him in his
intrenchments,

On the 24th of April the combined army advanced to the Adda; and having driven in Moreau's outpoſts, Suwarrow reſolved, on the 26th, to attack him in his entrenchments. For this purpoſe, while the ſhew of an attack was maintained along the whole line, a bridge was ſecretly thrown over among the rocks at the upper part of the river, where the French had thought ſuch an enterpriſe unlikely or impoſſible. A party of the combined army was thus enabled, on the following morning, after croſſing the river, to turn the French fortifications, and to attack their flank and rear, while the reſt of the army forced the paſſage of the river at different points. The French fought obſtinately, but were ſpeedily driven from all their poſitions, and compelled to retire to Pavia, leaving 6000 men on the field; while upwards of 5000 priſoners, including 4 generals, fell into the hands of the allies, together with 80 pieces of cannon.

French
Revolution,
1799.

359
And defeats him
with great
ſlaughter.

The advantage thus obtained over the French, in conſequence of the addreſs with which the Adda was croſſed, is ſaid to have gained for Suwarrow more eſtimation from his antagoniſts than they had originally been diſpoſed to grant to any military officer coming from Ruſſia, and who had never before had perſonal experience of the mode in which war is conducted in the ſouth of Europe. But this is probably affectation. The French had ſurely no cauſe to deſpiſe Ruſſian generals, ſince they could not but know that Laudohn was born in Ruſſia, that he had his military education there, and that he had riſen to a high rank in the army before he entered into the ſervice of the Empreſs Queen Maria Thereſa. Indeed it is evident, that while their orators were declaiming againſt Suwarrow and his Ruſſians as mercileſs barbarians, they were ſecretly trembling at his prowefs and reſources, which they could not but remember had more than once ſaved the armies of the Prince of Cobourg in the Turkiſh war.

Moreau now eſtabliſhed the wreck of the French army, amounting to about 12,000 men, upon the Po, between Aleſſandria and Valentia. On the 11th of May he compelled a body of Auſtrians to retire, though they had already paſſed the river, and took a great number of them priſoners. On the following day, 7000 Ruſſians croſſed the Po at Baſignano, and advanced on Pecetto. Moreau immediately fell upon them with his army. They maintained a long and deſperate conflict; but being at laſt thrown into confuſion, and refuſing to lay down their arms, about 2000 of them were drowned in recroſſing the river, and the French, with difficulty, took a ſmall number of them priſoners. But Suwarrow ſoon advanced, and terminated this active, but petty warfare, which was all that the French could now maintain. Moreau was under the neceſſity of retiring with his troops to occupy the Bochetta, and other paſſes which lead to the Genoeſe territory; and the combined army commenced vigorouſly, and at once, the ſiege of all the fortreſſes in the part of Italy which it now occupied. Peſchiera, Mantua, Ferrara, Tortona, Aleſſandria, and the citadels of Turin and Milan, were all attacked. The French were driven from the Engadine by Bellegarde; Maſſena, cloſely preſſed in Switzerland by the Archduke Charles, was compelled to retreat to the neighbourhood of Zurich, and almoſt all Piedmont had riſen in inſurrection againſt the French; ſo that in every quarter their affairs ſeemed deſperate. Few or no reinforcements arrived from the interior, and their generals were left to act upon the defenſive, and to detain the enemy at a diſtance from the frontiers of France as long as poſſible. One effort of offenſive war only remained, and, after ſome delay, it was made with much vigour.

360
Macdonald and Moreau concert meaſures for attacking the allies.

Macdonald was ſtill with a conſiderable French army in the ſouthern parts of Italy, and occupied the territories of Rome and Naples. No attempt was made on the part of the combined powers to cut off his retreat; probably from the conviction that ſuch an enterpriſe could not be accompliſhed with ſucceſs in the mountainous countries of Tuſcany and Genoa, through which it would be in his power to paſs. Aware of this circumſtance, he was in no haſte to remove, though the combined army now occupied almoſt the whole territory between him and France. He gradually concentrated his forces, however, and drew near to the ſcene of action. His army amounted to 30,000 men; and he was ordered by the Directory to evacuate the new-born republics of Rome and Naples, and to form a junction, if poſſible, with the army of Moreau. The preſent ſituation of the allies, however, tempted Macdonald to hazard an action by himſelf. Marſhal Suwarrow had extended his forces over Lombardy and part of Piedmont, in order to afford protection to the well-diſpoſed inhabitants of theſe countries; and Macdonald and Moreau had concerted between them a plan for dividing their antagoniſts, and vanquiſhing them, as the French generals had often vanquiſhed their enemies in detail. It was only by Macdonald, however, that any important blow could be ſtruck; but it was neceſſary that Moreau ſhould draw upon himſelf a great part of the Auſtro-Ruſſian forces, that the remainder might be more completely expoſed to his colleague's attack. For this purpoſe he had recourſe to a ſtratagem.

361
Junction of the French and Spaniſh fleets.

Towards the end of April, the French fleet, amounting to 16 ſhips of the line, had ventured out of Breſt harbour. Ireland was ſuppoſed to be the place of its deſtination; and the Britiſh fleet was ſtationed in the ſituations moſt likely to prevent its arrival there. The French, however, intending to form a junction with the Spaniſh fleet, which was ſtill blockaded in the port of Cadiz, ſailed ſouthward. When they approached Cadiz, a ſtorm aroſe, which prevented any attempt on their part to enter the harbour, and any effort on the part of the Britiſh admiral, Lord Keith, to bring them to an engagement. On the 4th and 5th of May, therefore, they paſſed the Strait of Gibraltar, and ſteered for Toulon. Lord Keith kept his ſtation near Cadiz till the 9th of May, and then entered the Mediterranean in queſt of the French fleet. The Spaniards immediately put to ſea, and went into the Mediterranean alſo. The French fleet entered Toulon, and afterwards went out in queſt of the Spaniſh fleet. They ſailed towards Genoa, and afterwards to Carthagena, where they met their allies. The two fleets being now united once more, paſſed Gibraltar, and ſailed round to Breſt, where they arrived in ſafety, without being overtaken by the Britiſh.

362
Partial ſucceſſes of Macdonald.

Moreau, in the mean time, took advantage of the arrival of the French and Spaniſh ſquadrons in the vicinity of Genoa, to ſpread a report that they had brought him a powerful reinforcement of troops, in the hope of withdrawing from Macdonald the attention of Suwarrow. This laſt officer was himſelf at Turin. His advanced troops poſſeſſed the paſſes of Suſa, Pignerol, and the Col d'Aſſiette; while, at the lower extremity of the vaſt track of country over which his army was ſcattered, General Hohenzollern was poſted at Modena with a conſiderable force, and General Ott was at Reggio with 10,000 men. On the 12th of June, Macdonald began his operations. His advanced diviſions attacked Hohenzollern at Modena on that day, defeated him, and took 2000 of his men priſoners. The French, at the ſame time, attacked General Ott; and, after obliging him to retreat, they entered Parma on the 14th of June. On the 17th, General Ott was again attacked, and compelled to retire upon Caſtel St Giovanni. But here the progreſs of Macdonald was arreſted.

363
He is completely defeated by Suwarrow.

Suwarrow had been informed of his approach and alarming ſucceſſes; and with that preſence of mind, and that promptitude of energy, which ſo ſtrongly mark the whole of his conduct, he ſuddenly left Turin on the 15th of June, at the head of 20,000 men; and having marched ſeventeen leagues in eight-and-forty hours, came up with Macdonald's army on the banks of the Tidone. The Ruſſian Generals Roſenberg and Foerſter commanded the right and the centre; the left wing was commanded by the Auſtrian General Melas; the Ruſſian General Prince Procration commanded the advanced guard, and Prince Lichtenſtein the reſerve. A deſperate action now commenced, which, conteſted with equal obſtinacy on both ſides, was fought during three ſucceſſive days. At length victory, ſtill faithful to the ſtandard of Suwarrow, declared for the allies. The French, driven on the 1ſt day from the Tidone to the Trebbia, were there ultimately defeated on the 19th, after a carnage on both ſides, ſuch as ſome of the oldeſt officers in the army declared that they had never before ſeen. The Ruſſians and French repeatedly turned each others line, and were mutually repulſed. Suwarrow, who appeared in perſon wherever the fire was heavieſt, and his troops moſt cloſely preſſed, is ſaid to have had 7 horſes killed under him, and to have ſtript himſelf to the ſhirt on the 19th, running on foot from rank to rank, to urge the troops forward by his preſence and example (H). With all theſe exertions of heroiſm, however, and greater have ſeldom been made, the iſſue of the conteſt continued doubtful, till the gallant Kray, in direct diſobedience to the pernicious orders of the Aulic Council at Vienna, arrived at the head of a large detachment from the army beſieging Mantua, and, on the 19th, decided the fate of the day.

The French fled during the night; and, on the morning of the 20th, Suwarrow purſued them with his army in two columns. It ſeldom happens that German troops can overtake the French in a march. The Ruſſians now did ſo, however; and at Zena the rear guard of the French, being ſurrounded, laid down their arms. The

---

(H) We had this information from an officer of high rank, now reſiding in Weimar, who was preſent in the action; and who added, that the Coſſacs, as ſoon as they ſaw their old commander in his *ſhirt*, ruſhed upon the enemy with an impetuoſity which nothing could withſtand. The ſtory is by no means incredible; for Suwarrow, who deſpiſes coſtume, is known to have fought repeatedly in his ſhirt againſt the Turks; and he would be as hot on the Trebbia as ever he was on the Danube.

The reſt of the French army found ſafety in the paſſes of the Appennines and the Genoeſe territory, after having loſt on this occaſion, in killed, wounded, and priſoners, not leſs than 17,000 men.

64 tual plaints uwar- and Aulic ncil.

Moreau, in the mean time, had attacked the Auſtrians under General Bellegarde in the vicinity of Alexandria. Though ſuperior to him in numbers, they were completely beaten; but Suwarrow having returned with infinite rapidity after his victory over Macdonald, the temporary advantage gained by Moreau became of no importance. Suwarrow complained loudly of the conduct of the Aulic Council on this occaſion; while they, in return, imputed their diſaſter under Bellegarde to his unſkilful diſtribution of the whole troops, which had expoſed an immenſe army to great danger from the enterpriſes of an handful of men. It is not our buſineſs to decide between them. The inſtructions of the Council to Kray not to co-operate with the commander in chief of the combined army, ſeem to us in the higheſt degree abſurd, if not treacherous; and we have heard a general officer, whoſe name, were we at liberty to give it, would do honour to theſe pages, ſay, that the diſtribution of the troops, of which that council complained, was the moſt maſterly thing that has been done during the war. Be this as it may, a diſtruſt and mutual miſunderſtanding thus commenced, or, at leaſt, made its firſt open appearance, which gave good reaſon to ſuſpect that little cordiality of co-operation would long exiſt between theſe allies. They continued, however, for ſome time to enjoy uninterrupted proſperity under the command of Suwarrow. The ſieges of the different Italian fortreſſes were very cloſely preſſed. They all ſurrendered in ſucceſſion; and the period appeared faſt approaching when it would be in the power of the allied armies to enter the ancient territory of France.

365 napar- s unſuc- ſful at- k of re.

If we turn our eyes to a different quarter, we ſhall find the French as much humbled at this time in Paleſtine by Britiſh valour, as they were in Italy by the united armies of Ruſſia and Auſtria. The hero of France, the conqueror of Italy, the boaſted legiſlator of Europe, after having defeated the Mamalukes, taken poſſeſſion of Alexandria and Cairo, and profeſſed himſelf a Mahometan in Egypt, led an army into Paleſtine with the avowed purpoſe, it has been ſaid, to take poſſeſſion of Jeruſalem, and by rebuilding the temple, and reſtoring the Jews, to give the lie to the prophecies of the Divine founder of the Chriſtian religion. At the head of a choſen band, exceeding 12,000 in number, and poſſeſſed of a ſtaff eminent for military ſkill and experience, he arrived at the ſmall town of Acre, ſituated on the ſea-coaſt, 28 miles ſouth of Tyre, and 37 north of Jeruſalem. To this town, which was wretchedly fortified, and defended only by a ſmall garriſon of Muſſelmans, he laid ſiege in form; and the governor would have ſurrendered unconditionally, had he not been, we ſay not *perſuaded*, but *decoyed*, by an Engliſh *naval* officer, to make a vigorous reſiſtance. We need not add, that the naval officer was Sir Sidney Smith, or that the beſieging general was Bonaparte.

The command of the garriſon being entruſted to Sir Sidney Smith, who was not to be bribed by French gold, or corrupted by French philoſophy, the hero who, by the aid of theſe allies, had ſo quickly routed armies, and conquered ſtates in Italy, was detained before the town of Acre *ſixty-nine* days; though the number of the allies who defended that town exceeded not 2000 men! Foiled in *eleven* different attempts to carry it by aſſault, one of which was made during the truce which he himſelf had ſolicited to bury the dead, he was ultimately obliged to retreat, leaving eight of his generals, eighty-five of his officers, and *one half* of his army behind him. The ſuperiority of the Britiſh over the Corſican hero was, during this ſiege, more fully diſplayed in conduct than even in courage. The true magnanimity evinced by the former; his temperate replies to the audacious calumnies and atrocious falſehoods of his adverſary; and the moderation and humanity which characteriſed his diſpatches, and invariably marked his behaviour to thoſe whom the fortune of war ſubjected to his power—give additional luſtre to the brilliant victory which his valour, his energy, and his perſeverance, ſo eſſentially contributed to ſecure.

But while we pay a tribute of juſtice to the merits of our gallant countryman, we muſt not omit to notice the high deſerts of the brave, the loyal, the virtuous Philipeaux, his gallant comrade, the partner of his toils, and the partaker of his glory. The ſkill of this French officer as an engineer was moſt ſucceſsfully diſplayed in the defence of Acre: and, indeed, his exertions on that memorable occaſion ſo far ſurpaſſed his ſtrength, that he actually periſhed through fatigue.

366 His vaſt projects, had he ſucceeded.

The defeat of Bonaparte at Acre, which effectually ſtopped his deſtructive career, will be conſidered as important indeed, when it is known that his arts of intrigue had ſo far ſucceeded as to prevail on the numerous tribe of the Druſes to join his ſtandard with *ſixty thouſand* men immediately after the reduction of that town. Had this junction been effected, it was intended to proceed to Conſtantinople, and, after plundering the city, to lay it in aſhes! It is ſcarcely poſſible to calculate the dreadful conſequences of ſuch an event on the political ſtate of Europe. If ſervices are to be eſtimated in proportion to their effects, we know of none, during the preſent war, fertile as it has been in brilliant atchievements, that deſerves a higher reward than the defeat of Bonaparte at Acre.

During theſe reverſes abroad, France had begun to ſuffer much internal agitation, and the Directory found itſelf in a very difficult ſituation. The elections, as uſual, were unfavourable to them; and amidſt the contempt with which they now began to be regarded, it was no longer poſſible to ſecure a majority in the Councils, by unconſtitutionally annulling the elections of their political opponents. They demanded money, and were anſwered by reproaches, on account of their profuſion, and the rapacity of their agents. The royaliſts in the ſouth and the weſt began to form inſurrections. They were ſubdued with much difficulty, on account of the abſence of the troops. The people had totally loſt that enthuſiaſm which, in the earlier periods of the revolution, induced them to ſubmit to ſo many evils, and to make the moſt violent efforts without murmuring. They beheld the renewal of the war with regret, and were unwilling to aſſiſt by their exertions to reſtore power and ſplendour to the faction which had trampled upon their freedom.

Amidſt all theſe difficulties, an event occurred which, for a time, gave the Directory the hope of being once more able to rouſe the dormant energies of their countrymen. After the defeat of Jourdan, a detachment from

French Revolution, 1799

from the army of the Archduke Charles had occupied Raſtadt, where the Congreſs ſtill ſat. On the 28th of April an order was ſent by an Imperial officer to the French miniſters, requiring them to quit Raſtadt in 24 hours. They demanded a paſſport from Colonel Barbaſcy, who had ſent the order; but this he could not grant, none having that power but the commander in chief.

367 Aſſaſſination of the French envoys.

They declared themſelves determined to depart without delay, although the evening approached. They were detained about an hour at the gate of the town, in conſequence of general orders which had been received by the military to ſuffer none to paſs. In conſequence of an explanation, however, and of the interpoſition of ſuperior officers, they were allowed to depart. The three miniſters, Bonnier, Roberjot, and Jean Debry, were in carriages. The wife of Roberjot, and the wife and daughters of Jean Debry, were along with them; and they were attended by the miniſters of the Ciſalpine republic. When they had advanced to a very ſhort diſtance from Raſtadt, they were met by about 50 huſſars of the regiment of Szeckler, who made the carriages to halt, and advancing to the firſt of them, containing Jean Debry, demanded his name. He told them his name; and added that he was a French miniſter returning to France. On receiving this anſwer, they immediately tore him from his carriage, wounded him in ſeveral places with their ſabres, and caſt him into a ditch, on the ſuppoſition that he was killed. They treated in the ſame manner the two other ambaſſadors, Bonnier and Roberjot, whom they murdered upon the ſpot. They offered no perſonal violence, however, to the reſt of the company, who were allowed to return to Raſtadt; but they robbed the carriages of whatever effects they contained; and the papers of the ambaſſadors were conveyed to the Auſtrian commander. After the departure of the ſoldiers, and the return of the carriages to Raſtadt, Jean Debry wandered about the woods all night, and returned alſo to Raſtadt on the following day. He claimed the papers belonging to the legation from the Auſtrian commander, but they were refuſed to be reſtored.

During the whole of the long period that the Congreſs had ſat, Raſtadt and its vicinity had been occupied by French troops, and it was only a few days ſince the Auſtrians had obtained poſſeſſion of it. This event therefore caſt, at leaſt, a ſevere reproach upon the diſcipline of the Auſtrian army. It did more; it made every honeſt man regret, that troops, engaged in the ſupport of a good cauſe, ſhould think to promote that cauſe by the murder even of the greateſt villains.

368 Turned by the Directory to its own advantage.

The Archduke Charles made haſte to diſclaim all knowledge of it in a letter to Maſſena; but the French Directory, regarding it as a fortunate occurrence, from its tendency to rouſe the reſentment of the nation, addreſſed to the two Councils, on the 5th of May, a meſſage, in which they aſcribed it to a deliberate purpoſe on the part of the Auſtrian government to inſult France by the aſſaſſination of her ambaſſadors. They thus converted the private act of a few deſperate individuals into a meaſure of public policy; as if the death of thoſe wretched miſcreants could have been of conſequence to the enemies of the *great* nation. The unpopularity of the Directory, however, and the obvious inutility of ſo groſs a crime, prevented this accuſation from obtaining much credit, or producing great effects upon the people. In a private letter which a friend of our's received at that period from the Continent, he was aſſured that the murder of the envoys "*fait plus de bruit que de ſenſation;*" and that the general opinion was, that the Directory itſelf knew more of the authors of that crime than the Archduke or the Auſtrian government.

French Revolutio 1799.

369 Diſſenſion in France.

Upon the introduction of the new third of this year into the Councils, a violent oppoſition to the Directory commenced. Sieyes, who was ambaſſador at Berlin, and who had enjoyed, during the whole progreſs of the revolution, a very conſiderable influence over all the parties that had ſucceſſively enjoyed the ſupreme authority, was elected into the Directory. At the firſt eſtabliſhment of the conſtitution he had refuſed to occupy this ſtation, and it excited much ſurpriſe when he readily accepted the office in the preſent calamitous ſtate of the Republic. His admiſſion into the Directory, however, did not reconcile the public or the two Councils to that body. A violent conteſt for power betwixt the Moderate and the Jacobin parties ſeemed to approach; but they ſoon came to a compromiſe. Treilhard was removed from the Directory, under the pretence that he had held an office in the ſtate within leſs than a year previous to his nomination. Merlin and Reveillere were compelled to reſign, to avoid an impeachment with which they were threatened; but Barras ſtill contrived to retain his ſtation. Moulins, Gohier, and Ducos, men little known, and by no means leaders of the contending parties, were appointed Directors. The power was underſtood to be divided, and that neither party greatly predominated. An attempt was made to revive public ſpirit, by encouraging anew the inſtitution of clubs, which had been ſuppreſſed by the Directory. The violent Jacobins were the firſt to take advantage of this licence. They reſumed their ancient ſtyle, their propoſals for violent meaſures, and their practice of denouncing the members and the meaſures of government. But the Directory becoming alarmed by their intemperance, obtained leave from the Councils to ſuppreſs their meetings before they were able to intereſt the public in their favour.

370 Warlike forts of t Director

Conſiderable efforts were now made by the French government to recruit their armies; but the deranged ſtate of the finances, which the votes of the Councils could not immediately remedy, prevented the poſſibility of their gaining a ſuperiority during the preſent campaign. The difficulty was alſo increaſed by the neceſſity of reſiſting immenſe armies in different quarters at the ſame time, France being aſſailed at once on the ſide of Holland, Switzerland, and Italy. Such, however, were the exertions of the Directory, that they ſeemed not deſtitute of the hope of being able ſpeedily to aſſume, on the frontier, a formidable, and even menacing poſture. In the beginning of Auguſt, their Italian army amounted to 45,000 men. The different bodies of troops of which it conſiſted had been drawn together, and concentrated nearly in the ſame poſitions which Bonaparte had occupied before his battles of Montenotte and Milleſimo.

371 Joubert aſſumes comma in Italy

The command of the whole was given to Joubert, a young man, who had been much diſtinguiſhed under Bonaparte; and who, in the ſtyle of gaſconade employed by that general, aſſured his government of victory, declaring, that he and Suwarrow ſhould not both ſurvive the firſt battle. In this boaſting declaration he ſeems to have been in earneſt;

72 cceſſes of allies.

earneſt; for, on taking the command, he prevailed with Moreau to remain in the army as a volunteer till the firſt battle ſhould be fought. The allies had now taken Turin, Aleſſandria, Milan, Peſchiera, and Ferrara, with a rapidity which would lead one to ſuppoſe that ſome new mode had been invented of materially abridging the duration of ſieges. The ſtrong citadel of Turin opened its gates, to the aſtoniſhment of Europe, after a bombardment of only *three days;* the citadel of Aleſſandria ſurrendered to the Auſtrian General Bellegarde, on the 22d of July, after a ſiege of *ſeven days;* and the ſtill more important fortreſs of Mantua ſurrendered to the brave General Kray, on the 29th of the ſame month, after a ſiege of only *fourteen days.* The garriſon of Aleſſandria amounted to 2400 men; that of Mantua to 13,000. The former were detained priſoners of war, and the latter were allowed to return to France on their *parole;* a parole which the commanders of the allied armies could not reaſonably expect to be kept. This has given riſe to a ſuſpicion, that the fortreſs was voluntarily ſurrendered to the Auſtrians, in order that the Directory might recruit its armies with the garriſon.

373 war- w's victory over ubert, ho is lled.

The allies next began to beſiege Tortona, and Joubert reſolved to attempt its relief. He hoped to accompliſh this object, and to gain ſome advantage over their army, before General Kray could arrive to the aſſiſtance of Suwarrow with the troops that had been occupied in the ſiege of Mantua. On the 13th of Auguſt, the French drove in the whole of the Auſtrian poſts, and took poſſeſſion of Novi. Here they encamped on a long and ſteep, but not high, ridge of hills, with their centre at Novi, their right towards Seravalle, and their left towards Baſaluzzo. On the 14th they remained quiet; and on the 15th they were attacked by Suwarrow, whoſe army was now reinforced by the arrival of General Kray from Mantua. The right wing of the allied army was commanded by Kray, its left by Melas, and its centre was occupied by the Ruſſians, under Prince Pongrazion (Procration) and Suwarrow in perſon. The attack began at 5 o'clock in the morning, and was continued during many hours. Soon after the commencement of the battle, while the French commander in chief, Joubert, was urging his troops forward to a charge with the bayonet, he received a muſquet ſhot in his body, and, falling from his horſe, immediately expired. Moreau inſtantly reſumed the command. After an obſtinate conteſt, the allied army gave way, and was compelled to fall back in all quarters. The attack, however, was repeatedly renewed, and much blood was ſhed. From the obſtinate manner in which they fought, the Ruſſians, in particular, ſuffered very ſeverely. They made three unſucceſsful efforts againſt the centre of the French army, and on each occaſion thoſe immediately engaged were rather deſtroyed than repulſed. The laſt attack along the whole line was made at three in the afternoon. The French remained unbroken; and the day muſt have terminated in the defeat of the allies, had not General Melas ſucceeded in turning the right flank of the French line. Their right wing was thus thrown into confuſion. Melas purſued his advantage till he obtained poſſeſſion of Novi, and the whole French army made a rapid retreat under the direction of Moreau.

374 Unaccountable conduct of the allies.

According to the accounts given by the Auſtrians, the French loſt in this battle 4000 killed and an equal number taken priſoners. They acknowledged their own loſs in killed to be equal to that of the French, but the loſs ſuſtained by the Ruſſians was never publiſhed. The general reſult of the battle was the total ruin of the French affairs in this quarter. The allies retained their decided ſuperiority; and there was no enterpriſe which, on the preſent theatre of the war, they might not have ventured to undertake. The French renounced all hope of defending Genoa, and prepared to evacuate that city and its territory. The Directory expected an immediate invaſion of the ſouth of France, and addreſſed a proclamation to the people, urging them to act with firmneſs and energy amidſt the calamities with which the country was now menaced. But theſe apprehenſions were unneceſſary. The court of Vienna had other objects in view that were leſs dangerous to their enemy. They neither invaded Genoa nor France, but quietly proceeded in the ſiege of Tortona. The vanquiſhed army was ſurpriſed to find itſelf unmoleſted after ſuch a defeat; and in a few days ventured to ſend back parties to inveſtigate the movements of the allies. The new commander Championnet, who had ſucceeded Joubert, found to his no ſmall aſtoniſhment that they had rather retreated than advanced; and he immediately occupied the ſame poſitions which his army had held before the battle of Novi.

375 Suwarrow leaves Italy, and marches to Switzerland.

Inſtead of purſuing the advantages they had gained in Italy, the Aulic council, or council of war at Vienna, now perſuaded Suwarrow to leave that country with his Ruſſians, and to ſet out for Switzerland to drive the French from thence. In the early part of the campaign, the Archduke Charles had ſucceeded, after various attacks, in driving the French from the eaſtern part of Switzerland beyond Zurich, of which laſt city he retained poſſeſſion. The Directory, however, had ſent their new levies chiefly towards this quarter; ſo that in the middle of the month of Auguſt Maſſena's army amounted to 70,000 men. The Archduke was now ſo far from being able to purſue the advantages he had gained, that of late the French had reſumed the offenſive, and threatened to endanger his poſition. Their right wing under Lecourbe had even ſucceeded in taking poſſeſſion of Mount St Gothard, which is the great paſs that leads from the centre and eaſtern part of Switzerland into Italy. The cabinet of Vienna probably wiſhed to throw the ſevereſt duties of the war upon their northern aſſociates. The veteran Suwarrow had never, during his long military career, ſuffered a ſingle defeat. His preſumption of ſucceſs was therefore high; and he perhaps felt himſelf not a little flattered by the requeſt to undertake an enterpriſe in which the Auſtrians had failed. though led by their moſt fortunate commander. It is indeed certain that he conſidered himſelf as called out of Italy too ſoon. Though confident of being properly ſupported, he agreed to proceed with his troops from Piedmont to Switzerland, where another Ruſſian army had lately arrived. Delays, however, were thrown in his way. Tortona did not fall quite ſo ſoon as was expected; and when he was ready to march, the Auſtrian commander in Italy refuſed to ſupply him with mules for the tranſport of his baggage. Unable to reply to the indignant expoſtulations of the Ruſſian hero, this man deſcended to a pitiful falſehood, by aſſuring him that he would find a ſufficient number of mules at Bellinzone, where, when he arrived, not one was to be had. He had now no other reſource but to diſmount the cavalry, and employ their horſes to drag along the baggage. Under all theſe difficulties, he arrived, by forced marches, on the confines of Switzerland, on the day appointed by him and the Archduke; but the Auſtrian cabinet had, in the mean time, taken a ſtep which made all his exertions uſeleſs.

376 Is deſerted, if not betrayed, by the Auſtrians.

Thinking it degrading to a Prince of the Imperial houſe, who had ſo long held the higheſt military rank, to ſerve under the Ruſſian General, and not having the confidence to require the moſt experienced leader in Europe to receive the orders of a man ſo young as the Archduke, they ſent that prince with his army to attack the French, who, in a ſmall body, had entered into Swabia. He began accordingly to draw off his troops in the beginning of September, before Suwarrow was in readineſs to leave Italy. The number which he took with him has been differently eſtimated, the loweſt computation ſtating it at 48,000, and the higheſt at 60,000. The former is the moſt probable; ſince it is well known that 20,000 would have been fully adequate to the purpoſe for which he marched. The army which he left behind him is more perfectly aſcertained: it conſiſted of 21,000 Ruſſians, 18,900 Auſtrians, Bavarians, and other auxiliaries, forming a total of 39,900 men.

Upon what principle of military tactics the Aulic council could ſuppoſe that a ſkilful and intrepid commander like Maſſena, with a force nearly double that of the allies, would remain in a ſtate of inactivity, it is not eaſy to conceive. He perceived at once the advantage which might be derived from this unaccountable movement of the Archduke. The French troops in Swabia were therefore ordered to advance rapidly, and to threaten the rear of the Archduke's army. As the repulſe of theſe troops, and the invaſion of France towards Alſace, formed a part of the Auſtrian commander's plan of operations, he marched againſt them with his army. The French made as much reſiſtance as the ſmallneſs of their force would permit. The Archduke, however, gradually drove them towards the Rhine. The better to carry on their plan of deception, they made a ſerious ſtand in the neighbourhood of Manheim, and were defeated with the loſs of 1800 men. The Auſtrians entered Manheim, and ſeemed ready to croſs the Rhine in this quarter.

377 The allies defeated in Switzerland.

All this while Switzerland was left completely expoſed to the enterpriſes of Maſſena. General Hotze, with the Auſtrians, occupied the right wing of the allied army there. The newly arrived Ruſſian army was ſtationed in the centre at Zurich, under the command of General Korſakof; and the left, conſiſting chiefly of Bavarians and other troops of the empire, was commanded by Nauendorf. Maſſena remained quiet till he learned that the Archduke had entered Manheim, and that Suwarrow, having taken Tortona, was on his march towards Switzerland by Mount St Gothard. This laſt poſition was defended by Lecourbe; and Maſſena reſolved, in the mean time, to anticipate the arrival of Suwarrow. On the 24th of September, having drawn the attention of the Ruſſians to another quarter by a falſe attack, he ſuddenly croſſed the Limmat, a river which divided the two armies near the convent of Farr, which is three leagues diſtant from Zurich. A part of the French troops engaged the Auſtrians, while the greater part of the army marched againſt the Ruſſians at Zurich. The Auſtrian General Hotze was killed in the commencement of the action. General Petrarch, who ſucceeded him in the command, contrived to avoid a total rout, and retired during the night with the loſs of about 4000 men. The conteſt with the Ruſſians was ſingularly obſtinate. In a mountainous country, to which they were ſtrangers, and contending againſt the moſt ſkilful military leaders that the ſouth of Europe had been able to produce, they laboured under every diſadvantage. They could not be put to flight, however; and even when different diviſions of them were ſurrounded, they refuſed to lay down their arms, and were ſlaughtered upon the ſpot. By the retreat of the Auſtrians on the evening of the 25th, they found themſelves on the 26th nearly ſurrounded in Zurich. They now began to retreat alſo; and we are only ſurpriſed at the ability of the Ruſſian General in effecting his retreat in ſuch good order, and with ſuch little loſs; for if the official accounts deſerve credit, his loſs in killed, wounded, and taken, did not exceed 3000 men. He was obliged, however, to abandon his baggage and cannon to the enemy.

378 Suwarrow's march.

During theſe operations, Suwarrow was advancing on the ſide of Italy with an army rated, in ſome accounts, at 18,000, in others at only 15,000; and forcing the French from their ſtrong poſitions on Mount St Gothard, deſcended, on the very day on which Maſſena made his general attack, into the valley of Urſeren; and driving Lecourbe before him, with conſiderable ſlaughter, advanced as far as Altorf. He even penetrated on the next day into the canton of Glaris, and took 1000 of the French priſoners; while the Ruſſian General Roſemberg was equally ſucceſsful in the canton of Schwitz, where General Auffenberg had effected a junction with him; and General Linken defeated and took another corps of French, conſiſting of 1300 men.

379 His admirable conduct.

Maſſena, however, now turned upon the Field-marſhal with the greater part of his army; and, by hemming him in on all ſides, expected to have made him, and the Grand Duke Conſtantine, priſoners. Suwarrow, however, defended himſelf againſt every attack with unexampled vigour and addreſs. A ſingle paſs among the mountains was all that remained unoccupied by the French. He diſcovered this circumſtance, and eſcaped, though cloſely purſued. He loſt his cannon, baggage, and proviſions, among the dreadful mountains and precipices with which that country abounds. He made his way, however, eaſtward through the Griſon country, and at length arrived at Coire with about 6000 men in great diſtreſs.

380 His indignation at the court of Vienna.

Nothing could exceed the indignation of this old warrior when he diſcovered the manner in which affairs had been conducted, the hazardous ſtate in which the Ruſſians had been abandoned by the Archduke, and the conſequent ruin which they had encountered. He conſidered himſelf and his countrymen as treacherouſly expoſed to deſtruction; he loudly complained of the Commander of the allied forces in Switzerland; publicly taxed the council of Vienna with ſelfiſhneſs and injuſtice; and refuſed all farther co-operation with the Auſtrian army. He ſent an account of the whole tranſaction to St Peterſburgh in a letter, of which the compoſition would do honour to the fineſt writer of the age, and withdrew with his troops to the neighbourhood of Augſburg to wait for farther orders.

0
In ion of
H and.

In the mean time, Great Britain prepared to invade Holland with an army of 40,000 men, conſiſting of Britiſh troops and Ruſſian auxiliaries. The firſt diviſion, under General Sir Ralph Abercromby, ſailed in the month of Auguſt, under the protection of a fleet commanded by Admiral Lord Duncan. Bad weather prevented a landing from being attempted till the 27th. On the morning of that day the troops landed without oppoſition upon the ſhore of Helder Point in north Holland, at the entrance to the Zuyder Sea. They had not been expected in this quarter, and the troops in the neighbourhood were conſequently few. The Britiſh, however, had no ſooner begun to move forward, than they were attacked by a conſiderable body of infantry, cavalry, and artillery, who had been haſtily aſſembled from the neareſt towns. The Dutch troops maintained the conteſt with much obſtinacy; but they were gradually fatigued by the ſteady oppoſition they encountered, and retired to the diſtance of two leagues. In the night they evacuated the fort of Helder, of which the Britiſh took poſſeſſion on the morning of the 28th. A detachment from the Britiſh fleet, commanded by Vice Admiral Mitchell, now entered the Zuyder Sea by the ſtrait of the Texel, to attack the Dutch fleet under Admiral Story. This laſt officer, inſtead of retiring for ſafety to any of the ports, or to the ſhallow water with which that ſea abounds, ſurrendered the whole fleet on the 30th of Auguſt without firing a gun, under pretence that his ſeamen were mutinous, and would not fight.

81
C ture of
t Dutch
f t.

Had the expedition terminated here, it might have been regarded as extremely fortunate, and as eſtabliſhing the power of the Britiſh navy without a rival. But it was reſolved to follow up this firſt ſucceſs by an effort on land to reſtore the authority of the Stadtholder, and the ancient government of the United Provinces. Many circumſtances were hoſtile to this enterpriſe. The whole army had not been ſent at once from Britain. As no more than the firſt diviſion had arrived, the troops could only reſt upon the ground they had gained till reinforcements ſhould be ſent. The terror ariſing from the firſt appearance of an invading army was thus allowed to paſs away, the enemies of the preſent Dutch government were diſcouraged, and leiſure was afforded to adopt effectual meaſures of defence. The place where the landing was effected was well choſen for an attack upon the Dutch fleet; but for an invaſion, with a view to the reſtoration of the Stadtholder, it was the worſt that could have been ſelected. North Holland, at the extremity of which it was made, is a narrow peninſula, everywhere interſected by canals and ditches, of about 40 miles in length. Here the invaders might be detained, and even ſucceſsfully reſiſted, by a force greatly inferior to their own. This alſo is the quarter of the country the moſt unfavourable to the cauſe of the Stadtholder. In Zealand, where his eſtates are ſituated, and in Rotterdam, which is full of Scotchmen and of families of Scottiſh extraction, his friends are numerous and powerful; but in Amſterdam, and in North Holland, which is under its influence, his enemies abound, and the reſiſtance to his power has been very great during every period of the Dutch hiſtory. When to all this it is added, that the rainy ſeaſon was approaching, and that a winter campaign in Holland is almoſt impoſſible, it will not appear ſurpriſing that this expedition was attended with little ultimate ſucceſs. It is ſaid that, amidſt the preſſure of the many difficulties which ſurrounded them, the French Directory heſitated much about undertaking the defence of Holland; but the place, and the time of landing the invading army, at once brought them to a determination. General Brune was ſent thither, with whatever troops could be haſtily collected, to ſupport the Dutch General Daendels.

382
Progreſs of
the invaders.

General Abercromby, in the mean time, remained upon the defenſive at Schager Brug, waiting for reinforcements. His inactivity encouraged the enemy on the 10th of September to venture an attack upon his poſition. They advanced in three columns, two of which conſiſted of Dutch and one of French troops. They were repulſed, however, in all quarters, and retired to Alkmaer. On the 13th the Duke of York arrived with additional troops, and aſſumed the chief command. The Ruſſian auxiliaries having alſo arrived, offenſive operations were immediately reſolved upon. On the 19th the army advanced. General Abercromby commanded the left, which proceeded along the ſhore of the Zuyder Sea againſt Hoorne. The centre columns were commanded by Generals Dundas and Pultney; and the right wing, conſiſting of Ruſſians, was commanded by their own General D'Herman. In conſequence of ſome ſtrange miſunderſtanding, the Ruſſians advanced to the attack ſoon after three o'clock in the morning, which was ſome hours previous to the movement of the reſt of the army. They were ſucceſsful in their firſt efforts, and obtained poſſeſſion of the village of Bergen; but preſſing eagerly forward, and being unſupported by the other columns, they were nearly ſurrounded. Their commander was taken priſoner; and though the Britiſh came in time to protect their retreat, they loſt at leaſt 3000 men. This failure on the right obliged the Britiſh Commander in Chief to recal his troops from the whole advanced poſitions they had gained, though General Abercromby had actually taken Hoorne with its garriſon, and although General Pultney's column had carried by aſſault the principal poſition of the Dutch army called *Ourds Carſpel*.

The ſeverity of the weather prevented another attack till the 2d of October, when, after an engagement that laſted from ſix in the morning till the ſame hour in the evening, the Britiſh army ſucceeded in driving the united Dutch and French troops from Alkmaer and the villages in its neighbourhood. The conteſt was chiefly conducted among the ſand hills in the vicinity of the ocean; and the battle was maintained with ſuch obſtinacy, that the fatigue of the troops, together with the difficult nature of the country, prevented the Britiſh from gaining any great advantage in the purſuit. The retreating army immediately occupied a new poſition between Baverwyck and Wyck op-zee. The Duke of York once more attacked them on the 6th; and after an obſtinate and bloody engagement, which was maintained till night, he remained in poſſeſſion of the field of battle. But this was the laſt ſucceſs of the invaders. Finding himſelf unable to make farther progreſs, in conſequence of the increaſing numbers of the enemy, the impracticable nature of the country, and the badneſs

383

the enemy
and the inclemency
of the weather.

French Revolution, 1799.

of the weather, which, during the whole of this year, was unuſually ſevere, the Duke of York retired to Schager Brug, and there waited for orders from England to return home. He was, in the mean time, cloſely preſſed by the United Dutch and French forces, ſo that his embarkation muſt have been attended with much hazard. He therefore entered into a convention with the French and Dutch generals; by which it was agreed, that they ſhould no farther moleſt him in his retreat, and that, in return, he ſhould not injure the country by breaking down any of the dykes which protect it againſt the ſea, and that Great Britain ſhould reſtore to France and Holland 8000 priſoners of war, taken previous to the preſent campaign.

In conſequence of theſe events, the affairs of France now began to aſſume a leſs unfavourable aſpect. They were indeed driven to the extremities of Italy, Championet was defeated in every effort which he there made againſt the Auſtrians during the reſt of the year, and Ancona, which was the laſt place of any ſtrength poſſeſſed by the French, alſo ſurrendered on the 13th of November to General Frolich; but they retained the Genoeſe territory, and Switzerland and Holland continued under their power. 384 Coalition againſt France ready to be diſſolved. The new coalition againſt them ſeemed once more ready to diſſolve. From the commencement of the French Revolution, a ſpirit of ſelfiſhneſs had mingled with all the efforts made by the continental powers of Europe againſt it, and had rendered them fruitleſs. To prevent the aggrandiſement of Auſtria, Pruſſia had early withdrawn, and ſtill ſtood aloof. Spain and Holland were retained under the influence of France by the efforts of her arms, and by the univerſal diffuſion of her wild principles among the people. Even the Britiſh cabinet, which of all the European powers has remained moſt true to the original purpoſe of the war, ſometimes forgot that object. Thus, when invading Holland, the Dutch were informed, by a proclamation, that their ancient government was to be reſtored; but no offer was made to reſtore their diſtant poſſeſſions. Of all the coaleſced powers, however, Auſtria purſued her ſeparate intereſts with the leaſt diſguiſe. With much facility ſhe relinquiſhed the Netherlands, and ſuffered the principal bulwarks of Germany, Mentz, and Ehrenbreitſtein, to fall into the hands of the French, upon obtaining in exchange the Venetian territories, which Bonaparte had conquered, and thought himſelf authoriſed to ſell. During the preſent campaign, the whole conqueſts made by the united efforts of the Auſtrian and Ruſſian forces were ſeized by Auſtria in her own name, and none of the Princes of Italy obtained leave to reſume the government of their own territories. This conduct on the part of the allies gave every advantage to the French. They broke off the negociations at Liſle, under the pretence of defending the Dutch and Spaniſh ſettlements which the Britiſh government refuſed to relinquiſh. They found it eaſy to alarm the King of Pruſſia, by diſplaying the unbounded ambition of the houſe of Auſtria; and the Emperor of Ruſſia, having publicly declared to the members of the German empire, that the purpoſe for which he had taken up arms was not to diſmember France, but to reſtore peace to Europe, became jealous of the Court of Vienna, when he ſaw it purſue a conduct ſo very different. This jealouſy was encreaſed by the misfortunes of the Ruſſian troops; and all circumſtances ſeemed now to promiſe that the new coalition would ſpeedily be deſerted by its northern auxiliary.

French Revolution, 1799.

385 Bonaparte vanquiſhes the Turks in Egypt. While affairs were in this ſtate, an event occurred which exhibited the French Revolution under a new aſpect. When Bonaparte found himſelf compelled to retreat, baffled and diſgraced, from the ruins of Acre, he learned that a Turkiſh army was ready to invade Egypt by ſea. He returned, therefore, with his uſual celerity, by way of Suez, acroſs the deſart of Arabia Petrea, which divides Syria from that country, and was in the neighbourhood of the Pyramids on the 11th of July, when an army of 18,000 Turks landed from 100 ſhips at Aboukir. They took this fort by aſſault, and gave no quarter to the French garriſon of 500 men that it contained. On the 15th, Bonaparte began to march down the country againſt them. On the 25th he came in ſight of them. at ſix o'clock in the morning.

It is not wonderful that thoſe barbarians afforded him an advantage which had ſo often been preſented by the armies of Auſtria. They had divided their force into two parts, which were encamped on the oppoſite ſides of a beautiful plain. He had now formed a conſiderable body of cavalry, by obtaining for his men fleet horſes from Arabia. Theſe advanced rapidly into the centre of the Turkiſh army, and cut off the communication between its different parts. His infantry then attacked the right, which was the weakeſt diviſion of the Turks. They being ſpeedily panic ſtruck, attempted to fly to their ſhips, and every man was drowned in the ſea. The left diviſion of the Turks was next attacked. It made a more obſtinate reſiſtance, but was ſoon alſo put to flight. Some caſt themſelves into the ſea, and periſhed in attempting to reach the boats of their fleet; the reſt took refuge in the fort of Aboukir. The news of this battle reached France towards the end of September, and revived the memory of Bonaparte's victories, contraſted with the reverſes which the Republican armies had lately experienced. On the 10th of October a diſpatch was received from him by the Directory, and read to the Councils, giving an account of the capture of the fort of Aboukir, with the whole remains of the Turkiſh army. 386 Arrives with his principal officers in France, On the 14th of the ſame month a meſſage from the Directory announced, to the aſtoniſhment of all men, that Bonaparte, along with his principal officers, had juſt arrived in France, and that they left the army in Egypt in a proſperous ſtate. This laſt part of the meſſage was ſoon afterwards proved, by the intercepted letters of Kleber, and the other generals left behind, to be a ſcandalous falſehood. In one of theſe letters, Pouſſielgue ſays, "Every victory carries off ſome of our beſt troops, and their loſs cannot be repaired. A defeat would annihilate us all; and however brave the army may be, it cannot long avert that fatal event."

Bonaparte, however, was received at Paris with diſtinction, though nobody could tell why he had deſerted his army and come thither. The parties in the government were equally balanced; and both the Jacobins, and what were called the *Moderates*, ſolicited his aſſiſtance. The Jacobins ſtill poſſeſſed a majority in the Council of Five Hundred; but in the other Council their antagoniſts were ſuperior. The Director Sieyes was underſtood to be of the party of the Moderates; and the Jacobins had of late unſucceſsfully attempted to

nch
ution,
99.

to remove him from his office, under the pretence that the interval appointed by the conſtitution had not elapſed between his going out of the Council of Five Hundred and his election to the office of director. Neither party was ſatisfied with the exiſting authorities; but none of the uſual indications of approaching hoſtilities appeared. The Jacobins were far from ſuſpecting that Sieyes had a plot ripe for execution, which was to overwhelm them in an inſtant. They were even in ſome meaſure laid aſleep by an artful ſcene of feſtivity, in which the whole members of the Councils were induced to engage, on the 6th of November, under pretence of doing honour to the arrival of Bonaparte. On the morning of the 9th, one of the committees of the Council of Ancients, called the committee of Inſpectors of the Hall, preſented a report; in which they aſſerted, that the country was in danger, and propoſed to adjourn the ſitting of the legiſlature to St Cloud, a village about ſix miles from Paris. We have already mentioned, that the conſtitution entruſted to the Council of Ancients the power of fixing the reſidence of the legiſlative bodies, and that this Council could in no other caſe aſſume the initiative, or propoſe any law; their powers of legiſlation being otherwiſe limited to the unconditional approbation or diſapprobation of the decrees paſſed by the Council of Five Hundred. The Council of Ancients now ſuddenly decreed, that both Councils ſhould meet next day at St Cloud. As the Council of Five Hundred had no conſtitutional right to diſpute the authority of this decree, and as the ruling party in it was completely taken by ſurpriſe, its members ſilently ſubmitted, and both Councils aſſembled on the 10th of November at the place appointed.

87
ſeizes
reins
overn-
t.

The Council of Five Hundred exhibited a ſcene of much agitation. They received a letter from Legarde, ſecretary to the Directory, ſtating, that four of its members had ſent reſignations of their offices, and that the fifth (Barras) was in cuſtody by order of General Bonaparte, who had been appointed commander of their guard by the Council of Ancients. While the Council were deliberating, Bonaparte entered the hall, attended by about twenty officers and grenadiers. He advanced towards the chair, where his brother Lucien Bonaparte ſat as preſident. Great confuſion enſued; he was called a Cromwell, a Cæſar, an uſurper. The members began to preſs upon him, and his countryman Arena attempted to ſtab him with a dagger. He was reſcued by his military eſcort. Lucien Bonaparte then left the chair, and caſt aſide the badge of office which he wore as a member of the Council. The confuſion did not diminiſh; but in a ſhort time a party of armed men ruſhed into the hall, and carried off Lucien Bonaparte. A tumultuous debate now began; in which it was propoſed that Bonaparte ſhould be declared an outlaw. The debate was ſoon terminated, however. The doors of the hall were once more burſt open. Military muſic was heard; and a body of troops proceeding into the hall in full array, the members were compelled to diſperſe. The Council of Ancients, in the mean time, ſetting aſide the conſtitution, paſſed a variety of decrees. They aboliſhed the Directory, and appointed in its ſtead an Executive Commiſſion; to conſiſt of Bonaparte, Sieyes, and Roger Ducos, under the appellation of Conſuls. They adjourned the ſittings of the legiſlative bodies till the 20th of February, and appointed two committees, conſiſting of twenty-one members, ſelected from each of the two councils, to act as legiſlators in the mean time. They alſo expelled a great number of members from their ſeats in the councils.

French
Revolution,
1799.

Moſt of the members of the Council of Five Hundred returned to Paris, after having been driven from their hall by the military; but a part of them remained at St Cloud, and, on the evening of the ſame day, confirmed all the decrees of the Council of Ancients. The new government entered upon its functions at Paris on the following day. That city remained tranquil, and the public funds even roſe upon the occaſion. On the 17th of November the conſuls decreed the tranſportation of a great number of the leading Jacobins and zealous republicans to Guiana, and ordered many others to be impriſoned; but theſe decrees were ſpeedily recalled, and affairs went on as quietly as if nothing unuſual had occurred.

388
Motions of Tippoo Sultan in India.

While Bonaparte was thus obtaining boundleſs perſonal aggrandiſement in Europe, the African expedition in which he had been engaged was utterly unſucceſsful in all its objects. The circumſtances which led to it, ſo far as concerned foreign nations, now came to light, and were ſhortly theſe: Tippoo Sultan, the ſon and ſucceſſor of the celebrated Hyder Ally, and ſovereign of the Myſore country, which forms a part of the peninſula of India, had been compelled to conclude a treaty of peace in the year 1792 with the Britiſh governor general, Lord Cornwallis, under the walls of Seringapatam his capital. By this treaty he reſigned to the invaders a part of his territory, and agreed to pay a large ſum of money. He was, moreover, under the humiliating neceſſity of conſenting that two of his ſons ſhould be delivered as hoſtages, to remain with the Britiſh till the pecuniary payments could be completed.

A war thus concluded could not become the foundation of much cordial amity between the parties. Tippoo had inherited from his father a deep ſentiment of hoſtility againſt the growing power of Britain in India. Though he ſubmitted on the occaſion now mentioned to the neceſſity of his circumſtances, yet he only waited a more fortunate opportunity to endeavour to recover what he had loſt; and even, if poſſible, to accompliſh the favourite object of all his enterpriſes, the complete expulſion of the Britiſh from India. At a former period, almoſt the whole of the native princes of this vaſt continent had entered into a combination againſt the power of Britain; but their deſigns had been defeated by the talents and exertions of Warren Haſtings, Eſq; The aſcendency of the Britiſh government in this quarter was now ſo great, that no ſuch combination could again be formed, and Tippoo felt that its power could only be ſhaken by the aid of an European army. France was the only country from which he could hope to obtain an adequate force. By the events of the revolution, however, and by the preſſure of the war at home, the rulers of France had been prevented from attending to diſtant views and intereſts. Their ſettlements in India had been ſeized by the Britiſh, and they had ceaſed to retain any poſſeſſions beyond the Cape of Good Hope, excepting the iſlands of Mauritius and Bourbon. In the year 1797, Tippoo reſolved to endeavour to renew his intercourſe with the French by means of theſe iſlands. One Repaud, who had once been a lieutenant in the French navy, and had reſided for ſome time at Seringapatam,

389
He renews his intercourſe with the French.

gapatam, had miſled Tippoo into a belief that the French had a great force at the Mauritius, which could immediately be ſent to his aid in caſe of a war. He therefore fitted out a ſhip, of which he gave the command to Ripaud, and ſent two perſons in it as his miniſters, with powers to negociate with the French leaders at the Mauritius. But, at the ſame time, to avoid exciting the ſuſpicions of the Britiſh government in his neighbourhood, he directed his meſſengers to aſſume the character of merchants, to act in that capacity in public, and to conduct their political negociations with ſecrecy. They arrived at the Mauritius towards the cloſe of the year 1797, and opened their propoſals to Malartic the governor, for an alliance between Tippoo and the French nation, with the view of obtaining the aid of an European army. They were received with great joy, and veſſels were inſtantly diſpatched to France to communicate their propoſals to the Directory.

390
His conduct watched by the Britiſh.

In the mean time, Malartic the governor of the Mauritius, from folly, from treachery, or from a deſire to involve Tippoo, at all hazards, in a quarrel with the Britiſh, took a ſtep which ultimately was in a great meaſure the means of defeating the plans, and accompliſhing the ruin of that prince. On the 30th of January 1798, he publiſhed and diſtributed a proclamation, in which he recited the whole private propoſals of Tippoo, and invited all French citizens to enliſt in his ſervice. Copies of this proclamation were ſpeedily conveyed by different veſſels, touching at the Mauritius, to the continent of India, to Britain, and to all quarters of the world. Accordingly, as early as the 18th of June 1798, the ſecret committee of the Court of Directors of the Eaſt India Company in London wrote to their governor general in India, requiring him, in conſequence of this proclamation, to watch the conduct of Tippoo, and even to engage in hoſtilities, if the meaſure ſhould appear neceſſary. Before that period, however, the government in India had been alarmed by the ſame means, and was making preparations for war. This, however, was no eaſy matter. It is the nature of European power, in theſe countries, gradually to decline. The nature of the climate, the view of returning home, and the diſtance from the ſeat of government, ſpeedily introduce a relaxation of the efforts and the vigilance by which dominion was originally acquired. The troops require to be continually renewed by levies from the parent country; and if this precaution is neglected for a very ſhort time, or negligently attended to, they become unable to protect the extenſive territories ſuch as Britain now poſſeſſed in India. When Lord Mornington, the governor-general, enquired into the ſtate of the Britiſh army at Madras, and whether he might hazard an offenſive war againſt Tippoo; he was informed, that three, if not ſix months would be neceſſary to aſſemble the ſcattered diviſions of the army, and to prepare them to defend their own territory. It was added, that ſuch was the feeble ſtate of the Britiſh forces in that quarter, that it might even be unſafe to excite ſuſpicion in Tippoo by military preparations, as he might, in that caſe, ruin them by a ſudden attack. Lord Mornington, however, reſolved to encounter every hazard, and ordered immediate and active preparations in every quarter.

In the meanwhile, Tippoo did not truſt for ſucceſs to the aid of France alone. He endeavoured to bring an attack upon the Britiſh and their allies, or ſubjects, in India, from the north weſt, by inviting Zemaun Shah to invade the country. This prince is at the head of a formidable kingdom, made up of provinces torn from both Perſia and India. It was founded about ſixty years ago by Ahmed Khaun Abdalla, an Affghan chief, who followed Nadir Shah on his invaſion of India in 1739. He himſelf afterwards invaded India no leſs than ſeven times; and, in particular, he overthrew, with dreadful ſlaughter, the united forces of the Mahratta empire, in the year 1761, on the plains of Paniput. He was ſucceeded, in 1773 by his ſon Timmur Shah, who died, and was ſucceeded by his own ſon, the preſent prince. The dominions of Zemaun Shah extend from the left bank of the river Indus, on the ſea-coaſt, as far northward as the latitude of Caſhmeer; and from eaſt to weſt they are 650 Engliſh miles in length, comprehending the provinces of Cabal, Candahar, Peiſhere, Ghizni, Gaur, Sigiſtan, and Koraſun. He uſually keeps in pay an army of 150,000 horſe, beſides infantry to garriſon his fortreſſes. In expectation of direct aid from France, by Bonaparte's expedition to Egypt, and of an important diverſion to be made by Zemaun Shah, Tippoo endeavoured to remain quiet, and to temporiſe with the Britiſh.

Since the firſt victories of Lawrence and of Clive, the native princes of India have been eager to introduce the European art of war among their ſubjects. For this purpoſe they retain European adventurers to command and diſcipline a part of their troops, and even endeavour to form a guard for their perſons of European ſoldiers. The Nizam, a prince in alliance with the Britiſh, though in a great meaſure under their influence, had long retained around his perſon a conſiderable body of French, and of troops under their management. Theſe, under the command of one Perou, now poſſeſſed great influence at Hydrabad, the capital of the Nizam. It was of much importance that theſe ſhould be removed out of the way, to enable the Britiſh to obtain the aid of this prince as an ally in the approaching conteſt with Tippoo. Lord Mornington procured this object to be accompliſhed with ſo much ſucceſs, that, on the 22d of October 1798, the French corps under Perou was ſurrounded and diſarmed without bloodſhed, and a Britiſh force was ſubſtituted as a guard to the Nizam in its ſtead. The military preparations being in a conſiderable ſtate of forwardneſs, Lord Mornington next warned Tippoo Sultan, in a letter dated the 8th of November 1798, of his having a knowledge of his hoſtile deſigns and connection with the French. He alſo propoſed to ſend an ambaſſador to treat about the means of reſtoring a good underſtanding between the ſtates. Tippoo avoided returning an anſwer till the 18th of December, and then merely denied the accuſation, and refuſed to receive the ambaſſador. On the 9th of January 1799, the Britiſh governor again urged in writing that the ambaſſador ſhould be received. No anſwer was returned for a month; and, in the mean time, an army of 5000 men having arrived from England, orders were iſſued to General Harris to advance at the head of the Madras army againſt the kingdom of Myſore. Tippoo now offered to receive the ambaſſador, providing he came without an attendance; but this conceſſion was not accounted ſufficient, and the army advanced. An army from

391
General Harris advances againſt him.

from Bombay was, at the ſame inſtant, advancing on the oppoſite ſide of his dominions. A part of Tippoo's forces encountered this army and were defeated; and within a few days thereafter, on the 27th of March, the reſt of his army was defeated by General Harris. When an European army in India is tolerably numerous, the detail of its military operations againſt the natives is by no means intereſting; for the inhabitants of theſe enfeebling and fertile regions can never be made, by any kind or degree of diſcipline, to poſſeſs that moral energy which enables men to encounter danger with coolneſs and ſelf-command. They can ruſh on death under the influence of rage or deſpair, but they cannot meet the hazard of it with calmneſs and recollection. It is ſufficient to remark that, on the 7th of April, General Harris ſat down before Seringapatam. On the 9th, Tippoo ſent a letter to this officer, alleging his own adherence to treaties, and enquiring into the cauſe of the war. He was anſwered by a reference to Lord Mornington's letters. On the 20th he made another attempt to negociate, by writing to General Harris, requeſting him to nominate commiſſioners to treat of a peace. In anſwer to this propoſal, certain articles were ſent to him as the only conditions that would be granted. By theſe he was required to ſurrender half his dominions, to pay a large ſum of money, to admit reſident ambaſſadors from the Britiſh and their allies, to renounce all connection with the French, and to give hoſtages for the fulfilment of theſe ſtipulations.

92 takes ngapa-

On the 28th of April Tippoo again wrote to General Harris, requeſting leave to treat by ambaſſadors; but his propoſal was refuſed, upon the footing that he was already in poſſeſſion of the only terms of peace which would be granted. Could Seringapatam have held out for little more than a fortnight longer, the invading army muſt have retreated. The rainy ſeaſon was about to commence; and, by ſome ſtrange effect of negligence or treachery, proviſions were ſo deficient in the camp, that it was only by reducing the troops to half allowance that they could be made to laſt till the 15th of May. On the 30th of April, the beſiegers began to batter the walls of Seringapatam; and a breach being made, the city was taken by aſſault on the 4th of May. One o'clock afternoon had been choſen for this purpoſe, as the hotteſt hour of the day, and conſequently the time when it would be leaſt expected. Tippoo was in his palace; but on being informed of the attack, he haſtened to the breach, and fell undiſtinguiſhed in the conflict. His treaſures, and the plunder of the city, which was immenſe, went to enrich the conquering army, after deducting a ſhare for the Britiſh government and Eaſt India Company. His kingdom immediately ſubmitted. The part of it which formed the ancient kingdom of Myſore, was beſtowed upon a deſcendant of the former race of its kings, whom Hyder Ally had deprived of the ſovereignty; the additional territories that had been conquered by Hyder Ally were divided between the Britiſh and their allies, the Nizam and the Mahrattas. The family of Tippoo were either taken in the capital, or voluntarily ſurrendered themſelves to the conquerors. They were removed from that part of the country, and allowed a conſiderable penſion.

393 Immenſe power of Britain in India.

In the mean time, Zemaun Shah had actually invaded India from the north-weſt. He advanced to the vicinity of Delhi, ſpreading terror and deſolation wherever he came. Had the French army in Egypt been able to detach a body of 15,000 men to the aſſiſtance of Tippoo, while all India was in the ſtate of alarm naturally produced by the approach of this northern invaſion, it is extremely probable that the Britiſh forces might ſpeedily have found themſelves deſerted by every ally, and ſunk under an unequal conteſt. But the actual reſult was very different. Satiſfied with the plunder he had obtained, Zemaun Shah ſoon withdrew; and the French army being detained in Egypt by the war with the Turks, and by the want of veſſels at Suez wherewith to reach India, Tippoo was left to contend, unaſſiſted, againſt the whole power of Britain, and of its allies in the eaſt. By the conqueſt and diviſion of his territory, the Britiſh power was left without a rival in that quarter of the world, and raiſed to ſuch a ſtate of impoſing ſuperiority, that if affairs are only preſerved in their preſent ſituation, by periodical ſupplies of European troops, no native prince, or even combination of princes, can henceforth bring it into danger. Thus, notwithſtanding the vaſt military efforts made by the people of France during this revolutionary war, yet all foreigners who truſted to their aid were ruined by placing confidence in them. In Italy, Germany, Switzerland, and Holland, the rapacity of the commiſſaries of the French government, ſoon rendered odious and intolerable the preſence of thoſe armies whoſe arrival had been eagerly deſired. In Ireland and in India, the promiſe and the hope of aſſiſtance which they were never able to beſtow, only ſerved to produce premature hoſtility, and to encreaſe and eſtabliſh the power of the Britiſh government.

But to return to the domeſtic hiſtory of France, which has now become only an hiſtory of the uſurpation of Bonaparte.

394 New conſtitution of France.

In the middle of the month of December, the Conſuls, with their legiſlative committees, produced to the public their plan of a new conſtitution, which they preſented to the primary aſſemblies, and which is ſaid to have been accepted by them without oppoſition, like all the former conſtitutions. It is a very ſingular production, and neither admits of repreſentative government, nor indeed of any other form of political freedom. Eighty men, who elect their own ſucceſſors, poſſeſs, under the appellation of a *Conſervative Senate*, the power of nominating the whole legiſlators and executive rulers of the ſtate; but cannot themſelves hold any office in either of theſe departments. The ſovereignty is concentrated in one man, who, under the title of *Chief Conſul*, holds his power for ten years, and may be re-elected. The whole executive authority is entruſted to him, and he enjoys the excluſive privilege of propoſing new laws. He is aſſiſted by two other conſuls, who join at his deliberations, but cannot controul his will. The legiſlative power is entruſted to two aſſemblies: the one, conſiſting of 100 members, called a *Tribunate;* and the other, of a *Senate*, of 300 members. When a law is propoſed by the Chief Conſul, the Tribunate may debate about it, but have no vote in its enactment. The Senate votes for or againſt its enactment, but cannot debate about it. Neither the Conſuls, nor the members of the legiſlative bodies, nor of the conſervative ſenate, are reſponſible for their conduct. The miniſters of ſtate, however, who are appointed by

French Revolution, 1799.

the Chief Conſul, are reſpoſible for the meaſures they adopt.

The people in the primary aſſemblies elect one-tenth of their number as candidates for inferior offices; perſons thus choſen, elect one tenth of themſelves as candidates for higher offices; and theſe again elect a tenth of themſelves as candidates for all the higheſt offices of the ſtate. Out of this laſt tenth the Conſervative Senate muſt nominate the conſuls, legiſlators, and members of their own body. But this laſt regulation is to have no effect till the ninth year of the republic. In the mean time, the ſame committees that framed the conſtitution, appointed alſo the whole perſons who were to exerciſe the government. Bonaparte was appointed Chief Conſul, and Cambaceres and Lebrun ſecond and third Conſuls. Sieyes, with his uſual caution, avoided taking any active ſhare in the management of public affairs, and was appointed, or appointed himſelf, a member of his own Conſervative Senate; the whole being regarded as produced by him. As a gratuity for his ſervices, the Chief Conſul and his legiſlators preſented to him an eſtate belonging to the nation, called *Croſne*, in the department of Seine and Oiſe.

395 Abſolute power of Bonaparte.

Thus, after all their ſanguinary ſtruggles for freedom, did the ſon of a Corſican drive from their ſtations the repreſentatives of the French nation, and aſſume quiet poſſeſſion of the government of that country, with a power more abſolute than ever belonged to its ancient monarchs. The eſtabliſhed privileges of the clergy, the nobles, and the parliaments, always reſtrained, in ſome degree, the deſpotiſm of the kings of France; theſe being now deſtroyed, the will of Bonaparte could meet with no controul. Though an uſurper, however, he has not hitherto been a tyrant. He has rather attempted to induce the French nation to acquieſce in his authority, in conſequence of the mildneſs with which it has been exerciſed, and of the ability and reputation of the men whom he has employed in the public ſervice. He immediately ſent propoſals for negociating peace to the different powers at war with France. Great Britain refuſed to liſten to him on account of the probable inſtability of his government, and Auſtria appears to have given a ſimilar refuſal. It is indeed difficult to believe that he wiſhed his propoſals to be accepted. They were not addreſſed to the belligerent powers in the aggregate, but to each individually, as if his object had been to ſow diſſention and miſtruſt between the allies. When he made theſe propoſals, he did not even know whether the people of France would accept of the conſtitution which he had offered them; and he had taken no meaſures to procure a repeal of thoſe revolutionizing decrees which were the immediate cauſe of the war with England.

396 Difficulty of his ſituation.

His ſituation is, in the mean time, attended with great difficulties. The want both of an hereditary title, and of a national repreſentation as the baſis of his power, renders his character as an uſurper ſo obvious, that it is only by very cautious meaſures that his elevation can be maintained. If he is either unſucceſsful abroad, or compelled to preſs the people for money at home, there is little doubt that his fall muſt follow. Even independent of either of theſe events, it is a poſſible caſe that the violent Jacobins may recover their loſt energy, and by force or fraud deſtroy the man who has baffled all their projects. From the royaliſts he has leſs to fear; for the men of ardent ſpirits and violent paſſions belonging to that party, from whom alone great efforts can ever be expected, were early tempted to leave the country by the hopes held out to them by the coaleſced powers, which, by weakening, has hitherto prevented their party from becoming of much importance in the interior of France.

French Revolution 1800.

1800.

In the mean time, Bonaparte has been ſucceſsful in ſuppreſſing a new royaliſt revolt which had ariſen in La Vendee, and has made great exertions to begin the campaign with vigour. The low ſtate of the French finances, however, have much enfeebled all his efforts towards aſſembling very numerous armies. The army which he left in Egypt, after concluding a treaty with the Grand Vizier, by the terms of which they were to be landed ſafe in France, have ſeen reaſon to break the truce which had been agreed on. Kleber has attacked and completely defeated the main body of the Turkiſh army, while a detachment of that army has entered Cairo, and maſſacred, it is ſaid, every Frenchman found in the city, not ſparing the members of the National Inſtitute. The probable conſequence of this is, that no part of the army of Egypt will ever return to Europe.

397 Army of Egypt.

398 Recommencemer of war in Europe.

War has been recommenced between the Auſtrians and France, both in Switzerland and in Swabia, and carried on with great vigour. Maſſena, after giving complete proofs of conſummate ſkill, and the moſt undaunted valour, has been for ſome time blocked up in Genoa; and unleſs he has been relieved by the vigorous exertions of the Chief Conſul, he muſt before this period (June the 12th) have ſurrendered to the Auſtrian General Melas. The affairs of the French in that quarter ſeem indeed to be deſperate; but in Germany they have hitherto been ſucceſsful. Moreau has diſplayed his wonted abilities, and the gallant Kray has retreated before him, whether from neceſſity or to draw him into inextricable difficulties, a very ſhort time will evince.

* * *

399 Abrupt conclufior of this na rative.

But here we muſt interrupt this detail, without the fainteſt proſpect of bringing it to a concluſion during the publication of the preſent Work. We cannot, however, diſmiſs the momentous ſubject without correcting ſome errors into which we fell in the account of the riſe and progreſs of this revolution which was publiſhed in the *Encyclopædia*. We do not conſider theſe errors as diſgraceful to ourſelves; for in the midſt of commotions which have convulſed all Europe, it is hardly poſſible to arrive at the truth. When time ſhall have cooled the paſſions of men, and annihilated the parties which now divide the nation, the calm voice of Truth may be everywhere heard; but when the article referred to was written, the ears of every man was ſtunned with the clamour of faction.

400 Errors in the form part of th article co rected.

So ſenſible of this are the editors of the only impartial periodical hiſtory * which we have, that they venture not to publiſh their volumes till ſeveral years have elapſed from the era of the tranſactions which theſe volumes record; whilſt their rivals—the panders of faction—ſeize the earlieſt opportunities of obtruding their partial ſtatements and falſe reaſonings on the public mind.

It cannot be ſuppoſed that one or two men, ſuperintending the publication of a work ſo extenſive, and treating of ſubjects ſo various, as ours, have leiſure or opportunity to examine with much attention the correſpondence of ambaſſadors, or to expiſcate truth from the contradictory publications of the day. We are therefore

---

* *Old A nual Reg ſter.*

French Revolution.

therefore obliged to draw our materials from ſuch works as profeſs to give a ſummary, but impartial, detail of what is acting on the theatre of the world; and by theſe works we have often been miſled. For the firſt error, however, which we ſhall notice in our former account of the riſe of the revolution, we cannot plead even this excuſe. We ought to have known, that the French clergy and French nobleſſe were not exempted from the payment of taxes; and, of courſe, we ought not to have aſſigned ſuch exemption as one of the cauſes of the REVOLUTION. See that article, *Encycl.* n° 8. and 9.

401 First error.

By a writer, to whoſe patriotic exertions this country is deeply indebted, it has been proved, with a force of argument which precludes all poſſibility of reply, that the exemption from taxes ſo loudly complained of was very trifling, that it was not confined to the nobility and clergy, and that it did not extend over the whole kingdom of France. "The *vingtiemes*, which may be conſidered as an impoſt merely territorial, was paid alike by the nobility and the *tiers-etat*. A great part of the clergy was indeed exempted; but their contributions, under a different form, conſtituted an ample equivalent. The duties upon the different articles of conſumption were of courſe paid by all the conſumers, except that in the *pays d'etat*, ſuch as Artois and Brittany; the two firſt orders were exempted from paying the tax upon liquors. But theſe exemptions cannot be deemed very important, when it is known, that in the province of Artois they did not exceed 800 guineas annually, even including the exemptions enjoyed by the privileged members of the *tiers-etat*." The Britiſh officers ſerving on board ſhips of war are exempted from the taxes paid by the other members of the ſtate on wine; and we believe no good ſubject has ever murmured at that exemption. The French nobility were ſubject to the pole-tax.

"Of the *teilles*, the impoſt from which it has been falſely aſſerted that the nobility and clergy enjoyed a total exemption, there were two ſpecies; the one *perſonal*, the other *real*. In one part of the kingdom, the right of exemption was annexed to the property; in the other, to the quality of the proprietor. In the firſt caſe, the privilege was enjoyed by every claſs of perſons, by the tenants as well as the proprietor of a fief; whilſt the gentleman, whoſe eſtate was holden by a different tenure, was obliged to pay the tax. In thoſe provinces where the other cuſtom obtained, the exemption was confined to a certain extent of property, and to *that* only while it continued in the actual occupation of the privileged perſon; but as it very ſeldom happened that the French nobility kept any land in their own hands, and as the tax payable by the farmers was of courſe deducted from the rent, the *teilles* was, in this caſe, ultimately paid by the landlord. The ſame obſervations apply, with ſtill greater force, to the clergy, who always let their eſtates."

In a word, it appears from a formal declaration made by M. Necker to the Conſtituent Aſſembly, that all the pecuniary exemptions enjoyed by the privileged claſſes did not exceed L.292,000; that the exemptions appertaining to the privileged perſons of the *tiers-etat* amounted to one half of that ſum; and the *drôits de controle*, or duty impoſed upon public deeds, and the high capitation tax (proportioned to their rank), paid by the nobility and clergy, made ample amends to the revenue for the partial exemptions which they enjoyed from other taxes. So far indeed were the *tiers-etat* from murmuring at the exemptions of the privileged orders, that, previous to the illuminiſm of the 18th century, they diſplayed, at every convention of the ſtates-general, the greateſt anxiety to maintain the rights of the nobility and clergy; and humbly ſupplicated their ſovereign to ſuffer no invaſion thereof, but to reſpect their franchiſes and immunities *.

402 Second error.

We muſt likewiſe acknowledge, that in n° 11. of our article REVOLUTION, we have drawn a very overcharged picture of the miſeries and oppreſſion of the French peaſants under the old government. It is indeed true, that they were obliged to ſerve in the militia, the eſtabliſhment of which was conducted in France nearly on the ſame principles as it is in England. The men were called out by ballot only for a few days in the year during peace, when they received regular pay; but if a militia forms the beſt conſtitutional defence of a ſtate, this ſurely ought not to have been conſidered as a grievance, eſpecially ſince married men were exempted from the ſervice. The nobility, too, were exempted from the riſk of being drawn, for the beſt of all reaſons—becauſe moſt of them had commiſſions in the regulars, and becauſe ſuch as had not were engaged in profeſſions, which rendered it impoſſible for them to ſerve in the militia. In France, as elſewhere, the peaſants would no doubt be averſe from this ſervice, and might look perhaps with an anxious eye to the ſuppoſed immunities of their privileged ſuperiors: but if mirth, good humour, and ſocial eaſe, may be conſidered as ſymptoms of felicity and content, theſe men ſurely were not miſerable; for theſe ſymptoms never appeared in any people ſo ſtrong as among the French peaſants. They were indeed liable to be called out by the intendants of the provinces to work a certain number of days every year on the public roads; but to this ſpecies of oppreſſion, if ſuch it muſt be called, the Scotch peaſants are liable, and were ſtill more ſo than at preſent, during that period when our parliamentary orators declare that the inhabitants of Britain enjoyed as much freedom as is conſiſtent with the public tranquillity. It ought to be remembered, too, that Louis XVI. whoſe higheſt gratification ſeems to have conſiſted in contributing to the eaſe and welfare of his ſubjects, thought he ſaw the neceſſity of aboliſhing the cuſtom of the *corvée*, and had made conſiderable advances towards the accompliſhment of that object ſome years before the commencement of the revolution.

403 The French monarch not deſpotic.

That the French monarch was deſpotic; that no man in the kingdom was ſafe; that nothing was unknown to the jealous inquiſition of the police; and that every man was liable, when he leaſt expected it, to be ſeized by *lettres de cachet*, and ſhut up in the gloomy chambers of the Baſtile—has long been common language in England, and language which we muſt confeſs that we have adopted (REVOLUTION, n° 12.) without due limitations. The French government was certainly not ſo free as that of Britain; but he who underſtood it better than we do, and whoſe writings betray no attachment to arbitrary power, expreſsly diſtinguiſhes between it and *deſpotiſm*. "If (ſays Monteſquieu) France has, for two or three centuries paſt, inceſſantly augmented her power, ſuch augmentation muſt not be aſcribed to fortune, *but to the excellence of her laws* †." This,

---

* See *Gifford's Letter to the Earl of Lauderdale*, 2d ed.

† *De l'Eſprit des Loix*, liv. 20. c. 20.

This, ſurely, is not the language of a man who thought himſelf governed by an arbitrary tyrant whoſe *caprice* is the law; nor will it be ſaid to be the language of one who was either afraid to ſpeak the truth or not maſter of his ſubject.

404 No change of the old conſtitution wiſhed by the people of France.

The inſtructions of all the different orders to their repreſentatives, before the fatal meeting of the States General under the unfortunate Louis, are drawn up in language ſimilar to that of this illuſtrious magiſtrate, and furniſh a complete proof that they knew themſelves to be ſafe under the government of their monarchs. "The conſtitution of the ſtate (ſay the clergy) reſults from the *fundamental laws*, by which the reſpective *rights* of the *king* and of the *nation are aſcertained*, and from which not the ſmalleſt deviation can be made. The firſt of theſe laws is, that the government of France is purely monarchical. The nation muſt preſerve inviolate the form of its government, which it acknowledges to be a *pure monarchy regulated by the laws*; and ſuch it will have it to remain."

On the 28th of November 1788, in a general committee of the nobles aſſembled at Verſailles, the Prince of Conti delivered a note to the preſident, which was ſanctioned by the concurrence of moſt of the other princes of the blood, and was ſuppoſed to ſpeak the general ſenſe of the nobility; in which it was inſiſted, that the *proſcription of all* NEW SYSTEMS *was neceſſary* to inſure the ſtability of the throne, of *the laws*, and of *order*; and that the conſtitution, *with the ancient forms*, ſhould be preſerved entire. In their inſtructions to their repreſentatives, they inſiſt that it ſhall be expreſsly and ſolemnly proclaimed, that the conſtitution of the French empire is ſuch, that its government is, and muſt remain, monarchical; that the king, as ſupreme chief of the French, is only ſubordinate to the fundamental law of the kingdom, according to which the conſtitution muſt be eſtabliſhed on the ſacred and immutable principles of monarchy, tempered by the laws; and this form of government cannot be replaced by any other conſtitution.

"Let our deputies (ſays the third eſtate), before they attend to any other object, aſſiſt in giving to France a truly monarchical conſtitution, which muſt invariably fix the *rights* of the *king* and of the *nation*. Let it be declared, that the monarchical is the only form of government admiſſible in France; and that in the *king alone*, as chief of the nation, is veſted the power of *governing according to the laws*." Is this the language of men groaning under the iron rod of deſpotiſm, or wiſhing to reduce the power of the crown?

Even after the power of the crown was almoſt annihilated, and the order of nobility done away, ſo far were theſe innovations from being acceptable to the enlightened part of the French nation, that in many departments of the kingdom they excited open inſurrections, whilſt the members of all the provincial parliaments oppoſed them with unanſwerable arguments furniſhed by the law. The chamber of vacation of the parliament of Toulouſe, in particular, proteſted againſt the proceedings of the States General, becauſe the deputies, who were empowered only to put an end to the ruinous ſtate of the finances, could not change the conſtitution of the ſtate without violating their inſtructions, and the faith ſworn to their conſtituents *.

405 Lettres de cachet.

That *lettres de cachet* were liable to abuſe, and that occaſionally they were groſsly abuſed, is certain. The uſe of them ought therefore to have been either annulled, or, which would have been infinitely better, ſubjected to ſuch rules as ſhould prevent all danger from them to the real liberties of the people; for the government would be of no uſe whatever which ſhould poſſeſs no power capable of being abuſed by deſpotiſm. Yet after all the noiſe that has been made about *lettres de cachet*, it is but juſtice to obſerve, that in the towers of the Baſtile, when it was taken by the mob, were found no more than ſeven priſoners; of whom four were confined for forgery; one was confined at the requeſt of his family on charges of the moſt ſerious nature; and two were ſo deranged that they were ſent next day, by thoſe philanthropiſts who had taken them out of comfortable chambers, to the mad houſe! That the chambers of the Baſtile were as comfortable as the chambers of a priſon could be, we are aſſured by M. Bertrand de Moleville, who can be under no inducement to deceive the Britiſh public, and whoſe opportunities of diſcovering the truth were ſuch as no man will call in queſtion.

406 Blunder of Necker.

In our account of the opening of the States General, we have expreſſed too much deference to the character of M. Necker. To that man's irreſolute, if not treacherous, conduct, may, with truth, be attributed all the ſubſequent miſeries of France. It was about the mode of verifying their powers that the three orders of the ſtate firſt differed; but that mode ſhould have been defined by the miniſtry in the letters ſent to the different bailliwicks for the convention of the ſtates. Even this omiſſion might have been repaired after the arrival of the deputies at Verſailles; for none of them ſhould have been admitted into the hall of the ſtates, far leſs ſhould the king have met them there, till the Council had been ſatisfied of their being duly elected. Had either of theſe cautions been obſerved, the *tiers-etat* never could have got the aſcendant over the other two orders, and the buſineſs of the nation would have been conducted as formerly in three different chambers. M. Necker's rejection of Mirabeau's advances ſhewed him to be very ill qualified to conduct the helm of affairs at ſuch a criſis; and his abſenting himſelf from the royal ſeſſion, a meaſure which he had adviſed, betrayed the utmoſt ingratitude to his gracious maſter.

407 Royal Seſſion.

In our account of the royal ſeſſion, we were led into a miſtake, which calls loudly for correction. The circumſtances of that ſeſſion were very different from what they appeared to us when we wrote nº 24. and 25. of the article REVOLUTION. The royal ſeſſion was proclaimed in conſequence of the violent uſurpations of the *tiers-etat*, and the irreconcileable differences which ſubſiſted between that body and the two higher orders; and ſo far is it from being true that the preſident and members of the third eſtate found their hall *unexpectedly* ſurrounded by a detachment of guards, that their ſittings were only *ſuſpended*, for the beſt of all reaſons, with thoſe of the other orders. To be convinced of this, we need but to attend to the following proclamation which was made by the heralds, on the 20th of June, between ſeven and eight o'clock in the morning, in the ſtreets and croſs-ways of Verſailles:

"June 20th. (By order of the King.) The King having reſolved to hold a royal ſitting in the States General, on Monday next the 22d of June, the preparations to be made in the three halls uſed by the aſſemblies

---

* See the proteſt at large in *Bertrand's Memoirs*, vol. iii. c. 13.

F nch Re ution. blies of the orders, make it neceſſary that thoſe aſſemblies ſhould be ſuſpended until after the ſaid ſitting. His Majeſty will give notice, by another proclamation, of the hour of his going to the Aſſembly of the States on Monday."

M. Bailly, the preſident of the *tiers-etat*, had been made acquainted with the object of this proclamation, by a private letter which was ſent to him by the Marquis de Brezé at ſeven o'clock in the morning; and to which he replied, "that having received no orders from the King, and the aſſembly having been announced for eight o'clock, he ſhould attend where his duty called him."

He repaired, accompanied by a great number of the members of the *tiers-etat*, to the door of the hall of the States, demanded admiſſion; and on being refuſed by the officer on guard, according to his orders, with which he acquainted him, he declared that he proteſted againſt ſuch orders, and that he ſhould give a report of them to the Aſſembly. To do this he had not far to go, as three fourths of the deputies of the *tiers-etat* were already collected round him, or in the avenue leading to the palace. There it was that, ſurrounded by an immenſe crowd of people, they declaimed in the moſt violent manner againſt this pretended act of deſpotiſm. "The National Aſſembly is to be diſſolved (ſaid they), and the country to be plunged into the horrors of a civil war. *Want* reigns every where; every where the people ſee *famine* ſtaring them in the face. This we were about to put an *end to*, by rending the veil which covers the manœuvres of the monopoliſts, the engroſſers, and the whole tribe of miſcreants. The Louiſes XI. and XIII. the Richelieus, the Mazarins, the Briennes, attacked with their deſpotiſm only individuals or ſmall bodies; but here it is the whole nation that is made the ſport of the whims of a deſpotic miniſtry. "Let us meet upon the *Place d'Armes* (ſaid one of thoſe orators); there we ſhall recal ſome of the nobleſt days of our hiſtory, *the National Aſſemblies of the field of May*." "Let us aſſemble in the gallery of the palace (ſaid another); there we ſhall preſent a new ſight, by ſpeaking the language of liberty, in that corrupt hall, where a little while ſince the head of him who ſhould have uttered that ſacred word would have been devoted to the executioner.—"No, no (ſaid a third), let us go to Marli, and hold our ſitting on the Terrace:—let the King hear us; he will come from his palace, and will have nothing more to do than to place himſelf in the midſt of his people to hold the royal ſitting."

408 F ious i lence of t aſſem- b

At the concluſion of theſe declamations, the ſole object of which was to alarm and exaſperate the people, the Aſſembly decided upon transferring their ſitting to the Tennis-court, in the ſtreet called *Rue du Vieux Verſailles*. There M. Bailly read the letter which he had received from M. de Brezé, and his anſwer to it; which he had ſcarcely done, when a ſecond letter from M. de Brezé was put into his hands, the contents of which were as follows:

"It was by the King's poſitive order, Sir, that I did myſelf the honour of writing to you this morning, to acquaint you that, his Majeſty purpoſing to hold a royal ſitting on Monday, and ſome preparations being requiſite in the three halls of the Aſſemblies of the orders, it was his intention that no perſon ſhould be admitted into them, and that the ſittings ſhould be ſuſpended till after that to be held by his Majeſty." French Revolution.

In this there was ſurely no marked diſreſpect to the repreſentatives of the people; but ſuch notions were countenanced by M. Necker, who appears indeed, on this occaſion, to have been in cloſe compact with the leaders of the mob. The popular violence that was employed to compel the majority of the clergy to join the *tiers-etat* is well known; and we have, in *Bertrand's Annals of the Revolution*, what amounts to evidence almoſt *legal*, and quite ſufficient to enforce conviction, that Necker directed that violence.

In our account of the commotions which were excited in Paris on the firſt diſmiſſion of that miniſter and his baniſhment from the kingdom, we have been led by our democratic journaliſts to give circulation to a groſs calumny publiſhed by them againſt the Prince de Lambeſc. (See REVOLUTION, n° 36. and 37.) The truth, which is ſo much diſguiſed in theſe two numbers, is as follows:

409 Conduct of the Prince de Lambeſc vindicated.

"A detachment of the Royal Allemand, ſent to diſperſe the mob which was patroling the ſtreets in proceſſion with the buſts of Necker and the infamous Orleans, received a volley from the French guards as they were paſſing their quarters on the *Chauſſee d'Antin*, ſtopped to return it, and continued their march without quickening their pace. There were ſome ſoldiers killed and wounded on both ſides, but fewer of the regiment of Royal Allemand than on that of the French guards.

"The detachment marched to the Place Louis XV. and there found a body of dragoons who had been diſperſing the proceſſion. The two buſts were broken to pieces; and the populace in their fright taking refuge in the garden of the Thuilleries, the Prince de Lambeſc purſued them thither, at the head of the detachment of Royal Allemand, according to the orders which he received. This ſmall troop coming up to the head of the *Pont-tournant* (or turning bridge), at the extremity of the garden, found a kind of barricade, haſtily formed by chairs heaped upon one another: while they were removing this obſtacle, they received a ſhower of ſtones, broken chairs, and bottles, from the two terraces, between which the Prince de Lambeſc drew up his troop, keeping conſtantly at their head. Some guns and piſtols were diſcharged at them, which did no hurt; but ſeveral of the troopers were much bruiſed by the things that had been thrown at them, and an officer was ſeverely wounded by a ſtone.

"The Prince de Lambeſc, keeping at ſix paces from the bridge, oppoſed only a ſteady front to the aggreſſions of the populace. Seeing that this poſt became untenable, and that it was impoſſible for him any longer to reſtrain his troopers from repelling force by force, he gave the order for retreating out of the garden. At the ſame inſtant a cry was heard from all ſides of, *turn the bridge, turn the bridge;* and ſome perſons, in conſequence, ran and began to do it. The Prince de Lambeſc, juſtly fearing that a moſt bloody carnage would be the inevitable conſequence of it, ordered ſome piſtols to be fired in the air towards the bridge, to awe thoſe who were ſtriving to turn it. As the report of this volley did not deter them, he rode up himſelf, and with his ſabre ſtruck one of thoſe who were working hardeſt. The man ran off; and the Prince paſſing the bridge with

with his detachment into the Place Louis XV. drew up near the Statue, and being ſoon joined by the Swiſs regiment of Chateauvieux, took his poſt with this force near the *Garde-meuble*, where he remained ſome time, having placed the infantry before him. At ten at night part of the troops were diſmiſſed to their quarters, and the reſt ſent to Verſailles." Theſe facts being all judicially confirmed, prove how much the Prince de Lambeſc's conduct was calumniated by thoſe journaliſts whoſe detail we raſhly adopted.

410 True account of the taking of the Baſtile;

In our account of the taking of the Baſtile, miſled by our treacherous guides, the journaliſts, we have greatly magnified the military ſkill and proweſs of the aſſailants. That celebrated fortreſs was defended by a garriſon conſiſting of no more than 114 men, of whom 82 were invalids. It was attacked by 30,000 men and women, armed with muſkets and pikes, and furniſhed with a train of artillery which they had found at the *Hotel des Invalids*, given up to them by the timidity of the governor. Even this multitude would have been quickly repulſed from the Baſtile, if the governor of that ſtate-priſon, who had received no orders from the court, had been leſs reluctant to ſhed the blood of his rebellious countrymen; for the Pariſian mob had then diſplayed nothing of determined courage. A few diſcharges of muſquetry, and one of caniſter-ſhot from a ſingle cannon, had thrown them into confuſion, and made them ſkulk behind the walls, when the ill-timed humanity of the governor made him enter into a treaty with the rebels, ſtipulating only that the garriſon ſhould not be maſſacred. How the ſtipulation was obſerved with reſpect to the governor himſelf, we have faithfully related; but we were miſtaken when we ſaid that the "French guards ſucceeded in procuring the ſafety of the garriſon." The guards, with the utmoſt difficulty, ſaved indeed ſome of them, but moſt of the invalids remaining in the courts of the caſtle were put to death in the moſt mercileſs manner.

411 And of the murder of M. de Fleſſelles.

Our account of the murder of M. de Fleſſelles (n° 40.) appears likewiſe to be very incorrect. This man was preſident of the Aſſembly of Electors at Paris (See REVOLUTION, n° 45.), and had not quitted the *Hotel de Ville*, where their rebellious meetings were held, during the whole time of theſe dreadful commotions. He had even ſigned all their atrocious reſolutions, but became ſuddenly ſuſpected from the conſternation which he manifeſted at the ſight of ſo many horrors, and eſpecially at the cruel and treacherous murder of the governor of the Baſtile. The conſequence was, that he was treacherouſly murdered himſelf by one of the villains compoſing that aſſembly in which he preſided. "The electors (ſays M. Bertrand de Molleville) hoped to extenuate the horror of this aſſaſſination, by cauſing it to be conſidered as a natural and almoſt lawful vengeance for a treachery, the proof of which they pretended to have. In fact, they declared, that when M. de Launay, the governor of the Baſtile, was arreſted, a letter had been found in his pocket from M. de Fleſſelles, containing this expreſſion: 'I am amuſing the Pariſians with cockades and promiſes; hold out till night, and you will receive a reinforcement.' But this ſuppoſed letter, which, had it exiſted, they would not have failed to preſerve very carefully, was never ſeen by any body; and I heard M. Bailly himſelf ſay, in a viſit he paid me when he left the mayoralty, that he had no knowledge of it, and that it was not in his power to refer to any one who had told him that he had read it."

412 Ambition and cowardice of the Duke of Orleans.

In our account of the earlier tranſactions of the Revolution, we omitted to mention a very extraordinary inſtance of ambition to which the Duke of Orleans was incited by Count Mirabeau, but which that unnatural monſter wanted courage to carry into effect. During the commotions which prevailed in the capital on the diſmiſſal of M. Necker from the miniſtry, Orleans was perſuaded by Mirabeau to offer his ſervices as mediator between the king and his rebellious ſubjects; but to ſtipulate, at the ſane time, for his appointment to the high office of lieutenant-general of the kingdom as neceſſary to give his mediation due weight with the rebels. The real object of the profligate Count, in this dangerous propoſal, and which he did not deign even to conceal, was to pave the way for the infamous Duke ſtepping into the throne of his relation and virtuous ſovereign. He even went ſo far as to compoſe the ſpeech with which Orleans was to addreſs the king on the occaſion; but that coward, when he arrived at the palace, was ſo embarraſſed by the conſciouſneſs of his own wicked deſigns, that inſtead of aſking the office of lieutenant general, he only requeſted permiſſion to retire into England!! A requeſt which was inſtantly granted.

This brought upon him the contempt and indignation of Mirabeau; but ſtill there was a party deſirous of placing him on the throne. This we think evident from an atrocious fact mentioned in all the journals, and confirmed by M. Bertrand. "When the king, on his firſt viſit to Paris (See n° 44.) had arrived at the *Champ Eliſées*, three or four guns were fired at once. It was never known whence they proceeded; but it is certain that an unfortunate woman in the crowd, who was in the direction of his Majeſty's carriage, was ſhot at the time, and fell dead on the ſpot." As the King's carriage held at the time exactly four perſons, M. Bertrand very naturally concludes that theſe four ſhots, fired at once in its direction, had been ordered and paid for; and we are unwilling to believe that at that period of the revolution there was any party diſpoſed to *pay* for the murder of the ſovereign but the Duke of Orleans and his infamous adherents. That he was equal to this wickedneſs cannot be doubted, when it is known that legal evidence was afterwards produced that he, with ſome other members of the Aſſembly, ſecretly directed the inſurrection of the 5th of October, and promoted the outrages of that and the ſucceeding day by the diſtribution of money and bread *.

413 M. Memmay vindicated.

We have ſaid (n° 48.), the origin of the report of a train of gunpowder being laid by M. de Memmay, to blow into the air a number of patriots, has never been well explained. It was proved judicially, that at the period when the feaſt was given by M. Memmay to the inhabitants of Veſoul, he was ſetting vines in a ſtony ſoil, where he was often obliged to blow up the greater rocks. Some ſoldiers running through, and ferreting every where in the houſe and out-houſes, unfortunately took a candle to the dark corner where the barrel of gunpowder was lodged, and ſet it on fire, in trying to ſee if it contained wine. Theſe facts, reported and atteſted in a memorial drawn up by M. Courvoiſier, ſo completely juſtified M. de Memmay, that the Aſſem-

F..ch Rev..tion.

bly could not avoid teſtifying his innocence by a decree iſſued the 4th of June.

414 The ..wers of t.. aſ-ſem.. in dan.. of bein.. re-call by its ..ſti-tue..

In n° 70. we have ſaid that the National Aſſembly, after its removal from Verſailles to Paris, was in tolerable ſecurity; but M. Bertrand has proved, by evidence the moſt incontrovertible, that it did not think itſelf ſecure; and that if the miniſters had been capable of employing events to their own advantage, the powers of that factious body muſt have been recalled by its own conſtituents. The horrible outrages committed on the 5th and 6th of October had ſhocked all France. The wanton confiſcation of the property of the church, had demonſtrated to every man of ſound judgment, that under the new order of things no property could be ſecure; and by the deſertion of its more virtuous and moderate members, the Aſſembly had become *a rump aſſembly*. It was therefore much alarmed when the intermediate commiſſion of the ſtates of Cambreſis entered, on the 9th of November, into a reſolution, in which, conſidering—"that certain decrees of the National Aſſembly are paving the way for the ruin of the kingdom, and the annihilation of religion; that if they have been able to place one ſpecies of property at the diſpoſal of the nation, men of all kinds of property may expect the ſame fate; they declare, from this moment, the power of the deputies of Cambreſis to the National Aſſembly to be null and revoked." Had M. Necker and his colleagues had addreſs to get ſimilar reſolutions entered into at the ſame time by the electors of all the bailiwicks of the kingdom, the Aſſembly muſt have been diſſolved, and France, even then, might have been ſaved; but thoſe miniſters were themſelves nothing more than the humble and docile agents of the Aſſembly.

415 T.. ac-co.. of the re.. book,

There is no part of our former narrative more incorrect, or more likely to miſlead the public, than our account of the *red-book* (n° 75.). It is ſuch, however, as was then current, without any addition or aggravation by us. The villains (K) who, in direct contradiction to their own ſolemn promiſe, as well as to every principle of honour, made part of that book public, had the impudence to affirm, that, by the ſuppreſſion of the ſuperfluous penſions regiſtered in it, a ſaving would be made to the public *of near a fifth in the bulk of the expences of every year*. M. Bertrand, taking for granted the accuracy of their ſtatements, for the exaggeration of which, however, he urges arguments more than plauſible, proves, if arithmetical calculation affords proof, that by the ſuppreſſion of ſuch penſions as even *they* called ſuperfluous, the ſaving in the bulk of the annual expences could not poſſibly have amounted to more than *the two hundredth part!* It was not therefore without reaſon that M. Necker, in anſwer to their publication, ſaid, "I know not whether the books of the finances of any ſovereign in Europe can ſhew a ſimilar total."

416 .. of the ..iny at N..cy.

Our account of the mutiny of the ſoldiers at Nancy (n° 83.) is very inaccurate. Far from being excited by the officers, that mutiny was the natural conſequence of the abſurd decrees of the Aſſembly; which having declared *all men equal*, and made it criminal to puniſh diſobedient ſoldiers in that ſummary way, without which no armed force can be commanded, had completely diſorganiſed the army, and ſubſtituted for martial law patriotic exhortations, legiſlative decrees, and the novel juriſdiction of municipalities. The ſoldiers knew their own ſtrength, of which indeed they were continually informed by the friends of the revolution; and while they ſhook off the authority of their military commanders, they laughed at the impotent decrees of the Aſſembly. At Nancy they had impriſoned two general officers, and committed other outrages of the moſt ſerious nature. It was the duty of the Marquis de Bouillé, as governor of the province, to reduce the inſurgents by force, if force ſhould be found neceſſary; but he had accompliſhed his object without ſhedding blood, and was congratulating the two liberated generals, and ſome of the principal inhabitants, upon ſo happy a termination of the affair, when the populace, and many ſoldiers who had not followed their colours, fired upon the troops under his command, and killed fifty or ſixty men. The troops immediately returned the fire; and a great number of the rebellious mob and mutinous garriſon were of courſe put to the ſword. That ſuch able and firm conduct in Bouillé excited indignation among the Jacobins of Paris, is very probable; but even the king himſelf did not expreſs higher approbation of it than the National Aſſembly, who were duly ſenſible that it ſaved themſelves from deſtruction, which, had he failed in his enterpriſe, would have been inevitable. Three months afterwards, indeed, when the fabrication of counter-revolutionary plots became part of the daily buſineſs of this enlightened Aſſembly, ſome cenſures were thrown by the Jacobins upon the Marquis's conduct on this occaſion; and thoſe cenſures were loudly applauded.

French Revolution.

417 M. de Bouillé vindicated.

We have likewiſe been led, by our fallacious guides, to accuſe this gallant officer (n° 91.) of having laid open the country to the inroads of foreign armies; and we have given an incorrect account of the king's flight from Paris. There is no evidence whatever for the truth of the charge againſt the Marquis de Bouillé, and it is directly contrary to his general character. He was indeed a royaliſt, and would doubtleſs have cooperated with the Prince of Condé and the other emigrants in reſtoring the king to his lawful authority; but he was likewiſe a Frenchman and a patriot in the beſt ſenſe of the word; and he would have died in defence of the rights and independence of his country. He certainly meant to protect the king in his journey from Paris to Montmedi, where it was to terminate; and he had ſtationed troops of dragoons on the road for that purpoſe; but the unfortunate Louis had delayed his journey a day longer than was agreed upon; and even when he ſet out, neglected to ſend couriers before him to warn the troops of his approach. He thus travelled unprotected; and the conſequence was ſuch as we have related. Yet the gallant Bouillé, tho' this journey was undertaken contrary to his advice, declared himſelf the author of it, in that letter in which he threatened the Aſſembly with vengeance of all Eu-

rope

(K) Theſe were the Marquis de Montcalm-Gozon, Baron Felix de Wimpfen, de Menou, Freteau, L. M. de Lepeaux, the Abbé Expilly, Camus, Goupil de Prefeln, Gautier de Biauzat, Treilhard, Champeaux-Palaſuc, and Cottin.

rope if they ſhould dare to touch a hair of the heads of the royal family.

418 Erroneous account in n° 90. corrected.

In n° 90. we have moſt unaccountably ſaid that the king was permitted to continue his journey to St Cloud. This is directly contrary to truth. The preſident, after hearing his complaint againſt thoſe who had prevented it, replied indeed in a ſpeech, containing ſome expreſſions of gratitude and affection, mixed with reflections on the refractory prieſts; but the Aſſembly determined nothing reſpecting the propriety of the journey. They did not even ſuffer a ſingle motion to be made on the ſubject; and threatened with impriſonment one of the members who propoſed to take it into conſideration! The king was therefore obliged to abandon this excurſion, though it was firſt undertaken from religious motives; and it was then that he ſeriouſly thought of attempting to elude the vigilance of his rebellious guards, and of taking up his reſidence at Montmedi.

419 Treaty of Pavia a forgery.

In n° 96. we have publiſhed, with doubts indeed of its authenticity, what was called the *treaty of Pavia* and the *convention at Pilnitz*. The terms in which we introduced that ſcandalous fabrication to the notice of our readers, and the principles which we have uniformly avowed through the whole of this voluminous work, furniſh, we hope, ſufficient evidence that we could have no intention to deceive the public. Truth, however, demands of us to acknowledge, in the moſt explicit terms, that the pretended treaty of Pavia is not only a forgery, but a bungling forgery, defective in ſome of the moſt uſual diplomatic forms; and that the conferences at Pilnitz between the Emperor, the King of Pruſſia, and the Count d'Artois, related to objects very different from a partition of the French territories.

So early as the month of May 1791, a plan had been digeſted by the Emperor, the King of Pruſſia, and the King of Spain, with the concurrence of Louis XVI. for liberating that unfortunate monarch from the confinement in which he was kept in his own capital. The means to be employed were a coalition among the principal powers on the continent to lead armies in every quarter to the borders of France. During the alarm which ſo menacing an appearance could not but excite in that kingdom, a declaration by the houſe of Bourbon, complaining of the cruel and iniquitous treatment of its head, was to be circulated through France, and to be immediately followed by the manifeſto of the combined powers. This, it was preſumed, would furniſh a ſufficient reaſon, even to the National Aſſembly, for the king's going to the frontiers, and placing himſelf at the head of the army; but if it ſhould not, petitions were to be procured from the army and the provinces, requeſting his preſence, as the only means left of preventing a civil as well as foreign war. Had this meaſure, which was partly ſuggeſted by Mirabeau and partly by Montmorin and Calonne, been ſteadily purſued, there can be little doubt but it would have proved completely ſucceſsful. It was defeated, however, by the king's ill-concerted attempt to eſcape to Montmedi, and by a very imprudent and degrading letter which he was afterwards perſuaded to ſend to every foreign power.

420 Real convention at Pilnitz.

At Pilnitz, where the Emperor and the King of Pruſſia met, on the 25th of Auguſt, to ſettle between themſelves ſome intereſts too delicate to be adjuſted by the uſual diplomatic modes, an agreement was entered into by them to ſupport the cauſe of the French princes, to liberate the king, and to ſave, if poſſible, the monarchy. They delivered, accordingly, to the Count d'Artois the following declaration:

" His Majeſty the Emperor, and his Majeſty the King of Pruſſia, having heard the deſires and the repreſentations of Monſieur and his Royal Highneſs the Count d'Artois, declare, conjointly, that they conſider the ſituation in which his Majeſty the King of France is at preſent placed, as a matter which concerns the intereſt of every ſovereign of Europe.—They hope that that intereſt will not fail to be acknowledged by the powers whoſe aſſiſtance is required; and that conſequently they will not refuſe to employ, in conjunction with their Majeſties, the moſt efficacious means, according to their abilities, to put the King of France in a ſituation to eſtabliſh, in perfect liberty, the foundations of a monarchical government, equally agreeable to the rights of ſovereigns and the welfare of the French; then, and in that caſe, their Majeſties are determined to act promptly and by mutual conſent, with the forces neceſſary to obtain the end propoſed by all of them. In the mean time they will give orders for their troops to be ready for actual ſervice.

" *Pilnitz, Auguſt 27th*, 1791.

" Signed by the Emperor and the King of Pruſſia."

Such was the agreement entered into at Pilnitz, which was ſo groſsly miſrepreſented by the French Jacobins, and by their zealous partizans in this country. Had not Louis XVI. accepted the conſtitution ſimply and unconditionally, the conſequence of this convention might have been the ſaving of the French monarchy, and the preſervation of peace in Europe; but that acceptance, ſo little looked for by the high contracting powers, completely thwarted their meaſures for a time; and before their armies were put in motion, the monarchy was overturned, and the monarch a priſoner.

421 The Frenc the aggre ſors in the war with Britain.

In our account of the origin of the war between Great Britain and France (n° 147, 148.), we have proved, by evidence which to ourſelves appears irreſiſtible, that the French regicides were the aggreſſors, and that the Britiſh miniſtry did all that could be done, conſiſtently with the independence of their own country, to maintain the relations of amity between the two nations. That we have interpreted fairly that decree of the Convention by which this kingdom was forced into the war, is rendered incontrovertible by a ſubſequent decree on the 15th of December, by which their generals were ordered to regulate their conduct in the countries which their armies then occupied, or *might afterwards occupy*. In the preamble to this decree, they expreſsly declared, that *their principles would not permit them to acknowledge any of the inſtitutions militating againſt the ſovereignty of the people*; and the various articles exhibit a complete ſyſtem of demolition. They inſiſt on the immediate *ſuppreſſion of all exiſting authorities*, the *abolition of rank and privilege* of every deſcription, and the *ſuppreſſion of all exiſting impoſts*. Nay, theſe friends to freedom even declare, that they will treat as enemies *a whole nation* (un peuple entier) which ſhall preſume to *reject liberty and equality*, or enter into *a treaty with a prince or privileged caſts!*

It is worthy of remark, that *the very day* on which this decree, containing a ſyſtematic plan for diſorganizing all lawful governments, paſſed the Aſſembly, the provi-

proviſional executive council wrote to their agent, Chauvelin, inſtructing him to diſavow all hoſtile intentions on the part of France, and to proclaim her deteſtation of the idea of a war with England! Yet the ſame proviſional council, in their comments on the 11th article of this decree, thus expreſs themſelves: "The right of natural defence, the duty of ſecuring the preſervation of our liberty, and the ſucceſs of our arms, the univerſal intereſt of reſtoring to Europe a peace, *which ſhe cannot obtain but by* THE ANNIHILATION OF THE DESPOTS *and their ſatellites*, every thing impoſes on us the obligation of exerciſing all the *rigours of war*, and the *rights of conqueſt*, towards a people ſo fond of their chains, ſo obſtinately wedded to their degradation, as to refuſe to be reſtored to *their rights*, and who are the accomplices, not only *of their own deſpots*, but even of all the *crowned uſurpers*, who divide among themſelves the dominion of the earth and its inhabitants." That Britain is one of thoſe countries which the aſſembly thought their armies might afterwards occupy, and that the great majority of Britons were a people towards whom their principles obliged them to exerciſe all the rigours of war, and the rights of conqueſt, is evident from the following extract of a letter, written on the 31ſt of December 1792, by Monge, a member of the council, and miniſter of the marine to the ſea-ports. "The King and his parliament mean to make war upon us. Will the *Engliſh republicans ſuffer it?* Already theſe free men ſhew their diſcontent, and the repugnance which they have to bear arms againſt *their brothers the French*. Well! we will fly to their ſuccour. We will make a deſcent on the iſland; we will lodge there 50,000 *caps of liberty*; we will plant there *the ſacred tree*; and we will ſtretch out our arms to our REPUBLICAN BRETHREN. *The tyranny of their government will be deſtroyed.*"

As theſe two decrees of November and December 1792 have never been repealed, and as their object is ſo plainly avowed in the commentaries of the executive council, and in this letter of the miniſter of marine, they would alone ſufficiently authoriſe us to adopt as our own the following reflections of M. Bertrand de Moleville*. With theſe, as they give a conciſe but perſpicuous view of the riſe and progreſs of that revolution, or, to ſpeak more correctly, that ſeries of revolutions which has for ſeven long years oppreſſed, not France alone, but all Europe, we ſhall conclude this long article.

422 Bertrand's view of the riſe and progreſs of the revolution.

"Popular inſurrections, and an army (ſays this able and uſeful writer), have hitherto been the uſual means, or chief inſtruments, of every revolution; but thoſe inſurrections being of the moſt ignorant and unthinking claſs of the people, were always fomented by a certain number of factious men, devoted to, and dependent upon, ſome ambitious chief, daring, brave, of military talents, ſole and abſolute conductor of every ſtep of the revolt, and maſter of all the means of the inſurrection. In the hands of this chief, the ſoldiers, or people armed, were but machines, which he ſet in motion or reſtrained according to his pleaſure, and of which he always made uſe to put an end to revolutionary diſorders and crimes, as ſoon as the object of the revolution was gained. So Cæſar and Cromwell, after they had uſurped the ſupreme power, loſt no time in ſecuring it to themſelves, by placing it on the baſis of a wiſe and well-regulated government; and they employed, in quelling the troubles that had favoured their uſurpation, thoſe very legions, that ſame army, which they had uſed to excite them.

"This was not the caſe in France: there, the revolution, or rather the firſt of thoſe it experienced, and of which the others were the inevitable conſequence, was not, whatever be ſuppoſed, the reſult of a conſpiracy, or preconcerted plan, to overturn the throne, or to place an uſurper upon it. It was unexpectedly engendered by a commixture of weakneſs, ignorance, negligence, and numberleſs errors in the government. The States General, however imprudent their convocation may have been, would have produced only uſeful reforms, if they had found the limits of their power marked out by a hand ſufficiently firm to have kept them within that extent. It was, however, but too evident that, even before their opening, they were dreaded, and that conſequently they might attempt whatever they pleaſed. From that time, under the name of *Clubs*, various aſſociations and factions ſprang up; ſome more violent than others, but all tending to the ſubverſion of the exiſting government, without agreeing upon the form of that which was to be ſubſtituted: and at that juncture alſo the projects of the faction, whoſe views were to have the Duke of Orleans appointed lieutenant-general of the kingdom, began to appear.

"This faction, or more properly this conſpiracy, was indeed of the ſame nature as thoſe that had produced all former revolutions, and might have been attended with the ſame conſequences, had the Duke of Orleans been poſſeſſed of that energy of character, that bravery and daring ſpirit, requiſite in the leader of a party. The people had already declared in his favour, and he might very eaſily have corrupted and brought over a great part of the army, had he been equal to the command of it: but, on the very firſt occaſion of perſonal riſk, he diſcovered ſuch cowardice and meanneſs, that he defeated his own conſpiracy, and convinced all thoſe who had entered into it, that it was impoſſible to continue the revolution, either in his favour or in conjunction with him. The enthuſiaſm the people had felt for him ended with the efforts of thoſe who had excited it.

"Mr Necker, whom the multitude had aſſociated with him in their homage, ſtill preſerved for ſome time his adorers, and that little cabal which was for ever exalting him to the ſkies. But as he was inferior even to the Duke of Orleans in military talents and diſpoſitions, he was as little calculated to be the leader of a revolution, or of a great conſpiracy: for which reaſon his panegyriſts then confined themſelves in their pamphlets and placards, with which the capital was overrun, to inſinuating, that the only means of ſaving the ſtate was to declare Mr Necker *Dictator*; or at leaſt to confer upon him, under ſome title more conſiſtent with the monarchy, the authority and powers attached to that republican office. In fact, if after his diſmiſſion, in the month of July 1789, he had dared to make this a condition of his return to the miniſtry, it is more than probable that the king would have been under the neceſſity of agreeing to it, and perhaps of re-eſtabliſhing in his perſon the office of mayor of the palace. At that moment he might have demanded any thing: eight days later, he might have been refuſed every thing;

---

* Introduction to the *Annals of the French Revolution*.

and very ſoon after, he was reduced to ſneak out of the kingdom, in order to eſcape the effects of the general contempt and cenſure which he had brought upon himſelf.

"General La Fayette, who then commanded the Pariſian National Guard, gathered the wrecks of all this popularity, and might have turned them to the greateſt advantage, if he had poſſeſſed 'that reſolute character and heroic judgment' of which Cardinal de Retz ſpeaks, and 'which ſerves to diſtinguiſh what is truly honourable and uſeful from what is only extraordinary, and what is extraordinary from what is impoſſible.' With the genius, talents, and ambition of Cromwell, he might have gone as great a length; with a leſs criminal ambition, he might at leaſt have made himſelf maſter of the revolution, and have directed it at his pleaſure: in a word, he might have ſecured the triumph of whatever party he ſhould have declared himſelf the leader. But as unfit for ſupporting the character of Monk as that of Cromwell, he ſoon betrayed the ſecret of his incapacity to all the world, and was diſtinguiſhed in the crowd of conſtitutional ringleaders only by his three-coloured plume, his epaulets, white horſe, and famous ſaying—'Inſurrection is the moſt ſacred of duties when oppreſſion is at its height.'

"The revolution, at the period when the faction that had begun it for the Duke of Orleans became ſenſible that he was too much a coward to be the leader of it, and when La Fayette diſcovered his inability to conduct it, was too far advanced to recede or to ſtop; and it continued its progreſs, but in a line that no other revolution had taken, viz. without a military chief, without the intervention of the army, and to gain triumphs, not for any ambitious conſpirator, but for political and moral innovations of the moſt dangerous nature; the moſt ſuited to miſlead the multitude, incapable of comprehending them, and to let looſe all the paſſions. The more violent combined to deſtroy every thing; and their fatal coalition gave birth to Jacobiniſm, that terrible monſter till then unknown, and till now not ſufficiently unmaſked. This monſter took upon itſelf alone to carry on the revolution; it directed, it executed, all the operations of it, all the exploſions, all the outrages: it every where appointed the moſt active leaders, and, as inſtruments, employed the profligates of every country. Its power far ſurpaſſed that which has been attributed to the inquiſition, and other fiery tribunals, by thoſe who have ſpoken of them with the greateſt exaggeration. Its centre was at Paris; and its rays, formed by particular clubs in every town, in every little borough, overſpread the whole ſurface of the kingdom. The conſtant correſpondence kept up between thoſe clubs and that of the capital; or, to uſe their own expreſſion, *des Sociétés populaires affiliées avec la Société mere*—'between the affiliated popular Societies and the parent Society,' was as ſecret and as ſpeedy as that of free-maſons. In a word, the Jacobin clubs had prevailed in cauſing themſelves to be looked up to as the real national repreſentation. Under that pretence, they cenſured all the authorities in the moſt imperious manner; and whenever their denunciations, petitions, or addreſſes, failed to produce an immediate effect, they gained their point by having recourſe to inſurrection, aſſaſſination, and fire. While Jacobiniſm thus ſubjected all France to its controul, an immenſe number of emiſſaries propagated its doctrines among foreign nations, and prepared new conqueſts for it.

"The National Aſſembly, the capital, indeed we may ſay all France, was divided into three very diſtinct parties. The moſt conſiderable in number, but unhappily the weakeſt through a deficiency of plan and reſolution, was the party purely Royal: it was adverſe to every kind of Revolution, and was ſolely deſirous of ſome improvements, with the reform of abuſes and pecuniary privileges:—the moſt able, and moſt intriguing, was the Conſtitutional party, or that which was deſirous of giving France a new monarchical conſtitution, but modified after the manner of the Engliſh, or even the American, by a houſe of repreſentatives. The third party was the moſt dangerous of all, by its daring ſpirit, by its power, and by the number of proſelytes it daily acquired in all quarters of the kingdom: it compriſed the Democrats of every deſcription, from the Jacobin clubs, calling themſelves *Friends of the Conſtitution*, to the anarchs and robbers.

"The Democratic party, which at firſt was only auxiliary to the Conſtitutional one, in the end annihilated it, and became itſelf ſubdivided into ſeveral other parties, whoſe fatal ſtruggles produced the ſubſequent revolutions, and may ſtill produce many more. But in principle, the Conſtitutionaliſts and the Democrats formed two diſtinct, though confederate, factions; both were deſirous of a revolution, and employed all the uſual means of accompliſhing it, except troops, which could be of no uſe to them, for neither of them had a leader to put at the head of the army. But as it was equally of importance to both that the king ſhould be deprived of the power of making uſe of it againſt them, they laboured in concert to diſorganiſe it; and the complete ſucceſs of that manœuvre was but too fully proved by the fatal iſſue of the departure of the royal family for Montmedi. The revolution then took a more daring and rapid ſtride, which was concluded by the pretended conſtitution act of 1791. The incoherence of its principles, and the defects of its inſtitutions, preſent a faithful picture of the diſunion of its authors, and of the oppoſite intereſts by which they were ſwayed. It was, properly ſpeaking, a compact between the faction of the Conſtitutionaliſts and that of the Democrats, in which they mutually made conceſſions and ſacrifices.

423
Conſtitution of 1791 completes the firſt revolution.

"Be that as it may, this abſurd conſtitution, the everlaſting ſource of remorſe or ſorrow to all who bore part in it, might have been got over without a ſhock, and led back to the old principles of monarchical government, if the Aſſembly who framed it had not ſeparated before they witneſſed the execution of it; if, in impoſing on the king the obligation to maintain it, they had not deprived him of the power and the means; and above all, if the certain conſequence of the new mode of proceeding at the elections had not been to ſecure, in the ſecond Aſſembly, a conſiderable majority of the Democratic againſt the Conſtitutional party.

"The ſecond Aſſembly was alſo divided by three factions, the weakeſt of which was the one that wiſhed to maintain the conſtitution. The other two were for a new revolution and a republic; but they differed in this, that the former, compoſed of the Briſſotins and Girondiſts, was for effecting it gradually, by beginning with diveſting the king of popularity, and allowing the public

French Revolution.

public mind time to wean itſelf from its natural attachment to monarchy ; and the latter, which was the leaſt numerous, was eager to have the republic eſtabliſhed as ſoon as poſſible. Theſe two factions, having the ſame object in view, though taking different roads, were neceſſarily auxiliaries to each other ; and the pamphlets, excitations to commotion, and revolutionary meaſures of both, equally tended to overthrow the conſtitution of 1791.

“ Thoſe different factions, almoſt entirely compoſed of advocates, ſolicitors, apoſtate prieſts, doctors, and a few literary men, having no military chief capable of taking the command of the army, dreaded the troops, who had ſworn allegiance to the conſtitution, and obedience to the king, and who moreover might be influenced by their officers, among whom there ſtill remained ſome royaliſts. The ſureſt way to get rid of all uneaſineſs on this ſubject, was to employ the army in defending the frontiers. For this purpoſe a foreign war was neceſſary, to which it was known that the king and his council were equally averſe. No more was wanting to determine the attack which was directed, almoſt at the ſame time, againſt all the miniſters, in order to compel them to retire, and to put the king under the neceſſity of appointing others more diſpoſed to ſecond the views of the parties. Unhappily this attempt was attended with all the ſucceſs they had promiſed themſelves ; and one of the firſt acts of the new miniſtry was to declare war againſt the emperor. At the ſame time, the emigration that had been provoked, and which was almoſt every where applauded, even by the loweſt claſs of people, robbed France of the flower of the royal party, and left the king, deprived of his beſt defenders, expoſed to the ſuſpicions and inſults that ſprang from innumerable calumnies, for which the diſaſters at the beginning of the war furniſhed but too many opportunities.

424
The ſecond revolution.

“ In this manner was prepared and accelerated the new revolution, which was accompliſhed on the 10th of Auguſt 1792, by the depoſition and impriſonment of the king, and by the moſt flagrant violation of the conſtitution of 1791. The latter, however, was not entirely abandoned on that day ; for the project of the Girondiſts, who had laid the plot of that horrible conſpiracy, was then only to declare the king's depoſition, in order to place the prince royal upon the throne, under the guidance of a regency compoſed of their own creatures ; but they were hurried away much farther than they meant to go, by the violence with which the moſt furious of the Jacobins, who took the lead in the inſurrection, conducted all their enterpriſes. The prince royal, inſtead of being crowned, was ſhut up in the Temple ; and if France at that moment was not declared a republic, it was leſs owing to any remaining reſpect for the conſtitution, than to the fear the legiſlative body was in of raiſing the army againſt it, and alſo the majority of the nation, who would naturally be angry to ſee a conſtitution which ſeemed to be rendered ſecure and ſtable by ſo many oaths, thus precipitately overthrown, without their having been conſulted.

“ It was on theſe conſiderations that the opinion was adopted, that a National Convention ſhould be convoked, to determine the fate of royalty. Prompt in ſeizing all the means that might enſure the ſucceſs of this ſecond revolution, the Aſſembly, under pretence of giving every poſſible latitude to the freedom of elections, decreed, that all its members ſhould be eligible for the National Convention.

French Revolution.

“ From that moment the Girondiſts daily loſt ground, and the moſt flaming members of the Democratic party, ſupported by the club of Jacobins, by the new Commune of Paris, and by the Tribunes, made themſelves maſters of every debate. It was of the utmoſt importance to them to rule the enſuing elections ; and this was ſecured to them by the horrible conſternation which the maſſacres of the 2d of September ſtruck throughout the kingdom. The terror of being aſſaſſinated, or at leaſt cruelly treated, drove from all the Primary Aſſemblies, not only the royaliſts and conſtitutionaliſts, but moderate men of all parties. Of courſe, thoſe aſſemblies became entirely compoſed of the weakeſt men and the greateſt villains exiſting in France ; and from among the moſt frantic of them were choſen thoſe members of the Convention who were not taken from the legiſlative body. Accordingly, this third Aſſembly, in the firſt quarter of an hour of their firſt ſitting, were heard ſhouting their votes for the abolition of royalty, and proclaiming the republic, upon the motion of a member who had formerly been a player.

425
The third revolution.

“ Such an opening but too plainly ſhewed what was to be expected from that horde of plunderers which compoſed the majority of the National Convention, and of whom Robeſpierre, Danton, Marat, and the other ringleaders, formed their party. That of the Briſſotins and Girondiſts ſtill exiſted, and was the only one really republican. Theſe ſemi-wretches, glutted with the horrors already committed, ſeemed deſirous of arreſting the torrent of them, and laboured to introduce into the Aſſembly the calm and moderation that were neceſſary to give the new republic a wiſe and ſolid organization. But the ſuperiority of their knowledge, talents, and eloquence, which their opponents could not diſpute, had no power over tigers thirſting for blood, who neither attended to nor ſuffered motions but of the blackeſt tendency. No doubt they had occaſion for atrocities upon atrocities to prepare the terror ſtruck nation to allow them to commit, in its name, the moſt execrable of all, the murder of the unfortunate Louis XVI : and that martyrdom was neceſſary to bring about a third revolution, already brewing in the brain of Robeſpierre. Fear had greatly contributed to the two former : but this was effected by terror alone, without popular tumults, or the intervention of the armies ; which, now drawn by their conqueſts beyond the frontiers, never heard any thing of the revolutions at home, till they were accompliſhed, and always obeyed the prevailing faction, by whom they were paid.

“ By the degree of ferocity diſcovered by the members of the Convention in paſſing ſentence upon the king, and in the debates relative to the conſtitution of 1793, Robeſpierre was enabled to mark which of the deputies were likely to ſecond his views, and which of them it was his part to ſacrifice.

“ The people could not but with tranſport receive a conſtitution which ſeemed to realiſe the chimera of its ſovereignty, but which would only have given a kind of conſtruction to anarchy, if the execution of this new code had not been ſuſpended under the pretext, belonging in common to all acts of deſpotiſm and tyranny, of *the ſupreme law of the ſafety of the ſtate.* This ſuſpenſion was effected, by eſtabliſhing the Proviſionary Government, which, under the title of Revolutionary Government, concentrated all the powers in the National Convention until there was an end to the war and all inteſtine troubles.

“ Although the faction, at the head of which Robeſpierre was, had a decided majority in the Aſſembly, and might conſequently have conſidered themſelves as really and excluſively exerciſing the ſovereign power, he was a demagogue of too deſpotic a nature to ſtomach even the appearance of ſharing the empire with ſo many co-ſovereigns. He greatly reduced their number, by cauſing all the powers inveſted in the National Aſſembly by the decrees that had eſtabliſhed the revolutionary government, to be transferred to a committee, to which he got himſelf appointed, and where he was ſure of the ſole rule, by obtaining for colleagues men leſs daring than himſelf, though equally wicked; ſuch as Couthon, St Juſt, Barrere, and others like them. This committee, who had the aſſurance to ſtyle themſelves the *Committee of Public Safety*, very ſoon ſeized upon both the legiſlative and executive powers, and exerciſed them with the moſt ſanguinary tyranny ever yet heard of. The miniſters were merely their clerks; and the ſubjugated Aſſembly, without murmur or objection, paſſed all the revolutionary laws which were propoſed, or rather dictated, by them. One of their moſt horrible and deciſive conceptions was that of thoſe Revolutionary Tribunals which covered France with ſcaffolds, where thouſands of victims of every rank, age, and ſex, were daily ſacrificed; ſo that no claſs of men could be free from that ſtupefying and general terror which Robeſpierre found it neceſſary to ſpread, in order to eſtabliſh and make his power known. He ſoon himſelf dragged ſome members of his own party, ſuch as Danton, Camille des Moulins, and others, whoſe energy and popularity had offended him, before one of thoſe tribunals, where he had them condemned to death. By the ſame means he got rid of the chief leaders among the Briſſotines and Girondiſts; while he cauſed all the moderate republican party who were ſtill members of the Aſſembly, except thoſe who had time and addreſs to eſcape, to be ſent to priſon, in order to be ſentenced and executed on the firſt occaſion.

426 The fourth revolution produces

“ In this manner ended the third revolution, in which the people, frozen with terror, did not dare to take a part. Inſtead of an army of ſoldiers, Robeſpierre employed an army of executioners and aſſaſſins, ſet up as revolutionary judges; and the guillotine, ſtriking or menacing all heads indiſcriminately, made France, from one end to the other, ſubmit to him, by the means of terror or of death. Thus was this nation, formerly ſo proud, even to idolatry, of its kings, ſeen to expiate, by rivers of blood, the crime of having ſuffered his to be ſpilt who was the moſt virtuous of all their monarchs.

“ In the room of that famous Baſtile, whoſe celebrated capture and demolition had ſet only ſeven priſoners at liberty, two of whom had been long in a ſtate of lunacy, the colleges, the ſeminaries, and all the religious houſes of the kingdom, were converted into ſo many ſtate priſons, into which were inceſſantly crowded, from time to time, the victims devoted to feed the ever-working guillotines, which were never ſuffered to ſtand ſtill for a day, becauſe they were at once the chief reſource of ſupplies for the government, and the inſtrument of its ferocity. ‘ The guillotine coins money for the republic,’ was ſaid in the tribune by one of Robeſpierre's vileſt agents *. In fact, according to the juriſprudence of the Revolutionary Tribunals, the rich of every claſs, being declared ſuſpected perſons, received ſentence of death, for no other reaſon than that of giving the confiſcation of their property a ſhow of judicial form.

“ Still blood flowed too ſlowly to ſatiſfy Robeſpierre; his aim was but partly attained by the proſcription of the nobles, the prieſts, and the wealthy. He fancied, not only an ariſtocracy of talents and knowledge, but of the virtues, none of which would his truſty orators and journaliſts admit, ſave that horrid *patriotiſm* which was eſtimated according to the enormity of the crimes committed in favour of the revolution. His plan was to reduce the French people to a mere plantation of ſlaves, too ignorant, too ſtupid, or too puſillanimous, to conceive the idea of breaking the chains with which he would have loaded them in the name of liberty; and he might have ſucceeded in it, had not his ambition, as impatient as it was jealous, too ſoon unveiled the intention of reſorting to the guillotine to ſtrike off the ſhackles with which an aſſembly of repreſentatives of the nation fettered, or might fetter, his power. He was about to give this deciſive blow, which he had concerted with the Commune of Paris, the Revolutionary Tribunal, the Club of Jacobins, and the principal officers of the National Guard, when the members of the Convention, who were marked out to be the firſt ſacrificed, anticipated him at a moment when he leaſt expected it, by attacking himſelf in the Aſſembly, with energy ſufficient to rouſe all the ſections of the capital againſt him and againſt the Jacobins. The parties came to blows, and victory remained uncertain for ſeveral hours; but at length declared againſt Robeſpierre. In the ſpace of a day, that execrable monſter was dragged from the higheſt pitch of power ever attained by any tyrant, to the very ſcaffold that was ſtill reeking with the blood of his laſt victims. His principal accomplices in the Committee of Public Safety, in the Commune, in the National Guard, in the Revolutionary Tribunal, and many of his agents in the provinces, met the ſame fate. The Revolutionary Tribunals were ſuppreſſed, and the priſons thrown open to all whom they had caſt into them.

427 The conſtitution of 1795.

“ This fourth revolution, in which the faction then eſteemed the moderate party overthrew the terroriſts, and ſeized the ſupreme power, was no leſs complete than thoſe which had preceded it, and produced the conſtitution of 1795. All France received as a great bleſſing a conſtitution that delivered them from the revolutionary government and its infernal policy. Beſides, it had, in ſpite of great defects, the merit of coming nearer than the two preceding ones, to the principles of order, of juſtice, and real liberty; the violation of which had, for five years before, been the ſource of ſo many diſaſters and ſo many crimes. The royaliſts, conſidering it as a ſtep towards monarchy, were unfortunately ſo imprudent as to triumph in it; and their joy, as premature as indiſcreet, alarmed the Aſſembly to ſuch a degree, that they paſſed the famous law, ordaining the Primary Aſſemblies to return two-thirds of the members of the Convention to the legiſlative body, which

rench rolution.

was to ſucceed that aſſembly. It was thus that the ſpirit of the Convention continued, for the firſt year, to be diſplayed in the two councils.

" In the year following, the bias of the public mind, perhaps too haſtily turned towards royalty, ſhewed itſelf in the elections of the members for the new third, ſo clearly as to alarm the regicides who compoſed the Directory, and the Conventionaliſts, who ſtill made a third of the legiſlative body ; nor did they loſe a moment in deviſing means for their defence. That which appeared the ſureſt to them was, to publiſh notices of plots among the royaliſts, and annex one or more denunciations, in terms ſo vague as to leave room for implicating, when neceſſary, all their adverſaries ; while by the help of this impoſture they procured ſome ſecret information, artfully fabricated, and ever eaſily obtained through threats or rewards by thoſe who have at command the guillotine and the public treaſure.

" This maſked battery was ready to be opened before the members of the new third took their ſeats. Theſe at firſt confined themſelves to the ſecuring of a conſtant majority in the two councils in favour of the moderate opinions; but in a little time every ſitting was marked by the repeal of ſome revolutionary law, or by ſome decree tending to reſtrain the executive authority within the limits fixed by the conſtitution.

428 he fifth volution.

" The Directory, alarmed at the abridgment of their power, and dreading ſtill more ſerious attacks upon it, came to a reſolution of no longer poſtponing the blow they had been meditating againſt the legiſlative aſſembly : and they accompliſhed, in the manner related in nº 309, a fifth revolution, as complete as any of thoſe by which it was preceded. It differed indeed from them eſſentially in the facility and promptneſs with which it was effected, although the party which prevailed, that is to ſay, the majority of the Directory, and the minority of the Legiſlative Body, had to combat not only againſt the conſtitution, but againſt the opinion, and even againſt the indignation, of the public. That moral force, on which the majority of the two councils had unluckily placed all their reliance, vaniſhed in an inſtant before the phyſical force of a detachment of troops conſiſting of ſix or ſeven hundred men ; ſo true is it, that the power of the public opinion, ridiculouſly exaggerated in theſe days, is and can be no more, under a firm and well ordered government, than a mere fancy. Men accuſtom themſelves too eaſily to take for public opinion the private opinions made public by certain writers, whoſe caution or audaciouſneſs depends always upon the energy or feebleneſs of the ſupreme authority. It is the ſame thing with popular commotions : they are eaſily excited under a weak government, which does not poſſeſs the wiſdom to prevent or the ſpirit to ſuppreſs them ; but a vigorous, juſt, and ſtrict government has nothing to fear from them. The Directory, compelled to withdraw the larger body of troops, which they had thought neceſſary to enſure the revolution they were meditating, diſcovered, no doubt, great ability in ſecuring the two councils, by appearing to dread them : but it was chiefly to the energy of their meaſures, and to the concentration and promptneſs with which they were executed, that they owed their ſucceſs. Two days before, the legiſlative body might, without obſtruction, have impeached, arreſted, and even outlawed, the majority of the Directory, who were execrated by the public under the title of Triumvirate ; and, if requiſite, they would have been ſupported by more than 30,000 armed citizens, who, with Pichegru and Villot at their head, would ſoon have diſperſed, and perhaps brought over, the feeble detachments of troops of the line which the Directory had at their command. The legiſlative body, relying too much upon its popularity, did not ſufficiently conſider, that the people, whoſe impetuoſity is commonly deciſive when allowed to take advantage in attack, are always feeble on the defenſive, and totally unable to withſtand every aſſault made previous to an inſurrection, for it is always eaſy to prevent their aſſembling. It was on this principle that the Directory founded their operations, and the 5th of September too well proves how juſtly. That day reduced the legiſlative body, by the moſt degrading ſubjugation, to a mere diſguſting caricature of national repreſentation ; it inveſted the Directory with the moſt arbitrary and tyrannic power, and reſtored the ſyſtem of Robeſpierre, under a form leſs bloody, but not leſs pernicious ; for the Revolutionary Tribunals which that monſter had eſtabliſhed, were ſcarcely more expeditious than the military ones of the Directory. The power of arbitrary and unlimited tranſportation is, in time, as deſtructive as the guillotine, without poſſeſſing, like that, the advantage of exciting a ſalutary horror, which, by recovering the people from the ſtate of ſtupor and apathy, the conſtant effects of terror, gives them both recollection and force to break their chains. Though, in violating the moſt eſſential regulations of the conſtitution, the Directory obtained a temporary confirmation of their power, their example pointed out to Bonaparte and Sieyes the path which they purſued with infinite addreſs, and in which they accompliſhed a ſixth revolution."

429 The ſixth revolution, and conſular government.

How long the conſular government will continue, it is impoſſible to conjecture ; but we may, without preſumption, venture to predict, that it cannot be permanent. To the Jacobins and original conſtitutionaliſts it muſt be more obnoxious than the old government ; becauſe Bonaparte is more deſpotic than was Louis XIV ; and the royaliſts, though they may prefer the vigorous and comparatively mild government of one man, whoſe talents are indiſputable, to the ferocious tyranny of the loweſt of the rabble, muſt look with indignation at a foreign adventurer ſeated on the throne of their ancient monarchy.

RHABDOLOGY, or Rabdology, in arithmetic, a name given by Napier to a method of performing ſome of the more difficult operations of numbers by means of certain ſquare little rods. Upon theſe are inſcribed the ſimple numbers ; then by ſhifting them according to certain rules, thoſe operations are performed by ſimply adding or ſubtracting the numbers as they ſtand upon the rods. See Napier's *Rabdologia*, printed in 1617. See alſo the article Napier's *Bones*.

RHOMB Solid, conſiſts of two equal and right cones joined together at their baſes.

RICE (ſee that article, and Oryza, *Encycl.*) is ſtrongly recommended, in a late publication, as the beſt corrective of *ſprit* flour, of which there is a great quantity in Scotland every year, and of courſe a great deal of unpleaſant and unwholeſome bread. The gentleman, who writes the ſhort paper alluded to, directs ten pounds of flour and one pound of ground rice, with the uſual quantity of yeſt, to be placed, for about two hours before a fire, and then formed into bread in the common way. This addition of rice, beſides correcting the bad qualities of the damaged flour, adds, he ſays, much to its nutriment: and he is undoubtedly right; for the flour of rice, though very nutritious, is ſo dry, that it is difficult to make bread of it by itſelf. See *Bread of Rice*, in this *Suppl.*

As rice is a favourite ſubſtitute for bread in years of ſcarcity, it may not be diſagreeable to our readers to know the method of cultivating the plant in thoſe countries where it is the principal food of the inhabitants. We have the following full and perſpicuous account of the Chineſe practice by Sir George Staunton.

“ Much of the low grounds in the middle and ſouthern provinces of the empire are appropriated to the culture of that grain. It conſtitutes, in fact, the principal part of the food of all thoſe inhabitants, who are not ſo indigent as to be forced to ſubſiſt on other and cheaper kinds of grain. A great proportion of the ſurface of the country is well adapted for the production of rice, which, from the time the ſeed is committed to the ſoil till the plant approaches to maturity, requires to be immerſed in a ſheet of water. Many and great rivers run through the ſeveral provinces of China, the low grounds bordering on thoſe rivers are annually inundated, by which means is brought upon their ſurface a rich mud or mucilage that fertilizes the ſoil, in the ſame manner as Egypt receives its fecundative quality from the overflowing of the Nile. The periodical rains which fall near the ſources of the Yellow and the Kiang rivers, not very far diſtant from thoſe of the Ganges and the Burrumpooter, among the mountains bounding India to the north, and China to the weſt, often ſwell thoſe rivers to a prodigious height, though not a drop of rain ſhould have fallen on the plains through which they afterwards flow.

“ After the mud has lain ſome days upon the plains in China, preparations are made for planting them with rice. For this purpoſe, a ſmall ſpot of ground is incloſed by a bank of clay; the earth is ploughed up; and an upright harrow, with a row of wooden pins in the lower end, is drawn lightly over it by a buffalo. The grain, which had previouſly been ſteeped in dung diluted with animal water, is then ſown very thickly on it. A thin ſheet of water is immediately brought over it, either by channels leading to the ſpot from a ſource above it, or when below it by means of a chain pump, of which the uſe is as familiar as that of a hoe to every Chineſe huſbandman. In a few days the ſhoots appear above the water. In that interval, the remainder of the ground intended for cultivation, if ſtiff, is ploughed, the lumps broken by hoes, and the ſurface levelled by the harrow. As ſoon as the ſhoots have attained the height of ſix or ſeven inches, they are plucked up by the roots, the tops of the blades cut off, and each root is planted ſeparately, ſometimes in ſmall furrows turned with the plough, and ſometimes in holes made in rows by a drilling ſtick for that purpoſe. The roots are about half a foot aſunder. Water is brought over them a ſecond time. For the convenience of irrigation, and to regulate its proportion, the rice fields are ſubdivided by narrow ridges of clay, into ſmall incloſures. Through a channel, in each ridge, the water is conveyed at will to every ſubdiviſion of the field. As the rice approaches to maturity, the water, by evaporation and abſorption, diſappears entirely; and the crop, when ripe, covers dry ground. The firſt crop or harveſt, in the ſouthern provinces particularly, happens towards the end of May or beginning of June. The inſtrument for reaping is a ſmall ſickle, dentated like a ſaw, and crooked. Neither carts nor cattle are uſed to carry the ſheaves off from the ſpot where they were reaped; but they are placed regularly in frames, two of which, ſuſpended at the extremities of a bamboo pole, are carried acroſs the ſhoulders of a man, to the place intended for diſengaging the grain from the ſtems which had ſupported it. This operation is performed, not only by a flail, as is cuſtomary in Europe, or by cattle treading the corn in the manner of other Orientaliſts, but ſometimes alſo by ſtriking it againſt a plank ſet upon its edge, or beating it againſt the ſide of a large tub ſcolloped for that purpoſe; the back and ſides being much higher than the front, to prevent the grain from being diſperſed. After being winnowed, it is carried to the granary.

“ To remove the ſkin or huſk of rice, a large ſtrong earthen veſſel, or hollow ſtone, in form ſomewhat like that which is uſed elſewhere for filtering water, is fixed firmly in the ground; and the grain, placed in it, is ſtruck with a conical ſtone fixed to the extremity of a lever, and cleared, ſometimes indeed imperfectly, from the huſk. The ſtone is worked frequently by a perſon treading upon the end of the lever. The ſame object is attained alſo by paſſing the grain between two flat ſtones of a circular form, the upper of which turns round upon the other, but at ſuch a diſtance from it as not to break the intermediate grain. The operation is performed on a larger ſcale in mills turned by water; the axis of the wheel carrying ſeveral arms, which, by ſtriking upon the ends of levers, raiſe them in the ſame manner as is done by treading on them. Sometimes twenty of theſe levers are worked at once. The ſtraw from which the grain has been diſengaged is cut chiefly into chaff, to ſerve as provender for the very few cattle employed in Chineſe huſbandry.

“ The labour of the firſt crop being finiſhed, the ground is immediately prepared for the reception of freſh ſeeds. The firſt operation undertaken is that of pulling up the ſtubble, collecting it into ſmall heaps, which are burnt, and the aſhes ſcattered upon the field. The former proceſſes are afterwards renewed. The ſecond crop is generally ripe late in October or early in November. The grain is treated as before; but the ſtubble is no longer burnt. It is turned under with the plough, and left to putrefy in the earth. This, with the ſlime brought upon the ground by inundation, are the only manures uſually employed in the culture of rice.”

RIDEAU, in fortification, a ſmall elevation of earth, extending itſelf lengthwiſe on a plain; ſerving to cover a camp, or give an advantage to a poſt.

Rideau is ſometimes alſo uſed for a trench, the earth of which is thrown up on its ſide, to ſerve as a parapet for covering the men.

RIDLEY (Dr Gloſter), was of the ſame family with Dr Nicolas Ridley, Biſhop of London, and Martyr to the Reformation. (See Ridley, *Encycl.*) He was born at ſea, in 1702, on board the Glouceſter Eaſt Indiaman; to which circumſtance he was indebted for his idley.

his Chriſtian name. He received his education at Wincheſter ſchool, and thence was elected to a fellowſhip at New college, Oxford, where he proceeded B. C. L. April 29. 1729. In thoſe two ſeminaries he cultivated an early acquaintance with the muſes, and laid the foundation of thoſe elegant and ſolid acquirements for which he was afterwards ſo eminently diſtinguiſhed as a poet, an hiſtorian, and a divine. During a vacancy in 1728, he joined with four friends, viz. Mr Thomas Fletcher (afterwards Biſhop of Kildare), Mr (afterwards Dr) Eyre, Mr Morriſon, and Mr Jennens, in writing a tragedy called “The Fruitleſs Redreſs,” each undertaking an act on a plan previouſly concerted. When they delivered in their ſeveral proportions at their meeting in the winter, few readers would have known that the whole was not the production of a ſingle hand. This tragedy, which was offered to Mr Wilks, but never acted, is ſtill in MS. with another called “Jugurtha.” Dr Ridley in his youth was much addicted to theatrical performances. Midhurſt, in Suſſex, was the place where they were exhibited; and the company of gentlemen actors to which he belonged conſiſted chiefly of his coadjutors in the tragedy already mentioned. He is ſaid to have performed the characters of Marc Antony, Jaffier, Horatio, and Moneſes, with diſtinguiſhed applauſe; a circumſtance that will be readily believed by thoſe who are no ſtrangers to his judicious and graceful manner of ſpeaking in the pulpit.

For great part of his life he had no other preferment than the ſmall college living of Weſtow in Norfolk, and the donative of Poplar in Middleſex, where he reſided. To theſe his college added, ſome years after, the donative of Romford in Eſſex. “Between theſe two places the curricle of his life had (as he expreſſed it) rolled for ſome time almoſt perpetually upon poſtchaiſe wheels, and left him not time for even the proper ſtudies of economy, or the neceſſary ones of his profeſſion.” Yet in this obſcure ſituation he remained in poſſeſſion of, and content with, domeſtic happineſs; and was honoured with the intimate friendſhip of ſome who were not leſs diſtinguiſhed for learning than for worth.

In 1740 and 1741 he preached “Eight Sermons at Lady Moyer's Lecture,” which were publiſhed in 1742, 8vo. In 1756 he declined an offer of going to Ireland as firſt chaplain to the Duke of Bedford; in return for which he was to have had the choice of promotion, either at Chriſt-church, Canterbury, Weſtminſter, or Windſor. His modeſty inducing him to leave the choice of theſe to his patron, the conſequence was, that he obtained none of them. In 1763, he publiſhed the “Life of Biſhop Ridley,” in 4to, by ſubſcription, and cleared by it as much as brought him 800l. in the public funds. In the latter part of his life he had the misfortune to loſe both his ſons, each of them a youth of abilities. The elder, James, was author of “The Tales of the Genii,” and ſome other literary performances. Thomas, the younger, was ſent by the Eaſt India Company as a writer to Madras, where he was no ſooner ſettled than he died of the ſmall-pox. In 1765, Dr Ridley publiſhed his “Review of Philips's Life of Cardinal Pole;” and in 1768, in reward for his labours in this controverſy, and in another which “The Confeſſional” produced, he was preſented by Archbiſhop Secker to a golden prebend in the cathedral church of Saliſbury (an option), the only reward he received from the great during a long, uſeful, and laborious life, devoted to the duties of his function. At length, worn out with infirmities, he departed this life in 1774, leaving a widow and four daughters. His epitaph, which was written by Biſhop Lowth with his uſual elegance, informs us, that for his merits the univerſity of Oxford conferred upon him the degree of D. D. by diploma, which is the higheſt literary honour which that learned body has to beſtow.

Rienzi.

RIENZI (Nicolas Gabrini de), one of the moſt extraordinary men of the 14th century, was born at Rome, we know not in what year. His father, Lawrence Gabrini, was a mean vintner, or, as others ſay, a miller, and his mother a laundreſs. Theſe perſons, however, found the means of giving their ſon a liberal education; and to a good natural underſtanding he joined an uncommon aſſiduity, and made great proficiency in ancient literature. Every thing which he read he compared with ſimilar paſſages that occurred within his own obſervation; whence he made reflections, by which he regulated his conduct. To this he added a great knowledge in the laws and cuſtoms of nations. He had a vaſt memory: he retained much of Cicero, Valerius Maximus, Livy, the two Senecas, and Cæſar's Commentaries eſpecially, which he read continually, and often quoted by application to the events of his own times. This fund of learning proved the baſis and foundation of his riſe. The deſire he had to diſtinguiſh himſelf in the knowledge of monumental hiſtory, drew him to another ſort of ſcience, in which few men at that time exerted themſelves. He paſſed whole days among the inſcriptions which are to be found at Rome, and acquired ſoon the reputation of a great antiquary. Having hence formed within himſelf the moſt exalted notions of the juſtice, liberty, and ancient grandeur of the old Romans, words he was perpetually repeating to the people, he at length perſuaded not only himſelf, but the giddy mob his followers, that he ſhould one day become the reſtorer of the Roman republic. His advantageous ſtature, his countenance, and that air of importance which he well knew how to aſſume, deeply imprinted all that he ſaid in the minds of his audience.

Nor was it only by the populace that he was admired; he alſo found means to inſinuate himſelf into the favour of thoſe who partook of the adminiſtration. Rienzi's talents procured him to be nominated one of the deputies ſent by the Romans to Pope Clement VI. who reſided at Avignon. The intention of this deputation was to make his Holineſs ſenſible, how prejudicial his abſence was, as well to himſelf as to the intereſt of Rome. At his firſt audience, our hero charmed the court of Avignon by his eloquence and the ſprightlineſs of his converſation. Encouraged by ſucceſs, he one day took the liberty to tell the Pope, that the grandees of Rome were avowed robbers, public thieves, infamous adulterers, and illuſtrious profligates; who, by their example, authoriſed the moſt horrid crimes. To them he attributed the deſolation of Rome; of which he drew ſo lively a picture, that the Holy Father was moved, and exceedingly incenſed againſt the Roman nobility. Cardinal Colonna, in other reſpects a lover of real merit, could not help conſidering theſe reproaches as reflecting upon ſome of his family; and therefore found means of diſgracing Rienzi, ſo that he fell into extreme miſery, vexation, and ſickneſs, which, joined with indigence, brought him to an hoſpital. Nevertheleſs, the ſame hand that threw him down, raiſed him up again. The cardinal, who was all compaſſion, cauſed him to appear before the Pope, in aſſurance of his being a good man, and a great partizan for juſtice and equity. The Pope approved of him more than ever; and, to give him proofs of his eſteem and confidence, made him apoſtolic notary, and ſent him back loaded with favours.

Being returned to Rome, he began to execute the functions of his office; and by affability, candour, aſſiduity, and impartiality, in the adminiſtration of juſtice, he arrived at a ſuperior degree of popularity; which he ſtill improved by continued invectives againſt the vices of the great, whom he took care to render as odious as poſſible; till at laſt, for ſome ill-timed freedoms of ſpeech, he was not only ſeverely reprimanded, but diſplaced. From this time it was his conſtant endeavour to inſpire the people with a fondneſs for their ancient liberties; to which purpoſe he cauſed to be hung up in the moſt public places emblematic pictures, expreſſive of the former ſplendour and preſent decline of Rome. To theſe he added frequent harangues and predictions upon the ſame ſubject. In this manner he proceeded till one party looked on him only as a madman, while others careſſed him as their protector. At length he ventured to open himſelf to ſuch as he believed male contents. At firſt he took them ſeparately; afterwards, when he thought he had firmly attached a ſufficient number to his intereſt, he aſſembled them together, and repreſented to them the deplorable ſtate of the city, over-run with debaucheries, and the incapacities of their governors to correct or amend them. As a neceſſary foundation for the enterpriſe, he gave them an inſight into the immenſe revenues of the apoſtolic chamber: He demonſtrated, that the Pope could, only at the rate of fourpence, raiſe a hundred thouſand florins by firing, as much by ſalt, and as much more by the cuſtoms and others duties. As for the reſt, ſaid he, I would not have you imagine that it is without the Pope's conſent I lay hands on the revenues. Alas! how many others in this city plunder the effects of the church contrary to his will!

By this artful lie, he ſo animated his auditors, that they declared they would make no ſcruple of ſecuring theſe treaſures for whatever end might be moſt convenient; and that they were devoted to the will of him their chief. Having obtained ſo much, to ſecure his adherents from a revolt, he tendered them a paper, ſuperſcribed, "an *oath* to procure the good eſtabliſhment;" and made them ſubſcribe and ſwear to it before he diſmiſſed them. By what means he prevailed on the Pope's vicar to give a tacit ſanction to his project, is not certainly known; that he did procure that ſanction, and that it was looked on as a maſterpiece of policy, is generally admitted. "The 20th of May, being Whitſunday, he fixed upon to ſanctify in ſome ſort his enterpriſe; and pretended, that all he acted was by particular inſpiration of the Holy Ghoſt. About nine, he came out of the church bare-headed, accompanied by the Pope's vicar, ſurrounded by an hundred armed men. A vaſt crowd followed him with ſhouts and acclamations." The gentlemen conſpirators carried three ſtandards before him, on which were wrought devices, inſinuating, that his deſign was to re-eſtabliſh liberty, juſtice, and peace. In this manner he proceeded directly to the Capitol, where he mounted the roſtrum; and, with more boldneſs and energy than ever, expatiated on the miſeries to which the Romans were reduced: at the ſame time telling them, without heſitation, "that the happy hour of their deliverance was at length come, and that he was to be their deliverer, regardleſs of the dangers he was expoſed to for the ſervice of the Holy Father and the people's ſafety." After which, he ordered the laws of what he called the good eſtabliſhment to be read: "aſſured that the Romans would reſolve to obſerve theſe laws, he engaged in a ſhort time to re-eſtabliſh them in their ancient grandeur.".

The laws of the good eſtabliſhment promiſed plenty and ſecurity, which were greatly wanted; and the humiliation of the nobility, who were deemed common oppreſſors. Such laws could not fail of being agreeable to a people who found in them theſe double advantages; wherefore, "enraptured with the pleaſing ideas of a liberty to which they were at preſent ſtrangers, and the hope of gain, they came moſt zealouſly into the fanaticiſm of Rienzi. They reſumed the pretended authority of the Romans; they declared him ſovereign of Rome; and granted him the power of life and death, of rewards and puniſhments, of enacting and repealing the laws, of treating with foreign powers; in a word, they gave him the full and ſupreme authority over all the extenſive territories of the Romans.

Rienzi, arrived at the ſummit of his wiſhes, kept at a great diſtance his artifice: he pretended to be very unwilling to accept of their offers, but upon two conditions; the firſt, that they ſhould nominate the Pope's vicar (the Biſhop of Orvieto) his copartner; the ſecond, that the Pope's conſent ſhould be granted him, which (he told them) he flattered himſelf he ſhould obtain. "On the one hand, he hazarded nothing in thus making his court to the Holy Father; and, on the other, he well knew, that the Biſhop of Orvieto would carry a title only, and no authority. The people granted his requeſt, but paid all the honours to him: he poſſeſſed the authority without reſtriction; the good Biſhop appeared a mere ſhadow and veil to his enterpriſes. Rienzi was ſeated in his triumphal chariot, like an idol, to triumph with the greater ſplendour. He diſmiſſed the people replete with joy and hope. He ſeized upon the palace, where he continued after he had turned out the ſenate; and, the ſame day, he began to dictate his laws in the Capitol." This election, though not very pleaſing to the Pope, was ratified by him; nevertheleſs, Rienzi meditated the obtaining of a title, excluſive of the papal prerogative. Well verſed in the Roman hiſtory, he was no ſtranger to the extent of the tribunitial authority; and as he owed his elevation to the people, he choſe to have the title of their magiſtrate. He aſked it, and it was conferred on him and his copartner, with the addition of deliverers of their country. Our adventurer's behaviour in his elevation was at firſt ſuch as commanded eſteem and reſpect, not only from the Romans, but from all the neighbouring ſtates. But it is difficult for a perſon of mean birth, elevated at once, by the caprice of fortune, to the moſt exalted ſtation, to move rightly in a ſphere wherein he muſt breathe an air he has been unaccuſtomed to. Rienzi aſcended by degrees the ſummit of his fortune.

Rienzi.

Riches ſoftened, power dazzled, the pomp of his cavalcades animated, and formed in his mind ideas adequate to thoſe of princes born to empire. Hence luxury invaded his table, and tyranny took poſſeſſion of his heart. The Pope conceived his deſigns to be contrary to the intereſts of the holy ſee; and the nobles, whoſe power it had been his conſtant endeavours to depreſs, conſpired againſt him: they ſucceeded; and Rienzi was forced to quit an authority he had poſſeſſed little more than ſix months. It was to a precipitate flight that he was indebted, at this juncture, for his life; and to different diſguiſes for his ſubſequent preſervation.

Having made an ineffectual effort at Rome, and "not knowing where to find a new reſource to carry on his deſigns, he took a moſt bold ſtep, conformable to that raſhneſs which had ſo often aſſiſted him in his former exploits. He determined to go to Prague, to Charles king of the Romans, whom the year before he had ſummoned to his tribunal," and who, he foreſaw, would deliver him up to a Pope highly inceuſed againſt him. He was accordingly ſoon after ſent to Avignon, and there thrown into a priſon, where he continued three years. The diviſions and diſturbances in Italy, occaſioned by the number of petty tyrants that had eſtabliſhed themſelves in the eccleſiaſtical territories, and even at Rome, occaſioned his enlargement. Innocent VI. who ſucceeded Clement in the papacy, ſenſible that the Romans ſtill entertained an affection for our hero, and believing that his chaſtiſement would teach him to act with more moderation than he had formerly done, as well as that "gratitude would oblige him, for the remainder of his life, to preſerve an inviolable attachment to the holy ſee (by whoſe favour he ſhould be re-eſtabliſhed)," thought him a proper inſtrument to aſſiſt his deſign of reducing thoſe other tyrants; and therefore, not only gave him his liberty, but alſo appointed him governor and ſenator of Rome. He met with many obſtacles to the aſſumption of this newly-granted authority; all which, by cunnning and reſolution, he at length overcame. But giving way to his paſſions, which were immoderately warm, and inclined him to cruelty, he excited ſo general a reſentment againſt him, that he was murdered October 8. 1354.

"Such was the end of Nicolas Rienzi, one of the moſt renowned men of the age; who, after forming a conſpiracy full of extravagance, and executing it in the ſight of almoſt the whole world, with ſuch ſucceſs that he became ſovereign of Rome; after cauſing plenty, juſtice, and liberty, to flouriſh among the Romans; after protecting potentates, and terrifying ſovereign princes; after being arbiter of crowned heads; after re-eſtabliſhing the ancient majeſty and power of the Roman republic, and filling all Europe with his fame during the ſeven months of his firſt reign; after having compelled his maſters themſelves to confirm him in the authority he had uſurped againſt their intereſts—fell at length at the end of his ſecond, which laſted not four months, a ſacrifice to the nobility, whoſe ruin he had vowed, and to thoſe vaſt projects which his death prevented him from putting into execution*."

If the reader perceive any thing ſimilar at preſent to the riſe of this wonderful man to ſovereign authority, he may perhaps conſole himſelf with the hope that the modern conſul will in all probability fall like the modern tribune. Both roſe by diſplays of the moſt daring courage; the aſſociates of both were prieſts, who in the actual exerciſe of government were cyphers; both promiſed liberty and plenty to the people whom they ruled with abſolute ſway; and both have trampled upon the order of nobility.

Ring, || Rodney.

RING, in aſtronomy and navigation, an inſtrument uſed for taking the ſun's altitude, &c. It is uſually of braſs, about nine inches diameter, ſuſpended by a little ſwivel, at the diſtance of 45° from the point of which is a perforation, which is the centre of a quadrant of 90° divided in the inner concave ſurface. To uſe it, let it be held up by the ſwivel, and turned round to the ſun, till his rays, falling through the hole, make a ſpot among the degrees, which marks the altitude required. This inſtrument is preferred before the aſtrolabe, becauſe the diviſions are here larger than on that inſtrument.

ROBERVALLIAN LINES, a name given to certain lines uſed for the transformation of figures; thus called from their inventor Roberval, an eminent French mathematician, who died in 1675, aged 76 years. Theſe lines bound ſpaces that are infinitely extended in length, which are nevertheleſs equal to other ſpaces that are terminated on all ſides.

The Abbot Gallois, in the Memoirs of the Royal Academy, anno 1693, obſerves, that the method of transforming figures, explained at the latter end of Roberval's Treatiſe of Indiviſibles, was the ſame with that afterwards publiſhed by James Gregory, in his *Geometria Univerſalis*, and alſo by Barrow in his *Lectiones Geometricæ*; and that, by a letter of Torricelli, it appears, that Roberval was the inventor of this manner of transforming figures, by means of certain lines, which Torricelli therefore called *Robervallian lines*. He adds, that it is highly probable that J. Gregory firſt learned the method in the journey he made to Padua in 1668, the method itſelf having been known in Italy from the year 1646, though the book was not publiſhed till the year 1692.

This account has been, we think, completely refuted by David Gregory in his vindication of his uncle, publiſhed in the Philoſophical Tranſactions of 1694. The Abbot, however, rejoined in the Memoirs of the French Academy of 1703; and it is but fair to obſerve, that Dr Hutton, ſpeaking of the controverſy, expreſſes himſelf as if he thought it undecided.

RODNEY (Lord). In our ſhort ſketch of the life of that gallant officer (*Encycl.*), we mentioned with regret our not having heard of any monument being erected to his honour in his native country. We have ſince learned that there is a pillar upon the Brythen in Shropſhire, which was erected to his memory long before the publication of our article.

Having this great man again under our notice, we inſert with pleaſure the following extract of a letter, which we received from an obliging correſpondent ſoon after the publication of the volume which contains our biographical ſketch of the Admiral: "Whatever were Rodney's merits as a naval commander (ſays our correſpondent), there is a more brilliant part of his character which you have entirely neglected. Prior to his ſucceſs againſt the Spaniſh Admiral Don Langara, the Engliſh who had the misfortune to become priſoners of war to the Spaniards, were treated with the greateſt inhumanity, and it required more than a common ſtrength

---

* Biog. Dict. new edit.

ſtrength of conſtitution to exiſt for any length of time in a Spaniſh priſon. When the Spaniſh admiral fell into the hands of Rodney, he, his officers and ſeamen, expected to meet with the ſame treatment they had always inflicted, and which they would have inflicted on Rodney, his officers, and ſeamen, had the Spaniards been the victors; but, to their ſurpriſe, they found in Admiral Rodney (and, of courſe, in all that were under his command) a man who ſympathiſed in their misfortune, who miniſtered to their neceſſities, and, by a humane and polite behaviour to his priſoners, made an impreſſion on the minds of the Spaniards, which could not but have its effect in mitigating the ſufferings of the Engliſh in Spaniſh priſons: but he did not ſtop here; he took an opportunity, when their minds were expanded by gratitude (and in a ſtate to receive the full force of ſuch a repreſentation), to repreſent to them the miſerable condition of his countrymen who were priſoners in Spain, and obtained a promiſe (which, I believe, was punctually performed), that Engliſhmen, when priſoners in Spain, ſhould be made as comfortable as their ſituation would admit of. This was a piece of ſervice to his country which ſurely merits to be recorded, and which will exalt him as much in the opinion of good men as the moſt brilliant diſplay of *courage*, which is a quality as frequently diſcovered in the ſavage as in the cultivated mind."

ROEBUCK (John, M. D.), was born at Sheffield in Yorkſhire in the year 1718. His father was a conſiderable manufacturer and exporter of Sheffield goods, who by his abilities and induſtry had acquired a competent fortune. John, his eldeſt ſon, the ſubject of this memoir, was intended by his father for carrying on his own lucrative buſineſs at Sheffield; but was, from his early youth, irreſiſtibly attached to other purſuits, more calculated to gratify his ambition, and give fuller play to his powers. Notwithſtanding this diſappointment in his favourite object, his father had liberality enough to encourage his riſing genius, and to give him all the advantages of a regular education.

After he had gone through the uſual courſe of the grammar ſchool at Sheffield, both his father and mother being ſtrict diſſenters, they placed their ſon for ſome years under the tuition of the late Dr Doddridge, who was at that time maſter of an academy at Northampton, and had juſtly acquired high reputation among the diſſenters, both as a divine and as an inſtructor of youth. Under the Doctor's care Mr Roebuck made great proficiency, and laid the foundation of that claſſical taſte and knowledge for which he was afterwards eminently diſtinguiſhed. It would appear that Dr Doddridge had been much pleaſed with the ardour and enthuſiaſm, in the purſuit of knowledge, diſcovered by his pupil; for Mr Roebuck, in an after period of his life, uſed frequently to mention the ſubjects of converſation and inquiries of various kinds, in which the Doctor had engaged him. It was during his reſidence at this academy that he contracted an intimate acquaintance with his fellow-ſtudents, Mr Jeremiah Dyſon, afterwards much known in the political world, and Mr Mark Akenſide, afterwards Dr Akenſide, which terminated only with their lives.

From the academy at Northampton he was ſent to the univerſity of Edinburgh, where he applied to the ſtudy of medicine, and particularly to that of chemiſtry, which about that time began to attract ſome attention in Scotland. While he reſided there, he diſtinguiſhed himſelf much among his fellow-ſtudents in their literary ſocieties and converſations, by great logical and metaphyſical acuteneſs, and by great ingenuity and reſource in argumentation. The late ſagacious Dr Porterfield, to whom he had been introduced, obſerved and encouraged his riſing genius, and was greatly inſtrumental in promoting his improvement. There, too, he formed an intimate acquaintance with Mr Hume, Mr Robertſon, afterwards Dr Robertſon, Mr Pringle, afterwards Lord Alemoor, and ſeveral other perſons of literary eminence; a circumſtance which produced in his mind a partiality ever afterwards in favour of Scotland, and contributed not a little to his making choice of it for the chief field of his future exertions and induſtry.

After Mr Roebuck had gone through a regular courſe of medical education at Edinburgh, being now determined to follow the practice of phyſic, he next ſpent ſome time at the univerſity of Leyden, then in high reputation as the firſt ſchool of medicine in Europe. There, after the uſual reſidence and courſe of trials, he obtained a degree in medicine; and his diploma, dated 21ſt February 1743, has affixed to it the reſpectable names of Muſchenbroek, Oſterdyk, Van Royen, Albinus, Gaubius, &c. He left Leyden, after having viſited ſome part of the north of Germany, about the end of the year 1744.

Soon after his return from the continent, ſome circumſtances induced Dr Roebuck to ſettle as a phyſician at Birmingham. Before that time, Birmingham had begun to make a rapid progreſs in arts, manufactures, and population; and by the death of an aged phyſician, an opening was preſented to him, which afforded an immediate proſpect of encouragement in that line. His education, talents, and intereſting manners, were well calculated to promote his ſucceſs as a phyſician. He accordingly met there, at a period more early than he expected, with great encouragement; and was ſoon diſtinguiſhed, in that town and the country adjacent, for his ſkill, integrity, and charitable compaſſion, in the diſcharge of the duties of his profeſſion.

It appeared, however, ſoon after his reſidence was fixed at Birmingham, that his ſtudies and induſtry were turned to various objects beſides thoſe of his profeſſion. Strongly attached to the riſing ſcience of chemiſtry, he conceived high views of extending its uſefulneſs, and of rendering it ſubſervient to the improvement of arts and manufactures. With this view, he fitted up a ſmall laboratory in his own houſe, in which he ſpent every moment of his time which he could ſpare from the duties of his profeſſion. There, in the true ſpirit of his great maſter Lord Bacon, of whoſe philoſophy he was an ardent admirer, he carried on various chemical proceſſes of great importance, and laid the foundation of his future projects on well-tried and well-digeſted experiments.

The firſt efforts of his genius and induſtry, thus directed, led him to the diſcovery of certain improved methods of refining gold and ſilver, and particularly to an ingenious method of collecting the ſmaller particles of theſe precious metals, which had been formerly loſt in the practical operations of many of the manufacturers. By other chemical proceſſes, carried on about the ſame time in his little laboratory, he diſcovered alſo improved methods of making ſublimate, hartſhorn, and ſundry other articles of equal importance. After having received full ſatisfaction from the experiments upon which ſuch diſcoveries and improvement were founded, he next digeſted a plan for rendering them beneficial to himſelf, and uſeful to the public. A great part of his time being ſtill employed in the duties of his profeſſion, he found it neceſſary to connect himſelf with ſome perſon in whom he could repoſe confidence, and who might be, in other reſpects, qualified to give him ſupport and aſſiſtance in carrying on his intended eſtabliſhments. With this view, he choſe as his aſſociate Mr Samuel Garbet of Birmingham; a gentleman well qualified, by his abilities, activity, and enterpriſing ſpirit, for bearing his part in their future undertakings. Their firſt project was the eſtabliſhment of an extenſive laboratory at Birmingham, for the purpoſes above mentioned; which, conducted by Dr Roebuck's chemical knowledge, and Mr Garbet's able and judicious management, was productive of many advantages to the manufacturers of that place, and of ſuch emolument to themſelves, as contributed greatly to the boldneſs of their future projects. That laboratory has, ever ſince that time, continued at Birmingham, and is ſtill conducted by Mr Garbet. Dr Roebuck, long before his death, had given up his intereſt in it.

About this time, in 1747, the Doctor married Miſs Ann Roe of Sheffield, a lady of a great and generous ſpirit, whoſe temper and diſpoſition equally fitted her for enjoying the proſperous circumſtances of their early life, and for bearing her equal ſhare of thoſe anxieties and diſappointments in buſineſs which ſhaded, but did not obſcure, the later period of their lives.

Dr Roebuck's unremitted perſeverance in his chemical ſtudies, together with the ſucceſs that attended them, led him, ſtep by ſtep, to other reſearches of great public and private benefit.

The extenſive uſe of the vitriolic (ſulphuric) acid in chemiſtry, and the proſpect of its application to ſome of the mechanic arts, had produced a great demand for that article, and turned the attention of chemiſts to various methods of obtaining it. The late Dr Ward had obtained a patent for making it; and though the ſubſtances from which it might be obtained, as well as certain methods of obtaining it, had been known to others, and particularly pointed out by Lemery the Elder, and by Glauber, yet Dr Ward was the firſt, it is believed, who eſtabliſhed a profitable manufacture upon the diſcovery. Much, however, was wanting to render the acid of univerſal uſe in chemiſtry, and of extenſive utility in the arts, where great quantities of it were required. The price of it was high, ariſing from the great expence of the glaſs veſſels, which were made uſe of by Dr Ward in procuring it, and the frequent accidents to which they were liable in the proceſs.

Dr Roebuck had been for ſome time engaged in making experiments with a view to reduce the price, and at length diſcovered a method of preparing it, by ſubſtituting, in place of the glaſs veſſels formerly uſed, lead ones of a great ſize; which ſubſtitution, together with ſundry other improvements in different parts of the proceſs, completely effected his end.

After the neceſſary preparations had been made, Meſſrs Roebuck and Garbet eſtabliſhed a manufacture of the oil of vitriol at Preſtonpans, in Scotland, in the year 1749. This eſtabliſhment not a little alarmed Dr Ward, who attempted to defeat their plan, by taking out a patent for Scotland, in addition to the one he had formerly obtained. In this attempt he failed. Dr Roebuck's diſcovery was found not to come within the ſpecification of Dr Ward's patent.

The Preſtonpans company, convinced that patents are of little avail in preſerving the property of new inventions or diſcoveries, in conducting their vitriol works reſolved to have recourſe to the more effectual methods of concealment and ſecrecy. By that method they were enabled to preſerve the advantages of their ingenuity and induſtry for a long period of years, and not only ſerved the public at a much cheaper rate than had ever been done formerly, but, it is believed, they realized, in that manufacture, a greater annual profit from a ſmaller capital than had been done in any ſimilar undertaking. The vitriol work is ſtill carried on at Preſtonpans; but long before Dr Roebuck's death, he was obliged to withdraw his capital from it.

About this time Dr Roebuck was urged, by ſome of his friends, to leave Birmingham, and to ſettle as a phyſician in London, where his abilities might have had a more extenſive field of exertion. He had been early honoured with the acquaintance of the late Marquis of Rockingham, who, as a lover of arts, had frequently engaged him in chemical experiments at Rockingham-houſe. It was there, alſo, he became acquainted with the late Sir George Saville, and with ſeveral other perſons of rank and influence. His old friend and ſchool-fellow Mr Dyſon, too, by this time, had acquired conſiderable name and influence, and preſſed him much to take that ſtep. Under ſuch patronage, and with the energy of ſuch talents as Dr Roebuck poſſeſſed, there could be little doubt of his ſoon arriving at an eminent rank as a phyſician in London. But the chemical concerns, with which he was at that time deeply occupied, holding out to him a proſpect of a richer harveſt, determined him to give up the practice of medicine altogether, and to fix his reſidence for the greateſt part of the year in Scotland.

The ſucceſs of the eſtabliſhment at Preſtonpans, which had far exceeded their expectation, enabled the Doctor and his partner Mr Garbet to plan and execute other works of ſtill greater benefit and public utility. In the proſecution of his chemical ſtudies and experiments, Dr Roebuck had been led to beſtow great attention on the proceſſes of ſmelting iron-ſtone, and had made ſome diſcoveries, by which that operation might be greatly facilitated, particularly by uſing pit-coal in place of charcoal. Mr William Caddell of Cockenzie, in the neighbourhood of Preſtonpans, a gentleman earneſtly intent upon promoting manufactures in Scotland, had, for ſeveral years, laboured, without much ſucceſs, in eſtabliſhing a manufacture of iron; a circumſtance which may have probably contributed to turn Dr Roebuck's attention more particularly to that ſubject. As the capital which he and his partner Mr Garbet could appropriate for carrying on the iron manufacture was not equal to ſuch an undertaking, and chiefly depended upon the profits of their other works, their firſt intention was to attempt a ſmall eſtabliſhment of that kind in the vicinity of their vitriol works at Preſtonpans. But the flattering proſpects of ſucceſs, ariſing from a courſe of experiments which Dr Roebuck had lately made, encouraged them to extend their

Roebuck.

plan, and to project a very extenſive manufactory of iron. A ſufficient capital was ſoon procured, through the confidence which many of their friends repoſed in their abilities and integrity. In fact, the eſtabliſhment which they made, or rather the capital which gave it exiſtence, was the united capital of a band of relations and friends, who truſted to Dr Roebuck and Mr Garbet the management of a great part of their fortune. When all previous matters had been concerted reſpecting their intended eſtabliſhment, the chief exertions of chemical and mechanical ſkill, neceſſary in the execution, were expected from Dr Roebuck. It fell to his ſhare alſo to fix upon the beſt and moſt favourite ſituation for erecting their intended works. With that view Dr Roebuck examined many different places in Scotland, particularly thoſe on both ſides of the Frith of Forth; and after a careful and minute compariſon of their advantages and diſadvantages, he at length made choice of a ſpot on the banks of the river *Carron* as the moſt advantageous ſituation for the eſtabliſhment of the iron manufacture. There he found they could eaſily command abundance of water for the neceſſary machinery; and in the neighbourhood of it, as well as everywhere both along the north and ſouth-coaſts of the Frith, were to be found inexhauſtible quarries of ironſtone, limeſtone, and coal. From Carron, alſo, they could eaſily tranſport their manufactures to different countries by ſea. The communication with Glaſgow at that time by land carriage, which opened up to them a ready way to the American market, was ſhort and eaſy.

Many other things, that need not be here enumerated, fell to Dr Roebuck's ſhare in preparing and providing for the introduction of this new manufacture into Scotland, particularly with reſpect to the planning and erection of the furnaces and machinery. To inſure ſucceſs in that department, nothing was omitted which ability, induſtry, and experience could ſuggeſt. With this view, he called to his aſſiſtance Mr Smeaton, then by far the firſt engineer in England. It was from him he received plans and drawings of the water-wheels and blowing apparatus, which, notwithſtanding all the mechanical improvements which have been made ſince, remain unrivalled in any of the other iron-works erected in Britain. This was the firſt introduction of Mr Smeaton into Scotland, and was the occaſion of various other diſplays of the ſkill and experience of that celebrated engineer in that part of the iſland. With the ſame view, and to the ſame effect, in a future period of his operations, he employed Mr James Watt, then of Glaſgow, and had the merit of rendering that inventive genius, in the mechanical arts, better known both in this country and in England.

The neceſſary preparations for the eſtabliſhment of the iron-works at Carron were finiſhed in the end of the year 1759; and on the 1ſt January 1760 the firſt furnace was blown; and in a ſhort time afterwards a ſecond was erected.

No period of Dr Roebuck's life required from him more vigorous and laborious exertions than that of the eſtabliſhment of the Carron works, and the firſt trials of the furnaces and machinery. His family and friends remember well the ardour and intereſt which he diſcovered; the inceſſant labour and watchfulneſs which he exerted on that occaſion. Every thing was untried, the furnaces, the machinery, the materials, the workmen; the novelty of the undertaking in that country, its extent and difficulty, and the great ſtake at iſſue, were circumſtances that muſt have occaſioned much ſerious thought and anxiety to the partner, upon the credit of whoſe knowledge and experience the work had been undertaken. But the Doctor had great powers and great reſources; and the firſt trial gave ſufficient indications of future ſucceſs.

Roebuck.

For ſome time after the eſtabliſhment of the Carron works, Dr Roebuck continued to give his attention and aſſiſtance in the general management and ſuperintendance of them, and with him all meaſures of future operations were concerted. During this period, ſome alterations of great importance were ſuggeſted by him, and carried into effect. By carefully obſerving the progreſs of ſmelting in the furnaces, at firſt worked by bellows, beſides their being ſubject to various accidents, the Doctor diſcovered the neceſſity of rendering the blaſt both ſtronger and more equable; and propoſing, as a problem to Mr Smeaton, the beſt method of effecting that end, that celebrated engineer ſoon gave the plan of a blaſt by three or four cylinders, which was afwards tried, and ſucceeded even beyond expectation.

When the buſineſs at Carron ſunk by degrees into a matter of ordinary detail, and afforded leſs ſcope for the Doctor's peculiar talents, he was unfortunately tempted to engage in a new and different undertaking; from the failure of which he ſuffered a reverſe of fortune, was deprived of the advantages reſulting from his other works, and during the remainder of his life became ſubjected to much anxiety and diſappointment.

The eſtabliſhment of the Carron works, and the intereſt Dr Roebuck had in their ſucceſs, had naturally turned his attention to the ſtate of coal in the neighbourhood of that place, and to the means of procuring the extraordinary ſupplies of it which the iron-works might in future require. With the view, therefore, of increaſing the quantity of coal woked in that neighbourhood, by an adventure which he thought would alſo turn out to his own emolument, he was induced to become leſſee of the Duke of Hamilton's extenſive coal and ſalt works at Borrowſtounneſs. The coal there was repreſented to exiſt in great abundance, and underſtood to be of ſuperior quality; and as Dr Roebuck had made himſelf acquainted with the moſt improved methods of working coal in England, and then not practiſed in Scotland, he had little doubt of this adventure turning out beneficial and highly lucrative. In this, however, he was cruelly diſappointed. The opening of the principal ſtratum of coal required much longer time, and much greater expence, than had been calculated; and, after it was opened, the perpetual ſucceſſion of difficulties and obſtacles which occurred in the working and raiſing of the coal, was ſuch as has been ſeldom experienced in any work of that kind. The reſult was, that after many years of labour and induſtry, there were ſunk in the coal and ſalt works at Borrowſtounneſs, not only his own, and the conſiderable fortune brought him by his wife, but the regular profits of his more ſucceſsful works; and along therewith, what diſtreſſed him above every thing, great ſums of money borrowed from his relations and friends, which he was never able to repay; not to mention that, from the ſame cauſe, he was, during the laſt twenty years of his

his life, ſubjected to a conſtant ſucceſſion of hopes and diſappointments, to a courſe of labour and drudgery ill ſuited to his taſte and turn of mind, to the irkſome and teaſing buſineſs of managing and ſtudying the humours of working colliers. But all theſe difficulties his unconquerable and perſevering ſpirit would have overcome, if the never-ceaſing demands of his coal-works, after having exhauſted the profits, had not alſo compelled him to withdraw his capital from all his different works in ſucceſſion; from the refining work at Birmingham, the vitriol work at Preſtonpans, the iron-works at Carron, as well as to part with his intereſt in the project of improving the ſteam-engine, in which he had become a partner with Mr Watt, the original inventor, and from which he had reaſon to hope for future emolument.

It would be painful to mention the unhappy conſequences of this ruinous adventure to his family and to himſelf. It cut off for ever the flattering proſpect which they had of an independent fortune, ſuited to their education and rank in life. It made many cruel encroachments upon the time and occupations of a man whoſe mind was equally fitted to enjoy the high attainments of ſcience, and the elegant amuſements of taſte. As the price of ſo many ſacrifices, he was only enabled to draw from his colliery, and that by the indulgence of his creditors, a moderate annual maintenance for himſelf and family during his life. At his death, his widow was left without any proviſion whatever for her immediate or future ſupport, and without the ſmalleſt advantage from the extraordinary exertions and meritorious induſtry of her huſband.

Dr Roebuck had, ſome years before his death, been attacked by a complaint that required a dangerous chirurgical operation. That operation he ſupported with his uſual ſpirit, and reſolution. In a ſhort time he was reſtored to a conſiderable ſhare of his former health and activity; but the effects of it never entirely left him, and ſeveral ſlighter returns of the complaint gradually impaired his conſtitution. He ſtill, however, continued, till within a few weeks of his death, to viſit his works, and to give direction to his clerks and overſeers. He was confined to his bed only a few days; and died on the 17th July 1794, retaining to the laſt all his faculties, his ſpirit and good humour, as well as the great intereſt which he took, as a man of ſcience and reflection, in the uncommon events which the preſent age has exhibited.

From a man ſo deeply and ſo conſtantly engaged in the detail of active buſineſs, many literary compoſitions were not to be expected. Dr Roebuck left behind him many *works*, but few *writings*. The great object which he kept invariably in view was to promote arts and manufactures, rather than to eſtabliſh theories or hypotheſes. The few eſſays which he left, enable us to judge of what might have been expected from his talents, knowledge, and boldneſs of invention, had not the active undertakings in which, from an early period of life, he was engaged, and the fatiguing details of buſineſs, occupied the time for ſtudy and inveſtigation. A compariſon of the heat of London and Edinburgh, read in the Royal Society of London June 29. 1775; experiments on ignited bodies, read there 16th Feb. 1776; obſervations on the ripening and filling of corn, read in the Royal Society of Edinburgh 5th June 1784—are all the writings of his, two political pamphlets excepted, which have been publiſhed. The publication of the eſſay on ignited bodies was occaſioned by a report of ſome experiments made by the Comte de Buffon, from which the Comte had inferred, that *matter* is heavier when hot than when cold. Dr Roebuck's experiments, made with great accuracy before a committee of the Royal Society at London, ſeem to refute that notion.

It is the works and eſtabliſhments projected and executed by Dr Roebuck, with the immediate and more remote effects of them upon the induſtry, arts, and manufactures of Scotland, which urge a juſt claim to the reſpect and gratitude of his country. This tribute is more due from the diſcerning part of mankind, as this ſpecies of merit is apt to be overlooked by the buſy or the ſuperficial, and to fail in obtaining its due reward. The circumſtances of Dr Roebuck were, in this reſpect, peculiarly hard: for though, moſt certainly, the projector and author of new eſtabliſhments highly uſeful to his country, and every day becoming more ſo, he was, by a train of unfortunate events, obliged to break off his connection with them, at an unſeaſonable time, when much was yet wanting to their complete ſucceſs: and thus he left others in the poſſeſſion, not only of the lucrative advantages now derived from them, but even in ſome meaſure of the general merit of the undertaking, to a conſiderable part of which he had the moſt undoubted claim.

The eſtabliſhment of the laboratory at Birmingham in the year 1747, the firſt public exhibition of Dr Roebuck's chemical talents, was, at that particular period, and in the ſtate of the arts and manufactures at that time, highly beneficial, and ſubſervient to their future progreſs: and the continuance and ſucceſs of it, in that place, is a proof of the advantages which many of the manufacturers receive from it. Much had already been done, and many improvements made in arts and manufactures, chiefly by the ſuggeſtions of that ingenuity and experience which, in the detail of buſineſs, might be expected from the practical artiſt. Dr Roebuck was qualified to proceed a ſtep farther; to direct experience by principles, and to regulate the mechanical operation of the artiſt by the lights of ſcience. The effects of that eſtabliſhment extended, in a particular manner, to all that variety of manufactures in which gold and ſilver were required, to the preparing of materials, the ſimplifying of the firſt ſteps, to the ſaving of expence and labour, and to the turning to ſome account what had been formerly loſt to the manufacturer. It is well known that, while Dr Roebuck reſided at Birmingham, ſuch was the opinion formed of his chemical knowledge and experience by the principal manufacturers, that they uſually conſulted him on any new trial or effort to improve their ſeveral manufactures; and when he left that place, they ſincerely regretted the loſs of that eaſy and unreſerved communication they had with him on the ſubjects of their ſeveral departments.

On account of ſimilar circumſtances, the benefit to the public, from the eſtabliſhment of the vitriol works at Preſtonpans, in the extenſion and improvement of many of the arts, cannot now be exactly aſcertained. The vitriolic acid is one of the moſt active agents in chemiſtry, and every diſcovery which renders it cheap and acceſſible to the chemiſt muſt be greatly ſubſervient to the progreſs of that ſcience. By the eſtabliſhment at Preſtonpans, the price of that valuable acid was reduced from ſixteen to four-pence *per* pound. It is to Dr Roebuck, therefore, that chemiſts are indebted for being in poſſeſſion of a cheap acid, to which they can have recourſe in ſo many proceſſes.

But Dr Roebuck's object in the proſecution of that ſcheme, was not ſo much to facilitate the chemiſt's labour, as to render that acid, in a much higher degree than it had formerly been, ſubſervient to many of the practical arts. By rendering the vitriolic acid cheap, great uſe came to be made of it in preparing the muriatic acid, and Glauber's ſalts from common ſalts. Its uſe has been farther extended to many metallic proceſſes; and it has lately been employed in ſeparating ſilver from the clippings of plated copper, the uſe of which is very extenſive.

The project and eſtabliſhment, however, of the iron-works at Carron, the moſt extenſive eſtabliſhment of that kind hitherto in Britain, muſt be conſidered as Dr Roebuck's principal work. The great and increaſing demand for iron in the progreſſive ſtate of arts, manufactures, and commerce in Britain, and the great ſums of money ſent every year to the north of Europe for that article, turned the attention of chemiſts and artiſts to the means of promoting the manufacture of iron, with the view of reducing the importation of it. No perſon has a better founded claim to merit, in this particular, than Dr Roebuck. The ſmelting of iron by pitcoal, it is indeed believed, had been attempted in Britain in the beginning of the laſt century. In the reign of James I. ſeveral patents ſeem to have been granted for making hammered iron by pitcoal, particularly to the Hon. Dud Dudley and Simon Starlevant It does not appear, however, that any progreſs had been made in the manufacture in conſequence of theſe patents. In later times trials have been made by ſo many different perſons, and in ſo many different places in England, nearly about the ſame time, that it may be difficult to ſay where and by whom the firſt attempt was made, particularly as the diſcoverers of ſuch proceſſes wiſhed to conceal the knowledge they had gained as long as they could. But Dr Roebuck was certainly among the firſt who, by means of pitcoal, attempted to refine crude or pig iron, and to make bar iron of it, inſtead of doing it by charcoal, according to the former practice: And he was, without all queſtion, the perſon who introduced that method into Scotland, and firſt eſtabliſhed an extenſive manufacture of it. It is not meant to aſcribe to him the ſole merit of the eſtabliſhment at Carron. No man was ever more ready than he was to do juſtice to the abilities and ſpirit of his friends and partners Meſſrs Garbet, Caddell, &c. who firſt embarked with him in that great undertaking. But ſtill it may be ſaid with truth, that the original project of the iron-works at Carron, the chemical knowledge and experience on which they were founded, the complicated calculations which were previouſly required, the choice of the ſituation, the general conduct and direction of the buildings and machinery, the ſuggeſtion of many occaſional improvements, together with the removal of many unforeſeen obſtacles and difficulties, which occurred in the infant ſtate of that eſtabliſhment, were, in a great meaſure, the work and labour of Dr Roebuck. Nor can it, with the leaſt ſhadow of juſtice, detract from his merit, that a larger capital, and greater expence than was at firſt calculated, have been found neceſſary to bring the works at Carron to their preſent ſtate of perfection; or, that great alterations and improvements have taken place, during the courſe of forty years, in a great and progreſſive eſtabliſhment. In all works of that kind, the expence exceeds the calculation. The undertakers, even of the lateſt iron-works which have been erected, notwithſtanding all the advantages obtained from recent experience, will be ready to acknowledge, that, in theſe reſpects, there is little room to blame the original projector of the firſt eſtabliſhment of that kind in Scotland. But the beſt, and moſt infallible proof of Dr Roebuck's merit, and of the ſound principles on which theſe works were eſtabliſhed, is the preſent proſperous ſtate of that eſtabliſhment, the great perfection of many branches of their manufactures, and particularly the many extenſive and flouriſhing iron-works which have ſince been erected upon the model of Carron in different parts of Scotland, at Cleugh, Clyde, Muirkirk, and Devon. It cannot be denied that all theſe works have ſprung from the eſtabliſhment at Carron, and are ultimately founded upon the knowledge and experience which have been obtained from them; for ſome of the partners, or overſeers of theſe new works, and many of the workmen, have been, at one time or another, connected with that of Carron. Hence, then, it is owing to the projector and promoter of the eſtabliſhment at Carron, that Scotland is, at this moment, benefited to the amount of many hundred thouſand pounds, in working up the raw materials of that manufacture found in the country itſelf, and which, previous to that eſtabliſhment, was of no value whatever. Such are the *preſent*, but ſcarcely any idea can be formed of the *future*, advantages to this country, which may be derived from the extenſion of the iron manufacture. About 60,000 tons of iron have been annually imported into Great Britain for more than twenty years paſt; and though there has been for ſome time about 20,000 tons of bar iron made in Britain by pitcoal, yet the foreign imported iron has ſuffered little or no diminution in quantity. This great conſumption of iron, no doubt, is owing to the various improvements of late years, and the general extenſion throughout all Europe of commerce and the arts. The manufacture of iron muſt therefore continue to increaſe; and Scotland, abounding everywhere in ironſtone, pitcoal, and in command of water for machinery, has the proſpect of obtaining the largeſt ſhare of it.

To the eſtabliſhment of the Carron works, and to the conſequences of that eſtabliſhment, may be aſcribed alſo the exiſtence of other public works in Scotland of great importance and utility. The opening of a communication by water betwixt the Forth and the Clyde had long been projected, and frequently the ſubject of converſation in Scotland, but nothing in fact had been attempted. The eſtabliſhment of the iron-works at Carron ſoon called forth ſufficient intereſt and enterpriſe to bring about the execution of this grand deſign. Some of the partners of the Carron company, foreſeeing the advantages they would derive from ſuch a communication, propoſed, at their own expence, to execute a ſmall canal; and, after taking the preparatory ſteps, actually applied to Parliament to obtain authority for that purpoſe. But the project of the ſmall canal not meeting with the approbation of ſome noblemen and gentlemen in that part of Scotland, they oppoſed the bill, and obliged themſelves to execute a greater canal, which has now been many years finiſhed, and is found to be of the greateſt advantage to the trade and commerce of Scotland. The merit of this undertaking is not meant to be aſcribed to Dr Roebuck, excepting in ſo far as it neceſſarily aroſe from the eſtabliſhment of the Carron company, of which he was the original projector; and it may reaſonably be doubted whether, without that eſtabliſhment, it would have yet taken place. Several other canals have, ſince that time, been executed in different parts of Scotland, and other very important ones are at preſent projected.

The different eſtabliſhments which Dr Roebuck made at Borrowſtounneſs in carrying on the coal and ſalt works there, though ultimately of no advantage to himſelf, were attended, during the courſe of thirty years, with the moſt beneficial effects upon the trade, population, and induſtry of that part of Scotland. They were the means alſo of adding very conſiderably to the public revenue. Previous to the time theſe works fell under Dr Roebuck's management, they produced no advantage either to the proprietor, to the adventurers, or to the public. But by his mode of conducting them upon a more extenſive plan, by opening up new ſeams of coal, and of better quality, he was enabled to export a very conſiderable quantity, to increaſe the quantity of ſalt, and of courſe the revenue ariſing from theſe articles. In theſe works, and in the management of a large farm, Dr Roebuck gave employment to near a thouſand perſons at Borrowſtounneſs and in the neighbourhood.

Nor was it ſolely by the different eſtabliſhments which he projected and executed, but by many other things neceſſarily connected with them, that Dr Roebuck's labours were beneficial to Scotland. Along with them he may be ſaid to have introduced a ſpirit of enterpriſe and induſtry, before that time little known in Scotland, which ſoon pervaded many other departments of labour, and gave birth to many other uſeful projects. He brought from England, then much farther advanced in arts and induſtry, many ingenious and induſtrious workmen, at great expence, who, by their inſtructions and example, communicated and diffuſed ſkill and knowledge to others. At all times Dr Roebuck held out liberal encouragement to riſing genius and induſtrious merit; and ſpared no expence in making trials of improvements and diſcoveries which were connected with the different projects and works which he was carrying on.

Such was the active and uſeful life of Dr Roebuck, a man of no common caſt, who united, in a very high degree, a great number of ſolid and brilliant talents, which, even ſeparately, fall to the lot of but few individuals. Diſtinguiſhed by an ardent and inventive mind, delighting in purſuit and inveſtigation, always aſpiring at ſomething beyond the preſent ſtate of ſcience and art, and eagerly preſſing forward to ſomething better or more perfect, he thus united energies the moſt powerful with the moſt unwearied and perſevering induſtry. To that peculiarity of imagination, ſo fitted for ſcientific purſuit, which readily combines and unites, which ſteadily preſerves its combinations before the eye of the mind, and quickly diſcovers relations, reſults, and conſequences, was added, in his character, great promptitude and firmneſs in deciſion. Strongly and early impreſſed with the great importance of applying chemical and phyſical knowledge to the uſeful arts, to the melioration of civil life, he never loſt ſight of that favourite view, and diſcovered great boldneſs and reſource in the means and expedients which he adopted to promote it. He was certainly maſter of the beſt philoſophy of chemiſtry known in the earlier parts of his life; and though in every ſtage of that ſcience he marked and underſtood the progreſs of the diſcoveries, yet his numerous avocations did not permit him to follow them out by experimental proceſſes of his own. Upon that, and indeed almoſt upon every ſubject, his mind readily graſped the moſt uſeful and ſubſtantial points, and enabled him to throw out ſuch hints and hypotheſes as marked him the man of genius.

During the courſe of a regular education, both at Edinburgh and at Leyden, Dr Roebuck ſtudied the claſſic authors with great attention, particularly the hiſtorical and political parts of their works. Upon theſe ſubjects he had read much, ſelected with judgment, and was well acquainted with the facts and philoſophy of ancient governments. This taſte he carried with him, and improved in every period of his life, and in every ſituation. It abundantly rewarded him for the earneſtneſs and diligence with which it had been acquired. It became his favourite reſource, and indeed one of the chief enjoyments of his life. Poſſeſſing the happy talent of turning his mind from ſerious and fatiguing, to elegant and recreating purſuits, it was no uncommon thing with him to return from the laboratory or the coalpit, and draw relaxation or relief from ſome one or other of the various ſtores of claſſical learning.

No man was better acquainted with the hiſtory of his country than Dr Roebuck, or more admired and revered the conſtitution of its government. By temper and education he was a Whig, and at all times entered with great warmth into the political diſputes and controverſies which agitated parties in the different periods of his life. If the natural warmth of his temper, and his enthuſiaſm on theſe ſubjects, led him, on ſome occaſions, beyond the bounds of candid argumentation, his quick ſenſe of decorum, and his perfect habits of good manners, produced an immediate atonement, and reſtored the rights of elegant and poliſhed converſation.

The general acquaintance which Dr Roebuck had acquired with natural and experimental philoſophy, together with his claſſical and political knowledge, rendered him an agreeable companion to the learned almoſt of every department, and procured him the attachment and friendſhip of many of the firſt literary characters in Britain. With his friend Dr Black he lived till his death in cloſe habits of intimacy; and he often acknowledged, with much frankneſs, the advantages which he derived, in his various purſuits, from a free and unreſerved communication with that eminent chemiſt.

The amiable diſpoſitions of ſenſibility, humanity, and generoſity, which ſtrongly marked his character, in the general intercourſe of ſociety, were peculiarly preſerved and exerciſed in the boſom of his family, and in the circle of his friends. In the various relations of huſband, father, friend, or maſter, and in the diſcharge of the reſpective duties ariſing from them, it would not be eaſy to do juſtice to his character, or to determine in which of them he moſt excelled ; nor muſt it be forgot, for it reflected much honour on his benevolent heart, that his workmen not only found him at all times a kind and indulgent maſter, but many of them, when their circumſtances required it, a ſkilful and compaſſionate phyſician, who cheerfully viſited the humbleſt receſſes of poverty, and who attached them to his ſervice by multiplied acts of generoſity and kindneſs.

ROEMER (Olaus), a noted Daniſh aſtronomer and mathematician, was born at Arhuſen in Jutland, 1644; and at 18 years of age was ſent to the univerſity of Copenhagen. He applied aſſiduouſly to the ſtudy of the mathematics and aſtronomy, and became ſo expert in thoſe ſciences, that when Picard was ſent by Louis the XIV. in 1671, to make obſervations in the north, he was greatly ſurpriſed and pleaſed with him. He engaged him to return with him to France, and had him preſented to the king, who honoured him with the dauphin as a pupil in mathematics, and ſettled a penſion upon him. He was joined with Picard and Caſſini, in making aſtronomical obſervations; and in 1672 he was admitted a member of the Academy of Sciences.

During the ten years he reſided at Paris, he gained great reputation by his diſcoveries; yet it is ſaid he complained afterwards, that his coadjutors ran away with the honour of many things which belonged to him. Here it was that Roemer, firſt of any one, found out the velocity with which light moves, by means of the eclipſes of Jupiter's ſatellites. He had obſerved for many years, that when Jupiter was at his greateſt diſtance from the earth where he could be obſerved, the emerſions of his firſt ſatellite happened conſtantly 15 or 16 minutes later than the calculation gave them. Hence he concluded, that the light reflected by Jupiter took up this time in running over the exceſs of diſtance; and conſequently that it took up 16 or 18 minutes in running over the diameter of the earth's orbit, and 8 or 9 in coming from the ſun to us, provided its velocity was nearly uniform. This diſcovery had at firſt many oppoſers; but it was afterwards confirmed by Dr Bradley in the moſt ingenious and beautiful manner.

In 1681 Roemer was recalled to his native country by Chriſtian the Vth King of Denmark, who made him profeſſor of aſtronomy at Copenhagen. The king employed him alſo in reforming the coin and the architecture, in regulating the weights and meaſures, and in meaſuring and laying out the high roads throughout the kingdom; offices which he diſcharged with the greateſt credit and ſatisfaction. In conſequence he was honoured by the king with the appointment of chancellor of the exchequer and other dignities. Finally, he became counſellor of ſtate, and burgomaſter of Copenhagen, under Frederic the IV. the ſucceſſor of Chriſtian. Roemer was preparing to publiſh the reſult of his obſervations, when he died the 19th of September 1710, at 66 years of age: but this loſs was ſupplied by Horrebow, his diſciple, then profeſſor of aſtronomy at Copenhagen, who publiſhed, in 4to, 1753, various obſervations of Roemer, with his method of obſerving, under the title of *Baſis Aſtronomiæ*.—He had alſo printed various aſtronomical obſervations and pieces, in ſeveral volumes of the Memoirs of the Royal Academy of Sciences at Paris, of the inſtitution of 1666, particularly vol. 1. and 10. of that collection.

ROLLOCK (Robert), the firſt principal of the college of Edinburgh, was the ſon of David Rollock of *Poo houſe*, or, as it is now written, *Powis*, in the neighbourhood of Stirling. He was born in 1555; and learned the rudiments of the Latin tongue under one Mr Thomas Buchanan, who kept, ſays Archbiſhop Spottiſwood, a famous ſchool at that time, and was, according to Dr Mackenzie, one of the moſt eminent grammarians in Scotland. Where Mr Buchanan kept his ſchool, neither of theſe authors has informed us.

From ſchool Mr Rollock was ſent, we know not in what year, to the univerſity of St Andrews, and admitted a ſtudent in St Salvator's college. His progreſs in the ſciences, which were then taught, was ſo great and ſo rapid, that he had no ſooner taken his degree of M. A. than he was choſen a profeſſor of philoſophy, and immediately began to read lectures in St Salvator's college. This muſt have been at a very early period of life; for he quitted St Andrews in the year 1583, when, according to Mackenzie, he had taught philoſophy for ſome time in that univerſity.

Not long before this period, the magiſtrates of Edinburgh having petitioned the king to erect a univerſity in that city, he granted them a charter under the great ſeal, allowing them all the privileges of a univerſity; and the college being built in 1582, they made choice of Mr Rollock to be their principal and profeſſor of divinity.

At what time he was admitted into holy orders, by whom he was ordained, or indeed whether he ever was ordained, has been the ſubject of ſome acrimonious controverſy; but it is a controverſy which we ſhall not revive; for, conſidering the manner in which orders were then conferred in Scotland, the queſtion in debate is of very little importance. It is certain that he became famous in the univerſity, and among his countrymen in general, for his lectures in theology, and for the perſuaſive power of his preaching; for Calderwood aſſures us, that, in 1589, he and Mr Robert Bruce, another popular orator, made the Earl of Bothwel ſo ſenſible of his ſinful and vitious courſes, that, upon the 9th of November, his lordſhip humbled himſelf upon his knees in the eaſt church in the forenoon, and in the high church in the afternoon, confeſſing before the people, with tears in his eyes, his diſſolute and licentious life, and promiſing to prove, for the future, another man.

In the year 1593, Principal Rollock and others were appointed by the ſtates of parliament to confer with the popiſh lords; and in the next year he was one of thoſe who, by the appointment of the general aſſembly of the church, met at Edinburgh in the month of May, and preſented to his majeſty a paper, entitled, *The dangers which, through the impunity of* EXCOMMUNICATED PAPISTS, TRAFFICKERS WITH THE SPANIARDS, *and other enemies of the religion and eſtate, are imminent to the true religion profeſſed within this realm, his Majeſty's perſon, crown, and liberty of this our native country.* His zeal againſt Papiſts was indeed ardent; and he ſeems to have adopted that judaical doctrine, which was embraced in ſome degree by all the reformers, that it is the duty of the civil magiſtrate to puniſh idolatry with death.

In the year 1595 he was nominated one of the commiſſioners for the viſitation of colleges. Theſe comllock,

miſſioners were empowered to viſit all the colleges in the kingdom, to inquire into the doctrine and life of the ſeveral maſters, the diſcipline uſed by them, the ſtate of their rents and living, and to make their report to the next aſſembly.

In 1596, the factious behaviour of ſome of the miniſters having drawn upon them the juſt reſentment of the king, our principal was employed, on account of his moderation, to ſoften that reſentment, and to turn his majeſty's wrath againſt the *Papiſts!* In the year 1597, he was choſen moderator of the General Aſſembly—the higheſt dignity in the Scottiſh church; and he had the influence to get ſome great abuſes redreſſed. Being one of fourteen miniſters appointed by this aſſembly to take care of the affairs of the church, the firſt thing which he did was to procure an act of the legiſlature, reſtoring to the prelates their ſeats in parliament. He had here occaſion for all his addreſs; for he had to reconcile to this meaſure, not only ſuch of the miniſters as abhorred all kinds of ſubordination in the church, but likewiſe many of the lay lords, who were not delighted with the proſpect of ſuch aſſociates in parliament as the Scotch prelates were at that period (A).

Though he ſpent the greater part of his life in conducting the affairs of the church, we have the authority of Spottiſwood for ſaying, that he would have preferred retirement and ſtudy. To the buſtle of public life, eſpecially at that period of faction and fanaticiſm, his feeble conſtitution was not equal; and his inclination would have confined him to his college and his library. He was dreadfully afflicted with the ſtone; the torments of which he long bore with the fortitude and reſignation of a Chriſtian. He died at Edinburgh on the 28th of February 1598, in the 43d year of his age; having exhorted his brethren, with his dying breath, to carry themſelves more dutifully to their gracious ſovereign.

His works are, 1. A Commentary on the Firſt Book of Theodore Beza's Queſtions. 2. A Commentary on St Paul's Epiſtle to the Epheſians, 4to, Edinburgh, 1590. 3. A Commentary on the Prophet Daniel, 4to, Edinburgh, 1591. 4. A Logical Analyſis of St Paul's Epiſtle to the Romans, 8vo, Edinburgh, 1594. 5. Some Queſtions and Anſwers concerning the Covenant of Grace and the Sacraments, 8vo, Edinburgh, 1596. 6. A Treatiſe of Effectual Calling, 8vo, Edinburgh, 1597. 7. A Commentary on the Epiſtles of St Paul to the Theſſalonians and Philemon, 8vo, Geneva, 1597. 8. A Commentary upon Fifteen Select Pſalms, 8vo, Geneva, 1598. 9. A Commentary on the Goſpel of St John, with a harmony of the Four Evangeliſts upon the Death, Reſurrection, and Aſcenſion of Jeſus Chriſt, 8vo, Geneva, 1599. 10. Certain Sermons on Several Places of St Paul's Epiſtles, 8vo, Edinburgh, 1598. 11. A Commentary upon the Epiſtle to the Coloſſians, 8vo, publiſhed at Geneva, 1602. 12. A Logical Analyſis of the Epiſtle to the Hebrews, 8vo, Edinburgh, 1605. 13. A Logical Analyſis of the Epiſtle to the Galatians, 8vo, London, 1602. 14. A Commentary upon the Two Firſt Chapters of the Firſt Epiſtle of St Peter, 8vo, London, 1603. 15 and 16. A Treatiſe of Juſtification, and another of Excommunication, both in 8vo, London, 1604. All theſe works, except the ſermons, are in Latin. That Principal Rollock was held in high eſtimation in the college over which he preſided, is made at leaſt probable by the following epitaph:

Te Rolloce, extincto, Urbs mœſta, Academia mœſta eſt;
Et tota exequiis Scotia mœſta tuis.
Uno in te nobis dederat Deus omnia, in uno
Te Deus eripuit omnia quæ dederit.

Roſes, Rota.

ROSES Otter (or eſſential oil) of. In the *Encyclopædia*, under the word Roses, we have given one receipt for making this very high-priced perfume; and we ſhall here give another; which, whether it be as effectual or not, is at leaſt ſimpler and leſs expenſive. It is by an officer who was in the country where the *Otter* is prepared, and who aſſiſted in making it himſelf; and is as follows:

"Take a very large glazed earthen or ſtone jar, or a large clean wooden caſk; fill it with the leaves of the flowers of roſes, very well picked, and freed from all ſeeds and ſtalks; pour on them as much pure ſpring water as will cover them, and ſet the veſſel in the ſun, in the morning at ſun-riſe, and let it ſtand till the evening, then take it into the houſe for the night; expoſe it, in this manner, for ſix or ſeven ſucceſſive days, and, at the end of the third or fourth day, a number of particles, of a fine yellow oily matter, will float on the ſurface, which, in two or three days more, will gather into a ſcum, which is the otter of roſes. This is taken up by ſome cotton, tied to the end of a piece of ſtick, and ſqueezed with the finger and thumb into a ſmall phial, which is immediately well ſtopped; and this is repeated for ſome ſucceſſive evenings, or while any of this fine eſſential oil riſes to the ſurface of the water."

Dr Donald Monro, who communicated this receipt to the Royal Society of Edinburgh, ſays, that he has been informed, that ſome few drops of this eſſential oil have more than once been collected by diſtillation in London, in the ſame manner as the eſſential oils of other plants.

ROTA Ariſtotelica, or *Ariſtotle's Wheel*, denotes a celebrated problem in mechanics, concerning the mo-

---

(A) The conſtitution of the Scotch church was, at this period, a ſtrange ſyſtem of inconſiſtency and contradiction. It was, in fact, preſbyterian; for eccleſiaſtical diſcipline was adminiſtered then, as at preſent, by kirk-ſeſſions, preſbyteries, and general aſſemblies; and there was not a reformed biſhop in the kingdom. Whether provincial ſynods were then in uſe, the writer of this note does not at preſent recollect. The king, however, who was meditating the reſtoration of epiſcopacy, conferred the eſtates, or part of the eſtates, belonging to the different ſees, upon the moſt eminent parochial miniſters, and dignified them with the title of biſhops; though it does not appear that they had any juriſdiction over their brethren; and though they were certainly not *ex officio* ſo much as moderators of the preſbyteries within the bounds of which their churches were ſituated. Theſe were the men for whom Mr Rollock exerted himſelf to obtain ſeats in the parliament.

tion or rotation of a wheel about its axis; ſo called becauſe firſt noticed by Ariſtotle.

The difficulty is this. While a circle makes a revolution on its centre, advancing at the ſame time in a right line along a plane, it deſcribes, on that plane, a right line which is equal to its circumference. Now if this circle, which may be called the deferent, carry with it another ſmaller circle, concentric with it, like the nave of a coach wheel; then this little circle, or nave, will deſcribe a line in the time of the revolution, which ſhall be equal to that of the large wheel or circumference itſelf; becauſe its centre advances in a right line as faſt as that of the wheel does, being in reality the ſame with it

The ſolution given by Ariſtotle, is no more than a good explication of the difficulty.

Galileo, who next attempted it, has recourſe to an infinite number of infinitely little vacuities in the right line deſcribed by the two circles; and imagines that the little circle never applies its circumference to thoſe vacuities; but in reality only applies it to a line equal to its own circumference; though it appears to have applied it to a much larger. But all this is nothing to the purpoſe.

Tacquet will have it, that the little circle. making its rotation more ſlowly than the great one, does on that account deſcribe a line longer than its own circumference; yet without applying any point of its circumference to more than one point of its baſe. But this is no more ſatisfactory than the former.

After the fruitleſs attempts of ſo many great men, M. Dortous de Meyran, a French gentleman, had the good fortune to hit upon a ſolution. which he ſent to the Academy of Sciences; where being examined by Meſſ. de Louville and Soulmon, appointed for that purpoſe, they made their report that it was ſatisfactory. The ſolution is to this effect:

The wheel of a coach is only acted on. or drawn in a right line; its rotation or circular motion ariſes purely from the reſiſtance of the ground upon which it is applied. Now this reſiſtance is equal to the force which draws the wheel in the right line, inaſmuch as it defeats that direction; of conſequence the cauſes of the two motions, the one right and the other circular, are equal. And hence the wheel deſcribes a right line on the ground equal to its circumference.

As for the nave of the wheel, the caſe is otherwiſe. It is drawn in a right line by the ſame force as the wheel; but it only turns round becauſe the wheel does ſo, and can only turn in the ſame time with it. Hence it follows, that its circular velocity is leſs than that of the wheel, in the ratio of the two circumferences; and therefore its circular motion is leſs than the rectilinear one. Since then it neceſſarily deſcribes a right line equal to that of the wheel, it can only do it partly by ſliding, and partly by revolving, the ſliding part being more or leſs as the nave itſelf is ſmaller or larger.—*Hutton's Dictionary*.

ROWNING (John), an ingenious Engliſh mathematician and philoſopher, was fellow of Magdalen College, Cambridge, and afterwards Rector of Anderby in Lincolnſhire, in the gift of that Society. He was a conſtant attendant at the meetings of the Spalding Society, and was a man of a great philoſophical habit and turn of mind, though of a cheerful and companionable diſpoſition. He had a good genius for mechanical contrivances in particular. In 1738 he printed at Cambridge, A Compendious Syſtem of Natural Philoſophy, in 2 vols 8vo; a very ingenious work, which has gone through ſeveral editions. He had alſo two pieces inſerted in the Philoſophical Tranſactions, viz. 1. A Deſcription of a Barometer, wherein the Scale of Variation may be increaſed at pleaſure; vol. 38. p. 39. And, 2. Directions for making a Machine for finding the Roots of Equations univerſally, with the Manner of uſing it; vol. 60. p. 240.—Mr Rowning died at his lodgings in Carey-ſtreet, near Lincoln's-Inn Fields, the latter end of November 1771, at 72 years of age.

Though a very ingenious and pleaſant man, he had but an unpromiſing and forbidding appearance: he was tall, ſtooping in the ſhoulders, and of a ſallow downlooking countenance.

ROY-ROYAN, in Bengal, the chief officer in the revenue department, next to the Dewan under the native government.

RUTHERFORD (John, M. D.), one of the illuſtrious founders of the medical ſchool in the univerſity of Edinburgh, was the ſon of the Rev. Mr Rutherford miniſter of Yarrow, in the county of Selkirk, North Britain. He was born on the 1ſt Auguſt 1695, and received the rudiments of his education at the pariſh ſchool of Selkirk; where, from his future proficiency, there is every reaſon to believe that he made a rapid progreſs in the knowledge of the Latin and Greek languages.

After the death of his father, he went to Edinburgh in 1708 or 1710, where, in the univerſity, he applied himſelf to the ſtudy of claſſical literature, mathematics, and natural philoſophy. The celebrated Dr Pitcairn was then ſo highly reſpected for his medical ſkill, that it is not improbable but that a laudable deſire of obtaining a portion of ſimilar fame may have turned the attention of young Rutherford to the ſtudy of medicine. Be that as it may, he engaged himſelf apprentice to Mr Alexander Neſbit, at that time an eminent ſurgeon in Edinburgh, with whom he remained till 1716, when he went to London. There he attended ſome hoſpitals, and the lectures read on anatomy by Dr Douglas, on ſurgery by André, and on materia medica by Strother.

After a year's reſidence in London, he returned to Edinburgh; and having ſettled his affairs in that city, he went to Leyden, which, from the lectures of Boerhaave, was then the moſt celebrated medical ſchool in Europe. In 1719 he went into France, and was at the end of July in that year admitted to the degree of M. D. in the univerſity of Rheims He paſſed the following winter in Paris, chiefly for the ſake of Winſlow's private demonſtrations in anatomy; and in 1720 he returned to Britain.

In 1721 he ſettled as a phyſician in Edinburgh; and ſoon afterwards Drs Rutherford, Sinclair, Plummer, and Innes, purchaſed a laboratory, where they prepared compound medicines. This was an art then but little known in Scotland; and as a commercial ſpeculation, the laboratory muſt therefore have proved very advantageous to the partners. But they had higher objects in view than commerce. They demonſtrated, as far as they were then known, the operations of chemiſtry

Rutherford.

miſtry to a numerous audience; and ſoon afterwards, by the advice of their old maſter Boerhaave, they extended their lectures to the other branches of phyſic. In 1725 they were appointed joint profeſſors in the univerſity; where, we believe, each, for ſome time, read lectures in every department of medical ſcience, anatomy excepted, and carried forward their claſſes in rotation. The anatomical lectures were read by the elder Monro, who had been ſettled a year or two before them in Edinburgh, and whoſe eminence in that department is known to all Europe.

On the death of Dr Innes, a particular branch of medical ſcience was allotted to each of the other three profeſſors. Dr Plummer was appointed profeſſor of chemiſtry and materia medica, Dr Sinclair of the inſtitutes of phyſic, and Dr Rutherford of the practice; and thus was a regular medical ſchool eſtabliſhed in Edinburgh by Monro, Plummer, Sinclair, and Rutherford. The lectures on the inſtitutes and practice of phyſic were then, and for many years afterwards, delivered in Latin; and ſuch was Dr Rutherford's command of that language, that on every thing connected with medicine, he talked in it more fluently than in the language of his country.

Whether it was any improvement in the mode of medical education in Edinburgh to change the language of the lectures from Latin to Engliſh, is perhaps more than queſtionable. We have now diſperſed over the country a number of illiterate men, practiſing as ſurgeons, and even as phyſicians, who never could have boaſted of having gone through a regular courſe of medical inſtruction, had the lectures continued to be delivered in the language in which they were begun. Foreigners, too, would not have been under the neceſſity of learning a new language, before they could enter on the ſtudies, for the cultivation of which they came to Scotland; and though the medical claſſes might not have been ſo crowded perhaps as at preſent, the individuals compoſing them would have been at leaſt as reſpectable. Whether Dr Rutherford reaſoned in this way we know not; but he continued to lecture in Latin as long as he filled the practical chair

About the year 1748 he introduced a very great improvement in the courſe of medical education. Senſible that abſtract lectures on the ſymptoms and the mode of treating various diſeaſes, of which the ſtudents know little but the names, could ſcarcely be of any benefit, he had for ſome time encouraged his pupils to bring patients to him on Saturday, when he inquired into the nature of their diſeaſes, and preſcribed for them in the preſence of the claſs. This gave riſe to the courſe of *clinical* lectures; the utility of which was ſo obvious, that it was enacted, by a decree of the ſenate of the univerſity, that no man ſhould be admitted to an examination for his doctor's degree, who had not attended thoſe lectures; to which an excellent hoſpital, then lately erected (ſee EDINBURGH, in the *Encyclopædia*), gave the profeſſors every opportunity of doing ample juſtice. To men who mean to live by the practice of phyſic, and have no inordinate ambition to raiſe their fame by fanciful theories, this is perhaps the moſt valuable courſe of lectures that is given in Edinburgh; and if ſo, Dr Rutherford muſt be conſidered as one of the greateſt benefactors of the medical ſchool.

To untried theories in phyſic he was indeed no friend; and we have heard a favourite and very able pupil of his, who knew him well, and reſpected him highly, affirm that, to his knowledge, Dr Rutherford retained his profeſſorſhip longer than he otherwiſe would have choſen to do; merely that he might keep out a ſpeculatiſt, whom he knew to be aſpiring to the practical chair. Finding at laſt in the late Dr John Gregory (ſee GREGORY, *Encycl.*) a ſucceſſor entirely to his mind, he reſigned to him in 1765, after having taught medicine in its different departments for upwards of forty years. He lived, after this period, loved by his friends. and revered by many eminent phyſicians, who had been his pupils, till 1779, when he died in Edinburgh, where he had ſpent the greater part of his life, in the 84th year of his age.

S.

Saccharometer.

SACCHAROMETER, the name given, by Mr Richardſon of Hull, to an inſtrument invented by him for aſcertaining the value of worts, and the ſtrength of different kinds of malt liquors. In plain Engliſh, the name ſignifies a *meaſurer of ſweetneſs*; and therefore, if etymology were to be attended to, the inſtrument ſhould be employed merely as a meaſurer of the ſweetneſs of worts. It is in fact beſt adapted for this purpoſe, being merely an hydrometer contrived to aſcertain the ſpecific gravity of worts, or rather to compare the weight of worts with that of equal quantities of the water employed in the brewery where the inſtrument is uſed.

The principle which ſuggeſted the invention of the inſtrument to Mr Richardſon is as follows: The menſtruum or water, employed by the brewer, becomes heavier or more denſe by the addition of ſuch parts of the materials as have been diſſolved or extracted by, and thence incorporated with it: the operation of boiling, and its ſubſequent cooling, ſtill adds to the denſity of it by evaporation; ſo that when it is ſubmitted to the action of fermentation, it is more denſe than at any other period.

In paſſing through this operation of nature, a remarkable alteration takes place. The fluid no ſooner begins to ferment than its denſity begins to diminiſh; and as the fermentation is more or leſs perfect, the fermentable matter, whoſe acceſſion has been traced by the increaſe of denſity, becomes more or leſs attenuated; and in lieu of every particle thus attenuated, a ſpirituous particle, of leſs denſity than water, is produced: ſo that when the liquor is again in a ſtate of quietude, it is ſo much ſpecifically lighter than it was before, as the action of fermentation has been capable of attenuating the component parts of its acquired denſity; and, indeed, were it practicable to attenuate the whole, the liquor would become lighter or leſs denſe than water; becauſe the quantity of ſpirit produced from, and occupying the place of the fermentable matter, would diminiſh the denſity of the water in a degree bearing ſome proportion to that in which the latter had increaſed it.

From theſe facts, the reader, who is acquainted with hydroſtatical principles, will be able to conſtruct a saccharometer for himſelf. Brewers, who are ſtrangers to theſe principles, we muſt refer to Mr Richardſon's book for details, which our limits permit us not to give.

SAGITTA, in aſtronomy, the *Arrow* or *Dart*, a conſtellation of the northern hemiſphere near the eagle, and one of the 48 old aſteriſms.

SAHARA, or, as it is ſometimes written, ZAARA, the Great Deſert, is a vaſt ocean of ſand in the interior parts of Africa, which, with the leſſer deſerts of Bornou, Bilma, Barca, Sort, &c. is equal in extent to about one half of Europe. If the ſand be conſidered as the ocean, the Sahara has its gulphs and bays, as alſo its iſlands, or OASES, fertile in groves and paſtures, and in many inſtances containing a great population, ſubject to order and regular government.

The great body, or weſtern diviſion of this ocean, compriſed between Fezzan and the Atlantic, is no leſs than 50 caravan journeys acroſs, from north to ſouth; or from 750 to 800 G. miles; and double that extent in length: without doubt the largeſt deſert in the world. This diviſion contains but a ſcanty portion of iſlands (or oaſes), and thoſe alſo of ſmall extent: but the eaſtern diviſion has many, and ſome of them very large. Fezzan, Gadamis, Taboo, Ghanat, Agadez, Augela, Berdoa, are amongſt the principal ones: beſides which, there are a vaſt number of ſmall ones. In effect, this is the part of Africa alluded to by Strabo, when he ſays from *Cneius Piſo*, that Africa may be compared to a leopard's ſkin.

From the beſt inquiries that Mr Park could make when a kind of captive among the Moors at Ludamar, the Weſtern Deſert, he ſays, may be pronounced almoſt deſtitute of inhabitants; except where the ſcanty vegetation, which appears in certain ſpots, affords paſturage for the flocks of a few miſerable Arabs, who wander from one well to another. In other places, where the ſupply of water and paſturage is more abundant, ſmall parties of the Moors have taken up their reſidence. Here they live, in independent poverty, ſecure from the tyrannical government of Barbary. But the greater part of the deſert, being totally deſtitute of water, is ſeldom viſited by any human being; unleſs where the trading caravans trace out their toilſome and dangerous route acroſs it. In ſome parts of this extenſive waſte, the ground is covered with low ſtunted ſhrubs, which ſerve as land marks for the caravans, and furniſh the camels with a ſcanty forage. In other parts, the diſconſolate wanderer, wherever he turns, ſees nothing around him but a vaſt interminable expanſe of ſand and ſky; a gloomy and barren void, where the eye finds no particular object to reſt upon, and the mind is filled with painful apprehenſions of periſhing with thirſt. Surrounded by this dreary ſolitude, the traveller ſees the dead bodies of birds, that the violence of the wind has brought from happier regions; and, as he ruminates on the fearful length of his remaining paſſage, liſtens with horror to the voice of the driving blaſt; the only ſound that interrupts the awful repoſe of the deſert.

The few wild animals which inhabit theſe melancholy regions, are the antelope and the oſtrich; their ſwiftneſs of foot enabling them to reach the diſtant watering-places. On the ſkirts of the deſert, where the water is more plentiful, are found lions, panthers, elephants, and wild boars.

Of domeſtic animals, the only one that can endure the fatigue of croſſing the deſert is the camel. It is therefore the only beaſt of burden employed by the trading caravans which traverſe, in different directions, from Barbary to Nigritia. The fleſh of this uſeful and docile creature, though to our author's taſte it was dry and unſavory, is preferred by the Moors to all others. The milk of the female, he ſays, is in univerſal eſteem, and is indeed pleaſant and nutritive.

That the deſert has a dip towards the eaſt, as well as the ſouth, ſeems to be proved by the courſe of the Niger. Moreover, the higheſt points of North Africa, that is to ſay, the mountains of Mandinga and Atlas, are ſituated very far to the weſt. The deſert, for the moſt part, abounds with ſalt. But we hear of ſalt mines only in the part contiguous to Nigritia, from whence ſalt is drawn for the uſe of thoſe countries, as well as of the Mooriſh ſtates adjoining; there being no ſalt in the Negro countries ſouth of the Niger. There are ſalt lakes alſo in the the eaſtern part of the deſert.

SAI, a large town on the banks of the Niger, or at leaſt very near to that river, which Mr Park ſays ſtrongly excited his curioſity. It is completely ſurrounded by two very deep trenches, at about two hundred yards diſtant from the walls. On the top of the trenches are a number of ſquare towers; and the whole has the appearance of a regular fortification. Inquiring into the origin of this extraordinary entrenchment, our author learned from two of the towns people the following particulars; which, if true, furniſh a mournful picture of the enormities of African wars:

About fifteen years before our traveller viſited Sai, when the King of Bambarra deſolated Maniana, the Dooty of Sai had two ſons ſlain in battle, fighting in the king's cauſe. He had a third ſon living: and when the king demanded a further reinforcement of men, and this youth among the reſt, the Dooty refuſed to ſend him This conduct ſo enraged the king, that when he returned from Maniana, about the beginning of the rainy ſeaſon, and found the Dooty protected by the inhabitants, he ſat down before Sai with his army, and ſurrounded the town with the trenches which had attracted our author's notice. After a ſiege of two months, the towns-people became involved in all the horrors of famine; and whilſt the king's army were feaſting in their trenches, they ſaw with pleaſure the miſerable inhabitants of Sai devour the leaves and bark of the Bentang tree that ſtood in the middle of the town. Finding, however, that the beſieged would ſooner periſh than ſurrender, the king had recourſe to treachery. He promiſed, that if they would open the gates, no perſon ſhould be put to death, nor ſuffer any injury, but the Dooty alone. The poor old man determined to ſacrifice himſelf, for the ſake of his fellow-citizens, and immediately walked over to the king's army, where he was put to death. His ſon, in attempting to eſcape, was caught and maſſacred in the trenches; and the reſt of the towns-people were carried away captives, and ſold as ſlaves to the different Negro traders.

traders. Sai is placed by Major Rennel in 14° N. Lat. and 3° 7′ Weſt. Long.

SAINT CATHERINE, a Portugueſe iſland in the South Sea, not far diſtant from the coaſt of Brazil. It was viſited by La Perouſe, who aſcertained it to lie between 27° 19′ 10″, and 27° 49′ N. Lat. and its moſt northerly point to be in 49° 49′ longitude weſt from Paris Its breadth from eaſt to weſt is only two leagues; and it is ſeparated from the main land by a channel only 200 toiſes broad. On the point which ſtretches furtheſt into this channel is ſituated the city of Noſtra-Senora del Deſtero, the capital of the government, and the place of reſidence of the governor. It contains at moſt 3000 ſouls, and about 400 houſes. Its appearance is exceedingly pleaſant. According to Frezier's account, this iſland ſerved, in 1712, as a retreat to vagabonds, who made their eſcape from different parts of the Brazils; who were only nominal ſubjects of Portugal, and who acknowledged no authority whatever. The country is ſo fertile, that they were able to ſubſiſt without any ſuccour from the neighbouring colonies: and they were ſo deſtitute of money, that they could neither tempt the cupidity of the governor-general of the Brazils, nor inſpire him with any deſire of ſubduing them. The ſhips that touched at the iſland gave them in exchange for their proviſions nothing but clothes and ſhirts, of which they were in the utmoſt want. It was not till about 1740 that the court of Liſbon eſtabliſhed a regular government in the iſland of St Catherine, and the parts of the continent adjacent. This government extends ſixty leagues north and ſouth from the river San Franciſco to Rio Grande; its population being about 20,000 ſouls; but there are ſo great a number of children in the different families, that probably it will ſoon be much more conſiderable. The ſoil is exceedingly fertile, and produces all ſorts of fruit, vegetables, and corn, almoſt ſpontaneouſly. It is covered with trees of everlaſting green; but they are ſo interwoven with briars and creeping plants, that it is impoſſible to get through the foreſts otherwiſe than by opening a path with a hatchet. Danger is beſides to be apprehended from ſnakes, whoſe bite is mortal. The habitations, both on the iſland and continent, are all cloſe to the ſea ſide. The woods that ſurround them are delightfully fragrant, owing to the great number of orange trees and other odoriferous trees and ſhrubs that they contain. But, notwithſtanding all theſe advantages, the country is very poor, and totally deſtitute of manufactured commodities, ſo that the peaſants are almoſt naked, or elſe covered with rags. Their ſoil, which is very fit for the cultivation of ſugar, remains unproductive for the want of ſlaves, whom they are not rich enough to purchaſe. The whale fiſhery is very ſucceſsful; but it is the property of the crown, and is farmed by a company at Liſbon, which has three conſiderable eſtabliſhments upon the coaſt. Every year they kill about 400 whales; the produce of which, as well oil as ſpermaceti, is ſent to Liſbon by the way of Rio-Janeiro. The inhabitants are idle ſpectators of this fiſhery, from which they derive not the ſmalleſt advantage. La Perouſe gives a very amiable picture, however, of their hoſpitality to ſtrangers.

SALT. See CHEMISTRY-*Index*, in this *Suppl.*

Salt Mines, Saltpetre.

SALT-Mines of *Vielicza*, near Cracow in Poland, are very extraordinary caverns; for a deſcription of which we referred, in the article SALT (*Encycl.*) to M. Barniard in the *Journal de Phyſique* for the year 1786. Some of our readers have complained of this, and requeſted an account of them in the *Supplement*. With this requeſt we ſhall comply, by giving them Mr Wraxall's deſcription of theſe caverns *.

"After being let down (ſays he) by a rope to the depth of 230 feet, our conductors led us through galleries, which, for loftineſs and breadth, ſeemed rather to reſemble the avenues to ſome ſubterranean palace, than paſſages cut in a mine. They were perfectly dry in every part, and terminated in two chapels compoſed entirely of ſalt, hewn out of the ſolid maſs The images which adorn the altars, as well as the pillars and ornaments, were all of the ſame tranſparent materials; the points and ſpars of which, reflecting the rays of light from the lamps which the guides held in their hands, produced an effect equally novel and beautiful. Deſcending lower into the earth by means of ladders, I found myſelf in an immenſe hall or cavern of ſalt, many hundred feet in height, length, and dimenſions, the floor and ſides of which were cut with exact regularity. A thouſand perſons might dine in it without inconvenience, and the eye in vain attempted to trace or define its limits. Nothing could be more ſublime than this vaſt ſubterranean apartment, illuminated by flambeaux, which faintly diſcover its prodigious magnitude, and leave the imagination at liberty to enlarge it indefinitely. After remaining about two hours and a half under ground, I was drawn up again in three minutes with the greateſt facility."

SALTPETRE (ſee *Nitre*, CHEMISTRY-*Index*, in this *Suppl.*) is an article of ſo much importance, and ſometimes ſo difficult to be had, that it is wonderful more attention is not beſtowed in endeavouring to diſcover ſome eaſy method to increaſe the quantity. Such a method has been long practiſed by the farmers of Appenzell in Switzerland. In ſo hilly a country, moſt houſes and ſtables are built on ſlopes, one ſide of the edifice reſting on the hill, and the other being ſupported by two ſtrong poſts, elevated two or three feet above the ground; ſo that the air has a free current under the building. Immediately under the ſtable a pit is dug, uſually occupying both in breadth and length the whole ſpace of ground covered by the building; and inſtead of the clayey earth which is dug out, the pit is filled up with ſandy ſoil. This is the whole proceſs, and all the reſt is done by nature. The animal water, which is continually oozing through the planks of the floor, having drenched the earth contained in the pit for the ſpace of two or three years, the latter is emptied, and the ſaltpetre is refined and prepared in the uſual manner.

That manner, however, is not the beſt; and the French chemiſts, during the inceſſant wars occaſioned by the revolution, have, for the ſake of ſupplying their armies with gunpowder, turned their attention to the beſt method of refining ſaltpetre. The following are directions given for this purpoſe by Chaptal, Champy, and Bonjour.

The crude ſaltpetre is to be beaten ſmall with mallets, in order that the water may more eaſily attack every part of the maſs. The ſaltpetre is then to be put into tubs, five or ſix hundred pounds in each tub. Twenty *per cent.* of water is to be poured into each tub, and

---

* *Memoirs of the Courts of Berlin, Dreſden, Warſaw, and Vienna.*

and the mixture well ſtirred. It muſt be left to macerate or digeſt until the ſpecific gravity of the fluid ceaſes to augment. Six or ſeven hours are ſufficient for this firſt operation, and the water acquires the denſity of between 25 and 35 degrees. (Sp. gr. 1.21, and 1.306, aſcertained by Baumé's hydrometer. See Hydrometer, *Suppl.*

The firſt water muſt then be poured off, and a ſecond portion of water muſt be poured on the ſame ſaltpetre amounting to 10 *per cent.*; after which the mixture muſt be ſtirred up, ſuffered to macerate for one hour, and the fluid drawn or poured off.

Five *per cent.* of water muſt then be poured on the ſaltpetre; and after ſtirring the whole, the fluid muſt be immediately drawn off.

When the water is drained from the ſaltpetre, the ſalt muſt be thrown into a boiler containing 50 *per cent.* of boiling water. When the ſolution is made, it will mark between 66 and 68 degrees of the hydrometer. (Sp. gr. 1.848, and 1.898.)

The ſolution is to be poured into a proper veſſel, where it depoſits by cooling about two-thirds of the ſaltpetre originally taken. The precipitation begins in about half an hour, and terminates in between four and ſix hours. But as it is of importance to obtain the ſaltpetre in ſmall needles, becauſe in this form it is more eaſily dried, it is neceſſary to agitate the fluid during the whole time of the cryſtallization. A ſlight motion is communicated to this liquid maſs by a kind of rake; in conſequence of which the cryſtals are depoſited in very ſlender needles.

In proportion as the cryſtals fall down, they are ſcraped to the borders of the veſſel, whence they are taken with a ſkimmer, and thrown to drain in baſkets placed on treſſels, in ſuch a manner that the water which paſſes through may either fall into the cryſtallizing veſſel, or be received in baſons placed underneath.

The ſaltpetre is afterwards put into wooden veſſels in the form of a mill-hopper or inverted pyramid with a double bottom. The upper bottom is placed two inches above the lower on wooden ledges, and has many ſmall perforations through which water may paſs to the lower bottom, which likewiſe affords a paſſage by one ſingle aperture. A reſervoir is placed beneath. The cryſtallized ſaltpetre is waſhed in theſe veſſels with 5 *per cent.* of water; which water is afterwards employed in the ſolution of ſaltpetre in ſubſequent operations.

The ſaltpetre, after ſufficient draining, and being dried by expoſure to the air upon tables for ſeveral hours, may then be employed in the manufacture of gunpowder.

But when it is required to uſe the ſaltpetre in the ſpeedy and immediate manufacture of gunpowder, it muſt be dried much more ſtrongly. This may be effected in a ſtove, or more ſimply by heating it in a flat metallic veſſel. For this purpoſe the ſaltpetre is to be put into the veſſel to the depth of five or ſix inches, and heated to 40 or 50 degrees of the thermometer (or about 135° of Fahrenheit). The ſaltpetre is to be ſtirred for two or three hours, and dried ſo much that, when ſtrongly preſſed in the hand, it ſhall acquire no conſiſtence, nor adhere together, but reſemble a very fine dry ſand. This degree of dryneſs is not required when the powder is made by pounding.

From theſe circumſtances, we find that two ſaline liquids remain after the operation; (1) the water from the waſhing; and (2) that from the cryſtallizing veſſels.

We have already remarked, that the waſhing of the ſaltpetre is performed in three ſucceſſive operations, in which, upon the whole, the quantity of fluid made uſe of amounts to 35 *per cent.* of the weight of the crude ſaltpetre. Theſe waſhings are eſtabliſhed on the principle, that cold water diſſolves the muriats of ſoda, and the earthy nitrats and muriats, together with the colouring principle, but ſcarcely attacks the nitrat of potaſh.

The water of theſe three waſhings therefore contains the muriat of ſoda, the earthy ſalts, the colouring principle, and a ſmall quantity of nitrat of potaſh; the amount of which is in proportion to that of the muriat of ſoda, which determines its ſolution.

The water of the cryſtallizing veſſels contains a portion of the muriats of ſoda, and of the earthy ſalts which eſcaped the operation of waſhing, and a quantity of nitrat of potaſh, which is more conſiderable than that of the former ſolution.

The waters made uſe of at the end of the operation, to whiten and waſh the cryſtals depoſited in the pyramidal veſſel, contain nothing but a ſmall quantity of nitrat of potaſh.

Theſe waters are therefore very different in their nature. The water of the waſhings is really a mother water. It muſt be collected in veſſels, and treated with potaſh by the known proceſſes. It muſt be evaporated to 66 degrees (or 1,848 ſp. gr.), taking out the muriat of ſoda as it falls. This ſolution is to be ſaturated with 2 or 3 *per cent.* of potaſh, then ſuffered to ſettle, decanted, and poured into cryſtallizing veſſels, where 20 *per cent.* of water is to be added to keep the whole of the muriat of ſoda ſuſpended.

The waters which are thus obtained by treatment of the mother water may be mixed with the water of the firſt cryſtallization. From theſe the marine ſalt may be ſeparated by ſimple evaporation; and the nitrat of potaſh, which they hold in ſolution, may be afterwards obtained by cooling.

The ſmall quantity of water made uſe of to waſh and whiten the refined ſaltpetre, contains nothing but the nitrat of potaſh: it may therefore be uſed in the ſolution of the ſaltpetre when taken from the tubs.

From this deſcription it follows, that a manufactory for the ſpeedy refining of ſaltpetre ought to be provided with (1) mallets or rammers for pounding the ſaltpetre; (2) tubs for waſhing; (3) a boiler for ſolution; (4) a cryſtallizing veſſel of copper or lead, in which the ſaltpetre is to be obtained by cooling; (5) baſkets to drain the cryſtals; (6) a wooden caſe or hopper for the laſt waſhing and draining the ſaltpetre; (7) ſcales and weights for weighing; (8) hydrometers and thermometers, to aſcertain denſities and temperatures; (9) rakes to agitate the liquor in the cryſtallizing veſſel; (10) ſkimmers to take out the cryſtals, and convey them to the baſkets; (11) ſyphons or hand-pumps to empty the boilers.

The number and dimenſions of theſe ſeveral articles muſt vary according to the quantity of ſaltpetre intended to be refined.

Gum-SANDARAC, is ſaid, in the *Encyclopædia*, arac, ders.

to be produced from a ſpecies of juniper. This was long the common opinion; but M. Schouſboe has lately proved (A) it to be a miſtake. The *juniperus communis*, from which many have derived this gum, does not grow in Africa; and Sandarac ſeems to belong excluſively to that part of the world. The gum ſandarac of our ſhops is brought from the ſouthern provinces of the kingdom of Morocco. About ſix or ſeven hundred quintals of it are exported every year from Santa Cruz, Mogador, and Saffy. In the language of the country it is called *el graſſa*. The tree which produces it is a *Thuia*, found alſo by M. Vahl in the kingdom of Tunis. It was made known ſeveral years ago by Dr Shaw, who named it *Cypreſſus fructu quadrivalvi, Equiſeti inſtar articulatis*; but neither of theſe learned men was acquainted with the economical uſe of this tree; probably becauſe, being not common in the northern part of Barbary, the inhabitants find little advantage in collecting the reſin which exudes from it.

M. Schouſboe, who ſaw the ſpecies of *thuia* in queſtion, ſays that it does not riſe to more than the height of twenty or thirty feet at moſt, and that the diameter of its trunk does not exceed ten or twelve inches. It diſtinguiſhes itſelf, on the firſt view, from the two other ſpecies of the ſame genus, cultivated in gardens, by having a very diſtinct trunk, and the figure of a real tree; whereas in the latter the branches riſe from the root, which gives them the appearance rather of buſhes. Its branches alſo are more articulated and brittle. Its flowers, which are not very apparent, ſhew themſelves in April; and the fruit, which are of a ſpherical form, ripen in September. When a branch of this tree is held to the light, it appears to be interſperſed with a multitude of tranſparent veſicles which contain the reſin. When theſe veſicles burſt in the ſummer months, a reſinous juice exudes from the trunk and branches, as is the caſe in other coniferous trees. This reſin is the ſandarac, which is collected by the inhabitants of the country, and carried to the ports, from which it is tranſported to Europe. It is employed in making ſome kinds of ſealing-wax, and in different ſorts of varniſh. In 1793 a hundred weight of it coſt in Morocco from 13 to 13½ piaſtres, which make from about L. 3, 5s. to L 3, 7s. 6d. ſterling. The duty on exportation was about 7s. 6d. ſterling per quintal.

Sandarac, to be good, muſt be of a bright-yellow colour, pure and tranſparent. It is an article very difficult to be adulterated. Care, however, muſt be taken, that the Moors do not mix with it too much ſand. It is probable that a tree of the ſame kind produces the gum ſandarac of Senegal, which is exported in pretty conſiderable quantities.

Sanders.

SANDERS-RED (ſee PTEROCARPUS, *Encycl.*) is uſed as a dye ſtuff, but generally in a manner which is very diſadvantageous. In Crell's Chemical Annals are given, by Mr Vogler, the following directions for dyeing with this wood.

1. Into a ſolution of tin made with aquafortis (nitric acid), and mixed with three times as much ſalt water, put clean-waſhed wool, ſilk, linen, and cotton. After ſix hours, take them out, and waſh them carefully in three different quantities of clean cold water, wringing them well each time. Let them dry, and then put half the quantity of each article into the ſpirituous tincture of red ſanders, hereafter deſcribed in n° 6. letting them ſoak therein, without heat, from half an hour to an hour. To aſcertain the ſuperiority of his different proceſſes, the other half of each article muſt be boiled in the tincture of ſanders mixed with water, deſcribed in n° 7. a bare quarter of an hour. After being taken out, wrung, and dried in the ſhade, all of them will be dyed throughout of a fine rich poppy-colour.

2. Take three drams of powdered alum, and diſſolve it in twelve ounces of clean hot water. Into this ſolution, while yet warm, put ſome well-waſhed wool, ſilk, linen, and cotton. After ſuffering them to remain therein for the ſpace of twelve hours, take them out, waſh them well in three quantities of clean cold water (wringing them each time), and dry them. Then ſteep the half of each article in the cold ſpirituous tincture of ſanders (n° 6.), from half an hour to an hour; and boil the other half of each in the diluted tincture of ſanders (n° 7.) for the ſpace of ſix or ſeven minutes. After being taken out, wrung, and dried in the ſhade, they will be found to have acquired a very beautiful and rich ſcarlet colour.

3. Diſſolve three drams of blue vitriol, or vitriol of copper, in twelve ounces of hot water. Steep in this ſolution, for twelve hours, wool, ſilk, linen, or cotton; and having ſufficiently waſhed the ſtuff in clean cold water, immerſe the one half of it in the ſpirituous tincture of ſanders (n° 6.), from half an hour to an hour; and boil the other half of each for ſix or ſeven minutes in the diluted tincture, n° 7. Being then taken out, wrung, and dried in the ſhade, as before, they will have acquired a beautiful, rich, bright, crimſon colour.

4. Steep wool, ſilk, linen, and cotton, which has been well waſhed, during twelve hours, in a ſolution of three drams of white vitriol, or vitriol of zinc, in twelve ounces of hot water. After being taken out, well waſhed in clean cold water, and dried, immerſe one half of each in the cold ſpirituous tincture of ſanders (n° 6.) and boil the other half in the diluted tincture (n° 7.) as before. When taken out, wrung, and dried, they will be of a fine, rich, deep crimſon colour.

5. Diſſolve three drams of common green vitriol, or vitriol of iron, in twelve ounces of hot water: ſteep well-waſhed wool, ſilk, linen, and cotton, in the ſolution, for the ſpace of twelve hours. When taken out, waſhed ſeveral times in clean cold water, and dried, treat them, as in n° 4. and they will be generally found to be of a fine, rich, deep violet colour; though, on repeating his experiments, our author ſometimes found the colour a dark browniſh red.

The tincture in which the ſtuffs are to be dyed muſt be prepared in the following manner.

6. Take half an ounce of red ſanders wood, beat or ground to powder, as it is ſold at the colour ſhops or druggiſts. Having put it into a large glaſs bottle, pour upon it twelve ounces of malt ſpirit or common brandy; then cork the bottle, and ſet it in a moderately-warm place. In the ſpace of 48 hours, the ſpirit will have extracted all the colouring matter from the red ſanders, and thereby acquired a bright red colour. The bottle ſhould

---

(A) In a Daniſh Journal, intitled, *The Phyſical, Medical, and Economical Library*, Part III. 1799.

ſhould be often ſhaken during the digeſtion; and the tincture, thus prepared, may be uſed for dyeing without heat, and without ſeparating the powdered ſanders from the liquor. The articles to be dyed (after the application of the proper mordants, n° 1, 2, 3, 4, 5) are to be ſteeped in the tincture for half an hour, or a whole hour: they are then to be taken out, wrung, and dried in the ſhade. This tincture does not loſe its dyeing quality by age; but dyes ſubſtances, after being kept a long time, almoſt as well as when it is juſt made. Its colouring power is indeed weakened by the frequent immerſion and dyeing of different articles in it; and when that is the caſe, it muſt be again digeſted with ſome freſh ſanders-wood.

7. Mix the ſpirituous tincture of ſanders, juſt deſcribed, with from ſix to ten times as much clean cold water. The mixture was made by our author without any ſeparation of the colouring particles worth noticing; and in this diluted tincture, the various articles (having their proper mordants firſt applied, n° 1, 2, 3, 4, 5) were boiled, as before mentioned. Linen and cotton, by being dipped in glue-water, after the application of the mordants, acquire, in this diluted tincture, a much deeper and richer colour.

If a very fine and bright colour be deſired, the above ſpirituous tincture of ſanders ſhould not be too old, nor ſhould the digeſtion be protracted beyond 48 hours; for, after that period, the ſpirit appears to extract brown and yellow colouring particles from the wood. The powder of ſanders need not be ſeparated from the diluted tincture which is made uſe of by boiling; nor is it abſolutly neceſſary to waſh the articles in cold water after they are dyed; as the powder which adheres to them may eaſily be taken off by rubbing and ſhaking. M. Vogler, however, found it advantageous, after the articles were taken out of the dye, and wrung, to ſteep them for a few minutes in a cold ſolution of half an ounce of common ſalt, and a quarter of an ounce of alum, in 12 ounces of pure water. In this caſe, they ſhould afterwards be waſhed ſeveral times in clean cold water, then wrung and dried in the ſhade. By this method the colours are not only more beautiful, but are alſo more permanent. All the articles of wool, ſilk, linen, and cotton, which were dyed as is above mentioned, bore perfectly well the teſt of alkaline ley, ſoap, and acids; but, by expoſure to the open air and the ſun, the colours were more eaſily diſcharged, eſpecially from linen and cotton.

N. B. Red ſanders, by being ground to a fine powder, anſwers much better for dyeing by this proceſs, than when it is merely cut into ſmall pieces; but it muſt be remarked, that the powder of red ſanders which is ſold at the ſhops is ſometimes adulterated, by being mixed with other ſubſtances, and moiſtened with acids. The beſt kind is not light, but rather heavy; and is not of a dark red colour, but clear and bright.

GOODWIN SANDS, famous ſand banks off the coaſt of Kent, lying between the north and ſouth Foreland; and as they run parallel with the coaſt for three leagues together, at about two leagues and a half diſtant from it, they add to the ſecurity of that capacious road the Downs; for while the land ſhelters ſhips with the wind from ſouth-weſt to north-weſt only, theſe ſands break all the force of the ſea when the wind is at eaſt ſouth-eaſt. The moſt dangerous wind, when blowing hard on the Downs, is the ſouth-ſouth-weſt. Theſe ſands occupy the ſpace that was formerly a large tract of low ground belonging to Godwyn Earl of Kent, father of King Harold; and which being afterward given to the monaſtery of St Auguſtin at Canterbury, the abbot neglecting to keep in repair the wall that defended it from the ſea, the whole track was drowned, according to Salmon, in the year 1100, leaving theſe ſands, upon which ſo many ſhips have ſince been wrecked.

SANSANDING, a town in Africa, ſituated near the banks of the Niger, in Lat. 14° 24′ N. and 2° 23′ W. Long. It is inhabited by Moors and Negroes to the number of from eight to ten thouſand. The Negroes are kind, hoſpitable, and credulous; the Moors are at Sanſanding, as everywhere elſe in the interior parts of Africa, fanatical, bigotted, and cruel.

SAP, or SAPP, in building, as to ſap a wall, &c. is to dig out the ground from beneath it, ſo as to bring it down all at once for want of ſupport.

SAPHAN, in zoology. See MUS, *Encycl.* p. 467.

SAPHIES, a kind of charms, conſiſting of ſome ſcrap of writing, which the credulous Negroes believe capable of protecting them from all evil. The writers of ſaphies are generally Moors, who ſell ſcraps of the Koran for this purpoſe to a people who believe not either in the Koran or the prophet. Accordingly, any piece of writing may be ſold as a ſaphie; and Mr Park found the Negroes diſpoſed to place greater confidence in the ſaphies of a Chriſtian than in thoſe of a Moor. The manner in which theſe charms are ſuppoſed to operate, will be learned from the following ſtory:

Mr Park being at Koolikorro, a conſiderable town near the Niger, and a great market of ſalt, his landlord, hearing that he was a Chriſtian, immediately thought of procuring a ſaphie. For this purpoſe he brought out his *walha*, or writing board, aſſuring me (ſays our author) that he would dreſs me a ſupper of rice if I would write him a ſaphie to protect him from wicked men. The propoſal was of too great conſequence to me to be refuſed; I therefore wrote the board full, from top to bottom, on both ſides; and my landlord, to be certain of having the whole force of the charm, waſhed the writing from the board into a calabaſh with a little water; and having ſaid a few prayers over it, drank this powerful draught; after which, leſt a ſingle word ſhould eſcape, he licked the board until it was quite dry. A ſaphie writer was a man of too great conſequence to be long concealed: the important information was carried to the Dooty, who ſent his ſon with half a ſheet of writing-paper, deſiring me to write him a *naphula ſaphie* (a charm to procure wealth). He brought me, as a preſent, ſome meal and milk; and when I had finiſhed the ſaphie, and read it to him with an audible voice, he ſeemed highly ſatiſfied with his bargain, and promiſed to bring me in the morning ſome milk for my breakfaſt. Our author contrived to turn this abſurd ſuperſtition to his own advantage, by writing ſaphies for his ſubſiſtence when his money was exhauſted.

SARACOLETS, a Negro nation occupying the lands ſituated between the rivers of Senegal and Gambia. They are a laborious people, cultivate their lands with care, are plentifully ſupplied with all the neceſſaries of life, and inhabit handſome and well built villages; their houſes, of a circular form, are for the moſt part terra-

colets,
ville.

ced; the others are covered with reeds as at Senegal; they are incloſed with a mud wall a foot thick, and the villages are ſurrounded with one of ſtone and earth of double that ſolidity. There are ſeveral gates, which are guarded at night for fear of a ſurpriſe. This nation is remarkably brave, and it is very uncommon to find a Saracolet ſlave. They always defend themſelves with advantage againſt their aſſailants. Such Saracolets as are expoſed to ſale may be ſafely purchaſed, for (excepting when they are at war with the Poules) none are to be met with but ſuch as have been condemned by the laws for ſome miſdemeanour; in ſuch caſe, theſe wretches could not eſcape ſlavery even by taking refuge in their own country; for they would be reſtored to their maſters, or would be put to death, if the convoy ſhould have failed. The religious principles of this people are nearly allied to Mahometaniſm, and ſtill more to natural religion. They acknowledge one God; and believe that thoſe who ſteal, or are guilty of any crime, are eternally puniſhed. They admit a plurality of wives, and believe their ſouls to be immortal like their own. They think lightly of adultery; for as they allow themſelves ſeveral wives, they are not ſo unjuſt as to puniſh women who diſtribute their favours among ſeveral gallants; a mutual exchange is then permitted, one woman may be bartered for another, unleſs ſhe be free, or a native of the country. In this laſt caſe, the French cuſtom prevails; it is winked at, although the laws are particularly ſevere againſt the violation of the moſt ſacred of all property. This nation lies near that of the Poules. (See that article, *Suppl.*) Its extent up the country is unknown; all that we know is, that it is governed by four powerful princes, all bearing the name of Fouquet. The leaſt conſiderable, according to the teſtimony of the Sarcolets, is that of Tuago, who can aſſemble thirty thouſand horſe, and whoſe ſubjects occupy a territory two hundred leagues in extent, as well on the Senegal as on the track that reaches beyond the Felou; a rock which, according to the ſame report, forms cataracts, from whence proceed the Senegal and the river Gambia, equally conſiderable.

SAROS, in chronology, a period of 223 lunar months. The etymology of the word is ſaid to be Chaldean, ſignifying reſtitution, or return of eclipſes; that is, conjunctions of the ſun and moon in nearly the ſame place of the ecliptic. The Saros was a cycle like to that of Meto.

SARRASIN, or SARRAZIN, in fortification, a kind of port-cullis, otherwiſe called a herſe, which is hung with ropes over the gate of a town or fortreſs, to be let fall in caſe of a ſurpriſe.

Saville.

SAVILLE (Sir Henry), a very learned Engliſhman, the ſecond ſon of Henry Saville, Eſq; was born at Bradley, near Halifax, in Yorkſhire, November the 30th, 1549. He was entered of Merton College, Oxford, in 1561, where he took the degrees in arts, and was choſen fellow. When he proceeded maſter of arts in 1570, he read for that degree on the Almageſt of Ptolemy, which procured him the reputation of a man eminently ſkilled in mathematics and the Greek language; in the former of which he voluntarily read a public lecture in the univerſity for ſome time.

In 1578 he travelled into France and other countries; where, diligently improving himſelf in all uſeful learning, in languages, and the knowledge of the world, he became a moſt accompliſhed gentleman. At his return, he was made tutor in the Greek tongue to Queen Elizabeth, who had a great eſteem and liking for him.

In 1585 he was made warden of Merton College, which he governed ſix-and-thirty years with great honour, and improved it by all the means in his power.—In 1596 he was choſen provoſt of Eton College; which he filled with many learned men.—James the Firſt, upon his acceſſion to the crown of England, expreſſed a great regard for him, and would have preferred him either in church or ſtate; but Saville declined it, and only accepted the ceremony of knighthood from the king at Windſor in 1604. His only ſon Henry dying about that time, he thenceforth devoted his fortune to the promoting of learning. Among other things, in 1619, he founded, in the univerſity of Oxford, two lectures, or profeſſorſhips, one in geometry, the other in aſtronomy; which he endowed with a ſalary of 160l. a-year each, beſides a legacy of 600l. to purchaſe more lands for the ſame uſe. He alſo furniſhed a library with mathematical books, near the mathematical ſchool, for the uſe of his profeſſors; and gave 100l. to the mathematical cheſt of his own appointing: adding afterwards a legacy of 40l. a-year to the ſame cheſt, to the univerſity, and to his profeſſors jointly. He likewiſe gave 120l. towards the new building of the ſchools, beſide ſeveral rare manuſcripts and printed books to the Bodleian library; and a good quantity of Greek types to the printing-preſs at Oxford.

After a life thus ſpent in the encouragement and promotion of ſcience and literature in general, he died at Eton College the 19th of February 1622, in the 73d year of his age, and was buried in the chapel there. On this occaſion, the univerſity of Oxford paid him the greateſt honours, by having a public ſpeech and verſes made in his praiſe, which were publiſhed ſoon after in 4to, under the title of *Ultima Linea Savilii*.

As to the character of Saville, the higheſt encomiums are beſtowed on him by all the learned of his time: by Caſaubon, Mercerus, Meibomius, Joſeph Scaliger, and eſpecially the learned Biſhop Montague; who, in his *Diatribæ* upon Selden's Hiſtory of Tythes, ſtyles him, "that magazine of learning, whoſe memory ſhall be honourable amongſt not only the learned, but the righteous for ever."

Several noble inſtances of his munificence to the republic of letters have already been mentioned; in the account of his publications many more, and even greater, will appear. Theſe are,

1. Four Books of the Hiſtories of Cornelius Tacitus, and the Life of Agricola; with Notes upon them, in folio, dedicated to Queen Elizabeth, 1581.—2. A View of certain Military Matters, or Commentaries concerning Roman Warfare, 1598.—3 *Rerum Anglicarum Scriptores poſt Bedam*, &c. 1596. This is a collection of the beſt writers of our Engliſh hiſtory; to which he added chronological tables at the end, from Julius Cæſar to William the Conqueror.—4. The Works of St Chryſoſtom, in Greek, in 8 vols folio, 1613. This is a very fine edition, and compoſed with great coſt and labour. In the preface he ſays, "that having himſelf viſited, about 12 years before, all the public and private libraries in Britain, and copied out thence whatever he thought uſeful to this deſign, he then ſent ſome learned men into France, Germany,

Italy, and the Eaſt, to tranſcribe ſuch parts as he had not already, and to collate the others with the beſt manuſcripts." At the ſame time, he makes his acknowledgments to ſeveral eminent men for their aſſiſtance; as Thuanus, Velſerus, Schottus, Caſaubon, Ducæus, Gruter, Hoeſchelius, &c. In the 8th volume are inſerted Sir Henry Saville's own notes, with thoſe of other learned men. The whole charge of this edition, including the ſeveral ſums paid to learned men, at home and abroad, employed in finding out, tranſcribing, and collating the beſt manuſcripts, is ſaid to have amounted to no leſs than 8000l. Several editions of this work were afterwards publiſhed at Paris.—5. In 1618 he publiſhed a Latin work, written by Thomas Bradwardin, archbiſhop of Canterbury, againſt Pelagius, intitled, *De Cauſa Dei contra Pelagium, et de virtute cauſarum;* to which he prefixed the life of Bradwardin.—6. In 1621 he publiſhed a collection of his own Mathematical Lectures on Euclid's Elements, in 4to.—7. *Oratio coram Elizabetha Regina Oxoniæ habita,* anno 1592. Printed at Oxford in 1658, in 4to.—8. He tranſlated into Latin King James's Apology for the Oath of Allegiance. He alſo left ſeveral manuſcripts behind him, written by order of King James; all which are in the Bodleian library. He wrote notes likewiſe upon the margin of many books in his library, particularly Euſebius's Eccleſiaſtical Hiſtory; which were afterwards uſed by Valeſius, in his edition of that work in 1659.—Four of his letters to Camden are publiſhed by Smith, among Camden's Letters, 1691, 4to.

SAUSSURE (Horace Benedict de) was born at Geneva in 1740. His father, an intelligent farmer, to whom we are indebted for ſome memoirs relating to rural economy, reſided at Conches, a place ſituated on the banks of the Arve, at the diſtance of half a league from Geneva; and this country life, added to an active education, expanded no doubt in young De Sauſſure that phyſical ſtrength ſo neceſſary to the naturaliſt who devotes himſelf to travel. He repaired daily to town to enjoy the advantage of public inſtruction; and as he lived at the bottom of Saleve, a mountain which he has ſince rendered celebrated, he amuſed himſelf frequently with aſcending its ſteep and rugged ſides. Being thus ſurrounded by the phenomena of nature, and at the ſame time aided by ſtudy, he conceived a taſte for natural hiſtory, and avoided the error both of the learned, who form theories without having been out of their cloſets, and of thoſe farmers who, living too near to Nature, are incapable of admiring her beauties.

His earlieſt paſſion was botany: a variegated ſoil, abundant in plants of different kinds, invites the inhabitant of the banks of the Leman to cultivate that agreeable ſcience. This taſte produced an intimacy between De Sauſſure and the great Haller. He paid him a viſit in the year 1764, during his retreat to Bex; and he relates in his travels how much he admired that aſtoniſhing man, who excelled in every part of the natural ſciences. De Sauſſure was induced alſo to ſtudy the vegetable kingdom, by his connection with Ch. Bonnet, who had married his aunt, and who ſoon ſet a juſt value on the riſing talents of his nephew. Bonnet (See his life in this *Suppl.*) was then employed on the leaves of plants. De Sauſſure ſtudied theſe organs of vegetables alſo, and he publiſhed the reſult of his reſearches, under the title of Obſervations on the Bark of Leaves. This ſmall work, which appeared ſoon after the year 1760, contains new obſervations on the epidermis of leaves, and in particular on the miliary glands by which they are covered.

About that period, the place of profeſſor of philoſophy falling vacant, it was conferred upon De Sauſſure, who was then only twenty-one years of age. Experience proves, that if premature rewards extinguiſh the zeal of thoſe who labour merely for themſelves, they, on the contrary, ſtrengthen it in thoſe who labour only for truth. At that time the two profeſſors of philoſophy at Geneva taught phyſics and logic alternately. De Sauſſure diſcharged this double taſk with equal ſucceſs. He gave to his courſe of logic a practical, and, as one may ſay, experimental turn; and his method of teaching, which began by ſtudying the ſenſes to arrive at the general laws of the underſtanding, announced already an able obſerver of nature.

Phyſics, however, were the part for which he had the greateſt taſte, and which conducted him to the ſtudy of chemiſtry and mineralogy. He then began his travels through the mountains; not now to examine their vegetable productions, but to ſtudy the mountains themſelves, either in the ſtones of which they are compoſed, or the diſpoſition of their maſſes. Geology, a ſcience which was then ſcarcely in exiſtence, added charms to his numerous excurſions through the Alps; and it was then that the talents of the great philoſopher were really diſplayed. During the firſt fifteen or twenty years of his profeſſorſhip, he employed himſelf by turns in diſcharging the duties of his office, and in traverſing the different mountains in the neighbourhood of Geneva. He even extended his excurſions on one ſide as far as the banks of the Rhine, and on the other to Piedmont. At the ſame time he undertook a journey to Auvergne to examine there the extinguiſhed volcanoes, and another to Paris, England, and Holland. After that he viſited Italy, and even Sicily. Theſe were not mere journeys for the purpoſe of reaching any particular place; he undertook them only with a view of ſtudying nature; never travelled but ſurrounded by every inſtrument that could be of uſe to him, and never ſet out until he had drawn up a plan of the experiments and obſervations he intended to make. He often ſays in his works that he had found this method exceedingly uſeful.

In the year 1779 he publiſhed the firſt volume of his Travels through the Alps; which contains a minute deſcription of the environs of Geneva, and an excurſion as far as Chamouni, a village at the bottom of Mont Blanc. Philoſophers will read there with pleaſure the deſcription of his Magnetometer. The more he examined mountains, the more was he ſenſible of the importance of mineralogy. To ſtudy it with advantage, he learned the German language; and it may be ſeen, in the laſt volumes of his Travels, how much new mineralogical knowledge he had acquired.

Amidſt his numerous excurſions through the Alps, and at the time of the political troubles of Geneva in 1782, he found means to make his beautiful experiments on hygrometry, which he publiſhed in 1783, under the title of *Eſſays on Hygrometry.* This work, the beſt that ever came from his pen, eſtabliſhed fully his reputation as a philoſopher. We are indebted to him alſo for the invention of a new hygrometer. Deluc had already invented his whalebone hygrometer; and on that account there aroſe between him and De Sauſſure a ſort of conteſt, which degenerated into a pretty violent diſpute.

In the year 1786 De Sauſſure reſigned the profeſſor's chair, which he had filled for about twenty five years, to his pupil and fellow-labourer Pictet, who diſcharged with reputation the duties of an office rendered more difficult by ſucceeding ſo eminent a philoſopher.

When De Sauſſure was invited by the ſtate to take a ſhare in the public education, he made it one of the ſubjects of his meditations, and preſented the plan of a reform in the education of Geneva; the tendency of which was, to make young people early acquainted with the natural ſciences and mathematics. He even wiſhed that their phyſical education ſhould not be neglected, and with that view propoſed gymnaſtic exerciſes. This plan, which excited much attention in a city where every one is convinced of the importance of education, found admirers and partiſans; but the poverty of its pecuniary reſources was an obſtacle to every important innovation. It was beſides feared that, by altering eſtabliſhed forms, they might loſe the ſubſtance, and that things might be changed for the worſe. The Geneveſe were attached to their old ſyſtem of education; and they had reaſon to be ſo, becauſe it had not only proved the means of diffuſing knowledge generally amongſt them, but had called forth the talents of ſeveral eminent mathematicians (A) and philoſophers (B).

But De Sauſſure's attention was not confined to public education alone. He ſuperintended himſelf the education of his two ſons and a daughter, who have ſhewn themſelves worthy of ſuch an inſtructor. His daughter to the charms of her ſex unites an extenſive knowledge of the natural ſciences; and his eldeſt ſon has already made himſelf known by his phyſical and chemical labours.

The ſecond volume of his Travels was publiſhed in 1786. It contains a deſcription of the Alps around Mont Blanc, which the author conſiders as a mineralogiſt, a geologiſt, and a philoſopher. He gives alſo ſome intereſting experiments on electricity, and a deſcription of his electrometer, one of the moſt perfect that we have. We are indebted to him alſo for ſeveral inſtruments of meaſurement, ſuch as his *cyanometer*, deſtined to meaſure the degree of the blueneſs of the heavens, which varies according to the elevation of the obſerver; his *diaphanometer* (See PHOTOMETER, in this *Suppl.*), and his *anemometer*, which, by means of a kind of balance, meaſures the force of the wind.

Some years after the publication of the ſecond volume of his Travels, De Sauſſure was admitted as a foreign aſſociate of the Academy of Sciences of Paris; and Geneva could then boaſt of having two of its citizens in that claſs, which conſiſted only of ſeven members. De Sauſſure not only did honour to his country; he loved and ſerved it. He was the founder of the Society of Arts, to which Geneva is indebted for the high ſtate of proſperity it has attained within the laſt thirty years. He preſided over that ſociety till the laſt moment of his life; and one of his fondeſt wiſhes was the preſervation of this uſeful eſtabliſhment.

In conſequence of M. de Sauſſure's fatiguing labours in the Council of Two Hundred, of which he was a member, and afterwards in the National Aſſembly, his health began to be deranged, and in 1794 he was almoſt deprived of the total uſe of his limbs by a ſtroke of the palſy. However painful his condition then might be, his mind ſtill preſerved its activity; and after that accident he reviſed the two laſt volumes of his Travels, which appeared in 1796. They contain an account of his excurſions to the mountains of Piedmont and Swiſſerland, and in particular of his journey to the ſummit of Mont Blanc. Theſe volumes, inſtead of exhibiting any marks of his malady, preſent an enormous maſs of new facts and obſervations of the utmoſt importance to phyſics.

He rendered alſo an important ſervice to that ſcience by publiſhing the *Agenda*, which terminate his fourth volume, and in which that great man, ſurviving himſelf, conducts the young naturaliſt through the middle of mountains, and teaches him the method of obſerving them with advantage. Theſe *Agenda* are a proof of his genius, and of the ſtrength of mind which he retained amidſt his ſufferings. It was alſo during his illneſs that he directed the experiments made on the height of the bed of the Arve, and that he publiſhed Obſervations on the Fuſibility of Stones by the Blow-pipe, which were inſerted in the *Journal de Phyſique*.

Having gone for the ſake of his health to the baths of Plombiers, he ſtill obſerved the mountains at a diſtance, and cauſed to be brought to him ſpecimens of the ſtrata which he perceived in the ſteepeſt rocks. He had announced that he would conclude his travels with ſome ideas on the primitive ſtate of the earth; but the more he acquired new facts, and the more he meditated on the ſubject, the more uncertain did his opinions become in regard to thoſe grand revolutions which preceded the preſent epoch. In general he was a Neptunian; that is to ſay, aſcribed all the revolutions of our globe to water. He admitted the poſſibility of the mountains having been thrown up by elaſtic fluids diſengaged from the cavities of the earth.

Though the ſtate of his health began gradually to become worſe, he ſtill entertained hopes of recovery; and the French government having appointed him profeſſor of philoſophy at the Special School of Paris, he did not deſpair of being one day able to fill that office: but his ſtrength was exhauſted, a general languor ſucceeded the vigour he had always enjoyed, his ſlow and embarraſſed pronunciation no longer correſponded with the vivacity of his mind, and formed a melancholy contraſt with the pleaſantneſs by which he had been formerly diſtinguiſhed. It was a painful ſpectacle to ſee this great man reduced thus to imbecility at an age when meditation is beneficial, and when he might have enjoyed the fruits of his reputation and labours.

In vain did he try, for the re-eſtabliſhment of his health, all the remedies which medicine, enlightened by the

the phyſical ſciences, could afford—all aſſiſtance was uſeleſs. The vital power quitted him with ſlow and painful ſteps. Towards the beginning of autumn 1798 his decay became more viſible, his mind loſt all its activity, and on the 22d of March 1799 he terminated his brilliant career, at the age of 59, lamented by a family to whom he was dear—by a country to which he had done honour—and by Europe, the knowledge of which he had extended.

SCALE, in architecture and geography, a line divided into equal parts, placed at the bottom of a map or draught, to ſerve as a common meaſure to all the parts of the building, or all the diſtances and places of the map.

SCALES, in mathematics, ſee SCALES (*Encycl.*), and likewiſe *LOGARITHMIC Lines*, under which title are mentioned ſome improvements by Mr Nicholſon on Gunter's ſcale. Theſe improvements are valuable; and the reader will find a fuller account of them in the firſt volume of the author's *Philoſophical Journal*.

SCANTLING, a meaſure, ſize, or ſtandard, by which the dimenſions, &c. of things are to be determined. The term is particularly applied to the dimenſions of any piece of timber, with regard to its breadth and thickneſs.

SCAPEMENT, in clock-work, a general term for the manner of communicating the impulſe of the wheels to the pendulum. The ordinary ſcapements conſiſt of the ſwing-wheel and pallets only; but modern improvements have added other levers or detents, chiefly for the purpoſes of diminiſhing friction, or for detaching the pendulum from the preſſure of the wheels during part of the time of its vibration. See *WATCH Making*, in this *Suppl.*

SCARFING, a term in carpentry; by which is meant the joining of two beams of wood together to increaſe the length: the beams in the joint are indented into one another, as in figures 19, 24, and 25, Plate X. *Supplement*.

SCARLET, a beautiful bright red colour given to cloth, either by a preparation of kermes (See that article in *Suppl.*), or more completely by the American cochineal. Profeſſor Beckmann, in the ſecond volume of his Hiſtory of Inventions, ſeems to have eſtabliſhed the following concluſions:

1*ſt*, Scarlet, or the kermes-dye, was known in the Eaſt in the earlieſt ages, before Moſes, and was a diſcovery of the Phœnicians in Paleſtine, but certainly not of the ſmall wandering Hebrew tribes. 2*d*, *Tola* was the ancient Phœnician name uſed by the Hebrews, and even by the Syrians; for it is employed by the Syrian tranſlator, Iſaiah, chap. 1. ver. 18. Among the Jews, after their captivity, the Aramæan word *zehori* was more common. 3*d*, This dye was known alſo to the Egyptians in the time of Moſes; for the Iſraelites muſt have carried it along with them from Egypt. 4*th*, The Arabs received the name kermes, with the dye, from Armenia and Perſia, where it was indigenous, and had been long known; and that name baniſhed the old name in the Eaſt, as the name ſcarlet has in the Weſt. For the firſt part of this aſſertion we muſt believe the Arabs. 5*th*, Kermes were perhaps not known in Arabia; at leaſt they were not indigenous, as the Arabs appear to have had no name for them. 6*th*, Kermes ſignifies always *red dye*; and when pronounced ſhort, it becomes *deep red*.

Concerning the origin of the name ſcarlet, which was in uſe ſo early as the 11th century, our author has many conjectures, which we need not tranſcribe, as he ſeems not quite ſatisfied with any of them himſelf. The following reflections upon the comparative excellence of the ancient and modern ſcarlet, together with the progreſs of the art of dyeing that colour, are worthy of notice:

“ Of the preparation and goodneſs of the ancient ſcarlet we certainly know nothing: but as we find in many old pieces of tapeſtry of the 11th century, and perhaps earlier, a red which has continued remarkably beautiful even to the preſent time, it cannot at any rate be denied, that our anceſtors extolled their ſcarlet not without reaſon. We can, however, venture to aſſert, that the ſcarlet prepared at preſent is far ſuperior, owing principally to the effects of a ſolution of tin. —This invention may be reckoned amongſt the moſt important improvements of the art of dyeing, and deſerves a particular relation.

“ The tincture of cochineal alone yields a purple colour, not very pleaſant, which may be heightened to the moſt beautiful ſcarlet by a ſolution of tin in aqua-regia (nitro muriatic acid). This diſcovery was made as follows: Cornelius Drebbel, who was born at Alkmaar, and died at London in 1634, having placed in his window an extract of cochineal, made with boiling water, for the purpoſe of filling a thermometer, ſome aqua-regia dropped into it from a phial, broken by accident, which ſtood above it, and converted the purple dye into a moſt beautiful dark red. After ſome conjectures and experiments, he diſcovered that the tin by which the window-frame was divided into ſquares had been diſſolved by the aqua regia, and was the cauſe of this change. He communicated his obſervation to Kuffelar, that excellent dyer at Leyden, who was afterwards his ſon-in-law. The latter brought the diſcovery to perfection, and employed it ſome years alone in his dye houſe, which gave riſe to the name of Kuffelar's colour. In the courſe of time the ſecret became known to an inhabitant of Menin, called Gulich, and alſo to another perſon of the name of Van der Vecht, who taught it to the brothers Gobelins in France. Giles Gobelin, a dyer at Paris, in the time of Francis I. had found out an improvement of the then uſual ſcarlet dye; and as he had remarked that the water of the rivulet Bievre, in the ſuburbs St Marceau, was excellent for his art, he erected on it a large dye-houſe; which, out of ridicule, was called *Folie Gobelins*, Gobelin's Folly. About this period, a Flemiſh painter, whom ſome name Peter Koek, and others Kloek, and who had travelled a long time in the Eaſt, eſtabliſhed, and continued to his death in 1650, a manufactory for dyeing ſcarlet cloth by an improved method. Through the means of Colbert, one of the Gobelins learned the proceſs uſed for preparing the German ſcarlet dye from one Gluck, whom ſome conſider as the above-mentioned Gulich, and others as Kloek; and the Pariſian ſcarlet dye ſoon roſe into ſo great repute, that the populace imagined that Gobelin had acquired his art from the devil. It is well known that Louis XIV. by the advice of Colbert, purchaſed Gobelin's building from his ſucceſſors in the year 1667, and transformed it into a palace, to which he gave the name of *Hôtel royal des Gobelins,* and which he aſſigned for the uſe of firſt-rate artiſts, particularly painters, jewellers, weavers of tapeſtry, and others. After that time the rivulet was no longer called Bievre, but Gobelins. About the year 1643, a Fleming, named Kepler, eſtabliſhed the firſt dye-houſe for ſcarlet in England, at the village of Bow, not far from London; and on that account the colour was called, at firſt, by the Engliſh, the *Bow dye.* In the year 1667, another Fleming, named Brewer, invited to England by King Charles II. with the promiſe of a large ſalary, brought this art there to great perfection."

SCHEME, a draught or repreſentation of any geometrical or aſtronomical figure, or problem, by lines ſenſible to the eye; or of the celeſtial bodies in their proper places for any moment; otherwiſe called a diagram.

SCIAGRAPHY, or SCIOGRAPHY, the profile or vertical ſection of a building; uſed to ſhew the inſide of it.

SCIAGRAPHY, in aſtronomy, &c. is a term uſed by ſome authors for the art of finding the hour of the day or night, by the ſhadow of the ſun, moon, ſtars, &c.

SCIOPTIC, or *Scioptric Ball,* a ſphere or globe of wood, with a circular hole or perforation, where a lens is placed. It is ſo fitted, that, like the eye of an animal, it may be turned round every way, to be uſed in making experiments of the darkened room.

SCOLYMUS (ſee that article *Encycl.*) is, by Pliny and Theophraſtus, reckoned to belong to the genus of the thiſtles. The former ſays, that, like moſt others of the ſame kind, the ſeeds were covered by a ſort of wool (*pappus*). It had a high ſtem, ſurrounded with leaves, which were prickly, but which ceaſed to ſting when the plant withered. It flowered the whole ſummer through, and had often flowers and ripe ſeed at the ſame time; which is the caſe alſo with our artichoke plants. The calyx of the *ſcolymus* was not prickly; the root was thick, black, and ſweet, and contained a milky juice. It was eaten both raw and cooked; and Theophraſtus obſerves, as ſomething very remarkable, that when the plant was in flower, or, as others explain the words, when it had finiſhed blowing, it was moſt palatable. What renders this circumſtance ſingular is, that moſt milky roots uſed for food loſe their milk, and become unfit to be eaten as ſoon as they have blown. This is the caſe with the goat's beard, which is eatable only the firſt year.

Profeſſor Beckmann has, with much labour and erudition, endeavoured to aſcertain what is really the plant which was known to the ancients by the name of *ſcolymus.* He ſeems to have proved ſufficiently, that it was not the *cactus,* the *carduus,* or the *cinara;* but he has not been able to come to any other concluſion. "Were I appointed or condemned (ſays he) to form a new Latin dictionary, I ſhould explain the article *ſcolymus* in the following manner: *Planta compoſita, capitata. Caulis longus, obſitus foliis ſpinoſis. Radix carnoſa, lacteſcens, nigra, dulcis, edulis. Calix ſquamis inermibus, diſco carnoſo, ante efflореſcentiam eduli. Semina pappoſa. Turiones edules.* This deſcription, ſhort as it is, contains every thing that the ancients have ſaid in order to characteriſe that plant."

SCONCES, ſmall forts, built for the defence of ſome paſs, river, or other place. Some ſconces are made regular, of four, five, or ſix baſtions; others are of ſmaller dimenſions, fit for paſſes or rivers; and others for the field.

SCOTALES, were meetings held formerly in England for the purpoſe of drinking ale, of which the expence was defrayed by joint contribution. Thus the tenants of South Malling in Suſſex, which belonged to the Archbiſhop of Canterbury, were, at the keeping of a court, to entertain the Lord or his bailiff with a drinking, or an *ale;* and the ſtated quotas towards the charge were, that a man ſhould pay three pence halfpenny for himſelf and his wife, and a widow and a cottager three halfpence. In the manor of Ferring, in the ſame county, and under the ſame juriſdiction, it was the cuſtom for the tenants named to make a *ſcotale* of ſixteen pence halfpenny, and to allow out of each ſixpence three halfpence for the bailiff.

Common ſcotales in taverns, at which the clergy were not to be preſent, are noticed in ſeveral eccleſiaſtical canons. They were not to be publiſhed in the church by the clergy or the laity; and a meeting of more than ten perſons of the ſame pariſh or vicinage was a ſcotale that was generally prohibited. There were alſo common drinkings, which were denominated *leet-ale, bride-ale, clerk-ale,* and *church-ale.* To a *leet-ale* probably all the reſidents in a manorial diſtrict were contributors; and the expence of a *bride-ale* was defrayed by the relations and friends of a happy pair, who were not in circumſtances to bear the charges of a wedding dinner. This cuſtom prevails occaſionally in ſome diſtricts of Scotland even at this day, under the denomination of a *penny bride-ale,* and was very common fifty or ſixty years ago. The *clerk's* ale was in the Eaſter holidays, and was the method taken to enable clerks of pariſhes to collect more readily their dues.

Mr Warton, in his Hiſtory of Engliſh Poetry, has inſerted the following extract from an old indenture, which ſhews clearly the deſign of a *church*-ale. "The pariſhioners of Elveſton and Okebrook, in Derbyſhire, agree jointly to brew four ales, and every ale of one quarter of malt, betwixt this and the feaſt of St John the Baptiſt next coming; and that every inhabitant of the ſaid town of Okebrook ſhall be at the ſeveral ales. And every huſband and his wife ſhall pay two pence, every cottager one penny; and all the inhabitants of Elveſton ſhall have and receive all the profits and advantages coming of the ſaid ales, to *the uſe and behoof of the ſaid church of Elveſton.*"

The *give-ales* were the legacies of individuals; and from that circumſtance entirely gratuitous. They ſeem to have been very numerous, and were generally left to the poor; though, from the largeneſs of the quantity of ale enjoined to be brewed, it muſt have been ſometimes intended that others were to partake of them. Theſe bequeſts were likewiſe, not unfrequently, made to the light or altar of a ſaint, with directions for ſinging maſſes at the obit, trenthal, or anniverſary of the teſtator. Hence, though ſcotales were generally kept in houſes of public reſort, the give-ales were ſometimes diſpenſed in the church, and often in the churchyard; by which means "Godde's houſe (as Sumner ſays in his Treatiſe on Gavelkind) was made a tavern of gluttons." Such certainly would be Chalk church, if in it

Scowring.

Scowri
Scyll

was kept the give-ale of William May of that pariſh ; for he ordered his wife to "make in bread ſix buſhels of wheat, and in drink ten buſhels of mault, and in cheeſe twenty-pence, to give to poor people for the health of his ſoull ; and he ordered that, after the deceaſe of his wife, his executors and feoffees ſhould continue the cuſtom for evermore."

SCOWRING OF STUFFS, is an art much more generally practiſed than underſtood. It ſuppoſes, ſays Chaptal, 1ſt, a knowledge of the different ſubſtances capable of ſtaining any kind of cloth ; 2d, of the ſubſtances to which recourſe muſt be had, in order to make thoſe depoſited on the ſtuff to diſappear ; 3d, a knowledge of the effects produced on colours by thoſe reagents, which it may be neceſſary to employ to deſtroy ſtains ; 4th, a knowledge of the manner in which the cloth is affected by thoſe re-agents ; 5th, of the art of reſtoring a colour changed or faded. Of thoſe bodies which occaſion ſpots on different kinds of cloth, ſome are eaſily diſtinguiſhed by their appearance, ſuch as greaſy ſubſtances ; but others have more complex effects, ſuch as acids, alkalies, perſpired matter, fruits, urine, &c. Acids redden black, fawn, violet, and pucecolour, and every ſhade communicated with orchillaweed, iron, aſtringents, and every blue except indigo and pruſſian blue. They render the yellows paler, except that of arnatto, which they change into orange.

Alkalies change to violet the reds produced by Brazil-wood, logwood, and cochineal. They render the greens on woollen cloth yellowiſh, make yellow browniſh, and change the yellow produced by arnatto to aurora. Perſpired matter produces the ſame effects as alkalies.

When the ſpots are produced by ſimple bodies on ſtuffs, it is eaſy to remove them by the means already known. Greaſy ſubſtances are removed by alkalies, ſoaps, the yolk of eggs, fat earths ; oxyds of iron, by the nitric and oxalic acids ; acids by alkalies, and reciprocally. Stains of fruit on white ſtuffs may be removed by the ſulphureous acid, and ſtill better by the oxygenated muriatic acid. But when the ſpots are of a complex kind, it will be neceſſary to employ ſeveral means in ſucceſſion. Thus, to deſtroy the ſtain of coom from carriage-wheels, after the greaſe has been diſſolved, the oxyd of iron may be removed by the oxalic acid.

As colours are often changed by re-agents, it will be neceſſary, in order to reſtore them, that the ſcowrer ſhould poſſeſs a thorough knowledge of the art of dyeing, and how to modify the means according to circumſtances. This becomes the more difficult, when it is neceſſary to reproduce a colour ſimilar to that of the reſt of the ſtuff, to apply that colour only in one place, and often to reſtore the mordant by which it was fixed, and which has been deſtroyed, or even the firſt tint which gave the colour its intenſity. It may be readily conceived, that the means to be employed muſt depend on the nature of the colour and the ingredients by which it was produced ; for it is known that the ſame colour may be obtained from very different bodies. Thus, after an alkali has been employed to deſtroy an acid ſpot on browns, violets, blues, poppies, &c. the yellow ſpot which remains may be made to diſappear by a ſolution of tin ; a ſolution of ſulphat of iron reſtores the colour to brown ſtuffs which have been galled ; acids reſtore to their former ſplendour yellows which have been rendered duſky or brown by alkalies ; blacks produced by logwood become red by acids ; alkalies change theſe red ſpots to yellow, and a little of the aſtringent principle makes them again become black. A ſolution of one part of indigo in four parts of ſulphuric acid, diluted with a ſufficient quantity of water, may be employed with ſucceſs to revive the blue colour of cotton or wool which has been changed. Scarlet may be revived by means of cochineal and a ſolution of the muriat of tin, &c.

The choice of re-agents is not a matter of indifference. Vegetable acids are preferable; the ſulphureous acid, however, may be employed for ſtains occaſioned by fruit ; it does not change the blue of ſilk nor colours produced by aſtringents ; it does not degrade the yellow of cotton. Ammonia ſucceeds better than fixed alkalies in removing ſpots produced by acids. It is employed in vapour ; its action is ſpeedy, and ſeldom alters the colour.

The means of removing greaſy ſpots are well known. This effect is produced by alkalies, fullers earth, volatile oils diſſolved in alcohol, a heat proper for volatilizing greaſe, &c. Spots occaſioned by ink, ruſt, or ironmould of any kind, and all thoſe produced by the yellow oxyd of iron, are removed by the oxalic acid : the colour may be reſtored by alkalies, or a ſolution of the muriat of tin. Theſe ſpots may be removed alſo by the oxygenated muriatic acid, when they are on white ſtuffs or paper.

The action of alkalies, and that of perſpired matter, are the ſame : their ſpots may be effaced by acids, or even by a weak ſolution of the muriat of tin. When theſe ſpots ariſe from ſeveral unknown cauſes, in order to deſtroy them, recourſe muſt be had to polychreſt compoſitions. The following may be conſidered as one of the moſt efficacious : Diſſolve white ſoap in alcohol, and mix this ſolution with the yolks of from four to ſix eggs ; add gradually eſſence of turpentine ; and incorporate with the whole ſome fullers earth, in ſuch a manner as to form balls of a ſuitable conſiſtence. Moiſten the ſpot ; and having rubbed it with theſe balls, the ſpot will be removed by waſhing the ſtuff. All ſpots, except iron-mould and ink, may be removed in this manner.

Waſhing deſtroys the luſtre, and leaves a tarniſhed place diſagreeable to the eye ; but the luſtre may be reſtored by drawing over the waſhed place, and in the direction of the pile, a bruſh moiſtened in water, impregnated with a little gum. You may then apply a ſheet of paper, or a piece of cloth, and a conſiderable weight, under which the cloth muſt be left to dry.

SCYLLA. Under this title we gave, in the *Encyclopædia*, an account of Scylla and Charybdis, which, though taken from a work which we thought good authority, appears to be far from correct. Theſe places, ſo famous in the poems of Homer and Virgil, were examined with minute attention by that accurate obſerver of nature the Abbé Spallanzani ; who thus deſcribes Scylla.

"It is a lofty rock, diſtant twelve miles from Meſſina, which riſes almoſt perpendicularly from the ſea on the ſhore of Calabria, and beyond which is the ſmall city of the ſame name. Though there was ſcarcely any wind, I began to hear, two miles before I came to the rock, a murmur and noiſe like a confuſed barking of dogs, and on a nearer approach readily diſcovered the cauſe. This rock, in its lower parts, contains a number of caverns, one of the largeſt of which is called by the people there *Dragara*. The waves, when in the leaſt agitated, ruſhing into theſe caverns, break, daſh, throw up frothy bubbles, and thus occaſion theſe various and multiplied ſounds. I then perceived with how much truth and reſemblance of nature Homer and Virgil, in their perſonifications of Scylla, had pourtrayed this ſcene, by deſcribing the monſter they drew as lurking in the darkneſs of a vaſt cavern, ſurrounded by ravenous barking maſtiffs, together with wolves, to increaſe the horror.

"Such is the ſituation and appearance of Scylla: let us now conſider the danger it occaſions to mariners. Though the tide is almoſt imperceptible in the open parts of the Mediterranean, it is very ſtrong in the ſtrait of Meſſina, in conſequence of the narrowneſs of the channel, and is regulated, as in other places, by the periodical elevations and depreſſion of the water. Where the flow or current is accompanied by a wind blowing the ſame way, veſſels have nothing to fear, ſince they either do not enter the ſtrait, both the wind and the ſtream oppoſing them, but caſt anchor at the entrance; or, if both are favourable, enter on full ſail, and paſs through with ſuch rapidity that they ſeem to fly over the water. But when the current runs from ſouth to north, and the north wind blows hard at the ſame time, the ſhip which expected eaſily to paſs the ſtrait with the wind in its ſtern, on its entering the channel is reſiſted by the oppoſite current, and, impelled by two forces in contrary directions, is at length daſhed on the rock of Scylla, or driven on the neighbouring ſands; unleſs the pilot ſhall apply for the ſuccour neceſſary for his preſervation. For, to give aſſiſtance in caſe of ſuch accidents, 24 of the ſtrongeſt, boldeſt, and moſt experienced ſailors, well acquainted with the place, are ſtationed night and day along the ſhore of Meſſina; who, at the report of guns fired as ſignals of diſtreſs from any veſſel, haſten to its aſſiſtance, and tow it with one of their light boats. The current, where it is ſtrongeſt, does not extend over the whole ſtrait, but winds thro' it in intricate meanders, with the courſe of which theſe men are perfectly acquainted, and are thus able to guide the ſhip in ſuch a manner as to avoid it. Should the pilot, however, confiding in his own ſkill, contemn or neglect this aſſiſtance, however great his ability or experience, he would run the moſt imminent riſk of being ſhipwrecked. In this agitation and conflict of the waters, forced one way by the current, and driven in a contrary direction by the wind, it is uſeleſs to throw the line to diſcover the depth of the bottom, the violence of the current frequently carrying the lead almoſt on the ſurface of the water. The ſtrongeſt cables, though ſome feet in circumference, break like ſmall cords. Should two or three anchors be thrown out, the bottom is ſo rocky that they either take no hold; or, if they ſhould, are ſoon looſened by the violence of the waves. Every expedient afforded by the art of navigation, though it might ſucceed in ſaving a ſhip in other parts of the Mediterranean, or even the tremendous ocean, is uſeleſs here. The only means of avoiding being daſhed againſt the rocks, or driven upon the ſands in the midſt of this furious conteſt of the winds and waves, is to have recourſe to the ſkill and courage of theſe Meſſineſe ſeamen."

Charybdis is ſituated within the ſtrait, in that part of the ſea which lies between a projection of land named *Punta Secca*, and another projection on which ſtands the tower called *Lanterna*, or the light-houſe, a light being placed at its top to guide veſſels which may enter the harbour by night. Every writer, who has hitherto deſcribed Charybdis, has ſuppoſed it to be a whirlpool; but this is a miſtake, as Spallanzani has completely proved, by aſcertaining what it really is.

"Charybdis is diſtant from the ſhore of Meſſina about 750 feet, and is called by the people of the country *Caloſaro*, not from the agitation of the waves, as ſome have ſuppoſed, but from καλος and φαρος; that is, *the beautiful tower*, from the light-houſe erected near it for the guidance of veſſels. The phenomenon of the Calofaro is obſervable when the current is deſcending; for when the current ſets in from the north, the pilots call it the *deſcending rema*, or current; and when it runs from the ſouth, the *aſcending rema*. The current aſcends or deſcends at the riſing or ſetting of the moon, and continues for ſix hours. In the interval between each aſcent or deſcent, there is a calm which laſts at leaſt a quarter of an hour, but not longer than an hour. Afterwards, at the riſing or ſetting of the moon, the current enters from the north, making various angles of incidence with the ſhore, and at length reaches the Calofaro. This delay ſometimes continues two hours; ſometimes it immediately falls into the Calofaro; and then experience has taught that it is a certain token of bad weather."

When our author obſerved Charybdis from the ſhore, it appeared like a group of tumultuous waters; which group, as he approached, became more extenſive and more agitated. He was carried to the edge, where he ſtopped ſome time to make the requiſite obſervations; and was then convinced, beyond the ſhadow of a doubt, that what he ſaw was by no means a vortex or whirlpool.

Hydrologiſts teach us, that by a whirlpool in a running water we are to underſtand that circular courſe which it takes in certain circumſtances; and that this courſe or revolution generates in the middle a hollow inverted cone, of a greater or leſs depth, the internal ſides of which have a ſpiral motion. But Spallanzani perceived nothing of this kind in the Calofaro. Its revolving motion was circumſcribed to a circle of at moſt 100 feet in diameter; within which limits there was no incurvation of any kind, nor vertiginous motion, but an inceſſant undulation of agitated waters, which roſe, fell, beat, and daſhed on each other. Yet theſe irregular motions were ſo far placid, that nothing was to be feared in paſſing over the ſpot, which he did; though their little bark rocked very much from the continual agitation, ſo that they were obliged conſtantly to make uſe of their oars to prevent its being driven out of the Calofaro. Our author threw ſubſtances of different kinds into the ſtream. Such as were ſpecifically heavier than the water ſunk, and appeared no more; thoſe which were lighter remained on the ſurface, but were ſoon driven out of the revolving circle by the agitation of the water.

Though from theſe obſervations he was convinced that there was no gulph under the Calofaro, as otherwiſe

Scylla, Sea ſick-neſs.

wiſe there would have been a whirlpool, which would have carried down into it the floating ſubſtances; he determined to ſound the bottom with the plummet, and found its greateſt depth did not exceed 500 feet. He was likewiſe informed, to his no ſmall ſurpriſe, that beyond the Calofaro, towards the middle of the ſtrait, the depth was double.

When the current and the wind are contrary to each other, and both in their greateſt violence, eſpecially when the ſcilocco, or ſouth wind, blows, the ſwelling and daſhing of the waves within the Calofaro is much ſtronger, more impetuous, and more extenſive. It then contains three or four ſmall whirlpools, or even more, according to the greatneſs of its extent and violence. If at this time ſmall veſſels are driven into the Calofaro by the current or the wind, they are ſeen to whirl round, rock, and plunge, but are never drawn down into the vortex. They only ſink when filled with water, by the waves beating over them. When veſſels of a larger ſize are forced into it, whatever wind they have they cannot extricate themſelves; their ſails are uſeleſs; and after having been for ſome time toſſed about by the waves, if they are not aſſiſted by the pilots of the country, who know how to bring them out of the courſe of the current, they are furiouſly driven upon the neighbouring ſhore of the Lanterna, where they are wrecked, and the greater part of their crews periſh in the waves.

From theſe facts, the claſſical reader will perceive, that the ancient deſcriptions of Charybdis are by no means ſo accurate as thoſe of Scylla. The ſaying, however, which became proverbial among the ancients, viz. that "he who endeavours to avoid Charybdis, daſhes upon Scylla," is, in a great meaſure, true. If a ſhip be extricated from the fury of Charybdis, and carried by a ſtrong ſoutherly wind along the ſtrait towards the northern entrance, it will indeed paſs out ſafely; but ſhould it meet with a wind in a nearly oppoſite direction, it would become the ſport of both theſe winds, and, unable to advance or recede, be driven in a middle courſe between their two directions, that is to ſay, full upon the rock of Scylla, if it be not immediately aſſiſted by the pilots. It is likewiſe obſerved, that in theſe hurricanes a land wind frequently riſes, which deſcends from a narrow paſs in Calabria, and increaſes the force with which the ſhip is impelled towards the rock.

SEA-SICKNESS is a diſorder which has been but little treated of, notwithſtanding the frequency of its occurrence, and the irkſomeneſs and diſtreſs to which the patient is ſubjected during its continuance It has been found to be very beneficial in ſeveral diſeaſes, among which the principal are aſthmatic and pulmonary complaints; and there are very few inſtances of its being attended with fatal conſequences. The ſea-ſickneſs ſeems to be a ſpaſmodic affection of the ſtomach, produced by the alternate preſſure and receſs of the contents of that viſcus againſt its lower internal ſurface, according as the riſe and fall of the ſhip oppoſes or recedes from the action of gravity.

Sea-ſi
neſs

The ſeas in which this diſorder attacks the paſſenger with the greateſt violence, are thoſe where the waves have long uninterrupted freedom of action; of courſe, bays, gulphs, and channels, may be navigated with leſs inconvenience, as the waves, meeting with more frequent reſiſtance, and the repercuſſion being conſiderably ſtronger, the veſſel does not experience that gentle uniform vacillation which ſickens the ſtomach, and renders the head giddy. By the ſame argument, a perſon feels leſs inconvenience from the diſorder on the wide ocean in a ſmall veſſel, on which the ſlighteſt motion of the waves makes a ſtrong impreſſion. He is likewiſe leſs expoſed to it in a very large veſſel, as in a ſhip of the line, or a large merchantman deeply laden; as the waves, in this caſe, ſcarcely affect the veſſel. It is in ſhips of the middling ſize, and which carry but a light cargo, that the paſſenger ſuffers moſt from the ſea ſickneſs. It has been obſerved, that this diſorder affects people in years leſs than young perſons; thoſe of a dark leſs than thoſe of a fair complection, and that it ſeldom attacks infants. The duration is not limited to any fixed period of time; with ſome it laſts only a few days, with others weeks, months, and even during the whole courſe of the voyage. The ſooner it takes place after embarkation, the greater probability is there of its continuance. It does not always ceaſe immediately on landing, but has been known, in ſome caſes, to continue for a conſiderable time. Even the oldeſt and moſt ſkilful ſeamen have experienced a relapſe, eſpecially if they have quitted the ſea ſervice for a long term of years.

There have been many modes recommended for mitigating, if not entirely preventing, this diſorder; among which the following ſeem the moſt efficacious:

1. Not to go on board immediately after eating; and, when on board, not to eat in any great quantity at any one meal.

2. To take ſtrong exerciſe, with as little intermiſſion as conveniently can be done; for inſtance, to aſſiſt at the pumps, or any other active employment, as indolent and ſlothful paſſengers always ſuffer moſt from the diſorder.

3. To keep much upon deck, even in ſtormy and rainy weather, as the ſea breeze is leſs liable to affect the ſtomach than the ſtagnated air of the cabin, which is frequently rendered infectious for want of ſufficient circulation.

4. Not to watch the motion of the waves, eſpecially when ſtrongly agitated with tempeſt.

5. To avoid carefully all employments which haraſs the mind, as reading, ſtudy, meditation, and gaming; and, on the other hand, to ſeek every opportunity of mirth and mental relaxation.

6. To drink occaſionally carbonic acids, as the froth of ſtrong fermented beer, or wine mixed with Seltzer water, and fermented with pounded ſugar, or a glaſs of Champaign.

7. It will be found of great ſervice to take the acid of ſulphur dulcified, dropped upon lump ſugar, or in peppermint-water; or ten drops of ſulphureous ether.

With regard to eating, it is adviſable to be very ſparing, at leaſt not to eat much at one meal. The proper diet is bread and freſh meat, which ſhould be eaten cold with pepper. All ſweet favoured food ſhould be carefully avoided; and the paſſenger ſhould refrain from fat, but eſpecially from all meat that is in the leaſt degree tainted. Even the odour of flowers is very pernicious; for which reaſon, it is not expedient to examine marine productions, as theſe generally have a nauſeating ſmell. The fumes of vinegar may be inhaled with great benefit. The drink ſhould conſiſt of tart wines, lemonade, or Seltzer water, but never of common water. The paſſenger would do well to drink little and often. As experience has proved, that an accidental diarrhœa has frequently relieved the patient from the ſea-ſickneſs, it will be prudent to follow the clue of nature, and take a gentle laxative, or, if circumſtances will permit, a clyſter of ſalt-water and Venice ſoap, which is the more neceſſary, as ſea-faring people are liable to obſtructions. It will further be found uſeful to apply to the pit of the ſtomach a tonic anodyne antiſpaſmodic emplaſtrum, ſpread upon leather, and covered with linen.

Where the above preventives have not been employed, or have not ſucceeded in ſecuring the paſſenger from the ſea-ſickneſs, he may, however, experience conſiderable relief from the following remedies :

If ſymptoms of vomiting appear, they may frequently be remedied by the patient proſtrating himſelf in a horizontal poſition, upon the back or belly, and lying perfectly ſtill. We would recommend likewiſe a gentle compreſſion of the abdomen. But if the fits of vomiting are too violent to be repreſſed, in that caſe, it is beſt to promote them by a ſtrong doſe of ſalt-water; an expedient, however, which muſt not be too often repeated, as it tends ſtill more to weaken the ſtomach. When the emetic takes effect, let the patient bend his body, advancing his knees towards his breaſt, and ſupport his head againſt a firm and ſolid reſting-place. He muſt be particularly careful to untie his garters and cravat, as this precaution will ſecure him from the riſk of a rupture, and from the ill effects of the blood ruſhing violently towards the head and breaſt.

After the vomiting has ſubſided, its return may be guarded againſt by preſerving a ſtate of repoſe, and even keeping the eyes ſhut for a conſiderable time. Let the patient chooſe a cool, ventilated place, remembering to keep himſelf warm and well clothed, as perſpiration is highly ſalutary. But he muſt not indulge in too long ſleep during the day-time, as this induces torpidneſs. In the morning he ſhould conſtantly take a gargle of ſugar diſſolved in vinegar. Let him eat often, but ſparingly; and if he can content himſelf with a diſh of chocolate, coffee, or ſtrong tea, he will reap ſtill greater benefit. He ſhould never drink water in its pure elementary ſtate, but mix it with brandy, vinegar, or wine. In the morning, inſtead of brandy, he may take a glaſs of wine, with an infuſion of orange peel, gentian root, or peruvian bark (*quinquina*). A glaſs of punch taken occaſionally will prove of very eſſential ſervice, as it promotes perſpiration.

Perſons in the habit of ſmoking, will find a pleaſant and ſalutary companion in the pipe; but thoſe who are not accuſtomed to it will be ſufferers by taking to the practice.

In concluſion, it is proper to add, that warm clothing, flannel ſhirts, trowſers, caps, &c. are efficacious remedies againſt exceſſive expectoration, and all other ſymptoms of this terrible diſorder.

SECTOR of a Sphere, is the ſolid generated by the revolution of the ſector of a circle about one of its radii; the other radius deſcribing the ſurface of a cone, and the circular arc a circular portion of the ſurface of the ſphere of the ſame radius. So that the ſpherical ſector conſiſts of a right cone, and of a ſegment of the ſphere having the ſame common baſe with the cone. And hence the ſolid content of it will be found by multiplying the baſe or ſpherical ſurface by the radius of the ſphere, and taking a third part of the product.

Sector *of an ellipſe*, or *of an hyperbola*, &c. is a part reſembling the circular ſector, being contained by three lines, two of which are radii, or lines drawn from the centre of the figure to the curve, and the intercepted arc or part of that curve.

SEEDS, Preservation of, in a ſtate fit for vegetation, is a matter of great and general importance, becauſe, if it can be accompliſhed, it will enable us to rear many uſeful plants in one country which are there unknown, being indigenous only in others at a great diſtance from it. There is a letter on this ſubject in the 16th volume of the *Tranſactions of the Society of Arts*, &c. from which we ſhall extract what is fit for our purpoſe.

"Many years ago (ſays the author), having obſerved ſome ſeeds which had got accidentally amongſt raiſins, and that they were ſuch as are generally attended with difficulty to raiſe in England after coming in the uſual way from abroad, I ſowed them in pots, within a framing; and as all of them grew, I commiſſioned my ſons, who were then abroad, to pack up all ſorts of ſeeds they could procure in abſorbent paper, and ſend ſome of them ſurrounded by raiſins, and others by brown moiſt ſugar; concluding that the former ſeeds had been preſerved by a peculiarly favourable ſtate of moiſture thus afforded them. It occurred, likewiſe, that as many of our common ſeeds, ſuch as clover, charlock, &c. would lie dormant for ages within the earth, well preſerved for vegetation whenever they might happen to be thrown to the ſurface, and expoſed to the atmoſphere, ſo theſe foreign ſeeds might be equally preſerved, for many months at leaſt, by the kindly covering and genial moiſture that either raiſins or ſugar afforded them: and this conjecture was really fulfilled, as not one in twenty of them failed to vegetate, when thoſe of the ſame kinds, that I ordered to be ſent lapped in common parcels, and forwarded with them, would not grow at all. I obſerved, upon examining them all before they were committed to the earth, that there was a prevailing dryneſs in the latter, and that the former looked freſh and healthy, and were not in the leaſt infeſted by inſects, as was the caſe with the others. It has been tried repeatedly to convey ſeeds (of many plants difficult to raiſe) cloſed up in bottles, but without ſucceſs; ſome greater proportion of air, as well as a proper ſtate of moiſture, perhaps, being neceſſary. I ſhould alſo obſerve, that no difference was made in the package of the ſeeds, reſpecting their being kept in huſks, pods, &c. ſo as to give thoſe in raiſins or ſugar any advantage over the others, all being ſent equally guarded by their natural teguments."

SEGALIEN, the name given by Europeans to a large iſland ſeparated by a narrow channel from the coaſt of Chineſe Tartary, and called by the natives *Tchoka*, and by the Chineſe *Oku-Jeſſo*. It lies between the 46th and 54th degrees of north latitude, but its breadth from eaſt to weſt is not known. Indeed hardly any thing about it was known till the year 1787, that M. La Perouſe penetrated almoſt to the bottom of the channel which ſeparates it from the continent, and which grew ſo very ſhallow as he advanced northward that, in all probability, the iſland will ſoon become a peninſula. The French frigates came to anchor in different bays on the coaſt of Segalien; and the fineſt of theſe bays, to which the Commodore gave the name of *Baie d'Eſtaing*, is ſituated in 48° 59′ N. Lat. and 140° 32′ Lon. Eaſt from Paris.

La Perouſe and M. Rollin, the ſurgeon of his ſhip, both deſcribe the natives of this iſland as a worthy and intelligent people. Of the preſents which were made to them, they ſeemed to ſet a value only on ſuch as were uſeful. Iron and ſtuffs prevailed over every thing; they underſtood metals as well as their gueſts, and for ornament preferred ſilver to copper, and copper to iron. They make uſe of looms, which, though ſmall, are very complete inſtruments; and by means of ſpindles they prepare thread of the hair of animals, of the bark of the willow, and the great nettle, from which they make their ſtuffs. They are of a moderate ſize, ſquat, and ſtrong built, with the muſcles of their bodies very exactly defined: their common height is five feet, and the greateſt does not exceed five feet four inches; but men of this ſize are very uncommon among them. They have all a large head, and a broader and more rounded face than Europeans; their countenance is animated and agreeable, though, upon the whole, it is deſtitute of that regularity and grace which we eſteem ſo eſſential to beauty: they have large cheeks, a ſhort noſe rounded at its extremity, with very broad noſtrils: their eyes are lively. of a moderate ſize, for the moſt part black, though ſome have blue ones among them: their eyebrows are buſhy, their mouth of the common ſize, their voice is ſtrong, their lips are rather thick, and of a dull red: M. Rollin remarked, that in ſeveral the upper lip was tattoed, and tinged of a blue colour: theſe, as well as their eyes, are capable of every variety of expreſſion: their teeth are white, even, and of the uſual number; their chin is rounded and a little advancing; their ears are ſmall: they bore and wear in them glaſs ornaments or ſilver rings.

The women are not ſo large as the men, and are of a more rounded and delicate figure, though there is but little difference between the features of their faces. Their upper lip is tattoed all over of a blue colour, and they wear their hair long and flowing: their dreſs hardly differs from that of the men; the colour of the ſkin in both ſexes is tawny, and that of their nails, which they ſuffer to grow to a great length, is a ſhade darker than that of Europeans. Theſe iſlanders are very hairy, and have long beards, which gives, eſpecially to the old men, a grave and venerable air: theſe laſt appear to be held in much reſpect by the younger part of the inhabitants. The hair of their head is black, ſmooth, and moderately ſtrong; in ſome it is of a cheſnut colour: they all wear it round, about ſix inches long behind, and cut into a bruſh on the top of their head and over the temples.

Their clothing conſiſts of a kind of ſurtout which wraps over before, where it is faſtened by little buttons, ſtrings, and a girdle placed above the haunches. This ſurtout is made of ſkin or quilted nankeen, a kind of ſtuff that they make of willow bark: it generally reaches to the calf of the leg, and ſometimes even lower, which for the moſt part renders the uſe of drawers unneceſſary: ſome of them wear ſeal ſkin boots, the feet of which, in form and workmanſhip, reſembles the Chineſe ſhoe; but the greater number of them go bare-footed and bare-headed: a few indeed wear a bandage of bear-ſkin round the head; but this is rather as an ornament than a defence againſt the weather.

Like the lower claſſes of the Chineſe, they all wear a girdle, to which they hang their knife as a defence againſt the bears, and ſeveral little pockets, into which they put their flint and ſteel, their pipe, and their box of tobacco; for they make a general practice of ſmoking.

Their huts are ſufficient to defend them againſt the rain and other inclemencies of the air, but are very ſmall in proportion to the number of the inhabitants which they contain. The roof is formed of two inclined planes, which are from ten to twelve feet high at their junction, and three or four on the ſides: the breadth of the roof is about fifteen feet, and its length eighteen: theſe cabins are conſtructed of frame work, ſtrongly put together, the ſides being filled up with the bark of trees, and the top thatched with dry graſs in the ſame manner as our cottages are.

On the inſide of theſe houſes is a ſquare of earth raiſed about ſix inches above the ground, and ſupported on the ſides by ſtrong planking; on this they make the fire: along the ſides of the apartment are benches twelve or fifteen inches high, which they cover with mats, on which they ſleep.

The utenſils that they employ in cooking their food conſiſt of an iron pot, ſhells, veſſels made of wood and birch bark, of various ſhapes and workmanſhip; and, like the Chineſe, they take up their food with little ſticks: they have generally two meals in the day, one at noon, and the other in the evening.

The habitations in the ſouth part of the iſland are much better built and furniſhed, having for the moſt part planked floors: our author ſaw in them ſome veſſels of Japan porcelain, on which the owners appeared to ſet great value, probably becauſe they are not to be procured but with great trouble and at conſiderable expence. They cultivate no kind of vegetable, living only on dried and ſmoked fiſh, and what little game they take by hunting.

Each family has its own canoe, and implements for fiſhing and hunting. Their arms are bows, javelins, and a kind of ſpontoon, which they uſe principally in bear-hunting. By the ſide of their houſes are the magazines, in which they lay up the proviſion which they have prepared and collected during ſummer for their winter ſubſiſtence. It conſiſts of dried fiſh, and a conſiderable quantity of garlic and wild celery, angelica, a bulbous root which they call *apè*, better known under the name of the yellow lily of Kamtſchatka, and fiſh oil, which they preſerve in the ſtomachs of bears, and other large animals. Theſe magazines are made of planks, ſtrongly and cloſely put together, raiſed above the ground on ſtakes about four feet high.

Dogs are the only domeſtic animals belonging to the natives of Tchoka; they are of a middling ſize, with ſhaggy hair, pricked ears, and a ſharp long muzzle; their cry is loud and not ſavage.

Theſe people, who are of a very mild and unſuſpecting diſpoſition, appear to have commercial intercourſe with the Chineſe by means of the Mantchou Tartars, with the Ruſſians to the north of their iſland, and the Japaneſe to the ſouth: but the articles of trade are of no great conſequence, conſiſting only of a few furs and whale oil This fiſh is caught only on the ſouthern coaſt of the iſland. Their mode of extracting the oil is by no means economical; they drag the whale on ſhore on a ſloping ground, and ſuffering it to putrify, receive in a trench, at the foot of the ſlope, the oil, which ſeparates ſpontaneouſly.

The iſland is well wooded, and mountainous towards the centre, but is flat and level along the coaſt, the ſoil of which appears admirably adapted to agriculture: vegetation is extremely vigorous here; foreſts of pine, willow, oak, and birch, cover nearly the whole ſurface. The ſea abounds with fiſh, as well as the rivers and brooks, which ſwarm with ſalmon and trout of an excellent quality. The weather is, in general, foggy and mild. All the inhabitants have an air of health and ſtrength, which they retain even to extreme old age; nor did our author obſerve among them any inſtance of defective organization, or the leaſt trace of contagious or eruptive diſorders.

SEGMENTS, LINE OF, are two particular lines, ſo called on Gunter's ſector. They lie between the lines of ſines and ſuperficies, and are numbered with 5, 6, 7, 8, 9, 10. They repreſent the diameter of a circle, ſo divided into 100 parts, as that a right line drawn through thoſe parts, and perpendicular to the diameter, ſhall cut the circle into two ſegments, the greater of which ſhall have the ſame proportion to the whole circle, as the parts cut off have to 100.

SEGO, the capital of the kingdom of Bambarra in Africa, is ſituated on the banks of the Niger, in 14° 4′ N. Lat. and 2° 1′ Weſt Long. It conſiſts, properly ſpeaking, of four diſtinct towns; two on the northern bank of the Niger, called Sego Korro, and Sego Boo; and two on the ſouthern bank, called Sego Soo Korro, and Sego See Korro. They are all ſurrounded with high mud-walls; the houſes are built of clay, of a ſquare form, with flat roofs; ſome of them have two ſtories, and many of them are whitewaſhed. Beſides theſe buildings, Mooriſh moſques are ſeen in every quarter; and the ſtreets, though narrow, are broad enough for every uſeful purpoſe in a country where wheel carriages are entirely unknown. Mr Park informs us, that from the beſt inquiries that he could make, he has reaſon to believe that Sego contains altogether about thirty thouſand inhabitants. The King of Bambarra conſtantly reſides at Sego See Korro; he employs a great many ſlaves in conveying people over the river, and the money they receive (though the fare is only ten kowrie ſhells for each individual) furniſhes a conſiderable revenue to the king in the courſe of a year. The canoes are of a ſingular conſtruction, each of them being formed of the trunks of two large trees, rendered concave, and joined together, not ſide by ſide, but endwiſe; the junction being exactly acroſs the middle of the canoe: they are therefore very long and diſproportionably narrow, and have neither decks nor maſts; they are, however, very roomy; for our author obſerved in one of them four horſes, and ſeveral people, croſſing over the river. The view of this extenſive city; the numerous canoes upon the river; the crowded population, and the cultivated ſtate of the ſurrounding country, formed altogether a proſpect of civilization and magnificence which he little expected to find in the boſom of Africa.

He met not, however, in Sego with that hoſpitality which he had experienced in ſome other African towns. The Moors, who abound in it, and whoſe bigotry renders them the implacable enemies of every white man ſuſpected of being a Chriſtian, contrived to perſuade the king that it was for no good purpoſe he had come into the territories of Bambarra. He was therefore ordered to take up his reſidence as a village a little diſtant, without being admitted into the royal preſence. Even there, ſo ſtrong was the prejudice that had been excited againſt him, no perſon would admit him into his houſe. About ſunſet, however, as he was preparing to paſs the night in the top of a tree, that he might not be in danger of being torn to pieces by wild beaſts, a poor Negro woman conducted him to her hut, dreſſed a fine fiſh for his ſupper, and furniſhed him with a mat to ſleep on. She then called to the female part of her family, who had ſtood gazing on him all the while with fixed aſtoniſhment, to reſume their taſk of ſpinning cotton; in which they continued to employ themſelves great part of the night. They lightened their labour by ſongs; one of which was compoſed extempore, for our author was himſelf the ſubject of it. It was ſung by one of the young women, the reſt joining in a ſort of chorus. The air was ſweet and plaintive, and the words, literally tranſlated, were theſe—"The winds roared, and the rains fell.—The poor white man, faint and weary, came and ſat under our tree.—He has no mother to bring him milk; no wife to grind his corn. *Chorus*. Let us pity the white man; no mother has he", &c. &c. "Trifling (ſays Mr Park) as this recital may appear to the reader, to a perſon in my ſituation the circumſtance was affecting in the higheſt degree."

Having remained three days in this village, he was diſmiſſed on the fourth, after receiving from the king 5000 kowries, to enable him to purchaſe proviſions in the courſe of his journey. Though this ſum amounted only to one pound ſterling, ſo cheap are the neceſſaries of life in Bambarra, that it was ſufficient to purchaſe proviſions for himſelf, and corn for his horſe, for fifty days.

SELL, in building, is of two kinds, viz. *Ground Sell*, which denotes the loweſt piece of timber in a wooden building, and that upon which the whole ſuperſtructure is raiſed; and *Sell of a Window*, or *of a Door*, which is the bottom piece in the frame of them, upon which they reſt.

SENN, a kind of itinerant cowkeeper in Switzerland, particularly in the canton of Appenzell. Theſe men do not grow ſo much hay themſelves as they require for their cattle during the winter ſeaſon, and ſome of them have no graſs lands at all. To ſupply this deficiency, they employ agents throughout the canton, who are to inform them where good hay may be obtained, which farmers made it in favourable weather, &c. and then the Senn, or the great cowkeeper, who is in want of fodder, makes his agreements for the winter with the wealthier farmers, to whom he ſucceſſively drives his cattle as ſoon as they return from graſs. Thus the itinerant Senn, with his cows, often viſits five different places during the winter ſeaſon. He who ſells the hay furniſhes the Senn not only with ſtabling for his beaſts, but boards and lodges him as well as his whole family. In return, the Senn, beſides paying the ſtipulated price for the hay, allows to his hoſt as much milk, whey, and *zieger* (a kind of lean cheeſe) as may be

Senn.

be uſed in the houſe, and leaves him alſo the manure of his cows. In the middle of April, when Nature revives, the Senn again iſſues forth with his herd to the meadows and fertile Alps, which he rents for the ſummer. Thus the life of theſe men is a conſtant migration, affording the moſt pleaſing variety, and bleſſing them with health, content, and cheerfulneſs; but they had not been then curſed with French fraternity.

Fine cattle are the pride of the cowkeeper who inhabits the Alps:—but, not ſatisfied with their natural beauty, he will likewiſe pleaſe his vanity. He adorns his beſt cows with large bells ſuſpended from broad thongs; and the expence in ſuch bells is carried even to a luxurious exceſs. Every Senn has an harmonious ſet of at leaſt two or three bells, chiming in with the famous *ranz des vaches* (A). The inhabitants of the Tyrol bring a number of ſuch bells, of all ſizes, to every fair kept in the canton of Appenzell. They are fixed to a broad ſtrap, neatly pinked, cut out, and embroidered; which is faſtened round the cow's neck by means of a large buckle. A bell of the largeſt ſize meaſures upwards of a foot in diameter, is of an uniform width at top, ſwells out in the middle, and tapers towards the end. It coſts from forty to fifty gilders; and the whole peal of bells, including the thongs, will ſometimes be worth between 140 and 150 gilders, while the whole apparel of the Senn himſelf, when beſt attired, does not amount to the price of twenty gilders. The fineſt black cow is adorned with the largeſt bell, and thoſe next in appearance have two ſmaller. Theſe ornaments, however, are not worn on every day, but only on ſolemn occaſions, viz. when, in the ſpring, they are driven up the Alps, or removed from one paſture to another; or when they deſcend in the autumn, or travel in the winter to the different farms, where their owner has contracted for hay. On ſuch days, the Senn, even in the depth of winter, appears dreſſed in a fine white ſhirt, of which the ſleeves are rolled up above the elbow; neatly embroidered red braces keep up his yellow linen trowſers, which reach down to the ſhoes; a ſmall leather cap, or hat, covers his head; and a new milk bowl, of wood ſkilfully carved, hangs acroſs the left ſhoulder. Thus arrayed, the Senn precedes ſinging the *ranz des vaches*, and followed by three or four fine goats; next comes the handſomeſt cow with the great bell; then the two other cows with ſmaller bells; and theſe are ſucceeded by the reſt of the cattle walking one after another, and having in their rear the bull with a one-legged milking ſtool hanging on his horns; the proceſſion is cloſed by a *traineau*, or ſledge, on which are placed the implements for the dairy. It is ſurpriſing to ſee how proud and pleaſed the cows ſtalk forth when ornamented with their bells. Who would imagine that even theſe animals are ſenſible of their rank, nay, touched with vanity and jealouſy! If the leading cow, who hitherto bore the largeſt bell, be deprived of her honours, ſhe very plainly manifeſts her grief at the diſgrace, by lowing inceſſantly, abſtaining from food, and growing lean. The happy rival, on whom the diſtinguiſhing badge of ſuperiority has devolved, experiences her marked vengeance, and is butted, wounded, and perſecuted by her in the moſt furious manner; until the former either recovers her bell, or is entirely removed from the herd. However ſingular this phenomenon may appear, it is placed beyond all doubt by the concurring teſtimony of centuries.

Serriſhtehdar || Shadows.

The cows, when diſperſed on the Alps, are brought together by the voice of the Senn, who is then ſaid to *allure* them (*locken*). How well the cattle diſtinguiſh the note of their keeper appears from the circumſtance of their haſtening to him, though at a great diſtance, whenever he begins to hum the *ranz des vaches*. He furniſhes that cow which is wont to ſtray fartheſt with a ſmall bell, and knows by her arrival that all the reſt are aſſembled.

SERRISHTEHDAR, in Bengal, keeper of records or accounts.

SEVEN STARS, a common denomination given to the cluſter of ſtars in the neck of the ſign Taurus, the bull, properly called the *Pleiades*. They are ſo called from their number Seven which appear to the naked eye, though ſome eyes can diſcover only ſix of them; but by the help of teleſcopes there appears to be a great multitude of them.

SEZAWUL, in Bengal, an officer deputed occaſionally to enforce the due payment of the revenue.

SHADOWS (COLOURED), a curious optical phenomenon, which was obſerved, a conſiderable number of years ago, by Profeſſor Scheiffer of Vienna, and more lately by Count Rumford. The Count made the diſcovery when proſecuting his experiments upon light; of which the reader will find ſome account under the titles LAMP and PHOTOMETER in this *Suppl.* "Deſirous (ſays he) of comparing the intenſity of the light of a clear blue ſky by day with that of a common wax-candle, I darkened my room, and letting the day-light from the north, coming thro' a hole near the top of the window-ſhutter, fall at an angle of about 70° upon a ſheet of very fine white paper, I placed a burning wax-candle in ſuch a poſition that its rays fell upon the ſame paper, and, as near as I could gueſs, in the line of reflection of the rays of day-light from without; when, interpoſing a cylinder of wood, about half an inch in diameter, before the centre of the paper, and at the diſtance of about two inches from its ſurface, I was much ſurpriſed to find that the two ſhadows projected by the cylinder upon the paper, inſtead of being merely ſhades without colour, as I expected; the one of them, that which, correſponding with the beam of day-light, was illuminated by the candle, was yellow; while the other, correſponding to the light of the candle, and conſequently illuminated by the light of the heavens, was of the moſt beautiful blue that it is poſſible to imagine. This appearance, which was not only unexpected, but was really in itſelf in the higheſt degree ſtriking and beautiful,

---

(A) This famous paſtoral ſong is never ſung by the cowherds with words to it: all the tones of it are ſimple, and moſtly formed within the throat. Hence the tune produces very little or no motion of the jawbones, and its ſounds do not reſemble thoſe which commonly iſſue from the human throat, but rather ſeem to be the tones of ſome wind inſtrument; particularly as ſcarcely any breathing is perceived, and as the cowherds ſometimes ſing for minutes together without fetching breath.

beautiful, I found upon repeated trials, and after varying the experiment in every way I could think of, to be ſo perfectly permanent, that it is abſolutely impoſſible to produce two ſhadows at the ſame time, from the ſame body, the one anſwering to a beam of day-light, and the other to the light of a candle or lamp, without theſe ſhadows being coloured, the one yellow, and the other blue.

"If the candle be brought nearer to the paper, the blue ſhadow will become of a deeper hue, and the yellow ſhadow will gradually grow fainter; but if it be removed farther off, the yellow ſhadow will become of a deeper colour, and the blue ſhadow will become fainter; and the candle remaining ſtationary in the ſame place, the ſame varieties in the ſtrength of the tints of the coloured ſhadows may be produced merely by opening the window-ſhutter a little more or leſs, and rendering the illumination of the paper, by the light from without, ſtronger or weaker. By either of theſe means, the coloured ſhadows may be made to paſs through all the gradations of ſhade, from the deepeſt to the lighteſt, and *vice verſa;* and it is not a little amuſing to ſee ſhadows thus glowing with all the brilliancy of the pureſt and moſt intenſe priſmatic colours, then paſſing ſuddenly through all the varieties of ſhade, preſerving in all the moſt perfect purity of tint, growing ſtronger and fainter, and vaniſhing and returning, at command."

With reſpect to the cauſes of the colours of theſe ſhadows, there is no doubt (ſays the Count) but they ariſe from the different qualities of the light by which they are illuminated; but how they are produced, does not appear to him ſo evident. With the utmoſt deference to this amiable and very ingenious philoſopher, we think all the phenomena of coloured ſhadows which he enumerates *, have been, or may be accounted for by Profeſſor Scherffer's theory, of which the reader will find, we hope, a perſpicuous view under *Accidental Colours*, in this *Supplement*.

SHAGREEN, or CHAGRIN, in commerce, a kind of grained leather; of the proceſs of preparing which, we gave the beſt account that we could then find in the *Encyclopædia*. That account, however, as we learn from Profeſſor Pallas, is very defective. He ſays, indeed, that no accurate account of it has ever been publiſhed in Europe previous to his own; of which we ſhall now lay an abridgement before our readers.

"All kinds of horſes or aſſes ſkin, which have been dreſſed in ſuch a manner as to appear grained, are, by the Tartars, called *ſauwer*, by the Perſians *ſogre*, and by the Turks *ſagri*, from which the Europeans have made *ſhagreen* or *chagrin*. The Tartars who reſide at Aſtracan, with a few of the Armenians of that city, are the only people in the Ruſſian empire acquainted with the art of making ſhagreen. Thoſe who follow this occupation not only gain conſiderable profit by the ſale of their production to the Tartars of Cuban, Aſtracan, and Caſan, who ornament with it their Turkey leather boots, ſlippers, and other articles made of leather, but they derive conſiderable advantage from the great ſale of horſes hides, which have undergone no other proceſs than that of being ſcraped clean, and of which ſeveral thouſands are annually exported, at the rate of from 75 to 85 roubles per hundred, to Perſia, where there is a ſcarcity of ſuch hides, and from which the greater part of the ſhagreen manufactured in that country is prepared. The hind part only of the hide, however, which is cut out in the form of a creſcent about a Ruſſian ell and a half in length acroſs the loins, and a ſhort ell in breadth along the back, can properly be employed for ſhagreen. The remaining part, as is proved by experience, is improper for that purpoſe, and is therefore rejected.

"The preparation of the ſkins, after being cut into the above form, is as follows:—They are depoſited in a tub filled with pure water, and ſuffered to remain there for ſeveral days, till they are thoroughly ſoaked, and the hair has dropped off. They are then taken from the tub, one by one, extended on boards placed in an oblique direction againſt a wall, the corners of them, which reach beyond the edges of the board, being made faſt, and the hair with the epidermis is then ſcraped off with a blunt iron ſcraper called *urak*. The ſkins thus cleaned are again put in pure water to ſoak. When all the ſkins have undergone this part of the proceſs, they are taken from the water a ſecond time, ſpread out one after the other as before, and the fleſh ſide is ſcraped with the ſame kind of inſtrument. They are carefully cleaned alſo on the hair ſide, ſo that nothing remains but the pure fibrous tiſſue, which ſerves for making parchment, conſiſting of coats of white medullary fibres, and which has a reſemblance to a ſwine's bladder ſoftened in water.

"After this preparation, the workmen take a certain kind of frames called *pälzi*, made of a ſtraight and a ſemicircular piece of wood, having nearly the ſame form as the ſkins. On theſe the ſkins are extended in as ſmooth and even a manner as poſſible by means of cords; and during the operation of extending them, they are ſeveral times beſprinkled with water, that no part of them may be dry, and occaſion an unequal tenſion. After they have been all extended on the frames, they are again moiſtened, and carried into the houſe, where the frames are depoſited cloſe to each other on the floor with the fleſh ſide of the ſkin next the ground. The upper ſide is then thickly beſtrewed with the black exceedingly ſmooth and hard ſeeds of a kind of gooſe foot (*chenopodium album*), which the Tartars call *alabuta*, and which grows in abundance, to about the height of a man, near the gardens and farms on the ſouth ſide of the Volga; and that they may make a ſtrong impreſſion on the ſkins, a piece of felt is ſpread over them, and the ſeeds are trod down with the feet, by which means they are deeply imprinted into the ſoft ſkins. The frames, without ſhaking the ſeeds, are then carried out into the open air, and placed in a reclining poſition againſt a wall to dry, the ſide covered with the ſeeds being next the wall, in order that it may be ſheltered from the ſun. In this ſtate the ſkins muſt be left ſeveral days to dry in the ſun, until no appearance of moiſture is obſerved in them, when they are fit to be taken from the frames. When the impreſſed ſeeds are beat off from the hair ſide, it appears full of indentations or inequalities, and has acquired that impreſſion which is to produce the grain of the ſhagreen, after the ſkins have been ſubjected to the laſt ſmoothing or ſcraping, and have been dipped in a ley, which will be mentioned hereafter, before they receive the dye.

"The operation of ſmoothing is performed on an inclined bench or board, which is furniſhed with an iron hook, and is covered with thick felt of ſheep's wool, on which the dry ſkin may gently reſt. The ſkin is ſuſpended in the middle of the bench or board to its iron hook, by means of one of the holes made in the edge of the ſkin for extending it in its frame as before mentioned; and a cord, having at its extremity a ſtone or a weight, is attached to each end of the ſkin, to keep it in its poſition while under the hands of the workman. It is then ſubjected to the operation of ſmoothing and ſcraping by means of two different inſtruments. The firſt uſed for this purpoſe, called by the Tartars *tckar*, is a piece of ſharp iron bent like a hook, with which the ſurface of the ſhagreen is pretty cloſely ſcraped to remove all the projecting inequalities. This operation, on account of the corneous hardneſs of the dry ſkin, is attended with ſome difficulty; and great caution is at the ſame time required that too much of the impreſſion of the *alabuta* ſeed be not deſtroyed, which might be the caſe if the iron were kept too ſharp. As the iron, however, is pretty blunt, which occaſions inequalities on the ſhagreen, this inconvenience muſt afterwards be remedied by means of a ſharp ſcraping iron or *urak*, by which the ſurface acquires a perfect uniformity, and only faint impreſſions of the *alabuta* ſeed then remain, and ſuch as the workman wiſhes. After all theſe operations, the ſhagreen is again put into water, partly to make it pliable, and partly to raiſe the grain. As the ſeeds occaſion indentations in the ſurface of the ſkin, the intermediate ſpaces, by the operations of ſmoothing and ſcraping, loſe ſome part of their projecting ſubſtance; but the points which have been depreſſed, and which have loſt none of their ſubſtance, now ſwell up above the ſcraped parts, and thus form the grain of the ſhagreen. To produce this effect, the ſkins are left to ſoak in water for 24 hours; after which they are immerſed ſeveral times in a ſtrong warm ley, obtained, by boiling, from a ſtrong alkaline earth named *ſchora*, which is found in great abundance in the neighbourhood of Aſtracan. When the ſkins have been taken from this ley, they are piled up while warm, on each other, and ſuffered to remain in that ſtate ſeveral hours; by which means they ſwell, and become ſoft. They are then left 24 hours in a moderately ſtrong pickle of common ſalt, which renders them exceedingly white and beautiful, and fit for receiving any colour. The colour moſt uſual for theſe ſkins is a ſea-green; but old experienced workmen can dye them blue, red, or black, and even make white ſhagreen.

"For the green colour nothing is neceſſary but filings of copper and ſal ammoniac. Sal ammoniac is diſſolved in water till the water is completely ſaturated; and the ſhagreen ſkins, ſtill moiſt, after being taken from the pickle, are waſhed over with the ſolution on the ungrained fleſh ſide, and when well moiſtened a thick layer of copper filings is ſtrewed over them: the ſkins are then folded double, ſo that the ſide covered with the filings is innermoſt. Each ſkin is then rolled up in a piece of felt; the rolls are all ranged together in proper order, and they are preſſed down in an uniform manner by ſome heavy bodies placed over them, under which they remain 24 hours. During that period, the ſolution of ſal ammoniac diſſolves a quantity of the cupreous particles ſufficient to penetrate the ſkin and to give it a ſea-green colour. If the firſt application be not ſufficient, the proceſs is repeated in the ſame manner; after which the ſkins are ſpread out and dried.

"For the blue dye, indigo is uſed. About two pounds of it, reduced to a fine powder, are put into a kettle; cold water is poured over it, and the mixture is ſtirred round till the colour begins to be diſſolved. Five pounds of pounded *alakar*, which is a kind of barilla or crude ſoda, prepared by the Armenians and Calmucs, is then diſſolved in it, with two pounds of lime and a pound of pure honey, and the whole is kept ſeveral days in the ſun, and during that time frequently ſtirred round. The ſkins intended to be dyed blue muſt be moiſtened only in the natrous ley *ſchora*, but not in the ſalt brine. When ſtill moiſt, they are folded up and ſewed together at the edge, the fleſh ſide being innermoſt, and the ſhagreened hair ſide outwards; after which they are dipped three times in the remains of an exhauſted kettle of the ſame dye, the ſuperfluous dye being each time expreſſed; and after this proceſs they are dipped in the freſh dye prepared as above, which muſt not be expreſſed. The ſkins are then hung up in the ſhade to dry; after which they are cleaned and paired at the edges.

"For black ſhagreen, gall-nuts and vitriol are employed in the following manner:—The ſkins, moiſt from the pickle, are thickly beſtrewed with finely pulveriſed gall nuts. They are then folded together, and laid over each other for 24 hours. A new ley, of bitter ſaline earth or *ſchora*, is in the mean time prepared, and poured hot into ſmall troughs. In this ley each ſkin is ſeveral times dipped; after which they are again beſtrewed with pounded gall-nuts, and placed in heaps for a certain period, that the galls may thoroughly penetrate them, and they are dried and beat, to free them from the duſt of the galls. When this is done, they are rubbed over, on the ſhagreen ſide, with melted ſheep's tallow, and expoſed a little in the ſun, that they may imbibe the greaſe. The ſhagreen-makers are accuſtomed alſo to roll up each ſkin ſeparately, and to preſs or ſqueeze it with their hands againſt ſome hard ſubſtance, in order to promote the abſorption of the tallow. The ſuperfluous particles are removed by means of a blunt wooden ſcraper *(urac)*; and when this proceſs is finiſhed, and the ſkins have lain ſome time, a ſufficient quantity of vitriol of iron is diſſolved in water, with which the ſhagreen is moiſtened on both ſides, and by this operation it acquires a beautiful black dye. It is then dreſſed at the edges, and in other places where there are any blemiſhes.

"To obtain white ſhagreen, the ſkins muſt firſt be moiſtened on the ſhagreen ſide with a ſtrong ſolution of alum. When the ſkin has imbibed this liquor, it is daubed over on both ſides with a paſte made of flour, which is ſuffered to dry. The paſte is then waſhed off with alum-water, and the ſkin is placed in the ſun till it is completely dry. As ſoon as it is dry, it is gently beſmeared with pure melted ſheep's tallow, which it is ſuffered to imbibe in the ſun; and to promote the effect, it is preſſed and worked with the hands. The ſkins are then faſtened in ſucceſſion to the before-mentioned bench, where warm water is poured over them, and the ſuperfluous fat is ſcraped off with a blunt wooden inſtrument. In the laſt operation the warm water is of great ſervice. In this manner ſhagreen perfectly white is obtained, and nothing remains but to pare the edges and dreſs it.

"But this white ſhagreen is not intended ſo much for remaining in that ſtate, as for receiving a dark red dye; becauſe, by the above previous proceſs, the colour becomes much more perfect. The ſkins deſtined for a red colour muſt not be immerſed firſt in ley of bitter ſalt earth (*ſchora*), and then in pickle, but after they have been whitened, muſt be left to ſoak in the pickle for 24 hours. The dye is prepared from cochineal, which the Tartars call *kirmitz*. About a pound of the dried herb *tſchagann*, which grows in great abundance in the neighbourhood of Aſtracan, and is a kind of ſoda-plant or kali (*ſalſola ericoides* (A), is boiled a full hour in a kettle containing about four common pailfuls of water; by which means the water acquires a greeniſh colour. The herb is then taken out, and about half a pound of pounded cochineal is put into the kettle, and the liquor is left to boil a full hour, care being taken to ſtir it that it may not run over. About 15 or 20 drams of a ſubſtance which the dyers call *lüter* (orchilla) is added, and when the liquor has been boiled for ſome time longer, the kettle is removed from the fire. The ſkins taken from the pickle are then placed over each other in troughs, and the dye-liquor is poured over them four different times, and rubbed into them with the hands, that the colour may be equally imbibed and diffuſed. The liquor each time is expreſſed; after which they are fit for being dried. Skins prepared in this manner are ſold at a much dearer rate than any of the other kinds."

SHARP (Abraham), an eminent mathematician, mechaniſt, and aſtronomer, was deſcended from an ancient family at Little-Horton, near Bradford, in the Weſt Riding of Yorkſhire, where he was born about the year 1651. At a proper age he was put apprentice to a merchant at Mancheſter; but his genius led him ſo ſtrongly to the ſtudy of mathematics, both theoretical and practical, that he ſoon became uneaſy in that ſituation of life. By the mutual conſent, therefore, of his maſter and himſelf, though not altogether with that of his father, he quitted the buſineſs of a merchant. Upon this he removed to Liverpool, where he gave himſelf up wholly to the ſtudy of mathematics, aſtronomy, &c.; and where, for a ſubſiſtence, he opened a ſchool, and taught writing and accounts, &c.

He had not been long at Liverpool when he accidentally fell in company with a merchant or tradeſman viſiting that town from London, in whoſe houſe it ſeems the aſtronomer Mr Flamſteed then lodged. With the view therefore of becoming acquainted with this eminent man, Mr Sharp engaged himſelf with the merchant as a book-keeper. In conſequence he ſoon contracted an intimate acquaintance and friendſhip with Mr Flamſteed, by whoſe intereſt and recommendation he obtained a more profitable employment in the dock-yard at Chatham; where he continued till his friend and patron, knowing his great merit in aſtronomy and mechanics, called him to his aſſiſtance, in contriving, adapting, and fitting up the aſtronomical apparatus in the Royal Obſervatory at Greenwich, which had been lately built, namely, about the year 1676. He was principally employed in the conſtruction of the mural arch; which in the compaſs of 14 months he finiſhed ſo greatly to the ſatisfaction of Mr Flamſteed, that he ſpeaks of him in terms of the higheſt praiſe. According to Mr Smeaton, this was the firſt good and valid inſtrument of the kind; and Mr Sharp the firſt artiſt who cut accurate and delicate diviſions upon aſtronomical inſtruments. At the time this inſtrument was conſtructed, Mr Flamſteed was 30 and Mr Sharp 25 years of age.

Sharp.

Theſe two friends continued together for ſome time, making obſervations on the meridional zenith diſtances of the fixed ſtars, ſun, moon, and planets, with the times of their tranſits over the meridian; alſo the diameters of the ſun and moon, and their eclipſes, with thoſe of Jupiter's ſatellites, the variation of the compaſs, &c.

Mr Sharp aſſiſted Mr Flamſteed alſo in making a catalogue of near 3000 fixed ſtars, with their longitudes and magnitudes, their right aſcenſions and polar diſtances, with the variations of the ſame while they change their longitude by one degree.

But from the fatigue of continually obſerving the ſtars at night, in a cold thin air, joined to a weakly conſtitution, he was reduced to a bad ſtate of health; for the recovery of which he deſired leave to retire to his houſe at Horton; where, as ſoon as he found himſelf on the recovery, he began to fit up an obſervatory of his own; having firſt made an elegant and curious engine for turning all kinds of work in wood or braſs, with a maundril for turning irregular figures, as ovals, roſes, wreathed pillars, &c. Beſide theſe, he made himſelf moſt of the tools uſed by joiners, clockmakers, opticians, mathematical inſtrument makers, &c. The limbs or arcs of his large equatorial inſtrument, ſextant, quadrant, &c. he graduated with the niceſt accuracy, by diagonal diviſions into degrees and minutes. The teleſcopes he made uſe of were all of his own making, and the lenſes ground, figured, and adjuſted with his own hands.

It was at this time that he aſſiſted Mr Flamſteed in calculating moſt of the tables in the ſecond volume of his *Hiſtoria Cæleſtis*, as appears by their letters, to be ſeen in the hands of Mr Sharp's friends at Horton. Likewiſe the curious drawings of the charts of all the conſtellations viſible in our hemiſphere, with the ſtill more excellent drawings of the planiſpheres both of the northern and ſouthern conſtellations. And though theſe drawings of the conſtellations were ſent to be engraved at Amſterdam by a maſterly hand, yet the originals far exceeded the engravings in point of beauty and elegance: theſe were publiſhed by Mr Flamſteed, and both copies may be ſeen at Horton.

The mathematician, ſays Dr Hutton, meets with ſomething extraordinary in Sharp's elaborate treatiſe of *Geometry Improved* (in 4to, 1717, ſigned A. S. Philomath): 1ſt, by a large and accurate table of ſegments of circles, its conſtruction and various uſes in the ſolution of ſeveral difficult problems, with compendious tables for

---

(A) The beautiful red Turkey leather is dyed with cochineal prepared in the ſame manner. Profeſſor Gmelin junior, in the ſecond part of his Travels through Ruſſia, explains the herb *tſchagann* by *artemiſia annua*, having doubtleſs been deceived by the appearance the plant acquires after it has been dried. Beſides, this *artemiſia* is found only in the middle of Siberia, and never on the weſt ſide of the Irtiſch.

for finding a true proportional part; and their uſe in theſe or any other tables exemplified in making logarithms, or their natural numbers, to 60 places of figures; there being a table of them for all primes to 1100, true to 61 figures. 2d, His conciſe treatiſe of Polyedra, or ſolid bodies of many baſes, both the regular ones and others: to which are added twelve new ones, with various methods of forming them, and their exact dimenſions in ſurds, or ſpecies, and in numbers; illuſtrated with a variety of copperplates, neatly engraved by his own hands. Alſo the models of theſe polyedra he cut out in boxwood with amazing neatneſs and accuracy. Indeed few or none of the mathematical inſtrument makers could exceed him in exactly graduating or neatly engraving any mathematical or aſtronomical inſtrument, as may be ſeen in the equatorial inſtrument above mentioned, or in his ſextant, quadrants, and dials of various ſorts; alſo in a curious armillary ſphere, which, beſide the common properties, has moveable circles, &c. for exhibiting and reſolving all ſpherical triangles; alſo his double ſector, with many other inſtruments, all contrived, graduated, and finiſhed, in a moſt elegant manner, by himſelf. In ſhort, he poſſeſſed at once a remarkably clear head for contriving, and an extraordinary hand for executing, any thing, not only in mechanics, but likewiſe in drawing, writing, and making the moſt exact and beautiful ſchemes or figures in all his calculations and geometrical conſtructions.

The quadrature of the circle was undertaken by him for his own private amuſement in the year 1699, deduced from two different ſeries, by which the truth of it was proved to 72 places of figures; as may be ſeen in the introduction to Sherwin's Tables of Logarithms; that is, if the diameter of a circle be 1, the circumference will be found equal to 3·14159265358979323846264338327950288419716939937510582097494459230781640 5, &c. In the ſame book of Sherwin's may alſo be ſeen his ingenious improvements on the making of logarithms, and the conſtructing of the natural ſines, tangents, and ſecants.

He alſo calculated the natural and logarithmic ſines, tangents, and ſecants, to every ſecond in the firſt minute of the quadrant; the laborious inveſtigation of which may probably be ſeen in the archives of the Royal Society, as they were preſented to Mr Patrick Murdoch for that purpoſe; exhibiting his very neat and accurate manner of writing and arranging his figures, not to be equalled perhaps by the beſt penman now living.

Mr Sharp kept up a correſpondence by letters with moſt of the eminent mathematicians and aſtronomers of his time, as Mr Flamſteed, Sir Iſaac Newton, Dr Halley, Dr Wallis, Mr Hodgſon, Mr Sherwin, &c. the anſwers to which letters are all written upon the backs, or empty ſpaces, of the letters he received, in a ſhort-hand of his own contrivance. From a great variety of letters (of which a large cheſtful remain with his friends) from theſe and many other celebrated mathematicians, it is evident that Mr Sharp ſpared neither pains nor time to promote real ſcience. Indeed, being one of the moſt accurate and indefatigable computers that ever exiſted, he was for many years the common reſource for Mr Flamſteed, Sir Jonas Moore, Dr Halley, and others, in all ſorts of troubleſome and delicate calculations.

Mr Sharp continued all his life a bachelor, and ſpent his time as recluſe as a hermit. He was of a middle ſtature, but very thin, being of a weakly conſtitution. He was remarkably feeble the laſt three or four years before he died, which was on the 18th of July 1742, in the 91ſt year of his age.

In his retirement at Little Horton, he employed four or five rooms or apartments in his houſe for different purpoſes, into which none of his family could poſſibly enter at any time without his permiſſion. He was ſeldom viſited by any perſons, except two gentlemen of Bradford, the one a mathematician, and the other an ingenious apothecary; theſe were admitted, when he choſe to be ſeen by them, by the ſignal of rubbing a ſtone againſt a certain part of the outſide wall of the houſe. He duly attended the diſſenting chapel at Bradford, of which he was a member, every Sunday; at which time he took care to be provided with plenty of halfpence, which he very charitably ſuffered to be taken ſingly out of his hand, held behind him during his walk to the chapel, by a number of poor people who followed him, without his ever looking back, or aſking a ſingle queſtion.

Mr Sharp was very irregular as to his meals, and remarkably ſparing in his diet; which he frequently took in the following manner. A little ſquare hole, ſomething like a window, made a communication between the room where he was uſually employed in calculations, and another chamber or room in the houſe where a ſervant could enter; and before this hole he had contrived a ſliding board: the ſervant always placed his victuals in this hole, without ſpeaking or making any the leaſt noiſe; and when he had a little leiſure, he viſited his cupboard to ſee what it afforded to ſatisfy his hunger or thirſt. But it often happened, that the breakfaſt, dinner, and ſupper, have remained untouched by him, when the ſervant has gone to remove what was left—ſo deeply engaged had he been in calculations.

SHARPS in flour, the finer part of what we have denominated Pollards. See that article, *Suppl.*

SHASTAH, the ſame as Shaster; which ſee, *Encycl.*

SHEA, the name of a tree, from the fruit of which the Negroes, in the interior parts of Africa between the tropics, prepare a kind of vegetable butter. Theſe trees are not planted by the natives, but are found growing naturally in the woods; and in clearing wood land for cultivation, every tree is cut down but the Shea. The tree itſelf very much reſembles the American oak; and the fruit, from the kernel of which being firſt dried in the ſun the butter is prepared, by boiling the kernel in water, has ſomewhat the appearance of a Spaniſh olive. The kernel is enveloped in a ſweet pulp, under a thin green rind; and the butter produced from it, beſides the advantage of its keeping the whole year without ſalt, is whiter, firmer, and, Mr Park ſays, to his palate, of a richer flavour than the beſt butter which he ever taſted made from cows milk. The growth and preparation of this commodity, ſeem to be among the firſt objects of African induſtry in this and the neighbouring ſtates; and it conſtitutes a main article of their inland commerce. In ſome places they dry the fruit in kilns, containing each about half a cart load of fruit, under which is kept up a clear wood fire. Our author, who ſaw the fruit in one of theſe kilns, was informed, that in three days the fruit would

would be ready for pounding and boiling ; and that the butter thus manufactured, is preferable to that which is prepared from fruit dried in the ſun ; eſpecially in the rainy ſeaſon, when the proceſs by inſolation is always tedious, and oftentimes ineffectual. Might it not be worth while, if practicable, to cultivate Shea-trees in ſome of our Weſt India iſlands ?

SHEAVE, in mechanics, a ſolid cylindrical wheel, fixed in a channel, and moveable about an axis, as being uſed to raiſe or increaſe the mechanical powers applied to remove any body.

SHEBBEARE (John) was born at Bideford, a conſiderable ſea-port and corporation town in Devonſhire, in the year 1709. His father was an attorney ; but having ſmall practice and little fortune, he carried on alſo the buſineſs of a corn factor. He had four children, two ſons and two daughters. Of the ſons, John, the ſubject of our preſent memoir, was the eldeſt. The other ſon was called Richard, and entirely the reverſe of his brother in diſpoſition ; he was bred to the ſea, and died young.

John received the rudiments of his education at the free grammar ſchool of Exeter, then conducted by the learned Mr Zachary Mudge (author of an Eſſay for a new Verſion of the Pſalms, and a volume of excellent Sermons), afterwards Rector of St Andrew in Plymouth. It has oftentimes been remarked, that the future life of a man may be nearly gueſſed at from his puerile character. Thus Shebbeare, while a ſchool-boy, gave the ſtrongeſt indications of his future eminence in miſanthropy and literature, by the remarkable tenaciouſneſs of his memory, and the readineſs of his wit, and no leſs ſo by the malignity of his diſpoſition ; being univerſally conſidered as a lad of ſurpriſing genius, while at the ſame time he was as generally deſpiſed for his malicious and ungrateful temper. This may eaſily be believed, when it is ſaid, that he formed not one connection, either at ſchool or afterwards, with any perſon in the way of friendſhip, except with a young barber of an abandoned character, but whoſe ſoul was perfectly congenial to that of Shebbeare's.

Such is the account of Shebbeare's boyiſh years which we have in the 14th volume of the *European Magazine*. It is probably much exaggerated ; for Shebbeare continued through life a ſtaunch Tory, if not a Jacobite ; and it is well known that many of our journaliſts conſider themſelves as at liberty to give what characters they pleaſe of ſuch men.

In the fifteenth or ſixteenth year of his age, young Shebbeare was bound apprentice to a very eminent and worthy ſurgeon in his native town ; in which ſituation he acquired a conſiderable ſhare of medical knowledge. His genius for lampoon appeared at this early period, and he could not forbear from exerciſing it on his maſter. No one indeed could give him the ſlighteſt offence with impunity ; for which reaſon almoſt every perſon avoided his acquaintance, as we would avoid the careſſing of an adder. The chief marks, however, of the arrows of his wit were the gentlemen of the corporation : one or other, and ſometimes all of them, were almoſt conſtantly expoſed in a libel upon the public poſts and corners of the ſtreets. But though the wiſer part of them only laughed at theſe harmleſs trifles, yet ſome were more irritable, and many a proſecution was commenced againſt, but not one could fix itſelf upon him, ſo artfully had he contrived to conceal himſelf. He was alſo ſeveral times ſummoned to appear at the ſeſſions, for daring to ſpeak and write irreverently of the worſhipful magiſtrates ; but the laugh was always on the ſide of Shebbeare, nor could they ever come at his back, ſo cloſely had he fitted on his armour, with the whip of authority.

Shebbeare.

When he was out of his time he ſet up trade for himſelf, and then ſhewed a taſte for chemiſtry; and ſoon after he married a very agreeable and amiable young woman, of no fortune, but of a genteel family. Whether his inſuperable propenſity to ſatire deprived him of friends and of buſineſs, or that he ſpent too much in chemical experiments, we know not; but failing at Bideford, he removed, about the year 1736, to Briſtol, where he entered into partnerſhip with a chemiſt, and never afterwards ſet his foot in his native town.

In the year 1739 he attracted the attention of the public, by an epitaph to the memory of Thomas Coſter, Eſq; member for Briſtol ; in which, it has been truly obſerved, that he has contrived to raiſe emotions of pity, grief, and indignation, to a very high degree. The next year he publiſhed a pamphlet on the Briſtol waters ; from which period there is a chaſm in our author's life we are unable to fill up. In this interval may probably be placed his failure in buſineſs, and his effort to obtain a higher ſituation in his profeſſion. It is certain that in the year 1752 he was at Paris, and there he obtained the degree, if he obtained it at all, which gave him the addition to his name which accompanied him during the reſt of his life, that of Doctor. Until this time he appears to have lived in obſcurity ; but at an age when vigorous exertion uſually ſubſides, he ſeems to have reſolved to place himſelf in a conſpicuous ſituation, whatever hazard might attend it, and commenced a public writer with a degree of celerity and virulence for which it would be difficult to find a parallel even in the moſt intemperate times. To read over his works now, when the paſſions they then raiſed have ſubſided, we feel ſurpriſe at the effect they produced ; and it is within the memory of many yet living, that their influence was very conſiderable. In the year 1754, he began his career with The Marriage Act, a political novel ; in which he treated the legiſlature with ſuch freedom, that it occaſioned his being taken into cuſtody, from whence, however, he was ſoon releaſed.

The performances, however, moſt celebrated, were a ſeries of Letters to the People of England, which were written in a ſtyle vigorous and energetic, though ſlovenly and careleſs, well calculated to make an impreſſion on common readers ; and were accordingly read with avidity, and circulated with diligence. They had a very conſiderable effect on the minds of the people, and galled the miniſtry, who ſeem to have been at firſt too eager to puniſh the author. On the publication of the Third Letter, we find warrants, dated 4th and 8th of March, 1756, iſſued by Lord Holderneſſe, to take up both Scott the publiſher and the author. This proſecution, however, ſeems to have been dropt, and the culprit proceeded for ſome time unmoleſted, " having declared (ſays one of his anſwerers) that he would write himſelf into a poſt or into the pillory ; in the laſt of which he at length ſucceeded." On the 12th of January 1758, a general warrant was ſigned by Lord Holderneſſe, to ſearch for the author, printer, and publiſhers of a wicked, audacious, and treaſonable libel, entitled, " A Sixth Letter to the People of England, on the progreſs of national ruin; in which is ſhewn that the preſent grandeur of France and calamities of this nation are owing to the influence of Hanover on the councils of England;" and them having found, to ſeize and apprehend, together with their books and papers.

At this juncture government ſeem to have been effectually rouſed; for having received information that a ſeventh letter was printing, by virtue of another warrant, dated January 23, all the copies were ſeized and entirely ſuppreſſed. In Eaſter Term an information was filed againſt him by Mr Pratt, then attorney general, afterwards Lord Camden; in which it is now worthy of remark, that the crown officer, in his application to the court, in expreſs terms admitted a point, ſince much diſputed, that of the jury's right to determine both the law and the fact in matters of libel. " What I urge (ſays the advocate) to the court, is only to ſhew there is reaſonable ground for conſidering this publication as a libel, and for putting it in a way of trial, and therefore it is I pray to have the rule made abſolute; for I admit, and your lordſhip well knows, that the jury in matter of libel are judges of the law as well as the fact, and have an undoubted right to conſider whether, upon the whole, the pamphlet in queſtion be, or be not, a falſe, malicious, and ſcandalous libel." On the 17th of June, the information was tried, when our author was found guilty; and on the 28th November, he received ſentence, by which he was fined five pounds, ordered to ſtand in the pillory December 5, at Charing Croſs, to be confined three years, and to give ſecurity for his good behaviour for ſeven years, himſelf in 500l. and two others in 250l. each.

On the day appointed, that part of the ſentence which doomed him to the pillory was put in execution, amidſt a prodigious concourſe of people aſſembled on the occaſion. The under ſheriff, at that time, happened to be Mr Beardmore, who had ſometimes been aſſiſted by the Doctor in writing the Monitor, a paper in its principles of the ſame tendency with the writings of the culprit, who conſequently might expect every indulgence from the officer to whom the execution of his ſentence was committed. The manner in which it was conducted may be learned from the affidavits on which afterwards the under ſheriff's conduct became the ſubject of animadverſion in the court of King's Bench, and which aſſert, " that the defendant only ſtood upon the platform of the pillory, unconfined, and at his eaſe, attended by a ſervant in livery (which ſervant and livery were hired for the occaſion only) holding an umbrella over head all the time: but his head, hands, neck, and arms, were not at all confined, or put into the holes of the pillory; only that he ſometimes put his hands upon the holes of the pillory in order to reſt himſelf." For this neglect of duty, Beardmore was fined 50l. and ſuffered two months impriſonment.

Some time before he was tried for the obnoxious publication already mentioned, the Ducheſs of Queensbury, as heir of Lord Clarendon, obtained an injunction in the Court of Chancery to ſtop the publication of the continuation of that nobleman's hiſtory; a copy of which had got into the hands of Francis Gwyn, Eſq; between whom and the Doctor there had been an agreement to publiſh it and equally divide the profits. The care and expences attending the uſhering this work into the world were to be wholly Dr Shebbeare's, who performed his part of the agreement, and cauſed it to be handſomely printed in quarto, with a Tory preface, containing frequent reflections on, and alluſions to recent events, and to living characters, which gave it the appearance rather of a temporary pamphlet than of a work calculated for poſterity. On the injunction being obtained, Dr Shebbeare was under the neceſſity of applying to the aid of law to recover the money expended by him in printing, amounting to more than 500l. Of that ſum more than half had been waſted on his ſide in the courts of law and equity. And ſome years afterwards, ſpeaking of the ſituation of his affairs, he ſays, " It may be eaſily imagined, that my circumſtances were not improved by three years impriſonment. I had no club of partizans to maintain me during that time, to diſcharge my debts, nor even the fine, which I was obliged to pay after a three years confinement for a ſingle offence. Notwithſtanding the difficulties which inevitably aroſe from theſe particulars, and although an inſolvent act was paſſed ſoon after his Majeſty's acceſſion to the throne, and my circumſtances might have apologiſed for my taking that opportunity which it offered; I nevertheleſs declined from availing myſelf of that occaſion to evade the payment of my debts. I preferred the labour of endeavouring to pay them, and the riſk of being again impriſoned if I did not ſucceed. But, thank Heaven, I am in no danger of a ſecond impriſonment on that account." During his confinement, he declares he never received as preſents more than twenty guineas from all the world.

While he was confined in the King's Bench, he ſolicited ſubſcriptions for the firſt volume of a Hiſtory of England, from the Revolution to the then preſent time. But at the perſuaſion of his friends he was induced to alter his deſign, and receipts were iſſued for a firſt volume of the Hiſtory of England, and of the Conſtitution thereof from its origin. That volume he wrote, and had tranſcribed. " But as it was impracticable (to uſe his own words), whilſt I was in confinement, to procure that variety of books, or to apply to manuſcript authorities, for all that was requiſite to the completing of this firſt volume, I found on being releaſed from my impriſonment, and on application to the former only, that the volume which I had written was incorrect, inſufficient, and erroneous, in too many particulars, to admit of its being publiſhed, without injuſtice to my ſubſcribers, and reprehenſions on myſelf. Into this diſpleaſing ſituation I had been miſled by relying on the authorities of modern hiſtorians, who pretend to cite the authors from whence their materials are taken, many of whom appear never to have ſeen them, but implicitly to have copied one another, and all of them manifeſtly defective; not only in the authorities they ſhould have ſought, but in their omiſſions and miſrepreſentations of thoſe whom they had conſulted: more eſpecially reſpecting thoſe parts of the old German codes, on which our conſtitution is erected, and without which it cannot be properly explained or underſtood. Such being the real ſituation of things, I perceived that more time than I could expect to live would be neceſſarily required for ſo extenſive a work as the whole hiſtory I had propoſed ; and that a ſingle volume, or even a few volumes of an hiſtory incomplete, would by no means anſwer either the intention of my ſubſcribers, or my own : I determined therefore to change my plan, and to include in one volume that which might require no others to complete this new deſign.

"In conſequence of this alteration, I reſolved to exert my beſt abilities, not only to trace the conſtitution of England from its origin in the woods of Germany, as M. de Monteſquieu expreſſes it, but from the firſt principles of human nature, from which the formation of all kinds of government is derived. With this view, I have attempted an analyzation of the mental and corporeal faculties, in order to ſhew in what manner they reciprocally influence each other in the various actions of man, not only as an individual, but as a gregarious being, impelled by nature to aſſociate in communities. From hence I have attempted to delineate in what manner legiſlature ſprang and proceeded from its ſource, through that variety of meanders which it hath formed in its current, both before and ſince the introduction of one common ſign, whereby to expreſs the intrinſic value, not only of all the productions of nature and of art, but even of the human faculties, as they are now eſtimated ; to compare the conſtitutions of thoſe different ſtates which have been, and are the moſt celebrated in ancient and modern hiſtory, with each other, and with that of England ; and then to derive ſome reaſonable grounds for the determination of that which ſeems to be the moſt conſentaneous with the primogenial inſtitutes of nature, and the happineſs of human kind. In conſequence of this intent, the manners that ſucceſſively aroſe and prevailed in ſuch ſtates, the benefits and miſchiefs which enſued from them, are delineated, in order to explain on what foundation the welfare of national communities may moſt probably be eſtabliſhed."

This plan, thus delineated, he at times employed himſelf in filling up ; but on being rudely attacked for not performing his promiſe with his ſubſcribers, he, in 1774, obſerved — "From the inevitable obligations, not only of ſupporting my own family, but thoſe alſo whom as ſon and brother it was my duty to ſuſtain for forty years, and which, reſpecting the claims of the latter, ſtill continues ; it will be eaſily diſcerned that many an avocation muſt have proceeded from theſe circumſtances, as well as from a ſenſe of gratitude to his majeſty, in defence of whoſe government I have thought it my duty occaſionally to exert my beſt abilities." He adds, however, that he did not intend to die until what he had propoſed was finiſhed ; a promiſe which the event has ſhewn he was unable to perform.

In priſon he was detained during the whole time of the ſentence, and with ſome degree of rigour ; for when his life was in danger from an ill ſtate of health, and he applied to the court of King's Bench for permiſſion to be carried into the rules a few hours in a day, tho' Lord Mansfield acceded to the petition, yet the prayer of it was denied and defeated by Judge Foſter. At the expiration of the time of his ſentence, a new reign had commenced ; and ſhortly afterwards, during the adminiſtration of Mr Grenville, a penſion was granted him by the crown. This he obtained by the perſonal application of Sir John Philips to the King, who, on that occaſion, was pleaſed to ſpeak of him in very favourable terms, which he promiſed undeviatingly to endeavour to deſerve by allegiance and gratitude.

From the time of that event we find Dr Shebbeare a uniform defender of the meaſures of Government, and the mark againſt whom every oppoſer of adminiſtration conſidered himſelf at liberty to throw out the groſſeſt abuſe. Even the friends of power were often adverſe to him. Dr Smollet introduced him in no very reſpectful light, under the name of Ferret, in the novel of Sir Launcelot Greaves, and Mr Hogarth made him one of the group in the third election print.

Scarce a periodical publication was without ſome abuſe of him, which he ſeems to have in general had the good ſenſe to neglect. In the year 1774, however, he departed from his general practice, and defended himſelf from ſome attacks at that time made upon him. In this pamphlet he repreſented the conduct and character of King William in ſuch a light as to excite the indignation of every Whig in the kingdom : he treated him in print with as great ſeverity as Johnſon uſed to do in converſation.

Early in life he appears to have written a comedy, which in 1766 he made an effort to get repreſented at Covent Garden. In 1768 he wrote the Review of Books in the Political Regiſter for three months, and was often engaged to write for particular perſons, with whom he frequently quarrelled when he came to be paid. This was the caſe with Sir Robert Fletcher, and we think of others. His pen ſeems to have been conſtantly employed, and he wrote with great rapidity, what certainly can now be read with little ſatisfaction, and muſt ſoon be forgotten. Though penſioned by government, he can ſcarce be ſaid to have renounced his opinions ; for in the pamphlet already mentioned, his abuſe of the Revolution is as groſs as in that for which he ſuffered the pillory. His violence defeated his own purpoſe, and made thoſe who agreed in party with him revolt from the virulence with which he treated his adverſaries. During the latter years of his life he ſeems to have written but little. He was a ſtrenuous ſupporter of the miniſtry during the American war, having publiſhed, in 1775, An Anſwer to the printed Speech of Edmund Burke, Eſq; ſpoken in the Houſe of Commons, April 19, 1774. In which his knowledge in polity, legiſlature, human kind, hiſtory, commerce, and finance, is candidly examined; his arguments are fairly refuted ; the conduct of adminiſtration is fully defended ; and his oratoric talents are clearly expoſed to view. — And An Eſſay on the Origin, Progreſs, and Eſtabliſhment of National Society ; in which the principles of Government, the definitions of phyſical, moral, civil, and religious Liberty contained in Dr Price's Obſervations, &c. are fairly examined, and fully refuted ; together with a juſtification of the Legiſlature in reducing America to obedience by force. To which is added, an Appendix on the Excellent and Admirable in Mr Burke's ſecond printed Speech of the 22d of March 1775, both 8vo.

His publications, ſatirical, political, and medical, amount to thirty-four, beſides a novel, entitled Lydia, or Filial Piety ; in which religious hypocriſy and bluſtering courage are very properly chaſtiſed. He died on the 1ſt of Auguſt 1788, leaving, among thoſe who knew him beſt, the character of a benevolent man ; a character which, from the manner in which he ſpeaks of his connections, he probably deſerved.

SHEERS, aboard a ſhip, an engine uſed to hoiſt or diſplace the lower maſts of a ſhip.

SHEIBON, a diſtrict in Africa, lying to the ſouth-eaſt of the kingdom of Dar-Fur (See Soudan in this volume), where much gold is found both in duſt and in ſmall pieces. The natives, who are idolaters and ſavages, collect the duſt in quills of the oſtrich and vulture, and in that condition ſell it to the merchants. They have a ceremony on diſcovering a large piece of gold, of killing a ſheep on it before they remove it. The people, who are all black, have ſome form of marriage, *i. e.* of an agreement between man and woman to cohabit. Women of full age wear a piece of platted graſs on their parts. The younger and unmarried are quite naked. The ſlaves, which are brought in great numbers from this quarter, are ſome priſoners of war among themſelves (for their wars are frequent), and ſome ſeduced by treachery, and ſold. But it is ſaid to be a common practice for a father in time of ſcarcity to ſell his children.

At Sheibon are ſome Mohammedans, who live among the idolaters, and wear clothing: it is not ſaid whether Arabs or not. Mr Browne, from whoſe travels we have taken this account of Sheibon, does not give its latitude or longitude.

SHILLUK, a town in Africa on the banks of the Bahr-el-abiad, or true Nile. The houſes are built of clay, and the inhabitants, who are idolaters, have no other clothing than bands of long graſs, which they paſs round the waiſt and between the thighs. They are all black; both ſexes are accuſtomed to ſhave their heads. The people of Shilluk have the dominion of the river, and take toll of all paſſengers, in ſuch articles of traffic as paſs among them. The name Shilluk is not Arabic, and its meaning is unknown.—When aſked concerning their name or country, the people reply Shilluk. When employed in tranſporting Mohammedans acroſs the ferry, they occaſionally exhibit the importance which their ſituation gives them. After the Muſlim has placed himſelf in the boat, they will aſk him, "Who is the maſter of that river?" The other replies, as is uſual, "Ullah or Rubbani"— God is the maſter of it. "No (anſwers the Shilluk), you muſt ſay that ſuch a one (naming his chief) is the maſter of it, or you ſhall not paſs." They are repreſented as ſhewing hoſpitality to ſuch as come among them in a peaceable manner, and as never betraying thoſe to whom they have once accorded protection. The particulars of their worſhip have not been deſcribed. In Mr Browne's map, Shilluck is placed in about 13° N. Lat. and 32° 26′ E. Long.

SHIP. See that article, and Shipbuilding (*Encycl.*), and likewiſe *Floating Bodies* (*Suppl.*) In the *Tranſactions of the Royal Society of London* for 1798, Mr Atwood has completed his diſquiſition on the *Stability* of Ships; but as the memoir cannot be abridged, we muſt refer the ſcientific naval architect to the original for much uſeful information.

A ſmall work has lately been publiſhed by Charles Gore, Eſq; of Weimar in Saxony, upon *the reſpective Velocity of Floating Bodies varying in Form.* It contains merely the reſults of two ſeries of experiments: from the firſt of which ſeries, it ſeems to appear that the form beſt calculated for velocity is a long parallel body, terminating at each end in a parabolic cuneus, and having the extreme breadth in the centre. Alſo, that making the cuneus more obtuſe than is neceſſary to break with fairneſs the curve line into the ſtraight, creates a conſiderable degree of impediment. And Mr Gore is inclined to think, that the length of ſhips, which has already been extended with ſucceſs, to four times the breadth, is capable, with advantage, of ſtill further extenſion, perhaps to five, and, in ſome caſes, even to ſix times.

The ſecond ſet of experiments was inſtituted to aſcertain the reſpective degrees of ſtability, or power of reſiſting the preſſure of the wind, in carrying ſail, on bodies of different forms. The bodies uſed in the experiments had their ſpecific capacities and weights preciſely equal, but their forms different; and from the reſults, it appears that the form of a midſhip body, beſt adapted for ſtability only, is a flat bottom, with perpendicular ſides; and that the next beſt adapted is a ſemicircle. But as there exiſts much difficulty in conſtructing the former with ſufficient ſtrength, beſides its being ill adapted to heavy ſeas, as, by the ſudden deſcent in pitching, the bottom will ſtrike the water nearly at right angles, and ſuſtain thereby a tremendous ſhock. And as the latter ſeems to be too inclinable to tranſverſe oſcillation, or rolling, and alſo to be deficient in capacity for many ſervices, our author is of opinion, that a midſhip body, of a compounded form, is moſt applicable to general purpoſes.

On account of the few documents before us, we are unable to ſpeak critically concerning this tract. To benefit naval architecture, we are of opinion, that the method of experiment is more ſure and expeditious than that of calculation: yet concluſions from experiments muſt be drawn with great caution. It is by no means certain that a reſult obtained for a body of a given bulk will obtain for ſimilar bodies which differ in dimenſions.

We ſhall conclude this ſhort article with a ſtatement of the principles upon which Patrick Miller, Eſq; of Dalſwinton (Scotland), propoſes to conſtruct ſhips and veſſels which cannot founder.

The veſſel is to be kept afloat, without the aid of its ſides, ſolely by the buoyancy of its bottom, which is flat; the bottom never being ſo deeply immerſed as to bring the upper ſurface thereof on a level with the water; ſuch veſſels not being conſtructed for the purpoſe of carrying cargoes, but for that of carrying paſſengers, with the neceſſary ſtores and proviſions; and as theſe veſſels are not kept afloat by the aid of their ſides, but by the buoyancy of their bottom, as above deſcribed, they cannot ſink, and therefore pumps are not required, nor are they in any reſpect neceſſary for the preſervation of ſuch veſſels. The ſaid veſſel is put in motion, during calms, and againſt light winds, by means of wheels. Theſe wheels project beyond the ſides of the veſſel, and are wrought by means of capſtans: the number and the dimenſions of the wheels depend upon the length of the veſſel. Theſe wheels are built with eight arms, which conſiſt entirely of plank. Sliders are uſed to work and to keep the veſſel to windward when under ſail. Theſe ſliders are placed in the centre of the veſſel, from ſtem to ſtern; they are made of plank, and the number and dimenſions muſt depend on the length of the veſſel; and they are raiſed and let down, either by the hand, or by means of a purchaſe, according to the ſize of the veſſel. Veſſels of this conſtruction draw water, in proportion to their dimenſions, as follows: a veſſel of forty feet in length, and from thirteen to nineteen feet in breadth, will draw from thirteen to ſixteen inches of water. One of fifty feet in length, and from ſeventeen to twenty-four feet in breadth, will draw from fifteen to eighteen inches of water. One ſixty feet long, and from twenty to twenty-eight feet broad, will draw from eighteen to twenty-one inches of water. One ſeventy feet long, and from twenty-three to thirty-two feet broad, will draw from twenty-one to twenty-four inches of water. One eighty feet long, and from twenty-ſeven to thirty-ſeven feet broad, will draw from twenty-four to twenty-ſeven inches of water. One ninety feet long, and from thirty to forty-two feet broad, will draw from twenty-ſeven to thirty inches of water. One of one hundred feet in length, and from thirty-three to forty-ſeven feet in breadth, will draw from thirty to thirty-three inches of water.

As, from the principle upon which this veſſel is conſtructed, ſhe cannot ſink, the invention muſt prove a means of ſaving many lives; and as it will give more room and height between the decks than any veſſel of the ſame dimenſions of another conſtruction, it muſt add greatly to the comfort and accommodation of perſons at ſea of all deſcriptions. It is expected that, from theſe advantages, a more general and friendly intercourſe amongſt nations will take place, which will have the effect to diffuſe knowledge, and to remove national prejudices, thereby promoting the general welfare of mankind. At preſent (ſays Mr Miller), it would be altogether improper to give any deſcription of ſhips of greater dimenſions, leſt it ſhould be converted to a purpoſe very different from that intended by the inventor.

SHIPWRECK, a well-known diſaſter, by which numbers of lives are yearly loſt. In that valuable miſcellany entitled, *The Philoſophical Magazine*, we have an account of means for preventing that loſs, when the ſhip is in danger within two or three hundred fathoms of the ſhore; and as the anonymous author (a Frenchman) ſays that he has by experiment aſcertained the efficacy of theſe means, we ſhall ſtate them to our readers.

The only certain means of ſaving the crew of a veſſel in ſuch a ſtate is, to eſtabliſh a rope of communication from the ſhore to the ſhip. But how is this to be done? The author ſays, by fixing the end of the rope to a bomb or cannon ball, and extending the rope afterwards, in a zig zag direction, before the morter or cannon, or ſuſpending it on a piece of wood raiſed ſeveral feet. A rope, ſo placed, will not break (he ſays) by the greateſt velocity which can be given to the bomb or ball; and thus the end of it can be ſent aſhore by a diſcharge of artillery. He prefers the bomb to the cannon ball, for reaſons which he does not aſſign. He propoſes, however, other means to effect his benevolent purpoſe.

"It ought to be remembered (ſays he), that a veſſel is never caſt away, or periſhes on the coaſt, but becauſe it is driven thither againſt the will of the captain, and by the violence of the waves and the wind, which almoſt always blows from the ſea towards the ſhore, without which there would be no danger to be apprehended: conſequently, in theſe circumſtances, the wind comes always from the ſea, either directly or obliquely, and blows towards the ſhore.

Ship, Silla.

"1*ſt*, A common paper kite, therefore, launched from the veſſel and driven by the wind to the ſhore, would be ſufficient to ſave a crew conſiſting of 1500 ſeamen, if ſuch were the number of a ſhip of war. This kite would convey to the ſhore a ſtrong packthread, to the end of which might be affixed a cord, to be drawn on board by means of the ſtring of the kite; and with this cord a rope, or as many as ſhould be neceſſary, might be conveyed to the ſhip.

"2*d*, A ſmall balloon, of ſix or ſeven feet in diameter, and raiſed by rarified air, would be alſo an excellent means for the like purpoſe: being driven by the wind from the veſſel to the ſhore, it would carry thither a ſtring capable of drawing a cord with which ſeveral ropes might be afterwards conveyed to the veſſel. Had not the diſcovery of Montgolfier produced any other benefit, it would be entitled on this account to be conſidered as of great importance.

"3*d*, A ſky-rocket, of a large diameter, would be of equal ſervice. It would alſo carry, from the veſſel to the ſhore, a ſtring capable of drawing a rope after it.

"*Laſtly*, A fourth plan for ſaving the crew of a ſhipwrecked veſſel, is that of throwing from the veſſel into the ſea an empty caſk with a cord attached to it. The wind and the waves would drive the caſk to the ſhore, and afford the means of eſtabliſhing that rope of communication already mentioned."

SILLA, a large town on the Niger, which bounded Mr Park's travels eaſtward. He gives no deſcription of the place, which he had not ſpirits or health to ſurvey; but fills a page of his work with the reaſons which determined him to proceed no farther. "When I arrived (ſays he), I was ſuffered to remain till it was quite dark, under a tree, ſurrounded by hundreds of people. But their language was very different from the other parts of Bambarra; and I was informed that, in my progreſs eaſtward, the Bambarra tongue was but little underſtood, and that when I reached Jenné, I ſhould find that the majority of the inhabitants ſpoke a different language, called *Jenné Kummo* by the Negroes, and *Kalam Soudan* by the Moors.

"With a great deal of entreaty, the Dooty allowed me to come into his baloon, to avoid the rain; but the place was very damp, and I had a ſmart paroxyſm of fever during the night. Worn down by ſickneſs, exhauſted with hunger and fatigue, half naked, and without any article of value, by which I might procure proviſions, clothes, or lodging, I began to reflect ſeriouſly on my ſituation. I was now convinced, by painful experience, that the obſtacles to my further progreſs were inſurmountable. The tropical rains were already ſet in with all their violence; the rice grounds and ſwamps were everywhere overflowed; and in a few days more, travelling of every kind, unleſs by water, would be completely obſtructed. The kowries which remained of the king of Bambarra's preſent were not ſufficient to enable me to hire a canoe for any great diſtance; and I had but little hopes of ſubſiſting by charity, in a country where the Moors have ſuch influence. But above all, I perceived that I was advancing more and more within the power of thoſe mercileſs fanatics; and from my reception both at SEGO and SANSANDING (ſee theſe articles, *Suppl.*), I was apprehenſive that, in attempting to reach even Jenné (unleſs under the protection of ſome man of conſequence amongſt them, which I had no means of obtaining). I ſhould ſacrifice my life to no purpoſe; for my diſcoveries would periſh with me. The proſpect either way was gloomy. In returning to the Gambia, a journey on foot of many hundred miles preſented itſelf to my contemplation, through regions and countries unknown. Nevertheleſs, this ſeemed to be the only alternative; for I ſaw inevitable deſtruction in attempting to proceed to the eaſtward. With this conviction on my mind, I hope my readers will acknowledge that I did right in going no farther. I had made every effort to execute my miſſion in its fulleſt extent which prudence could juſtify. Had there been the moſt diſtant proſpect of a ſucceſsful termination, neither the unavoidable hardſhips of the journey, nor the dangers of a ſecond captivity, ſhould have forced me to deſiſt. This, however, neceſſity compelled me to do; and whatever may be the opinion of my general readers on this point, it affords me inexpreſſible ſatisfaction, that my honourable employers have been pleaſed, ſince my return, to expreſs their full approbation of my conduct." He would be a very unreaſonable man, indeed, who could on this point think differently from Mr Park's employers. Silla is placed in the new map of Africa in about 14° 48′ N. Lat. and 1° 24′ W. Long.

SILLON, in fortification, an elevation of earth, made in the middle of the moat, to fortify it, when too broad. It is more uſually called the *envelope*.

SIMANCAS, a village on the eaſtern limit of the kingdom of Leon in Spain, two leagues below Valladolid, on the river Giſuerga. It is mentioned by Dr Robertſon in the introduction to his Hiſtory of America, and is remarkable for the archives or regiſter office of the kingdoms of Leon and Caſtile, kept in the caſtle there. This collection was begun when the kings reſided often at Valladolid; in which city to this day is the chancery or civil and criminal tribunal for almoſt all Spain to the north of the Tagus. It was thought convenient to have thoſe papers kept in the neighbourhood of that court; and this caſtle was particularly fit for that purpoſe, as it is all built of ſtone. Some years ago there were two large halls in this office filled with papers relating to the firſt ſettlement of the Spaniards in South America. There was alſo in the room called the *ancient royal patronage* a box containing treaties with England, in which are many letters and treaties between the kings of England and Spain from about the year 1400 down to 1600. There was alſo in the ſame archives a ſtrong box, with five locks, which, it is ſaid, has not been opened ſince the time of Philip II. and it is conjectured that it contains the proceſs againſt Philip's ſon Prince Charles. But it ſeems ſome of the ſtate papers have been removed to Madrid.

SITUS, in algebra and geometry, denotes the ſituation of lines, ſurfaces, &c. Wolfius delivers ſome things in geometry, which are not deduced from the common analyſis, particularly matters depending on the *ſitus* of lines and figures. Leibnitz has even founded a particular kind of analyſis upon it, called *calculus ſitus*.

SIWA, a town in Egypt, to the weſtward of Alexandria, built on a ſmall fertile ſpot or Oaſis, which is ſurrounded on all ſides by deſert land. A large proportion of this ſpace is filled with date trees; but there are alſo pomegranates, figs, and olives, apricots, and plantains; and the gardens are remarkably flouriſhing. They cultivate a conſiderable quantity of rice, which, however, is of a reddiſh hue, and different from that of the Delta. The remainder of the cultivable land furniſhes wheat enough for the conſumption of the inhabitants. Water, both ſalt and freſh, abounds; but the ſprings which furniſh the latter are moſt of them tepid; and ſuch is the nature of the water, air, and other circumſtances, that ſtrangers are often affected with agues and malignant fevers.

The greateſt curioſity about Siwa is a ruin of undoubted antiquity, which, according to Mr Browne, reſembles too exactly thoſe of the Upper Egypt, to leave a doubt that it was erected and adorned by the ſame intelligent race of men. The figures of Iſis and Anubis are conſpicuous among the ſculptures; and the proportions are thoſe of the Egyptian temples, though in miniature. What of it remains is a ſingle apartment, built of maſſy ſtones, of the ſame kind as thoſe of which the pyramids conſiſt; and covered originally with ſix large and ſolid blocks, that reach from one wall to the other. The length is 32 feet in the clear, the height about 18, the width 15. A gate, ſituated at one extremity, forms the principal entrance; and two doors, alſo near that extremity, open oppoſite to each other. The other end is quite ruinous; but, judging from circumſtances, it may be imagined that the building has never been much larger than it now is. There is no appearance of any other edifice having been attached to it, and the leſs ſo as there are remains of ſculpture on the exterior of the walls. In the interior are three rows of emblematical figures, apparently deſigned to repreſent a proceſſion; and the ſpace between them is filled with hieroglyphic characters, properly ſo called. The people of Siwa have no tradition concerning this edifice, nor attribnte to it any quality, but that of concealing treaſures, and being the haunt of demons. It has, however, been ſuppoſed, with ſome degree of probability, that Siwa is the *Siropum* of Pliny, and that this building was coeval with the famous temple of Jupiter Ammon, and a dependency on it. This may be ſo; but neither the natives of Siwa, nor the various tribes of Arabs who frequent that place, know any thing of the ruins of that temple, about which Mr Browne made every poſſible enquiry. "It may (as he obſerves) ſtill ſurvive the lapſe of ages, yet remain unknown to the Arabs, who traverſe the wide expanſe of the deſert; but ſuch a circumſtance is ſcarcely probable. It may be completely overwhelmed in the ſand; but this is hardly within the compaſs of belief."

The complexion of the people of Siwa is generally darker than that of the Egyptians. Their dialect is alſo different. They are not in the habitual uſe either of coffee or tobacco. Their ſect is that of Malik. The dreſs of the lower claſs is very ſimple, they being almoſt naked: among thoſe whoſe coſtume was diſcernible, it approaches nearer to that of the Arabs of the deſert than of the Egyptians or Moors. Their clothing conſiſts of a ſhirt of white cotton, with large ſleeves, and reaching to the feet; a red Tuniſine cap, without a turban; and ſhoes of the ſame colour. In warm weather they commonly caſt on the ſhoulder a blue and white cloth, called in Egypt *melayé*; and in winter they are defended from the cold by an *ihhram* or blanket. The liſt of their houſehold furniture is very ſhort; ſome earthen ware made by themſelves, and a few mats, form the chief part of it, none but the richer order being

being poſſeſſed of copper utenſils. They occaſionally purchaſe a few ſlaves from the Murzouk caravan. The remainder of their wants is ſupplied from Cairo or Alexandria, whither their dates are tranſported, both in a dry ſtate and beaten into maſh, which when good in ſome degree reſembles a ſweet meat. They eat no large quantity of animal food; and bread of the kind known to us is uncommon. Flat cakes, without leaven, kneaded, and then half baked, form part of their nouriſhment. The remainder conſiſts of thin ſheets of paſte, fried in the oil of the palm tree, rice, milk, dates, &c. They drink in great quantities the liquor extracted from the date-tree, which they term *date tree water*, though it have often, in the ſtate they drink it, the power of inebriating Their domeſtic animals are, the hairy ſheep and goat of Egypt, the aſs, and a very ſmall number of oxen and camels. The women are veiled, as in Egypt. After the rains, the ground in the neighbourhood of Siwa is covered with ſalt for many weeks. Siwa is ſituated in 29° 12′ N. Lat. and 44° 54′ E. Long.

SKIRMISH BAY, the name given by Lieutenant Broughton to a bay in an iſland, which was diſcovered by him in latitude 43° 48′ ſouth, and in longitude 183° eaſt. The Chatham armed tender, which Mr Broughton commanded, under Captain Vancouver in his voyage of diſcovery, worked up into the bay, and came to anchor about a mile from the ſhore. The Lieutenant, the maſter, and one of the mates, landed, and found the people ſo extremely inhoſpitable, that they were obliged to fire upon them in their own defence. The land, whether iſland or continent, is of conſiderable magnitude; the part which they ſaw extended nearly 40 miles from eaſt to weſt; and the appearance of the country, according to the deſcription given, is very promiſing. In many reſpects, the natives reſemble thoſe of New Zealand; from which country they are diſtant about 100 leagues: but their ſkins were deſtitute of any marks, and they had the appearance of being cleanly in their perſons. Their dreſſes were of ſeal or ſea-bear ſkin, and ſome had fine woven mats faſtened round the waiſt. "They ſeemed a cheerful race, our converſation (ſays Mr Broughton) frequently exciting violent burſts of laughter amongſt them. On our firſt landing, their ſurpriſe and exclamations can hardly be imagined: they pointed to the ſun, and then to us, as if to aſk, whether we had come from thence?" Their arms were ſpears, clubs, and a ſmall weapon reſembling the New Zealand patoo

SLIDING-RULE (ſee that article, as likewiſe *Gauging Rod*, GEOMETRY, and *Logarithmic Lines*, Encycl.) is introduced here, for the ſake of a new, and (except in working direct proportions) a more commodious method than the common, of applying the ſlider. This method, which is propoſed by the Rev. W. Pearſon of Lincoln, is as follows:

Invert the ſlider B on any common ſliding rule, whereby the numerical figures will aſcend on it, and on the fixed line A, in contrary directions: now, as the diſtance from unity to any multiplier, on Gunter's line, will invariably extend from any multiplicand to their product, it follows, that if any particular number on the inverted ſlider B be placed oppoſite to any other given number on A, the product of thoſe numbers will ſtand on the ſlider B, againſt unity on A; for, in any poſition of the inverted ſlider, the diſtance from unity to the multiplier on A, inſtead of being carried forward on B, as when the ſlider is in a direct poſition, is brought back thereby to unity again; ſo that unity (or *ten* on ſingle lines where the ſlider is too ſhort for the operation) is invariably the index for the product of any two coincident numbers throughout the lines.

In diviſion, by the ſame proceſs, if the dividend on B be put to the index, or unity on A, the diviſion and quotient will coincide on the two oppoſite lines; ſo that when one is given, and ſought for on either line, the other is ſeen on its oppoſite line at the ſame time.

The next operation which offers itſelf here is reciprocal proportion, which can be effected by no other method than by inverting the ſlider, but which is rendered as eaſy by this application, as direct proportion is in the common way; for if any antecedent number on B inverted be ſet to its conſequent on A, any other antecedent on B, in the ſame poſition, will ſtand againſt its conſequent on A, ſo as that the terms may be in a reciprocal ratio. In ſquaring any number, it will appear, from what has been already ſaid, that if the number to be ſquared be placed on B, inverted againſt the ſame on A, the ſquare will ſtand on B, againſt unity on A. Therefore, to extract the ſquare root of any number, let that number on B ſtand againſt unity on A; and then wherever the coincident numbers are both of the ſame value, that point indicates the root. If two dividing lines of the ſame value do not exactly coincide, the coincident point will be at the middle of the ſpace contained between thoſe two which are neareſt a coincidence; and as there is only one ſuch point, there can be no miſtake in readily aſcertaining it. The finding of a mean proportional between any two numbers is extremely eaſy at one operation; for if one of the numbers on B inverted be ſet to the other on A, the coincident point of two ſimilar numbers ſhews either of thoſe to be the mean, or ſquare root of their product, according to the preceding proceſs. Thus have we a ſhort and eaſy method of multiplying, dividing, working reciprocal proportion, ſquaring and extracting the ſquare root, at one poſition of the inverted ſlider, whereby the eye is directed to only one point of view for the reſult, after the ſlider is fixed: whereas, by the common method of extracting the ſquare root by A and B direct, the ſlider requires to be moved backwards and forwards by adjuſtment, the eye moving alternately to two points, till ſimilar numbers ſtand, one on B againſt unity on A, and the other on A againſt the ſquare number on B; which ſquare number, in the caſe of finding a mean proportional, muſt be found by a previous operation. Hence, for more convenience in the extraction of roots, and meaſuring of ſolids, an additional line called D has been added to the rule, which renders it more complex, and conſequently ſeldom underſtood by an artificer.

SNOW. See that article (*Encycl.*), where we have endeavoured to account for ſnow's contributing to the preſervation and growth of vegetables. It muſt be confeſſed, however, that if ſnow poſſeſſed only the property of preſerving vegetables, and of preventing them from periſhing by the ſeverity of the cold, it is not at all probable that the ancient philoſophers would have conſidered it as depoſiting on the earth nitrous ſalts, as they might have aſcertained, by a very ſimple experiment, that it contains none of that ſalt; for they did not aſcribe the ſame property to rain-water, but they remarked that ſnow burnt the ſkin in the manner of acids, as well as other bodies immerſed in it. Being induced to conclude that there was nitre in the air, it was natural that they ſhould aſcribe to this nitre the burning qualities of ſnow, and conſequently its influence on vegetation.

Such reflections induced Morveau, *alias* Citizen Guyton, to employ J. H. Haſſenfratz to inquire into the cauſe of the difference of the effects of ſnow and rain-water on various ſubſtances. Haſſenfratz found that theſe differences are occaſioned by the oxygenation of the ſnow; and that theſe effects are to be aſcribed to a particular combination of oxygen in this congealed water. He put 1000 grammes of ſnow in a jar, and 1000 grammes of diſtilled water in another. He poured into each of the jars an equal quantity of the ſame ſolution of turnſole. He placed both the jars in a warm temperature; and after the ſnow melted, he remarked that the dye was redder in the ſnow water than in the diſtilled water. He repeated this experiment, and with the ſame reſult. He put into a jar 1000 grammes of diſtilled water, and into another 1000 grammes of ſnow. Into each of the jars he put 6·5 grammes of very pure and clean ſulphat of iron. In the firſt, there was precipitated 0·150 grammes of the oxyd of iron, and 0·010 grammes in the other. As the oxyd of iron was precipitated from a ſolution of the ſulphat by oxygen, it thence follows, that the ſnow contained more oxygen than the diſtilled water; and it follows, from the firſt experiment, that this quantity of oxygen was conſiderable enough to redden the tincture of turnſole.

It is fully demonſtrated by theſe two experiments, that ſnow is oxygenated water, and that it muſt conſequently have on vegetation an action different from that of common ice. The experiments of Dr Ingenhouſs on the germination of ſeeds have taught us, that the preſence and contact of oxygen are abſolutely neceſſary for the plant to expand. They have ſhewn alſo, that the more abundant the oxygen is, the more rapidly will the ſeeds grow. Moſt plants ſuffered to attain to their perfect maturity ſhed on the earth a part of their ſeed. Theſe ſeeds, thus abandoned and expoſed to the action of cold, are preſerved by the ſnow which covers them, at the ſame time that they find in the water it produces by melting, a portion of oxygen that has a powerful action on the principle of germination, and determines the ſeeds that would have periſhed to grow, to expand, and to augment the number of the plants that cover the ſurface of the earth.

A very conſiderable number of the plants which are employed in Europe for the nouriſhment of men, are ſown in the months of September, October, and November. The ſeeds of ſeveral of theſe germinate before the cold commences its action upon them, and changes the principle of their life. The ſnow which covers the reſt, acting on the germ by its oxygenation, obliges them to expand, and to increaſe the number of uſeful plants which the farmer and gardener commit to the earth, and conſequently to multiply their productions.

Here, then, we have three effects of ſnow upon vegetation, all very different, which contribute each ſeparately to increaſe, every year, the number of our plants; to give them more vigour, and conſequently to multiply our crops. Theſe effects are: 1. To prevent the plants from being attacked by the cold, and from being changed or periſhing by its force. 2. To furniſh vegetables with continual moiſture, which helps them to procure thoſe ſubſtances neceſſary for their nutrition, and to preſerve them in a ſtrong healthy ſtate. 3. To cauſe a greater number of ſeeds to germinate, and conſequently to increaſe the number of our plants.

SOAP. See Chemistry *Index*, Suppl.

SOLDERING. Under this title, in the *Encyclopædia*, we have given directions for ſoldering ſilver, braſs, and iron: but there are other metals which muſt ſometimes be ſoldered; and the following account of different ſolders, taken from the *Philoſophical Magazine*, may be uſeful to many of our readers.

"When lead, tin, and biſmuth, are mixed in a certain proportion, they produce a metal exceedingly fuſible, which is known by the name of *ſoft ſolder*; but which, from its ſingular properties, may be applied with advantage to many other uſeful purpoſes. Newton, and after him Kraft and Muſchenbroek, obſerved, that five parts of biſmuth, three of tin, and two of lead, alſo five parts of biſmuth, four of tin, and one part of lead, melted with a heat of 220 degrees of Fahrenheit; and they found that various mixtures of this kind were fuſible by a heat not much greater than that of boiling water. At a later period, V. Roſe, a German naturaliſt, diſcovered, that a mixture of four parts of biſmuth, two of tin, and two of lead, as Kunkel recommended for ſoldering tin; and D'Arcet, among the French, that a mixture of eight parts of biſmuth, three of tin, and five of lead; or eight of biſmuth, four of tin, and four of lead; or eight of biſmuth, two of tin; and ſix of lead; alſo ſixteen of biſmuth, ſeven of tin, and nine of lead—all melted, or at leaſt became ſoft, in boiling water.

"According to the experiments made by Profeſſor Gmelin, reſpecting the fuſion of theſe three metals, a mixture, conſiſting of two parts of biſmuth, one part of tin, and one of lead, which is the ſame as Roſe propoſed, gave a metal that was fuſed in boiling water. A mixture of ſix or more parts of biſmuth, ſix of tin, and three of lead, or one part of biſmuth, two parts of tin, and two of lead, gave, according to Klein, the ſolder uſed by the tin button makers. The ſame workmen uſe alſo for ſoldering, according to Klein, a mixture of four parts of biſmuth, three parts of tin, and five parts of lead. Among the many ſoft ſolders employed by the tin men, a mixture of one part of biſmuth, two parts of tin, and one part of lead, is, according to Klein, very much employed. Reſpecting this kind of ſolder, the experiments of Profeſſor Gmelin give the following reſult: One part of biſmuth, two parts of tin, and one part of lead, melt in boiling water. According to Klein, the tin-men employ for ſoldering a mixture of one part of biſmuth, twenty four parts of tin, and four parts of lead. Eight parts of biſmuth, three of tin, and five of lead, gave a metal exceedingly like tin in its colour and brightneſs, but very brittle; in water beginning to boil, it became not only ſoft, but was completely fuſed. This imitation, however, may be better accompliſhed by the mixture of Profeſſor Lightenberg, which conſiſts of five parts of biſmuth, three

three of tin, and two of lead. This metal is very like the former, though not ſo brittle; but it ſeemed to melt in hot water even before it came to boil."

As this ſubject has again come under our notice, it may be proper to lay before our readers what M. Van Braam ſays of the Chineſe method of ſoldering frying-pans and other veſſels of caſt-iron, when cracked and full of holes. As the author admits that it *muſt* appear *impoſſible* to thoſe who have not *witneſſed* the proceſs, ſuch of our artiſts as have not been in China will give to the tale what credit they think it deſerves.

"All the apparatus of the workman conſiſts in a little box, 16 inches long and 6 wide, and 18 inches in depth, divided into two parts. The upper contains three drawers with the neceſſary ingredients; in the lower is a bellows, which when a fire is wanted is adapted to a furnace eight inches long and four inches wide. The crucibles for melting the ſmall pieces of iron intended to ſerve as ſolder are a little larger than the bowl of a common tobacco pipe, and of the ſame earth of which they are made in Europe: thus the whole buſineſs of ſoldering is executed.

"The workman receives the melted matter out of the crucible upon a piece of *wet paper*, approaches it to one of the holes or cracks in the frying-pan, and applies it there, while his aſſiſtant ſmooths it over by ſcraping the ſurface, and afterwards rubs it with a bit of *wet linen*. The number of crucibles which have been deemed neceſſary are thus ſucceſſively emptied, in order to ſtop up all the holes with the melted iron, which conſolidates and incorporates itſelf with the broken utenſil, and which becomes as good as new. The furnace which our author ſaw was calculated to contain eight crucibles at a time; and while the fuſion was going on, was covered with a ſtone, by way of increaſing the intenſity of the heat."—M. Van Braam affects frequently to correct the miſtakes of Sir George Staunton!

SOUDAN, literally ſignifies the country of the negroes; but it is likewiſe uſed as one of the names of an African kingdom, otherwiſe called DAR-FUR. We know not that this kingdom has been viſited by any European beſides Mr Browne, who places it between the 11th and 16th degrees of north latitude, and between the 26th and 30th degrees of eaſt longitude. Theſe numbers are not exact: it does not reach ſo far eaſt as the 30th degree, nor ſo far north as the 16th; but on his map minutes are not marked. On the north, it is bounded by a deſert which ſeparates it from Egypt; on the eaſt, by Kordofan, which is now ſubject to Soudan, and lies between it and Sennaar; and on the ſouth and eaſt, by countries of which the names are hardly known. Mr Browne was induced to viſit Soudan in hopes of being able to trace the Bahr-el-abiad, or true Nile, to its ſource: but he was diſappointed; for that river riſes in mountains conſiderably farther ſouth than the limits of this kingdom; and the Sultan, a cruel and capricious tyrant, detained him a priſoner at large almoſt three years.

Soudan, or Dar-fur, abounds with towns or villages, ill built, of clay, and none of them very large. Of theſe it is not worth while to give an account. Its ſeaſons are divided into rainy and dry. The perennial rains, which fall in Dar-Fur from the middle of June till the middle of September in greater or leſs quantity, but generally both frequent and violent, ſuddenly inveſt the face of the country, till then dry and ſteril, with a delightful verdure. Except where the rocky nature of the ſoil abſolutely impedes vegetation, wood is found in great quantity; nor are the natives aſſiduous completely to clear the ground, even where it is deſigned for the cultivation of grain. As ſoon as the rains begin, the proprietor, and all the aſſiſtants that he can collect, go out to the field; and having made holes at about two feet diſtance from each other, with a kind of hoe, over all the ground he occupies, the *dokn*, a kind of millet, is thrown into them, and covered with the foot, for their huſbandry requires not many inſtruments. The time for ſowing the wheat is nearly the ſame. The *dokn* remains ſcarcely two months before it is ripe; the wheat about three.

The animals in Soudan, both wild and tame, are the ſame as in other parts of Africa in the ſame latitude. Though the Furians breed horſes, and purchaſe very fine ones in Dongola, and from the Arabs to the eaſt of the Nile, the aſs is more uſed for riding; and an Egyptian aſs (for the aſſes of Dar-Fur are diminutive and indocile like thoſe of Britain) fetches from the value of one to that of three ſlaves. The villages of this country, like thoſe of Abyſſinia, are infeſted with hyenas; and in the unfrequented parts of the country are the elephant, the rhinoceros, the lion, the leopard, and all the other quadrupeds of Africa. The Arabs often eat the fleſh of the lion and the leopard; and ſometimes they ſo completely tame thoſe animals, as to carry them looſe into the market place. Our author tamed two lions, of which one acquired moſt of the habits of a dog. He ſatiated himſelf twice a week with the offal of the butchers, and then commonly ſlept for ſeveral hours ſucceſſively. When food was given them, they both grew ferocious towards each other, and towards any one who approached them. Except at that time, though both were males, he never ſaw them diſagree, nor ſhew any ſign of ferocity towards the human race. Even lambs paſſed them unmoleſted.

Among the birds, the *vultur perenopterus*, or white-headed vulture, is moſt worthy of notice. It is of ſurpriſing ſtrength, and is ſaid by the natives to be very long-lived, *ſed fides penes auctores*. "I have lodged (ſays Mr Browne) a complete charge of large ſhot, at about 50 yards diſtance, in the body of this bird: it ſeemed to have no effect on him, as he flew to a conſiderable diſtance, and continued walking afterwards. I then diſcharged the ſecond barrel, which was loaded with ball: this broke his wing; but on my advancing to ſeize him, he fought with great fury with the other. There are many thouſands of them in the inhabited diſtrict. They divide the field with the hyena: what carrion the latter leaves at night, the former come in crowds to feed on in the day. Near the extremity of each wing is a horny ſubſtance, not unlike the ſpur of an old cock. It is ſtrong and ſharp, and a formidable inſtrument of attack. Some fluid exudes from this bird that ſmells like muſk; but from what part of him I am uncertain." The ſerpents found in Soudan are the ſame as in Egypt; but the natives have not the art of charming them, like the Egyptians. The locuſt of Arabia is very common, and is frequently roaſted and eaten, particularly by the ſlaves.

In Dar-Fur there ſeems to be a ſcarcity of metals;

Soudan.

but in its neighbourhood to the ſouth and weſt all kinds are to be found. The copper brought by the merchants from the territories of certain idolatrous tribes bordering on Fur, is of the fineſt quality, in colour reſembling that of China, and appears to contain a portion of zinc, being of the ſame pale hue. Iron is found in abundance; but they have not yet learned the art of converting it into ſteel. Silver, lead, and tin, our author never heard mentioned in Soudan, but as coming from Egypt; but of gold, in the countries to the eaſt and weſt, the ſupply is abundant. Alabaſter, and various kinds of marble, are found within the limits of Fur, as is foſſil ſalt within a certain diſtrict; and there is a ſufficient ſupply of nitre, of which, however, no uſe is made.

The reſtraint under which Mr Browne was kept in this inhoſpitable country, prevented him from making a full catalogue of its vegetable productions. Of the trees which ſhade our foreſts or adorn our gardens in Europe, very few exiſt in Dar-Fur. The characteriſtic marks of thoſe ſpecies which moſt abound there, are their ſharp thorns, and the ſolid and unperiſhable quality of their ſubſtance. They ſeem to be much the ſame as thoſe which Bruce found in Abyſſinia. There is a ſmall tree called *enneb*, to the fruit of which they have given the name of grapes. It bears leaves of light green hue; and the fruit, which is of a purple colour, is attached, not in bunches, but ſingly to the ſmaller branches, and interſperſed among the leaves. The internal ſtructure of the fruit is not very unlike the grape, which it alſo reſembles in ſize: but the pulp is of a red hue, and the taſte is ſtrongly aſtringent. The water-melon *(cucurbita citrullus)* grows wild over almoſt all the cultivable lands, and ripens as the corn is removed. In this ſtate it does not attain a large ſize. The inſide is of a pale hue, and has little flavour. As it ripens, the camels, aſſes, &c. are turned to feed on it, and it is ſaid to fatten them. The ſeeds, as they grow blackiſh, are collected to make a kind of tar, *kutran*. Thoſe plants of the melon which receive artificial culture grow to a large ſize, and are of exquiſite flavour. Tobacco is produced in abundance; and our author ſpeaks of cochineal as found in Dar-Fur, or ſome of the neighbouring countries.

The harveſt is conducted in a very ſimple manner. The women and ſlaves of the proprietor are employed to break off the ears with their hands, leaving the ſtraw ſtanding, which is afterwards applied to buildings and various other uſeful purpoſes. They then accumulate them in baſkets, and carry them away on their heads. When thraſhed, which is aukwardly and incompletely performed, they expoſe the grain to the ſun till it become quite dry; after this a hole in the earth is prepared, the bottom and ſides of which are covered with chaff to exclude the vermin. This cavity or magazine is filled with grain, which is then covered with chaff, and afterwards with earth. In this way the maize is preſerved tolerably well. In uſing it for food, they grind it, and boil it in the form of polenta, which is eaten either with freſh or ſour milk, or ſtill more frequently with a ſauce made of dried meat pounded in a mortar, and boiled with onions, &c. The Furians uſe little butter; with the Egyptians and Arabs it is an article in great requeſt. There is alſo another ſauce which the poorer people uſe and highly reliſh; it is compoſed of an herb called *cowel* or *cawel*, of a taſte in part aceſcent and in part bitter, and generally diſagreeable to ſtrangers.

Soudan.

The magiſtracy of one, which ſeems tacitly, if it be not expreſsly, favoured by the diſpenſation of Mohammed, as in moſt other countries profeſſing that religion, prevails in Dar-Fur. The monarch indeed can do nothing contrary to the Koran, but he may do more than the laws eſtabliſhed thereon will authoriſe; and as there is no council to controul or even to aſſiſt him, his power may well be termed deſpotic. He ſpeaks in public of the ſoil and its productions as his perſonal property, and of the people as little elſe than his ſlaves.

His power in the provinces is delegated to officers, who poſſeſs an authority equally arbitrary. In thoſe diſtricts, which have always, or for a long time, formed an integral part of the empire, theſe officers are generally called *Meleks*. In ſuch as have been lately conquered, or, perhaps more properly, have been annexed to the dominion of the Sultan under certain ſtipulations, the chief is ſuffered to retain the title of Sultan, yet is tributary to and receives his appointment from the Sultan of Fur.

Deſpotic and arbitrary as he is, the Sultan here does not ſeem wholly inattentive to that important object, agriculture. Nevertheleſs, it may be eſteemed rather a blind compliance with ancient cuſtom, than individual public ſpirit, in which has originated a practice adopted by him, in itſelf ſufficiently laudable, ſince other o his regulations by no means conduce to the ſame end At the beginning of the *Hariſ*, or wet ſeaſon, which is alſo the moment for ſowing the corn, the king goes out with his Meleks and the reſt of his train; and while the people are employed in turning up the ground and ſowing the ſeed, he alſo makes ſeveral holes with his own hand. The ſame cuſtom, it is ſaid, obtains in Bornou and other countries in this part of Africa: It calls to the mind a practice of the Egyptian kings mentioned by Herodotus.

The population of Dar-Fur is not large. An army of 2000 men was ſpoken of, when Mr Browne was in the country, as a great one; and he does not think that the number of ſouls within the empire can much exceed 200,000. The troops of this country are not famed for ſkill, courage, or perſeverance. In their campaigns, much reliance is placed on the Arabs who accompany them, and who are properly tributaries rather than ſubjects of the Sultan. One energy of barbariſm they indeed poſſeſs in common with other ſavages, that of being able to endure hunger and thirſt; but in this particular they have no advantage over their neighbours. In their perſons the Furians are not remarkable for cleanlineſs. Though obſerving as Mahommedans all the ſuperſtitious formalities of prayer, their hair is rarely combed, or their bodies completely waſhed. The hair of the pubes and axillæ it is uſual to exterminate; but they know not the uſe of ſoap; ſo that with them poliſhing the ſkin with unguents holds the place of perfect ablutions and real purity. A kind of farinaceous paſte is however prepared, which being applied with butter to the ſkin, and rubbed continually till it become dry, not only improves its appearance, but removes from it accidental ſordes, and ſtill more the effect of continued tranſpiration, which, as there are no baths in the country, is a conſideration of ſome importance. The female ſlaves are dexterous in the application of it; and to undergo this operation is one of the refinements of African ſenſuality.

Nothing reſembling current coin is found in Soudan, unleſs it be certain ſmall tin rings, the value of which is in ſome degree arbitrary. The Auſtrian dollars, and other ſilver coins brought from Egypt, are all ſold as ornaments for the women.

The diſpoſition of the Furians is cheerful; and that gravity and reſerve which the precepts of Mahommediſm inſpire, and the practice of the greater number of its profeſſors countenances and even requires, ſeems by no means as yet to ſit eaſy on them. A government perfectly deſpotic, and not ill adminiſtered, as far as relates to the manners of the people, yet forms no adequate reſtraint to their violent paſſions. Prone to inebriation, but unprovided with materials or ingenuity to prepare any other fermented liquor than *buza*, with this alone their convivial exceſſes are committed. But though the Sultan publiſhed an ordnance (March 1795), forbidding the uſe of that liquor under pain of death, the plurality, though leſs publicly than before, ſtill indulge themſelves in it. A company often ſits from ſunriſe to ſun ſet, drinking and converſing, till a ſingle man ſometimes carries off near two gallons of that liquor. The buza has, however, a diuretic and diaphoretic tendency, which precludes any danger from theſe exceſſes. In this country dancing is practiſed by the men as well as the women, and they often dance promiſcuouſly.

The vices of thieving, lying, and cheating in bargains, with all others nearly or remotely allied to them, as often happen among a people under the ſame circumſtances, are here almoſt univerſal. No property, whether conſiderable or trifling, is ſafe out of the ſight of the owner, nor indeed ſcarcely in it, unleſs he be ſtronger than the thief. In buying and ſelling, the parent glories in deceiving the ſon, and the ſon the parent; and God and the Prophet are hourly invocated, to give colour to the moſt palpable frauds and falſehoods.

The privilege of polygamy, which, as is well known, belongs to their religion, the people of Soudan puſh to the extreme. By their law, they are allowed four free women, and as many ſlaves as they can maintain; but the Furians take both free women and ſlaves without limitation. The Sultan has more than a hundred free women, and many of the Meleks have from twenty to thirty. In their indulgence with women, they pay little regard to reſtraint or decency. The form of the houſes ſecures no great ſecrecy to what is carried on within them; yet even the concealment which is thus offered is not always ſought. The ſhade of a tree, or long graſs, is the ſole temple required for the ſacrifices to the Cyprian goddeſs. In the courſe of licentious indulgence, father and daughter, ſon and mother, are ſometimes mingled; and the relations of brother and ſiſter are exchanged for cloſer intercourſe.

Previouſly to the eſtabliſhment of Iſlamiſm* and kingſhip, the people of Fur ſeem to have formed wandering tribes; in which ſtate many of the neighbouring nations to this day remain. In their perſons they differ from the negroes of the coaſt of Guinea. Their hair is generally ſhort and woolly, though ſome are ſeen with it of the length of eight or ten inches, which they eſteem a beauty. Their complexion is for the moſt part perfectly black. The Arabs, who are numerous within the empire, retain their diſtinction of feature, colour, and language. They moſt commonly intermarry with each other. The ſlaves, which are brought from the country they call *Fertit* (land of idolaters), perfectly reſemble thoſe of Guinea, and their language is peculiar to themſelves.

The revenues of the crown conſiſt of a duty on all merchandiſe imported, which, in many inſtances, amounts to near a tenth; of a tax on all ſlaves exported to Egypt; of all forfeitures for miſdemeanors; of a tenth on all merchandiſe, eſpecially ſlaves, brought from every quarter but Egypt, and when ſlaves are procured by force, this tenth is raiſed to a fifth; of a tribute paid by the Arabs, who breed oxen, horſes, camels, ſheep; of a certain quantity of coin paid annually by every village; beſides many valuable preſents, which muſt be paid by the principal people, both at ſtated times and on particular occaſions. Add to all this, that the king is chief merchant in the country; and not only diſpatches with every caravan to Egypt a great quantity of his own merchandiſe, but alſo employs his ſlaves and dependents to trade with the goods of Egypt on his own account, in the countries adjacent to Soudan.

The commodities brought by the caravans from Egypt are, 1. Amber beads. 2. Tin, in ſmall bars. 3. Coral beads. 4. Cornelian beads. 5. Falſe cornelian beads. 6. Beads of Venice. 7. Agate. 8. Rings, ſilver and braſs, for the ancles and wriſts. 9. Carpets, ſmall. 10. Blue cotton cloths of Egyptian fabric. 11. White cotton ditto. 12. Indian muſlins and cottons. 13. Blue and white cloths of Egypt, called *Melayes*. 14. Sword blades, ſtrait (German), from Cairo. 15. Small looking-glaſſes. 16. Copper face-pieces, or defenſive armour for the horſes heads. 17. Fire arms. 18. Kohhel for the eyes. 19. Rhea, a kind of moſs from European Turkey, for food and a ſcent. 20. *She*, a ſpecies of abſynthium, for its odour, and as a remedy: both the laſt ſell to advantage. 21. Coffee. 22. *Mahleb*, *Krumphille*, *Symbille*, *Sandal*, nutmegs. 23. *Dufr*, the ſhell of a kind of fiſh in the Red Sea, uſed for a perfume. 24. Silk unwrought. 25. Wire, braſs and iron. 26. Coarſe glaſs beads, made at Jeruſalem, called *herſh* and *munjur* 27. Copper culinary utenſils, for which the demand is ſmall. 28. Old copper for melting and reworking. 29. Small red caps of Barbary. 30. Thread linens of Egypt—ſmall conſumption. 31. Light French cloths, made into beniſhes. 32. Silks of Scio, made up. 33. Silk and cotton pieces of Aleppo, Damaſcus, &c. 34. Shoes of red leather. 35. Black pepper. 36. Writing paper (*papier des trois lunes*), a conſiderable article. 37. Soap of Syria.

The goods tranſported to Egypt are, 1. Slaves, male and female. 2. Camels. 3. Ivory. 4. Horns of the rhinoceros 5. Teeth of the hippopotamus. 6. Oſtrich feathers. 7. Whips of the hippopotamus's hide. 8. Gum. 9. Pimento. 10. Tamarinds, made into round cakes. 11. Leather ſacks for water (*ray*) and dry articles (*geraub*). 12. Peroquets in abundance, and ſome monkeys and Guinea fowls. 13. Copper, white, in ſmall quantity.

SOUFFRIERE, a ſmall town, ſituated at the bottom of a bay, towards the leeward extremity of the iſland of St Lucia. There is nothing in the town itſelf which could

---

* bout a ce ry an a l f ago

could have entitled it to notice in this work; but the ground about it is very remarkable. It has been deſcribed by different authors; and our readers will probably not be ill pleaſed with the following deſcription of this wonderful ſpot by Dr Rollo.

"Souffriere (ſays he) is ſurrounded by hills covered with trees, the declivities of which, and every part capable of produce, are cultivated, and afford good ſugar-cane. This place has its marſhes, but not ſo extenſive, or ſo much to windward as thoſe about Carenage.

"The extremity of the ſouth ſide of Souffriere Bay runs into two ſteep hills of a conical figure, which are nearly perpendicular: they are reckoned the higheſt on the iſland, and are known by the name of the *Sugar-Loaf Hills*. From their height and ſtraitneſs it is impoſſible to aſcend them: we were told it was once attempted by two negroes, but they never returned. They are covered with trees and ſhrubs, and are the ſhelter of goats, ſeveral of which ſometimes deſcend, and are ſhot by the natives.

"After you paſs the hills to windward of Souffriere, a fine clear and level country preſents itſelf. From the back of the Sugar Loaf Hills, and all along the ſea-coaſt, to the diſtance, we ſuppoſe, of from fifteen to twenty miles, this flat or level extends: it is all cultivated and divided into rich eſtates, affording ſugar-cane equal to any in our iſlands. This beautiful ſpot is interſected by many rivers of very clear water, and theſe are conducted by art to the purpoſe of ſugar making. The rains in this part are leſs frequent than on any other part of he iſland; however, they have often a proportion more than ſufficient. The wind here blows from the ſea, or nearly ſo.

"We cannot finiſh this deſcription without taking notice of a volcano in the neighbourhood of Souffriere. You paſs over one or two ſmall hills to the ſouthward of the town, and before any mark of the place is perceived you are ſenſible of the ſmell of ſulphur. The firſt thing you diſcern is a rivulet of black running water, ſending forth ſteams as if nearly boiling. From the proſpect of this you ſoon open on the volcano, which appears in a hollow, ſurrounded cloſe on every ſide by hills. There are only two openings; the one we entered, and another almoſt oppoſite to it on the north ſide. In the hollow there are many pits of a black and thick boiling matter, which ſeems to work with great force. Lava is ſlowly thrown out; and in the centre of the hollow there is a large maſs of it, forming a kind of hill. This we aſcended; but were ſoon obliged to return from the exceſſive heat. The lava is a ſulphur mixed with a calcareous earth and ſome ſaline body. We found ſmall quantities of alum in a perfect ſtate. In the opening, at the north ſide of the hollow, there is a rivulet of very good water. On ſtirring the bottom, over which this water runs, we were ſurpriſed with feeling it very hot; and on placing a tumbler filled with ſome of the water cloſe to the bottom of the rivulet, it ſoon became ſo hot as not to be touched. The liquid which runs from the pits is ſtrongly impregnated with ſulphur, and reſembles a good deal the preparation ſold in the ſhops, known by the name of *aqua ſulphurata*, or *gas ſulphuris*."

SOUND-BOARD, the principal part of an organ, and that which makes the whole machine play. This ſound-board, or ſummer, is a reſervoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and thence diſtributed into the pipes placed over the holes of its upper part. This wind enters them by valves, which open by preſſing upon the ſtops or keys, after drawing the regiſters, which prevent the air from going into any of the other pipes beſide thoſe it is required in.

Sound Board denotes alſo a thin broad board placed over the head of a public ſpeaker, to enlarge and extend or ſtrengthen his voice.

Sound-boards, in theatres, are found by experience to be of no ſervice; their diſtance from the ſpeaker being too great to be impreſſed with ſufficient force. But ſound boards immediately over a pulpit have often a good effect, when the caſe is made of a juſt thickneſs, and according to certain principles.

Sound-Poſt, is a poſt placed withinſide of a violin, &c. as a prop between the back and the belly of the inſtrument, and nearly under the bridge.

SOWAL, in the language of Bengal, a queſtion or requeſt.

SPALLANZANI (Lazarus), was born at Scandiano, in the dutchy of Modena, on the 10th of January 1729. He was ſon of Jean Nicholas Spallanzani, an eſteemed juriſconſult, and of Lucia Zugliani. He commenced his ſtudies in his own country, and at the age of fifteen years went to Reggio de Modena in order to continue them. The Jeſuits, who inſtructed him in the belles lettres, and the Dominicans, who heard of his progreſs, were each deſirous of attaching him to them; but his paſſion for extending his knowledge led him to Bologna, where his relation Laura Baſſi, a woman juſtly celebrated for her genius, her eloquence, and her ſkill in natural philoſophy and the mathematics, was one of the moſt illuſtrious profeſſors of the Inſtitute and of Italy. Under the direction of this enlightened guide, he learned to prefer the ſtudy of Nature to that of her commentators, and to judge of the value of the commentary by its reſemblance to the original. He inſtantly availed himſelf of the wiſdom of that lady's counſels, and was not long before he experienced the happy effects of it. How agreeable it is to ſee him in 1765 painting his gratitude for his inſtructor, to whom he dedicated a Latin diſſertation at that time, in which he mentions the applauſes that Laura Baſſi received at Modena, when ſhe entered the auditory of her pupil, then become profeſſor. The taſte of Spallanzani for philoſophy was not excluſive; he already thought, like all great men, that the ſtudy of antiquity and the belles-lettres was requiſite to give to ideas that clearneſs, to expreſſions that accuracy, and to reaſonings that connection, without which the fineſt thoughts become barren. He ſtudied his own language with care, and perfected himſelf in the Latin tongue; but above all, he attached himſelf to the Greek and the French. Homer, Demoſthenes, St Baſil, were his favourite authors. Spallanzani applied himſelf to juriſprudence at the inſtance of a father whom he tenderly loved: he was upon the point of receiving the degree of doctor of civil law, when Anthony Valliſneri, profeſſor of natural hiſtory at Padua, perſuaded him to renounce this vocation, by promiſing to obtain the conſent of his father, who was ſenſibly touched by his ſon's devotion to his will, and who thereby left him at liberty to follow his own inclinations. From that moment he gave himſelf up

Spallanzani.

up with more ardour than ever to the ſtudy of mathematics, continuing that alſo of the living and dead languages.

Spallanzani was preſently known all over Italy, and his own country was the firſt to do homage to his talents The univerſity of Reggio, in 1754, choſe him to be profeſſor in logic, metaphyſics, and Greek. He taught there for ten years; and during that period conſecrated all the time he could ſpare from his leſſons to the obſervation of Nature. Now and then an accidental diſcovery would increaſe his paſſion for natural hiſtory, which always augmented by new ſucceſſes. His obſervations upon the animalculæ of infuſions fixed the attention of Haller and of Bonnet; the latter of whom aſſiſted him in his glorious career, and thenceforth diſtinguiſhed him as one of the learned interpreters of Nature.

In 1760 Spallanzani was called to the univerſity of Modena; and although his intereſt would have made him accept the advantageous offers of the univerſity of Coimbra, of Parma, and of Ceſena; yet his patriotiſm and his attachment to his family confined his ſervices to his own country. The ſame conſiderations engaged him to refuſe the propoſitions made him by the academy of Peterſburg ſome years after. He remained at Modena till the year 1768, and he ſaw raiſed by his care a generation of men conſtituting at this time the glory of Italy. Among them may be counted *Venturi*, profeſſor of natural philoſophy at Modena; *Belloni*, biſhop of Carpi; *Luccheſini*, ambaſſador of the late king of Pruſſia; and the poet *Angelo Mazzo* of Parma.

During his reſidence at Modena, Spallanzani publiſhed, in 1765, *Saggio di Oſſervazioui Microſcopiche concernente il Syſtema di Needham e Buffon* He therein eſtabliſhes the *animality* of what had been called, but not generally aſſented to as, *microſcopic animalculæ*, by the moſt ingenious, and at the ſame time ſolid, experiments. He ſent this work to Bonnet, who formed his opinion of the author accordingly, and who lived to ſee the accompliſhment of the prophecy he drew from it. From that moment the moſt intimate acquaintance was formed between them, and it laſted during their lives, of which it conſtituted the chief happineſs. In the ſame year Spallanzani publiſhed a diſſertation truly original: *De Lapidibus ab Aqua reſilientibus*. In that work he proves, by ſatisfactory experiments, contrary to the commonly received opinion, that the ducks and drakes (as they are called) are not produced by the elaſticity of the water, but by the natural effect of the change of direction which the ſtone experiences in its movement, after the water has been ſtruck by it, and that it has been carried over the bend or hollow of the cup formed by the concuſſion.

In 1768 he prepared the philoſophers for the ſurpriſing diſcoveries he was about to offer them throughout his life, in publiſhing his *Prodromo di un Opera da Imprimerſi ſopra le Riproduzioni Animali.* He therein lays down the plan of a work which he was anxious to get up on this important ſubject; but this ſimple proſpectus contains more real knowledge than all the books which had appeared, becauſe it taught the method that ought to be followed in this dark reſearch, and contained many unexpected facts; ſuch as the pre-exiſtence of tadpoles at the fecundation, in many ſpecies of toads and frogs; the reproduction of the head cut off from ſnails, which he had already communicated to Bonnet in 1766, and which was diſputed for ſome time, in ſpite of the repeated confirmation of this phenomenon by Heriſſant and Lavoiſier. He demonſtrated it again afterwards in the *Memorie della Socicta Italiana;* as alſo the renewal of the tail, the limbs, and even the jaws, taken from the aquatic ſalamander. Theſe facts continue to aſtoniſh even at this day, when they are thought of, notwithſtanding every one has had the opportunity of familiariſing himſelf with them: and we hardly know which we ought moſt to admire, the expertneſs of Spallanzani in affording ſuch deciſive proofs, or his boldneſs in ſearching after them, and ſeizing them. We have to regret, that the project of his great undertaking is not realized; but various circumſtances prevented him from giving way to the ſolicitations of his friends for its accompliſhment. Perhaps he deſpaired of throwing upon every part of it all the light which at firſt he thought he might be able; and found it prudent to mature his ideas by new meditations: this may probably have been as powerful a cauſe as that other calls and occupations, perpetually accumulating, ſhould not have allowed him to purſue it as he had intended. He has always laid Nature open to full view; and the thinneſt veil darkened her till he ſucceeded in removing it altogether.

The phyſiology of Haller that Spallanzani ſtudied, fixed his attention upon the circulation of the blood, in which he diſcovered ſeveral remarkable phenomena. He publiſhed, in 1768, a ſmall tract: *Dell' Azione del Cuore ne' Vaſi Sanguigni nuovi Oſſervazioni*, and he reprinted it in 1773, with three new diſſertations, *De' Fenomeni della Circolazione oſſervata nel' Giro univerſali de' Vaſi; De' Fenomeni della Circolazione Languente; De' Moti del Sangue, independente del Azione del Cuore e del Pulſare delle Arterie.* This work, but little known, contains a ſeries of obſervations and experiments, of the moſt ingenious and delicate nature, upon a ſubject of which the ſurface only is known. It merits the attention of thoſe who are intereſted in the progreſs of phyſiology.

When the univerſity of Padua was re-eſtabliſhed upon a larger ſcale, the Empreſs Maria Thereſa directed the Count de Firmian to invite him to fill a chair, as profeſſor of natural hiſtory; his great reputation rendered him eligible for this diſtinction, ſolicited by many celebrated men, and he merited it by his ſucceſs, and by the crowd of ſtudents who thronged to his leſſons. Only great men make excellent maſters,. becauſe their ideas are the moſt perſpicuous, the moſt extenſive, and beſt connected.

Spallanzani united a vaſt extent of knowledge to a fine genius; a method ſimple, but rigorous in its nature; and he connected what he knew to principles firmly eſtabliſhed. His ardent love of truth made him diſcuſs, with the utmoſt care, the theories which prevailed; to ſound their ſolidity, and diſcover their weak ſides. The great art which he had acquired, of interpreting Nature by herſelf, diffuſed ſuch a light over his leſſons, as made every thing perſpicuous that was capable of affording inſtruction. An eloquence at once plain and lively animated his diſcourſe; the purity and elegance of his ſtyle charmed all who heard it: in ſhort, it was known that he always occupied himſelf about the

the means of rendering his leſſons uſeful, which he prepared a year beforehand. They became always new and engaging, by his new obſervations, and by the enlarged views that his meditations preſented to him. The learned perſons who attended his lectures were pleaſed to become his ſcholars, in order to know better what they already knew, and to learn that which otherwiſe they would perhaps never have known.

In arriving at the univerſity, Spallanzani took the *Contemplation de la Nature* of Bonnet for the text of his leſſons: he filled up the vacancies in it, he unfolded the ideas, and confirmed the theories by his experiments. He believed, with reaſon, that the book which inſpired him with the love of natural hiſtory by reading it, was the moſt proper to give birth to it in the minds of his diſciples.

He tranſlated it into Italian, and enriched it with notes; he added a preface to it, wherein he pointed out the ſubjects of the vegetable and animal economy, which in an eſpecial manner deſerved the attention of his pupils; and ſometimes pointing out to them the means of ſucceeding in their reſearches. It was thus he at firſt devoted himſelf to the pleaſing employment of inſtructor of his countrymen, and that he became the model of thoſe who were deſirous of inſtructing uſefully. He publiſhed the firſt volume of his tranſlation in 1769. and the ſecond in 1770.

The connection of Spallanzani with Bonnet had an influence upon his genius, which bent to the ſevere method of the philoſopher of Geneva. He prided himſelf in being his pupil, and he unceaſingly meditated upon his admirable writings; and thus it was that he became deſirous of ſeeking in Nature for the proofs of Bonnet's opinion upon the generation of organized bodies, and that this charming ſubject fixed his attention for a long time.

He publiſhed, in 1776, the two firſt volumes of his *Opuſcoli di Fiſica Animale e Vegetabile:* they are the explanation of a part of the microſcopic obſervations which had already appeared.

If the art to obſerve be the moſt difficult, it is nevertheleſs the moſt neceſſary of all the arts; but it ſuppoſes every quality, every talent: and further, though each believes himſelf more or leſs conſummate therein, yet it is obvious, that only great men have exerciſed it in a diſtinguiſhed manner. Genius alone fixes the objects worthy of regard; that alone directs the ſenſes to the obſcurities which it is neceſſary to diſſipate; it watches over them to prevent error; it animates them to follow by the ſcent, as it were, that which they have but a diſtant view of: it takes off the veil which covers what we are looking after; it ſupports the patience which waits the moment for gratifying the ſight in the midſt of obſtacles multiplying one upon another: in ſhort, it is genius that concentrates the attention upon an object, which communicates that energy to him for imagining, that ſagacity for diſcovering, that promptneſs for perceiving, without which we ſee only one ſide of truth, when we do not happen to let it eſcape altogether. But this is not all; for after Nature has been read with preciſion, it is neceſſary to interpret her with fidelity; to analyſe by the thought the phenomena anatomiſed by the ſenſes; to conſider of the ſpecies by obſerving the individual, and to anticipate the general propoſitions by conſidering the unconnected facts. Here prudence and circumſpection will not always ſecure us againſt error, if an ardent love for the truth does not aſſay obſervations and their conſequences in its crucible, and thereby reduce every thing to *ſcoriæ* which is not truth.

Such was Spallanzani in all his reſearches; ſuch we ſee him in all his writings. Occupied by the great phenomenon of generation, he examined the opinion of Needham to demonſtrate its want of foundation. The latter, not ſatisfied with the microſcopic obſervations of Spallanzani, which weakened the imagined vegetative force to put the matter in motion, challenged the profeſſor of Reggio to a reperuſal of what he had written; but he proved to the other, that we in common practice always ſee that which has been *well obſerved*, but that we never again ſee that which we have been contented with *imagining we ſaw*.

Spallanzani has received much praiſe for the politeneſs with which he carried on this controverſy, and for the ſevere logic with which he demonſtrates to Needham the cauſes of his error; and proves, that the animalculæ of infuſions are produced by germs; that there are ſome of them which defy, like certain eggs and ſeeds, the moſt exceſſive cold, as well as the heat of boiling water. On this occaſion, he treats on the influence of cold upon animals, and proves that the lethargic numbneſs of ſome, during winter, does not depend upon the impreſſion the blood may receive from it; ſince a frog, deprived of his blood, becomes lethargic when he is reduced to the ſame cold ſtate by an immerſion in ice, and ſwims as before when reſtored to warmth. In the ſame manner he ſhews that odours, various liquors, the vacuum, act upon animalculæ as upon other animals; that they are oviparous, viviparous, and hermaphrodite. Thus, in running over theſe diſtant regions of Nature with this illuſtrious traveller, we are always meeting with new facts, profound remarks, precious details, and ſome curious anecdotes; in ſhort, an univerſal hiſtory of thoſe beings which are the moſt numerous of the globe, although their exiſtence is ſcarcely ſuſpected, and whoſe organization is in many reſpects different from that of known animals.

The ſecond volume of this work is a new voyage into the moſt unknown parts: a ſublime pencil had already painted it, but the picture was not done after Nature. Spallanzani here gives a hiſtory of the ſpermatic animalculæ, which the eloquent hiſtorian above alluded to always confounds with the animalculæ of infuſions. We cannot but admire the modeſt diffidence of this new demonſtrator, ſtruggling againſt his own opinion and the authority of Buffon; and he appears to admit, with repugnance, the reſults of his multiplied, and in a thouſand ways varied, obſervations, which expoſe the feebleneſs of the ſyſtem of organic moleculæ.

Spallanzani afterwards deſcribes the volvox and the ſlow-moving animalculæ *(rotifère* and *tardigrade)*, thoſe coloſſuſes of the microſcopic world, ſo ſingular by their figure and organization, but more ſingular ſtill by their faculty of reſuming life, after a total ſuſpence of all the apparent acts of it during many years.

We will not here ſpeak of the experiments of Spallanzani on the death of animals in cloſe veſſels, becauſe he took up the ſubject again, and enlarged and exemplified it by the new lights of chemiſtry; but this collection

lection he concludes with another on the hiſtory of vegetable mould growing on the ſurface of liquors and moiſt ſubſtances, the ſeeds of which he ſhews to float in the air; and he remarks, that theſe microſcopic champignons or muſhrooms diſtinguiſh themſelves from other plants by their tendency to grow in all directions, without conforming to the almoſt univerſal law of perpendicularity of ſtalk to the ground.

Spallanzani was placed at the head of the univerſity's cabinet of natural hiſtory, but he was little more than titular depoſitary of a treaſure which no longer exiſted. He laid the foundations, however, for its renewal, and by his care it is become one of the moſt precious and uſeful. He enriched it through his repeated travels by land and ſea, in Europe, in Aſia, acroſs the Apennines, the Alps, the Krapacks, at the bottom of mines, on the top of volcanoes, at the mouth of craters: ſupported by his ardent paſſion in the midſt of perils, he preſerved the *ſang-froid* of the philoſopher to contemplate theſe wonders, and the piercing eye of an obſerver to ſtudy them. It is thus that he always diſtinguiſhed the proper objects for improving ſcience by favouring inſtruction; it is thus that he filled this depoſitary with treaſures, that all the gold in the world could not have obtained, becauſe gold never ſupplies the genius and the diſcernment of the enlightened naturaliſt.

In 1779 Spallanzani ran over Switzerland and the Griſons; he then went to Geneva, where he ſpent a month with his friends, who admired him the more in his converſations after having admired him in his writings. He then returned to Pavia, and publiſhed, in 1780, two new volumes of his *Diſſertazione di Fiſica Animale e Vegetabile.* He therein reveals the ſecrets of the interpretation of two very obſcure phenomena, concerning the vegetable and animal economy.

Some experiments made by Spallanzani upon *digeſtion*, for his leſſons, engaged him to ſtudy this dark operation: he repeated Reaumur's experiments upon the gallinaceous birds; and he obſerved that the trituration, which is in this caſe an aid to digeſtion, could not, however, be a very powerful means. He ſaw that the gizzard of thoſe birds which pulveriſe the ſtones of fruit to pieces, as if done with needles or other ſharp-pointed inſtruments, did not digeſt the powder ſo formed: that it was neceſſary it ſhould undergo a new operation in the ſtomach, before it could become fit chyle for affording the elements of the blood and other humours. He eſtabliſhed the point, that the digeſtion was performed in the ſtomach of numerous animals by the powerful action of a juice which diſſolves the aliments; and to render his demonſtration the more convincing, he had the courage to make ſeveral experiments on himſelf which might have proved fatal, and had the addreſs to complete his proofs by artificial digeſtions, made in glaſſes upon the table, by mixing the chewed aliments with the gaſtric juice of animals, which he knew how to extract from their ſtomachs. But this book, ſo original by the multitude of experiments and curious obſervations which it contains, is ſtill more worthy of attention by the philoſophic ſpirit which detected it.

This ſubject is one of the moſt difficult in phyſiology: the obſerver is always compelled to act and to look with darkneſs around him; he is obliged to manage the animal with care, to avoid the derangement of his operations; and when he has laboriouſly completed his experiments, it is neceſſary that he ſhould well diſtinguiſh the conſequences, ſometimes erroneous, which may be drawn from thoſe of obſervation, which never deceive when they are immediate. Spallanzani, in this work, is truly a fine ſpectacle; ſcrupulouſly analyſing the facts in order to diſcover their cauſes with certainty; inventing happy reſources for ſurmounting the obſtacles which renew themſelves; comparing Nature with his experiments, to judge of them; catching hold in his obſervations of every thing that is eſſential in them; meaſuring their ſolidity by the augmentation or diminution of ſuppoſed cauſes; drawing the beſt-founded concluſions, and rejecting the moſt plauſible hypotheſes; modeſtly expoſing the errors of thoſe who have gone before him, and employing analogy with that wiſe circumſpection which inſpires confidence in an inſtrument at once ſo dangerous and ſo uſeful. But let it be known, Spallanzani had a capacity in particular for diſcovering the truth, while the greater part of obſervators ſcarcely ever attain it; and then, after having deſcribed around them a circuitous trace, he runs upon it by a ſtraight line, and poſſeſſes himſelf of it ſo as that it cannot eſcape him.

This work put John Hunter out of humour; and he publiſhed, in 1785, *Some Obſervations upon Digeſtion*, wherein he threw out ſome bitter ſarcaſms againſt Spallanzani; who took ample revenge by publiſhing this work in Italian, and addreſſing to *Caldani*, in 1788, *Una Lettera Apologetica in Riſpoſta alle Oſſervazione del Signor Giovanni Hunter.* He expoſes, with moderation, but with an irreſiſtible logic, the overſights of the Engliſh phyſiologiſt, and points out his errors in a manner which left him no hope of a reply.

The ſecond volume treats of the generation of animals and plants. Spallanzani proves, by experiments as ſatisfactory as they are ſurpriſing, the pre-exiſtence of germs to fecundation; he ſhews the exiſtence of tadpoles in the females of five different ſpecies of frogs, in toads, and in ſalamanders, before their fecundation: he recounts the ſucceſs of ſome artificial fecundations upon the tadpoles of thoſe five ſpecies, and even upon a quadruped. He in the ſame manner ſhews the ſeed in the flowers, before the emiſſion of their farina; and by a ſubtle anatomy of which one can hardly form an idea, he exhibits to the eye in the flower of the *ſpartium junceum*, the ſiliqua, its ſeeds, with their lobes, and the embryo plant; he purſues them in their expanſion before and after fecundation, and leaves not a doubt but that the ſeeds and the pericarpia exiſted long before the bloſſoming of the buds, and conſequently a long time before they could have been fecundated. He has repeated theſe obſervations upon various ſpecies of plants with the ſame reſults; in ſhort, he has raiſed the individuals of plants with female flowers which have borne fecundated ſeeds, although they were out of the reach even of ſuſpicion of a communication with the farina of the male flowers. Such is the ſeries of ſurpriſing phenomena Spallanzani adds to the hiſtory of Nature.

According to cuſtom, he availed himſelf of the academical vacation of 1781, to make a journey, the object of which was to add to the cabinet of Pavia. He ſet out in the month of July for Marſeilles, where he commenced a new hiſtory of the ſea, which had preſented him with a crowd of novel and curious facts up-

Spallanzani.

on numerous genera of the inhabitants of the ocean. He went likewiſe to Finale, to Genoa, to Maſſa, and to Carrara, to obſerve the quarries of marble ſo famous with the ſtatuaries; he returned to Spezzia, and thence brought to Pavia an immenſe harveſt of fiſhes, cruſtaceous and teſtaceous, which he depoſited in that cabinet of which his voyages and travels had rendered him ſo worthy to be the guardian. He viſited, in the ſame view, and with the ſame ſucceſs, the coaſts of Iſtria in 1782; the Apennine Mountains in 1783, where he noticed the terrible hurricanes, and the ſurpriſing vapours which rendered that year ſo famous in meteorology. The cabinet of Pavia thus every year ſaw its riches increaſe; and in the ſame proportion it became the object of ſtrangers admiration; but every one admired ſtill more the immenſe labour of Spallanzani, who had collected every part of it.

The Emperor Joſeph knew this when he came into Lombardy: he deſired to have a converſation with Spallanzani; and his majeſty expreſſed his approbation by preſenting him with his medal in gold.

The univerſity of Padua offered to Spallanzani, in 1785, the chair of natural hiſtory, which the death of Anthony Valliſneri had left vacant, promiſing him more conſiderable advantages than thoſe which he enjoyed at Pavia; but the archduke doubled his penſion, and allowed him to accompany to Conſtantinople the Chevalier Zuliani, who had juſt been nominated ambaſſador from the republic of Venice.

He left this city the 21ſt of Auguſt; and during his voyage made ſeveral obſervations upon the marine productions he met with in thoſe climates, as well as upon the meteorological events of every day, among which he had the advantage of beholding a ſpecies of waterſpout. He touched at ſeveral iſlands in the Archipelago, which he examined, and went aſhore at Troy to viſit the places ſung by the poet whom he preferred to all others; and in treading upon that ground ſo anciently famous, he made ſome geological obſervations truly original. One may judge before hand of the intereſt we ſhall feel in reading the Voyage of Spallanzani, by ſome memoirs which have appeared in the *Memorie della Societa Italiana* upon the water-ſpouts at ſea, the ſtroke of the torpedo, divers marine productions, and the iſland of Cytherea, where he diſcovered a mountain compoſed of various ſpecies of foſſils. Spallanzani arrived at Conſtantinople the 11th of October, and remained there eleven months: he muſt have been greatly out of his element in that country of ignorance and ſuperſtition, if he had not had Nature to ſtudy, and Zuliani to hear him. The phyſical and moral phenomena of this country, quite new to him, fixed his attention; he ſtrayed over the borders of the two ſeas, and climbed up the neighbouring hills; he viſited the iſland of Chalki, where he made known to the Turks a mine of copper, the exiſtence of which they never ſo much as ſuſpected. He went to the Principi iſland, a few miles diſtant from Conſtantinople, where he diſcovered an iron mine equally unthought of by the Turks. He returned to Europe loaded with ſpoils from the Eaſt, compoſed of the creatures of the three kingdoms, peculiar to thoſe regions: after having been uſeful to the Orientals, who were incapable of appreciating his merit, or rather of imagining he could have any, he ſet out on his return for Italy the 16th of Auguſt, 1786.

A voyage by ſea was in every reſpect the moſt ſafe and the moſt commodious; but Spallanzani conſidered the dangers and the inconveniences of the road as nothing when employed in any beneficial purſuit; he braved all the perils of thoſe deſert regions, where there is no police, no ſecurity. When he arrived at Buchareſt, he was retained there during nine days by the celebrated and unhappy Mauroceni, hoſpodar of Walachia. This prince, the friend of ſcience, received him with diſtinction, preſented him with many of the rarities of his country, furniſhed him with horſes for travelling, and alſo gave him an eſcort of thirty troopers throughout the whole extent of his dominions. Spallanzani paſſed by Hermanſtadt in Tranſylvania, and arrived at Vienna the 7th of December, after having viewed the numerous mines of Tranſylvania, of Hungary, and of Germany, which lay in the neighbourhood of his route. Spallanzani remained five days in this capital of Auſtria; he had two very long audiences with the Emperor Joſeph II.; was well received by the higheſt nobility in that metropolis, and viſited by the men of letters. At length arrived at Pavia; the ſtudents came to meet him out of the gates of the city, and accompanied him home, manifeſting their joy all the way by repeated ſhouts. Their great deſire to hear him, drew him almoſt immediately to the auditory, where they forced him to aſcend the chair from which he had been accuſtomed to deliver his lectures to them. Spallanzani, affected by this ſcene, teſtified with eloquence his gratitude and attachment;—friendly wiſhes, cries of joy, clapping of hands, recommenced with more force, and he was obliged to requeſt them to deſiſt, and allow him to take in his houſe that repoſe which was more neceſſary than ever. He had in the courſe of this year above 500 ſtudents.

Spallanzani had acquired glory enough to merit the attacks of envy; but his diſcoveries were too new, too original, too ſolid to be diſputed; envy itſelf was therefore forced to admire him: but that unworthy paſſion, being tired out by the increaſing reputation of that great man, watched the moment to prove that it had not forgotten him. Envy and malignity then called in queſtion his uprightneſs in the adminiſtration of the cabinet of Pavia; the whole of which was the fruit of his own labours: but the darts aimed at his honour only made it ſhine with new luſtre. The integrity of Spallanzani appeared even more pure after the juridical examination of the tribunals. But let us ſtop here; Spallanzani had the fortitude to forget this event which had torn his heart to pieces; the greater part of his enemies acknowledged their miſtake, abjured their hatred, and did not deſpair of regaining his friendſhip.

The cabinet of Pavia was always the object of Spallanzani's thoughts; amidſt the numerous rarities which he had placed there, he only ſaw thoſe that were wanting. Struck with its deficiency in volcanic matters, which had neither ſeries nor order, and conſequently excited little intereſt, being a mute article with reſpect to inſtruction (although Italy was the theatre where the fires of volcanoes had for ſo many ages exerciſed their deſolating powers), he took the reſolution, with which his talents, his courage, and his zeal, inſpired

him

him. He was deſirous to inſtruct his pupils, his nation, himſelf, concerning the phenomena ſo ſtriking, and yet ſo little known, and to collect the documents of their hiſtory in the places where they have always been the terror of thoſe who ſurrounded them, and where they have been uſeleſsly the ſubject of the obſervations of the philoſopher. He therefore prepared himſelf for this great enterpriſe by deep ſtudies. He ſet out for Naples, in the ſummer of 1788, and aſcended mount Veſuvius; he looked attentively into its crater, examined and made notes in his books, and embarked for the Lipari iſlands. He diſſected, as it were, the uninhabited volcanoes, with the exactneſs of a naturaliſt anatomiſing a butterfly, and the intrepidity of a warrior defying the moſt imminent dangers. It was then that he had the boldneſs to walk over that ſulphurous cruſt, cleft with chinks, trembling, ſmoking, burning, and ſometimes treacherouſly covering the hearth of the volcano. He paſſed into Sicily, where he climbed up to Etna, and coaſted its immenſe crater. His curioſity not being exhauſted, he would collect around him, and have in his mind, all the ſingular phenomena that Sicily contained; he examined the ſtones and the mountains, and diſcovered many new marine animals; he approached Scylla and Charybdis, and in a boat croſſed the frothy billows of thoſe deadly rocks, celebrated for ſo many ſhipwrecks, and ſo often ſung by the poets; but in the very midſt of their frightful waves, he diſcovered the cauſe of their fury (See SCYLLA, *Suppl.*) It was thus that, at the age of 60, he picked up thoſe numberleſs anecdotes which fill his voyages in the two Sicilies; and that he compared the deſcription which Homer, Pindar, Virgil, Diodorus Siculus, and Strabo, have given of theſe ever famous places, with that which he made himſelf. In this manner he ſhewed the connection of ancient literature with natural hiſtory.

We find in the voyages of Spallanzani a new volcanology. He therein teaches the way to meaſure the intenſity of the fire of volcanoes, to glance at the cauſes, to touch almoſt, in the analyſis which he makes of the lava, that particular gas which, reſembling a powerful lever, tears from the bowels of the earth, and raiſes up to the top of Etna, thoſe torrents of ſtone in fuſion which it diſgorges; to ſurvey the nature of thoſe pumice ſtones, which he has ſince explained in his artificial pumice-ſtones. He concludes this charming work with ſome intereſting inquiries into the nature of ſwallows, their mild diſpoſitions, rapid flight; ſuggeſting that an advantage might be drawn from them in the way of aerial poſt; their migrations determined by the temperature of the air, and the birth of inſects it occaſions: in ſhort, he diſcuſſes the famous problem of their remaining benumbed during winter; and proves, that artificial cold, much greater than that ever naturally felt in our climates, does not render theſe birds lethargic. He next ſpeaks of a ſpecies of owl, hitherto very ill deſcribed; and, laſtly, of eels and their generation, which is a problem ſtill in ſome meaſure to be ſolved; but he carries it on by his inquiries to that ſtep which alone remains to be made for obtaining a complete ſolution; or to get over it eaſily by a ſmall number of obſervations in thoſe times and places pointed out, but which the academical occupations of Spallanzani forced him to give up to others.

Spallanzani.

Spallanzani followed the progreſs of the French chemiſtry with much ſatisfaction, nor was he long before he adopted it; it was calculated for a juſt conception like his, delighting to give an account of every phenomenon he obſerved. The ſolidity of principles in this new doctrine, the preciſion in its way of proceeding, the elegance of its interpretation, the generality of its conſequences, preſently replaced in his mind the heſitations and the obſcurities of the ancient chemiſtry; and his heart anticipated with pleaſure the triumphs that it was about to obtain.

In 1791, Spallanzani publiſhed a letter addreſſed to Profeſſor Fortis, upon the Pennet Hydroſcope. He there relates the experiments which he had directed to be made for aſcertaining the degree of confidence which might be allowed to the ſingular talents of this man; but he ingenuouſly confeſſes, that he is not decided upon the reality of the phenomenon.

Spallanzani has often diſcovered that which might have been deemed impoſſible. In 1795 he made a diſcovery of this nature, which he publiſhed in his *Lettere ſopra il ſoſpetto d'un nuovo ſenſo nei Pipiſtrelli.* We therein learn that the bats, if blinded, act in every reſpect with the ſame preciſion as thoſe which have their eyes; that they in the ſame manner avoid the moſt trifling obſtacles, and that they know where to fix themſelves on ceaſing their flight. Theſe extraordinary experiments were confirmed by ſeveral natural philoſophers, and gave occaſion to ſuſpect a new ſenſe in theſe birds, becauſe Spallanzani thought he had evinced by the way of excluſion, that the other ſenſes could not ſupply the deficiency of that ſight which he had deprived them of; but the anatomical details of Profeſſor Jurine, upon the organ of hearing in this ſingular bird, made him incline afterwards towards the idea, that the ſenſe of hearing might in this caſe ſupply that of ſight, as in all thoſe where the bats are in the dark.

Spallanzani concluded his literary carreer for the public, by a letter addreſſed to the celebrated Giobert; *Sopra la piante chiuſe ne' vaſi dentro l'aqua e l'aria, eſpoſte a l' immediàta lume ſolare e a l'ombra.* It is a misfortune for this part of the ſcience, that his death has deprived us of the diſcoveries he was about to make in it.

Theſe numerous works, printed and applauded, did not however contain all the ſeries of Spallanzani's labours. He had been occupied a conſiderable time upon the phenomena of reſpiration; their reſemblances and differences in a great number of ſpecies of animals; and he was buſily employed in reducing to order his reſearches upon this ſubject, which will aſtoniſh by the multitude of unforeſeen and unexpected facts. He has left a precious collection of experiments and new obſervations upon animal reproductions, upon ſponges, the nature of which he determines, and upon a thouſand intereſting phenomena which he knew how to draw out of obſcurity. He had almoſt finiſhed his voyage to Conſtantinople, and had amaſſed conſiderable materials for a Hiſtory of the Sea, when an end was put to his life and his labours.

On the 4th of February 1799, he was ſeized with a retention of urine, the ſame night was unquiet, and in the morning he loſt all powers of reaſon, which he never recovered but during very ſhort intervals. His intimate friends, Tourdes, a French phyſician, and the celebrated Profeſſor Scarpa, did every thing which could be expected from genius, experience, and friendſhip, to ſave him; but he died the 17th, after having edified thoſe around him by his piety. This lamentable event overwhelmed all his family in ſorrow, occaſioned the tears to flow from all his friends, filled his diſciples with a deep affliction, and excited the regret of a nation proud of having given him birth.

The reader cannot but have perceived in this ſketch the ſtrain of panegyric, rather than the calm narrative of impartial biography. It is, in fact, an abridged tranſlation of an *eloge* by a *citizen* philoſopher of Geneva, who has adopted the calendar, and probably the principles of republican France. Some abatement therefore will naturally be made by every Briton of the praiſes beſtowed upon the piety of Spallanzani; but after proper allowance of this kind, truth will proclaim him a very great man. Accordingly, France, Germany, England, all were eager to avail themſelves of his works by means of tranſlations. He was admitted into the academies and learned ſocieties of London, Stockholm, Gottingen, Holland, Lyons, Bologna, Turin, Padua, Mantua, and Geneva. He was a correſpondent of the academy of ſciences of Paris and of Montpelier: and received from the great Frederic himſelf the diploma of member of the academy of Berlin.

SPECIES, in algebra, are the letters, ſymbols, marks, or characters, which repreſent the quantities in any operation or equation.

Species, in optics, the image painted on the retina by the rays of light reflected from the ſeveral points of the ſurface of an object, received in by the pupil, and collected in their paſſage through the cryſtalline, &c.

SPECTACLES (See *Encycl.*) are certainly the moſt valuable of all optical inſtruments, though there is not the ſame ſcience and mechanical ingenuity diſplayed in the making of them as in the conſtruction of microſcopes and teleſcopes. A man, eſpecially if accuſtomed to ſpend his time among books, would be much to be pitied, when his ſight begins to fail, could he not, in a great meaſure, reſtore it by the aid of ſpectacles; but there are ſome men whoſe ſight cannot be aided by the uſe either of convex or concave glaſſes. The following method adopted by one of thoſe to aid his ſight is certainly worthy of notice:

When about ſixty years of age, this man had almoſt entirely loſt his ſight, ſeeing nothing but a kind of thick miſt, with little black ſpecks which appeared to float in the air. He knew not any of his friends, he could not even diſtinguiſh a man from a woman, nor could he walk in the ſtreets without being led. Glaſſes were of no uſe to him; the beſt print, ſeen through the beſt ſpectacles, ſeemed to him like a daubed paper. Wearied with this melancholy ſtate, he thought of the following expedient.

He procured ſome ſpectacles with very large rings; and, taking out the glaſſes, ſubſtituted in each circle a conic tube of black Spaniſh copper. Looking through the large end of the cone he could read the ſmalleſt print placed at its other extremity. Theſe tubes were of different lengths, and the openings at the end were alſo of different ſizes; the ſmaller the aperture the better could he diſtinguiſh the ſmalleſt letters; the larger the aperture the more words or lines it commanded; and conſequently the leſs occaſion was there for moving the head and the hand in reading. Sometimes he uſed one eye, ſometimes the other, alternately relieving each, for the rays of the two eyes could not unite upon the ſame object when thus ſeparated by two opaque tubes. The thinner theſe tubes, the leſs troubleſome are they. They muſt be totally blackened within ſo as to prevent all ſhining, and they ſhould be made to lengthen or contract, and enlarge or reduce the aperture at pleaſure.

When he placed convex glaſſes in theſe tubes, the letters indeed appeared larger, but not ſo clear and diſtinct as through the empty tube: he alſo found the tubes more convenient when not fixed in the ſpectacle rings; for when they hung looſely they could be raiſed or lowered with the hand, and one or both might be uſed as occaſion required. It is almoſt needleſs to add, that the material of the tubes is of no importance, and that they may be made of iron or tin as well as of copper, provided the inſides of them be ſufficiently blackened. See *La Nouvelle Bigarure* for February 1754, or *Monthly Magazine* for April 1799.

SPECTRE of the Broken, a curious phenomenon obſerved on the ſummit of the *Broken*, one of the Harz mountains in Hanover. We have the following account of it by M. Haue. "After having been here (ſays he) for the thirtieth time, and having procured information reſpecting the abovementioned atmoſpheric phenomenon, I was at length, on the 23d of May 1797, ſo fortunate as to have the pleaſure of ſeeing it; and perhaps my deſcription may afford ſatisfaction to others who viſit the Broken through curioſity. The ſun roſe about four o'clock, and, the atmoſphere being quite ſerene towards the eaſt, his rays could paſs without any obſtruction over the Heinrichſhöhe. In the ſouth-weſt, however, towards Achtermannſhöhe, a briſk weſt wind carried before it thin tranſparent vapours, which were not yet condenſed into thick heavy clouds.

"About a quarter paſt four I went towards the inn, and looked round to ſee whether the atmoſphere would permit me to have a free proſpect to the ſouth-weſt; when I obſerved, at a very great diſtance towards Achtermannſhöhe, a human figure of a monſtrous ſize. A violent guſt of wind having almoſt carried away my hat, I clapped my hand to it by moving my arm towards my head, and the coloſſal figure did the ſame.

"The pleaſure which I felt on this diſcovery can hardly be deſcribed; for I had already walked many a weary ſtep in the hopes of ſeeing this ſhadowy image, without being able to gratify my curioſity. I immediately made another movement by bending my body, and the coloſſal figure before me repeated it. I was deſirous of doing the ſame thing once more—but my coloſſus had vaniſhed. I remained in the ſame poſition, waiting to ſee whether it would return; and in a few minutes it again made its appearance on the Achtermannſhöhe. I paid my reſpects to it a ſecond time, and it did the ſame to me. I then called the landlord of the Broken; and having both taken the ſame poſition which I had taken alone, we looked towards the Achtermannſhöhe, but ſaw nothing. We had not, however, ſtood long, when two ſuch coloſſal figures were formed over the above eminence, which repeated our compliments by bending their bodies as we did; after which they vaniſhed. We retained our poſition; kept our eyes fixed on the ſame ſpot, and in a little the two figures again ſtood before us, and were joined by a third. Every movement that we made by bending our bodies theſe figures imitated—but with this difference, that the phenomenon was ſometimes weak and faint, ſometimes ſtrong and well defined. Having thus had an opportunity of diſcovering the whole ſecret of this phenomenon, I can give the following information to ſuch of my readers as may be deſirous of ſeeing it themſelves. When the riſing ſun, and according to analogy the caſe will be the ſame at the ſetting ſun, throws his rays over the Broken upon the body of a man ſtanding oppoſite to fine light clouds floating around or hovering paſt him, he needs only fix his eyes ſtedfaſtly upon them, and, in all probability, he will ſee the ſingular ſpectacle of his own ſhadow extending to the length of five or ſix hundred feet, at the diſtance of about two miles before him."

If our memory does not deceive us, there is in one of the volumes of the *Mancheſter Tranſactions* an account of a ſimilar phenomenon obſerved by Dr Ferrier, on a hill ſomewhere in England.

SPECULUM for reflecting teleſcopes. Under this title (*Encycl.*) we have given the compoſition of the mixt metal of which it has been found by experience that the beſt ſpeculums are made; we have likewiſe given, under the ſame title, ſome directions for caſting ſpeculums: but owing to a circumſtance in which the public can take no intereſt, we neglected to give directions for grinding and poliſhing them, and omitted ſome other circumſtances, which, though not ſo important as theſe, are certainly worthy of notice. Theſe omiſſions it is the object of this article to ſupply.

When the metal is taken out of the flaſks (See n° 3. of the article referred to), which it ſhould be as ſoon as it has become ſolid, and while it is yet red-hot, care muſt be taken to keep the face downwards to prevent it from ſinking. Holding it in that poſition by the git, force out the ſand from the hole in the middle of the mirror with a piece of wood or iron, and place the ſpeculum in an iron pot, with a large quantity of hot aſhes or ſmall coals, ſo as to bury the ſpeculum in them a ſufficient depth. If the ſand is not forced out of the hole in the manner above directed, the metal, by ſinking as it cools, will embrace the ſand in the middle of the ſpeculum ſo tight, as to cauſe it to crack before it becomes entirely cold. And if the metal is not taken out of the ſand, and put in a pot with hot aſhes or coals to anneal it, the moiſture from the ſand will always break the metal. Let the ſpeculum remain in the aſhes till the whole is become quite cold. The git may be eaſily taken off by marking it round with a common fine half round file, and giving it then a gentle blow. The metal is then to be rough ground and figured.

It may be proper, however, before we proceed to deſcribe that proceſs, to give an account of another compoſition for the ſpeculum of a reflecting teleſcope, which has been employed with great ſucceſs, by Rochon director of the marine obſervatory at Breſt. Of this compoſition the principal ingredient is platinum; which, in grains, muſt be purified in a ſtrong fire by means of nitre and the ſalt of glaſs, or that flux which in the Engliſh glaſs-houſes is called by the workmen *ſandifer*. To the platinum, when purified, add the eighth part of the metal employed in the compoſition of common ſpecula; for tin without red copper would not produce a good effect. This mixture is then to be expoſed to the moſt violent heat, which muſt be ſtill excited by the oxygen gas that diſengages itſelf from nitre when thrown into the fire. One melting would be inſufficient: five or ſix are requiſite to bring the mixture to perfection. It is neceſſary that the metal ſhould be in a ſtate of complete fuſion at the moment when it is poured into the mould. By this proceſs I have been enabled (ſays our author) to conſtruct a teleſcope with platinum, which magnifies the diameters of objects five hundred times, with a degree of clearneſs and diſtinctneſs requiſite for the niceſt obſervations. The large ſpeculum of platinum weighs fourteen pounds: it is eight inches in diameter, and its focus is ſix feet. Though the high price of platinum will, in all probability, for ever prevent it from coming into general uſe for the ſpeculums of teleſcopes, we thought it proper to notice this diſcovery, and ſhall now proceed to the grinding of the ſpeculum.

For the accompliſhing of this object, a very complicated proceſs is recommended in Smith's Optics, and one not much more ſimpler by Mr Mudge in the 67th volume of the *Philoſophical Tranſactions*; but according to Mr Edwards, whoſe ſpeculums are confeſſedly the beſt, neither of theſe is neceſſary. Beſides a common grindſtone, all the tools that he made uſe of are a rough grinder, which ſerves alſo as a poliſher, and a bed of hones. When the ſpeculum was cold, he ground its ſurface bright on a common grindſtone, previouſly brought to the form of the gage; and then took it to the rough grinder.

This tool is compoſed of a mixture of lead and tin, or of pewter, and is made of an elliptical form, of ſuch dimenſions, that the ſhorteſt diameter of the ellipſe is equal to the diameter of the mirror or ſpeculum, and the longeſt diameter is to the ſhorteſt in the proportion of ten to nine. This rough grinder may be fixed upon a block of wood, in order to raiſe it higher from the bench; and as the metal is ground upon it with fine emery, Mr Mudge, with whom, in this particular, Mr Edwards agrees, directs a hole or pit to be made in the middle of it as a lodgement for the emery, and deep grooves to be cut out acroſs its ſurface with a graver for the ſame purpoſe. By means of a handle, fixed on the back of the metal with ſoft cement, the ſpeculum can be whirled round upon this grinder ſo rapidly, that a common labourer has been known to give a piece of metal, four inches in diameter, ſo good a face and figure as to fit it for the hones in the ſpace of two hours. The emery, however fine, will break up the metal very much; but that is remedied by the ſubſequent proceſſes of honing and poliſhing.

When the metal is brought to a true figure, it muſt be taken to a convex tool, formed of ſome ſtones from a place called Edgedon in Shropſhire, ſituated between Ludlow and Biſhop's Caſtle. The common blue hones, uſed by many opticians for this purpoſe, will ſcarcely touch the metal of Mr Edwards's ſpeculums; but where they muſt be employed for want of the others, as little water ſhould be uſed as poſſible when the metal is put upon them; becauſe it is found by experience that they cut better when but barely wet, than when drenched with water. The ſtones, however, from Edgedon are greatly preferable; for they cut the metal more eaſily, and having a very fine grain, they bring it to a ſmooth face. Theſe ſtones are directed by Mr Mudge to be cemented in ſmall pieces upon a thick round piece of marble, or of metal made of tin and lead like the former compoſition, in ſuch a manner, that the lines between the ſtones may run ſtraight from one ſide to the other; ſo that placing the teeth of a very fine ſaw in each of theſe diviſions, they may be cleared from one end to the other of the cement which riſes between the ſtones. As ſoon as the hones are cemented down, this tool muſt be fixed in the lathe, and turned as exactly true to the gage as poſſible. It ſhould be of a circular figure, and but very little larger than the metal intended to be figured upon it. If it be made conſiderably larger, it will grind the metal into a larger ſphere and a bad figure; and if it be made exactly of the ſame ſize, it will work the metal indeed into a figure truly ſpherical, but will be apt to ſhorten its focus, unleſs the metal and tool be worked alternately upwards. On theſe accounts, Mr Edwards recommends it to be made about one twentieth part longer in diameter than the ſpeculum, becauſe he has found that it does not then alter its focus; and he earneſtly diſſuades the uſe of much water on the hone pavement at the time of uſing it, otherwiſe, he ſays, that the metal in different parts of it will be of different degrees of brightneſs.

When the metal is brought to a very fine face and figure by the bed of ſtones, it is ready to receive a poliſh, which is given to it by the elliptical rough grinder covered with pitch. With reſpect to the conſiſtency of this pitch, Mr Mudge and Mr Edwards give very different directions. Whilſt the former ſays that it ſhould be neither too hard nor too ſoft, the latter affirms that the harder the pitch is, the better figure it will give to the metal. Pitch may be eaſily made of a ſufficient hardneſs by adding a proper quantity of roſin; and when it is hardened in this way, it is not ſo brittle as pitch alone, which is hardened by boiling. Mr Edwards adviſes to make the mixture juſt ſo hard as to receive, when cold, an impreſſion from a moderate preſſure of the nail of one's finger. When the elliptical tool is to be covered with this mixture, it muſt be made pretty warm, and in that ſtate have the mixture poured upon it when beginning to cool in the crucible. Our author recommends this coating to be made everywhere of about the thickneſs of half-a-crown; and to give it the proper form, it muſt, when ſomewhat cool, be preſſed upon the face of the mirror, which has firſt been dipped in cold water, or covered over with very fine writing paper. If it be not found to have taken the exact figure from the firſt preſſure, the ſurface of the pitch muſt be gently warmed, and the operation repeated as before. All the ſuperfluous pitch is now to be taken away from the edge of the poliſher with a pen knife, and a hole to be made in the middle, accurately round, with a conical piece of wood. This hole ſhould go quite through the tool, and ſhould be made of the ſame ſize, or ſomewhat leſs than the hole in the middle of the ſpeculum. Mr Edwards ſays, that he has always found that ſmall mirrors, though without any hole in the middle, poliſh much better, and take a more correct figure, for the poliſher's having a hole in the middle of it.

The poliſher being thus formed, it muſt be very gently warmed at the fire, and divided into ſeveral ſquares by the edge of a knife. Theſe, by receiving the ſmall portion of metal that works off in poliſhing, will cauſe the figure of the ſpeculum to be more correct than if no ſuch ſquares had been made. Mr Mudge directs the poliſher to be ſtrewed over with very fine *putty*; but Mr Edwards prefers Colcothar of vitriol. (See that article, *Encycl.*) Putty (ſays he) gives metals a white luſtre, or, as workmen call it, a ſilver hue; but good colcothar of vitriol will poliſh with a very fine and high black luſtre, ſo as to give the metal finiſhed with it the complection of poliſhed ſteel. To know if the colcothar of vitriol is good, put ſome of it into your mouth, and if you find it diſſolves away it is good; but if you find it hard, and crunch between your teeth, then it is bad, and not well burned. Good colcothar of vitriol is of a deep red, or of a deep purple colour, and is ſoft and oily when rubbed between the fingers; bad colcothar of vitriol is of a light red colour, and feels harſh and gritty. The colcothar of vitriol ſhould be levigated between two ſurfaces of poliſhed ſteel, and wrought with a little water; when it is worked dry, you may add a little more water, to carry it lower down to what degree you pleaſe. When the colcothar of vitriol has been wrought dry three or four times, it will acquire a black colour, and will be low enough, or ſufficiently fine, to give an exquiſite luſtre. This levigated colcothar of vitriol muſt be put into a ſmall phial, and kept with ſome water upon it. When it is to be uſed, every part of the pitch-poliſher muſt be firſt bruſhed over with a fine camel's hair bruſh, which has been dipped in pure water, and rubbed gently over a piece of dry clean ſoap. The waſhed colcothar of vitriol is then to be put upon the poliſher; and Mr Edwards directs a large quantity of it to be put on at once, ſo as to ſaturate the pitch, and form a fine coating. If a ſecond or third application of this powder be found neceſſary, it muſt be uſed very ſparingly, or the poliſh will be deſtroyed which has been already attained. When the metal is nearly poliſhed, there will always appear ſome black mud upon its ſurface, as well as upon the tool. Part of this muſt be wiped away with ſome very ſoft waſh leather; but if the whole of it be taken away, the poliſhing will not be ſo well completed.

With reſpect to the *parabolic figure* to be given to the mirror, Mr Edwards aſſures us, that a very little experience in theſe matters will enable any one to give it with certainty, by poliſhing the ſpeculum in the common manner, only with croſs ſtrokes in every direction, upon an elliptical tool of the proper dimenſions.

SPINDLE, in geometry, a ſolid body generated by the revolution of ſome curve line about its baſe or double ordinate; in oppoſition to a conoid, which is generated by the rotation of the curve about its axis or abſciſs, perpendicular to its ordinate. The ſpindle is denominated circular, elliptic, hyperbolic, or parabolic, &c. according to the figure of its generating curve.

Spindle, in mechanics, ſometimes denotes the axis of a wheel, or roller, &c. and its ends are the pivots.

SPINNING machine. The ancient Greeks were not, like the modern philoſophers, unwilling to acknowledge their obligations to Providence for all the comforts and enjoyments of life, nor felt pride in deriving every thing from their own talents. They were even diſpoſed to think that thoſe very talents were inſpired. Their firſt inſtructors, the poets, gave to Apollo the honour of that power of invention and imagination by which they inſtructed and charmed their admiring hearers. The propheteſs dictated her oracles,

Sp ing-
M hine.

the poet ſung his enraptured ſtrain only when inſpired. The happy thought of twining a thread, and working it into a blanket, when viewed by that ingenious and acutely ſenſible people in all its importance, as the protector of the human race from the ſeverity of the weather, ſeemed a preſent from heaven, as the inſpiration of a divinity; and the diſtaff and the loom were Minerva's firſt title to a ſeat among the great gods on Olympus.

We are much inclined to be of the ſame opinion. When we obſerve, that in all the countries which have been diſcovered by the navigators of the three laſt centuries, the diſtaff and ſpindle, and the needle, have been found, we own ourſelves much diſpoſed to think that they are the reſults of inſtinct. Our inſtincts are not all ſimple and blind, like that which directs the new-born animal to the breaſt of its mother without knowing why. We have inſtincts of intellect as well as of appetite; and the logic of common converſation is an example of many ſuch. We doubt not but that the noble-minded inhabitants of Pelew would have worſhipped as a divinity an Engliſh maiden with her ſpinning wheel and fly. Surely he who ſhould carry them this homely but ingenious machine, and a potter's wheel, would do them more ſervice than if he taught them all the ſcience of a Newton, with all the philoſophy of the 18th century into the bargain. We do not know, except perhaps the ſteam engine, any mechanical invention that has made ſuch amazing addition to the activity and induſtry and opulence of this highly favoured iſland, as the invention of Mr Arkwright for ſpinning by water, where dead matter is made to perform all that the niceſt finger can do when directed by the never-ceaſing attention of the intelligent eye. Minerva has the undiſputed honours of the diſtaff and ſpindle. We know not to what benefactor we owe the fly-wheel. Mr Arkwright has the honour of combining them both, and inſpiring them with his own ſpirit; for we may truly ſay of the contrivance which pervades the wonderful machinery of a cotton mill,

Totoſque infuſa per artus
Mens agitat molem et magno ſe corpore miſcet.

To give an intelligible and accurate deſcription of a cotton mill would be abundant employment for a volume. Our limits admit of nothing like this; but as we are certain that many of our readers have viewed a cotton mill with wonder, but not with intelligence, nor with leiſure to trace the ſteps by which the wool from the bag ultimately aſſumes the form of a very fine thread. Bewildered by ſuch a complication of machinery, all in rapid motion, very few, we imagine, are able to recollect with diſtinctneſs and intelligence the eſſential part of the proceſs by which the form of the cotton is ſo wonderfully changed. Such readers will not think a page or two miſemployed, if they are thereby able to underſtand this particular, to which all the reſt of the proceſs is ſubſervient.

We paſs over the operation of carding, by which all the clots and inequalities of the cotton wool are removed, and the whole is reduced to an uniform thin fleece, about 20 inches broad. This is gradually detached from the finiſhing card, and, if allowed to hang down from it, would pile up on the floor as long as the mill continues to work; but it is guided off from the card, very tenderly, in a horizontal direction, by laying its detached end over a roller, which is ſlowly turned round by the machine. Another roller lies above the fleece, preſſing it down by its weight. By this preſſure, a gentle hold is taken of the fleece, and therefore the ſlow motion of the rollers draws it gently from the card at the ſame rate as it is diſengaged by the comb; but between the card and the rollers a ſet of ſmooth pins are placed in two rows, leading from the card to the rollers, and gradually approaching each other as we approach the rollers. By theſe pins the broad fleece is hemmed in on both ſides, and gradually contracted to a thick roll; and in this ſtate paſſes between the rollers, and is compreſſed into a pretty firm flat riband, about two inches broad, which falls off from the rollers, and piles up in deep tinplate cans ſet below to receive it.

Spinning-Machine.

It is upon this ſtripe or riband of cotton wool that the operation of ſpinning begins. The general effect of the ſpinning proceſs is to draw out this maſſive roll, and to twiſt it as it is drawn out. But this is not to be done by the fingers, pulling out as many cotton fibres at once as are neceſſary for compoſing a thread of the intended fineneſs, and continuing this manipulation regularly acroſs the whole end of the riband, and thus, as it were, nibbling the whole of it away. The fingers muſt be directed, for this purpoſe, by an attentive eye. But in performing this by machinery, the whole riband muſt be drawn out together, and twiſted as it is drawn. This requires great art, and very delicate management. It cannot be done at once; that is, the cotton roll cannot firſt be ſtretched or drawn out to the length that is ultimately produced from a tenth of an inch of the roll, and then be twiſted. There is not coheſion enough for this purpoſe; we ſhould only break off a bit of the roll, and could make no farther uſe of it. The fibres of cotton are very little implicated among each other in the roll, becauſe the operation of carding has laid them almoſt parallel in the roll; and though compreſſed a little by its contraction from a fleece of 20 inches to a riband of only 2, and afterwards compreſſed between the diſcharging rollers of the carding machine, yet they cohere ſo ſlightly, that a few fibres may be drawn out without bringing many others along with them. For theſe reaſons, the whole thickneſs and breadth of two or three inches of the riband is ſtretched to a very minute quantity, and then a very ſlight degree of twiſt is given it, viz. about three turns in the inch; ſo that it ſhall now compoſe an extremely ſoft and ſpungy cylinder, which cannot be called a thread or cord, becauſe it has ſcarcely any firmneſs, and is merely rounder and much ſlenderer than before, being ſtretched to about thrice its former length. It is now called ſlab, or roove.

Although it be ſtill extremely tender, and will not carry a weight of two ounces, it is much more coheſive than before, becauſe the twiſt given to it makes all the longitudinal fibres bind each other together, and compreſs thoſe which lie athwart; therefore it will require more force to pull a fibre from among the reſt, but ſtill not nearly enough to break it. In drawing out a ſingle fibre, others are drawn out along with it; and if we take hold of the whole aſſemblage, in two places, about an inch or two inches aſunder, we ſhall find that we may draw it to near twice its length without any riſk of its ſeparating in any intermediate part, or becoming much ſmaller in one part than another. It ſeems to yield equably over all.

Such is the ſtate of the ſlab or roove of the firſt formation. It is uſually called the *preparation*; and the operation of ſpinning is conſidered as not yet begun. This preparation is the moſt tedious and requires more attendance and hand labour than any ſubſequent part of the proceſs. For the ſtripes or ribands from which it is made are ſo light and bulky, that a few yards only can be piled up in the cans ſet to receive them. A perſon muſt therefore attend each thread of ſlab, to join freſh ſtripes as they are expended. It is alſo the moſt important in the manufacture; for as every inch of the ſlab meets with preciſely the ſame drawing and the ſame twiſting in the ſubſequent parts of the proceſs, therefore every inequality and fault in the ſlab (indeed in the fleece as it quits the finiſhing card) will continue through the whole manufacture. The ſpinning of cotton yarn now divides into two branches. The firſt, performed by what are called *jennies*, perfectly reſembles the ancient ſpinning with the diſtaff and ſpindle; the other, called *ſpinning of twiſt*, is an imitation of the ſpinning with the fly-wheel. They differ in the ſame manner as the ſpinning with the old wool or cotton-wheel differs from the ſpinning with the flax-wheel. Mr Arkwright's chief invention, the ſubſtitution of machinery for the immediate work of the human finger, is ſeen only in the manufacture of twiſt. We ſhall therefore confine our attention to this.

The reſt of the proceſs is little more than a repetition of that gone through in making the firſt ſlab or roove. It is formed on bobins. Theſe are ſet on the back part of the drawing frame; and the end of the ſlab is brought forwards toward the attending workman. As it comes forward, it is ſtretched or drawn to about $\frac{4}{3}$ of its former length, or lengthened $\frac{1}{3}$; and is then twiſted about twice as much as before, and in this ſtate wound up on another bobin. In ſome mills two rooves, after having been properly drawn, are brought together through one hole, and twiſted into one; but we believe that, in the greater number of mills, this is deferred to the ſecond drawing. It is only after the firſt drawing that the produce of the operation gets the name of *ſlab*; before this it is called *preparation*, or *roove*, or by ſome other name The ſlab is ſtill a very feeble, ſoft, and delicate yarn, and will not carry much more weight than it did before in the form of roove. The perfection of the ultimate thread or yarn depends on this extreme ſoftneſs; for it is this only which makes it ſuſceptible of an equable ſtretching; all the fibres yielding and ſeparating alike.

The next operation is the *ſecond drawing*, which no way differs from the firſt, except in the different proportions of the lengthening, and the proportion between the lengthening and the ſubſequent twiſt. On theſe points we cannot give any very diſtinct information. It is different in different mills, and with different ſpecies of cotton wool, as may be eaſily imagined. The immediate mechaniſm or manipulation muſt be ſkilfully accommodated to the nature of that friction which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a conſiderable degree of elaſticity which it poſſeſſes. In this reſpect it greatly reſembles woollen fibres, and differs exceedingly from thoſe of flax: and it is for this reaſon that it is ſcarcely poſſible to ſpin flax in this way: its fibres become lank, and take any ſhape by the ſlighteſt compreſſion, eſpecially when damp in the ſlighteſt degree. But beſides this, the ſurface of a cotton fibre has a harſhneſs or roughneſs, which greatly augments their mutual friction. This is probably the reaſon why it is ſo unfit for tents and other dreſſings for wounds, and is refuſed by the ſurgeon even in the meaneſt hoſpitals. But this harſhneſs and its elaſticity fit it admirably for the manufacture of yarn. Even the ſhortneſs of the fibre is favourable; and the manufacture would hardly be poſſible if the fibre were thrice as long as it generally is. If it be juſt ſo long that in the finiſhed thread a fibre will rather break than come out from among the reſt, it is plain that no additional length can make the yarn any ſtronger with the ſame degree of compreſſion by twining. A longer fibre will indeed give the ſame firmneſs of adherence with a ſmaller compreſſion. This would be an advantage in any other yarn; but in cotton yarn the compreſſion is already as ſlight as can be allowed; were it leſs, it would become woolly and rough by the ſmalleſt uſage, and is already too much diſpoſed to teazle out. It can hardly be uſed as ſewing thread. Now ſuppoſe the fibres much longer; ſome of them may chance to be ſtretched along the ſlab through their whole length. If the ſlab is pulled in oppoſite directions, by pinching it at each end of ſuch fibres, it is plain that it will not ſtretch till this fibre be broken or drawn out; and that while it is in its extended ſtate, it is acting on the other fibres in a very unequable manner, according to their poſitions, and renders the whole apt to ſeparate more irregularly. This is one great obſtacle to the ſpinning of flax by ſimilar machinery; and it has hitherto prevented (we believe) the working up of any thing but the *ſhorts* or tow, which is ſeparated from the long fine flax in the operation of hatcheling.

A third, and ſometimes even a fourth, drawing is given to the ſlab formed on the bobins of this ſecond operation. The ſlab produced is now a ſlender, but ſtill extremely ſoft cord, ſuſceptible of conſiderable extenſion, without riſk of ſeparation, and without the ſmalleſt chance of breaking a ſingle fibre in the attempt. In one or more of the preparatory drawings now deſcribed, two, and ſometimes three ſlabs, of a former drawing, are united before the twiſt is given them. The practice is different in different mills. It is plain, that unleſs great care be taken to preſerve the ſlab extremely ſoft and compreſſible during the whole proceſs, the ſubſequent drawing becomes more precarious, and we run a riſk of at laſt making a bad and looſe thread inſtead of a uniform and ſimple yarn. Such a thread will have very little lateral connection, and will not bear much handling without ſeparating into ſtrands. The perfection of the yarn depends on having the laſt ſlab as free of all appearance of ſtrands as poſſible.

The laſt operation is the ſpinning this ſlab. This hardly differs from the foregoing drawings in any thing but the twiſt that is given it after the laſt ſtretching in its length. This is much greater than any of the preceding, being intended to give the yarn hardneſs and firmneſs, ſo that it will now break rather than ſtretch any more.

The

The reader, moderately acquainted with mechanics, cannot but perceive that each of the operations now deſcribed, by which the roove is changed into the ſoft ſlab, and each of theſe into one ſlenderer and ſomewhat firmer, by alternately teazling out and twining the ſoft cord, is a ſubſtitute for a ſingle pull of the finger and thumb of the ſpinſter, which ſhe accommodates preciſely to the peculiar condition of the lock of wool which ſhe touches at the moment. She can follow this thro' all its irregularities; and perhaps no two ſucceeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we muſt be careful to introduce the roove in a ſtate of perfect uniformity; and then every inch being treated in the ſame manner, the final reſult will be equable—the yarn will be uniform.

We are now to deſcribe the mechaniſm by which all this is effected. But we do not mean to deſcribe a cotton mill; we only mean to deſcribe what comes into immediate contact with the thread; and in ſo doing, to confine ourſelves to what is neceſſary for making the reader perceive its ability to perform the required taſk. We ſee many caſes where individuals can apply this knowledge to uſeful purpoſes. More than this would, we think, be improper, in a national point of view.

Let ABC repreſent the ſection of a roller, whoſe pivot D does not turn in a pivot hole, but in the bottom of a long narrow notch DE, cut in an iron ſtandard. *abc* is the ſection of another iron roller, whoſe pivot *d* is in the ſame notches at each end, while the roller itſelf lies or reſts on the roller ABC below it. The ſurfaces of theſe rollers are fluted lengthwiſe like a column; only the flutings are very ſmall and ſharp, like deep ſtrokes of engraving very cloſe together. It is plain, that if the roller ABC be made to turn ſlowly round its axis by mach[illegible] in the direction ABC (as expreſſed by the da[illegible] roughneſs of the flutings will take hold of the ſimilar roughneſs of the upper roller *abc*, and carry it round alſo in the direction of the dart, while its pivots are engaged in the notches DE, which they cannot quit. If therefore we introduce the end F of the cotton ſtring or riband, formed by the carding machine, it will be pulled in by this motion, and will be delivered out on the other ſide at H, conſiderably compreſſed by the weight of the upper roller, which is of iron, and is alſo preſſed down by a lever which reſts on its pivots, or other proper places, and is loaded with a weight. There is nothing to hinder this motion of the riband thus compreſſed between the rollers, and it will therefore be drawn thro' from the cans. The compreſſed part at H would hang down, and be piled up on the floor as it is drawn thro'; but it is not permitted to hang down in this manner, but is brought to another pair of ſharp fluted iron rollers K and L. Suppoſing this pair of rollers to be of the ſame diameter, and to turn round in the ſame time, and in the ſame direction with the rollers ABC, *abc*; it is plain that K and L drag in the compreſſed riband at I, and would deliver it on the other ſide at M, ſtill more compreſſed. But the roller K is made (by the wheelwork) to turn round more ſwiftly than ABC. The difference of velocity at the ſurface of the rollers is, however, very ſmall, ſeldom exceeding one part in 12 or 15. But the conſequence of this difference is, that the ſkein of cotton HI will be lengthened in the ſame proportion; for the upper rollers preſſing on the under ones with a conſiderable force, their ſharp flutings take good hold of the cotton between them; and ſince K and L take up the cotton faſter than ABC, and *abc* deliver it out, it muſt either be forcibly pulled through between the firſt rollers, or it muſt be ſtretched a little by the fibres ſlipping among each other, or it muſt break. When the extenſion is ſo very moderate as we have juſt now ſaid, the only effect of it is merely to begin to draw the fibres (which at preſent are lying in every poſſible direction) into a more favourable poſition for the ſubſequent extenſions.

The fibres being thus drawn together into a more favourable poſition, the cotton is introduced between a third pair of rollers O, P, conſtructed in the ſame way, but ſo moved by the wheelwork that the ſurface of O moves nearly or fully twice as faſt as the ſurface of K. The roller P being alſo well loaded, they take a firm hold of the cotton, and the part between K and O is nearly or fully doubled in its length, and now requires a little twining to make it roundiſh, and to conſolidate it a little.

It is therefore led ſloping downwards into a hole or eye in the upper pivot of the firſt fly, called a *jack*. This turns round an upright axis or ſpindle; the lower end of which has a pulley on it to give it motion by means of a band or belt, which paſſes round a drum that is turned by the machinery. This jack is of a very ingenious and complicated conſtruction. It is a ſubſtitute for the fly of the common ſpinning wheel. If made preciſely in the form of that fly, the thread, being ſo very bulky and ſpongy, and unable to bear cloſe packing on the bobin, would ſwag out by the whirling of the fly, and would never coil up. The bobin therefore is made to lie horizontally; and this occaſions the complication, by the difficulty of giving it a motion round a horizontal axis, in order to coil up the twiſted roove. Mr Arkwright has accompliſhed this in a very ingenious manner; the eſſential circumſtances of which we ſhall here briefly deſcribe. A is a roller of hard wood, having its ſurface cut into ſharp flutes longitudinally. On the axis, which projects through the ſide of the general frame, there is a pulley P, connected by a band with another pulley Q, turning with the horizontal axis QR. This axis is made to turn by a contrivance which is different in every different cotton mill. The ſimpleſt of all is to place above the pulley C (which is turned by the great band of the machinery, and thus gives motion to the jack), a thin circular diſc D, looſe upon the axis, ſo as to turn round on it without obſtruction. If this diſc exceed the pulley in breadth about $\frac{1}{10}$th of an inch, the broad belt which turns the pulley will alſo turn it; but as its diameter is greater than that of the pulley, it will turn ſomewhat ſlower, and will therefore have a relative motion with reſpect to the axis QR. This can be employed, in order to give that axis a very ſlow motion, ſuch as one turn of it for 20 or 30 of the jack. This we leave to the ingenuity of the reader. The bobin B, on which the roove is to be coiled up, lies on this roller, its pivots paſſing through upright ſlits in the ſides of the general frame. It lies on A, and is moved round by it, in the ſame manner as the uppermoſt of a pair of drawing rollers lies on the under one, and receives motion from it. It is evident that the fluted ſurface of A, by turning ſlowly

ſlowly round, and carrying the weight of the bobin, compreſſes a little the cotton that is between them; and its flutings, being ſharp, take a ſlight hold of it, and cauſe it to turn round alſo, and thus coil up the roove, pulling it in through the hole E in the upper pivot (which reſembles the fore pivot or eye of a ſpinning wheel fly) in ſo gentle a manner as to yield whenever the motion of the bobin is too great for the ſpeed with which the cotton ſkein is diſcharged by the rollers O and P.—*N. B.* The axis QR below, alſo gives motion to a guide within the jack, which leads the roove gradually from one end of the bobin to the other, and back again, ſo as to coil it with regularity till the bobin is full. The whole of this internal mechaniſm of the jack is commonly ſhut up in a tin cylinder. This is particularly neceſſary when the whirling motion muſt be rapid, as in the ſecond and third drawings. If open, the jacks would meet with much reſiſtance from the air, which would load the mill with a great deal of uſeleſs work.

The reader is deſired now to return to the beginning of the proceſs, and to conſider it attentively in its different ſtages. We apprehend that the deſcription is ſufficiently perſpicuous to make him perceive the efficacy of the mechaniſm to execute all that is wanted, and prepare a ſlab that is uniform, ſoft, and ſtill very extenſible; in ſhort, fit for undergoing the laſt treatment, by which it is made a fine and firm yarn.

As this part of the proceſs differs from each of the former, merely by the degree of twiſt that is given to the yarn, and as this is given by means of a fly, not materially different from that of the ſpinning wheel for flax, we do not think it at all neceſſary to ſay any thing more about it.

The intelligent reader is ſurely ſenſible that the yarn produced in this way muſt be exceedingly uniform. The uniformity really produced even exceeds all expectation; for even although there be ſome ſmall inequalities in the carded fleece, yet if theſe are not matted clots, which the card could not equaliſe, and only conſiſt of a little more thickneſs of cotton in ſome places than in others, when ſuch a piece of the ſtripe comes to the firſt roller, it will be rather more ſtretched by the ſecond, and again by the bobin, after the firſt very ſlight twining. That this may be done with greater certainty, the weights of the firſt rooving rollers are made very ſmall, ſo that the middle part of the ſkein can be drawn through, while the outer parts remain faſt held.

We are informed that a pound of the fineſt Bourbon cotton has been ſpun into a yarn extending a few yards beyond 119 miles!

ELATER SPRING, in phyſics, denotes a natural faculty, or endeavour, of certain bodies to return to their firſt ſtate, after having been violently put out of the ſame by compreſſing, or bending them, or the like. This faculty is uſually called by philoſophers *elaſtic force*, or *elaſticity*.

T. SQUARE, or *Tee Square*, an inſtrument uſed in drawing, ſo called from its reſemblance to the capital letter T.

STAPELIA, a genus of plants belonging to the claſs pentandria, in the Linnæan arrangement, and to the order digynia. The generic characters are the following: The *calyx* is monophyllous, quinquefid, acute, ſmall, and permanent. The *corolla* is monopetalous, flat, large, and divided, deeper than the middle, into five parts, with broad, flat, pointed *laciniæ*. The *nectarium* is ſmall, ſtar-ſhaped, flat, quinquefid, with linear *laciniæ*; and embracing with its ragged points the ſeed-forming parts. Another ſmall ſtar, which is alſo flat and quinquefid, covers the ſeminiferous parts with its entire acute *laciniæ*. The *ſtamina* are five in number; the *filaments* are erect, flat, and broad; and the *antheræ* are linear, on each ſide united to the ſide of the filament. The *piſtillum* has two *germina*, which are oval and flat on the inſide. There are no *ſtyles*; and the *ſtigmata* are obſolete. The *ſeed-veſſel* conſiſts of two oblong, awl-ſhaped, unilocular and univalved follicles. The *ſeeds* are numerous, imbricated, compreſſed, and crowned with a *pappus* or down.

This ſingular tribe of plants is peculiar to the ſandy deſerts of Africa and Arabia. They are extremely ſucculent. From this peculiarity of ſtructure, the power of retaining water to ſupport and nouriſh them, they are enabled to live during the prevalent droughts of thoſe arid regions. On this account the ſtapelia has been compared to the camel; and we are told that, by a very apt ſimilitude, it has been denominated "the *camel* of the vegetable kingdom." We muſt confeſs ourſelves quite at a loſs to ſee the propriety or aptitude of this compariſon. In many parts of the animal and vegetable economy there is doubtleſs a very obvious and ſtriking analogy: but this analogy has been often carried too far; much farther than fair experiment and accurate obſervation will in any degree ſupport. It is perhaps owing to this inaccuracy in obſerving the peculiarity of ſtructure and diverſity of functions, that a reſemblance is ſuppoſed to exiſt, as in the preſent caſe, where in reality there is none. The camel is provided with a bag or fifth ſtomach, in addition to the four with which ruminant animals are furniſhed. This fifth ſtomach is deſtined as a reſervoir to contain water; and it is ſufficiently capacious to receive a quantity of that neceſſary fluid, equal to the wants of the animal, for many days: and this water, as long as it remains in the fifth ſtomach, is ſaid to be perfectly pure and unchanged. The *ſtapelia*, and other ſucculent plants, have no ſuch reſervoir. The water is equally, or nearly ſo, diffuſed through the whole plant. Every veſſel and every cell is fully diſtended. But beſides, this water, whether it be received by the roots, or abſorbed from the atmoſphere, has probably undergone a complete change, and become, after it has been a ſhort time within the plant, a fluid poſſeſſed of very different qualities.

The peculiar economy in the ſtapelia, and other ſucculent plants, ſeems to exiſt in the abſorbent and exhalant ſyſtems. The power of abſorption is as much increaſed as the power of the exhalant or perſpiratory veſſels is diminiſhed. In theſe plants, a ſmall quantity of nouriſhment is required. There is no ſolid part to be formed, no large fruit to be produced. They generally have very ſmall leaves, often are entirely naked; ſo that taking the whole plant, a ſmall ſurface only is expoſed to the action of light and heat, and conſequently a much ſmaller proportion of water is decompoſed than in plants which are much branched and furniſhed with leaves.

Two ſpecies of ſtapelia only were known at the beginning of the century. The unfortunate Forſkâl, the companion

companion of Niebhur, who was ſent out by the king of Denmark to explore the interior of Arabia, and who fell a ſacrifice to the peſtilential diſeaſes of thoſe inhoſpitable regions, diſcovered two new ſpecies. Thunberg, in his *Prodromus*, has mentioned five more. Forty new ſpecies have been diſcovered by Mr Maſſon of Kew Gardens, who was ſent out by his preſent Majeſty for the purpoſe of collecting plants round the Cape of Good Hope. Deſcriptions of theſe, with elegant and highly finiſhed coloured engravings, have lately been publiſhed. They are chiefly natives of the extenſive deſerts called *Karro*, on the weſtern ſide of the Cape.

STAR, in fortification, denotes a ſmall fort, having five or more points, or ſaliant and re-entering angles, flanking one another, and their faces 90 or 100 feet long.

STARCH (ſee *Encycl.*) is commonly made of wheat, and the very beſt ſtarch can perhaps be made of nothing elſe. Wheat, however, is too valuable an article of food to be employed as the material of ſtarch, when any thing elſe will anſwer the purpoſe; and it has long been known that an inferior kind of ſtarch may be made of potatoes. Potatoes, however, are themſelves a valuable article of food; and it is therefore an object of importance to try if ſtarch may not be made of ſomething ſtill leſs uſeful.

On the 8th of March 1796, a patent was granted to Lord William Murray for his diſcovery of a method by which ſtarch may be extracted from horſe-cheſnuts. That method is as follows:

Take the horſe-cheſnuts out of the outward green prickly huſks; and then, either by hand, with a knife or other tool, or elſe with a mill adapted for that purpoſe, very carefully pare off the brown rind, being particular not to leave the ſmalleſt ſpeck, and to entirely eradicate the ſprout or growth. Next take the nuts, and raſp, grate, or grind them fine into water, either by hand, or by a mill adapted for that purpoſe. Waſh the pulp, which is thereby formed in this water, as clean as poſſible, through a coarſe horſe-hair ſieve; this again waſh through a finer ſieve, and then again through a ſtill finer, conſtantly adding clean water, to prevent any ſtarch from adhering to the pulp. The laſt proceſs is, to put it with a large quantity of water (about four gallons to a pound of ſtarch) through a fine gauze, muſlin, or lawn, ſo as entirely to clear it of all bran or other impurities. As ſoon as it ſettles, pour off the water; then mix it up with clean water, repeating this operation till it no longer imparts any green, yellow, or other colour to the water. Then drain it off till nearly dry, and ſet it to bake, either in the uſual mode of baking ſtarch, or elſe ſpread out before a briſk fire; being very attentive to ſtir it frequently to prevent its horning, that is to ſay, turning to a paſte or jelly, which, on being dried, turns hard like horn. The whole proceſs ſhould be conducted as quickly as poſſible.

Mention is here made of a mill which may be employed to grind the horſe-cheſnuts; but none is deſcribed as proper for that purpoſe. Perhaps the following mill, which was invented by M. Baumé for grinding potatoes, with a view to extract ſtarch from them, may anſwer for grinding horſe cheſnuts.

Plate LII.

He had a grater made of plate iron, in a cylindrical form (fig. 1.) about ſeven inches in diameter, and about eight inches high: the burs made by ſtamping the holes are on the inſide. This grater is ſupported upon three feet AAA, made of flat iron bars, ſeven feet high, ſtrongly rivetted to the grater; the bottom of each foot is bent horizontally, and has a hole in it which receives a ſcrew, as at A, fig. 4. A little below the upper end of the three feet is fixed a croſs piece B (fig. 1. and 4.), divided into three branches, and rivetted to the feet. This croſs piece not only ſerves to keep the feet at a proper diſtance from each other, and to prevent their bending; but the centre of it having a hole cut in it, ſerves to ſupport an axis or ſpindle of iron, to be preſently deſcribed.

Starch.

The upper end of this cylindrical grater has a diverging border of iron C (fig. 1. 4. and 7.), about ten inches in diameter at the top, and five inches in height.

Within this cylindrical grater is placed a ſecond grater (fig. 2. and 3.), in the form of a cone, the point of which is cut off. The latter is made of thick plate iron, and the burs of the holes are on the outſide; it is fixed, with the broad end at the bottom, as in fig. 4. At the upper end of the cone is rivetted a ſmall triangle, or croſs piece of iron, conſiſting of three branches D (fig. 2.), in the middle of which is made a ſquare hole, to receive an axis or ſpindle; to give more reſiſtance to this part of the cone, it is ſtrengthened by means of a cap of iron E, which is fixed to the grater by means of rivets, and has alſo a ſquare hole made in it, to let the axis paſs through.

Fig. 3. repreſents the ſame cone ſeen in front; the baſe F has alſo a croſs piece of three branches, rivetted to a hoop of iron, which is fixed to the inner ſurface of the cone; the centre of this croſs piece has alſo a ſquare hole for the paſſage of the axis.

Fig. 5. is a ſpindle or axis itſelf; it is a ſquare bar of iron about 16 inches long, and more than half an inch thick; round at the bottom, and alſo towards the top, where it fits into the croſs piece I, fig. 7. and B, fig. 1. and 4.; in theſe pieces it turns round, and by them it is kept in its place. It muſt be ſquare at its upper extremity, that it may have a handle, about nine inches long, fixed to it, by means of which the conical grater is turned round. At G, (fig. 5.), a ſmall hole is made through the axis, to receive a pin H, by means of which the conical grater is kept at its proper height within the cylindrical one.

Fig. 6. is a bird's-eye view, in which the mill is repreſented placed in an oval tub, like a bathing-tub. I is the fore-mentioned triangular iron croſs, fixed with ſcrews to the ſide of the tub; the centre of it has a round hole, for the axis of the mill to move in when it is uſed.

Fig. 7. repreſents the mill in the oval tub; it is placed at one end of it, that the other end may be left free for any operation to be performed in it which may be neceſſary. A part of the tub is cut off, that the inſide of it, and the manner of fixing the mill, may be ſeen. That the bottom of the tub may not be worn by the ſcrews which paſs through the feet of the mill, a deal board, about an inch thick, and properly ſhaped, is placed under the mill.

When we wiſh to make uſe of this mill, it is to be fixed by the feet, in the manner already deſcribed; it is alſo fixed at the top, by means of the croſs piece I, fig. 6. and 7. The tub is then to have water poured into it as high as K, and the top of the mill is to be filled with potatoes, properly waſhed and cut; the handle L is to be turned round, and the potatoes, after being ground between the two graters, go out gradually at the lower part, being aſſiſted by the motion produced in the water by the action of the mill.

It is not neceſſary, in the conſtruction of ſuch a mill, to be very particular with reſpect to its proportions; but, in order to make known thoſe which experience has proved to be good ones, a ſcale is given with the figures, to which recourſe may be had. With a mill of this ſize, 100 pounds of potatoes may be ground in the ſpace of two hours.

We are perſuaded that this mill will anſwer perfectly well for grinding horſe cheſnuts; and we hope, that where they can be had they will be uſed in preference to potatoes. We ſhall, however, give M. Baumé's method of extracting ſtarch from the ground potatoes, not only becauſe it will be acceptable to thoſe who have not horſe-cheſnuts, but alſo becauſe thoſe who have may, by following it, be able, perhaps, to make ſtarch of them, without encroaching upon Lord William Murray's patent.

In order to prepare ſtarch from potatoes, ſays M. Baumé, any quantity of theſe roots may be taken, and ſoaked in a tub of water for about an hour; they are afterwards to have their fibres and ſhoots taken off, and then to be rubbed with a pretty ſtrong bruſh, that the earth, which is apt to lodge in the inequalities of their ſurface, may be entirely removed; as this is done, they are to be waſhed, and thrown into another tub full of clean water. When the quantity which we mean to make uſe of has been thus treated, thoſe which are too large are to be cut into pieces about the ſize of eggs, and thrown into the mill; that being already fixed in the oval tub, with the proper quantity of water; the handle is then turned round, and as the potatoes are grated they paſs out at the bottom of the mill. The pulp which collects about the mill muſt be taken off from time to time with a wooden ſpoon, and put aſide in water.

When all the potatoes are ground, the whole of the pulp is to be collected in a tub, and mixed up with a great quantity of clean water. At the ſame time, another tub, very clean, is to be prepared, on the brim of which are to be placed two wooden rails, to ſupport a hair ſieve, which muſt not be too fine. The pulp and water are to be thrown into the ſieve; the flour paſſes through with the water, and freſh quantities of water are ſucceſſively to be poured on the remaining pulp, till the water runs through as clear as it is poured in. In this way we are to proceed till all the potatoes that were ground are uſed.

The pulp is commonly thrown away as uſeleſs; but it ſhould be boiled in water, and uſed as food for animals; for it is very nouriſhing, and is about $\frac{7}{8}$ths of the whole quantity of potatoes uſed.

To return from this ſhort digreſſion. The liquor which has paſſed through the ſieve is turbid, and of a browniſh colour, on account of the extractive matter which is diſſolved in it; it depoſits, in the ſpace of five or ſix hours, the flour which was ſuſpended in it. When all the flour is ſettled to the bottom, the liquor is to be poured off and thrown away, being uſeleſs; a great quantity of very clean water is then to be poured upon the flour remaining at the bottom of the tub, which is to be ſtirred up in the water, that it may be waſhed, and the whole is to ſtand quiet till the day following. The flour will then be found to have ſettled at the bottom of the tub; the water is again to be poured off as uſeleſs, the flour waſhed in a freſh quantity of pure water, and the mixture paſſed through a ſilk ſieve pretty fine, which will retain any ſmall quantity of pulp which may have paſſed through the hair ſieve. The whole muſt once more be ſuffered to ſtand quiet till the flour is entirely ſettled; if the water above it is perfectly clear and colourleſs, the flour has been ſufficiently waſhed; but if the water has any ſenſible appearance either of colour or of taſte, the flour muſt be again waſhed, as it is abſolutely neceſſary that none of the extractive matter be ſuffered to remain.

When the flour is ſufficiently waſhed, it may be taken out of the tub with a wooden ſpoon; it is to be placed upon wicker frames covered with paper, and dried, properly defended from duſt. When it is thoroughly dry, it is to be paſſed through a ſilk ſieve, that if any clotted lumps ſhould have been formed they may be divided. It is to be kept in glaſs veſſels ſtopped with paper only. See *Vegetable* SUBSTANCES, Suppl.

N. B. Almoſt all the flour of potatoes that is to be bought contains a ſmall quantity of ſand, which is perceived between the teeth; it is owing to the potatoes not having been properly waſhed; for the ſand which lodges in the knobs and wrinkles of theſe roots, is not always eaſy to get out.

STARLINGS, or STERLINGS, the name given to the ſtrong pieces of timber which were driven into the bed of the river to protect the piles, on the top of which were laid the flat beams upon which were built the baſes of the ſtone piers that ſupport the arches of London bridge. In general, ſtarlings are large piles placed on the outſide of the foundation of the piers of bridges, to break the force of the water, and to protect the ſtone work from injury by floating ice. They are otherwiſe called JETTES, which ſee in this *Supplement*; and their place is often ſupplied by large ſtones thrown at random round the piers of bridges, as may be ſeen at Stirling bridge when the river is low; and as was done by Mr Smeaton's direction round the piers of the centre arch of London bridge, when it was thought in danger of being undermined by the current. See SMEATON, *Encycl.*

STATIONARY, in aſtronomy, the ſtate of a planet when, to an obſerver on the earth, it appears for ſome time to ſtand ſtill, or remain immoveable in the ſame place in the heavens. For as the planets, to ſuch an obſerver, have ſometimes a progreſſive motion, and ſometimes a retrograde one, there muſt be ſome point between the two where they muſt appear ſtationary.

STEAM, STEAM-ENGINE. The few following corrections of theſe articles in the *Encycl.* were communicated by the author.

Page 745. col. 1.—It was not at the York Building waterworks in London that the boiler burſt, but in the country in an engine erected by Dr Deſaguilliers. See his *Experimental Philoſophy*, Vol. II. p. 489.

Page 746. col. 2.—The condenſation requires more cold water than is here allowed, as will appear by and bye; and we alſo ſuſpect that the rapidity is overrated with which a great volume of ſteam is condenſed by

by the cold ſurface of a veſſel. We are well informed that Mr Watt was much diſappointed in his expectations from a conſtruction in which this mode of condenſation was adopted. The condenſer employed by Mr Cartwright (ſee *Phil. Mag.*) was one of the very firſt thought of and tried for this purpoſe, and was given up, as well as all others on the ſame principle; and the immediate contact of cold water was preferred as incomparably more effective. The great ſuperiority of the capacity of water for heat is now well known. It is true, that when we employ an extenſive cold ſurface of the condenſer, this ſurface is kept cold by the water round it; and therefore we ſtill avail ourſelves of this great avidity of water for heat. But this water muſt act through the intervention of the veſſel; and the ſubſtance of the veſſel does not convey heat to the ſurrounding water in an inſtant.

Page 749. col. 2.—No diſtinct experiment ſhews ſo great an expanſion of water, when converted into ſteam at the temperature 212°; and under the preſſure of the air Mr Watt never found it more than 1800 times rarer than water.

Page 753. col. 1.—The heat expended in boiling off a cubic foot of water is about ſix times as much as would bring it to a boiling heat from the medium temperature (55°) in this climate.

Page 758. col. 2.—The quantity of water neceſſary for injection may be determined on principle, at leaſt for an engine having a ſeparate condenſer. Every cubic foot of common ſteam produces about an inch of water when condenſed, and contains about as much latent heat as would raiſe 1100 inches of water one degree. This ſteam muſt not only be condenſed, but muſt be cooled to the temperature of the hot well; therefore as many inches of cold water muſt be employed as will require all this heat to raiſe it to the temperature of the hot well. Therefore let *x* be the cubic feet of ſteam, or capacity of the cylinder, and let *y* be the inches of cold water expended in condenſing it. Let *a* be the difference between 212° and the temperature of the hot well, and *b* the difference between the temperature of the well and the injection ciſtern. We have $yb = x \times \overline{1100 + a}$, or $y = \frac{\overline{1100 + a} \times x}{b}$.

Thus, if the temperature of the hot well be 100° (and it ſhould never be higher, if we would have a tolerable vacuum in the cylinder), and that of the injection ciſtern be 50°, we have $a = 112$, and $b = 50$, and $y = \frac{1212}{50}x, = 24{,}24\,x$, or $24\frac{1}{4}x$; that is, every foot of the capacity of the cylinder, or every inch of water evaporated from the boiler, requires more than 24 inches of water to condenſe the ſteam. A wine pint for every inch of water boiled off, or every cubic foot of capacity of the cylinder, may be kept in mind, as a large allowance. Or, more exactly, if the engine be in good order, and the injection water as low as 50°, and the hot well not above 100°, we may allow 25 gallons of injection for one gallon of water boiled off. This greatly exceeds the quantity mentioned in the caſe of a good Newcomen's engine, the cylinder of which contained almoſt 30 cubic feet of ſteam. And this circumſtance ſhews the ſuperiority of the engine with a ſeparate condenſer. The injection of Newcomen's engine had been adjuſted by experience, ſo as to make the beſt compenſation for the unavoidable waſte in the cylinder. We preſume that this machine was not loaded above eight pounds per inch, more likely with ſeven; whereas Watt's engine, working in the condition now deſcribed, bears a load not much below twelve, making at leaſt twelve ſtrokes per minute.

This is not a matter of mere curioſity; it affords a very exact rule for judging of the good working order of the engine. We can meaſure with accuracy the water admitted into the boiler during an hour, without allowing its ſurface to riſe or fall, and the water employed for injection. If the laſt be below the proportion now given (adapted to the temperatures 50° and 100°), we are certain that ſteam is waſted by leaks, or by condenſation in ſome improper place. The rule is not ſtrictly conformable to the latent heat of ſteam which balances the atmoſphere, 1100° being ſomewhat too great a value. It is accommodated to the actual performance of Watt's engines, when in their beſt working condition.

It is evident that it is of great importance to have the temperature of the hot well as low as poſſible; becauſe there always remains a ſteam in the cylinder, of the ſame, or rather higher temperature, poſſeſſing an elaſticity which balances part of the preſſure on the other ſide of the piſton, and thus diminiſhes the power of the engine. This is clearly ſeen by the barometer, which Mr Watt applies to many of his beſt engines, and is a moſt uſeful addition for the proprietor. It ſhews him, in every moment, the ſtate of the vacuum, and the real power of his engine, and tells him when there are leaks by which air gets in.

Page 762. cols. 1. 2.—Mr Watt's firſt experiment was not exactly as here related, but much more analogous to the preſent form of his engine. The condenſer was a cylinder of tinplate, fitted with a piſton, which was drawn up from the bottom to the top, before the eduction cock was opened. Without this previous rarefaction in the condenſer, there was no inducement for the ſteam to take this courſe, unleſs it were made much ſtronger than that of ordinary boiling water.

The deſcription of the firſt form of the engine is alſo faulty, by the omiſſion of a valve immediately below the eduction pipe. This valve is ſhut along with the valve I, to prevent the ſteam, which ſhould then go into the lower part of the cylinder, from alſo going down into the condenſer. This is not abſolutely neceſſary, but its advantage is evident.

Page 766. col. 1.—This form of the engine was very early put in practice by Mr Watt—about the year 1775. The ſmall engine at Mr Boulton's works at Soho was erected in 1776; and the engine at Shadwell waterworks, one of the beſt yet erected, had been working ſome time when we ſaw it in 1778. We mention this, becauſe we have been told that Mr Hornblower puts in ſome claim to priority in this invention. We do not think that Mr Hornblower erected any of his engines before 1782; and as Mr Hornblower was, we believe, working with Boulton and Watt before that time, we think it fully more probable that he has in this reſpect profited by the inſtruction of ſuch intelligent employers. We may alſo obſerve, that Mr Watt employed the ſame contrivance which we have deſcribed with much approbation in p. 772. *Encycl.* for keeping the

the collar round the piſton rods ſteam and air tight. He found them effectual, but that they required more attention for keeping them in fit condition than the uſual mode of packing. He made a ſimilar packing for the piſton, and with a ſimilar reſult.

Page 769. cols. 1. 2.—Mr Boulton eſtimates the performance of the engines in the following manner. Seeing that the great expence of the engine is the conſumption of fuel, he makes this the ſtandard of computation, and eſtimates the performance by the work which he *engages* to perform by the conſumption of one buſhel of good Newcaſtle coal, London meaſure, or containing 84 lbs. without regard to the time in which this buſhel is expended. This depends on the ſize of the engine.

The burning one buſhel of coal will,

1. Raiſe 30 million pounds one foot high.
2. It will grind and dreſs 11 buſhels of wheat.
3. It will ſlit and draw into nail rods 5 cwt. of iron.
4. It will drive 1000 cotton ſpindles, with all the preparation machinery, with the proper velocity.
5. It is equivalent to the work of ten horſes.

The general performance of the double ſtroke expanſive engines is ſomewhat beyond this; and their performance in cotton ſpinning, or as compared with horſe work, is much under rated. The firſt eſtimation is without ambiguity. Suppoſe the engine of ſuch a ſize as to conſume a buſhel of coals per hour. This will be found equivalent to raiſing 97 wine hogſheads of water ten feet high in a minute, which ten ſtout draught horſes cannot do for a quarter of an hour together. They can raiſe 60 in that time, and work at this rate eight or perhaps ten hours from day to day.

Mr Watt finds that, with the moſt judiciouſly conſtructed furnaces, it requires eight feet of ſurface of the boiler to be expoſed to the action of fire and flame to boil off a cubic foot of water in an hour, and that a buſhel of coals ſo applied will boil off from eight to twelve cubic feet.

Boulton and Watt now make ſteam-engines equivalent in power to one or two horſes. The cylinder and whole machinery does not occupy more room than a fine lady's working table, ſtanding in a ſquare of about 2½ feet, and about 5 feet high.

STEEL (ſee that article *Encycl.* and CHEMISTRY, n° 114. *Suppl.*) is compoſed of iron and carbon. In addition to the old proofs which we had of this fact, it occurred to *Morveau*, alias *Guyton*, to attempt to convert ſoft iron into ſteel, by uſing the diamond inſtead of charcoal in the proceſs of cementation. This expenſive experiment, which was ſuggeſted by M. Clouet, was made, by incloſing within a ſmall crucible of very ſoft iron a diamond, and ſhutting up the crucible by a ſtopper well adjuſted. This crucible of iron, with its contents, was placed, without the addition of any ſurrounding matter, in a very ſmall Heſſian crucible, and the latter in a ſecond crucible of the ſame earth; but the ſpace between the two latter crucibles was filled with ſiliceous ſand, free from all ferruginous particles. In the laſt place, the large crucible was luted with earth ariſing from pounded crucibles and unbaked clay, and the whole was expoſed about an hour to a three blaſt forge fire. When the whole was cooled, the iron was found in the interior Heſſian crucible converted into a ſolid ingot of caſt ſteel. Thus the diamond diſappeared by the affinity which iron exerciſed on it by the help of the high temperature to which they were both expoſed, in the ſame manner as a metal diſappears in the alloy of another metal. The diamond therefore furniſhed here the ſame principle as carbon, ſince the product of the union has the ſame properties.

The converſion into ſteel could not be doubted. The ingot having been poliſhed on a lapidary's wheel, a drop of weak nitrous acid immediately produced a dark-grey ſpot, abſolutely like that exhibited on Engliſh caſt ſteel, and on caſt ſteel produced by the proceſs of C. Clouet. Thoſe who have often tried ſteel by this kind of proof, long ago pointed out by Rinmann, had occaſion to remark, that the ſpot of caſt ſteel, tho' very ſenſible, is, however, leſs black than that of ſteel made by cementation, which depends perhaps on the different degree of oxydation of the carbon which they have taken in.

The proceſs of M. Clouet here mentioned, for producing caſt ſteel, conſiſts in nothing more than throwing a quantity of glaſs into the maſs of iron and charcoal during the formation of the former into ſteel. The ſame chemiſt has aſcertained that iron, during its converſion into ſteel, abſorbs 0.2013 of its weight of carbon; and that the affinity of iron for carbon is ſo ſtrong, that, at a white heat, it is capable of decompoſing carbonic acid gas. This he proved by the following experiment.

If ſix parts of iron be mixed with four parts of a mixture compoſed of equal quantities of carbonat of lime and clay, and kept in a crucible at a white heat for an hour or longer, according to the quantity, the iron will be converted into ſteel. The decompoſition of carbonic acid is evidently the conſequence of a compound affinity; part of the iron combining with the carbon, and another part with the oxygen of the carbonic acid gas. Accordingly the commiſſioners, who were appointed to examine the proceſs, remark, that a quantity of oxyd of iron was always mixed with the melted earthy ſubſtance, which was ſeparated from the ſteel.

STEEVENS (George), the moſt ſucceſsful of all the editors and commentators of Shakeſpeare, was born 1735. Of his parents we know nothing, but that they ſeem to have been in circumſtances which may be deemed affluent. George received the rudiments of his claſſical education at Kingſton-upon-Thames, under the tuition of Dr Woodeſon and his aſſiſtants; and had for a companion at that ſchool Gibbon the hiſtorian. From Kingſton he went to Eton, whence, after ſome years, he was admitted a fellow-commoner of King's College, Cambridge; but with the courſe of his ſtudies in the univerſity we are not acquainted. If we might hazard a conjecture, from the manner in which he employed his riper years, we ſhould ſuppoſe that he had little reliſh for thoſe mathematical ſpeculations which in Cambridge lead to academical honours. After he left the univerſity, he accepted a commiſſion in the Eſſex militia on its firſt eſtabliſhment: and he ſpent the latter years of his life at Hampſtead in almoſt total ſecluſion from the world; ſeldom mixing with ſociety but in the ſhops of bookſellers, in the Shakeſpeare Gallery, or in the morning *converſations* of Sir Joſeph Banks. He died January 1800.

This is a very meagre account of the incidents which muſt have taken place in the life of a man ſo conſpicuous in the republic of letters: but we have had no opportunity of improving it. His character, as drawn in the Monthly Magazine, believing it to be juſt, we ſhall adopt, as it will ſupply in ſome degree the defects of our narrative

Though Mr Steevens is known rather as a commentator than as an original writer; yet, when the works which he illuſtrated, the learning, ſagacity, taſte, and general knowledge which he brought to the taſk, and the ſucceſs which crowned his labours, are conſidered, it would be an act of injuſtice to refuſe him a place among the firſt literary characters of the age. Adorned by a verſatility of talents, he was indeed eminent both by his pen and his pencil. With the one there was nothing which he could not compoſe, and with the other there was nothing which he could not imitate ſo cloſely, as to leave a doubt which was the original and which the copy. But his chief excellence lay in his critical knowledge of an author's text; and the beſt ſpecimen of his great abilities is his edition of Shakeſpeare, in which he has left every competitor far behind him. He had, in ſhort, ſtudied the age of Shakeſpeare, and had employed his perſevering induſtry in becoming acquainted with the writings, manners, and laws of that period, as well as the provincial peculiarities, whether of language or cuſtom, which prevailed in different parts of the kingdom, but more particularly in thoſe where Shakeſpeare paſſed the early years of his life. This ſtore of knowledge he was continually increaſing, by the acquiſition of the rare and obſolete publications of a former age, which he ſpared no expence to obtain; while his critical ſagacity and acute obſervation were employed inceſſantly in calling forth the hidden meanings of the great dramatic bard, from their covert, and conſequently enlarging the diſplay of his beauties. This advantage is evident from his laſt edition of Shakeſpeare, which contains ſo large a portion of new, intereſting, and accumulated illuſtration. In the preparation of it for the preſs, he gave an inſtance of editorial activity and perſeverance which is without example. To this work he devoted ſolely, and excluſively of all other attentions, a period of 18 months; and during that time he left his houſe every morning at one o'clock with the Hampſtead patrole, and proceeded, without any conſideration of the weather or the ſeaſon, to his friend Mr Iſaac Read's chambers, in Barnard's Inn, where he was allowed to admit himſelf, and found a room prepared to receive him, with a ſheet of the Shakeſpeare letter preſs ready for correction. There was every book which he might wiſh to conſult; and to Mr Read he could apply, on any doubt or ſudden ſuggeſtion, as to a man whoſe knowledge of Engliſh literature was perhaps equal to his own. This nocturnal toil greatly accelerated the printing of the work; as while the printers ſlept the editor was awake; and thus, in leſs than twenty months, he completed his laſt ſplendid edition of Shakeſpeare, in fifteen large octavo volumes; an almoſt incredible labour, which proved the aſtoniſhing energy and perſevering powers of his mind.

That Mr Steevens contented himſelf with being a commentator, aroſe probably from the habits of his life, and his devotion to the name, with which his own will deſcend to the lateſt poſterity. It is probable that many of his *jeux d'eſprit* might be collected: there is a poem of his in Dodſley's Annual Regiſter, under the title of *The Frantic Lover*, which is ſuperior to any ſimilar production in the Engliſh language. Mr Steevens was a claſſical ſcholar of the firſt order. He was equally acquainted with the belles lettres of Europe. He had ſtudied hiſtory, ancient and modern, but particularly that of his own country. He poſſeſſed a ſtrong original genius, and an abundant wit; his imagination was of every colour, and his ſentiments were enlivened with the moſt brilliant expreſſions. His colloquial powers ſurpaſſed thoſe of other men. In argument he was uncommonly eloquent; and his eloquence was equally logical and animated. His deſcriptions were ſo true to nature, his figures were ſo finely ſketched, of ſuch curious ſelection, and ſo happily grouped, that he might be conſidered as a ſpeaking Hogarth. He would frequently, in his ſportive and almoſt boyiſh humours, condeſcend to a degree of ribaldry but little above O'Keefe—with him, however, it loſt all its coarſeneſs, and aſſumed the air of claſſical vivacity. He was indeed too apt to catch the ridiculous, both in characters and things, and indulge an indiſcreet animation wherever he found it. He ſcattered his wit and his humour, his gibes and his jeers, too freely around him, and they were not loſt for want of gathering.

Mr Steevens poſſeſſed a very handſome fortune, which he managed with diſcretion, and was enabled by it to gratify his wiſhes, which he did without any regard to expence, in forming his diſtinguiſhed collections of claſſical learning, literary antiquity, and the arts connected with it. His generoſity alſo was equal to his fortune; and though he was not ſeen to give eleemoſynary ſixpences to ſturdy beggars or ſweepers of the croſſings, few perſons diſtributed banknotes with more liberality; and ſome of his acts of pecuniary kindneſs might be named, which could only proceed from a mind adorned with the nobleſt ſentiments of humanity. He poſſeſſed all the grace of exterior accompliſhment, acquired at a period when civility and politeneſs were characteriſtics of a gentleman.

He has bequeathed his valuable Shakeſpeare, illuſtrated with near 1500 prints, to Lord Spencer; his Hogarth perfect, with the exception of one or two pieces, to Mr Windham; and his corrected copy of Shakeſpeare, with 200 guineas, to his friend Mr Read.

STEREOMETER, an inſtrument lately invented in France for meaſuring the volume of a body, however irregular, without plunging it in any liquid. If the capacity of a veſſel, or, which is the ſame thing, the volume of air contained in that veſſel, be meaſured, when the veſſel contains air only, and alſo when the veſſel contains a body whoſe volume is required to be known, the volume of air aſcertained by the firſt meaſurement, deducting the volume aſcertained by the ſecond, will be the volume of the body itſelf. Again, if it be admitted as a law, that the volume of any maſs of air be inverſely as the preſſure to which it is ſubjected, the temperature being ſuppoſed conſtant, it will be eaſy to deduce, from the mathematical relations of quantity, the whole bulk, provided the difference between the two bulks under two known preſſures be obtained by experiment.

Let it be ſuppoſed, for example, that the firſt preſſure is double the ſecond, or, which follows as a conſequence,

quence, that the ſecond volume of the air be double the firſt, and that the difference be fifty cubic inches, it is evident that the firſt volume of the air will likewiſe be fifty cubic inches. The ſtereometer is intended to aſcertain this difference at two known preſſures.

Plate XLIII.

The inſtrument is a kind of funnel AB (fig. 1.), compoſed of a capſule A, in which the body is placed, and a tube B as uniform in the bore as can be procured. The upper edge of the capſule is ground with emery, in order that it may be hermetically cloſed with a glaſs cover M ſlightly greaſed. A double ſcale is paſted on the tube, having two ſets of graduations; one to indicate the length, and the other the capacities, as determined by experiment.

When this inſtrument is uſed, it muſt be plunged in a veſſel of mercury with the tube very upright, until the mercury riſes within and without to a point C of the ſcale. See fig. 2.

The capſule is then cloſed with the cover, which being greaſed will prevent all communication between the external air and that contained within the capſule and tube.

In this ſituation of the inſtrument, in which the mercury ſtands at the ſame height within and without the tube, the internal air is compreſſed by the weight of the atmoſphere, which is known and expreſſed by the length of the mercury in the tube of the common barometer.

The inſtrument is then to be elevated, taking care to keep the tube conſtantly in the vertical poſition. It is repreſented in this ſituation, fig. 2. ſecond poſition. The mercury deſcends in the tube, but not to the level of the external ſurface, and a column DE of mercury remains ſuſpended in the tube, the height of which is known by the ſcale. The interior air is therefore leſs compreſſed than before, the increaſe of its volume being equal to the whole capacity of the tube from C to D, which is indicated by the ſecond ſcale.

It is known therefore that the preſſures are in proportion to the barometrical column, and to the ſame column diminiſhed by the ſubtraction of DE. And the bulks of the air in theſe two ſtates are inverſely in the ſame proportion; and again the difference between theſe bulks is the abſolute quantity left void in the tube by the fall of the mercury; from which data, by an eaſy analytical proceſs, the following rule is deduced: Multiply the number which expreſſes the leſs preſſure by that which denotes the augmentation of capacity, and divide the product by the number which denotes the difference of the preſſures. The quotient will be the bulk of the air when ſubject to the greater preſſure.

To render this more eaſy by an example, ſuppoſe the height of the mercury in the barometer to be 78 centimetres, and the inſtrument being empty to be plunged in the mercury to the point C. It is then covered, and raiſed until the ſmall column of mercury DE is ſuſpended, for example, at the height of ſix centimetres. The internal air, which was at firſt compreſſed by a force repreſented by 78 centimetres, is now compreſſed only by a force repreſented by 78—6, or 72 centimetres.

Suppoſe it to be obſerved, at the ſame time, by means of the graduations of the ſecond ſcale, that the capacity of the part CD of the tube which the mercury has quitted is two cubic centimetres. Then by the rule $\frac{72}{6} \times 2$ give 24 cubical centimetres, which is the volume of the air included in the inſtrument when the mercury roſe as high as C in the tube.

The body of which the volume is to be aſcertained muſt then be placed in the capſule, and the operation repeated. Suppoſe, in this caſe, the column of mercury ſuſpended to be eight centimetres, when the capacity of the part CD of the tube is equal to two centimetres cube. Then the greateſt preſſure being denoted by 78 centimetres, as before, the leaſt will be 70 centimetres, the difference of the preſſures being 8, and the difference of the volumes two cubical centimetres. Hence $\frac{70}{8} \times 2$ gives the bulk of the included air under the greateſt preſſure 17,5 cubic centimetres. If therefore 17,5 centimetres be taken from 24 centimetres, or the capacity of the inſtrument when empty, the difference 6,5 cubic centimetres will expreſs the volume of the body which was introduced. And if the abſolute weight of the body be multiplied by its bulk in centimetres. and divided by the abſolute weight of one cubic centimetre of diſtilled water, the quotient will expreſs the ſpecific gravity of the body in the common form of the tables where diſtilled water is taken as unity, or the term of compariſon.

After this deſcription and explanation of the uſe of his inſtrument, the author proceeds with the candour and acuteneſs of a philoſopher to aſcertain the limits of error in the reſults; an object ſeldom ſufficiently attended to in the inveſtigation of natural phenomena. From his reſults it appears, that with the dimenſions he has aſſumed, and the method preſcribed for operating, the errors may affect the ſecond figure. He likewiſe gives the formulæ by means of which the inſtrument itſelf may be made to ſupply the want of a barometer in aſcertaining the greateſt preſſure. He likewiſe adverts to the errors which may be produced by change of temperature. To prevent theſe as much as poſſible, the actual form of the inſtrument and arrangements of its auxiliary parts are ſettled, as in fig. 3. by which means the approach of the hand near the veſſel and its tube is avoided. In this figure the vertical poſition of the tube is ſecured by the ſuſpenſion of the veſſel, and a perforation in the table through which the tube paſſes. The table itſelf ſupports the capſule in its firſt poſition, namely, that at which the cover is required to be put on.

Mr Nicholſon, from whoſe Journal this abſtract is immediately taken, ſuppoſes, with great probability, that the author of the invention had not finiſhed his meditations on the ſubject, when the memoir giving an account of it was publiſhed. If he had, ſays the ingenious journaliſt, it is likely that he would have determined his preſſures, as well as the meaſures of bulks by weight. For it may be eaſily underſtood, that if the whole inſtrument were ſet to its poſitions by ſuſpending it to one arm of a balance at H (fig. 3.), the quantity of counterpoiſe, when in equilibrio, might be applied to determine the preſſures to a degree of accuracy much greater than can be obtained by linear meaſurement.

STEWART-DENHAM (Sir James) was born at Edinburgh on the 10th of October, O. S. in the year 1713. His father was Sir James Stewart of Goodtrees, Bart. Solicitor-general for Scotland; and his mother

ther was Anne, daughter of Sir Hugh Dalrymple of North Berwick, Bart. preſident of the college of juſtice.

The firſt rudiments of his education he received at the grammar-ſchool of North-Berwick, which at the time of his father's death he quitted at the age of fourteen, with the reputation of being a good ſcholar, but without any extraordinary advancement in knowledge.

It is remarkable, that many men who have been ſingularly uſeful to ſociety have not ſhewn early ſymptoms of the greatneſs of their intellectual powers. A great underſtanding muſt be the offspring of happy organization in a healthy body, with co-operation of time, of circumſtance, and of inſtitution, without being forced into prematurity by exceſſive cultivation. This holds with reſpect to the growth and perfection of every creature; and the truth appears remarkable with reſpect to our own ſpecies, becauſe we are apt to miſtake the flimſy attainments of artificial education for the ſteady and permanent foundations of progreſſive knowledge.

From the ſchool of North-Berwick Sir James was ſent to the univerſity of Edinburgh, where he continued until the year 1735, when he paſſed advocate before the Court of Seſſion, and immediately afterwards went abroad to viſit foreign countries. He was then in the 23d year of his age, had made himſelf well acquainted with the Roman law and hiſtory, and the municipal law of Scotland. He had likewiſe maturely ſtudied the elements of juriſprudence; was verſed in the general, as well as the particular, politics of Europe; and was bent upon applying his knowledge to the inveſtigation of the ſtate of men and of manners in other nations, with a view to promote the benefit of his own, and to confirm himſelf in the love of a free conſtitution of government, by contemplating the baneful effects of unlimited monarchy in Germany, Italy, and Spain, and of extravagant attachment to a king and nobility, to war, and to pernicious ſplendour in France.

He travelled firſt, however, into Holland, with a view to ſtudy the conſtitution of the empire before he ſhould viſit Germany, and to attend ſome of the lectures of the moſt eminent profeſſors at Utrecht and Leyden, on public law and politics. From thence he paſſed into Germany, reſided about a year in France, travelled thro' ſome part of Spain, where he had a fever, that obliged him, for his perfect recovery from its effects, to go by the advice of his friends to the ſea-coaſt of the lovely province of Valencia; thence returning, he croſſed the Alps, and by Turin made the tour of Italy, where chiefly at Rome and Florence he reſided till the beginning of the year 1740; when, having ſpent five years on his travels, he returned to Scotland, and married the Lady Frances Wemyſs, eldeſt daughter of the Earl of Wemyſs, about two years after his return.

A few months after his marriage the repreſentation of the county of Mid-Lothian became vacant, by the member being made a lord of trade and plantation. The candidates were the late member and Sir John Baird of Newbyth. On the day of election Mr Dundas of Arniſton, one of the ſenators of the college of juſtice, was choſen preſes of the meeting; and ſome how or other omitted to cauſe the name of Sir James Stewart to be called on the roll of freeholders. For this illegal uſe of his temporary power, Sir James commenced a ſuit againſt the preſident; and reſuming the gown as an advocate, pleaded his own cauſe with great energy and eloquence, and with the applauſe of the bench, the bar, and the public. This called Lord Arniſton from the bench to plead in his own defence at the bar; and Sir James could not have been oppoſed to an antagoniſt better qualified to call forth all his powers; for that judge is talked of at this day in Edinburgh as the profoundeſt lawyer and the ableſt pleader that ever graced the Scottiſh bench or the Scottiſh bar.

With the iſſue of this conteſt we are not acquainted; but it drew upon Sir James Stewart very general attention, and convinced the public, that had he continued at the bar, he muſt have riſen rapidly to the head of his profeſſion. On his travels, however, he had contracted friendſhips with Lord Mariſchal, and other eminent men, attached to the pretenſions of the royal family of Stuart, and had received flattering attentions from the Pretender to the Britiſh throne; the impreſſion ariſing from which, added to the irritations of his controverſy with the powerful party in Scotland attached to the court, led him, unadviſedly, into connections with the movers of the rebellion in 1745.

As he was by far the ableſt man of their party, the Jacobites engaged him to write the Prince Regent's manifeſto, and to aſſiſt in his councils. Information having been given of his participation in theſe affairs, he thought it prudent, on the abortion of this unhappy attempt, to leave Britain; and by the zeal, it is ſaid, of Arniſton, he was excepted afterwards from the bill of indemnity, and rendered an exile from his country.

He choſe France for his reſidence during the ten firſt years of his baniſhment; and was chiefly at Angouleſme, where he ſuperintended the education of his ſon; from thence he went to Tubingen in Suabia, for the benefit of its univerſity, in proſecution of the ſame dutiful and laudable deſign; but in the end of the war 1756, having been ſuſpected by the court of Verſailles of communicating intelligence to the court of London, he was ſeized at Spa, and kept ſome time in confinement; from which being liberated, after the acceſſion of the preſent king of Great Britain, he came, by toleration, to England, and reſided at London, where he put the laſt hand to his Syſtem of Political Economy, the copy right of which he ſold to Andrew Millar; and being permitted to dedicate this work to the king, he applied for a *noli proſequi*, which, after ſome malicious objections, he obtained, and had the comfort of returning to his family eſtate in Scotland.

Having nothing profeſſional to do during his long reſidence in France, the active mind of Sir James was occupied in ſtudy. His book on the Principles of Political Economy contains moſt of the fruits of it. He turned himſelf, in the intervals of leiſure, to conſider the reſources of France, that he might the better compile that part of his great work which was to treat of revenue and expenditure. It was by ſtudying the language of the finances, without which nobody can aſk a proper queſtion concerning them, ſo as to be underſtood, that he attained his great purpoſe.

As ſoon as he could aſk queſtions properly, he applied in familiar converſation to the intendants and their ſubſtitutes in the provinces where he reſided, whom he found extremely deſirous to learn the ſtate of the Britiſh finances, under the branches of the land-tax, cuſtoms, exciſe, and other inland duties. This led him to

compare

compare the ſtate of the two nations. The information he gave was an equivalent for the information he received; curioſity balanced curioſity, each was ſatisfied and inſtructed. The department of the intendants in France was confined to the taxes which compoſed the *recettes generales*, namely, the *taille*, the *capitation*, and the *twentieths*, or *vingtiemes*. All the intendants had been *Maitres des Requetes*, bred at Paris, and could not fail to have much knowledge of the general *fermes* and other branches of the revenue. He carefully noted down at all times the anſwers he got; and when he came to reſide at Paris, he obtained more ample information, both from the gentlemen of the revenue, and from perſons of the parliament of Paris, who to the number of 25 had been for 15 months exiled in the province where he had ſo long reſided at Angouleſme.

With theſe advantages, with much ſtudy and attention to arrangement, he was enabled to compoſe the ſixth chapter of the fourth part of the fourth book of his Syſtem of Political Economy; a portion of that great work well worthy the attention of thoſe who wiſh to know the ſtate of France in reſpect of revenue under the old government.

Although Sir James Stewart's leiſure, during the firſt ten years of his exile, was chiefly employed in ſocial intercourſe with the moſt learned, elegant, and poliſhed characters in France, who delighted in the converſation and friendſhip of a man who poſſeſſed at once immenſe information, on almoſt every ſubject, important or agreeable to ſociety, and the talent of clearly and beautifully expreſſing his ſentiments in flowing and animated converſation; yet he did not allow the pleaſures of the circle and of the table to blunt the fine feelings of a man of genius and ſcience. The labour of collecting materials for his great political work was oppreſſive, and he relieved himſelf with various enquiries, ſuited to the exalted ambition of his cultivated underſtanding, while he turned the charms of converſation to the permanent delight of his aſſociates and of poſterity. The motto of Apelles, "*Nulla dies ſine linea*," was the emblem of his employment; and it is amazing what may be done by daily attention for improvement, without appearing to abſtract any extraordinary time from the common offices and rational pleaſures of ſociety.

In the beginning of the year 1755, Sir James wrote his Apology, or Defence of Sir Iſaac Newton's Chronology, which at that time he intended to publiſh, but was prevented by other engagements. It was communicated to ſeveral perſons of eminence in France and Germany in MS. and produced, in the month of December that year in the "*Mercure de France*," an anſwer from M. Deſhoulieres, to which Sir James ſoon after replied.

The great Newton, applying aſtronomical and ſtatiſtical principles to the ancient chronology of Greece, had chaſtiſed the vanity of nations, and arreſted the progreſs of infidelity in delineating the hiſtory of the world. Loſt in the confuſion of exceſſive pretenſions to an antiquity beyond all meaſure, and diſguſted by the ſuperſtitious aids that were aſſumed to ſupport theſe pretenſions among ancient nations, the revivers of learning in Europe, during the laſt and the preceding century, turmoiled themſelves with controverſies between the comparative merits of the ancients and moderns; and the abettors of the latter, entrenching themſelves behind the falſehoods of the ancients, on the ſcope of their remote hiſtory, gave the lie to all antiquity, and in deſpair plunged themſelves into the ocean of ſcepticiſm.

Happy had it been for ſociety if this ſcepticiſm had confined itſelf to the hiſtory of ancient nations in general; but the ſame ſpirit, taking diſguſt at the horrors of Chriſtian ambition and bigotry, and contemplating with deriſion the ridiculous legends of modern miracles, gave the lie to all religious ſcripture of the Jews and Chriſtians, and attempted to baniſh divine intelligence, the ſuperintending providence of Deity, and the true dignity of the human ſpecies, from the face of the earth!

It was a noble undertaking, therefore, in Sir James, to attempt to diſperſe this miſt of error, by diſpaſſionately and ſcientifically explaining and ſupporting the chronology of Sir Iſaac Newton. He has done it with great preciſion and effect; and it is a book well worth the peruſal of thoſe who wiſh to read ancient hiſtory with improvement, or to prevent themſelves from being bewildered in the mazes of modern conjecture. It was printed in 4to at Franckfort on the Maine, for John Bernard Eichemberg the Elder, in 1757

In the year 1758, and the following, the Britiſh Houſe of Commons took up the conſideration of a ſtatute to regulate a general uniformity of weights and meaſures throughout the united kingdoms, which had been ſo often unſucceſsfully attempted.

This called the attention of Sir James, not only to the inveſtigation of the particular ſubject that engaged that of the Houſe of Commons, but to deviſe a method of rendering an uniformity of weights and meaſures univerſal. He thought the cauſe of former diſappointments in this uſeful purſuit had been the miſtaken notion that one or other of our preſent meaſures ſhould be adopted for the new ſtandard. After the plan had been relinquiſhed by the parliament of England, he digeſted his notes and obſervations on this important diſquiſition into the form of an epiſtolary diſſertation, which he tranſmitted to his friend Lord Barrington, and reſolved, if there had been a congreſs aſſembled, as was once propoſed, to adjuſt the preliminaries of the general peace in 1763, to have laid his plan before the miniſters of the different nations, who were to prepare that ſalutary pacification of the contending powers.

This epiſtolary diſſertation Sir James afterwards reduced at Coltneſs, in the year 1777, into a form more proper for the public eye, and ſent a corrected copy to a friend, reſerving another for the preſs, which was printed 1790 for Stockdale in Piccadilly.

In this tract the author ſhews, from the ineffectual attempts that have been made to alter partially, by innovation, the ſtandards of meaſures or weights, that the effectual plan to be adopted, is to depart entirely from every meaſure whatſoever now known, and to take, *ad libitum*, ſome new maſs inſtead of our pound, ſome new length inſtead of our ell, ſome new ſpace inſtead of our acre, and ſome new ſolid inſtead of our gallon and buſhel.

For this purpoſe Sir James propoſes as the unit a maſs to be verified with the greateſt poſſible accuracy, equal in weight to ten thouſand Troy grains. The pendulum, as it ſwings at London, to beat ſeconds of time, he propoſes to be the meaſure of length; and after having laid down his fundamental principles, he propoſes an ingenious plan for rendering their adoption univerſal through the whole world.

Having obtained his pardon, Sir James Stewart retired to Coltheſs, in the county of Lanark, the paternal eſtate of his family, where he turned his attention to the improvement of his neighbourhood by public works and police, and drew the firſt good plan for a turnpike bill, ſuited to the circumſtances of Scotland, which has been ſince generally adopted. He repaired his houſe, planted, improved, and decorated his eſtate, and in ſocial intercourſe rendered himſelf the delight of his neighbourhood and country.

Never was there a man who, with ſo much knowledge, and ſo much energy of expreſſion in converſation, rendered himſelf more delightful to his company, or was more regretted by his acquaintance when he died. Nor was the active mind of Sir James unemployed for the general benefit of his country during his retreat. He was engaged by the directors of the Eaſt India Company of England to digeſt a code for the regulation of the current coin of Bengal; the plan for which important regulation he printed, and received from the court of directors a handſome diamond ring, as a mark of their approbation.

He prepared for the preſs, but never publiſhed, an antidote to the *Syſteme de la Nature* by Mirabeau, wherein the parallelogiſms and fooliſh reaſoning of that infidel work are examined, detected, and confuted. It is written in French; and were the work of Mirabeau worth refutation, might be printed with much advantage to Sir James's reputation as a controverſial writer.

This great and good man died in November 1780, and was buried at Cambuſnethan, in Lanarkſhire, on the 28th of the ſame month; the Duke of Hamilton and his neighbours performing the laſt offices to the remains of their highly valued friend, and bedewing his aſhes with their tears.

For this ſhort ſketch of the principal events in the life of Sir James Stewart-Denham, we are indebted to his nephew the Earl of Buchan, who, juſtly proud of his relation to ſuch a man, cannot be ſuppoſed to view all his projects, or even all his reaſonings, with the cool impartiality of ſtrangers. His plan, for inſtance, of a univerſal ſtandard of weights and meaſures for the *whole world*, though certainly a grand conception, we cannot help conſidering as romantic and impracticable. The author indeed was ſenſible, that time would be requiſite for its execution; and ſo large a portion of time, that, compared with it, a thouſand years are but as one day, when compared with the ordinary life of man: but ſchemes of this magnitude are not for creatures ſo blind and weak as we are, who, when we wander to a diſtance beyond the limits of our narrow ſphere, with the ambitious view of benefiting poſterity, are almoſt certain to injure ourſelves, without a probability of ſerving thoſe for whom we dream that we are exerting our abilities. Sir James's Political Economy, however, is a very great work, which has not received half the praiſes to which it is entitled, and which, we ſuſpect, provoked the envy of another great writer on ſimilar ſubjects, who exerted himſelf privately to leſſen its fame. The defence of Newton's chronology is likewiſe very valuable, though we certainly do not think that part of the ſyſtem invulnerable, in which the great aſtronomer attempts to prove, that *Oſiris*, *Seſoſtris*, and *Seſac*, are three names of the ſame Egyptian king. This, however, is a very trifling miſtake; and the modern ſciolist, who can lay hold of it to reject the whole, has certainly never read, or, if he has read, does not underſtand the defence of the ſyſtem by Sir James Stewart.

SUBCONTRARY POSITION, in geometry, is when two equiangular triangles are ſo placed, as to have one common angle at the vertex, and yet their baſes not parallel; conſequently the angles at the baſes are equal, but on the contrary ſides.

SUBDUCTION, in arithmetic, the ſame as *Subtraction*.

ANIMAL AND VEGETABLE SUBSTANCES.

THE reader will recollect, that the article CHEMISTRY, in this *Supplement*, was divided into four parts; of which only the firſt three, comprehending the elements of the ſcience, were given under the word CHEMISTRY. The *fourth part*, which was entitled an examination of bodies as they are preſented to us by nature in the mineral, vegetable, and animal kingdoms, naturally ſubdivides itſelf into three parts, comprehending reſpectively, 1. Minerals; 2. Vegetables; 3. Animals.

1 ure of article.

The firſt of theſe ſubdiviſions, which has been diſtinguiſhed by the name of MINERALOGY, we have treated of already in a former part of this Volume. As the other two ſubdiviſions have not hitherto received any appropriate name, we have ſatiſfied ourſelves with the word SUBSTANCE, by which chemiſts have agreed to denote the objects which belong to theſe ſubdiviſions. This name, it muſt be acknowledged, is not unexceptionable; but we did not conſider ourſelves as at liberty to invent a new one.

The preſent article, then, ſeems to divide itſelf into two parts: the firſt part comprehending *vegetable*; the ſecond *animal* ſubſtances. But there are certain animal and vegetable ſubſtances diſtinguiſhed from all others by being uſed as articles of clothing. It is uſual to tinge theſe of various colours, by combining with them different colouring matters for which they have an affinity. This proceſs, well known by the name of DYEING, is purely chemical; and as it belongs excluſively to animal and vegetable ſubſtances, it comes naturally to be examined here. We ſhall therefore add a *third part*, in which we ſhall give a view of the preſent ſtate of DYEING, as far, at leaſt, as is conſiſtent with the nature of a ſupplementary article.

2 Diviſion of it.

PART I. OF VEGETABLE SUBSTANCES.

VEGETABLES, or plants, as they are alſo called, are too well known to require any definition. Their number is prodigious, and their variety, regularity, and beauty, are wonderful. But it is not our intention in this place either to enumerate, to deſcribe, or to claſſify plants. Theſe taſks belong to the botaniſt, and have been ſucceſsfully accompliſhed by the zeal, the ſingular addreſs, and the indefatigable labour of Linnæus and his followers.

3 Chemical examination of vegetables. It is the buſineſs of the chemiſt to analyſe vegetables, to diſcover the ſubſtances of which they are compoſed, to examine the nature of theſe ſubſtances, to inveſtigate the manner in which they are combined, to detect the proceſſes by which they are formed, and to aſcertain the chemical changes to which plants, after they have ceaſed to vegetate, are ſubject. Hence it is evident, that a chemical inveſtigation of plants comprehends three particulars:

1. An account of the *ſubſtances* of which plants are compoſed.
2. An account of the *vegetation* of plants, as far as it can be illuſtrated by chemiſtry.
3. An account of the *changes* which plants undergo after they ceaſe to vegetate.

We therefore divide this part into three chapters, aſſigning a chapter to each of theſe particulars.

CHAP. I. OF THE INGREDIENTS OF PLANTS.

THE ſubſtances hitherto found in the vegetable kingdom, all of them at leaſt which have been examined with any degree of accuracy, may be reduced to the following heads:

1. Sugar,
2. Starch,
3. Gluten,
4. Albumen,
5. Gum,
6. Jelly,
7. Extract,
8. Tan,
9. Oils,
10. Camphor,
11. Reſins,
12. Caoutchouc,
13. Wax,
14. Wood,
15. Acids,
16. Alkalies,
17. Earths,
18. Metals.

Theſe ſhall form the ſubject of the following ſections:

SECT. I. *Of SUGAR.*

SUGAR, which at preſent forms ſo important an article in our food, ſeems to have been known at a very early period to the inhabitants of India and China. 4 Diſcovery of ſugar. But Europe probably owes its acquaintance with it to the conqueſts of Alexander the Great. For ages after its introduction into the weſt, it was uſed only as a medicine; but its conſumption gradually increaſed, and during the time of the Cruſades, the Venetians, who brought it from the eaſt, and diſtributed it to the northern parts of Europe, carried on a lucrative commerce with ſugar. It was not till after the diſcovery of America, and the extenſive cultivation of ſugar in the Weſt Indies, that its uſe in Europe, as an article of food, became general [*].

Sugar is obtained from the *arundo ſaccharifera*, or *ſugar cane.* The juice of this plant is preſſed out and

boiled in as low a temperature as poſſible, till the ſugar precipitates in the form of confuſed cryſtals. Theſe cryſtals, known by the name of *raw ſugar*, are again 5 How obtained. diſſolved in water, the ſolution is clarified, and purer cryſtals are obtained by a ſubſequent evaporation. But for the particulars of the art of manufacturing ſugar, we refer the reader to the article SUGAR in the *Encyclopædia.*

6 Its properties. Sugar, after it has been purified, or *refined* as the manufacturers term it, is uſually ſold in Europe in the form of a white opake maſs, well known by the name of *loaf ſugar*. Sometimes alſo it is cryſtallized, and then it is called *ſugar candy*.

Sugar has a very ſtrong ſweet taſte; when pure it has no ſmell; its colour is white, and when cryſtallized it is ſomewhat tranſparent. It has often a conſiderable degree of hardneſs; but it is always ſo brittle that it can be reduced without difficulty to a very fine powder. It is not altered by expoſure to the atmoſphere.

7 Solubility in water. It is exceedingly ſoluble in water. At the temperature of 48°, water, according to Mr Wenzel, diſſolves its own weight of ſugar. The ſolvent power of water increaſes with its temperature; when nearly at the boiling point, it is capable of diſſolving any quantity of ſugar whatever. Water thus ſaturated with ſugar is known by the name of *ſyrup*.

Syrup is thick, ropy, and very adheſive; when ſpread thin upon paper, it ſoon dries, and forms a kind of varniſh, which is eaſily removed by water. Its ſpecific caloric, according to the experiments of Dr Crawford, is 1.086. 8 Its cryſtals. When ſyrup is ſufficiently concentrated, the ſugar which it contains precipitates in cryſtals. The primitive form of theſe cryſtals is a four-ſided priſm, whoſe baſe is a rhomb, the length of which is to its breadth as 10 to 7; and whoſe height is a mean proportion between the length and breadth of the baſe. The cryſtals are uſually four or ſix-ſided priſms, terminated by two ſided, and ſometimes by three-ſided ſummits [†].

Sugar is ſoluble in alcohol, but not in ſo large a proportion as in water. According to Wenzel, four parts of boiling alcohol diſſolve one of ſugar [§]. It unites 9 Solubility in alcohol. readily with oils, and renders them miſcible with water. A moderate quantity of it prevents, or at leaſt retards, the coagulation of milk; but Scheele diſcovered that a very large quantity of ſugar cauſes milk to coagulate [‖].

Sugar abſorbs muriatic acid gas ſlowly, and aſſumes a brown colour and very ſtrong ſmell [‡].

Sulphuric acid, when concentrated, readily decompoſes ſugar; water is formed, and perhaps alſo acetous 10 Action of acids. acid; while charcoal is evolved in great abundance, and gives the mixture a black colour, and a conſiderable degree of conſiſtency. The charcoal may be eaſily ſeparated by dilution and filtration. When heat is applied the ſulphuric acid is rapidly converted into ſulphurous acid.

11 Of potaſh. When ſugar is mixed with potaſs, the mixture acquires a bitter and aſtringent taſte, and is inſoluble in alcohol, though each of the ingredients is very ſoluble in that liquid. When the alkali is ſaturated with ſulphuric

---

[§] *Enc. Meth. Chim.* i. 271.

[‖] *Scheele* ii. 52. Dijon tranſlation.

[‡] *Prieſtley*, ii. 291.

ric acid, and precipitated by means of alcohol, the ſweet taſte of the ſugar is reſtored; a proof that it had undergone no decompoſition from the action of the potaſs, but had combined with it in the ſtate of ſugar *.

Lime boiled with ſugar produces nearly the ſame effect as potaſs; when an alkali is added to the compound, a ſubſtance precipitates in white flakes. This ſubſtance is ſugar combined with lime †. Sugar and chalk compoſe, as Leonardi informs us, a kind of cement ‡.

Sugar, when thrown upon a hot iron, melts, ſwells, becomes browniſh black, emits air bubbles, and exhales a peculiar ſmell, known in French by the name of *caromel*. At a red heat it inſtantly burſts into flames with a kind of exploſion. The colour of the flame is white with blue edges.

14

When ſugar is diſtilled in a retort, there comes over a fluid which, at firſt, ſcarcely differs from pure water; by and bye it is mixed with pyromucous acid, afterwards ſome empyreumatic oil makes its appearance; and a bulky charcoal remains in the retort. This charcoal very frequently contains lime, becauſe lime is uſed in refining ſugar; but if the ſugar, before being ſubmitted to diſtillation, be diſſolved in water, and made to cryſtallize by evaporation in a temperature ſcarcely higher than that of the atmoſphere, no lime whatever, nor any thing elſe, except pure charcoal, will be found in the retort. During the diſtillation, there comes over a conſiderable quantity of carbonic acid, and carbonated hydrogen gas*. Sugar therefore is decompoſed by the action of heat; and the following compounds are formed from it: Water, pyromucous acid, oil, charcoal, carbonic acid, carbonated hydrogen gas. The quantity of oil is inconſiderable; by far the moſt abundant product is pyromucous acid. Sugar indeed is very readily converted into pyromucous acid; for it makes its appearance always whenever ſyrup is raiſed to the boiling temperature. Hence the ſmell of caromel, which ſyrup at that temperature emits. Hence alſo the reaſon that, when we attempt to cryſtallize ſyrup by heat, there always remains behind a quantity of incryſtallizable matter, known by the name of *molaſſes*; whereas if the ſyrup be cryſtallized without artificial heat, every particle of ſugar may be obtained from it in a cryſtalline form †. Hence we ſee the importance of properly regulating the fire during the cryſtallization of ſugar, and the immenſe ſaving that would reſult from conducting the operation at a low heat.

15

It follows from theſe facts, and from various other methods of decompoſing ſugar, that it is compoſed of oxygen, hydrogen, and carbon; for all the ſubſtances obtained from ſugar by diſtillation may be reſolved into theſe elements. Lavoiſier has made it probable, by a ſeries of very delicate experiments, that theſe ſubſtances enter into the compoſition of ſugar in the following proportions:

	64 oxygen,
	28 carbon,
	8 hydrogen.
	100

Of the way in which theſe ingredients are combined in ſugar, we are ſtill entirely ignorant. Lavoiſier's concluſions can only be conſidered as approximations to the truth.

Sugar is conſidered as a very nouriſhing article of food. It is found moſt abundantly in the juice of the ſugar cane, but many other plants alſo contain it. The juice of the acer ſaccharinum, or *ſugar maple*, contains ſo much of it, that in North America ſugar is often extracted from that tree *. Sugar is alſo found in the roots of carrot, parſnip, beet, &c. Mr Achard has lately pointed out a method of increaſing the quantity of ſugar in beet ſo much, that, according to his own account, it is at preſent cultivated in large quantities in Pruſſia, and ſugar extracted from it with advantage †. Parmentier has alſo aſcertained that the grains of wheat, barley, &c. and all the other ſimilar ſeeds which are uſed as food, contain at firſt a large quantity of ſugar, which gradually diſappears as they approach to a ſtate of maturity. This is the caſe alſo with peas and beans, and all leguminous ſeeds, and is one reaſon why the flavour of young peas is ſo much ſuperior to that of old ones.

Starch.

16 Plants containing it.

* *Ruſſ. Tranſ Phil.* iii. 64.

† *Ann. de Chim.* xxxii. 163.

SECT. II. *Of STARCH.*

WHEN a quantity of wheat flour is formed into a paſte, and water poured upon it till it runs off colourleſs, this water ſoon depoſits a very fine whitiſh powder; which, when properly waſhed and dried, is known by the name of *ſtarch*. When firſt prepared, it is of a grey colour; but the ſtarchmakers render it white by ſteeping it in water ſlightly acidulated. The acid ſeems to diſſolve and carry off the impurities.

17 Method of obtaining ſtarch.

Starch was well known to the ancients. Pliny informs us, that the method of obtaining it was firſt invented by the inhabitants of the iſland of Chio†.

† *Lib* xviii. c. 7.

Starch has a fine white colour, and is uſually concreted in longiſh maſſes; it has ſcarcely any ſmell, and very little taſte. When kept dry, it continues for a long time uninjured though expoſed to the air.

18 Its properties.

Starch does not diſſolve in cold water, but very ſoon falls to powder. It combines with boiling water, and forms with it a thick paſte. Linen dipt into this paſte, and afterwards dried ſuddenly, acquires, as is well known, a great degree of ſtiffneſs. When this paſte is left expoſed to damp air it ſoon loſes its conſiſtency, acquires an acid taſte, and its ſurface is covered with mould.

19 How acted on by water,

Starch is ſo far from diſſolving in alcohol, even when aſſiſted by heat, that it does not even fall to powder.

20 Alcohol,

When ſtarch is thrown into any of the mineral acids, at firſt no apparent change is viſible. But if an attempt is made to break the larger pieces while in acids to powder, they reſiſt it, and feel exceedingly tough and adheſive. Sulphuric acid diſſolves it ſlowly, and at the ſame time a ſmell of ſulphurous acid is emitted, and ſuch a quantity of charcoal is evolved, that the diſh containing the mixture may be inverted without ſpilling any of it. Indeed if the quantity of ſtarch be ſufficient, the mixture becomes perfectly ſolid. The charcoal may be ſeparated by dilution and filtration. In muriatic acid ſtarch diſſolves ſtill more ſlowly. The ſolution reſembles mucilage of gum arabic, and ſtill retains the peculiar odour of muriatic acid. When allowed to ſtand for ſome time, the ſolution gradually ſeparates into two parts; a perfectly tranſparent ſtraw-coloured liquid below, and a thick, muddy, oily, or rather mucilaginous ſubſtance, above. When water is poured in, the muriatic ſmell inſtantly diſappears, and a ſtrong ſmell is exhaled, preciſely ſimilar to that which is felt in corn-mills,

21 Acids,

mills. Ammonia occaſions a ſlight precipitate, but too ſmall to be examined.

Nitric acid diſſolves ſtarch more rapidly than the other two acids; it acquires a green colour, and emits nitrous gas. The ſolution is never complete, nor do any cryſtals of oxalic acid appear unleſs heat be applied. In this reſpect ſtarch differs from ſugar, which yields oxalic acid with nitric acid, even at the temperature of the atmoſphere. When heat is applied to the ſolution of ſtarch in nitric acid, both oxalic and malic acid is formed, but the undiſſolved ſubſtance ſtill remains. When ſeparated by filtration, and afterwards edulcorated, this ſubſtance has the appearance of a thick oil, not unlike tallow; but it diſſolves readily in alcohol. When diſtilled, it yields acetous acid, and an oil having the ſmell and the conſiſtence of tallow *.

22 Heat. When ſtarch is thrown upon a hot iron, it melts, blackens, froths, ſwells, and burns with a bright flame like ſugar, emitting, at the ſame time, a great deal of ſmoke; but it does not explode, nor has it the caromel ſmell which diſtinguiſhes burning ſugar. When diſtilled, it yields water impregnated with an acid, ſuppoſed to be the pyromucous, and mixed with a little empyreumatic oil. The charcoal which remains is eaſily diſſipated when ſet on fire in the open air; a proof that it contains very little earth.

23 Its compoſition. Barley grain conſiſts almoſt entirely of ſtarch, not however in a ſtate of perfect purity. In the proceſs of malting, which is nothing elſe than cauſing the barley to begin to vegetate, a great part of the ſtarch is converted into ſugar. During this proceſs oxygen gas is abſorbed, and carbonic acid gas is emitted. Water, too, is abſolutely neceſſary; hence it is probable, that it is decompoſed, and its hydrogen retained †. Starch, then, ſeems to be converted into ſugar by diminiſhing the proportion of its carbon, and encreaſing that of its hydrogen and oxygen. Its diſtillation ſhews us that it contains no other ingredients than theſe three.

24 Subſtances containing it. Starch is contained in a great variety of vegetable ſubſtances; moſt commonly in their ſeeds or bulbous roots; but ſometimes alſo in other parts. Mr Parmentier, whoſe experiments have greatly contributed towards an accurate knowledge of ſtarch, has given us the following liſt of the plants from the roots of which it may be extracted.

Arctium lappa,
Atropa belladonna,
Polygonum biſtorta,
Bryonia alba,
Colchicum autumnale,
Spiræa filipendula,
Ranunculus bulboſus,
Scrophularia nodoſa,
Sambucus ebulus,
——— ——— nigra,
Orchis morio,
Imperatoria oſtrutheum,
Hyoſcyamus niger,
Rumex obtuſifolius,
——— acutus,
——— aquaticus,
Arum maculatum,
Orchis maſcula,
Iris pſeudacorus,
——— fœtidiſſima,
Orobus tuberoſus,
Bunium bulbocaſtanum.

It is found alſo nearly pure in the following ſeeds:

Oats,
Rice,
Maiz,
Millet,
Cheſnut,
Horſecheſnut,
Peas,
Beans,
Acorn,
And alſo in
Salop,
Sago.

SECT. III. *Of* GLUTEN.

25 Gluten, how obtained. WHEN wheat flour is waſhed in the manner deſcribed in the laſt ſection, in order to obtain ſtarch from it, the ſubſtance which remains, after every thing has been waſhed away which cold water can ſeparate, is called *gluten*. It was diſcovered by Beccaria an Italian philoſopher, to whom we are indebted for the firſt analyſis of wheat flour †.

26 Its properties. Gluten, when thus obtained, is of a grey colour, exceedingly tenacious, ductile, and elaſtic, and may be extended to twenty times its original length. When very thin, it is of a whitiſh colour, and has a good deal of reſemblance to animal tendon or membrane. In this ſtate it adheres very tenaciouſly to other bodies, and has often been uſed to cement together broken pieces of porcelain. Its ſmell is agreeable. It has ſcarce any taſte, and does not loſe its tenacity in the mouth.

27 Action of air. When expoſed to the air, it gradually dries; and, when completely dry, it is pretty hard, brittle, ſlightly tranſparent, of a dark brown colour, and has ſome reſemblance to *glue*. It breaks like a piece of glaſs, and the edges of the fracture reſemble in ſmoothneſs thoſe of broken glaſs; that is to ſay, it breaks with a *vitreous* fracture.

28 Water. When expoſed to the air, and kept moiſt, it ſoon putrifies; but when dry, it may be kept any length of time without alteration. It is inſoluble in water; tho' it imbibes and retains a certain quantity of it with great obſtinacy. To this water it owes its elaſticity and tenacity. When boiled in water, it loſes both theſe properties. It is ſoluble in alcohol, as Mr Vauquelin informs us ‡; and precipitated again, as Mr Fourcroy has obſerved, by pouring into the alcohol two parts of water §.

29 Acids. Gluten is ſoluble in the three mineral acids. When nitric acid is poured on it, and heat applied, there is a quantity of azotic gas emitted, as Berthollet diſcovered; and, by continuing the heat, a quantity of oxalic acid is formed ||.

30 Alkalies. Alkalies diſſolve gluten when they are aſſiſted by heat. The ſolution is never perfectly tranſparent. Acids precipitate the gluten from alkalies, but it is deſtitute of its elaſticity ¶.

31 Heat. When moiſt gluten is ſuddenly dried, it ſwells amazingly. Dry gluten, when expoſed to heat, cracks, ſwells, melts, blackens, exhales a fetid odour, and burns preciſely like feathers or horn. When diſtilled, there comes over water impregnated with ammonia and an empyreumatic oil; the charcoal which remains is with difficulty reduced to aſhes.

32 Its compoſition. From theſe phenomena, it is evident that gluten is compoſed of carbon, hydrogen, azot, and oxygen: perhaps alſo it contains a little lime. In what manner theſe ſubſtances are combined is unknown.

33 Subſtances containing it. The only vegetable ſubſtance which has been hitherto found to contain it abundantly, is wheat flour. Vauquelin alſo found it in the fruit of the *caſſia fiſtuloris* *, and Fourcroy in the bark of a ſpecies of quinquina from St Domingo †. It probably exiſts in many other plants.

SECT. IV. *Of* ALBUMEN.

IF the water in which wheat flour has been waſhed in order to obtain ſtarch and gluten, according to the directions laid down in the two laſt ſections, be filtrated, and afterwards boiled, a ſubſtance precipitates in white flakes; to which Mr Fourcroy, who firſt pointed it

---

* *Scheele, Crell's Jour.* ii. 14. Engliſh tranſlation.

† *Cruikſhank, Rollo on Diabetes.*

† *Collect. Acad.* x. 1.

‡ *Ann. de Chim.* vi. 278.

§ *Ibid.* viii. 135.

|| *Vauquelin Ibid* vi. 278.

¶ *Fourcroy.*

* *Ibid.*

† *Ibid.* viii. 135.

lly.

it out, has given the name of *albumen* (A), on account of its reſemblance to the *white* of an egg ‡.

‡ n. de Ch. iii.

34 erties umen.

It is evident, from the method of obtaining it, that albumen, in its natural ſtate, is ſoluble in water, and that heat precipitates it from that fluid in a concrete ſtate. While diſſolved in water, it has ſcarcely any taſte; but it has the property of changing vegetable blues, eſpecially that which is obtained from the flowers of the mallow (*malva ſylveſtris*), into a green §. When allowed to remain diſſolved in water, it putrifies without becoming previouſly acid ‖.

§ rcroy, 257.

‖ d.

After it has been precipitated from water in a concrete ſtate by boiling, it is no longer ſoluble in water as before. Alcohol alſo precipitates it from water preciſely in the ſame ſtate as when it is precipitated by heat.

When concrete albumen is dried it becomes ſomewhat tranſparent, and very like glue. In that ſtate it is ſoluble in alkalies, eſpecially ammonia*.

* d.

35 ompo- n.

When diſtilled it gives out carbonat of ammonia, a red fetid oil, and carbonated hydrogen gas; and a ſpongy charcoal remains behind †. From this, it is evident that albumen, like gluten, is compoſed of carbon, azot, hydrogen, and oxygen; but the proportions and combinations of theſe ſubſtances are altogether unknown.

† d.

Mr Fourcroy found albumen in the expreſſed juice of ſcurvy graſs, creſſes, cabbage, and almoſt all cruciform plants. He found it, too, in a great many young and ſucculent plants; but never a particle in thoſe parts of vegetables which contain an acid. He obſerved alſo that the quantity decreaſed conſtantly with the age of the plant.

SECT. V. *Of Jelly*.

If we preſs out the juice of ripe blackberries, currants, and many other fruits, and allow it to remain for ſome time in a ſtate of reſt, it partly coagulates into a tremulous ſoft ſubſtance, well known by the name of *jelly*. If we pour off the uncoagulated part, and waſh the coagulum with a ſmall quantity of water, we obtain *jelly* approaching to a ſtate of purity.

36 erties lly.

In this ſtate it is nearly colourleſs, unleſs tinged by the peculiar colouring matter of the fruit; it has a pleaſant taſte, and a tremulous conſiſtency. It is ſcarcely ſoluble in cold water, but very ſoluble in hot water; and, when the ſolution cools, it again coagulates into the form of a jelly †. When long boiled, it loſes the property of gelatiniſing by cooling, and becomes analagous to mucilage ‡. This is the reaſon that in making currant jelly, or any other jelly, when the quantity of ſugar added is not ſufficient to abſorb all the watery parts of the fruit, and conſequently it is neceſſary to concentrate the liquid by long boiling, the mixture often loſes the property of coagulating, and the jelly, of courſe, is ſpoiled §.

† uquelin, . de . vi.

‡ . Ibid. 00.

Gum.

§ Ann. de Chim. v. 102.

Jelly combines readily with alkalies; nitric acid converts it into oxalic acid, without ſeparating any azotic gas ‖. When dried it becomes tranſparent ¶. When diſtilled it affords a great deal of pyromucous acid, a ſmall quantity of oil, and ſcarcely any ammonia †.

‖ Ibid. vi. 282.

¶ Ibid. v. 100.

† Ibid. vi. 286.

Jelly exiſts in all acid fruits, as oranges, lemons, gooſeberries, &c. and no albumen is ever found in thoſe parts of vegetables which contain an acid. This circumſtance has induced Fourcroy to ſuppoſe that jelly is albumen combined with an acid *: but this conjecture has not been verified by experiment; nor indeed is it probable that it ever ſhall; as albumen evidently contains a quantity of azot, and jelly ſcarcely any. The products of jelly by diſtillation ſhew that it approaches nearer than any other vegetable ſubſtance to the nature of ſugar.

* Ibid. iii. 261.

SECT. VI. *Of Gum*.

There is a thick tranſparent taſteleſs fluid which ſometimes exſudes from certain ſpecies of trees. It is very adheſive, and gradually hardens without loſing its tranſparency; but eaſily ſoftens again when moiſtened with water. This exſudation is known by the name of *gum*. The gum moſt commonly uſed is that which exſudes from different ſpecies of the *mimoſa*, particularly the *nilotica* †. It is known by the name of *gum arabic*. Gum likewiſe exſudes abundantly from the *prunus avium*, or common wild cherry tree of this country.

37 Gum how obtained.

† Schouſboe, Philoſ. Mag. v. 241.

Gum is uſually obtained in ſmall pieces like tears, moderately hard, and ſomewhat brittle while cold, ſo that it can be reduced by pounding to a fine powder. Its colour is uſually yellowiſh, and it is not deſtitute of luſtre. It has no ſmell; its taſte is inſipid.

Gum undergoes no change from being expoſed to the atmoſphere; but the light of the ſun makes it aſſume a white colour. Water diſſolves it in large quantities. The ſolution which is known by the name of *mucilage* (B), is thick and adheſive: it is often uſed as a paſte, and to give ſtiffneſs and luſtre to linen. When ſpread out thin it ſoon dries, and has the appearance of a varniſh; but it readily attracts moiſture, and becomes glutinous. Water waſhes it away entirely. When mucilage is evaporated the gum is obtained unaltered.

38 Action of water.

Gum is inſoluble in alcohol. When alcohol is poured into mucilage, the gum immediately precipitates; becauſe the affinity between water and alcohol is greater than that between water and gum.

39 Alcohol.

The action of alkalies and earths upon gum has not been

(A) The exiſtence of albumen in vegetables was known to Scheele. He mentions it particularly in his paper on Milk, firſt publiſhed in the year 1780. See *Scheele's Works*, II. 55. Dijon edition.

(B) Hermſtadt uſes this word in a different ſenſe. He makes a diſtinction between *gum* and *mucilage*. The ſolution of *gum* in water is tranſparent and glutinous, and can be drawn out into threads; whereas that of *mucilage* is opake, does not feel glutinous, but ſlippery, and cannot be drawn into threads. Gum may be ſeparated from mucilage by the following proceſs:

Let the gum which is ſuppoſed to be mixed with mucilage, previouſly reduced to a dry maſs, be diſſolved in as ſmall a quantity of water as poſſible, and into the ſolution drop at intervals diluted ſulphuric acid. The mucilage coagulates while the gum remains diſſolved. When no more coagulation takes place, let the mixture remain at reſt for ſome time, and the mucilage will precipitate to the bottom, and aſſume the conſiſtence of jelly. Decant off the liquid part, and evaporate the mucilage to dryneſs by a gentle heat till it acquires the conſiſtence of horn. *Med. and Phyſ. Jour.* iii. 370.

been examined. Acids do not precipitate it from mucilage ‡. The concentrated mineral acids deſtroy it. Concentrated ſulphuric acid decompoſes it; water is formed, and perhaps alſo acetous acid; while charcoal is precipitated. Nitric acid converts it into oxalic acid; oxy-muriatic acid, on the contrary, into citric acid *.

40
Of heat.

When gum is expoſed to heat it ſoftens and ſwells, but does not melt; it emits air bubbles, blackens, and at laſt, when nearly reduced to charcoal, emits a low blue flame. This flame appears ſooner if a flaming ſubſtance be held juſt above the gum. After the gum is conſumed, there remains a ſmall quantity of white aſhes, compoſed chiefly of the carbonats of lime and potaſs.

When gum is diſtilled in a retort, the products are water impregnated with a conſiderable quantity of pyromucous acid, a little empyreumatic oil, carbonic acid gas, and carbonated hydrogen gas. When the pyromucous acid obtained by this proceſs is ſaturated with lime, a quantity of ammonia is diſengaged with which that acid had been combined. The charcoal which remained in the retort leaves behind it, after incineration, a little lime, and phoſphat of lime §.

41
Its compoſition.

Theſe experiments ſhew us that gum is compoſed of hydrogen, carbon, oxygen, azot, lime, and phoſphorus; but the proportions and combinations of theſe ſubſtances are unknown to us. Mr Cruickſhank has rendered it probable that the quantity of carbon is greater, and the quantity of oxygen leſs, in gum than in ſugar ||.

Gum, or mucilage, exiſts moſt abundantly in young plants, and gradually diſappears as they arrive at perfection. It forms a great proportion of the leaves and roots of many eatable plants.

SECT. VII. *Of Extract.*

42
Extract, how obtained.

THE word *extract* was at firſt applied to all thoſe ſubſtances which were extracted from plants by means of water, and conſequently included gum, jelly, and ſeveral other bodies. But of late it has been confined, by thoſe chemiſts who have paid attention to the uſe of language, to a ſubſtance which exiſts in many plants, and which may be obtained by infuſing *ſaffron* in water for ſome time, filtrating the infuſion, and evaporating it to dryneſs. The reſiduum, after evaporation, is *extract* nearly pure ¶. It poſſeſſes the following properties:

43
Its properties.

Water diſſolves it in conſiderable quantities, eſpecially hot water. Alcohol alſo diſſolves it with facility. This property of being ſoluble both in water and alcohol has induced ſome chemiſts to give *extract* the name of *ſoap*. It is inſoluble in ſulphuric ether. Theſe three properties are ſufficient to diſtinguiſh it from every other vegetable ſubſtance *.

When the ſolution of extract in water is expoſed for ſome time in the open air, the extract precipitates, and is now no longer ſoluble in water. This change is ſuppoſed to proceed from the addition of a quantity of oxygen which it imbibes from the atmoſphere †.

When oxy-muriatic acid is poured into a watery ſolution of extract, that ſubſtance precipitates in yellow flakes. Theſe flakes are inſoluble in water; they are inſoluble alſo in alcohol at the temperature of 97°; but that liquid diſſolves them at the temperature of 120°. They are ſoluble alſo in alkalies, and in boiling-hot water they melt into a yellow maſs ‡.

Extract is ſoluble in acids. Heat ſoftens but does not melt it §.

It is found in a great variety of plants; but as no method of obtaining it perfectly pure has hitherto been diſcovered, the extracts of different plants differ ſomewhat from each other both in their colour and ſmell.

SECT. VIII. *Of Tan.*

44
Preparation of tan

IF a quantity of nut galls, coarſely powdered, be kept for ſome time infuſed in cold water, if the water be filtered, and a ſolution of muriat of tin be dropt into it, a copious white precipitate falls to the bottom. This precipitate is to be carefully waſhed and diffuſed (for it will not diſſolve) thro' a large quantity of water, and this water is to be ſaturated with ſulphurated hydrogen gas ſo completely that it will not abſorb any more. By this treatment the white precipitate will gradually diſappear, and a brown precipitate will take its place. This brown precipitate muſt be ſeparated by filtration; and the water, which has now acquired the colour and the taſte of the infuſion of nut galls, muſt be evaporated to dryneſs. A ſubſtance remains behind, known by the name of *tan* or *tannine*.

It was firſt diſcovered by Seguin, who pointed out ſome of its properties, and the method of detecting it in plants ||. The above method of obtaining it in a ſtate of purity was contrived by Mr Prouſt. Tan exiſts in the ſolution of nut galls combined with gallic acid. The oxyd of tin has a ſtrong affinity for it. When muriat of tin is poured in, the tan combines with the oxyd, and the compound, being inſoluble, falls to the bottom. Sulphur has a ſtronger affinity for the oxyd than tan has. Hence when ſulphurated hydrogen gas is thrown upon this compound, the ſulphur leaves the gas and combines with the tin; and the compound, being inſoluble, falls to the bottom: The hydrogen gas eſcapes, and nothing remains in the water except the tan.

45
Its properties.

Tan is a brittle ſubſtance, of a brown colour. It breaks with a vitreous fracture, and does not attract moiſture from the air. Its taſte is exceedingly aſtringent. It is very ſoluble in water. The ſolution is of a deep brown colour, a very aſtringent and bitter taſte, and has the odour which diſtinguiſhes a ſolution of nut galls. It froths, when agitated, like a ſolution of ſoap; but does not feel unctuous. Acids precipitate the tan from this ſolution.

Tan is ſtill more ſoluble in alcohol than in water.

When the ſolution of tan is poured into a ſolution of the brown ſulphat of iron, a deep blue coloured precipitate immediately appears, conſiſting of the tan combined with the oxyd. This precipitate, when dried, aſſumes a black colour. It is decompoſed by acids. The green ſulphat of iron is not altered by tan.

When too great a proportion of brown ſulphat of iron is poured into a ſolution of tan, the ſulphuric acid, ſet at liberty by the combination of the iron and tan, is ſufficient to rediſſolve the precipitate as it appears; but the precipitate may eaſily be obtained by cautiouſly ſaturating this exceſs of acid with potaſs. When the experiment is performed in this manner, all the red ſulphat of iron which remains in the ſolution undecompoſed is converted into green ſulphat. Mr Prouſt, to whom we are indebted for almoſt every thing yet known concerning the properties of tan, ſuppoſes that this change is produced

---

ıphor.

produced by the tan abſorbing oxygen from the iron. This may very poſſibly be the caſe; but his experiments are inſufficient to prove that it is. The ſame change takes place if red oxyd be mixed with a conſiderable exceſs of ſulphuric acid, and diluted with water.

Tan combines readily with oxygen. When oxy muriatic acid is poured upon it, its colour deepens, and it loſes all its peculiar characters *.

46
ts con-
rg it.

Tan exiſts in almoſt all thoſe vegetable ſubſtances which have an aſtringent taſte. It is almoſt conſtantly combined with gallic acid. The following table, drawn up by Mr Biggin †, though the rule which the author followed in making his experiments precluded rigid accuracy, will ſerve to give ſome idea of the proportions of tan which exiſt in different plants:

	Prop. of Tan.		*Prop. of Tan.*
Elm	2,1	Sallow	4,6
Oak cut in winter	2,1	Mountain aſh	4,7
Horſe cheſnut	2,2	Poplar	6,0
Beech	2,4	Hazel	6,3
Willow (boughs)	2,4	Aſh	6,6
Elder	3,0	Spaniſh cheſnut	9,0
Plum tree	4,0	Smooth oak	9,2
Willow (trunk)	4,0	Oak cut in ſpring	9,6
Sycamore	4,1	Huntingdon or Leiceſter willow	10,1
Birch	4,1		
Cherry tree	4,2	Sumach	16,2

SECT. IX. *Of OILS.*

THERE are two ſpecies of oils; namely, *fixed* and *volatile*: both of which are found abundantly in plants.

1. Fixed oil is found in the ſeeds of many plants; eſpecially of the olive, beech, flax, almond, rape, &c.

2. Volatile oil is obtained by diſtillation from the leaves, flowers, or roots of aromatic plants, as lavender, roſes, roſemary, &c.

As an account of the properties of oils has been given already in the article CHEMISTRY, *Suppl.* it would be ſuperfluous to repeat it here.

SECT. X. *Of CAMPHOR.*

THE laurus camphorata is a tree which grows in China, Japan, and ſeveral parts of India. When the roots of this tree are put into an iron pot furniſhed with a capital, and a ſufficient heat is applied, a particular ſubſtance ſublimes into the capital, which is known by the name of *camphor*. The Dutch afterwards purify this camphor by a ſecond ſublimation.

Camphor is a white brittle ſubſtance, having a peculiar aromatic odour and a ſtrong taſte.

47
perties
mphor

It is not altered by atmoſpheric air; but it is ſo volatile, that if it be expoſed during warm weather in an open veſſel, it evaporates completely. When ſublimed in cloſe veſſels it cryſtalliſes in hexagonal plates or pyramids *.

It is inſoluble in water; but it communicates to that liquid a certain portion of its peculiar odour.

It diſſolves readily in alcohol, and is precipitated again by water. If the alcohol be diluted with water as much as poſſible, without cauſing the camphor to precipitate, ſmall cryſtals of camphor reſembling feathers gradually form †.

Camphor is ſoluble alſo in hot oils, both fixed and volatile; but as the ſolution cools the camphor precipitates, and aſſumes the form of plumoſe, or feather-like cryſtals ‡.

Camphor is not acted on by alkalies, either pure or in the ſtate of carbonats. Pure alkalies indeed ſeem to diſſolve a little camphor; but the quantity is too ſmall to be perceptible by any other quality than its odour §. Neither is it acted upon by any of the neutral ſalts which have hitherto been tried.

Acids diſſolve camphor, but it is precipitated again, unaltered, by alkalies, and even by water. The ſolution of camphor in ſulphuric acid is red; that in the nitric acid is yellow. This laſt ſolution has obtained the abſurd name of *oil of camphor*. When nitric acid is diſtilled repeatedly off camphor, it converts it into camphoric acid.

Muriatic, ſulphurous, and fluoric acids, in the ſtate of gas, diſſolve camphor. When water is added, the camphor appears unaltered in flakes, which ſwim on the ſurface of the water §.

When heat is applied to camphor it is volatilized. If the heat be ſudden and ſtrong, the camphor melts before it evaporates. It catches flame very readily, and emits a great deal of ſmoke as it burns, but it leaves no reſiduum. It is ſo inflammable that it continues to burn even on the ſurface of water. When camphor is ſet on fire in a large glaſs globe filled with oxygen gas, and containing a little water, it burns with a very bright flame, and produces a great deal of heat. The inner ſurface of the glaſs is ſoon covered with a black powder, which has all the properties of charcoal, a quantity of carbonic acid gas is evolved, the water in the globe acquires a ſtrong ſmell, and is impregnated with carbonic acid and camphoric acid ‖.

43
Its analyſis.

If two parts of alumina and one of camphor be formed into a paſte with water, and diſtilled in a glaſs retort, there comes over into the receiver (which ſhould contain a little water, and communicate with a pneumatic apparatus) a volatile oil of a golden yellow colour, a little camphoric acid which diſſolves in the water, and a quantity of carbonic acid gas, and carbonated hydrogen gas, which may be collected by means of a pneumatic apparatus. There remains in the retort a ſubſtance of a deep black colour, compoſed of alumina and charcoal. By this proceſs, from 122.284 parts of camphor, Mr Bouillon la Grange, to whom we are indebted for the whole of the analyſis of camphor, obtained 45.856 parts of volatile oil, and 30.571 parts of charcoal. The proportion of the other products was not aſcertained *.

From this analyſis, Mr Bouillon la Grange concludes, that camphor is compoſed of volatile oil, and charcoal or carbon, combined together. We learn, from his experiments, that the ultimate ingredients of camphor are carbon and hydrogen; and that the proportion of carbon is much greater than in oils.

49
Plants containing it.

Camphor exiſts in a great many plants. Neumann, Geoffroy, and Cartheuſer, extracted it from the roots of zedoary, thyme, ſage, &c. and rendered it probable that it is contained in almoſt all the labiated plants. It has been ſuppoſed to exiſt in theſe plants combined with volatile oil. Prouſt has ſhewn how it may be extracted, in conſiderable quantity, from many volatile oils †.

Camphor, which was unknown to the ancient Greeks and Romans, was introduced into Europe by the Arabians.

bians. Ætius is the firſt perſon who mentions it. It ſeems, however, to have been very early known to the eaſtern nations.

It is much uſed in medicine. It is a powerful ſtimulant; it is conſidered as peculiarly efficacious in diſeaſes of the urinary organs; it is often ſerviceable in mania, and procures ſleep when every other medicine fails.

Sect. XI. *Of Resins.*

There is a yellowiſh white coloured ſubſtance which often exſudes from the *Abies Montana*, or *common Scotch fir*, and likewiſe from other fir trees. It is ſomewhat tranſparent, is hard and brittle, of a diſagreeable taſte, and may be collected in conſiderable quantities. This ſubſtance is known by the name of *reſin*; and the ſame name is alſo applied to all ſubſtances which poſſeſs nearly the ſame properties with it. Reſin may be diſtinguiſhed from every other ſubſtance by the following properties:

50 Properties of reſin.

It is more or leſs concrete, and has an acrid and hot taſte.

It is totally inſoluble in water. By this property it may eaſily be ſeparated from gum, if they happen to be mixed together.

It is ſoluble in alcohol, and in ſulphuric ether *. By the firſt of theſe properties we may ſeparate it from gum, and by the laſt from extract; for extract is inſoluble in ſulphuric ether. When theſe ſolutions are evaporated the reſin is obtained unaltered. If the ſolution be ſpread thin upon any body, it ſoon dries by the evaporation of the alcohol; the reſin remains behind, and covers the body with a ſmooth ſhining tranſparent coat, which cannot be waſhed off by water. This proceſs is called *varniſhing*.

Reſin is ſoluble alſo in volatile oils; and theſe ſolutions are often uſed likewiſe in varniſhing.

Reſin is ſcarcely acted upon by acids. Alkalies combine with it, but the combination is not eaſily effected.

When reſin is heated it readily melts; and if the heat be increaſed it is volatilized, and burns with a white flame and ſtrong ſmell. When diſtilled it yields much volatile oil, but ſcarcely any acid.

When volatile oils are expoſed for ſome time to the action of the atmoſphere they acquire conſiſtency, and aſſume the properties of reſins. During this change they abſorb a quantity of oxygen from the air. Weſtrum put 30 grains of oil of turpentine into 40 cubic inches of oxy-muriatic acid gas. Heat was evolved, the oil gradually evaporated, and aſſumed the form of yellow reſin †. Theſe facts render it probable that reſin is merely volatile oil combined with a quantity of oxygen.

To know whether any vegetable ſubſtance contains reſin, we have only to pour ſome ſulphuric ether upon it in powder, and expoſe the infuſion to the light. If any reſin be preſent the ether will aſſume a brown colour ‡.

51 Number of reſins.

The number of reſins is conſiderable. They differ from each other chiefly in colour, taſte, ſmell, and conſiſtency. Whether theſe reſins be really different combinations, or, as is moſt likely, owe theſe differences to foreign ingredients, either combined with the reſin, or mechanically mixed with it, is not at preſent known. To deſcribe each reſin ſeparately would be to little purpoſe, as ſcarcely any thing is known of them except their general properties as reſins. The following is a liſt of the principal. The reader will find an account of the manner of obtaining them, and of their uſes, by conſulting the name of each in the *Encyclopædia*.

1. Common reſin,
2. Turpentine,
3. Pitch,
4. Galipot,
5. Elemi,
6. Maſtic,
7. Sandarac,
8. Guaiacum,
9. Labdanum,
10. Dragon's blood,
11. Copaiba.

52 Balſams.

There are three vegetable ſubſtances which have been denominated *balſams* by ſome of the later French writers. They appear to conſiſt of reſin, or volatile oil combined with benzoic acid. Theſe ſubſtances are, benzoin, balſam of Tolu, and ſtorax. For an account of them we refer to the *Encyclopædia*.

53 Gum reſins.

Many vegetable ſubſtances occur in medicine which conſiſt chiefly of a mixture of gum and reſin. Theſe ſubſtances, of courſe, have a number of the properties both of gums and reſins. For this reaſon they have been denominated *gum reſins*. The following are the moſt important of theſe ſubſtances:

Olibanum,
Galbanum,
Scammony,
Aſafœtida,
Aloes,
Myrrh,
Ammoniac,
Opium.

For an account of them we refer to the *Encyclopædia*.

Sect. XII. *Of Caoutchouc.*

54 Diſcovery of caoutchouc.

About the beginning of the 18th century a ſubſtance, called *caoutchouc*, was brought as a curioſity from America. It was ſoft, wonderfully elaſtic, and very combuſtible. The pieces of it that came to Europe were uſually in the ſhape of bottles, birds, &c. This ſubſtance is very much uſed in rubbing out the marks made upon paper by a black lead pencil; and therefore in this country it is often called *Indian rubber*. Nothing was known of its production, except that it was obtained from a tree, till the French academicians went to South America in 1735 to meaſure a degree of the meridian. Mr de la Condamine ſent an account of it to the French Academy in the year 1736. He told them, that there grew in the province of Eſmeraldas, in Brazil, a tree, called by the natives *Hhevé*; that from this tree there flowed a milky juice, which, when inſpiſſated, was *caoutchouc*. Don Pedro Maldonado, who accompanied the French academicians, found the ſame tree on the banks of the Maragnon; but he died ſoon after, and his papers were never publiſhed. Mr Freſnau, after a very laborious ſearch, diſcovered the ſame tree in Cayenne. His account of it was read to the French Academy in 1751.

55 Plants containing it.

It is now known that there are at leaſt two trees in South America from which caoutchouc may be obtained, the Hævea Caoutchouc and the Jatropha Elaſtica; and it is exceedingly probable that it is extracted alſo from other ſpecies of Hævea and Jatropha. Several trees likewiſe which grow in the Eaſt Indies yield caoutchouc; the principal of theſe are, the Ficus Indica, the Artocarpus Integrifolia, and the Urceola Elaſtica; a plant diſcovered by Mr Howiſon, and firſt deſcribed and named by Dr Roxburgh *.

---

* *Hermſtadt.*

† *Crell's Annals*, i. 1790.

‡ *Hermſtadt.*

* *Aſiatic Reſearches* v. 167. London edition.

Caout-
chouc.

When any of theſe plants is punctured, there exſudes from it a milky juice, which, when expoſed to the air, gradually lets fall a concrete ſubſtance, which is caoutchouc.

If oxy-muriatic acid be poured into the milky juice, the caoutchouc precipitates immediately, and, at the ſame time, the acid loſes its peculiar odour. This renders it probable that the formation of the caoutchouc is owing to its baſis abſorbing oxygen *. If the milky juice be confined in a glaſs veſſel containing common air, it gradually abſorbs oxygen, and a pellicle of caoutchouc appears on its ſurface †.

* *Fourcroy*, *n. de* *im.* xi. 9.
† *Ibid.*

56
operties
caout-
ouc.

Caoutchouc was no ſooner known than it drew the attention of philoſophers. Its ſingular properties promiſed that it would be exceedingly uſeful in the arts, provided any method could be fallen upon to mould it into the various inſtruments for which it ſeemed peculiarly adapted. Meſſrs de la Condimine and Freſnau had mentioned ſome of its properties; but Macquer was the firſt perſon who undertook to examine it with attention. His experiments were publiſhed in the memoirs of the French Academy for the year 1768. They threw a good deal of light on the ſubject; but Macquer fell into ſome miſtakes, which were pointed out by Mr Berniard, who publiſhed an admirable paper on caoutchouc in the 17th volume of the *Journal de Phyſique*. To this paper we are indebted for the greater number of facts at preſent known reſpecting caoutchouc. Mr Groſſart and Mr Fourcroy have likewiſe added conſiderably to our knowledge of this ſingular ſubſtance; both of their treatiſes have been publiſhed in the 11th volume of the *Annales de Chimie*.

Caoutchouc, when pure, is of a white colour (c), and without either taſte or ſmell ‡. The blackiſh colour of the caoutchouc of commerce is owing to the method employed in drying it after it has been ſpread upon moulds. The uſual way is to ſpread a thin coat of the milky juice upon the mould, and then to dry it by expoſing it to ſmoke; afterwards another coat is ſpread on, which is dried in the ſame way. Thus the caoutchouc of commerce conſiſts of numerous layers of pure caoutchouc alternating with as many layers of ſoot.

‡ *ourcroy*, . 232.

Caoutchouc is ſoft and pliable like leather. It is exceedingly elaſtic and adheſive; ſo that it may be forcibly ſtretched out much beyond its uſual length, and inſtantly recover its former bulk when the force is withdrawn. It cannot be broken without very conſiderable force.

57
ion of
er,

It is not altered by expoſure to the air; it is perfectly inſoluble in water: but if boiled for ſome time its edges become ſomewhat tranſparent, owing undoubtedly to the water carrying off the ſoot; and ſo ſoft, that when two of them are preſſed and kept together for ſome time, they adhere as cloſely as if they formed one piece. By this contrivance pieces of caoutchouc may be ſoldered together, and thus made to aſſume whatever ſhape we pleaſe §.

§ *roſſart.* *. de* *n.* xi.

58
hol,

Caoutchouc is inſoluble in alcohol. This property was diſcovered very early, and fully confirmed by the experiments of Mr Macquer. The alcohol, however, renders it colourleſs.

59
ther,

Caoutchouc is ſoluble in ether. This property was firſt pointed out by Macquer. Berniard, on the contrary, found that caoutchouc was ſcarcely ſoluble at all in ſulphuric ether, which was the ether uſed by Macquer, and that even nitric ether was but an imperfect ſolvent. The difference in the reſults of theſe two chemiſts was very ſingular; both were remarkable for their accuracy, and both were too well acquainted with the ſubject to be eaſily miſled. The matter was firſt cleared up by Mr Cavallo. He found that ether, when newly prepared, ſeldom or never diſſolved caoutchouc completely; but if the precaution was taken to waſh the ether previouſly in water, it afterwards diſſolved caoutchouc with facility. Mr Groſſart tried this experiment, and found it accurate ‖. It is evident from this that theſe chemiſts had employed ether in different ſtates. The waſhing of ether has two effects. It deprives it of a little acid with which it is often impregnated, and it adds to it about one-tenth of water, which remains combined with it.

‖ *Ann. de Chim.* xi. 47.

When the ether is evaporated, the caoutchouc is obtained unaltered. Caoutchouc, therefore, diſſolved in ether, may be employed to make inſtruments of different kinds, juſt as the milky juice of the hævea; but this method would be a great deal too expenſive for common uſe.

60
Oils,

Caoutchouc is ſoluble in volatile oils *; but, in general, when theſe oils are evaporated, it remains ſomewhat glutinous, and therefore is ſcarcely proper for thoſe uſes to which, before its ſolution, it was ſo admirably adapted.

* *Berniard.*

61
Acids and
alkalies,

It is inſoluble in alkalies †. The acids act upon it with more or leſs violence according to their nature. Sulphuric acid decompoſes it completely, charcoal precipitates, and part of the acid is converted into ſulphurous acid. Nitric acid converts it into a yellow ſubſtance, analogous to ſuberic acid. Muriatic acid does not affect it ‡. The other acids have not been tried.

† *Id.*
‡ *Id.*

Fabroni has diſcovered, that rectified petroleum diſſolves it, and leaves it unaltered when evaporated ¶.

¶ *Ibid.* 155. and xii. 156.

62
Heat.

When expoſed to heat it readily melts; but it never afterwards recovers its properties, but continues always of the conſiſtence of tar. It burns very readily with a bright white flame, and diffuſes a fetid odour. In thoſe countries where it is produced, it is often uſed by way of candle.

When diſtilled, it gives out ammonia §. It is evident from this, and from the effect of ſulphuric and nitric acid upon it, that it is compoſed of carbon, hydrogen, azot, and oxygen; but the manner in which they are combined is unknown.

§ *Fourcroy*, *nn de* *Chim* xi. 232.

When treated with nitric acid, there came over azotic gas, carbonic acid gas, pruſſic acid gas; and oxalic acid was formed ‖.

‖ *Ibid.*

63
How to ſe-
parate it
from plants.

It ſeems to exiſt in a great variety of plants; but is uſually confounded with the other ingredients. It may be ſeparated from reſins by means of alcohol. It may be extracted from the different ſpecies of *miſletoe* by water, with which, in the fluid ſtate in which it exiſts in theſe plants, it readily combines. When mixed with gum or extract, it may be ſeparated by the following proceſs: Digeſt a part of the plant containing it firſt in water and then in alcohol, till all the ſubſtances ſo-

---

(c) Mr De Fourcroy ſays, that blackiſh brown is the natural colour of caoutchouc. But we have ſeen ſome pieces of it from the Eaſt Indies, which had been allowed to inſpiſſate in the open air: They were white, with a ſlight caſt of yellow, and had very much the appearance and feel of white ſoap.

luble in theſe liquids be extracted. Dry the reſiduum, and digeſt it in five times its weight of rectified petroleum. Expreſs the liquid part by ſqueezing the ſubſtance in a linen cloth. Let this liquid remain ſeveral days to ſettle, then decant off the clear liquid part, mix it with a third part of water and diſtil, the caoutchouc remains behind [*].

SECT. XIII. *Of Wax.*

THE upper ſurface of the leaves of many trees is covered with a varniſh of wax. This varniſh may be ſeparated and obtained in a ſtate of purity by the following proceſs.

64
Wax a vegetable production.

Digeſt the bruiſed leaves, firſt in water and then in alcohol, till every part of them which is ſoluble in theſe liquids be extracted. Then mix the reſiduum with ſix times its weight of a ſolution of pure ammonia, and, after ſufficient maceration, decant off the ſolution, filter it, and drop into it, while it is inceſſantly ſtirred, diluted ſulphuric acid, till more be added than is ſufficient to ſaturate the alkali. The wax precipitates in the form of a yellow powder. It ſhould be carefully waſhed with water, and then melted over a gentle fire [†].

Mr Tingry firſt diſcovered that this varniſh poſſeſſed all the properties of *bees wax* [‡]. Wax then is a vegetable product. The bees extract it unaltered from the leaves of trees and other vegetable ſubſtances which contain it. They ſeem, however, to mix it with ſome of the pollen of flowers.

65
Its properties.

Wax, when pure, is of a whitiſh colour, it is deſtitute of taſte, and has ſcarcely any ſmell. Bees wax indeed has a pretty ſtrong aromatic ſmell; but this ſeems chiefly owing to ſome ſubſtance with which it is mixed; for it diſappears almoſt completely by expoſing the wax, drawn out into thin ribands, for ſome time to the atmoſphere. By this proceſs alſo, which is called *bleaching*, the yellow colour of the wax diſappears, and it becomes very white. Bleached wax is not affected by the air [§].

Wax is inſoluble in water and in alcohol. It combines readily with alkalies, and forms with them a ſoap which is ſoluble in water [‖].

Punic wax, which the ancients employed in painting in encauſto, is a ſoap compoſed of twenty parts of wax and one of ſoda [*]. Its compoſition was aſcertained by Mr Lorgna [†].

Sulphuric and nitric acids decompoſe wax completely; oxy-muriatic acid bleaches it inſtantaneouſly.

Wax combines readily with oils, and forms with them a ſubſtance of greater or leſs conſiſtency according to the quantity of oil. This compoſition, which is known by the name of *cerate*, is much employed by ſurgeons.

When heat is applied to wax it becomes ſoft; and at the temperature of 142°, if unbleached, or of 155° if bleached [‡], it melts into a colourleſs tranſparent fluid, which concretes again, and reſumes its former appearance as the temperature diminiſhes. If the heat be ſtill farther increaſed, the wax boils and evaporates; and if a red heat be applied to the vapour, it takes fire and burns with a bright flame. It is this property which renders wax ſo uſeful for making candles.

66
Analyſis.

Mr Lavoiſier, by means of the apparatus deſcribed in the article CHEMISTRY, *Suppl.* n° 353. contrived to burn wax in oxygen gas. The quantity of wax conſumed was 21.9 grains. The oxygen gas employed in conſuming that quantity amounted to 66.55 grains. Conſequently the ſubſtances conſumed amounted to 88:45 grains. After the combuſtion, there were found in the glaſs veſſel 62.58 grains of carbonic acid, and a quantity of water, which was ſuppoſed to amount to 25 87 grains. Theſe were the only products.

Now 62.58 grains of carbonic acid gas contain
44 56 of oxy. and 18.02 of carb; and 25 87 gr. of water contain
21.99 of oxy. and 3.88 of hydro.

66.55	21.90

Conſequently 21.9 parts of wax are compoſed of 18.02 of carbon, and 3.88 of hydrogen. And 100 parts of wax are compoſed of 82.28 carbon,
17.72 hydrogen,

100.00 [*].

If wax be diſtilled with a heat greater than 212°, there comes over a little water, ſome ſebacic acid, a little very fluid and odorous oil: the oil, as the diſtillation advances, becomes thicker and thicker, till at laſt it is of the conſiſtency of butter, and for this reaſon has been called *butter of wax*. There remains in the retort a ſmall quantity of coal, which is not eaſily reduced to aſhes. When the butter of wax is repeatedly diſtilled it becomes very fluid, and aſſumes the properties of volatile oil [†].

SECT. XIV. *Of the WOODY FIBRE.*

ALL trees, and moſt other plants, contain a particular ſubſtance, well known by the name of *wood*. If a piece of wood be well dried, and digeſted, firſt in a ſufficient quantity of water, and then of alcohol, to extract from it all the ſubſtances ſoluble in theſe liquids, there remains behind only the *woody fibre*.

67
Properties of wood.

This ſubſtance, which conſtitutes the baſis of wood, is compoſed of longitudinal fibres, eaſily ſubdivided into a number of ſmaller fibres. It is ſomewhat tranſparent; is perfectly taſteleſs; has no ſmell; and is not altered by expoſure to the atmoſphere.

It is inſoluble in water and in alcohol; but ſoluble in alkalies. The mineral acids decompoſe it. When diſtilled it yields, in all probability, pyrolignous acid. When burnt with a ſmothered fire it leaves behind it a conſiderable quantity of charcoal.

It is precipitated from alkalies unaltered by acids [*].

68
Its analyſis.

By nitric acid Fourcroy converted the reſiduum of quinquina, which does not ſeem to differ from the woody fibre, into oxalic acid; at the ſame time there was a little citric acid formed, and a very ſmall quantity of malic and acetous acids. Some azotic gas alſo was diſengaged. By this proceſs he obtained from 100 parts of woody fibre

56.250	oxalic acid,
3.905	citric acid,
0.388	malic acid,
0.486	acetous acid,
0.867	azotic gas,
8.330	carbonat of lime,
70.226	
32.031	reſiduum.
102.257	

There was likewiſe a quantity of carbonic acid gas diſengaged, the weight of which was unknown. This increaſe

---

[*] Fourcroy, Ann. de Chim. viii. 149.

increaſe of weight in the product was evidently owing to the oxygen derived from the nitric acid *.

When diſtilled in a retort, 100 parts yield the following products:

26.62 of a yellow liquid, containing alcohol, and acid which had the ſmell of pyromucous.
6.977 of concrete oil, moſtly ſoluble in alcohol.
22.995 charcoal } in the retort.
3.567 carbonat of lime } in the retort.

60.159
39.841 gas, half carbonic acid, half carbonated hydrogen.

100.000 *.

Theſe facts ſhew us, that the woody fibre is compoſed of oxygen, carbon, hydrogen, azot, and lime. Mr Chaptal ſuppoſes that mucilage differs from woody fibre merely in containing leſs oxygen. We are certain at leaſt that mucilage or gum is compoſed of the ſame ingredients; and Mr Chaptal has ſhewn, that the juices of plants are partly converted into woody fibre by oxy-muriatic acid, which imparts to them oxygen†. Theſe juices contain both gum and reſin: after the formation of the woody fibre the reſin is ſtill unaltered. This gives a good deal of probability to his opinion.

SECT. XV. *Of Acids.*

THE acids found ready formed in vegetables are the following:

1. Oxalic,
2. Tartarous,
3. Citric,
4. Malic,
5. Gallic,
6. Benzoic,
7. Phoſphoric.

Sometimes alſo the ſulphuric, nitric, and muriatic acids occur in vegetables, combined with alkalies or earths, but never except in very minute quantities.

69 1. Oxalic acid is eaſily detected and diſtinguiſhed by the following properties: It decompoſes all calcareous ſalts, and forms with lime a ſalt inſoluble in water. It readily cryſtallizes. Its cryſtals are quadrilateral priſms. It is totally deſtroyed by heat.

Oxalic acid was firſt detected in vegetables by Mr Scheele. It has been diſcovered in the following plants:

The leaves of the oxalis acetoſella †.
oxalis corniculata.
The root of rhubarb ‡.
The leaves of the geranium acidum §.

70 2. Tartarous acid is known by the following properties: When a little potaſs is cautiouſly dropt into a ſolution containing it, common tartar is formed, and precipitates to the bottom. Tartarous acid does not decompoſe the ſulphat, nitrat, or muriat of lime. Tartrite of lime is ſoluble in water. Tartarous acid cryſtallizes. Its cryſtals are long ſlender priſms. It is deſtroyed by heat.

Tartarous acid has been found in the following vegetable ſubſtances:

The pulp of the tamarind *.
The juice of grapes.
Mulberries †.
Rumex acetoſa, *ſorrel* †.
Rhus coriaria, *ſumach* †.
Rheum rhaponticum ‖.
Agave Americana ¶.
The roots of triticum repens †.
Leontodon taraxicum †.

71 Citric acid. 3. Citric acid is diſtinguiſhed by the following properties: It does not form tartar when potaſs is added to it. With lime it forms a ſalt inſoluble in water, which is decompoſed by ſulphuric, nitric, and muriatic acids. It readily cryſtallizes. It is deſtroyed by heat.

Citric acid has been found unmixed with other acids in the following vegetable ſubſtances*:

The juice of oranges and lemons.
The berries of vaccinium oxycoccos, *cranberry.*
——— vitis idæa, *red whortle berry.*
Prunus padus, *birdcherry.*
Solanum dulcamara, *nightſhade.*
Roſa canina, *hip.*

It occurs mixed with other acids in many other fruits.

72 Malic acid. 4. Malic acid is known by the following properties: It forms with lime a ſalt ſoluble in water, which is decompoſed by citric acid. It does not form tartar with potaſs. It is incryſtallizable. Heat deſtroys it.

Malic acid has been found, by Scheele †, in the fruits of the following plants, which contain no other acid:

Apples.
Berberis vulgaris, *barberry.*
Prunus domeſtica, *plum.*
——— ſpinoſa, *ſloe.*
Sambucus nigra, *elder.*
Sorbus aucuparia, *roan* or *ſervice.*

73 Malic and citric. In the following fruits he found nearly an equal quantity of malic and citric acids ‡.

Ribes groſſularia, *gooſeberry.*
——— rubrum, *currants.*
Vaccinium myrtillus, *bleaberry.*
Crategus aria, *beam.*
Prunus ceraſus, *cherry.*
Fragaria veſca, *ſtrawberry.*
Rubus chamæmorus, *cloudberries, evrochs.*
——— idæus, *raſpberry.*

Malic acid has alſo been found in the agave americana §, and in the pulp of tamarinds ‖. In the firſt of theſe it is mixed with tartarous acid; in the ſecond with tartarous and citric acids.

74 Gallic acid. 5. Gallic acid is known by the following properties: With the brown oxyd of iron it produces a black colour. It is cryſtallizable. Heat deſtroys it. It has been found in a great number of plants, chiefly in the bark.—The following table, drawn up by Mr Biggin *, will ſerve to ſhew the relative proportions of this acid in different plants:

Elm - - -	7	Sallow - -	8
Oak cut in winter -	8	Mountain aſh -	8
Horſe cheſnut -	6	Poplar - -	8
Beech - -	7	Hazel - - -	9
Willow (boughs) -	8	Aſh - -	10
Elder - -	4	Spaniſh cheſnut -	10
Plum tree - -	8	Smooth oak -	10
Willow (trunk) -	9	Oak cut in ſpring -	10
Sycamore - -	6	Huntingdon or Leiceſter willow	10
Birch - -	4		
Cherry tree -	8	Sumach - -	14

75 Benzoic acid. 6. Benzoic acid is diſtinguiſhed by its aromatic odour, and its volatility on the application of a very moderate heat. It has been found hitherto only in three vegetable ſubſtances, to which the French chemiſts have confined the term *balſam.* Theſe three are, *benzoin, balſam of tolu,* and *ſtorax.* In theſe ſubſtances it ſeems to be combined with a reſin, or ſomething which has nearly the properties of a reſin.

3 Y 2 7. Phoſ-

---

76 Phoſphoric acid.

7. Phoſphoric acid is eaſily diſtinguiſhed from the former ſix, for it is very fixed, and a violent heat does not deſtroy it as it does the others.

Phoſphoric acid has been found in different plants, but only in very ſmall quantities; it is almoſt conſtantly combined with lime. Meyer found it in the leaves of many trees*; Thuren found phoſphat of lime in the Aconitus Napellus†; and Bergmann found it in all kinds of grain‡.

* *Enc. Meth Phyſiol Veget.* i. 100

† *Ann de Chim.* ii 308.

‡ *Bergman*, v. 96.

SECT. XVI. *Of ALKALIES.*

THE only alkalies found in plants are potaſs and ſoda. Ammonia may indeed be obtained by diſtilling many vegetable ſubſtances, but it is produced during the operation. One or other of theſe alkalies is found in every plant which has hitherto been examined. The quantity indeed is uſually very ſmall.

77 Proportion of potaſs in plants.

1. Potaſs is found in almoſt all plants which grow at a diſtance from the ſea. It may be extracted by burning the vegetable, waſhing the aſhes in water, filtrating the water, and evaporating it to dryneſs. It is in this manner that all the potaſh of commerce is procured.

The following table exhibits the quantity of aſhes and potaſs which may be extracted from 100 parts of various plants:

	Aſhes.	*Potaſs.*
Sallow - -	2.8	0.285*(c)
Elm - - -	2.36727	0.39*
Oak - - -	1.35185	0.15343
Poplar - -	1.23476	0.07481
Hornbeam - - -	1.1283	0.1254
Beech - - -	0.58432	0.14572
Fir - - -	0.34133	
Vine branches -	3 379	0.55*
Common nettle -	10.67186	2.5033
Common thiſtle -	4.04265	0.53734
Fern - -	5.00781	0.6259
Cow thiſtle - -	10.5	1.96603
Great river ruſh -	3.85395	0.72234
Feathered ruſh - -	4.33593	0.50811
Stalks of turkey wheat -	8.86	1.75*
Wormwood - -	9.744	7.3*
Fumitory - -	21.9	7.9*
Trifolium pratenſe - -		0.078*
Vetches - - - -		2.75*
Beans with their ſtalks - -		2.0*

In general, three times as much aſhes are obtained from ſhrubs, and five times as much from herbs, as from trees. Equal weights of the branches of trees produce more aſhes than the trunk, and the leaves more than the branches. Herbs arrived at maturity produce more aſhes than at any other time. Green vegetables produce more aſhes than dry†.

† *Ann. de Chim.* xix. 174.

The ſalt which is obtained from plants does not conſiſt wholly of potaſs, there are other ſalts mixed with it; theſe uſually are ſulphat of potaſs, muriat of potaſs, ſulphat of lime, phoſphat of lime, &c.; but theſe bear, in general, but a ſmall proportion to the potaſs. The aſhes conſiſt of potaſs mixed with earths.

Some judgment may be formed of the quantity of potaſs which a plant contains from the quantity of aſhes which it yields: but the above table is ſufficient to ſhew us, that were we to truſt to that we would often be miſled.

78 Soda.

2. Soda is found in almoſt all the plants which grow in the ſea, and in many of thoſe which grow on the ſhore. In general, the quantity of ſoda which plants contain bears a much greater proportion to their weight than the potaſs does which is found in inland vegetables. 100 parts of the *ſalſola ſoda*, for inſtance, yield 19.921 of aſhes; and theſe contain 1.992 parts of ſoda, ſome of which, however, is combined with muriatic acid*. The plants from which the greater part of the ſoda, or *barilba*, as it is called, which is imported from Spain, is extracted, are the *ſalſola ſativa*, and *vermiculata*.

* *Vauquelin, Ann. de Chim.* xviii. 77.

SECT. XVII. *Of EARTHS.*

THE only earths hitherto found in plants are the four following; *lime, ſilica, magneſia, alumina.*

79 Lime.

1. Lime is uſually the moſt abundant of the earths of plants, and the moſt generally diffuſed over the vegetable kingdom. Indeed, it is a very uncommon thing to find a plant entirely deſtitute of lime: ſalſola ſoda is almoſt the only one in which we know for certain that this earth does not exiſt*.

* *Id. ibid.*

80 Silica.

2. Silica exiſts alſo in many plants, particularly graſſes and equiſetums. Mr Davy has aſcertained, that it forms a part of the epidermis, or outermoſt bark of theſe plants; and that in ſome of them almoſt the whole epidermis is ſilica.

		Parts Silica.
100 parts of the epid. of bonnet-cane yielded		90
	bamboo	71.4
(arundo phragm.)	common reed	48.1
	ſtalks of corn	6.5

The concretions which are ſometimes found in the bamboo cane have been aſcertained by Mr Macie to be compoſed of pure ſilica.

81 Magneſia.

3. Magneſia does not exiſt ſo generally in the vegetable kingdom as the two preceding earths. It has been found, however, in conſiderable quantities in ſeveral ſea plants, eſpecially fuci†. But the ſalſola ſoda contains a greater proportion of magneſia than any plant hitherto examined. Mr Vauquelin found that 100 parts of it contained 17.929 of that earth‡.

† *Id. ibid.* 80. and i 94.

‡ *Ibid.* 78.

82 Alumina.

4. Alumina has only been found in very ſmall quantities in plants.

83 Proportio of earth i plants.

The following table will ſhew the quantity of theſe four earths which exiſt in ſeveral vegetables.

100 parts of oak contain of earths	1.03*
Beech - -	0.453†
Fir - -	0.003†
Turkey wheat -	7.11†
Sunflower -	3.72†

This

(c) Thoſe marked * are from *Kirwan, Iriſh Tranſ.* v. 164. The reſt from *Pertuis, Ann. de Chim.* 19. 178.

Metals.

This table ſhews us, that the quantity of earth is greater in herbs than in trees.

Bergman found all the four earths in every kind of grain which he analyſed*.

Vauquelin found, that 100 parts of oat grain left 3.1591 of reſiduum. This reſiduum is compoſed of

60 7 ſilica,
39 3 phoſphat.

100.0†.

When the whole of the avena ſativa, however, ſtalk and ſeed together, are burnt, they leave a reſiduum compoſed of

55 ſilica,
15 phóſphat of lime,
20 potaſs,
5 carbonat of lime.

95, and a little oxyd of iron‡.

This ſhews us that the ſtalk contains ſeveral ſubſtances not to be found in the grain.

Sect. XVIII. *Of Metals.*

Several metallic ſubſtances have alſo been found in vegetables, but their quantity is exceedingly ſmall; ſo ſmall, indeed, that without very delicate experiments their preſence cannot even be detected.

84 hree me- ls found plants.

The metals hitherto diſcovered are iron, which is by far the moſt common, manganeſe, and gold.

Scheele firſt detected manganeſe in vegetables*. Prouſt found it in the aſhes of the pine, calendula, vine, green oak, and fig-tree†. M. Sage has ſhewn, that gold exiſts in many plants. Iron exiſts in moſt plants. The aſhes of ſome ſpecies of ſalſola contain a conſiderable quantity of it.

85 nple ſub- ces con- ned in nts.

We have now taken a ſurvey of all the ſubſtances which have hitherto been obtained from vegetables: by analyſing each of theſe, we come at laſt to thoſe bodies which we are at preſent obliged to conſider as ſimple, becauſe they have not yet been decompoſed, and of which accordingly we muſt ſuppoſe that vegetables are ultimately compoſed. Theſe bodies amount ot 16, namely,

1. Oxygen,
2. Sulphur,
3. Phoſphorus
4. Carbon,
5. Hydrogen,
6. Azot,
7. Iron,
8. Manganeſe,
9. Gold,
10. Lime,
11. Magneſia,
12. Silica,
13. Alumina,
14. Potaſs,
15. Soda,
16. Muriatic acid.

But of theſe ſubſtances there are twelve which compoſe but a very ſmall proportion indeed of vegetables. Almoſt the whole of vegetable ſubſtances are compoſed of four ingredients, namely,

Carbon, Oxygen,
Hydrogen, Azot.

Of theſe the laſt, namely azot, forms but a ſmall proportion even of thoſe vegetable ſubſtances of which it is a conſtituent part, while into many it does not enter at all: So that, upon the whole, by far the greater part of vegetable ſubſtances is compoſed of carbon, hydrogen, and oxygen. We do not mention caloric and light, concerning the nature of which too little is known to enable us to determine with certainty into what ſubſtances they enter.

Vegetation.

The ſubſtances at preſent known to chemiſts, which they have not been hitherto able to decompoſe, amount (omitting caloric and light) to 40. Sixteen of theſe exiſt in plants; the other 24 belong excluſively to the mineral kingdom: for it is a fact, that no ſubſtance (we mean ſimple ſubſtance) has been hitherto found in the animal kingdom which does not exiſt alſo in vegetables.

On the contrary, all the ſimple ſubſtances at preſent known may be found in minerals. This indeed ought not to ſurpriſe us, if we recollect, that the ſpoils of animals and vegetables, after they have undergone decompoſition, are ultimately confounded with minerals, and conſequently arranged under the mineral kingdom. Beſides, as vegetables draw all their food from the mineral kingdom, it would be abſurd to ſuppoſe that they contain ſubſtances which they could not have procured from minerals. It muſt follow, therefore, of neceſſity, that minerals contain all the ſimple ſubſtances which exiſt in this globe of our's; and that plants owe their diverſity merely to different modifications of thoſe principles which they imbibe from the ſoil. But it is impoſſible to have any preciſe notions about a ſubject ſo intricate, without conſidering with ſome attention the ſtructure of vegetables, the food which they imbibe, and the changes which they produce on that food. Theſe enquiries ſhall form the ſubject of the next chapter; in which we propoſe to take a view of thoſe phenomena of vegetation which are connected with chemiſtry, or which may be elucidated by the application of the principles of that ſcience.

Chap. II. Of Vegetation.

We have now ſeen the different ſubſtances which are contained in plants; but we have ſtill to examine the manner in which theſe ſubſtances are produced, and to endeavour to trace the different proceſſes which conſtitute vegetation. We muſt warn our readers not to expect complete information in this chapter. The wonders of the vegetable kingdom are ſtill but very imperfectly explored; many of the organs of plants are too minute for our ſenſes; and ſcarcely a ſingle proceſs can be completely traced.

86 Phenomena of vegetation very numerous.

The multiplicity of operations continually going on in vegetables at the ſame time, and the variety of different, and even oppoſite ſubſtances, formed out of the ſame ingredients, and almoſt in the ſame place, aſtoniſh and confound us. The order, too, and the ſkill with which every thing is conducted, are no leſs ſurpriſing. No two operations claſh; there is no diſcord, no irregularity, no diſturbance; every object is gained, and every thing is ready for its intended purpoſe. This is too wonderful to eſcape our obſervation, and of too much importance not to claim our attention. Many philoſophers, accordingly, diſtinguiſhed equally by their induſtry and ſagacity, have dedicated a great part of their lives to the ſtudy of *vegetation*. But hitherto their ſucceſs has not been equal to their exertions. No perſon has been able to detect this *agent*, always ſo buſy, and performing ſuch wonders, or to diſcover him at his work; nor have philoſophers been much more fortu-

Vegetation.

nate in their attempts to aſcertain the inſtruments which he employs in his operations. A great variety, however, of curious and intereſting facts, have been diſcovered. Theſe we ſhall attempt in this chapter to collect and arrange, to point out their dependence on each other, and perhaps to deduce ſuch conſequences as obviouſly reſult from this mutual dependence.

87 Plants ariſe from ſeed.

1. Natural hiſtorians have proved, by a very complete induction of facts, that all plants ariſe from *ſeeds*. The pretended exceptions have diſappeared, one after another, as our knowledge of vegetables increaſed: and now there remains ſcarcely a ſingle objection entitled to the ſmalleſt regard. The late attempt of Girtanner * to revive the doctrine of equivocal generation, deſerves no attention whatever; becauſe his concluſions are abſolutely incompatible with the *experiments* of Mr Senebier upon the very ſubſtance on which his theory is founded.

88 Seeds compoſed of three parts.

A SEED conſiſts of three parts; namely, the *cotyledons*, the *radicle*, and the *plumula*, which are uſually incloſed in a cover.

If we take a garden bean, we may perceive each of theſe three parts with great eaſe; for this ſeed is of ſo large a ſize, that all its organs are exceedingly diſtinct.

When we ſtrip off the external coats of the bean, which are two, and of different degrees of thickneſs in different parts, we find that it eaſily divides into two lobes, pretty nearly of the ſame ſize and figure. Each of theſe lobes is called a *cotyledon* (fig. 1. *a*). The cotyledons of the bean, then, are two in number.

Plate XLIII.

Near that part of the lobes which is contiguous to what is called the *eye* of the bean, there is a ſmall round white body *(b)*, which comes out between the two lobes. This body is called the *radicle*.

Attached to the radicle, there is another ſmall round body *(c)*, which lies between the cotyledons and wholly within them, ſo that it cannot be ſeen till they are ſeparated from each other. This body is called the *plumula*.

The appearance and ſhape of theſe three parts differ very much in different ſeeds, but there is no ſeed which wants them. The figure and ſize of the ſeed depend chiefly upon the cotyledons. This is evidently the caſe with the bean, and it is ſo with all other ſeeds. The number of cotyledons is different in different ſeeds. Some ſeeds have only one cotyledon, as the ſeeds of wheat, oats, barley, and the whole tribe of graſſes: ſome have three; others ſix, as the ſeeds of the garden graſs; but moſt ſeeds, like the bean, have two cotyledons.

89 Germination of ſeeds

2. When a ſeed is placed in a ſituation favourable to vegetation, it very ſoon changes its appearance. The radicle is converted into a root, and ſinks into the earth; the plumula, on the other hand, riſes above the earth, and becomes the trunk or ſtem. When theſe changes take place, the ſeed is ſaid to *germinate:* the proceſs itſelf has been called *germination*. Seeds do not germinate equally and indifferently in all places and ſeaſons. Germination, therefore, is a proceſs which does not depend upon the ſeed alone; ſomething external muſt alſo affect it.

90 Requires moiſture,

3. It is a well known fact, that ſeeds will not germinate unleſs *moiſture* have acceſs to them; for ſeeds, if they are kept perfectly dry, never vegetate at all, and yet their power of vegetating is not deſtroyed. There are indeed ſome apparent objections to this: potatoes, for inſtance, and other bulbous bodies, germinate, tho' kept ever ſo dry. But the reaſon of this is, that theſe bodies (which are not ſeeds, though they reſemble them in ſome particulars) have a ſufficient quantity of water within themſelves to give a beginning to germination. We may conclude, then, that no ſeed will germinate unleſs water has acceſs to it. *Water*, then, is eſſential to germination. Too much water, however, is no leſs prejudicial to moſt ſeeds than none at all. The ſeeds of water plants, indeed, germinate and vegetate extremely well in water; but moſt other ſeeds, if they are kept in water beyond a certain time, are rotted and deſtroyed altogether.

91 Heat,

4. It is well known alſo, that ſeeds will not germinate, even though ſupplied with water, provided the temperature be below a certain degree. No ſeed, for inſtance, on which the experiment has been tried, can be made to vegetate at or below the freezing point: yet this degree of cold does not injure the vegetating power of ſeeds; for many ſeeds will vegetate as well as ever after having been frozen, or after having been kept in frozen water. We may conclude, then, that a certain degree of heat is neceſſary for the germination of ſeeds. And every ſpecies of plants ſeems to have a degree peculiar to itſelf, at which its ſeeds begin to germinate; for we find that almoſt every ſeed has a peculiar ſeaſon at which it begins to germinate, and this ſeaſon varies always according to the temperature of the air. Mr Adanſon found that ſeeds, when ſown at the ſame time in France and in Senegal, always appeared ſooner above ground in the latter country, where the climate is hotter, than in France §.

92 And oxygen gas.

5. Seeds, although ſupplied with moiſture, and placed in a proper temperature, will not germinate, provided atmoſpherical air be completely excluded from them. Mr Ray found that grains of lettuce did not germinate in the vacuum of an air-pump, but they began to grow as ſoon as air was admitted to them †. Homberg made a number of experiments on the ſame ſubject, which were publiſhed in the Memoirs of the French Academy for the year 1693. He found, that the greater number of ſeeds which he tried refuſed to vegetate in the vacuum of an air-pump. Some, however, did germinate; but Boyle, Muſchenbroek, and Boerhaave, who made experiments on the ſame ſubject in ſucceſſion, proved beyond a doubt that no plant vegetates in the vacuum of an air-pump; and that in thoſe caſes in which Homberg's ſeeds germinated, the vacuum was far from perfect, a quantity of air ſtill remaining in the receiver. It follows, therefore, that no ſeed will germinate unleſs atmoſpherical air, or ſome air having the ſame properties, have acceſs to it. It is for this reaſon that ſeeds will not germinate at a certain depth below the ſurface of the earth.

Mr Scheele found that beans would not germinate except oxygen gas were preſent; Mr Achard afterwards proved, that oxygen gas is abſolutely neceſſary for the germination of all ſeeds, and that no ſeed will germinate in azotic gas, or hydrogen gas, or carbonic acid gas, unleſs theſe gaſes contain a mixture of oxygen gas. Theſe experiments have been confirmed by Mr

---

* Ann. de Chim. xxxiv. 35.

§ Enc. Meth. Phyſiol. Veget. 124.

† Phil. Tranſ. N° 53.

Mr Gough, Mr Cruickſhank, and many other philoſophers. It follows, therefore, that it is not the whole atmoſpheric air, but merely the oxygen gas which it contains, that is neceſſary for the germination of ſeeds.

93
jured by
e pre-
nce of
ght.

6. Seeds do not germinate equally well when they are expoſed to the light, and when they are kept in a dark place; light therefore has ſome effect on germination.

Mr Ingenhouſz found, that ſeeds always germinate faſter in the dark than when expoſed to the light *. His experiments were repeated by Mr Senebier with equal ſucceſs †; and it was concluded, in conſequence of their experiments, that light is injurious to germination. But the Abbé Bertholin, who diſtinguiſhed himſelf ſo much by his labours to demonſtrate the effect of electricity on vegetation, objected to the concluſions of theſe philoſophers, and affirmed, that the difference in the germination of ſeeds in the ſhade and in the light was owing, not to the light itſelf, but to the difference of the moiſture in the two ſituations; the moiſture evaporating much faſter from the ſeeds in the light than from thoſe in the ſhade; and he affirmed, that when precautions were taken to keep the ſeeds equally moiſt, thoſe in the ſun germinated ſooner than thoſe in the ſhade ‡. But when Mr Senebier repeated his former experiments, and employed every poſſible precaution to enſure the equality of moiſture in both ſituations, he conſtantly found the ſeeds in the ſhade germinate ſooner than thoſe in the light §. We may conclude, therefore, that light is injurious to germination; and hence one reaſon for covering ſeeds with the ſoil in which they are to grow.

7. Thus we have ſeen that ſeeds will not germinate unleſs *moiſture*, *heat*, and *oxygen gas*, be preſent; and that they do not germinate well if they are expoſed to the action of *light*. Now, in what manner do theſe ſubſtances affect the ſeed? What are the changes which they produce?

94
enome-
of ger-
nation.

We obſerved before, that all ſeeds have one or more cotyledons. Theſe cotyledons contain a quantity of farinaceous matter, laid up on purpoſe to ſupply the embryo plant with food as ſoon as it begins to require it. This food, however, muſt undergo ſome previous preparation, before it can be applied by the plant to the formation or completion of its organs. Now all the phenomena of germination which we can perceive conſiſt in the chemical changes which are produced in that food, and the conſequent developement of the organs of the plant.

95
e coty-
ons pre-
re food,

When a ſeed is placed in favourable circumſtances, it gradually imbibes moiſture, and very ſoon after emits a quantity of carbonic acid gas, even though no oxygen gas be preſent *. This ſeems to prove, as Mr Cruickſhank has ſuppoſed, that ſome of the water imbibed by the ſeed is decompoſed, that its oxygen combines with part of the carbon of the farina, and goes off in the form of carbonic acid gas, while the hydrogen remains behind, and combines with the ingredients contained in the cotyledon. The firſt part of germination, then, conſiſts in diminiſhing the quantity of carbon, and increaſing the hydrogen of the farina. If no oxygen gas be preſent, the proceſs ſtops here, and no germination takes place.

But if oxygen gas be preſent, it is gradually abſorbed and retained by the ſeed; and at the ſame time, the farina of the cotyledons aſſumes a ſweet taſte reſembling ſugar: it is therefore converted into ſugar, or ſome ſubſtance analogous to it †. Farina, then, is changed into ſugar, by diminiſhing its carbon, and augmenting the proportion of its hydrogen and oxygen. This is preciſely the proceſs of malting, or of converting grain into malt; during which it is well known that there is a conſiderable heat evolved; ſo much indeed, that in certain circumſtances grain improperly kept has even taken fire. We may conclude from this, that during the germination of ſeeds in the earth there is alſo an evolution of a conſiderable portion of heat. This indeed might have been expected, as it uſually happens when oxygen gas is abſorbed.

So far ſeems to be the work of chemiſtry alone; at leaſt we have no right to conclude that any other agent interferes; ſince *hay*, when it happens to imbibe moiſture, exhibits nearly the ſame proceſſes. Carbonic acid gas is evolved, oxygen gas is abſorbed, heat is produced ſo abundantly, that the hay often takes fire: at the ſame time a quantity of ſugar is formed. It is owing to a partial change of the ſame kind that old hay generally taſtes much ſweeter than new hay. Now we have no reaſon to ſuppoſe that any agents peculiar to the vegetable kingdom reſide in hay; as all vegetation, and all power of vegetating, are evidently deſtroyed.

96
Which paſſes into the radicle,

But when the farina in the ſeeds of vegetables is converted into ſugar, a number of veſſels make their appearance in the cotyledon. The reader will have a pretty diſtinct notion of their diſtribution, by inſpecting fig. 2. Theſe veſſels may indeed be detected in many ſeeds before germination commences, but they become much more diſtinct after it has made ſome progreſs. Branches from them have been demonſtrated by Grew, Malpighi, and Hedwig, paſſing into the radicle, and diſtributed through every part of it. Theſe evidently carry the nouriſhment prepared in the cotyledons to the radicle; for if the cotyledons be cut off even after the proceſſes above deſcribed are completed, germination, as Bonnet and Senebier aſcertained by experiment, immediately ſtops.

97
And converts it into a root.

The food therefore is conveyed from the cotyledons into the radicle, the radicle increaſes in ſize, aſſumes the form of a *root*, ſinks down into the earth, and ſoon becomes capable of extracting the nouriſhment neceſſary for the future growth of the plant. Even at this period, after the radicle has become a perfect root, the plant, as Senebier aſcertained by experiment, ceaſes to vegetate if the *cotyledons* be cut off. They are ſtill then abſolutely neceſſary for the vegetation of the plant.

98
Cotyledons become ſeminal leaves,

The cotyledons now aſſume the appearance of leaves, and appear above the ground, forming what are called the *ſeminal leaves* of the plant. After this the *plumula* gradually increaſes in ſize, riſes out of the earth, and expands itſelf into branches and leaves. The ſeminal leaves, ſoon after this, decay and drop off, and the plant carries on all the proceſſes of vegetation without their aſſiſtance.

Mr Eller attempted to ſhew, that there is a veſſel in ſeeds which paſſes from the cotyledons to the plumula; but later anatomiſts have not been able to perceive any ſuch veſſel. Even Mr Hedwig, one of the moſt patient, acute, and ſucceſsful philoſophers that ever turned their attention to the ſtructure of vegetables, could

never

---

* *Experi-ce ſur les Vegetaux*, ii.

† *Mem. byſico-imique*, iii 41.

‡ *Jour. de byſ.* 1789, ecemb.

§ *Enc Meth. byſiol. Ve-t.* 126.

* *Gough*, *ancb. Mem.* iv. 5. *Cruik-ank, Rollo Diabetes*, 452.

† *Ibid.*

never diſcover any ſuch veſſel, although he traced the veſſels of the cotyledons even through the radicle. As it does not appear, then, that there is any communication between the cotyledons and the plumula, it muſt follow that the nouriſhment paſſes into the plumula from the radicle: and accordingly we ſee, that the plumula does not begin to vegetate till the radicle has made ſome progreſs. Since the plant ceaſes to vegetate, even after the radicle has been converted into a root, if the cotyledons be removed before the plumula is developed, it follows, that the radicle is inſufficient of itſelf to carry on the proceſſes of vegetation, and that the cotyledons ſtill continue to perform a part. Now we have ſeen already what that part is: they prepare *food* for the nouriſhment of the plant. The root, then, is of itſelf inſufficient for this purpoſe. When the cotyledons aſſume the form of ſeminal leaves, it is evident that the nouriſhment which was originally laid up in them for the ſupport of the embryo plant is exhauſted, yet they ſtill continue as neceſſary as ever. They muſt therefore receive the nouriſhment which is imbibed by the root; they muſt produce ſome changes on it, render it ſuitable for the purpoſes of vegetation, and then ſend it back again to be tranſmitted to the plumula.

99
Which prepare the food ſent from the root.

After the plumula has acquired a certain ſize, which muſt be at leaſt a *line*, if the cotyledons be cut off, the plant, as Mr Bonnet aſcertained by a number of experiments, afterwards repeated with equal ſucceſs by Mr Senebier, does not ceaſe to vegetate, but it continues always a mere pigmy ; its ſize, when compared with that of a plant whoſe cotyledons are allowed to remain, being only as 2 to 7*.

100
Plumula forms the ſtem and leaves.

When the plumula has expanded completely into leaves, the cotyledons may be removed without injuring the plant, and they very ſoon decay of themſelves. It appears, then, that this new office of the cotyledons is afterwards performed by that part of the plant which is above ground.

Thus we have traced the phenomena of germination as far as they have been detected. The facts are obvious; but the *manner* in which they are produced is a profound ſecret. We can neither explain how the food enters into the veſſels, how it is conveyed to the different parts of the plant, how it is depoſited in every organ, nor how it is employed to increaſe the ſize of the old parts, or to form new parts. Theſe phenomena are analogous to nothing in mechanics or chemiſtry. He that attempts to explain them on the principles of theſe ſciences, merely ſubſtitutes new meanings of words inſtead of old ones, and gives us no aſſiſtance whatever in conceiving the proceſſes themſelves. As the ſubſtances employed in vegetation are all material, it is evident that they poſſeſs the properties of matter, and that they are arranged in the plant according to theſe laws. It follows, therefore, that all the changes which take place in the plant are produced according to the known laws of mechanics and chemiſtry. This cannot be diſputed: but it explains nothing; for what we want to know is the *agent* that brings every particle of matter to its proper place, and enables the laws of chemiſtry and mechanics to act only in order to accompliſh a certain end. Who is the agent that acts according to this end? To ſay that it is chemiſtry or mechanics is to pervert the uſe of words. For what are the laws of chemiſtry and mechanics? Are they not certain fixed and unalterable properties of matter? Now, to ſay that a property of matter has an end in view, or that it acts in order to accompliſh ſome deſign, is a downright abſurdity. There muſt therefore be ſome agent in all caſes of germination, which regulates and directs the mechanical and chemical proceſſes, and which therefore is neither a mechanical nor chemical property.

8. When the proceſs of germination is accompliſhed, the plant is complete in all its parts, and capable of vegetating in a proper ſoil, for a time and with a vigour proportional to its nature.

101
Plants compoſed of bark, wood, and pith.

Plants, as every body knows, are very various, and of courſe the ſtructure of each ſpecies muſt have many peculiarities. Trees have principally engaged the attention of anatomiſts, on account of their ſize and the diſtinctneſs which they expected to find in their parts. We ſhall therefore take a tree as an inſtance of the ſtructure of plants; and we ſhall do it the more readily, as the greater number of vegetables are provided with analogous organs, dedicated to ſimilar uſes.

A TREE is compoſed of a *root*, a *trunk*, and *branches*; the ſtructure of each of which is ſo ſimilar, that a general deſcription of their component parts will be ſufficient. Each of them conſiſts of three parts, the *bark*, the *wood*, and the *pith*.

102
Bark.

The BARK is the outermoſt part of the tree. It covers the whole plant from the extremity of the roots to the extremity of the branches. It is uſually of a green colour: if a branch of a tree be cut acroſs, the bark is eaſily diſtinguiſhed from the reſt of the branch by this colour. If we inſpect ſuch a horizontal ſection with attention, we ſhall perceive that the bark itſelf is compoſed of three diſtinct bodies, which, with a little care, may be ſeparated from each other. The outermoſt of theſe bodies is called the *epidermis*, the middlemoſt is called the *parenchyma*, and the innermoſt, or that next the wood, is called the *cortical layers*.

103
Compoſed of epidermis,

The *epidermis* is a thin tranſparent membrane, which covers all the outſide of the bark. It is pretty tough. When inſpected with a microſcope, it appears to be compoſed of a number of ſlender fibres croſſing each other, and forming a kind of network. It ſeems even to conſiſt of different thin retiform membranes, adhering cloſely together. This, at leaſt, is the caſe with the epidermis of the birch, which Mr Duhamel ſeparated into ſix layers. The epidermis, when rubbed off, is reproduced. In old trees it cracks and decays, and new epidermes are ſucceſſively formed. This is the reaſon that the trunks of many old trees have a rough ſurface.

104
Parenchyma,

The *parenchyma* lies immediately below the epidermis; it is of a deep green colour, very tender, and ſucculent. When viewed with a microſcope, it ſeems to be compoſed of fibres which croſs each other in every direction, like the fibres which compoſe a hat. Both in it and the epidermis there are numberleſs interſtices, which have been compared to ſo many ſmall bladders.

105
And cortical layer

The *cortical layers* form the innermoſt part of the bark, or that which is next to the wood. They conſiſt of ſeveral thin membranes, lying the one above the other; and their number appears to increaſe with the age of the plant. Each of theſe layers is compoſed of longitudinal fibres, which ſeparate and approach each other alternately, ſo as to form a kind of network. The meſhes of this network correſpond in each of the layers;

---

* Enc. Meth. Phyſiol Veget. 42.

egeta-
ion.

ers; and they become ſmaller and ſmaller in every layer as it approaches the wood. Theſe meſhes are filled with a green coloured cellular ſubſtance, which has been compared by anatomiſts to a number of bladders adhering together, and communicating with each other.

106
od com-
ed of

The WOOD lies immediately under the bark, and forms by far the greateſt part of the trunk and large branches of trees. It conſiſts of concentric layers, the number of which increaſes with the age of the part. Each of theſe layers, as Mr Du Hamel aſcertained, may be ſeparated into ſeveral thinner layers, and theſe are compoſed chiefly of longitudinal fibres. Hence the reaſon that wood may be much more eaſily ſplit aſunder than cut acroſs.

The *wood*, when we inſpect it with attention, is not, through its whole extent, the ſame; the part of it next the bark is much ſofter and whiter, and more juicy than the reſt, and has for that reaſon obtained a particular name: it has been called the *alburnum* or *aubier*. The *perfect wood* is browner, and harder, and denſer, than the alburnum, and the layers increaſe in denſity the nearer they are to the centre. Sir John Hill gave to the innermoſt layer of wood the name of *corona*, or rather he gave this name to a thin zone which, according to him, lies between the wood and the pith.

107
burnum
d perfect
ood.

108
th.

The PITH occupies the centre of the wood. It is a very ſpongy body, containing a prodigious number of cells, which anatomiſts have compared to bladders. In young ſhoots it is very ſucculent; but it becomes dry as the plant advances, and at laſt in the large trunks of many trees diſappears altogether.

109
eaves.

The LEAVES are attached to the branches of plants by ſhort footſtalks. From theſe footſtalks a number of fibres iſſue, which ramify and communicate with each other in every part of the leaf, and form a very curious network. Theſe fibres may be obtained ſeparately, by keeping the leaf long in moiſture. Every other part of it putrefies and falls off, or may eaſily be rubbed off, and only the fibres remain, conſtituting a ſkeleton of the leaf. In every leaf there are two layers of theſe fibres, forming two diſtinct ſkeletons, which had conſtituted the upper and under ſurface of the leaf.

The whole leaf is covered with the epidermis of the plant; and this epidermis, as Sauſſure has ſhewn, contains in it a great number of glands. The other parts of the bark may alſo be traced on many leaves; at leaſt Sauſſure has ſhewn, that the *bark* of leaves is compoſed of two different layers. The interſtices between the fibres of the leaf are filled up by a pulpy-like ſubſtance, to which the green colour of the leaf is owing.

Such is a ſhort deſcription of the moſt conſpicuous parts of plants. A more minute account would have been foreign to the ſubject of the preſent article.

110
lants in-
reaſe in
ze.

9. Plants, after they have germinated, do not remain ſtationary, but are continually increaſing in ſize. A tree, for inſtance, every ſeaſon, adds conſiderably to its former bulk. The root ſends forth new ſhoots, and the old ones become larger and thicker. The ſame increment takes place in the branches and the trunk. When we examine this increaſe more minutely, we find that a new layer of wood, or rather of alburnum, has been added to the tree in every part, and this addition has been made juſt under the bark. We find, too, that a layer of alburnum has aſſumed the appearance of perfect wood. Beſides this addition of vegetable fibre, a great number of leaves have been produced; and the tree puts forth flowers, and forms ſeeds.

Vegetation.

111
Therefore
require
food.

It is evident from all this, that a great deal of new matter is continually making its appearance in plants. Hence, ſince it would be abſurd to ſuppoſe that they *create* new matter, it muſt follow that they receive it by ſome channel or other. Plants, then, require food as well as animals. Now, what is this food, and whence do they derive it? Theſe queſtions can only be anſwered by an attentive ſurvey of the ſubſtances which are contained in vegetables, and an examination of thoſe ſubſtances which are neceſſary for their vegetation. If we could ſucceed completely, it would throw a great deal of light upon the nature of ſoils and of manures, and on ſome of the moſt important queſtions in agriculture. But we are far indeed at preſent from being able to examine the ſubject to the bottom.

112
Water neceſſary.

10. In the firſt place, it is certain that plants will not vegetate without water; for whenever they are deprived of it, they wither and die. Hence the well known uſe of rains and dews, and the artificial watering of ground. We may conclude, then, that water is at leaſt an eſſential part of the food of plants.

But many plants grow in pure water; and therefore it may be queſtioned whether water is not the only food of plants. This opinion was adopted very long ago, and numerous experiments have been made in order to demonſtrate it. Indeed, it was the general opinion of the 17th century; and ſome of the moſt ſucceſsful improvers of the phyſiology of plants, in the 18th century, have embraced it. The moſt zealous advocates for it were, Van Helmont, Boyle, Bonnet, Duhamel, and Tillet.

113
Suppoſed
the whole
food of
plants;

Van Helmont planted a willow which weighed five pounds, in an earthen veſſel filled with ſoil previouſly dried in an oven, and moiſtened with rain water. This veſſel he ſunk into the earth, and he watered his willow, ſometimes with rain, and ſometimes with diſtilled water. After five years it weighed 169½ lbs. and the earth in which it was planted, when again dried, was found to have loſt only two ounces of its original weight. Here, it has been ſaid, was an increaſe of 164 lb. and yet the only food of the willow was pure water; therefore it follows that pure water is ſufficient to afford nouriſhment to plants. The inſufficiency of this experiment to decide the queſtion was firſt pointed out by Bergman in 1773 *. He ſhewed, from the experiments of Margraff, that the rain water employed by Van Helmont contained in it as much earth as could exiſt in the willow at the end of five years. For, according to the experiments of Margraff, 1 lb. of rain water contains 1 gr. of earth †. The growth of the willow, therefore, by no means proves that the earth which plants contain has been formed out of water. Beſides, as Mr Kirwan has remarked ‡, the earthen veſſel muſt have often abſorbed moiſture, from the ſurrounding earth, impregnated with whatever ſubſtance that earth contained; for unglazed earthen veſſels, as Hales * and Tillet † have ſhewn, readily tranſmit moiſture.

Hence it is evident that no concluſion whatever can be drawn from this experiment; for all the ſubſtances which the willow contained, except water, may have been derived from the rain water, the earth in the pot, and the moiſture imbibed from the ſurrounding ſoil.

114
But without reaſon.

---

* *Opuſc.* v. 92.

† *Opuſc.* ii. 15. and 19.

‡ *Iriſh Tranſ.* v. 150.

* *Veget. Stat.* i. 5.

† *Mem. Par.* 1772. 298.

The experiments of Duhamel and Tillet are equally inconcluſive; ſo that it is impoſſible from them to decide the queſtion, Whether water be the ſole nouriſhment of plants or not? We owe the ſolution of this difficulty to the experiments of Mr Haſſenfratz, who pointed out the fallacy of thoſe juſt mentioned.

He analyſed the bulbous roots of hyacinths, in order to diſcover the quantity of water, carbon, and hydrogen, which they contained; and by repeating the analyſis on a number of bulbs, he diſcovered how much of theſe ingredients was contained in a given weight of the bulb. He analyſed alſo kidney beans and creſs ſeeds in the ſame manner. Then he made a number of each of theſe vegetate in pure water, taking the precaution to weigh them beforehand, in order to aſcertain the preciſe quantity of carbon which they contained. The plants being then placed, ſome within doors, and others in the open air, grew and flowered, but produced no ſeed. He afterwards dried them, collecting with care all their leaves and every other part which had dropt off during the courſe of the vegetation. On ſubmitting each plant to a chemical analyſis, he found that the quantity of carbon, which it contained, was ſomewhat leſs than the quantity which exiſted in the bulb or the ſeed from which the plant had ſprung *.

* *Ann. de Chim.* xiii. 188.

Hence it follows irreſiſtibly, that plants growing in pure water do not receive any increaſe of *carbon*; that the water merely ſerves as a vehicle for the carbonaceous matter already preſent, and diffuſes it thro' the plant. Water, then, is not the ſole food of plants; for all plants during vegetation receive an increaſe of carbonaceous matter, without which they cannot produce perfect ſeeds, nor even continue to vegetate beyond a certain time; and that time ſeems to be limited by the quantity of carbonaceous matter contained in the bulb or the ſeed from which they grow. For Duhamel found, that an oak which he had raiſed by water from an acorn, made leſs and leſs progreſs every year. We ſee, too, that thoſe bulbous roots, ſuch as hyacinths, tulips, &c. which are made to grow in water, unleſs they be planted in the earth every other year, refuſe at laſt to flower, and even to vegetate; eſpecially if they produce new bulbous roots annually, and the old ones decay.

115
A certain portion only proper.

So far, indeed, is water from being the ſole food of plants, that in general only a certain proportion of it is ſerviceable, too much being equally prejudicial to them as too little. Some plants, it is true, grow conſtantly in water, and will not vegetate in any other ſituation; but the reſt are entirely deſtroyed when kept immerſed in that fluid beyond a certain time. Moſt plants require a certain degree of moiſture, in order to vegetate well. This is one reaſon why different ſoils are required for different plants. Rice, for inſtance, requires a very wet ſoil: were we to ſow it in the ground on which wheat grows luxuriouſly, it would not ſucceed; and wheat, on the contrary, would rot in the rice ground.

We ſhould, therefore, in chooſing a ſoil proper for the plants which we mean to raiſe, conſider the quantity of moiſture which is beſt adapted for them, and chooſe our ſoil accordingly. Now, the dryneſs or moiſture of a ſoil depends upon two things; the nature and proportions of the earths which compoſe it, and the quantity of rain which falls upon it. Every ſoil contains at leaſt three earths, ſilica, lime, and alumina, and ſometimes alſo magneſia. The ſilica is always in the ſtate of ſand. Now ſoils retain moiſture longer or ſhorter according to the proportions of theſe earths. Thoſe which contain the greateſt quantity of ſand retain it the ſhorteſt, and thoſe which contain the greateſt quantity of alumina retain it longeſt. The firſt is a dry, the ſecond a wet ſoil. Lime and magneſia are intermediate between theſe two extremes: they render a ſandy ſoil more retentive of moiſture, and diminiſh the wetneſs of a clayey ſoil. It is evident, therefore, that, by mixing together proper proportions of theſe four earths, we may form a ſoil of any degree of dryneſs and moiſture that we pleaſe.

But whatever be the nature of the ſoil, its moiſture muſt depend in general upon the quantity of rain which falls. If no rain at all fell, a ſoil, however retentive of moiſture it be, muſt remain dry; and if rain were very frequently falling, the ſoil muſt be open indeed, if it be not conſtantly wet. The proportion of the different earths in a ſoil, therefore, muſt depend upon the quantity of rain which falls. In a rainy country, the ſoil ought to be open; in a dry country, it ought to be retentive of moiſture. In the firſt, there ought to be a greater proportion of ſand; in the ſecond, of clay.

116
Earth neceſſary;

11. Almoſt all plants grow in the earth, and every ſoil contains at leaſt ſilica, lime, alumina, and often magneſia. We have ſeen already, that one uſe of theſe earths is to adminiſter the proper quantity of water to the vegetables which grow in the ſoil. But as all plants contain earths as a part of their ingredients, is it not probable that earths alſo ſerve as a food for plants? It has not yet indeed been ſhewn, that thoſe plants which vegetate in pure water do not contain the uſual quantity of earth; but as earths are abſolutely neceſſary for the perfect vegetation of plants, as they are contained in all plants, and are even found in their juices, we can ſcarcely doubt that they are actually imbibed, though only in ſmall quantities (D).

117
And ſalts

12. We have ſeen in the laſt chapter, that all plants contain various ſaline ſubſtances; and if we analyſe the moſt fertile ſoils, and the richeſt manures, we never find them deſtitute of theſe ſubſtances. Hence it is probable that different ſalts enter as ingredients into the food of plants. It is probable alſo, that every plant abſorbs particular kinds of ſalts. Thus ſea plants yield ſoda by analyſis, while inland plants furniſh potaſs. The potaſs contained in plants has indeed been ſuppoſed to be the produce of vegetation; but this has not been proved in a ſatisfactory manner. We find potaſs in the very juices of plants, even more abundantly than in the vegetable fibres themſelves. But this ſubject is ſtill buried in obſcurity; and indeed it is extremely dif-

ficult

(D) Mr Tennant has aſcertained, that magneſia, when uncombined with carbonic acid gas, is injurious to corn when employed as a manure; and that lime, which contains a mixture of magneſia, likewiſe injures corn.—See *Phil. Tranſ.* 1799, p. 2. This important fact demonſtrates, that earths are not mere vehicles for conveying water to plants.

ficult to make deciſive experiments, on account of the very ſmall quantity of potaſs which moſt plants contain.

The phoſphorus, too, and the iron, and other metals which are found in plants, are no doubt abſorbed by them as a part of their food. We may ſuppoſe alſo, that the ſulphuric and muriatic acids, and perhaps even the nitric acid, when found in plants, are imbibed by them along with the reſt of their aliment.

Nothing is at preſent known concerning thoſe ſaline ſubſtances which form an eſſential part of the food of plants; though it has been long remarked that certain ſalts are uſeful as manures.

118 nd car-on.

13 Water, then, and earths, and perhaps alſo ſalts, form a part of the food of plants. But plants contain carbon, which cannot be derived from any of theſe ſubſtances; conſequently ſome ſubſtance or other beſides, which contains carbon, muſt conſtitute a part of the food of plants.

Mr Giobert mixed together the four earths, ſilica, alumina, lime, magneſia, in the proper proportions, to conſtitute a fertile ſoil; and after moiſtening them with water, planted ſeveral vegetables in them; but none of his plants grew well, till he moiſtened his artificial ſoil with water from a dunghill *. Now it is certain, from the experiments of Haſſenfratz, that this water contains carbon; for when evaporated, it conſtantly left behind it a reſiduum of charcoal † We know likewiſe, from a great variety of experiments, that all fertile ſoils contain a conſiderable quantity of carbonaceous matter; for all of them, when expoſed to heat, are ſuſceptible of partial combuſtion, during which a quantity of carbonic acid gas eſcapes. Thus Fourcroy and Haſſenfratz found, that 9216 parts of fertile ſoil contained 305 parts of carbon, beſides 279 parts of oil; which, from the analyſis of Lavoiſier, we may ſuppoſe to contain about 220 parts of carbon. It follows, therefore, from the experiments of theſe chemiſts ‡, that 9216 parts of ſoil contain 525 parts of carbon. But theſe 9216 parts of ſoil contained 806 parts of roots of vegetables which were excluded from the analyſis; conſequently a fertile ſoil contains (excluſive of the roots of vegetables) about one-ſixteenth of its weight of carbon.

119 Which muſt be in a particular ſtate;

But the carbon muſt exiſt in the ſoil in a particular ſtate of combination, otherwiſe it does not anſwer as food for plants: For inſtance, powdered pitcoal, mixed with earths, is not found to act, at leaſt immediately, as a manure; yet pitcoal contains a very great quantity of carbon. Farther, it appears, from the experiments of Mr Haſſenfratz, that ſubſtances employed as manures produce effects in times proportioned to their degree of putrefaction; thoſe ſubſtances which are moſt putrid producing the moſt ſpeedy effects, and of courſe ſooneſt loſing their efficacy. Having manured two pieces of the ſame kind of ſoil, the one with a mixture of dung and ſtraw highly putrefied, the other with the ſame mixture newly made, and the ſtraw almoſt freſh, he obſerved that, during the firſt year, the plants which grew on the land manured with the putrefied dung produced a much better crop than the other: but the ſecond year (no new dung being added), the ground which had been manured with the unputrified dung produced the beſt crop; the ſame thing took place the third year; after which, both ſeemed to be equally exhauſted *. Here it is evident that the putrified dung acted ſooneſt, and was ſooneſt exhauſted. It follows from this, that carbon only acts as a manure when in a particular ſtate of combination; and this ſtate, whatever it may be, is evidently produced by putrefaction. Another experiment of the ſame chemiſt renders this truth ſtill more evident. He allowed ſhavings of wood to remain for about ten months in a moiſt place till they began to putrefy, and then ſpread them over a piece of ground by way of manure. The firſt two years this piece of ground produced nothing more than others which had not been manured at all; the third year it was better, the fourth year ſtill better, the fifth year it reached its maximum of fertility; after which it declined conſtantly till the ninth, when it was quite exhauſted †. Here the effect of the manure evidently depended upon its progreſs in putrefaction.

120 And ſoluble in water.

Now what is the particular ſtate into which carbon muſt be reduced before it be fit for the food of plants? This ſubject has never been examined with attention; the different combinations of carbon having been in a great meaſure overlooked. And yet it is evident, that it is only by an accurate examination of theſe combinations, and a thorough analyſis of manures, in order to diſcover what particular combinations of carbon exiſt in them, and in what the moſt efficacious manures differ from the reſt, that we can expect to throw complete light upon the nature and uſe of manures, one of the moſt important ſubjects to which the farmer can direct his attention. We know, from the experiments of Mr Haſſenfratz, that all thoſe manures which act with efficacy and celerity contain carbon in ſuch a ſtate of combination, that it is ſoluble in water; and that the efficacy of the manure is proportional to the quantity of carbon ſo ſoluble. He found that all efficacious manures gave a brown colour to water, and that the water ſo coloured, when evaporated, left a reſiduum, which conſiſted in a great meaſure of carbon *. He obſerved, too, that the ſoil which gives the deepeſt colour to water, or which contains the greateſt quantity of carbon ſoluble in water, is, other things being the ſame, the moſt fertile.

This is not, however, to be underſtood without limitation; for it is well known that if we employ exceſſive quantities of manure, we injure vegetation inſtead of promoting it. This is the reaſon that plants will not, as Mr Duhamel found by experiment, vegetate in ſaturated ſolutions of dung †.

121 This ſtate not carbonic acid gas;

One of the combinations of carbon which is ſoluble in water, and with which we are beſt acquainted, is carbonic acid gas. It has been ſuppoſed by many philoſophers, particularly by Mr Senebier, that this gas, diſſolved in water, ſupplies plants with a great part of their carbon. But Mr Haſſenfratz, on making the experiment, found, that the plants which he raiſed in water, impregnated with carbonic acid gas, differed in no reſpect from thoſe which grew in pure water, and did not contain a particle of carbon which had not exiſted in the ſeeds from which they ſprung ‡. This experiment proves, that carbonic acid gas, diſſolved in water, does not ſerve as food for plants. It appears, however, from the experiments of Ruckert, that when plants growing in ſoil are watered daily with water impregnated with carbonic acid gas, they vegetate faſter than when this watering is omitted. He planted two beans

122 Though that gas is uſeful.

---

* Encyc. Meth. Phyſ. Veget. p. 275.

in pots of equal dimenſions, filled with garden mould. One of theſe was watered almoſt daily with diſtilled water, the other with water, every ounce of which was impregnated with half a cubic inch of carbonic acid gas. Both were placed in the open air, but in a ſituation where they were ſecure from rain. The bean treated with the water impregnated with carbonic acid gas appeared above ground nine days before the other, and produced 25 beans; whereas the other produced only 15. The ſame experiment was tried on other plants with equal ſucceſs [†]. This ſhews us that carbonic acid gas is ſomehow or other uſeful to plants when they vegetate in mould; but it gives us no information about its mode of acting. Some ſoils, we know, are capable of decompoſing it; for ſome ſoils contain the green oxyd of iron: and Gadolin has proved, that ſuch ſoils have the property of decompoſing carbonic acid gas [*]. Indeed almoſt all ſoils contain iron, either in the ſtate of the brown or the green oxyd; and Beaumé has ſhewn, that oils convert the brown oxyd of iron into the green [†]. Now dung contains a quantity of oily ſubſtance; and this is the caſe alſo with rich ſoils. One uſe of manures, therefore, may be, to reduce the brown oxyd of iron to the green, that it may be capable of decompoſing carbonic acid gas; and the carbon, thus precipitated, doubtleſs enters into ſome new combination, in which ſtate it ſerves as food for plants.

Mr Humbolt has lately proved, that ſoils have the property of abſorbing oxygen. It can ſcarcely be doubted that this abſorption has an influence on vegetation, eſpecially as watering plants with weak ſolutions of oxy-muriatic acid accelerates vegetation [*]. But we know too little of the ſubject at preſent to be able to ſpecify preciſely what that influence is.

123
Food abſorbed by the roots.

14. Since the only part of plants which is contiguous to the ſoil is the root, and ſince the plant periſhes when the root is pulled out of the ground, it is evident that the food of plants muſt be imbibed by the roots.

When we examine the roots, we do not find them to contain any large opening. The paſſages by which the food enters are too ſmall for the naked eye. This ſhews us, that the food can enter plants only in a fluid ſtate; and that conſequently every thing which can be rendered uſeful as food for plants muſt be previouſly in a ſtate of ſolution.

It ſeems moſt probable, that the whole, or the greateſt part of the food, enters at the extremities of the roots; for Duhamel obſerved, that the portion of the ſoil which is ſooneſt exhauſted, is preciſely that part in which the greateſt number of the extremities of roots lies [‡]. This ſhews us the reaſon why the roots of plants are continually increaſing in length. By this means they are enabled, in ſome meaſure, to go in queſt of nouriſhment. The extremities of the roots ſeem to have a peculiar ſtructure adapted for the imbibing of moiſture. If we cut off the extremity of a root, it never increaſes any more in length: therefore its uſe as a root has been in a great meaſure deſtroyed. But it ſends out fibres from its ſides which act the part of roots, and imbibe food by their extremity. Nay, in ſome caſes, when the extremity of a root is cut off, the whole decays, and a new one is formed in its place. This, as Dr Bell informs us, is the caſe with the hyacinth [†].

124
Diſſolved in water.

Since the food of plants muſt be in a fluid ſtate, and ſince no plant will live if it be deprived of moiſture, we may conclude that all its food is previouſly diſſolved in water. As for the carbon, we know, that in all active manures it is in ſuch a ſtate of combination, that it is ſoluble in water. We know, too, that all the ſalts which we can ſuppoſe to make a part of the food of plants, are more or leſs ſoluble in water. Lime alſo is ſoluble in water, whether it be pure or in the ſtate of a ſalt; magneſia and alumina may be rendered ſo by means of carbonic acid gas; and Bergman, Macie, and Klaproth, have ſhewn, that even ſilica may be diſſolved in water. We can ſee, therefore, in general, though we have no preciſe notions of the very combinations which are immediately imbibed by plants, that all the ſubſtances which form eſſential parts of that food *may* be diſſolved in water.

125
Therefore fluid.

15. Since the food of plants is imbibed by their roots in a fluid ſtate, it muſt exiſt in plants in a fluid ſtate; and unleſs it undergoes alterations in its compoſition juſt when imbibed, we may expect to find it in the plant unaltered. If there were any method of obtaining this fluid food from plants before it has been altered by them, we might analyſe it, and obtain by that means a much more accurate knowledge of the food of plants than we can by any other method. This plan indeed muſt fail, provided the food undergoes alteration juſt when it is abſorbed by the roots: but if we conſider, that when one ſpecies of tree is grafted upon another, each bears its own peculiar fruit, and produces its own peculiar ſubſtances, we can ſcarcely avoid thinking that the *great* changes, at leaſt which the food undergoes after abſorption, are produced, not in the roots, but in other parts of the plant.

126
Sap of plants.

If this concluſion be juſt, the food of plants, after being imbibed by the roots, muſt go directly to thoſe organs where it is to receive new modifications, and to be rendered fit for being aſſimilated to the different parts of the plant. There ought therefore to be certain juices continually aſcending from the roots of plants; and theſe juices, if we could get them pure and unmixed with the other juices or fluids which the plant muſt contain, and which have been ſecreted and formed from theſe primary juices, would be, very nearly at leaſt, the food as it was imbibed by the plant. Now during the vegetation of plants, there actually is a *juice* continually aſcending from their roots. This juice has been called the *ſap*, the *ſuccus communis*, the *lymph* of plants. We ſhall adopt the firſt of theſe names, becauſe it has been moſt generally received.

The firſt ſtep towards an accurate knowledge of the food, and of the changes which take place during vegetation, is an analyſis of the ſap. The ſap is moſt abundant during the ſpring. At that ſeaſon, if a cut be made through the bark and part of the wood of ſome trees, the ſap flows out very profuſely. The trees are then ſaid to *bleed*. By this contrivance any quantity of ſap we think proper may be collected. It is not probable, indeed, that by this method we obtain the aſcending ſap in all its purity: it is no doubt mixed with the peculiar juices of the plant; but the leſs progreſs vegetation has made, the purer we may expect to find it; both becauſe the peculiar juices muſt be in much ſmaller quantity, and becauſe its quantity may

may be ſuppoſed to be greater. We ſhould therefore examine the ſap as early in the ſeaſon as poſſible, and at all events before the leaves have expanded.

127
lyſed.

For the moſt complete ſet of experiments hitherto made upon the ſap, we are indebted to Mr Vauquelin. An account of his experiments has been publiſhed in the 31ſt volume of the *Annales de Chimie*. He has neglected to inform us of the ſtate of the tree when the ſap which he analyſed was taken from it; ſo that we are left in a ſtate of uncertainty with reſpect to the purity of the ſap: but from the compariſon which he has put it in our power to draw between the ſtate of the ſap at different ſucceſſive periods, we may in ſome meaſure obviate this uncertainty.

He found that 1039 parts of the ſap of the ulmus campeſtris, or common elm, were compoſed of

1027.567 water and volatile matter,
9.553 acetite of potaſs,
1.062 vegetable matter,
0.818 carbonat of lime,

Beſides ſome ſlight traces of ſulphuric and muriatic acids.

On analyſing the ſame ſap ſomewhat later in the ſeaſon, Mr Vauquelin found the quantity of vegetable matter a little increaſed, and that of the carbonat of lime and acetite of potaſs diminiſhed. Still later in the ſeaſon the vegetable matter was farther increaſed, and the other two ingredients farther diminiſhed. The acetite of potaſs, in 1039 parts of this third ſap, amounted to 8.615 parts *.

If theſe experiments warrant any conſequence to be drawn from them, they would induce us to ſuppoſe that the carbonat of lime and acetite of potaſs were contained in the pure aſcending ſap, and that part at leaſt of the vegetable matter was derived from the peculiar juices altered by the ſecreting organs of the plant; for the two ſalts diminiſhed in quantity, and the vegetable matter increaſed as the vegetation of the tree advanced. Now this is preciſely what ought to have taken place, on the ſuppoſition that the ſap became more and more mixed with the peculiar juices of the tree, as we are ſuppoſing it to do. If theſe concluſions have any ſolidity, it follows from them, that carbonat of lime and acetite of potaſs are abſorbed by plants as a part of their food. Now theſe ſalts, before they are abſorbed, muſt be diſſolved in water. But the carbonat of lime may be diſſolved in water by the help of carbonic acid. This ſhews us how water ſaturated with carbonic acid may be uſeful to plants vegetating in a proper ſoil, while it is uſeleſs to thoſe that vegetate in pure water. In the pure water there is no carbonat of lime to be diſſolved; and therefore carbonic acid gas cannot enter into a combination which renders it proper for becoming the food of plants. Part of the vegetable matter was precipitated from the ſap by alcohol. This part ſeems to have been gummy. Now gums we know are produced by vegetation.

The ſap of the fagus ſylvatica, or beech, contained the following ingredients.

Water,
Acetite of lime with exceſs of acid,
Acetite of potaſs,
Gallic acid,
Tan,
A mucous and extractive matter,
Acetite of alumina.

Although Mr Vauquelin made two different analyſes of this ſap at different ſeaſons, it is impoſſible to draw any ſatisfactory concluſions from them, as he has not given us the proportions of the ingredients. It ſeems clear that the gallic acid and tan were combined together; for the ſap taſted like the infuſion of oak bark. The quantity of each of theſe ingredients increaſed as vegetation advanced; for the colour of the ſecond ſap collected later was much deeper than that of the firſt. This ſhews us that theſe ingredients were produced by vegetation, and that they did not form a part of the aſcending ſap. Probably they were derived from the bark of the tree. The preſence of alumina, and the abſence of carbonic acid gas, would ſeem to indicate that all plants do not imbibe the very ſame food.

The ſap of the carpinus ſylveſtris contains water, acetite of potaſs, acetite of lime, ſugar, mucilage, vegetable extract. It cannot be doubted that the ſugar and the mucilage are the produce of vegetation.

The ſap of the betula alba, or common birch, contains water, ſugar, vegetable extract, acetite of lime, acetite of alumina, and acetite of potaſs.

Theſe experiments are curious, and certainly add to the preciſion of our notions concerning the food of plants; but they are not deciſive enough to entitle us to draw concluſions. They would ſeem to ſhew, either that acetite of potaſs and lime are a part of the food of plants, or at leaſt ſome ſubſtances which have the property of aſſuming theſe combinations.

128
Whether the food is altered by the roots.

16. Theſe experiments lead to the concluſion that acetous acid forms a component part of the ſap. Now it is not eaſy to ſuppoſe that this ſubſtance is actually abſorbed by the roots in the ſtate of acetous acid. The thing might be determined by examining the mould in which plants grow. This examination indeed has been performed; but no chemiſt has ever found acetous acid, at leaſt in any ſenſible quantity. Is it not probable, then, that the food, after it is imbibed, is ſomewhat modified and altered by the roots? In what manner this is done we cannot ſay, as we know very little about the vaſcular ſtructure of the roots. We may conclude, however, that this modification is nearly the ſame in moſt plants: for one plant may be engrafted on another, and each continue to produce its own peculiar products; which could not be, unleſs the proper ſubſtances were conveyed to the digeſtive organs of all. There are ſeveral circumſtances, however, which render the modifying power of the roots ſomewhat probable. The ſtrongeſt of theſe is the nature of the ingredients found in the ſap. It is even poſſible that the roots may, by ſome means or other, throw out again ſome part of the food which they have imbibed as excrementitious. This has been ſuſpected by ſeveral phyſiologiſts; and there are ſeveral circumſtances which render it probable. It is well known that ſome plants will not vegetate well after others; and that ſome again vegetate unuſually well when planted in ground where certain plants had been growing. Theſe facts, without doubt, may be accounted for on other principles. If there be any excrementitious matter emitted by the roots, it is much more probable that this happens in the laſt ſtage of vegetation. That is to ſay, when the food, after digeſtion, is applied to the purpoſes which the root requires. But the fact ought to be ſupported by experiments, otherwiſe it cannot be admitted.

---

* Ann. de
m xxxi.

17. The ſap, as Dr Hales has ſhewn us, aſcends with a very conſiderable force. It iſſued during the bleeding ſeaſon with ſuch impetuoſity from the cut end of a vine branch, that it ſupported a column of mercury 32½ inches high*.

129 Sap aſcends

Now what is the particular channel through which the ſap aſcends, and what is the cauſe of the force with which it moves? Theſe are queſtions which have excited a great deal of the attention of thoſe philoſophers who have made the phyſiology of vegetables their particular ſtudy; but the examination of them is attended with ſo many difficulties that they are very far from being decided.

It is certain that the ſap flows from the roots towards the ſummit of the tree. For if in the bleeding ſeaſon a number of openings be made in the tree, the ſap begins firſt to flow from the loweſt opening, then from the loweſt but one, and ſo on ſucceſſively, till at laſt it makes its appearance at the higheſt of all. And when Duhamel and Bonnet made plants vegetate in coloured liquors, the colouring matter, which was depoſited in the wood, appeared firſt in the loweſt part of the tree, and gradually aſcended higher and higher, till at laſt it reached the top of the tree, and tinged the very leaves.

130 Through the wood.

It ſeems certain, too, that the ſap aſcends through the wood, and not through the bark of the tree: for a plant continues to grow even when ſtript of a great part of its bark; which could not happen if the ſap aſcended through the bark. When an inciſion, deep enough to penetrate the bark, and even part of the wood, is carried quite round a branch, provided the wound be covered up from the external air, the branch continues to vegetate as if nothing had happened; which could not be the caſe if the ſap aſcended between the bark and the wood. It is well known, too, that in the bleeding ſeaſon little or no ſap can be got from a tree unleſs our inciſion penetrate deeper than the bark.

131 Not by the parenchyma;

If the ſap aſcended thro' the parenchyma of plants, as ſome phyſiologiſts have ſuppoſed, ſince there is a communication between every part of that organ, it is evident that the tree ought to bleed whenever any part of the parenchyma is wounded. But this is not the caſe. Conſequently the ſap does not aſcend through the parenchyma. Beſides, if the ſuppoſition were true, the ſap, from the very ſtructure of the parenchyma, muſt aſcend in the ſame manner as water through a ſponge; and in that caſe could not poſſibly poſſeſs the force with which we know that it aſcends. But if the ſap is not found in the parenchyma, as is now well known to be the caſe, it muſt, of neceſſity, be confined in particular veſſels; for if it were not, it would undoubtedly make its appearance there. Now what are the veſſels through which the ſap aſcends?

132 But in veſſels.

Grew and Malpighi, the firſt philoſophers who examined the ſtructure of plants, took it for granted that the woody fibres were tubes, and that the ſap aſcended through them. For this reaſon they gave theſe fibres the name of *lymphatic* veſſels. But they were unable, even when aſſiſted by the beſt microſcopes, to detect any thing in theſe fibres which had the appearance of a tube; and ſucceeding obſervers have been equally unſucceſsful. The conjecture therefore of Malpighi and Grew, about the nature and uſe of theſe fibres, remains totally unſupported by any proof. Duhamel has even gone far to overturn it altogether. For he found that theſe woody fibres are diviſible into ſmaller fibres, and theſe again into ſtill ſmaller; and even, by the aſſiſtance of the beſt microſcopes, he could find no end of this ſubdiviſion*. Now granting theſe fibres to be veſſels, it is ſcarcely poſſible, after this, to ſuppoſe that the ſap really moves through tubes, whoſe diameters are almoſt infinitely ſmall. There are, however, veſſels in plants which may eaſily be diſtinguiſhed by the help of a ſmall microſcope, and even, in many caſes, by the naked eye. Theſe were ſeen, and diſtinctly deſcribed, by Grew and Malpighi. They conſiſt of a fibre twiſted round like a corkſcrew. If we take a ſmall cylinder of wood, and wrap round it a ſlender braſs wire, ſo cloſely that all the rings of the wire touch each other, and if, after this, we pull out the wooden cylinder altogether, the braſs wire thus twiſted will give us a very good repreſentation of theſe veſſels. If we take hold of the two ends of the braſs wire thus twiſted, and pull them, we can eaſily draw out the wire to a conſiderable length. In the ſame manner, when we lay hold of the two extremities of theſe veſſels, we can draw them out to a great length. Malpighi and Grew finding them always empty, concluded that they were intended for the circulation of the air through the plant, and therefore gave them the name of *tracheæ;* which word is uſed to denote the *windpipe* of animals. Theſe *tracheæ* are not found in the bark; but Hedwig has ſhewn that they are much more numerous in the wood than was ſuppoſed; and that they are of very different diameters; and Reichel has demonſtrated that they go to the minuteſt branches, and ſpread through every leaf. He has ſhewn, too, that they contain ſap; and Hedwig has proved that the notion which generally prevailed of their containing nothing but air, aroſe from this circumſtance, that the larger tracheæ, which alone were attended to, loſe their ſap as ſoon as they are cut; and, of courſe, unleſs they are inſpected the inſtant they are divided, they appear empty†. Is it not probable, then, or rather is it not certain, from the diſcoveries of that very ingenious phyſiologiſt, that the tracheæ are, in reality, the ſap veſſels of plants? Indeed it ſeems eſtabliſhed by the experiments both of Reichel and Hedwig, that all, or almoſt all the veſſels of plants may, if we attend only to their ſtructure, be denominated *tracheæ*.

133 Why it aſcends

But by what powers is the ſap made to aſcend in theſe veſſels? And not only to aſcend, but to move with very conſiderable force; a force, as Hales has ſhewn, ſufficient to overcome the preſſure of 43 feet perpendicular of water‡?

134 Hypot of Grew Malpig and De Hire.

Grew aſcribed this phenomenon to the levity of the ſap; which, according to him, entered the plant in the ſtate of a very light vapour. But this opinion will not bear the ſlighteſt examination. Malpighi ſuppoſed that the ſap was made to aſcend by the contraction and dilation of the air contained in the air veſſels. But even were we to grant that the tracheæ are air veſſels, the ſap, according to this hypotheſis, could only aſcend when a change of temperature takes place; which is contrary to fact. And even if we were to wave every objection of that kind, the hypotheſis would not account for the circulation of the ſap, unleſs the ſap veſſels be provided with valves. Now the experiments of Hales and Duhamel ſhew that no valves can poſſibly exiſt in them. For branches imbibe moiſture nearly equally

---

* *Veg. Stat.* i. 105.

* *Phyſiqu des Arbres* i. 57.

† *Fundament. H Nat M cor. Fro* Part i. 54.

‡ *Veget Stat.* i.

equally by either end ; and conſequently the ſap moves with equal facility both upwards and downwards, which it could not do were there valves in the veſſels. Beſides, it is known, from many experiments, that we may convert the roots of a tree into the branches, and the branches into the roots, by covering the branches with earth, and expoſing the roots to the air. Now this would be impoſſible if the ſap veſſels were provided with valves. The ſame remarks overturn the hypotheſis of Mr de la Hire, which is merely that of Malpighi, expreſſed with greater preciſion, and with a greater parade of mechanical knowledge. Like Borelli, he placed the aſcending power of the ſap in the parenchyma. But his very experiments, had he attended to them with care, would have been ſufficient to ſhew the imperfection of his theory.

The greater number of philoſophers (for it is needleſs to mention thoſe who, like Perrault, had recourſe to fermentation, nor thoſe who introduced the weight of the atmoſphere) have aſcribed the motion of the ſap to *capillary attraction*.

135 cribed to pillary raction.

There exiſts a certain attraction between many ſolid bodies and liquids ; in conſequence of which, if theſe ſolid bodies be formed into ſmall tubes, the liquid enters them, and riſes in them to a certain height. But this is perceptible only when the diameter of the tube is very ſmall. Hence the attraction has been denominated *capillary*. We know that there is ſuch an attraction between vegetable fibres and watery liquids. For ſuch liquids will aſcend through dead vegetable matter. It is highly probable, therefore, that the food of plants enters the roots, in conſequence of the capillary attraction which ſubſiſts between the ſap veſſels and the liquid imbibed. This ſpecies of attraction then, will account perfectly well for the entrance of moiſture into the mouths of the ſap veſſels. But will it account alſo, as ſome have ſuppoſed, for the aſcent of the ſap, and for the great force with which it aſcends ?

136 is opi- n exa- ed;

The nature and laws of capillary attraction have been very much overlooked by philoſophers. But we know enough concerning it to enable us to decide the preſent queſtion. It conſiſts in a certain attraction between the particles of the liquid and of the tube. It has been demonſtrated, that it does not extend, or at leaſt that it produces no ſenſible effect, at greater diſtances than $\frac{1}{1000}$ part of an inch. It has been demonſtrated, that the water aſcends, not by the capillary attraction of the whole tube, but of a ſlender film of it ; and Clairaut has ſhewn that this film is ſituated at the lowermoſt extremity of the tube (G). This film attracts the liquid with a certain force ; and if this force be greater than the coheſion between the particles of the liquid, part enters the tube, and continues to enter, till the quantity above the attracting film of the tube juſt equals, by its weight, the exceſs of the capillary attraction between the tube and the liquid, above the cohesion of the liquid. The quantity of water therefore in the tube is pretty nearly the meaſure of this exceſs ; for the attracting film is probably very minute.

It has been demonſtrated, that the heights to which liquids riſe in capillary tubes, are inverſely as the diameter of the tube. Conſequently the ſmaller the diameter of the tube, the greater is the height to which the liquid will riſe. But the particles of water are not infinitely ſmall ; therefore whenever the diameter of the tube is diminiſhed beyond a certain ſize, water cannot aſcend in it, becauſe its particles are now larger than the bore of the tube. Conſequently the riſe of water in capillary tubes muſt have a limit : if they exceed a certain length, how ſmall ſoever their bore may be, water will either not riſe to the top of them, or it will not enter them at all. We have no method of aſcertaining the preciſe height to which water would riſe in a capillary tube, whoſe bore is juſt large enough to admit a ſingle particle of water. Therefore we do not know the limit of the height to which water may be raiſed by capillary attraction. But whenever the bore is diminiſhed beyond a certain ſize, the quantity of water which riſes in it is too ſmall to be ſenſible. We can eaſily aſcertain the height which water cannot exceed in capillary tubes before this happens ; and if any perſon calculate, he will find that this height is not nearly equal to the length of the ſap veſſels of many plants. But beſides all this, we ſee in many plants very long ſap veſſels, of a diameter too large for a liquid to riſe in them a ſingle foot by capillary attraction, and yet the ſap riſes in them to very great heights.

If any perſon ſays that the ſap veſſels of plants gradually diminiſh in diameter as they aſcend ; and that, in conſequence of this contrivance, they act preciſely as an indefinite number of capillary tubes, one ſtanding upon another, the inferior ſerving as a reſervoir for the ſuperior : we anſwer, that the ſap may aſcend by that means to a conſiderable height ; but certainly not in any greater quantity than if the whole ſap veſſel had been preciſely of the bore of its upper extremity. For the quantity of ſap raiſed muſt depend upon the bore of the upper extremity, becauſe it muſt all paſs through that extremity. The quantity of ſap, too, on that ſuppoſition, muſt diminiſh the farther we go from the root, becauſe the bore of the ſap veſſels is conſtantly diminiſhing ; the aſcending force muſt alſo diminiſh, becauſe it is, in all caſes, proportional to the quantity of water raiſed. Now neither of theſe, as Dr Hales has demonſtrated, is true.

137 And refuted.

But farther, if the ſap moved only in the veſſels of plants by capillary attraction, it would be ſo far from flowing out at the extremity of a branch, with a force ſufficient to overcome the preſſure of a column of water 43 feet high, that it could not flow out at all. It would be impoſſible in that caſe for any ſuch thing as the bleeding of trees ever to happen.

If we take a capillary tube, of ſuch a bore that a liquid will riſe in it ſix inches, and after the liquid has riſen to its greateſt height, break it ſhort three inches from the bottom, none of the liquid in the under half flows over. The tube, thus ſhortened, continues indeed full, but not a ſingle particle of liquid ever eſcapes from it. And how is it poſſible for it to eſcape ? The film,

---

(G) The action of all the other films, of which the tube is compoſed, on the water, as far as it is meaſured by its effect, is nothing at all. For every particle of water in the tube (except thoſe attracted by the undermoſt film) is attracted upwards and downwards by the ſame number of films : it is therefore preciſely in the ſame ſtate as if it were not attracted at all.

film, at the *upper* extremity of the tube, muſt certainly have as ſtrong an attraction for the liquid as the film at the *lower* extremity. As part of the liquid is within its attracting diſtance, and as there is no part of the tube above to counterbalance this attraction, it muſt of neceſſity attract the liquid neareſt it, and with a force ſufficient to counterbalance the attraction of the undermoſt film, how great ſoever we may ſuppoſe it. Of courſe no liquid can be forced up, and conſequently none can flow out of the tube. Since then the ſap *flows out* at the upper extremity of the ſap veſſels of plants, we are abſolutely certain that it does not aſcend in them merely by its capillary attraction, but that there is ſome other cauſe.

It is impoſſible therefore to account for the motion of the ſap in plants by any mechanical or chemical principles whatever; and he who aſcribes it to theſe principles has not formed to himſelf any clear or accurate conception of the ſubject. We know indeed that heat is an agent; for Dr Walker found that the aſcent of the ſap is much promoted by heat, and that after it had begun to flow from ſeveral inciſions, cold made it give over flowing from the higher orifices while it continued to flow at the lower*. But this cannot be owing to the dilating power of heat; for unleſs the ſap veſſels of plants were furniſhed with valves (and they have no valves), dilatation would rather retard than promote the aſcent of the ſap. Conſequently the effect of heat can give us no aſſiſtance in explaining the aſcent of the ſap upon mechanical and chemical principles.

138
The veſſels muſt contract,

We muſt therefore aſcribe it to ſome other cauſe: the veſſels themſelves muſt certainly act. Many philoſophers have ſeen the neceſſity of this, and have accordingly aſcribed the aſcent of the ſap to *irritability*. But the firſt perſon who gave a preciſe view of the manner in which the veſſels probably act was Sauſſure. He ſuppoſes that the ſap enters the open mouths of the veſſels, at the extremity of the roots; that theſe mouths then contract, and by that contraction propel the ſap upwards; that this contraction gradually follows the ſap, puſhing it up from the extremity of the root to the ſummit of the plant. In the mean time the mouths are receiving new ſap, which in the ſame manner is puſhed upwards†. Whether we ſuppoſe the contraction to take place preciſely in this manner or not, we can ſcarcely deny that it muſt take place; but by what means it is impoſſible to ſay. The agents cannot preciſely reſemble the muſcles of animals; becauſe the whole tube, however cut or maimed, ſtill retains its contracting power, and becauſe the contraction is performed with equal readineſs in every direction. It is evident, however, that they muſt be the ſame in kind. Perhaps the particular ſtructure of the veſſels may fit them for their office. Does ring after ring contract its diameter? The contracting agents, whatever they are, ſeem to be excited to act by ſome ſtimulus communicated to them by the ſap. This capacity of being excited to action is known in phyſiology by the name of *irritability*; and there are not wanting proofs that plants are poſſeſſed of it. It is well known that different parts of plants move when certain ſubſtances act upon them. Thus the flowers of many plants open at ſunriſe, and cloſe again at night. Linnæus has given us a liſt of theſe plants. Des Fontaines has ſhewn that the ſtamina and antheræ of many plants exhibit diſtinct motions‡. Dr Smith has obſerved, that the ſtamina of the barberries are thrown into motions when touched §. Roth has aſcertained that the leaves of the droſera longifolia and rotundifolia have the ſame property. Mr Coulon, too, who has adopted the opinion that the motion of the ſap in plants is produced by the contraction of veſſels, has even made a number of experiments in order to ſhew this contraction. But the fact is, that every one has it in his power to make a deciſive experiment. Simply cutting a plant, the *euphorbia peplis* for inſtance, in two places, ſo as to ſeparate a portion of the ſtem from the reſt, is a complete demonſtration that the veſſels actually do contract. For whoever makes the experiment, will find that the milky juice of that plant flows out at both ends ſo completely, that if afterwards we cut the portion of the ſtem in the middle, no juice whatever appears. Now it is impoſſible that theſe phenomena could take place without a contraction of the veſſels; for the veſſels in that part of the ſtem which has been detached cannot have been *more* than full; and their diameter is ſo ſmall, that if it were to continue unaltered, the capillary attraction would be more than ſufficient to retain their contents, and conſequently not a drop could flow out. Since, therefore, the whole liquid eſcapes, it muſt be driven out forcibly, and conſequently the veſſels muſt contract.

139
In conſequence of ſtimuli.

It ſeems pretty plain, too, that the veſſels are excited to contract by various ſtimuli; the experiments of Coulon and Sauſſure render this probable, and an obſervation of Dr Smith Barton makes it pretty certain. He found that plants growing in water vegetated with much greater vigour, provided a little camphor was thrown into the water *.

140
Peculiar juice formed from the ſap;

18. Beſides the ſap which aſcends upwards towards the leaves, they contain alſo another fluid, known by the name of *ſuccus proprius*, or *peculiar juice*. This juice differs very conſiderably in different plants. It ſeems to be the ſap altered by ſome proceſs or other, and fitted for the various purpoſes of vegetation. That it flows from the leaves of the plant towards the roots, appears from this circumſtance, that when we make an inciſion into a plant, into whatever poſition we put it, much more of the ſuccus proprius flows from that ſide of the wound which is next the leaves and branches, than from the other ſide: and this happens even though the leaves and branches be held undermoſt †. When a ligature is tied about a plant, a ſwelling appears above, but not below the ligature.

The veſſels containing the peculiar juice are found in all the parts of the plant. Hedwig, who has examined the veſſels of plants with very great care, ſeems to conſider them as of the ſame ſtructure with the tracheæ. The peculiar juice is eaſily known by its colour and its conſiſtence. In ſome plants it is green, in ſome red, in many milky. It cannot be doubted that its motion in the veſſels is performed in the ſame way as that of the ſap.

141
In the leaves.

19. It appears, then, that the ſap aſcends to the leaves, that there it undergoes certain alterations, and is converted into the peculiar juices; which, like the blood in animals, are afterwards employed in forming the various ſubſtances found in plants. Now the changes which the ſap undergoes in the leaves, provided we can trace them, muſt throw a great deal of light upon the nature of vegetation.

rt of the
per-
res thro'
: leaves.

No ſooner has the ſap arrived at the leaves, than a great part of it is thrown off by evaporation. The quantity thus perſpired bears a very great proportion to the moiſture imbibed. Mr Woodward found that a ſprig of mint in 77 days imbibed 2558 grains of water, and yet its weight was only increaſed 15 grains * ; therefore it muſt have given out 2543 grains. Another branch, which weighed 127 grains, increaſed in weight 128, and it had imbibed 14190 grains. Another ſprig, weighing 76 grains, growing in water mixed with earth, increaſed in weight 168 grains, and had imbibed 10731 grains of water. Theſe experiments demonſtrate the great quantity of matter which is conſtantly leaving the plant. Dr Hales found that a cabbage tranſmitted daily a quantity of moiſture equal to about half its weight ; and that a ſun flower, three feet high, tranſmitted in a day 1 lb. 14 oz. avoirdupois †. He ſhewed, that the quantity of tranſpiration in the ſame plant was proportional to the ſurface of the leaves, and that when the leaves were taken off, the tranſpiration nearly ceaſed ‡. By theſe obſervations, he demonſtrated that the leaves are the organs of tranſpiration. He found, too, that the tranſpiration was nearly confined to the day, very little taking place during the night § ; that it was much promoted by heat, and ſtopped by rain and froſt ||. And Millar ¶, Guettard *, and Senebier, have ſhewn that the tranſpiration is alſo very much promoted by ſunſhine.

ir. 1748.

The quantity of moiſture imbibed by plants depends very much upon what they tranſpire : the reaſon is evident : when the veſſels are once filled with ſap, if none be carried off, no more can enter ; and, of courſe, the quantity which enters muſt depend upon the quantity emitted.

In order to diſcover the nature of the tranſpired matter, Hales placed plants in large glaſs veſſels, and by that means collected a quantity of it †. He found that it reſembled pure water in every particular, excepting only that it ſometimes had the odour of the plant. He remarked, too, as Guettard and Du Hamel did after him, that when kept for ſome time it putrefied, or at leaſt acquired a ſtinking ſmell. Senebier ſubjected a quantity of this liquid to a chemical analyſis.

† Ibid. 49.

143
s nature,

He collected 13030 grains of it from a vine during the months of May and June. After filtration he gradually evaporated the whole to dryneſs. There remained behind two grains of reſiduum. Theſe two grains conſiſted of nearly $\frac{1}{2}$ grain of carbonat of lime, $\frac{1}{12}$ grain of ſulphat of lime, $\frac{1}{2}$ grain of matter ſoluble in water, and having the appearance of gum, and $\frac{1}{2}$ grain of matter which was ſoluble in alcohol, and apparently reſinous. He analyzed 60768 grains of the ſame liquid, collected from the vine during the months of July and Auguſt. On evaporation he obtained $2\frac{1}{8}$ grains of reſiduum, compoſed of $\frac{3}{4}$ grain of carbonat of lime, $\frac{1}{4}$ grain of ſulphat of lime, $\frac{1}{2}$ grain of mucilage, and $\frac{1}{2}$ grain of reſin. The liquid tranſpired by the *aſter novæ Angliæ* afforded preciſely the ſame ingredients ‡.

144
nd quan-
y.

Senebier attempted to aſcertain the proportion which the liquid tranſpired bore to the quantity of moiſture imbibed by the plant. But it is eaſy to ſee that ſuch experiments are liable to too great uncertainties to be depended on. His method was as follows : He plunged the thick end of the branch on which he made the experiment into a bottle of water, while the other end, containing all its leaves, was thruſt into a very large glaſs globe. The apparatus was then expoſed to the ſunſhine. The quantity imbibed was known exactly by the water which diſappeared from the bottle, and the quantity tranſpired was judged of by the liquid which condenſed and trickled down the ſides of the glaſs globe. The following table exhibits the reſult of his experiments :

Plants.	*Imbibed.*	*Perſpired.*	*Time.*
Peach	100 gr.	35 gr.	
Ditto	210	90	
Ditto	220	120	
Mint	200	90	2 days.
Ditto	575	120	10
Raſp	725	560	2
Ditto	1232	765	2
Peach	710	295	1
Apricot	210	180	1

In ſome of his experiments no liquid at all was condenſed. Hence it is evident that the quantity of matter tranſpired cannot be deduced from theſe experiments. The mouth of the glaſs globe does not ſeem to have been accurately cloſed ; the air within it communicated with the external air : conſequently the quantity condenſed muſt have depended entirely upon the ſtate of the external air, the heat, &c.

The firſt great change, then, which takes place upon the ſap after it arrives at the leaves, is the evaporation of a great part of it ; conſequently what remains muſt be very different in its proportions from the ſap. The leaves ſeem to have particular organs adapted for throwing off part of the ſap by tranſpiration. For the experiments of Guettard *, Duhamel †, and Bonnet ‡, ſhew that it is performed chiefly by the upper ſurfaces of leaves, and may be nearly ſtopped altogether by varniſhing the upper ſurface.

145
Why the
leaves fall
off.

The leaves of plants become gradually leſs and leſs fit for this tranſpiration ; for Senebier found, that when all other things are equal, the tranſpiration is much greater in May than in September *. Hence the reaſon that the leaves are renewed annually. Their organs become gradually unfit for performing their functions, and therefore it is neceſſary to renew them. Thoſe trees which retain their leaves during the winter, were found by Hales and ſucceeding phyſiologiſts to tranſpire leſs than others. It is now well known that theſe trees alſo renew their leaves.

285.

20. Leaves have alſo the property of abſorbing carbonic acid gas from the atmoſphere.

146
Leaves abſorb carbonic acid
gas.

We are indebted for this very ſingular diſcovery to the experiments of Dr Prieſtley, though he himſelf did not diſcover the truth, and though he even refuſed to acknowledge it when it was pointed out by others. It has been long known, that when a candle has been allowed to burn out in any quantity of air, no candle can afterwards be made to burn in it. In the year 1771 Dr Prieſtley made a ſprig of mint vegetate for ten days in contact with a quantity of ſuch air; after which he found that a candle would burn in it perfectly well ¶. This experiment he repeated frequently, and found that it was always attended with the ſame reſult. According to the opinion at that time univerſally received, that the

¶ On Air,
iii. 251.

the burning of candles rendered air impure by communicating phlogiſton to it, he concluded from it, that plants, while they vegetate, abſorb phlogiſton.

Carbonic acid gas was at that time ſuppoſed to contain phlogiſton. It was natural, therefore, to ſuppoſe that it would afford nouriſhment to plants, ſince they had the property of abſorbing phlogiſton from the atmoſphere. Dr Percival had publiſhed a ſet of experiments; by which he endeavoured to ſhew that this was actually the caſe.

Theſe experiments induced Dr Prieſtley, in 1776, to conſider the ſubject with more attention. But as, in all the experiments which he made, the plants confined in carbonic acid gas very ſoon died, he concluded, that carbonic acid gas was not a food, but a poiſon to plants[*]. Mr Henry of Mancheſter was led, in 1784, probably by the contrariety of theſe reſults, to examine the ſubject. His experiments, which were publiſhed in the Mancheſter Tranſactions[†], perfectly coincided with thoſe of Dr Percival. For he found, that carbonic acid gas, ſo far from killing plants, conſtantly promoted their growth and vigour. Meanwhile Mr Senebier was occupied at Geneva with the ſame ſubject; and he publiſhed the reſult of his reſearches in his *Memoires Phyſico-chymique* about the year 1780. His experiments ſhewed, in the cleareſt manner, that carbonic acid gas is uſed by plants as food. The ſame thing was ſupported by Ingenhouſz in his ſecond volume. The experiments of Sauſſure the Son, publiſhed in 1797, have at laſt put the ſubject beyond the reach of diſpute. From a careful compariſon of the experiments of theſe philoſophers, it will not be difficult for us to diſcover the various phenomena, and to reconcile all the ſeeming contradictions which occur in them. The facts are as follows:

Mr Sauſſure has ſhewn, that plants will not vegetate when totally deprived of carbonic acid gas. They vegetate indeed well enough in air which has been previouſly deprived of carbonic acid gas; but when a quantity of lime was put into the glaſs veſſel which contained them, they no longer continued to grow, and the leaves in a few days fell off[‡]. The air, when examined, was found to contain no carbonic acid gas. The reaſon of this phenomenon is, that plants (as we ſhall ſee afterwards) have the power of forming and giving out carbonic acid in certain circumſtances; and this quantity is ſufficient to continue their vegetation for a certain time. But if this new formed gas be alſo withdrawn, by quicklime, for inſtance, which abſorbs it the inſtant it appears, the leaves droop, and refuſe to perform their functions. Carbonic acid gas, then, applied to the leaves of plants, is *eſſential* to vegetation.

147
Decompoſe it and emit the oxygen;

Dr Prieſtley, to whom we are indebted for many of the moſt important facts relative to vegetation, obſerved, in the year 1778, that plants, in certain circumſtances, emitted oxygen gas[||]; and Ingenhouſz very ſoon after diſcovered that this gas is emitted by the *leaves* of plants, and only when they are expoſed to the bright light of day. His method was to plunge the leaves of different plants into veſſels full of water, and then expoſe them to the ſun, as Bonnet, who had obſerved the ſame phenomenon, though he had given a wrong explanation of it, had done before him. Bubbles of oxygen gas very ſoon detached themſelves from the leaves, and were collected in an inverted glaſs veſſel[*]. He obſerved, too, that it was not a matter of indifference what kind of water was uſed. If the water, for inſtance, had been previouſly boiled, little or no oxygen gas eſcaped from the leaves; river water afforded but little gas; but pump water was the moſt productive of all[†].

Senebier proved, that if the water be previouſly deprived of all its air by boiling, the leaves do not emit a particle of air; that thoſe kinds of water which yield moſt air, contain in them the greateſt quantity of carbonic acid gas; that leaves do not yield any oxygen when plunged in water totally deſtitute of carbonic acid gas; that they emit it abundantly when the water, rendered unproductive by boiling, is impregnated with carbonic acid gas; that the quantity of oxygen emitted, and even its purity, is proportional to the quantity of carbonic acid gas which the water contains; that water impregnated with carbonic acid gas gradually loſes the property of affording oxygen gas with leaves; and that whenever this happens, all the carbonic acid gas has diſappeared; and on adding more carbonic acid gas the property is renewed[‡]. Theſe experiments prove, in a moſt ſatisfactory manner, that the oxygen gas which the leaves of plants emit depends upon the preſence of carbonic acid gas; that the leaves abſorb carbonic acid gas, decompoſe it, give out the oxygen, and retain the carbon.

148
But durin the day only.

We now ſee why plants will not vegetate without carbonic acid gas. They abſorb it and decompoſe it; but this proceſs goes on only when the plants are expoſed to the light of day. Therefore we may conclude, that the abſorption and decompoſition of carbonic acid gas is confined to the day, and that light is an eſſential agent in the decompoſition. Probably it is by its agency, or by its entering into combination with the oxygen, that this ſubſtance is enabled to aſſume the gaſeous form, and to ſeparate from the carbon.

If we reaſon from analogy, we ſhall conclude, that during this proceſs a quantity of caloric is neceſſary; and that therefore no increaſe of temperature takes place, but rather the contrary. This may be one reaſon why the operation takes place only during the day.

149
In this w plants ma acquire much carbon.

It is extremely probable that plants by this proceſs acquire the greateſt part of the carbonaceous matter which they contain; for if we compare the quantity of carbon contained in plants vegetating in the dark, where this proceſs cannot go on, with the quantity which thoſe plants contain which vegetate in the uſual manner, we ſhall perceive a very conſpicuous difference. Chaptal found that a byſſus, which was vegetating in the dark, contained only $\frac{1}{35}$ of its weight of carbonaceous matter; but the ſame plant, after being made to vegetate in the light for 30 days, contained $\frac{1}{13}$th of its weight of carbonaceous matter[*]. Haſſenfratz aſcertained, that plants growing in the dark contain much more water, and much leſs carbon and hydrogen, than plants growing in the light. Senebier analyſed both with the ſame reſult. Plants growing in the dark yielded leſs hydrogen gas and oil: their reſinous matter was to that of plants growing in the light as 2 to 5,5, and their moiſture as 13 to 6; they contain even one-half leſs of fixed matters.

It is evident, however, that this abſorption and decompoſition of carbonic acid gas does not depend upon the

Vegetation.

the light alone. The nature of the ſap has alſo its influence; for Haſſenfratz found, that the quantity of carbon did not increaſe when plants vegetated in pure water. Here the ſap ſeems to have wanted that part which combines with and retains the carbon; and which therefore is by far the moſt important part of the food of plants. Upon the diſcovery and mode of applying this ſubſtance, whatever it is, the improvements in agriculture muſt in a great meaſure depend.

If we conſider the difference in the proportion of carbonaceous matter in plants vegetating in the dark and in the uſual manner, we can ſcarcely avoid concluding that the quantity of carbonic acid gas abſorbed by plants is conſiderable. To form an eſtimate of it, would require a ſet of experiments performed in a very different manner from any hitherto made. The ſtems and branches of plants vegetating in a rich ſoil ſhould be confined within a large glaſs globe, the inſide of which ought to have no communication with the external air. A very ſmall ſtream of carbonic acid gas ſhould be made occaſionally to flow into this globe, ſo as to ſupply the quantity that may appear neceſſary; and there ſhould be a contrivance to carry off and examine the air within the globe when it increaſes beyond a certain quantity. Experiments conducted in this manner would probably throw a great deal of light upon this part of vegetation, and enable us to calculate the quantity of carbonic acid decompoſed, and the quantity of oxygen emitted by plants; to compare theſe with the waſte of oxygen by the reſpiration of animals and combuſtion, and to ſee whether or not they balance each other.

150
he decompoſi-
ion per-
ormed by
he paren
hyma.

Senebier has aſcertained, that the decompoſition of the carbonic acid takes place in the parenchyma. He found, that the epidermis of a leaf would, when ſeparated, give out no air, neither would the nerves in the ſame circumſtances; but upon trying the parenchyma, thus ſeparated from its epidermis and part of its nerves, it continued to give out oxygen as before †. He remarked alſo, that every thing elſe being equal, the quantity of oxygen emitted, and conſequently of carbonic acid decompoſed, is proportional to the thickneſs of the leaf; and this thickneſs depends upon the quantity of parenchyma.

That the decompoſition is performed by peculiar organs, is evident from an experiment of Ingenhouſz. Leaves cut into ſmall pieces continued to give out oxygen as before; but leaves pounded in a mortar loſt the property entirely. In the firſt ſtate, the peculiar ſtructure remained; in the other, it was deſtroyed. Certain experiments of Count Rumford, indeed, are totally incompatible with this concluſion; and they will naturally occur to the reader as an unſurmountable objection. He found, that dried leaves, black poplar, fibres of raw ſilk, and even glaſs, when plunged into water, gave out oxygen gas by the light of the ſun. But when Senebier repeated theſe experiments, not one of them would ſucceed ‡; and we have attempted them with the ſame bad ſucceſs. The Count muſt have been miſled by ſomething which he has not mentioned.

Thus we have ſeen, that when the ſap arrives at the leaves, great part is thrown off by evaporation, and that the nature of the remainder is conſiderably altered by the addition of a quantity of carbon: but theſe are by no means all the alterations produced upon the ſap in the leaves.

Vegetation.

151
Leaves abſorb oxygen,

21. Plants will not vegetate unleſs atmoſpheric air or oxygen gas have acceſs to their leaves. This was rendered probable by thoſe philoſophers who, about the end of the 17th century, turned their attention particularly towards the phyſical properties of the air: But Mr Ingenhouſz was perhaps the firſt of the modern chemiſts who put it beyond doubt. He found that carbonic acid gas, azot, and hydrogen gas, deſtroyed plants altogether, unleſs they were mixed with atmoſpheric air or oxygen gas. He found alſo, that plants grew very well in oxygen gas and in atmoſpheric air *. Theſe experiments are ſufficient to ſhew, that oxygen gas is neceſſary to vegetation. The leaves of plants ſeem to abſorb it; and moſt probably this abſorption takes place only in the night. We know, at leaſt, that in germination light is injurious to the abſorption of oxygen gas; and therefore it is probable that this is the caſe alſo in vegetation.

152
And water,

22. The leaves of plants not only abſorb carbonic acid gas and oxygen gas, but water alſo. This had been ſuſpected in all ages: the great effect which dew, ſlight ſhowers, and even wetting the leaves of plants, have in recruiting their ſtrength, and making them vegetate with vigour, are ſo many proofs that the leaves imbibe moiſture from the atmoſphere. Hales rendered this ſtill more probable, by obſerving, that plants increaſe conſiderably in weight when the atmoſphere is moiſt; and Mr Bonnet put the matter beyond doubt in his *Reſearches concerning the Uſe of the Leaves.* He ſhewed, that leaves continue to live for weeks when one of their ſurfaces is applied to water; and that they not only vegetate themſelves, but even imbibe enough of water to ſupport the vegetation of a whole branch, and the leaves belonging to it. He diſcovered alſo, that the two ſurfaces of leaves differ very conſiderably in their power of imbibing moiſture; that in trees and ſhrubs, the under ſurface poſſeſſes almoſt the whole of the property, while the contrary holds in many of the other plants; the kidney bean for inſtance.

Theſe facts prove, not only that the leaves of plants have the power of abſorbing moiſture, but alſo that the abſorption is performed by very different organs from thoſe which emit moiſture; for theſe organs lie on different ſides of the leaf. If we conſider that it is only during the night that the leaves of plants are moiſtened with dew, we can ſcarcely avoid concluding, that, except in particular caſes, it is during the night that plants imbibe almoſt all the moiſture which they do imbibe.

153
And emit carbonic acid gas.

23. During the night the leaves of plants emit carbonic acid gas. This fact was firſt demonſtrated by Mr Ingenhouſz †, and it has been ſince confirmed by every philoſopher who has attended to the ſubject.

Thus we have ſeen that the leaves of plants perform very different operations at different times. During the day they are giving out moiſture, abſorbing carbonic acid gas, and emitting oxygen gas; during the night, on the contrary, they are abſorbing moiſture, giving out carbonic acid gas, and abſorbing oxygen gas.

The emiſſion of the carbonic acid gas ſeems to be the conſequence of the decompoſition of water; either of the water which is already contained in the ſap, or

---

Ann. de Chim. i. 15.

* *Ingenhouſz* ii. paſſim.

† *On Vegetables*, i. 47. and ii. paſſim.

Vegetation.

of that which the leaves imbibe during the night; but which of the two, it is impoſſible to determine, nor is it of much conſequence. We may conclude that this is the caſe, becauſe it takes place during the germination of the ſeed, where all the circumſtances ſeem to be perfectly analogous. The water is decompoſed, its oxygen is combined with part of the carbon which had been abſorbed during the day, and the hydrogen enters into new combinations in the ſap. It appears, alſo, that this decompoſition of water depends in a good meaſure upon the quantity of oxygen gas abſorbed; for Dr Ingenhouſz found, that when plants are confined in oxygen gas, they emit more carbonic acid gas than when they are confined in common air †.

154 Sap converted by theſe proceſſes into the peculiar juice.

To deſcribe in what manner theſe decompoſitions take place, is impoſſible; becauſe we neither know preciſely the ſubſtances into which the ſap has been converted by the operations performed during the day, nor the new ſubſtances formed by the operations of the night. We only ſee the elementary ſubſtances which are added and ſubtracted; which is far from being ſufficient to give us preciſe notions concerning the chemical changes and the affinities by which theſe changes are produced. We have reaſon, however, to conclude, that during the day the carbon of the ſap is increaſed, and that during the night the hydrogen and oxygen are increaſed; but the preciſe new ſubſtances formed are unknown to us. Nor let any one ſuppoſe that the increaſe of the hydrogen, and of the oxygen of the ſap, is the ſame thing as the addition of a quantity of water. Far from it. The ſubſtances into which the ſap is converted have been enumerated in the laſt chapter; almoſt all of them conſiſt chiefly of carbon, hydrogen, and oxygen, and yet none of them has the ſmalleſt reſemblance to water. In water, oxygen and hydrogen are already combined together in a certain proportion; and this combination muſt be broken before theſe elementary bodies can enter into thoſe triple compounds with carbon, of which a great part of the vegetable products conſiſt. We have not the ſmalleſt conception of the manner in which theſe triple combinations are formed, and as little of the manner in which the bodies which compoſe vegetable ſubſtances are combined together. The combination may, for any thing we know to the contrary, be very complicated, though it conſiſts only of three ingredients; and analogy leads us to ſuppoſe, that it actually is very complicated: for in chemiſtry it may be conſidered as a truth, to which at preſent few or no exceptions are known, that bodies are decompoſed with a facility inverſely as the ſimplicity of their compoſition; that is to ſay, that thoſe bodies which conſiſt of the feweſt ingredients are moſt difficultly decompoſed, and that thoſe which are formed of many ingredients are decompoſed with the greateſt facility.

Neither let any one ſuppoſe, that the abſorption of carbonic acid gas, during the day, is balanced by the quantity emitted during the night, and that therefore there is no increaſe of carbon: for Ingenhouſz has ſhewn, that the quantity of oxygen gas emitted during the day is much greater than the carbonic acid gas emitted during the night; and that in favourable circumſtances, the quantity of oxygen gas in the air ſurrounding plants is very much increaſed, and the carbonic acid gas diminiſhed; ſo much ſo, that both Dr Prieſtley and Dr Ingenhouſz found, that air which had been ſpoiled by a lighted candle, or by animals, was rendered as good as ever by plants. Now we know, that combuſtion and reſpiration diminiſh the oxygen gas, and add carbonic acid gas to air; therefore vegetation, which reſtores the purity of air altered by theſe proceſſes, muſt increaſe the oxygen, and diminiſh the carbonic acid gas of that air; conſequently the quantity of carbonic acid gas abſorbed by plants during the day is greater than the quantity emitted by them during the night, and of courſe the carbon of the ſap is increaſed in the leaves.

It is true, that when plants are made to vegetate for a number of days in a given quantity of air, its ingredients are not found to be altered. Thus Haſſenfratz aſcertained, that the air in which young cheſnuts vegetated for a number of days together, was not altered in its properties, whether the cheſnuts were vegetating in water or in earth *. And Sauſſure the Younger proved, that peaſe growing for ten days in water did not alter the ſurrounding air †. But this is preciſely what ought to be the caſe, and what muſt take place, provided the concluſions which we have drawn be juſt. For if plants only emit oxygen gas, by abſorbing and decompoſing carbonic acid gas, it is evident, that unleſs carbonic acid gas be preſent, they can emit no oxygen gas; and whenever they have decompoſed all the carbonic acid gas contained in a given quantity of air, we have no longer any reaſon to look for their emitting any more oxygen gas; and if the quantity of carbonic acid gas emitted during the night be ſmaller than that abſorbed during the day, it is evident, that during the day the plant will conſtantly decompoſe all the acid which had been formed during the night. By theſe proceſſes, the mutual changes of day and night compenſate each other; and they are prevented from more than compenſating each other by the forced ſtate of the plant. It is probable, that when only part of a plant is made to vegetate in this forced ſtate, ſome *carbonated ſap* (if we may be allowed the expreſſion) is ſupplied by the reſt of the plant; and that therefore the quantity of carbonic acid gas emitted during the night may bear a nearer proportion to that emitted in a ſtate of nature, than that of the abſorption of fixed air can poſſibly do. And probably, even when the whole plant is thus confined, the nightly proceſs goes on for a certain time at the expence of the carbon already in the ſap; for Haſſenfratz found, that in theſe caſes the quantity of carbon in the plant, after it had vegetated for ſome time in the dark, was leſs than it had been when it began to vegetate *. This is the reaſon that plants growing in the dark, when confined, abſorb all the oxygen gas, and emit an equal quantity of carbonic acid gas: and whenever this has happened, they die; becauſe then neither the daily nor nightly proceſſes can go on.

24. Certain changes are alſo produced on the ſap in the leaves by the action of light; and theſe changes ſeem to be in ſome meaſure independent, or at leaſt different from the abſorption and decompoſition of carbonic acid gas, in which light, as we have ſeen, acts an important part.

155 Green colour of plants pr duced b light.

The green colour of plants is owing entirely to their vegetating in the light; for when they vegetate in the dark they are white; and when expoſed to the light, they acquire a green colour in a very ſhort time, in what-

---

† Ingenhouſz ii.

* Ann. de Chim. xiii. 325.

† Ibid xxiv 139.

* Ann de Chim. xii 188.

egeta-tion.

whatſoever ſituation they are placed, even though plunged in water, provided always that oxygen be preſent; for Mr Gough has ſhewn, that light without oxygen has not the power of producing the green colour *. In what manner this change is operated, cannot, in the preſent limited ſtate of our knowledge, be aſcertained. We know too little about the properties of light to be able even to conjecture with any plauſibility. We know indeed, that part of the light is abſorbed by green plants; but this will not account for the phenomenon. When dilated, it amounts to no more than this, that plants which have grown in the dark reflect all the rays of light; while thoſe which vegetate in the light reflect the green and abſorb the others. The very mention of this phenomenon is enough to ſhew us, that we have not advanced far enough to be able to explain it.

* anch. noirs, i 501.

Etiolated (E) plants want ſomething, or poſſeſs ſomething peculiar; and it is on this ſomething that the phenomenon depends. But what is this ſomething? The ſudden appearance of the green colour is rather againſt the ſuppoſition, that it is owing to any ſpecific change in the qualities of the ſap.

Senebier has obſerved, that when plants are made to vegetate in the dark, their etiolation is much diminiſhed by mixing a little hydrogen gas with the air that ſurrounds them *. Ingenhouſz had already remarked, that when a little hydrogen gas is added to the air in which plants vegetate, even in the light, it renders their verdure deeper †: and he ſeems to think alſo, that he has proved by experiments, that plants abſorb hydrogen gas in theſe circumſtances‡. Mr Humbolt has obſerved, that the poa annua and compreſſa, plantago lanceolata, trifolium arvenſe, cheiranthus cheiri, lichen verticillatus, and ſeveral other plants which grow in the galleries of mines, retain their green colour even in the dark, and that in theſe caſes the air around them contains a quantity of hydrogen gas. Theſe facts are ſufficient to ſhew that there is ſome connection between the green colour of plants and the action of hydrogen gas on them; but what that connection is, it is impoſſible at preſent to ſay.

* Enc. Me- l. Phyſ. get. 77.

† Ann. de im. iii.

‡ Ibid. 61.

25. By theſe different changes which go on in the leaves, the nature of the ſap is altogether changed. It is now converted into what is called the *peculiar juice*, and is fit for being aſſimilated to the different parts of the plant, and for being employed in the formation of thoſe ſecretions which are neceſſary for the purpoſes of the vegetable economy.

156 eaves the geſting gans of ants.

The leaves, therefore, may be conſidered as the digeſting organs of plants, and as equivalent in ſome meaſure to the ſtomach and lungs of animals. The leaves conſequently are not mere ornaments; they are the moſt important parts of the plant. Accordingly we find, that whenever we ſtrip a plant of its leaves, we ſtrip it entirely of its vegetating powers till new leaves are formed. It is well known, that when the leaves of plants are deſtroyed by inſects, they vegetate no longer, and that their fruit never makes any farther progreſs in ripening, but decays and dries up. Even in germination no progreſs is made in the growth of the ſtem till the ſeed leaves appear. As much food indeed is laid up in the cotyledons as advances the plant to a certain ſtate, the root is prepared, and made ready to perform its functions; but the ſap which it imbibes muſt be firſt carried to the ſeed leaves, and digeſted there, before it be proper for forming the plumula into a ſtem. Accordingly if the ſeed leaves are cut off, the plant refuſes to vegetate.

157 How they are produced.

It will be very natural to aſk, If this be true, how come the leaves themſelves to be produced? Even if no anſwer could be given to this queſtion, it could not overturn a ſingle fact which has been formerly mentioned, nor affect a ſingle concluſion as far as it has been fairly deduced from theſe facts. We know that the leaves exiſt long before they appear; they have been traced even five years back. They are completely formed in the bud, and fairly rolled up for evolution, many months before that ſpring in which they expand. We know, too, that if we take a bud, and plant it properly, it vegetates, forms to itſelf a root, and becomes a complete plant. It will not be ſaid, ſurely, that in this caſe the bud imbibes nouriſhment from the earth; for it has to form a root before it can obtain nouriſhment in that manner; and this root cannot be formed without nouriſhment. Is not this a demonſtration that the bud contains, already laid up in itſelf, a ſufficient quantity of nouriſhment, not only to develope its own organs, but alſo to form new ones. This we conſider as a ſufficient anſwer to the objection. During the ſummer, the plant lays up a ſufficient quantity of nouriſhment in each bud, and this nouriſhment is afterwards employed in developing the leaves. This is the reaſon that the leaves make their appearance, and that they grow during the winter, when the plant is deprived of its organs of digeſtion.

Hence we ſee why the branch of a vine, if it be introduced into a hothouſe during the winter, puts forth leaves and vegetates with vigour, while every other part of the plant gives no ſigns of life. Hence alſo the reaſon that the inoculation of plants ſucceeds (F).

If a tree be deprived of its leaves, new leaves make their appearance, becauſe they are already prepared for that purpoſe: but what would be the conſequence if a tree were deprived of its leaves and of all its buds for five

---

(E) Plants of a white colour, from vegetating in the dark, are called *etiolated*, from a French word which ſignifies a *ſtar*, as if they grew by *ſtar light*.

(F) Hence alſo the cauſe of another well known phenomenon. The ſap flows out of trees very readily in ſpring before the leaves appear, but after that the bleeding ceaſes altogether. It is evident that there can be ſcarcely any circulation of ſap before the leaves appear; for as there is no outlet, when the veſſels are once full, they can admit no more. It appears, however, from the bleeding, that the roots are capable of imbibing, and the veſſels of circulating, the ſap with vigour. Accordingly, whenever there is an outlet, they perform their functions as uſual, and the tree bleeds; that is, they ſend up a quantity of ſap to be digeſted as uſual: but as there are no digeſting organs, it flows out, and the tree receives no injury, becauſe the ſap that flows out would not have been imbibed at all, had it not been for the artificial opening. But when the digeſtive organs appear, the tree will not bleed; becauſe theſe organs require all the ſap, and it is conſtantly flowing to them.

five years back? That plants do not vegetate without leaves, is evident from an experiment of Duhamel. He ſtript the bark off a tree in ringlets, ſo as to leave five or ſix rings of it at ſome diſtance from each other, with no bark in the intervals. Some of theſe rings had buds and leaves; theſe increaſed conſiderably in ſize; but one ring which had none of theſe remained for years unaltered.

158 Nature of the peculiar juices.

26. The peculiar juice thus formed in the leaves is carried by veſſels intended for that uſe to all the parts of the plant, in order to be employed for the purpoſes of vegetation;—to increaſe the wood, the bark, the roots; to prepare the ſeeds, lay up nouriſhment for the buds, and to repair the decayed parts of the ſyſtem, or form new ones.

If we had any method of obtaining this peculiar juice in a ſtate of purity, the analyſis of it would throw a great deal of light upon vegetation; but this is ſcarce poſſible, as we cannot extract it without dividing at the ſame time the veſſels which contain the ſap. In many caſes, however, the peculiar juice may be known by its colour; and then its analyſis may be performed with an approach towards accuracy. The experiments made on ſuch juices have proved, as might have been expected, that they differ very conſiderably from each other, and that every plant has a juice peculiar to itſelf. Hence it follows, that the proceſſes which go on in the leaves of plants muſt differ at leaſt in degree, and that we have no right to transfer the concluſions deduced from experiments on one ſpecies of plants to thoſe of another ſpecies. It is even probable, that the proceſſes in different plants are not the ſame in kind; for it is not reaſonable to ſuppoſe, that the phenomena of vegetation in an agaric or a boletus are preciſely the ſame as thoſe which take place in trees and in larger vegetables, on which alone experiments have hitherto been made.

To attempt any general account of the ingredients of the peculiar juice of plants, is at preſent impoſſible. We may conclude, however, from the experiments of Chaptal, that it contains the *vegetable fibre* of wood, either ready formed, or very nearly ſo; juſt as the blood in animals contains a ſubſtance which bears a ſtrong reſemblance to the muſcular fibres.

When oxy-muriatic acid was poured into the peculiar juice of the euphorbia, which in all the ſpecies of that ſingular genus is of a milky colour and conſiſtency, a very copious white precipitate fell down. This powder, when waſhed and dried, had the appearance of fine ſtarch, and was not altered by keeping. It was neither affected by water nor alkalies. Alcohol, aſſiſted by heat, diſſolved two thirds of it; which were again precipitated by water, and had all the properties of reſin. The remaining third part poſſeſſed the properties of the *woody fibre*. Mr Chaptal tried the ſame experiment on the juices of a great number of other plants, and he conſtantly found that oxy-muriatic acid precipitated from them *woody fibre*. The ſeeds of plants exhibited exactly the ſame phenomenon; and a greater quantity of woody fibre was obtained from them than from an equal portion of the juices of plants *. Theſe experiments are ſufficient to ſhew, that the proper juices of plants contain their nouriſhment ready prepared, nearly in the ſtate in which it exiſts in the ſeed for the uſe of the young embryo.

159 Its uſes.

The peculiar juices of plants, then, contain more carbon, hydrogen, and oxygen, and leſs water, and probably lime alſo, than the ſap. They are conveyed to every part of the plant; and all the ſubſtances which we find in plants, and even the organs themſelves, by which they perform their functions, are formed from them. But the thickeſt veil covers the whole of theſe proceſſes; and ſo far have philoſophers hitherto been from removing this veil, that they have not even been able to approach it. All theſe operations, indeed, are evidently chemical decompoſitions and combinations; but we neither know what theſe decompoſitions and combinations are, nor the inſtruments in which they take place, nor the agents by which they are regulated.

160 Plants decay and die.

27. Such, as far as we are acquainted with them, are the changes produced by vegetation. But plants do not continue to vegetate for ever; ſooner or later they decay, and wither, and rot, and are totally decompoſed. This change indeed does not happen to all plants at the end of the ſame time. Some live only for a ſingle ſeaſon, or even for a ſhorter period; others live two ſeaſons, others three, others a hundred or more; and there are ſome plants which continue to vegetate for a thouſand years. But ſooner or later they all ceaſe to live; and then thoſe very chemical and mechanical powers which had promoted vegetation combine to deſtroy the remains of the plant. Now, What is the cauſe of this change? Why do plants die?

This queſtion can only be anſwered by examining with ſome care what it is which conſtitutes the *life* of plants; for it is evident, that if we can diſcover what that is which conſtitutes the life of a plant, it cannot be difficult to diſcover what conſtitutes its death.

161 Phenomena of vegetable life.

Now the phenomena of vegetable life are in general *vegetation*. As long as a plant continues to vegetate, we ſay that it lives; when it ceaſes to vegetate, we conclude that it is dead.

The life of vegetables, however, is not ſo intimately connected with the phenomena of vegetation that they cannot be ſeparated. Many ſeeds may be kept for years without giving any ſymptom of vegetation; yet if they vegetate when put into the earth, we ſay that they poſſeſs life: and if we would ſpeak accurately, we muſt ſay alſo, that they poſſeſſed life even before they were put into the earth; for it would be abſurd to ſuppoſe that the ſeed *obtained* life merely by being put into the earth. In like manner, many plants decay, and give no ſymptoms of vegetation during winter; yet if they vegetate when the mild temperature of ſpring affects them, we conſider them as having lived all winter. The life of plants, then, and the phenomena of vegetation, are not preciſely the ſame thing; for the one may be ſeparated from the other, and we can even ſuppoſe the one to exiſt without the other. Nay, what is more, we can, in many caſes, *decide*, without heſitation, that a vegetable is not dead, even when no vegetation appears; and the proof which we have for its life is, that it *remains unaltered*; for we know that when a vegetable is dead, it ſoon changes its appearance, and falls into decay.

Thus it appears that the *life* of a vegetable conſiſts in two things. 1. In remaining unaltered, when circumſtances are unfavourable to vegetation; 2. In exhibiting

---

* *Ann. de Chim.* xxi. 285.

ta- on. hibiting the phenomena of vegetation when circumſtances are favourable. When neither of theſe two things happens, we ſay that a vegetable is dead.

The phenomena of vegetation have been enumerated above. They conſiſt in the formation or expanſion of the organs of the plant, in the taking in of nouriſhment, in carrying it to the leaves, in digeſting it, in diſtributing it through the plant, in augmenting the bulk of the plant, in repairing decayed parts, in forming new organs when they are neceſſary, in producing ſeeds capable of being converted into plants ſimilar to the parent. The *cauſe* of theſe phenomena, whatever it may be, is the *cauſe* alſo of *vegetable life*.

All the ſubſtances which have been enumerated in the firſt part of the article CHEMISTRY, *Suppl.* together with their compounds and component parts, poſſeſs certain qualities in common; in conſequence of which, a term has been invented which includes them all This term is *matter*. Now theſe common qualities may all ultimately be reſolved into certain attractions and repulſions which theſe ſubſtances exert. Theſe qualities may be ſaid, without any impropriety, to be *eſſential to matter*; becauſe every body to which we give the name of *matter* poſſeſſes them; and if any body were to be deprived of theſe qualities, it could no longer be included under the denomination *matter*. In ſhort, the word *matter* comprehends under it certain qualities; every ſubſtance which poſſeſſes theſe qualities is called *matter*; and no other ſubſtance except theſe can receive the name of *matter* without altering the meaning of the word.

162 relu- e to the s of tter;

The attractions and repulſions of matter have been examined with care; and the changes which they produce have been aſcertained with conſiderable accuracy. They have even been reduced to general principles under the name of *mechanical and chemical laws*. Whenever any change is obſerved, if that change be a caſe of a mechanical or chemical law, we ſay that the agent is *matter*; but if the change cannot be reduced under theſe laws, or if it be incompatible with theſe laws, we muſt ſay, unleſs we would pervert the meaning of words altogether, that the agent is not *matter*.

Now it cannot be diſputed that ſeveral of the phenomena of life in vegetables are incompatible with the laws of mechanics and chemiſtry. The motion of the ſap, for inſtance, muſt be produced by the contraction of the veſſels; and the contraction of veſſels, on the application of ſtimuli, is incompatible with the laws of chemiſtry, becauſe no decompoſition takes place; and of mechanics, becauſe a much greater force is generated than the generating body itſelf poſſeſſed. The evolution of the organs of vegetables, the reparation of decayed organs, the formation of new ones to ſupply the place of the old, the production of ſeeds capable of producing new plants, the conſtant ſimilarity of individuals of the ſame ſpecies;—theſe, and many other well known phenomena, cannot be reduced under mechanical and chemical laws.

163 ſe- ntly ng to mma- al cauſe.

The cauſe of life, then, in plants, is a *ſubſtance* (for we can form no conception of an agent which is not a ſubſtance) which does not act according to the laws of mechanics and chemiſtry, and which conſequently is *not matter*. We ſhall therefore, till a better name be choſen, denominate it the *vegetative principle* (G).

Vegetation.

164 Nature of the vegetative principle.

The nature of the *vegetative principle* can only be deduced from the phenomena of vegetation. It evidently follows a fixed plan, and its actions are directed to promote the good of the plant. It has a power over matter, and is capable of directing its attractions and repulſions, in ſuch a manner as to render them the inſtruments of the formation, and improvement, and preſervation of the plant. It is capable alſo of generating ſubſtances endowed with powers ſimilar to itſelf. The plan according to which it acts, diſplays the moſt conſummate wiſdom and foreſight, and a knowledge of the properties of matter infinitely beyond what man can boaſt.

165 Whether endowed with conſciouſneſs.

Metaphyſicians have thought proper to divide all ſubſtances into two claſſes, *matter* and *mind*. If we follow this diviſion, the vegetative principle, as it is not *material*, muſt undoubtedly be ranked under *mind*. But if *conſciouſneſs* and *intelligence* be conſidered as eſſential to mind, which is the caſe according to their definition, we cannot give the vegetative principle the name of *mind*, becauſe it has not been proved that it poſſeſſes conſciouſneſs and intelligence. It acts indeed according to a fixed plan, which diſplays the higheſt degree of intelligence; but this plan may belong, not to the vegetative principle itſelf, but to the Being who formed that principle We can conceive it to have been endowed by the Author of Nature with peculiar powers, which it muſt always exert according to certain fixed laws; and the phenomena of vegetation *may be* the reſult of this mode of acting. This, as far as we can ſee, is not impoſſible. It muſt be ſhewn to be impoſſible by every perſon who wiſhes to prove that plants poſſeſs conſciouſneſs and intelligence; for the proofs of this conſciouſneſs can only be deduced from the deſign which the actions of plants manifeſt. Thoſe philoſophers who have aſcribed conſciouſneſs and intelligence to plants, have founded their belief principally on certain actions which plants perform on the application of ſtimuli. But theſe actions prove nothing more than what cannot be denied, that there exiſts a vegetative principle, which is not material, and which has certain properties in common with the living principles of animals; but whether or not this vegetative principle poſſeſſes conſciouſneſs and intelligence, is a very different queſtion, and muſt be decided by very different proofs. We do not ſay that the heart of an animal is conſcious, becauſe it continues to beat on the application of proper ſtimuli for ſome time after it has been ſeparated from the reſt of the body.

166 Death of plants.

The death of plants, if we can judge from the phenomena, is owing, not to the vegetative principle leaving them, but to the organs becoming at laſt altogether unfit for performing their functions, and incapable of being repaired by any of the powers which that principle poſſeſſes. The changes which vegetable ſubſtances undergo after death come now to be examined. They ſhall form the ſubject of the enſuing chapter.

CHAP.

(G) Phyſiologiſts have uſually given it the name of *living principle*. We would have adopted that name, if it had not been too general for our purpoſe.

CHAP. III. OF THE DECOMPOSITION OF VEGETABLE SUBSTANCES.

NOT only entire plants undergo decompoſition after death, but certain vegetable ſubſtances alſo, whenever they are mixed together, and placed in proper circumſtances, mutually decompoſe each other, and new compound ſubſtances are produced.

167 Vegetable decompoſitions,

Theſe mutual decompoſitions, indeed, are naturally to be expected: for as all vegetable ſubſtances are compoſed of ſeveral ingredients, differing in the ſtrength of their affinity for each other, it is to be ſuppoſed that, when two ſuch ſubſtances are mixed together, the divellent affinities will, in many caſes, prove ſtronger than the quieſcent; and therefore decompoſition, and the formation of new compounds, muſt take place: juſt as happens when the acetite of lead and ſulphat of potaſs are mixed together.

Theſe mutual decompoſitions of vegetable ſubſtances are by no means ſo eaſily traced, or ſo readily explained, as the mutual decompoſitions of neutral ſalts; partly on account of the number of ſubſtances, whoſe affinities for each other are brought into action, and partly becauſe we are ignorant of the manner in which the ingredients of vegetable ſubſtances are mutually combined.

168 Called FERMENTATION.

Chemiſts have agreed to give theſe mutual decompoſitions which take place in vegetable ſubſtances the name of *fermentation*; a word firſt introduced into chemiſtry by Van Helmont*; and the new ſubſtances produced they have called the *products* of fermentation. All the phenomena of fermentation lay for many years concealed in the completeſt darkneſs, and no chemiſt was bold enough to hazard even an attempt to explain them. They were employed, however, and without heſitation too, in the explanation of other phenomena; as if giving to one proceſs, the name of another of which we are equally ignorant, could, in reality, add any thing to our knowledge. The darkneſs which enveloped theſe phenomena, has lately begun to diſperſe; but they are ſtill ſurrounded with a very thick miſt; and we muſt be much better acquainted with the compoſition of vegetable ſubſtances, and the mutual affinities of their ingredients, than we are at preſent, before we can explain them in a ſatisfactory manner.

169 Diviſion of them.

The vegetable fermentations or decompoſitions may be arranged under five heads; namely, that which produces *bread*, that which produces *wine*, that which produces *beer*, that which produces *acetous acid* or *vinegar*, and the *putrefactive* fermentation, or that which produces the ſpontaneous decompoſition of decayed vegetables. Theſe ſhall be the ſubject of the five following ſections. In order to avoid long titles, we ſhall give to the firſt three ſections the name of the new ſubſtances produced by the fermentation.

SECT. I. *Of BREAD.*

170 Diſcovery of bread.

SIMPLE as the manufacture of bread may appear to us who have been always accuſtomed to conſider it as a common proceſs, its diſcovery was probably the work of ages, and the reſult of the united efforts of men, whoſe ſagacity, had they lived in a more fortunate period of ſociety, would have rendered them the rivals of Ariſtotle or of Newton.

The method of making bread ſimilar to ours was known in the Eaſt at a very early period; but neither the preciſe time of the diſcovery, nor the name of the perſon who publiſhed it to the world, has been preſerved. We are certain that the Jews were acquainted with it in the time of Moſes: for in Exodus* we find a prohibition to uſe leavened bread during the celebration of the paſſover. It does not appear, however, to have been known to Abraham; for we hear in his hiſtory of cakes frequently, but nothing of leaven. Egypt, both from the nature of the ſoil and the early period at which it was civilized, bids faireſt for the diſcovery of making bread. It can ſcarcely be doubted, that the Jews learned the art from the Egyptians The Greeks aſſure us, that they were taught the art of making bread by the god Pan. We learn from Homer that it was known during the Trojan war †. The Romans were ignorant of the method of making bread till the year 580, after the building of Rome, or 200 years before the commencement of the Chriſtian era ‡. Since that period the art has never been unknown in the ſouth of Europe; but it made its way to the north very ſlowly, and even at preſent in many northern countries fermented bread is but very ſeldom uſed.

171 Subſtance which make bread.

The only ſubſtance well adapted for making bread, we mean *loaf bread*, is wheat flour, which is compoſed of four ingredients; namely, gluten, ſtarch, albumen, and a *ſweet mucous matter*, which poſſeſſes nearly the properties of ſugar, and which is probably a mixture of ſugar and mucilage. It is to the gluten that wheat flour owes its ſuperiority to every other as the baſis of bread. Indeed, there are only two other ſubſtances at preſent known of which good loaf bread can be made; theſe are *rye* and *potatoes*. The rye loaf is by no means ſo well raiſed as the wheat loaf; and potatoes will not make bread at all without particular management. Potatoes, previouſly boiled and reduced to a very fine tough paſte by a rolling pin, muſt be mixed with an equal weight of potato ſtarch. This mixture, baked in the uſual way, makes a very white, well raiſed, pleaſant bread. We are indebted for the proceſs to Mr Permentier. Barley-meal perhaps might be ſubſtituted for ſtarch.

172 Baking bread.

The baking of bread conſiſts in mixing wheat flour with water, and forming it into a paſte. The average proportion of theſe is two parts of water to three of flour. But this proportion varies conſiderably, according to the age and the quality of the flour. In general, the older and the better the flour is, the greater is the quantity of water required. If the paſte, after being thus formed, be allowed to remain for ſome time, its ingredients gradually act upon each other, and the paſte acquires new properties. It gets a diſagreeable ſour taſte, and a quantity of gas (probably carbonic acid gas) is evolved. In ſhort, the paſte ferments (H). Theſe changes do not take place without water; that liquid, therefore, is a neceſſary agent. Poſſibly it is decompoſed by the action of the ſtarch upon it; for when ſtarch is diluted with water, it gradually becomes ſour. The gluten, too, is altered, either by the action of the water on it, or of the ſtarch; for if we examine the paſte after

---

* *Stahl, Fundament. Chem.* i. 124.

* Ch. xii. v. 15.

† *Iliad*, ix 216.

‡ *Plin.* l. 1 cap. 11.

(H) It was from this proceſs that Van Helmont transferred the word *fermentation* into chemiſtry.

ead. after it has undergone fermentation, the gluten is no longer to be found. If paſte, after ſtanding for a ſufficient time to ferment, be baked in the uſual way, it forms a loaf full of eyes like our bread, but of a taſte ſo ſour and unpleaſant that it cannot be eaten. If a ſmall quantity of this old paſte, or *leaven* as it is called, be mixed with new made paſte, the whole begins to ferment in a ſhort time; a quantity of gas is evolved; but the glutinous part of the flour renders the paſte ſo tough, that the gas cannot eſcape; it therefore cauſes the paſte to ſwell in every direction: and if it be now baked into loaves, the immenſe number of air bubbles impriſoned in every part renders the bread quite full of eyes, and very light. If the preciſe quantity of leaven neceſſary to produce the fermentation, and no more, has been uſed, the bread is ſufficiently light, and has no unpleaſant taſte; but if too much leaven be employed, the bread has a bad taſte; if too little, the fermentation does not come on, and the bread is too compact and heavy. To make good bread with leaven, therefore, is very difficult.

The ancient Gauls had another method of fermenting bread. They formed their paſte in the uſual way; and inſtead of leaven, mixed with it a little of the *barm* which collects on the ſurface of fermenting beer *. This mixture produced as complete and as ſpeedy a fermentation as leaven; and it had the great advantage of not being apt to ſpoil the taſte of the bread. About the end of the 17th century, the bakers in Paris began to introduce this practice into their proceſſes. The practice was diſcovered, and exclaimed againſt; the faculty of medicine, in 1688, declared it prejudicial to health; and it was not till after a long time that the bakers ſucceeded in convincing the public that bread baked with *barm* is ſuperior to bread baked with leaven. In this country the bread has for theſe many years been fermented with barm.

* *lin.* 7.

173 n. What is this *barm* which produces theſe effects? The queſtion is curious and important; but we are not able to anſwer it completely. Mr Henry of Mancheſter has concluded, from a number of very intereſting experiments, that the only uſeful part of barm is carbonic acid gas, and that this gas therefore is the real fermenter of paſte †.

† *anch.* v. ii.

That the barm of beer, in its uſual ſtate, contains carbonic acid gas, cannot be doubted; and that carbonic acid gas acts as a ferment, the experiments of Mr Henry prove deciſively. But that the only active part of barm is carbonic acid gas, and nothing but carbonic gas, is extremely doubtful, or rather we are certain that it is not true. It has been cuſtomary with the bakers of Paris to bring their barm from Flanders and Picardy in a ſtate of dryneſs. When ſkimmed off the beer, it is put into ſacks, and the moiſture allowed to drop out; then theſe ſacks are ſubjected to a ſtrong preſſure, and when the barm is dry it is made up into balls †. Now, in this ſtate, it is not to be ſuppoſed that bubbles of carbonic acid can remain entangled in the barm; they muſt have been ſqueezed out by the preſs, and by the ſubſequent formation of the barm into balls: yet this barm, when moiſtened with water, ferments the bread as well as new barm.

† *Meth.* 249.

174 Heat of the oven. After the bread has fermented, and is properly raiſed, it is put into the oven previouſly heated, and allowed to remain till it be baked. The mean heat of an oven, as aſcertained by Mr Tillet, is 448° *. The bakers do not uſe a thermometer; but they judge that the oven is arrived at the proper heat when flour thrown on the floor of it becomes black very ſoon without taking fire. We ſee, from Tillet's experiment, that this happens at the heat of 448°.

* *Enc. Meth.* art. i. 275.

175 Loſs of weight ſuſtained in it. When the bread is taken out of the oven, it is found to be lighter than when put in; as might naturally have been expected, from the evaporation of moiſture, which muſt have taken place at that temperature. Mr Tillet, and the other commiſſioners who were appointed to examine this ſubject in conſequence of a petition from the bakers of Paris, found that a loaf, which weighed before it was put into the oven 4.625 lbs. after being taken out baked, weighed, at an average, only 3.813 lbs. or 0.812 lb. leſs than the paſte. Conſequently 100 parts of paſte loſe, at an average, 17.34 parts, or ſomewhat more than $\frac{1}{5}$th by baking *. They found, however, that this loſs of weight was by no means uniform, even with reſpect to thoſe loaves which were in the oven at the ſame time, of the ſame form, and in the ſame place, and which were put in and taken out at the ſame inſtant. The greateſt difference in theſe circumſtances amounted to .2889, or 7.5 parts in the hundred, which is about $\frac{1}{13}$th of the whole. This difference is very conſiderable, and it is not eaſy to ſay to what it is owing. It is evident, that if the paſte has not all the ſame degree of moiſture, and if the barm be not accurately mixed through the whole, if the fermentation of the whole be not preciſely the ſame, that theſe differences muſt take place. Now it is needleſs to obſerve how difficult it is to perform all this completely. The French commiſſioners found, as might indeed have been expected, that other things being equal, the loſs of weight ſuſtained is proportional to the extent of ſurface of the loaf, and to the length of time that it remains in the oven; that is to ſay, the ſmaller the extent of the external ſurface, or, which is the ſame thing, the nearer the loaf approaches to a globular figure, the ſmaller is the loſs of weight which it ſuſtains; and the longer it continues in the oven, the greater is the loſs of weight which it ſuſtains. Thus a loaf which weighed exactly 4 lbs. when newly taken out of the oven, being replaced as ſoon as weighed, loſt, in ten minutes, .125 lb. of its weight, and in ten minutes more it again loſt .0625 lb †.

* *Ibid.* 275.

† *Ibid.* p. 270.

Loaves are heavieſt when juſt taken out of the oven; they gradually loſe part of their weight, at leaſt if not kept in a damp place, or wrapt round with a wet cloth (K). Thus Mr Tillet found that a loaf of 4 lbs. after being kept for a week, wanted .3125, or nearly $\frac{1}{13}$th of its original weight ‡.

‡ *Ibid.*

176 Properties of bread. When bread is newly taken out of the oven, it has a peculiar, and rather pleaſant ſmell, which it loſes by keeping; as it does alſo the peculiar taſte by which new bread is diſtinguiſhed. This ſhews us, that the bread undergoes chemical changes; but what theſe changes are, or what the peculiar ſubſtance is to which the odour of bread is owing, is not known.

(K) This is an excellent method of preſerving bread freſh, and free from mould, for a long time.

Bread differs very completely from the flour of which it is made, for none of the ingredients of the flour can now be diſcovered in it. The only chemiſt who has attempted an analyſis of bread is Mr Geoffroy. He found that 100 parts of bread contained the following ingredients :

24.735 water.
32.030 gelatinous matter, extracted by boiling water.
39.843 reſiduum inſoluble in water.

96.608
3.392 loſs.

100.

But this analyſis, which was publiſhed in the Memoirs of the French Academy for the year 1732, was made at a time when the infant ſtate of the ſcience of chemiſtry did not admit of any thing like accuracy.

Sect. II. *Of Wine.*

177
Fruits affording wine

There is a conſiderable number of ripe fruits from which a ſweet liquor may be expreſſed, having at the ſame time a certain degree of acidity. Of ſuch fruits we have in this country the apple, the cherry, the gooſeberry, the currant, &c. but by far the moſt valuable of theſe fruits is the *grape*, which grows luxuriantly in the ſouthern parts of Europe. From grapes, fully ripe, may be expreſſed a liquid of a ſweet taſte, to which the name of *muſt* has been given. This liquid is compoſed almoſt entirely of five ingredients ; namely, *water*, *ſugar*, *jelly*, *mucilage*, and *tartarous* acid partly ſaturated with potaſs. The quantity of ſugar which grapes fully ripe contain is very conſiderable ; it may be obtained in cryſtals by evaporating muſt to the conſiſtence of ſyrup, ſeparating the tartar which precipitates during the evaporation, and then ſetting the muſt aſide for ſome months. The cryſtals of ſugar are gradually formed.

178
Undergo the vinous fermentation ;

When muſt is put into the temperature of about 70°, the different ingredients begin to act upon each other, and what is called *vinous fermentation* commences. The phenomena of this fermentation are an inteſtine motion in the liquid, its becoming thick and muddy, a temperature equal to 72.5°, and an evolution of carbonic acid gas. In a few days the fermentation ceaſes, the thick part ſubſides to the bottom, the liquid becomes clear, it has loſt much of its ſaccharine taſte, and aſſumed a new one, its ſpecific gravity is diminiſhed ; and, in ſhort, it has become the liquid well known under the name of *wine*.

Now what is the cauſe of this fermentation ; what are the ſubſtances which mutually decompoſe each other ; and what is the nature of the new ſubſtance formed ?

Theſe changes are produced altogether by the mutual action of the ſubſtances contained in muſt ; for they take place equally well, and wine is formed equally well in cloſe veſſels as in the open air §.

179
For which water,

If the *muſt* be evaporated to the conſiſtency of a thick ſyrup, or to a *rob*, as the elder chemiſts termed it, the fermentation will not commence, though the proper temperature, and every thing elſe neceſſary to produce fermentation, be preſent ||. But if this ſyrup be again diluted with water, and placed in favourable circumſtances, it will ferment. Therefore the preſence of *water* is abſolutely neceſſary for the exiſtence of vinous fermentation.

180
Sugar,

If the juice of thoſe fruits which contain but little ſugar, as currants, be put into a favourable ſituation, fermentation indeed takes place, but ſo ſlowly, that the product is not *wine*, but *vinegar* : but if a ſufficient quantity of ſugar be added to theſe very juices, wine is readily produced. No ſubſtance whatever can be made to undergo vinous fermentation, and to produce wine, unleſs ſugar be preſent. *Sugar* therefore is abſolutely neceſſary for the exiſtence of vinous fermentation ; and we are certain that it is decompoſed during the proceſs ; for no ſugar can be obtained from properly fermented wine.

181
An acid,

All thoſe juices of fruits which undergo the vinous fermentation, either with or without the addition of ſugar, contain an acid. We have ſeen already in the firſt chapter that the vegetable acids are obtained chiefly from fruits. The apple, for inſtance, contains malic acid ; the lemon, citric acid ; the grape, tartarous acid. The Marquis de Bullion has aſcertained, that *muſt* will not ferment if all the tartarous acid which it contains be ſeparated from it*. We may conclude from this, that the preſence of a vegetable acid is abſolutely neceſſary for the commencement of the vinous fermentation. This renders it probable that the eſſential part of barm is a vegetable acid, or ſomething equivalent ; for if ſugar be diſſolved in four times its weight of water, mixed with the yeaſt of beer, and placed in a proper temperature, it undergoes the vinous fermentation †.

182
And jelly are nece ſary.

All the juices of fruits which undergo the vinous fermentation contain a quantity of jelly, or mucilage, or of both. Theſe two ſubſtances reſemble each other in ſo many particulars, and it is ſo difficult to ſeparate them, that we ſhall ſuppoſe they have the ſame effect in the mixture. The preſence of theſe ſubſtances renders it probable that they alſo are neceſſary for the vinous fermentation. Perhaps they act chiefly by their tendency to become acid.

Thus we ſee, that for the production of wine a certain temperature, a certain portion of water, ſugar, a vegetable acid, and, in all probability, jelly alſo, is neceſſary. Mr Lavoiſier found that ſugar would not ferment unleſs diſſolved in at leaſt four times its weight of water. This ſeems to indicate that the particles of ſugar muſt be removed to a certain diſtance from each other before the other ingredients can decompoſe them. The evolution and ſeparation of carbonic acid gas in ſuch quantity, ſhews us that the proportion of the carbon and the oxygen of the ſugar is diminiſhed. It is not certain that the mucilage of the wine is decompoſed ſo completely as the ſugar ; for it has been obſerved, that when the muſt abounds in mucilage, the wine is apt to become ſour.

183
Decomp ſition of wine.

When wine is diſtilled by means of a low heat, there comes over a quantity of *alcohol*, and the remainder is a ſolution of acetous acid. From this fact, it has been concluded that wine is compoſed of acetous acid and alcohol. But that the diſtillation occaſions a chemical change in the ingredients of wine is evident from this, that if we again mix the alcohol and acetous acid, we do not reproduce the wine.

Fourcroy has attempted to ſhew that alcohol exiſted ready formed ; but his proofs are not concluſive. Fabroni

† *Bergma*

roni has ſhewn, that alcohol cannot be obtained from new made wine by any other method than diſtillation. When wine is ſatured with very dry carbonat of potaſs, no alcohol makes its appearance on the ſurface of the mixture, yet a very ſmall quantity of alcohol, artificially mixed with wine, may be detected by this method. It is certain, however, that alcohol exiſts ready formed in old wine.

SECT. III. *Of Beer.*

THE method of making beer was known in the moſt remote ages; we are ignorant to whom the world is indebted for the diſcovery of it. Beer is uſually made from *barley*.

184 hod of ing

The barley is ſteeped in water for about ſixty hours, in order to ſaturate it with that liquid. It ought then to be removed as ſpeedily as poſſible, otherwiſe the water diſſolves, and carries off the moſt valuable part of the grain. The barley is then to be laid in a heap for twenty-four hours; heat is evolved, oxygen gas abſorbed, carbonic acid gas emitted, and germination commences with the ſhooting forth of the radicle. It is then ſpread upon a cool floor, dried ſlowly, and is afterwards known by the name of *malt* *.

185 t,

Malt, previouſly ground to a coarſe powder, is to be infuſed in a ſufficient quantity of pure water, of the temperature of 160°, for an hour. The infuſion is then to be drawn off, and more water may be added, at a higher temperature, till all the ſoluble part of the malt is extracted. This infuſion is known by the name of *wort*. It has a ſweet taſte, and contains a quantity of ſaccharine, and doubtleſs alſo of gelatinous matter.

186 l beer.

When *wort* is placed in the temperature of about 60°, fermentation gradually takes place in it, and the very ſame phenomena appear which diſtinguiſh the production of wine. The fermentation of wort, then, is nothing but a particular caſe of the vinous fermentation. But wort does not ferment ſo well, nor ſo ſoon, nor does it produce nearly ſo great a quantity of good fermented liquor, as when *yeaſt* is added to it. The reaſon of which is, probably, that the fermentation does not commence till an acid is generated in the wort, and before that happens part of the ſaccharine contents are decompoſed; whereas the yeaſt adds an acid, or, at leaſt, ſomething equivalent to it, at once.

Wort ferments in cloſe veſſels, as Mr Collier aſcertained by experiment, equally well as in the open air. Therefore the decompoſition is produced entirely by the ſubſtances contained in the wort, without the addition of any thing from the air. The quantity of beer produced in cloſe veſſels is much greater than when the proceſs takes place in the open air. The reaſon of which is, that in the open air the beer gradually evaporates during the fermentation. Thus Mr Collier found that 11 quarts, $3\frac{1}{2}$ oz. fermented in open veſſels, loſt, in 12 days, 40 oz.; whereas an equal weight, fermented in cloſe veſſels, loſt only 8 oz. in the ſame time. Yet the quality of the *beer* was the ſame in each; for equal quantities of both, when diſtilled, yielded preciſely the ſame portion of alcohol †.

During the fermentation, a quantity of carbonic acid gas is conſtantly diſengaged, not in a ſtate of purity, but containing, combined with it, a portion of the wort; and if this gas be made to paſs through water, it will depoſite wort, which may be fermented in the uſual manner *.

When beer is diſtilled, alcohol is obtained, and the reſiduum is an acid liquor †. The theory of beer is ſo obviouſly the ſame with that of wine that it requires no additional explanation.

SECT. IV. *Of the Acetous Fermentation.*

187 Subſtances which undergo the acetous fermentation.

IF wine or beer be kept at a temperature between 70° and 90°, it gradually loſes its properties, and is converted into *acetous acid*.

During this change, a quantity of oxygen gas is abſorbed, and the whole of the ſpirituous part of the wine or beer diſappears. Conſequently its ingredients have mutually decompoſed each other.

Neither pure alcohol, nor alcohol diluted with water, are capable of undergoing this change, neither do they abſorb any oxygen. This abſorption, then, is made by the mucilaginous matter which always exiſts in theſe liquids. No acetous acid is ever produced, unleſs ſome acid be preſent in the liquid. We may conclude, then, that the mucilage acquires the properties of an acid before it begins to act upon the ſpirituous part of the beer or the wine.

As the acetous acid has been already treated of in the article CHEMISTRY, *Suppl.* it is unneceſſary to dwell any longer on this ſubject here.

SECT. V. *Of Putrefaction.*

188 Nature of putrefaction.

ALL vegetable ſubſtances, both complete plants and their component parts ſeparately, when left entirely to themſelves, are gradually decompoſed and deſtroyed, provided moiſture be preſent, and the temperature be not much under 45°, nor too high to evaporate ſuddenly all the moiſture. This decompoſition has obtained the name of *putrefaction*.

It proceeds with moſt rapidity in the open air; but the contact of air is not abſolutely neceſſary. Water is, in all caſes, eſſential to the proceſs, and therefore is moſt probably decompoſed.

Putrefaction is conſtantly attended with a fetid odour, owing to the emiſſion of certain gaſeous matters, which differ according to the putrefying ſubſtance. Some vegetable ſubſtances, as gluten, and cruciform plants, emit ammonia; others, as onions, ſeem to emit phoſphorated hydrogen gas. Carbonic acid gas, and hydrogen gas, impregnated with unknown vegetable matters, are almoſt conſtantly emitted in abundance. When the whole proceſs is finiſhed, ſcarcely any thing remains but the earths, the ſalts, and the metals, which formed a conſtituent part of the vegetable. But our chemical knowledge of vegetable compounds is by far too limited to enable us to follow this very complicated proceſs with any chance of ſucceſs.

Part II. Of Animal SUBSTANCES.

Ingredients of Animals, Fibrina.

189 Claſſes of animals and vegetables

WHEN we compare animals and vegetables together, each in their moſt perfect ſtate, nothing can be eaſier than to diſtinguiſh them. The plant is confined to a particular ſpot, and exhibits no marks of conſciouſneſs or intelligence; the animal, on the contrary, can remove at pleaſure from one place to another, is poſſeſſed of conſciouſneſs, and a high degree of intelligence. But on approaching the contiguous extremities of the animal and vegetable kingdom, theſe ſtriking differences gradually diſappear, the objects acquire a greater degree of reſemblance, and at laſt approach each other ſo nearly, that it is ſcarcely poſſible to decide whether ſome of thoſe ſituated on the very boundary belong to the animal or vegetable kingdom.

190 Difficultly diſtinguiſhed.

To draw a line of diſtinction, then, between animals and vegetables, would be a very difficult taſk; but it is not neceſſary for us, in this place at leaſt, to attempt it; for almoſt the only animals whoſe bodies have been hitherto examined with any degree of chemical accuracy, belong to the moſt perfect claſſes, and conſequently are in no danger of being confounded with plants. Indeed the greater number of facts which we have to relate, apply only to the human body, and to thoſe of a few domeſtic animals. The taſk of analyſing all animal bodies is immenſe, and muſt be the work of ages of indefatigable induſtry.

191 Diviſion of this part.

We ſhall divide this part of the article into four chapters. In the firſt chapter, we ſhall give an account of the different ingredients hitherto found in animals, ſuch of them at leaſt as have been examined with any degree of accuracy: in the ſecond, we ſhall treat of the different members of which animal bodies are compoſed; which muſt conſiſt each of various combinations of the ingredients deſcribed in the firſt chapter: in the third, we ſhall treat of thoſe animal functions which may be elucidated by chemiſtry: and, in the fourth, of the changes which animal bodies undergo after death.

Chap. I. Of the Ingredients of Animals.

The ſubſtances which have been hitherto detected in the animal kingdom, and of which the different parts of animals, as far as theſe parts have been analyſed, are found to be compoſed, may be arranged under the following heads:

1. Fibrina,
2. Albumen,
3. Gelatine,
4. Mucilage,
5. Baſis of bile,
6. Urea,
7. Sugar,
8. Sulphur,
9. Oils,
10. Acids,
11. Alkalies,
12. Earths,
13. Metals.

Theſe ſhall form the ſubject of the following ſections:

Sect. I. *Of Fibrina.*

192 Fibrina how obtained.

If a quantity of blood, newly drawn from an animal, be allowed to remain at reſt for ſome time, a thick red clot gradually forms in it, and ſubſides. Separate this clot from the reſt of the blood, waſh it repeatedly in water till it ceaſes to give out any colour or taſte to the liquid; the ſubſtance which remains after this proceſs is denominated *fibrina*. It has been long known to phyſicians under the name of the *fibrous part of the blood*, but has not till lately been accurately deſcribed.

193 Its properties.

Fibrina is of a white colour, has no taſte, and is inſoluble in water and in alcohol. It is ſoft and ductile, has a conſiderable degree of elaſticity, and reſembles very much the gluten of vegetables.

Pure fixed alkalies do not act upon it, unleſs they be very much concentrated, and then they decompoſe it. All the acids combine with it readily, and diſſolve it. Water and alkalies ſeparate it again; but it has loſt entirely its former properties. With muriatic acid it forms a green coloured jelly.

When nitric acid is poured upon fibrina, azotic gas is diſengaged, as Berthollet firſt diſcovered. The quantity of this gas is greater than can be obtained from the ſame quantity of other animal ſubſtances by the ſame proceſs [*]. After this, pruſſic acid and carbonic acid gas are exhaled. By the aſſiſtance of heat the fibrina is diſſolved; much nitrous gas is diſengaged; the liquid, when concentrated, yields oxalic and malic acids; and white flakes are depoſited, conſiſting of an oily ſubſtance, and of phoſphat of lime [†].

When fibrina is diſtilled, it yields a very large quantity of ammonia [‡].

Theſe properties are ſufficient to ſhew us that this ſubſtance is compoſed of azot, hydrogen, and carbon; but neither the preciſe proportion of theſe ingredients, nor the manner of their combination, are at preſent known.

Sect. II. *Of Albumen.*

194 Albumen contained in eggs.

The eggs of fowls contain two very different ſubſtances: a yellow oily like matter, called the *yolk*; and a colourleſs gloſſy viſcid liquid, diſtinguiſhed by the name of *white*. This laſt is the ſubſtance which chemiſts have agreed to denominate *albumen* (L). The white of an egg, however, is not pure albumen. It contains, mixed with it, ſome carbonat of ſoda, and ſome ſulphur; but the quantity of theſe ſubſtances is ſo ſmall that they do not much influence its properties. We ſhall therefore conſider it as *albumen*.

195 Coagulated by heat.

On the application of a heat of 165 [§] it *coagulates*, as is well known, into a white ſolid maſs; the conſiſtency of which, when other things are equal, depends, in ſome meaſure, on the time during which the heat was applied. The coagulated maſs has preciſely the ſame weight that it had while fluid.

The taſte of coagulated albumen is quite different from that of liquid albumen: its appearance, too, and its

[*] *Fourcroy Ann. de Chim.* i. 41

[†] *Fourcroy.*

[‡] *Fourcroy Ann. de Chim.* i. 43

[§] *Cullen.*

(L) This is merely the Latin term for the white of an egg. It was firſt introduced into chemiſtry by the phyſiologiſts.

umen.

its properties, are entirely changed ; for it is no longer ſoluble, as before, either in hot or in cold water.

96
ome-
f this
ula-

The coagulation of albumen takes place even though air be completely excluded ; and even when air is preſent there is no abſorption of it, nor does albumen in coagulating change its volume *. Acids have the property of coagulating albumen, as Scheele aſcertained †. Alcohol alſo produces, in ſome meaſure, the ſame effect. *Heat*, then, *acids* and *alcohol*, are the agents which may be employed to coagulate albumen.

It is remarkable, that if albumen be diluted with a ſufficient quantity of water, it can no longer be coagulated by any of theſe agents. Scheele mixed the white of an egg with ten times its weight of water, and then, though he even *boiled* the liquid, no coagulum appeared. Acids indeed, and alcohol, even then coagulated it ; but they alſo loſe their power, if the albumen be diluted with a much greater quantity of water, as has been aſcertained by many experiments. Now we know, that when water is poured into albumen, not only a mechanical mixture takes place, but a chemical combination ; for the albumen is equally diſtributed through every part of the liquid. Conſequently its integrant particles muſt be farther ſeparated from each other, and their diſtance muſt increaſe with the quantity of water with which they are diluted. We ſee, therefore, that albumen ceaſes to coagulate whenever its particles are ſeparated from each other beyond a certain diſtance. That no other change is produced, appears evident from this circumſtance, that whenever the watery ſolution of albumen is ſufficiently concentrated by evaporation, coagulation takes place, upon the application of the proper agents, preciſely as formerly.

It does not appear that the diſtance of the particles of albumen is changed by coagulation ; for coagulated albumen occupies preciſely the ſame ſenſible ſpace as liquid albumen *.

197
uiry
its
ſe.

Thus two things ſeem certain reſpecting the coagulation of albumen : 1. That its particles muſt not be beyond a certain diſtance ; 2. That the coagulation does not produce any ſenſible change in their diſtance. To what, then, is the coagulation of albumen owing ? We can conceive no change to take place from a ſtate of liquidity to that of ſolidity, without ſome change in the figure of the particles of the body which has undergone that change : for if the figure and the diſtance of the particles of bodies continue the ſame, it is impoſſible to conceive any change at all to take place. Since, then, the diſtance of the particles of albumen does not, as far at leaſt as we can perceive, change, we muſt conclude, that the figure of the particles actually does change. Now ſuch a change may take place three ways: 1. The figure may be changed by the addition of ſome new molecules to each of the molecules of the body. 2. Some molecules may be abſtracted from every integrant particle of the body. 3. Or the molecules, of which the integrant particles are compoſed, may enter into new combinations, and form new integrant particles, whoſe form is different from that of the old integrant particles. Some one or other of theſe three things muſt take place during the coagulation of albumen.

1. Scheele and Fourcroy have aſcribed the coagulation of albumen to the firſt of theſe cauſes, namely, to the addition of a new ſubſtance. According to Scheele, *caloric* is the ſubſtance which is added. Fourcroy, on the contrary, affirms that it is *oxygen*.

Albumen.

Scheele ſupported his opinion with that wonderful ingenuity which ſhone ſo eminently in every thing which he did. He mixed together one part of white of egg and four parts of water, added a little pure alkali, and then dropt in as much muriatic acid as was ſufficient to ſaturate the alkali. The albumen coagulated : but when he repeated the experiment, and uſed carbonat of alkali inſtead of pure alkali, no coagulation enſued. In the firſt caſe, ſays he, there was a double decompoſition: the muriatic acid ſeparated from a quantity of caloric with which it was combined, and united with the alkali ; while, at the ſame inſtant, the caloric of the acid united with the albumen, and cauſed it to coagulate. The ſame combination could not take place when the alkaline carbonat was uſed, becauſe the carbonic acid gas carried off the caloric, for which it has a ſtrong affinity *.

This explanation is plauſible ; but it is contrary to every other known fact in chemiſtry, to ſuppoſe that caloric can combine with a ſubſtance without occaſioning any alteration in its bulk, and cannot therefore be admitted without the moſt rigid proof.

Fourcroy obſerves, in ſupport of his opinion, that the white of an egg is not at firſt capable of forming a hard coagulum, and that it only acquires that property by expoſure to the atmoſphere. It is well known that the white of a new laid egg is milky after boiling ; and that if the ſhell be covered over with greaſe, to exclude the external air, it continues long in that ſtate ; whereas the white of an old egg, which has not been preſerved in that manner, forms a very hard tough coagulum. Theſe facts are undoubted ; and they render it exceedingly probable, that albumen acquires the property of forming a hard coagulum only by abſorbing oxygen : but they by no means prove that coagulation itſelf is owing to ſuch an abſorption. And ſince coagulation takes place without the preſence of air, and ſince no air, even when it is preſent, is abſorbed, this opinion cannot be maintained without inconſiſtency.

2. The only ſubſtance which can be ſuppoſed to leave albumen during coagulation, ſince it does not loſe weight, is *caloric*. We know that in moſt caſes where a fluid is converted into a ſolid, caloric is actually diſengaged. It is extremely probable, then, that the ſame diſengagement takes place here. But the opinion has not been confirmed by any proof. Fourcroy indeed ſays, that in an experiment made by him, the thermometer roſe a great number of degrees. But as no other perſon has ever been able to obſerve any ſuch thing, it cannot be doubted that this philoſopher has been miſled by ſome circumſtance or other to which he did not attend †. It is uſual, in many caſes, for bodies to loſe bulk when they give out caloric ; but that there are exceptions to this rule, is well known.

3. Even if the ſecond opinion were true, it is ſcarcely poſſible to conceive the coagulation of albumen to take place without ſome change in its integrant particles. We can ſee how all the ſubſtances which coagulate albumen might produce ſuch a change ; and the inſolubility of coagulated albumen in water, and its other different properties, render it more than probable that ſome ſuch change actually takes place. But what that change is, cannot even be conjectured.

198
Properties of albumen

The coagulation of albumen is intimately connected with one of the moſt important problems in chemiſtry, namely, the cauſe of fluidity and ſolidity. But this problem can only be reſolved, with any proſpect of ſucceſs, by a geometrical inveſtigation of the phenomena of heat.

Coagulated albumen is diſſolved by the mineral acids, greatly diluted with water; and if a concentrated acid be added to the ſolution, the albumen is again precipitated [*]. Alkalies, however, do not precipitate it from its ſolution in acids [†]. But if a ſolution of tan be poured into the acid ſolution of albumen, a very copious precipitate appears [‡].

If the ſolution of tan be poured into an aqueous ſolution of uncoagulated albumen, it forms with it a very copious precipitate, which is inſoluble in water. This precipitate is a combination of tan and albumen. This property which albumen has of precipitating with tan, was diſcovered by Seguin [§]: it furniſhes us with a method of detecting the preſence of albumen in any liquid in which we ſuſpect it.

Pure alkalies and lime water alſo diſſolve albumen; at the ſame time ammonia is diſengaged, owing to the decompoſition of part of the albumen. Acids precipitate the albumen from alkalies, but its properties are changed [*].

Nitric acid, when aſſiſted by heat, diſengages azotic gas from albumen [†]; but the quantity is not ſo great as may be obtained from fibrina [‡]. The albumen is gradually diſſolved, nitrous gas is emitted, oxalic and malic acids are formed, and a thick oily matter makes its appearance on the ſurface [§]. When diſtilled, it furniſhes the ſame products as fibrina, only the quantity of ammonia is not ſo great [||].

Hence it follows, that albumen is compoſed of azot, hydrogen, and carbon, as well as fibrina; but the proportion of azot is not ſo great in the firſt ſubſtance as in the ſecond.

SECT. III. *Of Gelatine.*

199
Gelatine how obtained.

If a piece of the freſh ſkin of an animal, an ox for inſtance, after the hair and every impurity is carefully ſeparated, be waſhed repeatedly in cold water, till the liquid ceaſes to be coloured, or to abſtract any thing; if the ſkin, thus purified, be put into a quantity of pure water, and boiled for ſome time, part of it will be diſſolved. Let the decoction be ſlowly evaporated till it is reduced to a ſmall quantity, and then put aſide to cool. When cold, it will be found to have aſſumed a ſolid form, and to reſemble preciſely that tremulous ſubſtance well known to every body under the name of *gelly*. This is the ſubſtance called in chemiſtry *gelatine*. If the evaporation be ſtill farther continued, by expoſing the gelly to dry air, it becomes hard, ſemitranſparent, breaks with a glaſſy fracture, and is in ſhort the ſubſtance ſo much employed in different arts under the name of *glue*. Gelatine, then, is preciſely the ſame with glue; only that it muſt be ſuppoſed always free from thoſe impurities with which glue is ſo often contaminated.

200
Its properties.

Gelatine is tranſparent and colourleſs; when thrown into water, it very ſoon ſwells, and aſſumes a gelatinous form, and gradually diſſolves completely. By evaporating the water, it may be obtained again unaltered in the form of gelly.

When an infuſion of tan is dropt into a ſolution of gelatine in water, there is inſtantly formed a copious white precipitate, which has all the properties of leather. This precipitate is compoſed of tan and gelatine. Theſe two ſubſtances, therefore, when combined, form leather. Albumen and gelatine are the only animal ſubſtances known which have the property of combining with tan, and forming with it an inſoluble compound. They may be always eaſily detected, therefore, by means of tan; and they may be readily diſtinguiſhed from each other, as albumen alone coagulates by heat, and gelatine alone concretes into a gelly.

Gelatine is inſoluble in alcohol, and is even precipitated from water by it; but both acids and alkalies diſſolve it. Nitric acid diſengages from it a ſmall quantity of azotic gas; diſſolves it, when aſſiſted by heat, excepting an oily matter, which appears on the ſurface of the ſolution; and converts it, partly into oxalic and malic acids [*].

When diſtilled, there comes over firſt water, containing ſome animal matter; the gelatine then ſwells, becomes black, emits a fetid odour, accompanied with acrid fumes: Some empyreumatic oil then comes over, and a very ſmall quantity of carbonat of ammonia: its coaly reſiduum remains behind. Theſe phenomena ſhew, that gelatine is compoſed of carbon, hydrogen, and azot; but the proportion of azot is evidently much ſmaller than in either fibrina or albumen [†].

SECT. IV. *Of Animal Mucilage.*

No word in chemiſtry is uſed with leſs accuracy than *mucilage*. It ſerves as a common name for almoſt every animal ſubſtance which cannot be referred to any other claſs.

None of the ſubſtances to which the name of *animal mucilage* has been given, have been examined with care; of courſe it is unknown whether theſe ſubſtances be the ſame or different.

201
Properties of mucilage.

Whenever an animal ſubſtance poſſeſſes the following properties, it is at preſent denominated an animal mucilage by chemiſts

1. Soluble in water.
2. Inſoluble in alcohol.
3. Neither coagulable by heat, nor concreting into a gelly by evaporation.
4. Not precipitated by the ſolution of tan.

Moſt of the ſubſtances called *mucilage* have alſo the property of abſorbing oxygen, and of becoming by that means inſoluble in water

The mucilaginous ſubſtances ſhall be pointed out in the next chapter. In the preſent ſtate of our knowledge, any account of them here would merely be a repetition of the properties juſt mentioned.

SECT. V. *Of the Baſis of Bile.*

202
Baſis of bile how obtained.

Into 32 parts of freſh ox bile pour one part of concentrated muriatic acid. After the mixture has ſtood for ſome hours, paſs it through a filter, in order to ſeparate a white coagulated ſubſtance. Pour the filtrated liquor, which has a fine green colour, into a glaſs veſſel, and evaporate it by a moderate heat. When it has arrived at a certain degree of concentration, a green coloured ſubſtance precipitates. Decant off the clear liquid, and waſh the precipitate in a ſmall quantity of pure

[†] Fourcroy, Ann de Chim. i. 41

pure water. This precipitate is the *baſis of bile*, or the *reſin of bile*, as it is ſometimes called *.

203 ...roper The baſis of bile is of a black colour; but when ſpread out upon paper or on wood, it is green: its taſte is intenſely bitter †.

When heated to about 122°, it melts; and if the heat be ſtill farther increaſed, it takes fire, and burns with rapidity. It is ſoluble in water, both cold and hot, and ſtill more ſoluble in alcohol; but water precipitates it from that liquid ‡.

It is ſoluble alſo in alkalies, and forms with them a compound which has been compared to a ſoap. Acids, when ſufficiently diluted, precipitate it both from water and alkalies without any change; but if they be concentrated, the precipitate is rediſſolved §.

When diſtilled, it furniſhes ſome ſebacic acid ||.

204 ...bines oxy- From theſe properties, it is clear that the baſis of bile has a conſiderable reſemblance to oils; but it differs from them entirely in ſeveral of its properties. The addition of oxygen, with which it combines readily, alters it ſomewhat, and brings it ſtill nearer to the claſs of oils.

In this altered ſtate, the baſis of bile may be obtained by the following proceſs. Pour oxy-muriatic acid cautiouſly into bile till that liquid loſes its green colour; then paſs it through a filter to ſeparate ſome albumen which coagulates. Pour more oxy muriatic acid into the filtered liquid, and allow the mixture to repoſe for ſome time. The oxy-muriatic acid is gradually converted into common muriatic acid; and in the mean time the baſis of bile abſorbs oxygen, and acquires new properties. Pour into the liquid, after it has remained a ſufficient time, a little common muriatic acid, a white precipitate immediately appears, which may be ſeparated from the fluid. This precipitate is the baſis of bile combined with oxygen.

It has the colour and the conſiſtence of tallow, but ſtill retains its bitter taſte. It melts at the temperature of 104°. It diſſolves readily in alcohol, and even in water, provided it be aſſiſted by heat. Acids precipitate it from theſe ſolutions ¶.

SECT. VI. *Of UREA.*

205 ...a low ...ines. EVAPORATE, by a gentle heat, a quantity of human urine voided ſix or eight hours after a meal, till it be reduced to the conſiſtence of a thick ſyrup. In this ſtate, when put by to cool, it concretes into a cryſtalline maſs. Pour, at different times, upon this maſs four times its weight of alcohol, and apply a gentle heat; a great part of the maſs will be diſſolved, and there will remain only a number of ſaline ſubſtances. Pour the alcohol ſolution into a retort, and diſtil by the heat of a ſand bath till the liquid, after boiling ſome time, is reduced to the conſiſtence of a thick ſyrup. The whole of the alcohol is now ſeparated, and what remains in the retort cryſtallizes as it cools. Theſe cryſtals conſiſt of the ſubſtance known by the name of *urea* *.

This ſubſtance was firſt deſcribed by Rouelle the Younger in 1773, under the name of the *ſaponaceous extract of urine*. He mentioned ſeveral of its properties; but very little was known concerning its nature till Fourcroy and Vauquelin publiſhed their experiments on it in 1799. Theſe celebrated chemiſts have given it the name of *urea*, which we have adopted.

Urea.

206 Its properties. Urea, obtained in this manner, has the form of cryſtalline plates croſſing each other in different directions. Its colour is yellowiſh white; it has a fetid ſmell, ſomewhat reſembling that of garlic or arſenic; its taſte is ſtrong and acrid, reſembling that of ammoniacal ſalts; it is very viſcid and difficult to cut, and has a good deal of reſemblance to thick honey †. When expoſed to the open air, it very ſoon attracts moiſture, and is converted into a thick brown liquid. It is extremely ſoluble in water; and during its ſolution, a conſiderable degree of cold is produced ‡. Alcohol diſſolves it with facility, but ſcarcely in ſo large a proportion as water. The alcohol ſolution yields cryſtals much more readily on evaporation than the ſolution in water.

When nitric acid is dropt into a concentrated ſolution of urea in water, a great number of bright pearl coloured cryſtals are depoſited, compoſed of urea and nitric acid. No other acid produces this ſingular effect. The concentrated ſolution of urea in water is brown, but it becomes yellow when diluted with a large quantity of water. The infuſion of nut galls gives it a yellowiſh brown colour, but cauſes no precipitate. Neither does the infuſion of tan produce any precipitate ||.

207 Its component parts. When heat is applied to urea, it very ſoon melts, ſwells up, and evaporates, with an inſupportably fetid odour. When diſtilled, there comes over firſt benzoic acid, then carbonat of ammonia in cryſtals, ſome carbonated hydrogen gas, with traces of pruſſic acid and oil; and there remains behind a large reſiduum, compoſed of charcoal, muriat of ammonia, and muriat of ſoda. The diſtillation is accompanied with an almoſt inſupportably fetid alliaceous odour. Two hundred and eighty-eight parts of urea yield by diſtillation 200 parts of carbonat of ammonia, 10 parts of carbonated hydrogen gas, 7 parts of charcoal, and 68 parts of benzoic acid, muriat of ſoda, and muriat of ammonia. Theſe three laſt ingredients Fourcroy and Vauquelin conſider as foreign ſubſtances, ſeparated from the urine by the alcohol at the ſame time with the urea. Hence it follows, that 100 parts of urea, when diſtilled, yield

92.027	carbonat of ammonia,
4.608	carbonated hydrogen gas,
3.225	charcoal.
99.860	

Now 200 parts of carbonat of ammonia are compoſed of 86 ammonia, 90 carbonic acid gas, and 24 water. Hence it follows, that 100 parts of urea are compoſed of

39.5	oxygen,
32.5	azot,
14.7	carbon,
13.3	hydrogen.
100.0	

But it can ſcarcely be doubted, that the water which was found in the carbonat of ammonia exiſted ready formed in the urea before the diſtillation ¶.

When the ſolution of urea in water is kept in a boiling heat, and new water is added as it evaporates, the urea is gradually decompoſed, a very great quantity of carbonat of ammonia is diſengaged, and at the ſame time acetous acid is formed, and ſome charcoal precipitates *.

208 Spontaneous decompoſition. When a ſolution of urea in water is left to itſelf for ſome time, it is gradually decompoſed. A froth col-

¶ Ibid.

* Ibid, p. 96.

lects on its ſurface ; air bubbles are emitted which have a ſtrong diſagreeable ſmell, in which ammonia and acetous acid are diſtinguiſhable. The liquid contains a quantity of acetous acid. The decompoſition is much more rapid if a little gelatine be added to the ſolution. In that caſe more ammonia is diſengaged, and the proportion of acetous acid is not ſo great*

209 Action of acids.

When the ſolution of urea is mixed with one-fourth of its weight of diluted ſulphuric acid, no efferveſcence takes place ; but, on the application of heat, a quantity of oil appears on the ſurface, which concretes upon cooling ; the liquid, which comes over into the receiver, contains acetous acid, and a quantity of ſulphat of ammonia remained in the retort diſſolved in the undiſtilled maſs. By repeated diſtillations, the whole of the urea is converted into acetous acid and ammonia †.

When nitric acid is poured upon cryſtallized urea, a violent efferveſcence takes place, the mixture froths, aſſumes the form of a dark red liquid, great quantities of nitrous gas, azotic gas, and carbonic acid gas, are diſengaged. When the efferveſcence is over, there remains only a concrete white matter, with ſome drops of reddiſh liquid. When heat is applied to this reſiduum, it detonates like nitrat of ammonia. Into a ſolution of urea, formed by its attracting moiſture from the atmoſphere, an equal quantity of nitric acid, of the ſpecific gravity 1.460, diluted with twice its weight of water, was added ; a gentle efferveſcence enſued : very gentle heat was applied, which ſupported the efferveſcence for two days. There was diſengaged the firſt day a great quantity of azotic gas and carbonic acid gas ; the ſecond day, carbonic acid gas, and at laſt nitrous gas. At the ſame time with the nitrous gas an odour was perceivable of the oxygenated pruſſic acid of Berthollet. At the end of the ſecond day, the matter in the retort, which was become thick, took fire, and burnt with a violent exploſion. The reſiduum contained traces of pruſſic acid and ammonia. The receiver contained a yellowiſh acid liquor, on the ſurface of which ſome drops of oil ſwam ‡.

Muriatic acid diſſolves urea, but does not alter it. Oxy-muriatic acid gas is abſorbed very rapidly by a diluted ſolution of urea ; ſmall whitiſh flakes appear, which ſoon become brown, and adhere to the ſides of the veſſel like a concrete oil. After a conſiderable quantity of oxy-muriatic acid had been abſorbed, the ſolution, left to itſelf, continued to efferveſce exceeding ſlowly, and to emit carbonic acid and azotic gas. After this efferveſcence was over, the liquid contained muriat and carbonat of ammonia.

210 Of alkalies.

Urea is diſſolved very rapidly by a ſolution of potaſs or ſoda; and at the ſame time a quantity of ammonia is diſengaged, the ſame ſubſtance is diſengaged when urea is treated with barytes, lime, or even magneſia. Hence it is evident, that this appearance muſt be aſcribed to the muriat of ammonia, with which it is conſtantly mixed. When pure ſolid potaſs is triturated with urea, heat is produced, a great quantity of ammonia is diſengaged. The mixture becomes brown, and a ſubſtance is depoſited, having the appearance of an empyreumatic oil. One part of urea and two of potaſs, diſſolved in four times its weight of water, when diſtilled give out a great quantity of ammoniacal water; the reſiduum contained acetite and carbonat of potaſs ||.

When muriat of ſoda is diſſolved in a ſolution of urea in water, it is obtained by evaporation, not in cubic cryſtals, its uſual form, but in regular octohedrons. Muriat of ammonia, on the contrary, which cryſtallizes naturally in octohedrons, is converted into cubes, by diſſolving and cryſtallizing it in the ſolution of urea.

Such are the properties of this ſingular ſubſtance, as far as they have been aſcertained by the experiments of Fourcroy and Vauquelin. It differs from all animal ſubſtances hitherto examined, in the great proportion of azot which enters into its compoſition, and in the facility with which it is decompoſed, even by the heat of boiling water.

SECT. VII. *Of Sugar.*

SUGAR has been already deſcribed in the former part of this article as a vegetable ſubſtance ; nothing therefore is neceſſary here but to point out the different ſtates in which it is found in animals. It has never indeed been found in animals in every reſpect ſimilar to the ſugar of vegetables ; but there are certain animal ſubſtances which have ſo many properties in common with ſugar, that they can ſcarcely be arranged under any other name. Theſe ſubſtances are,

1. Sugar of milk,
2. Honey,
3. Sugar of diabetic urine.

211 Sugar of milk.

1. The method of obtaining ſugar of milk has been already detailed in the article CHEMISTRY, n° 488. to which we refer the reader. For an account of its properties, we are indebted to the obſervations of Mr Lichtenſtein.

When pure, it has a white colour, a ſweetiſh taſte, and no ſmell. Its cryſtals are ſemitranſparent regular parallelopipeds, terminated by four-ſided pyramids. Its ſpecific gravity, at the temperature of 55°, is 1.543. At that temperature, it is ſoluble in ſeven times its weight of water ; but is perfectly inſoluble in alcohol. When burnt, it emits the odour of caromel, and exhibits preciſely the appearance of burning ſugar. When diſtilled, it yields the ſame products as ſugar, only the empyreumatic oil obtained has the odour of benzoic acid §.

212 Honey.

2. Honey is prepared by bees, and perhaps rather belongs to the vegetable than the animal kingdom. It has a white or yellowiſh colour, a ſoft and grained conſiſtence, a ſaccharine and aromatic ſmell ; by means of alcohol, and even by water, with peculiar management, a true ſugar is obtained ; by diſtillation it affords an acid phlegm and an oil, and its coal is light and ſpongy like that of the mucilages of plants. Nitric acid extracts the oxalic acid, which is entirely ſimilar to that of ſugar ; it is very ſoluble in water, with which it forms a ſyrup, and like ſugar paſſes to the vinous fermentation *.

3. The urine of perſons labouring under the diſeaſe known to phyſicians by the name of *diabetes*, yields, when evaporated, a conſiderable quantity of matter, which poſſeſſes the properties of ſugar.

SECT. VIII. *Of Oils.*

213 Fixed oi

THE oily ſubſtances found in animals may be arranged under three heads: 1. Fixed oils; 2. Fat; 3. Spermaceti.

1. The fixed oils are obtained chiefly from different kinds of fiſh, as the whale, &c. ; and they are diſtinguiſhed

---

* *Fourcroy and Vauquelin, Ann. de Chim.* xxxii. p. 96

† *Ibid*, p. 204.

‡ *Ibid*, p. 207.

|| *Ibid.*

§ *Scheele*, ii. 70.

* *Fourcro*

guiſhed by the name of the animal from which they are obtained, as *whale oil*, &c. Theſe oils agree in their properties with other fixed oils; which have been already deſcribed in the article CHEMISTRY, Part II. Chap. iii. *Suppl.*

2. *Fat*, or rather tallow, is a well-known animal ſubſtance, much employed in the manufacture of candles and ſoap.

14 perties at.

It has a white colour, often with a ſhade of yellow. When freſh, it has no ſmell, and but little taſte. While cold, it is hard and brittle; but when expoſed to the heat of 92°, it melts, and aſſumes the appearance of oil. The fat, however, which is extracted from fleſh by boiling, does not melt till it reach the temperature of 127°*. Tallow and fat, in other reſpects, have the properties of fixed oils. They ſeem to be compoſed of a fixed oil combined with ſebacic acid. When ſtrongly heated, with contact of air, it emits a ſmoke of a penetrating ſmell, which excites tears and coughing, and takes fire when ſufficiently heated to be volatilized: the charcoal it affords is not abundant. If fat be diſtilled on a water-bath, an inſipid water, of a ſlight animal ſmell, is obtained, which is neither acid nor alkaline, but which ſoon acquires a putrid ſmell, and depoſites filaments of a mucilaginous nature. This phenomenon, which takes place with the water obtained by diſtillation on the water bath from any animal ſubſtance, proves, that this fluid carries up with it a mucilaginous principle, which is the cauſe of its alteration. Fat, diſtilled in a retort, affords phlegm, at firſt aqueous, and afterwards ſtrongly acid; an oil, partly liquid, and partly concrete; and a very ſmall quantity of charcoal, exceedingly difficult to incinerate, in which Crell found a ſmall quantity of phoſphat of lime. Theſe products have an acid and penetrating ſmell, as ſtrong as that of ſulphurous acid. The acid is the ſebacic.

215 perties ſperma-

3. *Spermaceti*, is an oily, concrete, cryſtalline, ſemitranſparent matter, of a peculiar ſmell, which is taken out of the cavity of the cranium of the cachalot; it is purified by liquefaction, and the ſeparation of another fluid and inconcreſcible oil, with which it is mixed. This ſubſtance exhibits very ſingular chemical properties; for it reſembles fixed oils in ſome reſpects, and volatile oils in others.

When heated to the temperature of 133°†, it melts; and if the heat be increaſed, it evaporates without much alteration. When repeatedly diſtilled, however, it loſes its ſolid form, and becomes like oil. When heated in contact with air, it takes fire, and burns uniformly without any diſagreeable odour: hence its uſe in making candles.

By long expoſure in hot air it becomes yellow and rancid. Pure alkali combines with it, and forms a ſoap. Nitric and muriatic acids do not affect it, but ſulphuric acid diſſolves it and alters its colour.

SECT. IX. *Of Acids.*

THE acids hitherto diſcovered in the animal kingdom are the nine following.

1. Sulphuric,
2. Muriatic,
3. Phoſphoric,
4. Carbonic,
5. Benzoic,
6. Sebacic,
7. Formic,
8. Bombyc,
9. Uric.

The firſt eight of theſe have been already deſcribed in the article CHEMISTRY, *Suppl.* it is unneceſſary therefore to deſcribe them here.

216 Diſcovery of uric acid.

Few perſons are ignorant that concretions ſometimes form in the human urinary bladder, and produce that very formidable diſeaſe known by the names of the *ſtone* and the *gravel*. Theſe concretions are often extracted by a ſurgical operation: they are called *urinary calculi*.

The moſt common of theſe calculi is of a brown colour, and very ſoluble in pure potaſs or ſoda ley.

If into an alkaline ſolution of one of theſe calculi a quantity of acetous acid be poured, a copious brown coloured precipitate immediately appears, which may be ſeparated and edulcorated in a ſmall quantity of water. This ſubſtance is *uric acid**.

It was diſcovered by Scheele in 1776, and the French chemiſts afterwards called it *lithic acid*: but this name, in conſequence chiefly of ſome remarks of Dr Pearſon on its impropriety, has been lately given up, and that of *uric* (L) acid ſubſtituted in its place. We have adopted the new name, becauſe we think it preferable to the old; which indeed conveyed a kind of inconſiſtency to thoſe who attended to the etymological meaning of the word.

217 Its properties.

Uric acid poſſeſſes the following properties: it cryſtallizes in thin plates; has a brown colour, and ſcarcely any taſte. Cold water ſcarcely diſſolves any part of it; but it is ſoluble in 360 parts of boiling water. The ſolution reddens vegetable blues, eſpecially the tincture of turnſol. A great part of the acid precipitates again as the water cools. It combines readily with alkalies and earths; but the compound is decompoſed by every other acid. Sulphuric acid, when concentrated, decompoſes it entirely*. Nitric acid diſſolves it readily: the ſolution is of a pink colour, and has the property of tinging animal ſubſtances, the ſkin for inſtance, of the ſame colour†. When this ſolution is boiled, a quantity of azotic gas, carbonic acid gas, and of pruſſic acid, is diſengaged‡. Oxy-muriatic acid converts it in a few minutes into oxalic acid §.

When diſtilled, about a fourth of the acid paſſes over a little altered, and is found in the receiver cryſtallized in plates; a few drops of thick oil make their appearance; $\frac{1}{8}$th of the acid of concrete carbonat of ammonia, ſome pruſſiat of ammonia, ſome water, and carbonic acid; and there remains in the retort charcoal, amounting to about $\frac{1}{80}$th of the weight of the acid diſtilled ||.

Theſe facts are ſufficient to ſhew us, that uric acid is compoſed of carbon, azot, hydrogen, and oxygen; and that the proportion of the two laſt ingredients is much ſmaller than of the other two.

The different ſalts which uric acid forms with alkaline and earthy baſes have not been examined with attention; but urat of potaſs, of ſoda, and of lime, have been formed both by Scheele and Fourcroy; and urat of

(L) From *urine*; becauſe this acid is always found in human urine.

of ammonia is not unfrequently found cryſtallized in urinary calculi.

The order of the affinities of the different baſes for uric acids is entirely unknown; but it has been aſcertained, that its affinity for theſe baſes is much weaker than that of any other acid. Its ſalts are decompoſed even by pruſſic and carbonic acid.

SECT. X. *Of* ALKALIES, EARTHS, *and* METALS.

1. ALL the three alkalies have been found in the animal kingdom, as we ſhall ſhew in the next chapter.

2. The only earths which have been found in animals are,

1. Lime,
2. Magneſia,
3. Silica.

The firſt in great abundance, almoſt in every large animal; the other two very rarely, and only as it were by accident.

3. The metals hitherto found in animals are,

1. Iron,
2. Manganeſe.

The firſt exiſts in all the larger animals in ſome conſiderable quantity; the ſecond has ſcarce ever been found in any quantity ſo great as to admit of being weighed.

218 Subſtances found in animals.

Such are the ſubſtances hitherto found in animals. The ſimple bodies of which all of them conſiſt are the following:

1. Azot,
2. Carbon,
3. Hydrogen,
4. Oxygen,
5. Lime,
6. Phoſphorus,
7. Muriatic acid,
8. Potaſs,
9. Soda,
10. Sulphur,
11. Magneſia,
12. Silica,
13. Iron,
14. Manganeſe.

Of theſe, magneſia and ſilica may in a great meaſure be conſidered as foreign bodies; for they are only found in exceedingly minute quantities, and the laſt not unleſs in caſes of diſeaſe. The principal elementary ingredients are the firſt ſix: animal ſubſtances may be conſidered as in a great meaſure compoſed of them. The firſt four conſtitute almoſt entirely the ſoft parts, and the other two form the baſis of the hard parts. But we will be able to judge of this much better, after we have taken a view of the various parts of animals as they exiſt ready formed in the body. This ſhall be the ſubject of the next chapter.

CHAP. II. OF THE PARTS OF ANIMALS.

THE different ſubſtances which compoſe the bodies of animals have been deſcribed with ſufficient minuteneſs in the article ANATOMY, *Encycl.* to which we beg leave to refer the reader. Any repetition in this place would be improper. Theſe ſubſtances are the following:

1. Bones and ſhells,
2. Muſcles,
3. Tendons,
4. Ligaments,
5. Membranes,
6. Cartilages,
7. Skin,
8. Brain and nerves,
9. Horns and nails,
10. Hair and feathers.

Beſides theſe ſubſtances which conſtitute the ſolid part of the bodies of animals, there are a number of fluids, the moſt important of which is the *blood*, which pervades every part of the ſyſtem in all the larger animals: The reſt are known by the name of *ſecretions*, becauſe they are formed or *ſecreted*, as the anatomiſts term it, from the blood. The principal animal ſecretions are the following:

1. Milk,
2. Saliva,
3. Pancreatic juice,
4. Bile and biliary calculi,
5. Tears,
6. Mucus of the noſe,
7. Sinovia,
8. Semen,
9. Liquor of the amnios,
10. Urine and urinary calculi.

Theſe ſubſtances ſhall form the ſubject of the following ſections.

SECT. I. *Of* BONES.

BY *bones*, we mean thoſe hard, ſolid, well known ſubſtances, to which the firmneſs, ſhape, and ſtrength of animal bodies, are owing; which, in the larger animals, form, as it were, the ground-work upon which all the reſt is built. In man, in quadrupeds, and many other animals, the bones are ſituated below the other parts, and ſcarcely any of them are expoſed to view; but ſhell-fiſh and ſnails have a hard covering on the outſide of their bodies, evidently intended for defence. As theſe coverings, though known by the name of *ſhells*, are undoubtedly of a bony nature, we ſhall include them alſo in this ſection. For the very ſame reaſons, it would be improper to exclude *egg-ſhells*, and thoſe coverings of certain animals, the tortoiſe for inſtance, known by the name of *cruſts*.

It had been long known, that bones may be rendered ſoft and cartilaginous by keeping them in diluted acid ſolutions, and that ſome acids even diſſolve them altogether; that when expoſed to a violent heat, they become white, opaque, and brittle; and Dr Lewis had obſerved, that a ſudden and violent heat rendered them hard, ſemitranſparent, and ſonorous. But their component parts remained unknown till Scheele mentioned, in his diſſertation on Fluor Spar, publiſhed in the Stockholm Tranſactions for 1771, that the earthy part of bones is *phoſphat of lime* (M). Since that time conſiderable additions have been made to the chemical analyſis of theſe ſubſtances by Berniard, Bouillon, and Rouelle. Mr Hatchett has publiſhed a very valuable paper on the ſubject in the Philoſophical Tranſactions for 1799; and in the 34th volume of the *Annales de Chimie*, Mr Merat-Guillot has given us a table of the component parts of the bones of a conſiderable number of animals.

The *bony parts* of animals may be divided into three claſſes; namely, *bones*, *cruſts*, and *ſhells*.

219 Properties of bones.

1. Bones have a conſiderable degree of hardneſs; when recent, they contain a quantity of marrow, which may be partly ſeparated from them. When the water in which bones have been for ſome time boiled is evaporated to a proper conſiſtence, it aſſumes the form of a *gelly*; bones therefore contain *gelatine*.

220 Their component parts.

If a piece of bone be kept for ſome time in diluted muriatic, or even acetous acid, it gradually loſes a conſiderable part of its weight, becomes ſoft, and acquires a

---

(M) The diſcoverer of this has not been completely aſcertained: Scheele does not claim it in that paper; Bergman gives it to Gahn; but Crell affirms that it was made by Scheele.

ones.

a certain degree of tranſparency; and, in ſhort, acquires all the properties of *cartilage*. Bone therefore conſiſts of *cartilage*, combined with ſome ſubſtance which theſe acids are capable of diſſolving and carrying off.

If pure ammonia be dropt into the acid which has reduced the bone to this ſtate, a quantity of white powder precipitates, which poſſeſſes all the properties of *phoſphat of lime*. The ſubſtance, then, which was combined with the cartilage is *phoſphat of lime*.

After the phoſphat of lime has precipitated, the addition of carbonat of ammonia occaſions a farther precipitate, which conſiſts of carbonat of lime: but the quantity of this precipitate is inconſiderable *. When concentrated acids are poured on bones, whether recent or calcined, an effervescence is perceptible; the gas which eſcapes renders lime water turbid, and is therefore *carbonic acid*. Now ſince bones contain carbonic acid, and ſince they contain lime alſo uncombined with any acid ſtronger than carbonic—it is evident that they contain a little *carbonat of lime*. Mr Hatchett found this ſubſtance in all the bones of quadrupeds and of fiſh which he examined †.

When bones are calcined, and the reſiduum is diſſolved in nitric acid, nitrat of barytes cauſes a ſmall precipitate, which is inſoluble in muriatic acid, and is therefore ſulphat of barytes‡. Conſequently bones contain ſulphuric acid. It has been aſcertained, that this acid is combined with lime. The proportion of *ſulphat of lime* in bones is very inconſiderable.

Thus we have ſeen, that bones are compoſed of cartilage, which conſiſts almoſt entirely of gelatine, of phoſphat of lime, carbonat of lime, and ſulphat of lime. The following table, drawn up by Merat-Guillot ||, exhibits a comparative view of the relative proportion of theſe ingredients in a variety of bones. The ſulphat of lime, which occurs only in a very ſmall quantity, has been confounded with phoſphat of lime.

One hundred parts contain	Gelatine.	Phoſp. of lime	Carb. of lime	Loſs.
Human bones from a burying ground,	16	67	1.5	15.5
Do. dry, but not from under the earth,	23	63	2	2

The enamel of the teeth is compoſed of the ſame earthy ingredients as other bones; but it is totally deſtitute of cartilage *.

221
mponent
rts of
ſts.

2. The cruſtaceous coverings of animals, as of echini, crabs, lobſters, prawns, and cray-fiſh, and alſo the ſhells of eggs, are compoſed of the ſame ingredients as bones; but in them the proportion of carbonat of lime far exceeds that of phoſphat *.

Bones.

Thus 100 parts of lobſter cruſt contain
60 carbonat of lime,
14 phoſphat,
26 cartilage,
———
100 †.

One hundred parts of crawfiſh cruſt contain
60 carbonat of lime,
12 phoſphat of lime,
28 cartilage.
———
100 ‡.

One hundred parts of hens egg-ſhells contain
89.6 carbonat of lime,
5.7 phoſphat of lime,
4.7 animal matter.
———
100.0 ||.

Mr Hatchett found traces of phoſphat of lime alſo in the ſhells of ſnails.

223
Component parts of ſhells.

3. The ſhells of ſea animals may be divided into two claſſes: The firſt has the appearance of porcelain; their ſurface is enamelled, and their texture is often ſlightly fibrous. Mr Hatchett has given them the name of *porcellaneous* ſhells. The ſecond kind of ſhell is known by the name of *mother of pearl*. It is covered with a ſtrong epidermis, and below it lies the ſhelly matter in layers *. The ſhell of the freſh water muſcle, mother of pearl, heliotis iris, and turbo olearius, are inſtances of theſe ſhells.

Porcellaneous ſhells are compoſed of carbonat of lime cemented together by a very ſmall quantity of animal matter †.

Mother of pearl ſhells are compoſed of alternate layers of carbonat of lime and a thin membranaceous or cartilaginous ſubſtance. This cartilage ſtill retains the figure of the ſhell, after all the carbonat of lime has been ſeparated by acids ‡.

Mother of pearl contains 66 carbonat of lime,
34 cartilage.
———
100 ||.

Coral, which is a bony ſubſtance formed by certain ſea inſects, has a nearer relation to mother of pearl ſhells in its ſtructure than to any other bony ſubſtance, as the following table ¶ will ſhew.

	White coral.	Red coral.	Articulated coraline.
Carbonat of lime,	50	53.5	49
Animal matter,	50	46.5	51
	100	100.0	100

SECT. II. *Of the* MUSCLES *of* ANIMALS.

THE muſcular parts of animals are known in common language by the name of *fleſh*. They conſtitute a conſiderable proportion of the food of man.

Muſcular fleſh is compoſed of a great number of fibres or threads, commonly of a reddiſh or whitiſh colour; but its appearance is too well known to require any deſcription. Hitherto it has not been ſubjected to any accurate chemical analyſis. Mr Thouvenel, indeed, has publiſhed a very valuable diſſertation on the ſubject;

ſubject; but his analyſis was made before the method of examining animal ſubſtances was ſo well underſtood as it is at preſent. It is to him, however, that we are indebted for almoſt all the facts known concerning the compoſition of muſcle.

It is ſcarcely poſſible to ſeparate the muſcle from all the other ſubſtances with which it is mixed. A quantity of fat often adheres to it cloſely; blood pervades the whole of it; and every fibre is enveloped in a particular thin membranous matter, which anatomiſts diſtinguiſh by the name of *cellular ſubſtance*. The analyſis of the muſcle, then, cannot be ſuppoſed to exhibit an accurate view of the compoſition of pure muſcular fibres, but only of muſcular fibre not perfectly ſeparated from other ſubſtances.

223 Analyſis of muſcles. 1. When a muſcle is well waſhed in cold water, ſeveral of its parts are diſſolved, and may be obtained by the uſual chemical methods. When the water is evaporated ſlowly, it at laſt coagulates, and the coagulum may be ſeparated by means of a filter. It poſſeſes the properties of *albumen*.

2. The water is then to be evaporated gently to dryneſs, and alcohol poured upon the dry maſs: part of it is diſſolved by digeſtion, and there remains a ſaline ſubſtance, which has not been examined; but which Fourcroy conjectures to be a *phoſphat*.

3. When the alcohol is evaporated to dryneſs, it leaves a peculiar mucous ſubſtance, ſoluble both in water and alcohol; and when its watery ſolution is very much concentrated, it aſſumes an acid and bitter taſte. It ſwells upon hot coals, and melts, emitting an acid and penetrating ſmell. It attracts moiſture from the air, and forms a ſaline efflorеſcence. In a hot atmoſphere it becomes ſour and putrefies. All theſe properties render it probable that this ſubſtance of Mr Thouvenel is that which is converted into *zoonic* acid during the roaſting of meat.

4. The muſcle is now to be boiled in water for ſome time. A quantity of fat appears on its ſurface in the form of oil, which may be taken off.

5. The water, when evaporated ſufficiently, aſſumes the form of a jelly on cooling, and therefore contains a portion of *gelatine*. It contains alſo a little of the ſaline ſubſtance, and of the mucous ſubſtance mentioned above.

6. The reſiduum of the muſcle is now white and inſipid, of a fibrous ſtructure, and inſoluble in water, and has all the properties of *fibrina*.

Thus it appears that muſcle is compoſed of

Albumen,
Mucous matter,
Gelatine,
Fibrina,
A ſalt.

The French chemiſts have diſcovered, that when a piece of muſcle is allowed to remain a ſufficient time in diluted ſulphuric acid, it is converted into a ſubſtance reſembling tallow: weak nitric acid, on the other hand, converts it into a ſubſtance reſembling *wax* [*].

SECT. III. *Of the Soft and White Parts of Animals.*

THOSE parts of animals to which anatomiſts have given the names of cartilage, tendon, ligament, membrane, differ altogether in their appearance from the muſcles. They have never been analyſed. We know only that they are compoſed, in a great meaſure, of *gelatine*; for it is partly from them that *glue* is made; which does not differ from gelatine, except in not being perfectly pure.

Mr Hatchett has aſcertained that they contain no phoſphat of lime as a conſtituent part, and ſcarcely any ſaline ingredients; for when calcined they leave but a very inconſiderable reſiduum. Thus 250 grains of hog's bladder left only 0.02 grain of reſiduum [†].

SECT. IV. *Of the Skin.*

THE ſkin is that ſtrong thick covering which envelopes the whole external ſurface of animals. It is compoſed chiefly of two parts: a thin white elaſtic layer on the outſide, which is called *epidermis*, or *cuticle*; and a much thicker layer, compoſed of a great many fibres, cloſely interwoven, and diſpoſed in different directions; this is called the *cutis*, or *true ſkin*. The *epidermis* is that part of the ſkin which is raiſed in bliſters.

224 Epidermis. 1. The epidermis is eaſily ſeparated from the cutis by maceration in hot water. It poſſeſſes a very great degree of elaſticity.

225 Its properties. It is totally inſoluble in water and in alcohol. Pure fixed alkalies diſſolve it completely, as does lime likewiſe, though ſlowly [‡]. Sulphuric and muriatic acids do not diſſolve it, at leaſt they have no ſenſible action on it for a conſiderable time; but nitric acid ſoon deprives it of its elaſticity, cauſes it to fall to pieces, and probably ſoon decompoſes it [§].

It is well known that the living epidermis is tinged yellow almoſt inſtantaneouſly by nitric acid; but this effect does not take place, at leaſt ſo ſpeedily, when the dead cuticle is plunged in nitric acid altogether [||].

226 Cutis. 2. When a portion of cutis is macerated for ſome hours in water, and agitation and preſſure is employed to accelerate the effect, the blood, and all the extraneous matter with which it was loaded, are ſeparated from it, but its texture remains unaltered. On evaporating the water employed, a ſmall quantity of gelatine may be obtained. No ſubſequent maceration in cold water has any farther effect; the weight of the cutis is not diminiſhed, and its texture is not altered: but if it be boiled in a ſufficient quantity of water, it may be completely diſſolved, and the whole of it, by evaporating the water, obtained in the ſtate of *gelatine* [*].

227 Compoſed of gelatine. Seguin informs us that he has aſcertained, by a great variety of experiments, that the cutis differs from gelatine merely in containing an additional quantity of oxygen. Hot water (he ſays) expels this oxygen, and thus converts cutis into gelatine [†]. As theſe experiments have not been publiſhed, it is impoſſible to form any judgment of their weight.

228 Nature of tanning. It is the ſkin or cutis of animals of which leather is formed. The proceſs of converting ſkin into leather is called *tanning*. This proceſs, though practiſed in the earlieſt ages, was merely empyrical, till the happy ingenuity of Mr Seguin led him to diſcover its real nature. After the epidermis and all the impurities of the ſkin have been ſeparated, and its pores have been ſo far opened as to admit of being completely penetrated, it is ſteeped in an infuſion of oak-bark, which conſiſts of gallic acid and tan. The gallic acid (if we believe Seguin) deprives the ſkin gradually of oxygen, and thus converts it into gelatine, and the tan combines with this gelatine the inſtant it is formed; and this proceſs goes

goes on ſo ſlowly that the texture of the ſkin is not altered. Leather, therefore, is merely a combination of gelatine and tan ‡.

‡ N olſon's Jou il, i. 271

SECT. V. *Of the Brain and Nerves.*

The brain and nerves are the inſtruments of ſenſation, and even of motion; for an animal loſes the power of moving a part the inſtant that the nerves which enter it are cut.

The brain and nerves have a ſtrong reſemblance to each other; and it is probable that they agree alſo in their compoſition. But hitherto no attempt has been made to analyſe the nerves. The only chemiſts who have examined the nature of *brain* are Mr Thouret * and Mr Fourcroy ‡.

* r. de Pl xx i 329

‡ de Ch xvi. 28

The brain conſiſts of two ſubſtances, which differ from each other ſomewhat in colour, but which, in other reſpects, ſeem to be of the ſame nature. The outermoſt matter, having ſome ſmall reſemblance in colour to wood-aſhes, has been called the *cineritious* part; the innermoſt part has been called the *medullary* part.

9 Pr ties of in.

Brain has a ſoft feel, not unlike that of ſoap; its texture appears to be very cloſe; its ſpecific gravity is greater than that of water.

When brain is kept in cloſe veſſels ſo that the external air is excluded, it remains for a long time unaltered. Fourcroy filled a glaſs veſſel almoſt completely with pieces of brain, and attached it to a pneumatic apparatus; a few bubbles of carbonic acid gas appeared at firſt, but it remained above a year without undergoing any farther change ‡.

‡ .297.

This is very far from being the caſe with brain expoſed to the atmoſphere. In a few days (at the temperature of 60°) it exhales a moſt deteſtible odour, becomes acid, aſſumes a green colour, and very ſoon a great quantity of ammonia makes its appearance in it.

Cold water does not diſſolve any part of the brain; but by trituration in a mortar, it forms, with water, a whitiſh coloured emulſion, which appears homogeneous, may be paſſed through a filter, and the brain does not precipitate by reſt. When this emulſion is heated to 145°, a white coagulum is formed. The addition of a great quantity of water alſo cauſes a coagulum to appear, which ſwims on the ſurface, but the water ſtill retains a milky colour. When ſulphuric acid is dropt into the watery emulſion of brain, white flakes ſeparate and ſwim on the ſurface, and the liquid becomes red. Nitric acid produces the ſame effects, only the liquid becomes yellow. Alcohol alſo ſeparates a white coagulum from the emulſion, after it has been mixed with it for ſome hours. When nitric acid is added to the emulſion till it becomes ſlightly acid, a coagulum is alſo ſeparated. This coagulum is of a white colour; it is inſoluble in water and in alcohol. Heat ſoftens, but does not melt it. When dried, it becomes tranſparent, and breaks with a glaſſy fracture. It has therefore ſome reſemblance to *albumen* §.

§ 1. 288.

When brain is triturated in a mortar with diluted ſulphuric acid, part is diſſolved, the reſt may be ſeparated, by filtration, in the form of a coagulum. The acid liquor is colourleſs. By evaporation, the liquid becomes black, ſulphurous acid is exhaled, and cryſtals appear; and when evaporated to dryneſs, a black maſs remains behind. When this maſs is diluted with water, a quantity of charcoal ſeparates, and the water remains clear. The brain is completely decompoſed, a quantity of ammonia combines with the acid and forms ſulphat of ammonia, while charcoal is precipitated. The water, by evaporation and treatment with alcohol, yields ſulphats of ammonia and lime, phoſphoric acid, and phoſphats of ſoda and ammonia. Brain therefore contains

Brain and Nerves.

230 Its analyſis.

Phoſphat of lime,
——— -- ſoda,
——— -- ammonia.

Traces alſo of ſulphat of lime can be diſcovered in it. The quantity of theſe ſalts is very ſmall; altogether they do not amount to $\frac{1}{230}$th part ‖.

‖ Ann. de Chim. xvi. 288.

Diluted nitric acid, when triturated with brain, likewiſe diſſolves a part, and coagulates the reſt. The ſolution is tranſparent. When evaporated till the acid becomes concentrated, carbonic acid gas and nitrous gas are diſengaged; an efferveſcence takes place, white fumes appear, an immenſe quantity of ammonia is diſengaged, a bulky charcoal remains mixed with a conſiderable quantity of oxalic acid *.

* Ibid 307.

When brain is gradually evaporated to dryneſs by the heat of a water bath, a portion of tranſparent liquid ſeparates at firſt from the reſt, and the reſiduum, when nearly dry, acquires a brown colour; its weight amounts to about one-fourth of the freſh brain. It may ſtill be formed into an emulſion with water, but very ſoon ſeparates again ſpontaneouſly.

When alcohol is repeatedly boiled upon this dried reſiduum till it ceaſes to have any more action, it diſſolves about five-eighths of the whole. When this alcohol cools, it depoſits a yellowiſh white ſubſtance, compoſed of brilliant plates. When kneaded together by the fingers, it aſſumes the appearance of a ductile paſte: at the temperature of boiling water it becomes ſoft, and when the heat is increaſed it blackens, exhales empyreumatic and ammoniacal fumes, and leaves behind it a charry matter †. When the alcohol is evaporated, it depoſites a yellowiſh black matter, which reddens paper tinged with turnſol, and readily diffuſes itſelf through water ‡.

† Ibid. 313.

‡ Ibid. 317.

Pure concentrated potaſs diſſolves brain, diſengaging a great quantity of ammonia.

Theſe facts are ſufficient to ſhew us, that, excluſive of the ſmall proportion of ſaline ingredients, brain is compoſed of a peculiar matter, differing in many particulars from all other animal ſubſtances, but having a conſiderable reſemblance in many of its properties to albumen. Brain has been compared to a ſoap; but it is plain that the reſemblance is very faint, as ſcarcely any oily matter could be extricated from brain by Fourcroy, though he attempted it by all the contrivances which the preſent ſtate of chemiſtry ſuggeſted; and the alkaline proportion of it is a great deal too ſmall to merit any attention.

SECT. VI. *Of Nails, Horns, Hair, Feathers.*

These ſubſtances have not hitherto been analyſed. We know only that they have a great reſemblance to each other. They give out the ſame ſmell, and exhibit the ſame phenomena when burnt, and they yield the ſame products when diſtilled.

Pure fixed alkali has the property of decompoſing theſe ſubſtances, and of converting them into ammonia and oil. The ammonia is diſengaged in great abundance, and the oil combines with the alkali, and forms a ſpecies of ſoap. When muriatic acid is poured into the ſolution of theſe ſubſtances in pure ſoda, a quantity of ſulphurated hydrogen gas is diſengaged, and a black ſubſtance, doubtleſs charcoal, precipitates. Hence it follows that theſe ſubſtances contain in their compoſition a quantity of ſulphur. Accordingly, if a bit of ſilver is put into the ſolution, it inſtantly aſſumes a black colour §.

Theſe ſubſtances ſcarcely contain any earthy ingredients. One hundred grains of ox horn, after calcination, left only 0.04 grain of reſiduum, half of which was phoſphat of lime. Seventy-eight grains of chamois horn left five grains of reſiduum ||.

Such is a very imperfect account of the ſolids which compoſe animal bodies. We proceed next to the fluid which circulates through living bodies, namely *blood;* and to the various *ſecretions* formed from the blood, either in order to anſwer ſome important purpoſe to the animal, or to be evacuated as uſeleſs, that the blood thus purified may be more proper for anſwering the ends for which it is deſtined. Many of theſe ſubſtances have been examined with more care by chemiſts than the animal ſolids.

SECT. VII. *Of Blood.*

231 Properties of blood.

BLOOD is a well known fluid, which circulates in the veins and arteries of the more perfect animals. It is of a red colour, has a conſiderable degree of conſiſtency, and an unctuous feel, as if it contained a quantity of ſoap. Its taſte is ſlightly ſaline, and it has a peculiar ſmell.

The ſpecific gravity of human blood is, at a medium, 1.0527 *. Mr Fourcroy found the ſpecific gravity of bullock's blood, at the temperature of 60°, to be 1.056 †. The blood does not uniformly retain the ſame conſiſtence in the ſame animal, and its conſiſtence in different animals is very various. It is eaſy to ſee that its ſpecific gravity muſt be equally various.

232 Compoſed of red globules,

When the blood is viewed through a microſcope, a great many globules, of a red colour, are ſeen floating in it. It is to theſe globules that the red colour of the blood is owing. They were firſt examined with attention by Leuwenhoeck. Their form, their proportion, and the changes which they undergo from the addition of various ſubſtances, have been examined with the greateſt care; but hitherto without adding much to our knowledge. We neither know the ingredients of which the red globules are compoſed, nor the changes to which they are ſubjected, nor the uſeful purpoſes which they ſerve; nor has any accurate method been diſcovered of ſeparating them from the reſt of the blood, and of obtaining them in a ſtate of purity.

When blood, after being drawn from an animal, is allowed to remain for ſome time at reſt, it very ſoon coagulates into a ſolid maſs, of the conſiſtence of curdled milk. This maſs gradually ſeparates into two parts: one of which is fluid, and is called *ſerum;* the other, the coagulum, has been called *cruor,* becauſe it alone retains the red colour which diſtinguiſhes blood. This ſeparation is very ſimilar to the ſeparation of curdled milk into curds and whey. The cruor uſually ſinks to the bottom of the veſſel, and, of courſe, is covered by the ſerum.

233 Cruor,

The cruor, or *clot* as it is ſometimes called, is of a red colour, and poſſeſſes conſiderable conſiſtence. Its mean ſpecific gravity is about 1.245 ‡. If we waſh the cruor in a ſufficient quantity of water, it gradually loſes its red colour, and aſſumes the appearance of a whitiſh, fibrous, elaſtic maſs, which poſſeſſes all the properties of *fibrina.* The cruor therefore is compoſed chiefly of fibrina. The water in which it has been waſhed aſſumes a red colour, but continues tranſparent. It is evident from this that it contains, diſſolved in it, the red globules; not, however, in a ſtate of purity, for it is impoſſible to ſeparate the cruor completely from the ſerum: conſequently the water muſt contain both ſerum and red globules. We know, however, from this, that the red globules are ſoluble in water. The cruor of the blood, then, is compoſed of red globules and fibrina.

If the cruor of the blood be expoſed to a gentle heat, it becomes gradually dry and brittle. If this dry maſs be ſubmitted to diſtillation, it yields water, ammonia, a thick empyreumatic oil, and much carbonat of ammonia: there remains a ſpongy coal of a brilliant appearance, from which ſulphuric acid extracts *ſoda* and *iron;* there remains behind a mixture of phoſphat of lime and charcoal ||.

When the fibrina is diſtilled, it yields preciſely the ſame products; but the reſiduum contains neither iron nor ſoda. The red water, on the contrary, which had been employed to waſh the cruor, contains both of theſe ſubſtances, eſpecially iron; which may be obtained in the ſtate of oxyd by evaporating this water to dryneſs, and calcining the reſiduum ¶. Theſe facts are ſufficient to demonſtrate that the red globules contain iron; conſequently the opinion that their colour depends upon that metal is at leaſt poſſible. It is probably owing to the ſoda which it contains, that the preſence of iron cannot be aſcertained in the ſolution of theſe globules by the uſual teſts. The pruſſian alkali cauſes no precipitate; the infuſion of nut galls gives it no blue or purpliſh tinge *.

234 And ſerum

The ſerum is of a light greeniſh yellow colour; it has the taſte, ſmell, and feel of the blood, but its conſiſtence is not ſo great. Its mean ſpecific gravity is about 1.0287 †. It converts ſyrup of violets to a green, and therefore contains an alkali. On examination, it is found that it owes this property to a portion of ſoda. When heated to the temperature of 156° §, the ſerum coagulates, as Harvey firſt diſcovered †. It coagulates alſo when boiling water is mixed with it; but if ſerum be mixed with ſix parts of cold water, it does not coagulate by heat ‡. When thus coagulated, it has a greyiſh white colour, and is not unlike the boiled white of an egg §. If the coagulum be cut into ſmall pieces, a muddy fluid may be ſqueezed from it, which has been termed the *ſeroſity.* After the ſeparation of this fluid, if the reſiduum be carefully waſhed in boiling water and examined, it will be found to poſſeſs all the properties of *albumen.* The ſerum, therefore, contains a conſiderable proportion of albumen. Hence its coagulation by heat, and the other phenomena which albumen uſually exhibits.

If the ſeroſity be gently evaporated till it becomes concentrated, and then be allowed to cool, it aſſumes the form of a jelly, as was firſt obſerved by De Haen ||. Conſequently it contains *gelatine.*

If ſerum be mixed with twice its weight of water, and, after coagulation by heat, the albumen be ſeparated

---

ted by filtration, and the liquid be ſlowly evaporated till it is conſiderably concentrated, a number of cryſtals are depoſited when the liquid is left ſtanding in a cool place. Theſe cryſtals conſiſt of muriat of ſoda and carbonat of ſoda [¶].

Thus it appears that the ſerum of the blood contains albumen, gelatine, ſoda, muriat of ſoda, and carbonat of ſoda, beſides a portion of water.

Gelatine may be precipitated from the ſeroſity by the three mineral acids. Mr Hunter obſerved, that Goulard's extract, or, which is the ſame thing, acetite of lead diſſolved in acetous acid, produces with gelatine a copious precipitate [¶]. When nitric acid is diſtilled off ſerum, it converts it partly into pruſſic acid [*]. Acids, alcohol, and tan, precipitate the albumen in different ſtates; but this, after what has been ſaid in the laſt chapter, ſection ii. requires no farther explanation.

The proportion between the cruor and ſerum of the blood varies much in different animals, and even in the ſame animal in different circumſtances. The moſt common proportion is about one part of cruor to three parts of ſerum; but in many caſes the cruor exceeds and falls ſhort of this quantity: the limits of the ratios of theſe ſubſtances to each other appear, from a compariſon of the concluſions of moſt of thoſe who have written accurately on the ſubject, to be 1 : 1 and 1 : 4; but the firſt caſe muſt be very rare indeed [*].

When new-drawn blood is ſtirred briſkly round with a ſtick, or the hand, the whole of the fibrina collects together upon the ſtick, and in this manner may be ſeparated altogether from the reſt of the blood. The red globules, in this caſe, remain behind in the ſerum. It is in this manner that the blood is prepared for the different purpoſes to which it is put: as clarifying ſugar, making puddings, &c. After the fibrina is thus ſeparated, the blood no longer coagulates when allowed to remain at reſt, but a ſpongy flaky matter ſeparates from it and ſwims on the ſurface [†].

When blood is dried by a gentle heat, water exhales from it, retaining a very ſmall quantity of animal matter in ſolution, and conſequently having the odour of blood. Blood dried in this manner being introduced into a retort and diſtilled, there comes over, firſt a clear watery liquor, then carbonic acid gas, and carbonat of ammonia, which cryſtallizes in the neck of the retort; after theſe products there comes over a fluid oil, carbonated hydrogen gas, and an oily ſubſtance of the conſiſtence of butter. The watery liquor poſſeſſes the property of precipitating from ſulphat of iron a green powder: muriatic acid diſſolves part of this powder, and there remains behind a little pruſſian blue. Conſequently this watery liquor contains both an alkali and pruſſic acid [‡].

9216 grains of dried blood being put into a large crucible, and gradually heated, at firſt became nearly fluid, and ſwelled up conſiderably, emitted a great many fetid fumes of a yellowiſh colour, and at laſt took fire and burned with a white flame, evidently owing to the preſence of oil. After the flame and the fumes had diſappeared, a light ſmoke was emitted, which affected the eyes and the noſe, which had the odour of pruſſic acid, and reddened moiſt papers ſtained with vegetable blues. At the end of ſix hours, when the matter had loſt five-ſixths of its ſubſtance, it melted anew, exhibited a purple flame on its ſurface, and emitted a thick ſmoke. This ſmoke affected the eyes and noſtrils, and reddened blue paper, but it had not the ſmell of pruſſic acid. When a quantity of it was collected and examined, it was found to poſſeſs the properties of phoſphoric acid. The reſiduum amounted to 181 grains; it had a deep black colour, and a metallic brilliancy, and its particles were attracted by the magnet. It contained no uncombined ſoda, though the blood itſelf, before combuſtion, contains it abundantly; but water extracted from it muriat of ſoda, part of the reſt was diſſolved by muriatic acid, and, of courſe, was lime; there was beſides a little ſilica, which had evidently been ſeparated from the crucible. The iron had been reduced during the combuſtion [‡].

235
Component parts of blood.

Such are the properties of blood, as far as they have been hitherto aſcertained by experiment. We have ſeen that it contains the following ingredients:

1. Water,
2. Fibrina,
3. Albumen,
4. Gelatine,
5. Iron,
6. Soda,
7. Muriat of ſoda,
8. Phoſphat of lime.

But our knowledge of this ſingular fluid is by no means ſo complete as it ought to be; a more accurate analyſis would probably diſcover the preſence of other ſubſtances, and enable us to account for many of the properties of blood which at preſent are inexplicable.

It would be of great conſequence alſo to compare together the blood of different animals, and of the ſame animal at different ages, and to aſcertain in what particulars they differ from each other. This would probably throw light on ſome of the obſcureſt parts of the animal economy. Very little progreſs has hitherto been made in theſe reſearches: if we except the labours of Rouelle, who obtained nearly the ſame ingredients, though in different proportions, from the blood of a great variety of animals, the experiments of Fourcroy on the blood of the human fœtus are almoſt the only ones of that kind with which we are acquainted.

236
Blood of the fœtus.

He found that it differs from the blood of the adult in three things: *1ſt*, Its colouring matter is darker, and ſeems to be more abundant; *2d*, It contains no fibrina, but probably a greater proportion of gelatine than blood of adults; *3d*, It contains no phoſphoric acid [§].

237
Diſeaſed blood.

The examination of diſeaſed blood, too, would be of great conſequence; becauſe the difference of its properties from the blood of people in health might throw much light on the nature of the diſeaſe. It is well known, that when a perſon labours under inflammation, his blood is not ſuſceptible of coagulating ſo ſoon as healthy blood. This longer time allows the red globules to ſink to the bottom, and the coagulated fibrina appears at the top, of its natural whitiſh colour. Hence the appearance of the *buffy coat*, as it is called, which characterizes blood during inflammation.

During that diſeaſe which is known by the name of *diabetes*, in which the urine is exceſſive in quantity, and contains ſugar, the ſerum of blood often, as appears from the experiments of Dr Dobſon and Dr Rollo, aſſumes the appearance of whey; and, like it, ſeems to contain ſugar, or, at leaſt, it has loſt its uſual ſalt taſte.

Fourcroy mentions a caſe of extreme feebleneſs, in which all the parts of the body were in an unuſual relaxed ſtate. In that patient a quantity of blood oozed

---

[‡] *Fourcroy, Ann. de Chim.* vii. 151.

[§] *Ibid.* 161.

out from the eye-lids, which tinged linen blue, as if it had been ſtained with pruſſian blue. Here pruſſic alkali ſeems to have been formed in the blood.

SECT. VIII. *Of Milk.*

MILK is a fluid ſecreted by the female of all thoſe animals denominated *mammalia*, and intended evidently for the nouriſhment of her offspring.

The milk of every animal has certain peculiarities which diſtinguiſh it from every other milk. But the animal whoſe milk is moſt made uſe of by man as an article of food, and with which, conſequently, we are beſt acquainted, is the *cow*. Chemiſts, therefore, have made choice of cow's milk for their experiments. We ſhall at firſt confine ourſelves to the properties and analyſis of cow's milk, and afterwards point out in what reſpect the milk of other animals differs from it, as far at leaſt as theſe differences have hitherto been aſcertained.

238 Properties of milk.

Milk is an opaque fluid, of a white colour, a ſlight peculiar ſmell, and a pleaſant ſweetiſh taſte. When newly drawn from the cow, it has a taſte very different from that which it acquires after it has been kept for ſome hours.

It is liquid, and wets all thoſe ſubſtances which can be moiſtened by water; but its conſiſtence is greater than that of water, and it is ſlightly unctuous. Like water, it freezes when cooled down to about 30°; but Parmentier and Deyeux, to whom we are indebted for by far the completeſt account of milk hitherto publiſhed, found that its freezing point varies conſiderably in the milk of different cows, and even of the ſame cow at different times *. Milk boils alſo when ſufficiently heated; but the ſame variation takes place in the boiling point of different milks, though it never deviates very far from the boiling point of water. Milk is ſpecifically heavier than water, and lighter than blood; but the preciſe degree cannot be aſcertained, becauſe almoſt every particular milk has a ſpecific gravity peculiar to itſelf.

When milk is allowed to remain for ſome time at reſt, there collects on its ſurface a thick unctuous yellowiſh coloured ſubſtance, known by the name of *cream*. The cream appears ſooner in milk in ſummer than in winter, evidently owing to the difference of temperature. In ſummer, about four days of repoſe are neceſſary before the whole of the cream collects on the ſurface of the liquid; but in winter it requires at leaſt double the time †.

After the cream is ſeparated, the milk which remains is much thinner than before, and it has a bluiſh white colour. If it be heated to the temperature of 100°, and a little *rennet*, which is water digeſted with the inner coat of a calf's ſtomach, and preſerved with ſalt, be poured into it, coagulation enſues; and if the coagulum be broken, the milk very ſoon ſeparates into two ſubſtances: a ſolid white part, known by the name of *curd*; and a fluid part, called *whey*.

Thus we ſee that milk may be eaſily ſeparated into three parts; namely, *cream*, *curd*, and *whey*.

239 Cream

CREAM is of a yellow colour, and its conſiſtence increaſes gradually by expoſure to the atmoſphere. In three or four days, it becomes ſo thick that the veſſel which contains it may be inverted without riſking any loſs. In eight or ten days more its ſurface is covered over with mucors and byſſi, and it has no longer the flavour of cream, but of very fat cheeſe *. This is the proceſs for making what in this country is called a *cream cheeſe*.

Cream poſſeſſes many of the properties of an oil. It is ſpecifically lighter than water, it has an unctuous feel, ſtains clothes preciſely in the manner of oil; and if it be kept fluid, it contracts at laſt a taſte which is very analogous to the rancidity of oils †. When kept boiling for ſome time, a little oil makes its appearance, and floats upon its ſurface ‡. Cream is neither ſoluble in alcohol nor oils §. Theſe properties are ſufficient to ſhew us that it contains a quantity of oil; but this oil is combined with a part of the curd, and mixed with ſome ſerum. Cream, then, is compoſed of a peculiar oil, curd, and ſerum. The oil may be eaſily obtained ſeparate by agitating the cream for a conſiderable time. This proceſs, known to every body, is called *churning*. After a certain time, the cream ſeparates into two portions: one fluid, and reſembling creamed milk; the other ſolid, and called *butter*.

240 Converte into butt

Butter is of a yellow colour, poſſeſſes the properties of an oil, and mixes readily with other oily bodies. When heated to the temperature of 96°, it melts, and becomes tranſparent; if it be kept for ſome time melted, ſome curd and water or whey ſeparate from it, and it aſſumes exactly the appearance of oil ‖. But this proceſs deprives it in a great meaſure of its peculiar flavour.

When butter is kept for a certain time, it becomes rancid, owing in a good meaſure to the preſence of theſe foreign ingredients; for if butter be well waſhed, and a great portion of theſe matters ſeparated, it does not become rancid nearly ſo ſoon as when it is not treated in this manner. It was formerly ſuppoſed that this rancidity was owing to the developement of a peculiar acid; but Parmentier and Deyeux have ſhewn, that no acid is preſent in rancid butter *. When butter is diſtilled, there comes over water, ſebacic acid, and oil, at firſt fluid, but afterwards concrete. The carbonaceous reſiduum is but ſmall

241 And h

Butter may be obtained by agitating cream newly taken from milk, or even by agitating milk newly drawn from the cow. But it is uſual to allow cream to remain for ſome time before it is churned. Now cream, by ſtanding, acquires a ſour taſte; butter therefore is commonly made from ſour cream. Freſh cream requires at leaſt four times as much churning before it yields its butter as ſour cream does †; conſequently cream acquires, by being kept for ſome time, new properties, in conſequence of which it is more eaſily converted into butter. When very ſour cream is churned, every one who has paid the ſmalleſt attention muſt have perceived, that the butter-milk, after the churning, is not nearly ſo ſour as the cream had been. The butter, in all caſes, is perfectly ſweet; conſequently the acid which had been evolved has in a great meaſure diſappeared during the proceſs of churning. It has been aſcertained, that cream may be churned, and butter obtained, though the contact of atmoſpheric air be excluded ‡. We have no doubt, that in all caſes where ſuch an experiment ſucceeded, the cream on which it was made had previouſly become ſour. On the other hand, it has been aſcertained, that when cream is churned in contact with air, it abſorbs a conſiderable quantity of it §; and it cannot

---

cannot be doubted, that the portion abſorbed is oxygen.

Theſe facts are ſufficient to afford us a key to explain what takes place during the proceſs of churning. There is a peculiar oil in milk, which has ſo ſtrong an affinity for the other ingredients, that it will not ſeparate from them ſpontaneouſly; but it has an affinity for oxygen, and when combined with it, forms the concrete body called *butter*. Agitation produces this combination of the oil with oxygen; either by cauſing it to abſorb oxygen from the air, or, if that be impoſſible, by ſeparating it from the acid which exiſts in ſour cream. Hence the abſorption of air during churning; hence alſo the increaſe of temperature of the cream, which Dr Young found to amount conſtantly to 4°; and hence the ſweetneſs of the butter milk compared with the cream from which it was obtained.

The affinity of the oil of cream for the other ingredients is ſuch, that it never ſeparates completely from them. Not only is curd and whey always found in the cream, but ſome of this oil is conſtantly found in creamed milk and even in whey: for it has been aſcertained by actual experiment, that butter may be obtained by churning whey; 27 Scotch pints of whey yield at an average about a pound of butter ‖. This accounts for a fact well known to thoſe who ſuperintend dairies, that a good deal more butter may be obtained from the ſame quantity of milk, provided it be churned as drawn from the cow, than when the cream alone is collected and churned.

The butter-milk, as Parmentier and Deyeux aſcertained by experiment, poſſeſſes preciſely the properties of milk deprived of cream ¶.

272
perties
urd.

Curd, which may be ſeparated from creamed milk by rennet, has all the properties of coagulated albumen. It is white and ſolid; and when all the moiſture is ſqueezed out, it has a good deal of brittleneſs. It is inſoluble in water; but pure alkalies and lime diſſolve it readily, eſpecially when aſſiſted by heat; and when fixed alkali is uſed, a great quantity of ammonia is emitted during the ſolution. The ſolution of curd in ſoda is of a red colour, at leaſt if heat be employed; owing probably to the ſeparation of charcoal from the curd by the action of the alkali *. Indeed, when a ſtrong heat has been uſed, charcoal precipitates as the ſolution cools †. The matter diſſolved by the alkali may be ſeparated from it by means of any acid; but it has loſt all the properties of curd. It is of a black colour, melts like tallow by the application of heat, leaves oily ſtains on paper, and never acquires the conſiſtence of curd ‡. Hence it appears that curd, by the action of a fixed alkali, is decompoſed, and converted into two new ſubſtances, ammonia, and oil or rather fat.

Curd is ſoluble alſo in acids. If, over curd newly precipitated from milk, and not dried, there be poured eight parts of water, containing as much of any of the mineral acids as gives it a ſenſibly acid taſte, the whole is diſſolved after a little boiling §. Acetous acid and lactic acid do not diſſolve curd when very much diluted ‖. But theſe acids, when concentrated, diſſolve it readily, and in conſiderable quantity ¶. It is remarkable enough, that concentrated vegetable acids diſſolve curd readily, but have very little action on it when they are very much diluted: whereas the mineral diſſolve it when much diluted; but when concentrated, have either very little effect on it, as ſulphuric acid *; or decompoſe it, as nitric acid. By means of this laſt acid, as Berthollet diſcovered, a quantity of azotic gas may be obtained from curd.

273
Of cheeſe.

Curd, as is well known, is uſed in making *cheeſe*; and the cheeſe is the better the more it contains of cream, or of that oily matter which conſtitutes cream. It is well known to cheeſemakers, that the goodneſs of it depends in a great meaſure on the manner of ſeparating the whey from the curd. If the milk be much heated, the coagulum broken in pieces, and the whey forcibly ſeparated, as is the practice in many parts of Scotland, the cheeſe is ſcarce good for any thing; but the whey is delicious, eſpecially the laſt ſqueezed-out whey, and butter may be obtained from it in conſiderable quantity. A full proof that nearly the whole creamy part of the milk has been ſeparated with the whey. Whereas if the milk be not too much heated (about 100° is ſufficient), if the coagulum be allowed to remain unbroken, and the whey be ſeparated by very ſlow and gentle preſſure, the cheeſe is excellent; but the whey is almoſt tranſparent, and nearly colourleſs.

Good cheeſe melts at a moderate heat; but bad cheeſe, when heated, dries, curls, and exhibits all the phenomena of burning horn. Hence it is evident, that all the properties in which curd differs from albumen are owing to its containing combined with it a quantity of the peculiar oil which conſtitutes the diſtinguiſhing characteriſtic of cream; hence its flavour and ſmell; and hence alſo the white colour of milk.

274
Coagulation of milk.

This ſameneſs of curd and albumen ſhews us, that the coagulation of milk and of albumen depend upon the ſame cauſe. Heat, indeed, does not coagulate milk, becauſe the albumen in it is diluted with too large a quantity of water. But if milk be boiled in contact with air, a pellicle ſoon forms on its ſurface, which has the properties of coagulated albumen: if this pellicle be removed, another ſucceeds; and by continuing the boiling, the whole of the albuminous or curdy matter may be ſeparated from milk *. When this pellicle is allowed to remain, it falls at laſt to the bottom of the veſſel, where, being expoſed to a greater heat, it becomes brown, and communicates to milk that diſagreeable taſte which, in this country is called a *ſinged* taſte. It happens more readily when milk is boiled along with rice, flour, &c.

If to boiling milk there be added as much of any neutral ſalt as it is capable of diſſolving, or of ſugar, or of gum arabic, the milk coagulates, and the curd ſeparates †. Alcohol alſo coagulates milk ‡; as do all acids, rennet, and the infuſion of the flowers of artichoke, and of the thiſtle ‖. If milk be diluted with ten times its weight of water, it cannot be made to coagulate at all ¶.

275
Properties of whey.

Whey, after being filtered, to ſeparate a quantity of curd which ſtill continues to float through it, is a thin pellucid fluid, of a yellowiſh green colour and pleaſant ſweetiſh taſte, in which the flavour of milk may be diſtinguiſhed. It always contains ſome curd; but nearly the whole may be ſeparated by keeping the whey for ſome time boiling; a thick white ſcum gathers on the ſurface, which in Scotland is known by the name of *float whey*. When this ſcum, which conſiſts of the curdy part, is carefully ſeparated, the whey, after being allowed to remain at reſt for ſome hours, to give the

remainder of the curd time to precipitate, is decanted off, almoſt as colourleſs as water, and ſcarcely any of the peculiar taſte of milk can be diſtinguiſhed in it. If it be now ſlowly evaporated, it depoſites at laſt a number of white coloured cryſtals, which are *ſugar of milk*. Towards the end of the evaporation, ſome cryſtals of muriat of potaſs and of muriat of lime make their appearance [*]. According to Scheele, it contains alſo a little phoſphat of lime[†].

After the ſalts have been obtained from whey, what remains concretes into a jelly on cooling [‡]. Hence it follows, that whey alſo contains *gelatine*. Whey, then, is compoſed of water, ſugar of milk, gelatine, muriat of potaſs, and muriat of lime. The other ſalts, which are ſometimes found in it, are only accidentally preſent.

If whey be allowed to remain for ſome time, it becomes ſour, owing to the formation of a peculiar acid known by the name of *lactic acid*. It is to this property of whey that we are to aſcribe the acidity which milk contracts; for neither curd nor cream, perfectly freed from ſerum, ſeem ſuſceptible of acquiring acid properties. Hence the reaſon, alſo, that milk, after it becomes ſour, always coagulates. Boiled milk has the property of continuing longer ſweet; but it is ſingular enough, that it runs ſooner to putrefaction than ordinary milk [*].

276 Vinegar obtained from milk.

The acid of milk differs conſiderably from the acetous; yet vinegar may be obtained from milk by a very ſimple proceſs. If to ſomewhat more than 8 lbs. troy of milk, ſix ſpoonfuls of alcohol be added, and the mixture well corked be expoſed to a heat ſufficient to ſupport fermentation (provided attention be paid to allow the carbonic acid gas to eſcape from time to time), the whey, in about a month, will be found converted into vinegar [†].

277 Milk undergoes fermentation.

Milk is almoſt the only animal ſubſtance which may be made to undergo the vinous fermentation, and to afford a liquor reſembling wine or beer, from which alcohol may be ſeparated by diſtillation. This ſingular fact ſeems to have been firſt diſcovered by the Tartars; they obtain all their ſpirituous liquors from mares milk. It has been aſcertained, that milk is incapable of being converted into wine till it has become ſour; after this, nothing is neceſſary but to place it in the proper temperature, the fermentation begins of its own accord, and continues till the formation of wine be completed [‡]. Scheele had obſerved, that milk was capable of fermenting, and that a great quantity of carbonic acid gas was extricated from it during this fermentation [||]. But he did not ſuſpect, that the reſult of this fermentation was the formation of an intoxicating liquor ſimilar to wine.

When milk is diſtilled by the heat of a water bath, there comes over water, having the peculiar odour of milk; which putrifies, and conſequently contains, beſides mere water, ſome of the other conſtituent parts of milk. After ſome time, the milk coagulates [¶], as always happens when hot albumen acquires a certain degree of concentration. There remains behind a thick unctuous yellowiſh white ſubſtance, to which Hoffman gave the name of *franchipann*. This ſubſtance, when the fire is increaſed, yields at firſt a tranſparent liquid, which becomes gradually more coloured; ſome very fluid oil comes over, then ammonia, an acid, and at laſt a very thick black oil. Towards the end of the proceſs carbonated hydrogen gas is diſengaged [*]. There remains in the retort a coal which contains carbonat of potaſs, muriat of potaſs, and phoſphat of lime, and ſometimes magneſia, iron, and muriat of ſoda [†].

278 Its component parts.

Thus we ſee, that cows milk is compoſed of the following ingredients.

1. Water,
2. Oil,
3. Albumen,
4. Gelatine,
5. Sugar of milk,
6. Muriat of lime,
7 Muriat of potaſs,
8. Sulphur.

The milk of all other animals, as far as it has hitherto been examined, conſiſts nearly of the ſame ingredients; but there is a very great difference in their proportion.

279 Woman's milk.

WOMAN'S MILK has a much ſweeter taſte than cows milk. When allowed to remain at reſt for a ſufficient time, a cream gathers on its ſurface. This cream is more abundant than in cows milk, and its colour is uſually much whiter. After it is ſeparated, the milk is exceedingly thin, and has the appearance rather of whey, with a bluiſh white colour, than of creamed milk. None of the methods by which cows milk is coagulated ſucceed in producing the coagulation of woman's milk [*]. It is certain, however, that it contains curd; for if it be boiled, pellicles form on its ſurface, which have all the properties of curd [†]. Its not coagulating, therefore, muſt be attributed to the great quantity of water with which the curd is diluted.

Though the cream be churned ever ſo long, no butter can be obtained from it; but if, after being agitated for ſome hours, it be allowed to remain at reſt for a day or two, it ſeparates into two parts; a fluid which occupies the inferior part of the veſſel, pellucid, and colourleſs, like water and a thick white unctuous fluid, which ſwims on the ſurface. The lowermoſt fluid contains ſugar of milk and ſome curd; the uppermoſt does not differ from cream except in conſiſtence. The oily part of the cream, then, cannot be ſeparated by agitation from the curd [‡]. This cream contains a greater portion of curd than the cream of cows milk [*].

When this milk, after the curd is ſeparated from it, is ſlowly evaporated, it yields cryſtals of ſugar of milk, and of muriat of ſoda. The quantity of ſugar is rather greater than in cow's milk. According to Haller, the ſugar obtained from cow's milk is to that obtained from an equal quantity of woman's milk as 35 : 58, and ſometimes as 37 : 67, and in all the intermediate ratios.

280 Its peculiarities.

Thus it appears, that woman's milk differs from that of cows in three particulars.

1. It contains a much ſmaller quantity of curd.
2. Its oil is ſo intimately combined with its curd, that it does not yield butter.
3. It contains rather more ſugar of milk.

Parmentier and Deyeux aſcertained, that the quantity of curd in woman's milk increaſes in proportion to the time after delivery [||]. Nearly the ſame thing has been obſerved with reſpect to cow's milk.

281 Aſſes milk.

ASSES MILK has a very ſtrong reſemblance to human milk: it has nearly the ſame colour, ſmell, and conſiſtence. When left at reſt for a ſufficient time, a cream forms upon its ſurface, but by no means in ſuch abundance as in woman's milk. This cream, by very long agitation, yields a butter, which is always ſoft, white, and taſteleſs; and, what is ſingular, very readily mixes again with the butter-milk; but it may be again ſeparated

ilk, liva.

rated by agitation, while the veſſel, which contains it, is plunged in cold water. Creamed aſſes milk is thin, and has an agreeable ſweetiſh taſte. Alcohol and acids ſeparate from it a little curd, which has but a ſmall degree of conſiſtence. The ſerum yields ſugar of milk and muriat of lime *.

282 I ecu- li ies.

Aſſes milk therefore differs from cows milk in three particulars.

1. Its cream is leſs abundant and more inſipid.
2. It contains leſs curd.
3. It contains more ſugar of milk: the proportion is 35 : 80.

283 ts milk

Goats milk, if we except its conſiſtence, which is greater, does not differ much from cows milk. Like that milk, it throws up abundance of cream, from which butter is eaſily obtained. The creamed milk coagulates juſt as cows milk, and yields a greater quantity of curd. Its whey contains ſugar of milk, muriat of lime, and muriat of ſoda †.

284 es milk

Ewes milk reſembles almoſt preciſely that of the cow. Its cream is rather more abundant, and yields a butter which never acquires the conſiſtence of butter from cows milk. Its curd has a fat and viſcid appearance, and is not without difficulty made to aſſume the conſiſtence of the curd of cows milk. It makes excellent cheeſe ‡.

285 res k

Mares milk is thinner than that of the cow, but ſcarcely ſo thin as human milk. Its cream cannot be converted into butter by agitation. The creamed milk coagulates preciſely as cows milk, but the curd is not ſo abundant. The ſerum contains ſugar of milk, ſulphat of lime, and muriat of lime ‖.

Sect IX. *Of Saliva.*

The fluid ſecreted in the mouth, which flows in conſiderable quantity during a repaſt, is known by the name of *ſaliva*. No accurate analyſis has hitherto been made of it, though it poſſeſſes ſome very ſingular properties.

286 pe tie- ſaliva.

It is a limpid fluid like water, but much more viſcid: it has neither ſmell nor taſte.

Its ſpecific gravity, according to Hamberger, is 1.0167 *. When agitated it froths like all other adheſive liquids; indeed it is uſually mixed with air, and has the appearance of froth.

It neither mixes readily with water nor oil †; but by trituration in a mortar, it may be mixed ſo with water as to paſs through a filter ‡ It has a great affinity for oxygen, abſorbs it readily from the air, and gives it out again to other bodies §. Hence the reaſon why gold or ſilver, triturated with ſaliva in a mortar, is oxydated, as Dutenner has obſerved; and why the killing of mercury by oils is much facilitated by ſpitting into the mixture ¶ Hence alſo, in all probability, the reaſon that ſaliva is a uſeful application to ſores of the ſkin. Dogs, and ſeveral other animals, have conſtantly recourſe to this remedy, and with much advantage.

Saliva is coagulated by oxy muriat of mercury, by alcohol, and by nitre *. Therefore, in all probability, it contains albumen and gelatine, or ſome analogous ſubſtances.

When 100 parts of ſaliva are diſtilled, there come over 80 parts of water nearly pure, then a little carbonat of ammonia, ſome oil, and an acid, which perhaps is the pruſſic. The reſiduum amounts to about 1.56 parts, and is compoſed of muriat of ſoda and phoſphat of lime †.

Bile.

287 Tartar of the teeth.

The *tartar* of the teeth, which is a cruſt depoſited from ſaliva, conſiſts, as Fourcroy has aſcertained, of phoſphat of lime.

288 Pa creatic j ice.

The pancreatic juice has never been examined with much attention; but it does not appear, from the experiments that have been made, to differ much from ſaliva.

Sect. X. *Of Bile.*

Bile is a liquid of a yellowiſh green colour, an unctuous feel, and bitter taſte, is ſecreted by the liver; and in moſt animals conſiderable quantities of it are uſually found collected in the gall bladder.

Great attention has been paid to this liquid by phyſicians; becauſe the ancients were accuſtomed to aſcribe a very great number of diſeaſes, and even affections of the mind, to its agency. The moſt accurate chemical analyſis of it which has hitherto appeared is that of Mr Cadet, which was publiſhed in the Memoirs of the French Academy of Sciences for the year 1767. Several important obſervations had been previouſly made on it by Boyle, Boerhaave, Verheyen, Ramſay, and Baglivi: and ſome facts have ſince been added to our chemical knowledge of bile by Maclurg and Fourcroy. The experiments have chiefly been confined to the bile of oxen, known in this country by the name of *gall*; becauſe it is moſt eaſily procured in large quantities.

289 Properties of bile.

The ſpecific gravity of bile ſeems to vary, like that of all other animal fluids. According to Hartmann, it is 1.027 *. When ſtrongly agitated, it lathers like ſoap; and for this reaſon, as well as from a medical theory concerning its uſe, it has been often called an *animal ſoap*.

It mixes readily with water in any proportion, and aſſumes a yellow colour: but it refuſes to unite with oil when the two fluids are agitated together; the inſtant that they are left at reſt, the oil ſeparates and ſwims on the ſurface †.

When muriatic acid is poured upon bile, let it be ever ſo freſh, an odour of ſulphurated hydrogen gas is conſtantly exhaled ‡. When on 100 parts of ox-bile four parts of ſtrong muriatic acid are poured, the whole inſtantly coagulates; but in ſome hours the greater part becomes again fluid; and when paſſed through the filter it leaves 0.26 of a white matter, which has all the properties of albumen §. This matter was detected by Ramſay; who found that it could be precipitated from bile by alcohol, acetous acid, ſulphat of potaſs, and muriat of ſoda *. Cadet aſcertained, that 100 parts of ox bile contain about 0.52 of albumen. It is precipitated in a ſtate of purity by oxy-muriatic acid, provided that acid be not employed in exceſs †.

290 Its component parts.

The muriatic acid ſolution, after the ſeparation of the albumen, has a fine graſs-green colour. When concentrated by ſome hours evaporation in a glaſs cucurbit on hot coals, it depoſites a very copious precipitate, and loſes almoſt the whole of its green colour. By longer evaporation, a new precipitate, ſimilar to the firſt, appears, and the remaining liquid aſſumes the colour of beer. This precipitate poſſeſſes all the properties of the *reſin of bile*. In its moiſt ſtate it amounts to 10.8 parts ‡. The ſame ſubſtances may be obtained from bile by nitric acid; but the reſin in that

‡ *Cadet, ibid.*

caſe has a yellow colour, and its properties are ſomewhat altered *.

If 100 parts of bile be gently evaporated to dryneſs by a very moderate heat, the dry maſs only weighs 10 parts, and has a browniſh black colour. When expoſed to a ſtrong heat in a crucible, this matter ſwells up, takes fire, and emits very thick fumes. The reſiduum amounts to 1.09. By lixiviation with water, 1.87 of cryſtallized ſoda may be obtained †; conſequently 100 parts of bile contain, according to Mr Kirwan's table, 0.403546 of pure ſoda. But it is evident that, by this method, part of the ſoda muſt have been evaporated; therefore 100 parts of bile contain more than 0.403546 of ſoda. Beſides the ſoda, there is found alſo a ſmall portion of muriat of ſoda ‡.

Cadet found the reſiduum, after the ſeparation of the ſalts, of a black colour: it gave ſome traces of iron. He alſo obtained a calcareous ſalt from bile, which he conſidered as a ſulphat; but it is more than probable that it was phoſphat of lime.

Cadet alſo obtained from bile, by evaporating the muriatic acid ſolution after the ſeparation of the reſin, a ſalt which cryſtallized in trapeziums; it had a ſweetiſh taſte, and was conſidered by him as analogous to ſugar of milk *.

Thus we ſee that bile contains the following ingredients:

1. Water,
2. Reſin,
3. Albumen,
4. Soda,
5. A ſweetiſh ſalt,
6. Muriat of ſoda,
7. Phoſphat of lime,
8. Iron.

The proportion of theſe ingredients has by no means been aſcertained. The preſence of iron has been denied in bile, becauſe it gives no blue precipitate with pruſſic alkali, and becauſe tincture of nut-galls does not give it a black colour †. But theſe reaſons are inſufficient to overturn the experiment of Cadet, who actually found it in bile.

When four parts of vinegar and five of bile are mixed together, the mixture has a ſweet taſte, and does not coagulate milk. The lactic acid has preciſely the ſame effect as vinegar ‡.

When bile is diſtilled in a water bath, it affords a tranſparent watery liquor, which contracts a pretty ſtrong odour, not unlike that of muſk or amber, eſpecially if the bile has been kept for ſome days before it is ſubmitted to diſtillation §. The reſiduum is of a deep browniſh green; it attracts moiſture from the air, and diſſolves readily in water. When diſtilled in a retort, it affords a watery liquor of a yellowiſh colour, and impregnated with alkali, oil, carbonat of ammonia, carbonic acid, and hydrogen gas. The coaly reſiduum is eaſily incinerated *. Bile, expoſed to a temperature between 65° and 85°, ſoon loſes its colour and viſcidity, acquires a nauſeous ſmell, and depoſites whitiſh mucilaginous flakes. After the putrefaction has made conſiderable progreſs, its ſmell becomes ſweet, and reſembles amber †. If bile be heated, and ſlightly concentrated by evaporation, it may be kept for many months without alteration ‡.

Sect. XI. *Of Biliary Calculi.*

Hard bodies ſometimes form in the gall bladder, or in the duct through which the bile paſſes into the inteſtinal canal, and ſtop up the paſſage altogether. Theſe concretions have got the name of *biliary calculi* or *gall-ſtones*. As they are formed in the midſt of bile, and as the ſubſtances of which they are compoſed muſt be derived from the bile, it is proper to give an account of them here, becauſe their properties cannot fail to throw ſome additional light on the nature of bile itſelf.

291 Biliary calculi of three kinds.

Biliary calculi, all of them at leaſt which have been hitherto examined with attention, may be divided into three claſſes.

1. The firſt kind comprehends thoſe which have a white colour, and a cryſtallized, ſhining, lamellated ſtructure.

2. The ſecond is dark coloured, and has preciſely the appearance of inſpiſſated bile. Both theſe kinds are combuſtible.

3. The third kind comprehends thoſe gall ſtones which do not flame, but gradually waſte away at a red heat.

We ſhall take a view of each of theſe kinds of biliary calculi in their order. For the greater part of the chemical knowledge which has been hitherto acquired of them, the world is chiefly indebted to Mr Fourcroy.

292 Properties of the firſt.

1. The firſt ſpecies of biliary calculi was pointed out for the firſt time by Haller, in a diſſertation publiſhed in 1749. Walther afterwards added ſeveral new facts; and at laſt it was accurately deſcribed by Vicq d'Azyr *. It is almoſt always of an oval ſhape, ſometimes as large as a pigeon's egg, but commonly about the ſize of a ſparrow's; and for the moſt part only one calculus (when of this ſpecies) is found in the gall bladder at a time. It has a white colour; and when broken, preſents cryſtalline plates or ſtriæ, brilliant and white like mica, and having a ſoft greaſy feel. Sometimes its colour is yellow or greeniſh; and it has conſtantly a nucleus of inſpiſſated bile †.

Its ſpecific gravity is lower than that of water: Gren found the ſpecific gravity of one 0.803 ‡.

When expoſed to a heat conſiderably greater than that of boiling water, this cryſtallized calculus ſoftens and melts, and cryſtallizes again when the temperature is lowered §. It is altogether inſoluble in water; but hot alcohol diſſolves it with facility. Alcohol, of the temperature of 167°, diſſolves $\frac{1}{10}$ of its weight of this ſubſtance; but alcohol, at the temperature of 60°, ſcarcely diſſolves any of it *. As the alcohol cools, the matter is depoſited in brilliant plates reſembling talc or boracic acid †. It is ſoluble in oil of turpentine ‡. When melted, it has the appearance of oil, and exhales the odour of melted wax: when ſuddenly heated, it evaporates altogether in a thick ſmoke. It is ſoluble in pure alkalies, and the ſolution has all the properties of a ſoap. Nitric acid alſo diſſolves it; but it is precipitated unaltered by water ‡.

This matter, which is evidently the ſame with the cryſtals which Cadet obtained from bile, and which he conſidered as analogous to ſugar of milk, has a ſtrong reſemblance to ſpermaceti. Like that ſubſtance, it is of an oily nature, and inflammable; but it differs from it in a variety of particulars.

Since it is contained in bile, it is not difficult to ſee how it may cryſtallize in the gall-bladder if it happens to be more abundant than uſual; and the conſequence muſt

Bil y Calli, ars.

muſt be a gall-ſtone of this ſpecies. Fourcroy found a quantity of the ſame ſubſtance in the dried human liver *.

2. The ſecond ſpecies of biliary calculus is of a round or polygonal ſhape, of a grey colour exteriorly, and brown within. It is formed of concentric layers of a matter which ſeems to be inſpiſſated bile; and there is uſually a nucleus of the white cryſtalline matter at the centre. For the moſt part there are many of this ſpecies of calculus in the gall-bladder together: indeed it is frequently filled with them. Their ſize is uſually much ſmaller than that of the laſt ſpecies.

13 Of e fe- co

This is the moſt common kind of gall ſtone. It may be conſidered as a mixture of inſpiſſated bile, and of the cryſtalline matter which forms the firſt ſpecies: and the appearance of calculi of this kind muſt vary conſiderably, according to the proportion of theſe ingredients.

94 Of e th

3. Concerning the third ſpecies of gall-ſtone, very little is known with accuracy. Dr Saunders tells us, that he has met with ſome gall-ſtones inſoluble both in alcohol and oil of turpentine; ſome which do not flame, but become red, and conſume to an aſh like a charcoal † Haller quotes ſeveral examples of ſimilar calculi ‡.

Gall-ſtones often occur in the inferior animals, particularly in cows and hogs; but the biliary concretions of theſe animals have not hitherto been examined with attention.

SECT. XII. *Of Tears.*

THAT peculiar fluid which is employed in lubricating the eye, and which is emitted in conſiderable quantities when we expreſs grief by weeping, is known by the name of *tears*. For an accurate analyſis of this fluid, chemiſtry is indebted to Meſſrs Fourcroy and Vauquelin. Before their diſſertation, which was publiſhed in 1791, appeared, ſcarcely any thing was known about the nature of tears.

95 P erties of ars.

The liquid called tears is tranſparent and colourleſs like water; it has ſcarcely any ſmell, but its taſte is always perceptibly ſalt. Its ſpecific gravity is ſomewhat greater than that of diſtilled water. It gives to paper, ſtained with the juice of the petals of mallows or violet, a permanently green colour, and therefore contains a fixed alkali *. It unites with water, whether cold or hot, in all proportions. Alkalies unite with it readily, and render it more fluid. The mineral acids produce no apparent change upon it †. Expoſed to the air, this liquid gradually evaporates, and becomes thicker. When nearly reduced to a ſtate of dryneſs, a number of cubic cryſtals form in the midſt of a kind of mucilage. Theſe cryſtals poſſeſs the properties of muriat of ſoda; only they tinge vegetable blues green, and therefore contain an exceſs of ſoda. The mucilaginous matter acquires a yellowiſh colour as it dries ‡.

This liquid boils like water, excepting that a conſiderable froth collects on its ſurface. If it be kept a ſufficient time at the boiling temperature, $\frac{96}{100}$ parts of it evaporate in water; and there remain about .04 parts of a yellowiſh matter, which by diſtillation in a ſtrong heat yield water and a little oil: the reſiduum conſiſts of different ſaline matters §.

When alcohol is poured into this liquid, a mucilaginous matter is precipitated in the form of large white flakes. The alcohol leaves behind it, when evaporated, traces of muriat of ſoda and ſoda. The reſiduum which remains behind, when inſpiſſated tears are burnt in the open air, exhibits ſome traces of phoſphat of lime and phoſphat of ſoda ||.

296 Component parts.

Thus it appears that tears are compoſed of the following ingredients:

1. Water,	4. Soda,
2. Mucilage,	5. Phoſphat of lime,
3. Muriat of ſoda,	6. Phoſphat of ſoda,

The ſaline parts amount only to about 0.01 of the whole, or probably not ſo much.

The *mucilage* contained in the tears has the property of abſorbing oxygen gradually from the atmoſphere, and of becoming thick and viſcid, and of a yellow colour. It is then inſoluble in water, and remains long ſuſpended in it without alteration. When a ſufficient quantity of oxy muriatic acid is poured into tears, a yellow flaky precipitate appears abſolutely ſimilar to this inſpiſſated mucilage The oxy muriatic acid loſes its peculiar odour; hence it is evident that it has given out oxygen to the mucilage. The property which this mucilage has of abſorbing oxygen, and of acquiring new qualities, explains the changes which take place in tears which are expoſed for a long time to the action of the atmoſphere, as is the caſe in thoſe perſons who labour under a fiſtula lachrymalis *.

297 Mucus of the noſe.

The MUCUS of the noſe has alſo been examined by Fourcroy and Vauquelin. They found it compoſed of preciſely the ſame ingredients with the tears. As this fluid is more expoſed to the action of the air than the tears, in moſt caſes its mucilage has undergone leſs or more of that change which is the conſequence of the abſorption of oxygen. Hence the reaſon of the greater viſcidity and conſiſtence of the mucus of the noſe; hence alſo the great conſiſtence which it acquires during colds, where the action of the atmoſphere is aſſiſted by the increaſed action of the parts †.

SECT. XIII. *Of Sinovia.*

WITHIN the capſular ligament of the different joints of the body, there is contained a peculiar liquid, intended evidently to lubricate the parts, and to facilitate their motion. This liquid is known among anatomiſts by the name of *ſinovia*.

Whether it be the ſame in different animals, or even in all the different joints of the ſame animal, has not been determined; as no accurate analyſis of the ſinovia of different animals has been attempted. The only analyſis of ſinovia which has hitherto appeared is that by Mr Margueron, which was publiſhed in the 14th volume of the *Annales de Chimie*. He made uſe of ſinovia obtained from the joints of the lower extremities of oxen.

298 Sinovia of the ox.

The ſinovia of the ox, when it has juſt flowed from the joint, is a viſcid ſemi-tranſparent fluid, of a greeniſh white colour, and a ſmell not unlike frog ſpawn. It very ſoon acquires the conſiſtence of jelly; and this happens equally whether it be kept in a cold or a hot temperature, whether it be expoſed to the air or excluded from it. This conſiſtence does not continue long; the ſinovia ſoon recovers again its fluidity, and at the ſame time depoſites a thready like matter *.

299 Its properties.

Sinovia mixes readily with water, and imparts to that liquid a great deal of viſcidity. The mixture frothes when agitated; becomes milky when boiled, and

---

* Margueron, Ann. de Chim. xiv. 124.

and depoſites ſome pellicles on the ſides of the diſh; but its viſcidity is not diminiſhed †.

300 Its component parts

When alcohol is poured into ſinovia, a white ſubſtance precipitates, which has all the properties of albumen. One hundred parts of ſinovia contain 4.52 of albumen. The liquid ſtill continues as viſcid as ever; but if acetous acid be poured into it, the viſcidity diſappears altogether, the liquid becomes tranſparent, and depoſites a quantity of matter in white threads, which poſſeſſes the following properties:

1. It has the colour, ſmell, taſte, and elaſticity of vegetable gluten.

2. It is ſoluble in concentrated acids and pure alkalies.

3. It is ſoluble in cold water, the ſolution frothes; acids and alcohol precipitate the fibrous matter in flakes One hundred parts of ſinovia contain 11.86 of this matter ‡.

When the liquid, after theſe ſubſtances have been ſeparated from it, is concentrated by evaporation, it depoſites cryſtals of acetite of ſoda Sinovia, therefore, contains *ſoda*. Margueron found that 100 parts of ſinovia contained about 0.71 of ſoda.

When ſtrong ſulphuric, muriatic, nitric, acetic, or ſulphurous acid is poured into ſinovia, a number of white flakes precipitate at firſt, but they are ſoon rediſſolved, and the viſcidity of the liquid continues. When theſe acids are diluted with five times their weight of water, they diminiſh the tranſparency of ſinovia, but not its viſcidity; but when they are ſo much diluted that their acid taſte is juſt perceptible, they precipitate the peculiar thready matter, and the viſcidity of the ſinovia diſappears §.

When ſinovia is expoſed to a dry atmoſphere it gradually evaporates, and a ſcaly reſiduum remains, in which cubic cryſtals, and a white ſaline efflореſcence, are apparent. The cubic cryſtals are muriat of ſoda. One hundred parts of ſinovia contain about 1.75 of this ſalt. The ſaline effloreſcence is carbonat of ſoda ‖.

Sinovia ſoon putrefies in a moiſt atmoſphere, and during the putrefaction ammonia is exhaled When ſinovia is diſtilled in a retort there comes over, firſt water, which ſoon putrefies; then water containing ammonia; then empyreumatic oil and carbonat of ammonia. From the reſiduum muriat and carbonat of ſoda may be extracted by lixiviation. The coal contains ſome phoſphat of lime ¶.

From the analyſis of Mr Margueron it appears that ſinovia is compoſed of the following ingredients:

11.86	fibrous matter,
4.52	albumen,
1.75	muriat of ſoda,
.71	ſoda,
.70	phoſphat of lime (N),
80.57	water,
100.00.	

SECT. XIV. *Of SEMEN.*

THE peculiar liquid ſecreted in the teſtes of males, and deſtined for the impregnation of females, is known by the name of *ſemen*. The human ſemen alone has hitherto been ſubjected to chemical analyſis. Nothing is known concerning the ſeminal fluid of other animals. Vauquelin publiſhed an analyſis of the human ſemen in 1791.

301 Properties of ſemen.

Semen, when newly ejected, is evidently a mixture of two different ſubſtances: the one, fluid and milky, which is ſuppoſed to be ſecreted by the proſtate gland; the other, which is conſidered as the true ſecretion of the teſtes, is a thick mucilaginous ſubſtance, in which numerous white ſhining filaments may be diſcovered *. It has a ſlight diſagreeable odour, an acrid irritating taſte, and its ſpecific gravity is greater than that of water. When rubbed in a mortar it becomes frothy, and of the conſiſtence of pomatum, in conſequence of its enveloping a great number of air bubbles. It converts paper ſtained with the bloſſoms of mallows or violets to a green colour, and conſequently contains an alkali †

As the liquid cools, the mucilaginous part becomes tranſparent, and acquires greater conſiſtency; but in about twenty minutes after its emiſſion, the whole becomes perfectly liquid. This liquefaction is not owing to the abſorption of moiſture from the air, for it loſes inſtead of acquiring weight during its expoſure to the atmoſphere; nor is it owing to the action of the air, for it takes place equally in cloſe veſſels ‡.

Semen is inſoluble in water before this ſpontaneous liquefaction, but afterwards it diſſolves readily in it. When alcohol or oxy muriatic acid is poured into this ſolution, a number of white flakes are precipitated §. Concentrated alkalies facilitate its combination with water. Acids readily diſſolve the ſemen, and the ſolution is not decompoſed by alkalies; neither indeed is the alkaline ſolution decompoſed by acids ‖.

Lime diſengages no ammonia from freſh ſemen; but after that fluid has remained for ſome time in a moiſt and warm atmoſphere, lime ſeparates a great quantity from it Conſequently ammonia is formed during the expoſure of ſemen to air ¶.

302 Its comp nent par

When oxy-muriatic acid is poured into ſemen, a number of white flakes precipitate, and the acid loſes its peculiar odour. Theſe flakes are inſoluble in water, and even in acids. If the quantity of acid be ſufficient, the ſemen acquires a yellow colour. Thus it appears that ſemen contains a mucilaginous ſubſtance, analogous to that of the tears, which coagulates by abſorbing oxygen. Mr Vauquelin obtained from 100 parts of ſemen ſix parts of this mucilage.

When ſemen is expoſed to the air about the temperature of 60°, it becomes gradually covered with a tranſparent pellicle, and in three or four days depoſites ſmall tranſparent cryſtals, often croſſing each other in ſuch a manner as to repreſent the ſpokes of a wheel. Theſe cryſtals, when viewed through a microſcope, appear to be four ſided priſms, terminated by very long four-ſided pyramids. They may be ſeparated by diluting the liquid with water, and decanting it off. They have all the properties of phoſphat of lime *. If, after the appearance of theſe cryſtals, the ſemen be ſtill allowed to remain expoſed to the atmoſphere, the pellicle on

---

(N) Mr Hatchett found only 0.268 of phoſphat of lime in the ſinovia which he examined. He found, however, traces of ſome other phoſphat; probably phoſphat of ſoda. *Phil. Tranſ.* 1799, p. 246.

* *Ibid.* 67, and

on its ſurface gradually thickens, and a number of white round bodies appear on different parts of it. Theſe bodies alſo are phoſphat of lime, prevented from cryſtallizing regularly by the too rapid abſtraction of moiſture. Mr Vauquelin found that 100 parts of ſemen contain three parts of phoſphat of lime †. If at this period of the evaporation the air becomes moiſt, other cryſtals appear in the ſemen, which have the properties of carbonat of ſoda. The evaporation does not go on to complete exſiccation, unleſs at the temperature of 77°, and when the air is very dry. When all the moiſture is evaporated, the ſemen has loſt 0.9 of its weight, the reſiduum is ſemi-tranſparent like horn, and brittle ‡.

When ſemen is kept in very moiſt air, at the temperature of about 77°, it acquires a yellow colour, like that of the yolk of an egg; its taſte becomes acid, it exhales the odour of putrid fiſh, and its ſurface is covered with abundance of the byſſus ſeptica §

When dried ſemen is expoſed to heat in a crucible, it melts, acquires a brown colour, and exhales a yellow fume, having the odour of burnt horn. When the heat is raiſed, the matter ſwells, becomes black, and gives out a ſtrong odour of ammonia. When the odour of ammonia diſappears, if the matter be lixiviated with water, an alkaline ſolution may be obtained, which, by evaporation, yields cryſtals of carbonat of ſoda. Mr Vauquelin found that 100 parts of ſemen contain one part of ſoda ¶. If the reſiduum be incinerated, there will remain only a quantity of white aſhes, conſiſting of phoſphat of lime.

Thus it appears that ſemen is compoſed of the following ingredients:

90 water,
6 mucilage,
3 phoſphat of lime,
1 ſoda,

100

SECT. XV. *Liquor of the Amnios.*

The fœtus in the uterus is enveloped in a peculiar membranous covering, to which anatomiſts have given the name of *amnios*. Within this amnios there is a liquid, diſtinguiſhed by the name of the *liquor of the amnios*, which ſurrounds the fœtus on every part. This liquid, as might have been expected, is very different in different animals, at leaſt the liquor amnii in women and in cows, which alone have hitherto been analyſed, have not the ſmalleſt reſemblance to each other. Theſe two liquids have been lately analyſed by Vauquelin and Buniva, and the reſult of their analyſis has been publiſhed in the 33d volume of the *Annales de Chimie*.

1. The liquor of the amnios of women is a fluid of a ſlightly milky colour, a weak but pleaſant odour, and a ſaltiſh taſte. The white colour is owing to a curdy matter ſuſpended in it, for it may be obtained quite tranſparent by filtration *.

Its ſpecific gravity is 1.005. It gives a green colour to the tincture of violets and yet it reddens very decidedly the tincture of turnſol. Theſe two properties would indicate at once the preſence of an acid and of an alkali. It froths conſiderably when agitated. On the application of heat it becomes opaque, and has then a great reſemblance to milk diluted with a large quantity of water. At the ſame time it exhales the odour of boiled white of egg †.

Liquor of the Amnios.

Acids render it more tranſparent. Alkalies precipitate an animal matter in ſmall flakes. Alcohol likewiſe produces a flaky precipitate, which, when collected and dried, becomes tranſparent, and very like glue. The infuſion of nut galls produces a very copious brown coloured precipitate. Nitrat of ſilver occaſions a white precipitate, which is inſoluble in nitric acid, and conſequently is muriat of ſilver †.

When ſlowly evaporated it becomes ſlightly milky, a tranſparent pellicle forms on its ſurface, and it leaves a reſiduum which does not exceed 0.012 of the whole. By lixiviating this reſiduum, and evaporating the ley, cryſtals of muriat and carbonat of ſoda, may be obtained. The remainder, when incinerated, exhales a fetid and ammoniacal odour, reſembling that of burning horn; the aſhes conſiſt of a ſmall quantity of carbonat of ſoda, and of phoſphat and carbonat of lime ‡.

Thus we ſee that the liquor of the human amnios is compoſed of about

98.8 water,

$$1.2\left\{\begin{array}{l}\text{albumen,}\\ \text{muriat of ſoda, ſoda,}\\ \text{phoſphat of lime, lime,}\end{array}\right.$$

100.0

304
Curdy matter depoſited on the fœtus.

While the fœtus is in the uterus, a curdy-like matter is depoſited on the ſurface of its ſkin, and in particular parts of its body. This matter is often found collected in conſiderable quantities. It is evidently depoſited from the liquor of the amnios; and conſequently the knowledge of its peculiar nature muſt throw conſiderable light upon the properties and uſe of that liquor. For an analyſis of this ſubſtance we are alſo indebted to Vauquelin and Buniva.

Its colour is white and brilliant; it has a ſoft feel, and very much reſembles newly prepared ſoap. It is inſoluble in water, alcohol, and oils. Pure alkalies diſſolve part of it, and form with it a kind of ſoap. On burning coals it decrepitates like a ſalt, becomes dry and black, exhales vapours which have the odour of empyreumatic oil, and leaves a reſiduum which is very difficultly reduced to aſhes. When heated in a platinum crucible it decrepitates, lets an oil exſude, curls up like horn, and leaves a reſiduum, conſiſting chiefly of carbonat of lime ‡.

Theſe properties ſhew that this matter is different from every one of the component parts of the liquor of the amnios, and that it has a great reſemblance to the *fat*. It is probable, as Vauquelin and Buniva have conjectured, that it is formed from the albumen of that liquid, which has undergone ſome unknown changes. It has been long known, that the parts of a fœtus which has lain for ſome time after it has been deprived of life in the uterus, are ſometimes converted into a kind of fatty matter. It is evident that this ſubſtance, after it is depoſited upon the ſkin of the fœtus, muſt preſerve it in a great meaſure from being acted upon by the liquor of the amnios.

305
Liquor of the amnios of the cow.

2. The liquor of the amnios of the cow has a viſcidity ſimilar to mucilage of gum arabic, a browniſh red colour, an acid and bitter taſte, and a peculiar odour, not unlike that of ſome vegetable extracts. Its ſpecific gravity is 1.028. It reddens the tincture of turnſol, and

---

† Ann. de Chim. xxxiii. 271.

† Ibid.

‡ Ibid. p. 272.

‡ Ibid p. 274.

and therefore contains an acid. Muriat of barytes cauſes a very abundant precipitate, which renders it probable that it contains ſulphuric acid. Alcohol ſeparates from it a great quantity of a reddiſh coloured matter §.

306 Its component parts. When this liquid is evaporated, a thick frothy ſcum gathers on the ſurface, which is eaſily ſeparated, and in which ſome white acid-taſted cryſtals may be diſcovered. By continuing the evaporation, the matter becomes thick, and viſcid, and has very much the look of honey. Alcohol boiled upon this thick matter, and filtered off, depoſites upon cooling brilliant needle-formed cryſtals nearly an inch in length. Theſe cryſtals may be obtained in abundance by evaporating the liquor of the amnios to a fourth part of its bulk, and then allowing it to cool. The cryſtals ſoon make their appearance. They may be ſeparated and purified by waſhing them in a ſmall quantity of cold water. Theſe cryſtals have the properties of an acid §.

If after the ſeparation of this acid the liquor of the amnios be evaporated to the conſiſtence of a ſyrup, large tranſparent cryſtals appear in it, which have all the properties of ſulphat of ſoda. The liquid of the amnios of cows contains a conſiderable quantity of this ſalt.

Thus it appears that the liquor of the amnios of cows contains the following ingredients:

1. Water,
2. A peculiar animal matter,
3. A peculiar acid,
4. Sulphat of ſoda.

307 Nature of the animal matter. The animal matter poſſeſſes the following properties: It has a reddiſh brown colour, and a peculiar taſte; it is very ſoluble in water, but inſoluble in alcohol, which has the property of ſeparating it from water. When expoſed to a ſtrong heat it ſwells, exhales firſt the odour of burning gum, then of empyreumatic oil and of ammonia, and at laſt the peculiar odour of pruſſic acid becomes very conſpicuous. It differs from gelatine in the viſcidity which it communicates to water, in not forming a jelly when concentrated, and in not being precipitated by tan. It muſt be therefore ranked among the very undefined and inaccurate claſs of *animal mucilages*.

When burnt, it leaves a very large coal, which is readily incinerated, and leaves a little white aſhes, compoſed of phoſphat of magneſia, and a very ſmall proportion of phoſphat of lime ‖.

308 Amniotic acid. The acid ſubſtance is of a white and brilliant colour; its taſte has a very ſlight degree of ſourneſs; it reddens the tincture of turnſol; it is ſcarcely ſoluble in cold water, but very readily in hot water, from which it ſeparates in long needles as the ſolution cools. It is ſoluble alſo in alcohol, eſpecially when aſſiſted by heat. It combines readily with pure alkalies, and forms a ſubſtance which is very ſoluble in water. The other acids decompoſe this compound; and the acid of the liquor of the amnios is precipitated in a white cryſtalline powder. This acid does not decompoſe the alkaline carbonats at the temperature of the atmoſphere, but it does ſo when aſſiſted by heat. It does not alter ſolutions of ſilver, lead, or mercury, in nitric acid. When expoſed to a ſtrong heat, it froths and exhales an odour of ammonia and of pruſſic acid. The properties are ſufficient to ſhew that it is different from every other acid. Vauquelin and Boniva have given it the name of *amniotic acid*. It approaches neareſt to the ſaccholactic and the *uric* acids; but the ſachlactic acid does not furniſh ammonia by diſtillation like the amniotic. The uric acid is not ſo ſoluble in hot water as the amniotic, it does not cryſtallize in white brilliant needles, and it is inſoluble in boiling alcohol; in both which reſpects it differs completely from amniotic acid *.

SECT. XVI. *Of URINE.*

309 Urine, No animal ſubſtance has attracted more attention than urine, both on account of its ſuppoſed connection with various diſeaſes, and on account of the very ſingular products which have been obtained from it. Mr Boyle, and the other chemiſts who were his contemporaries, were induced to attend particularly to this liquid, by the diſcovery of a method of obtaining phoſphorus from it. Boerhaave, Haller, Haupt, Margraf, Pott, Rouelle, Prouſt, and Klaproth, ſucceſſively improved the method of obtaining the phoſphoric ſalts from urine, or added ſomething to our knowledge of the component parts of theſe ſalts. Scheele added greatly to our knowledge of urine by detecting ſeveral new ſubſtances in it which had not been ſuſpected. Cruickſhank has given us a very valuable paper on urine in the ſecond edition of *Rollo's Diabetes*; and Fourcroy and Vauquelin have lately publiſhed the moſt complete analyſis of it which has hitherto appeared.

Freſh urine is a liquid of a peculiar aromatic odour, an orange colour, of greater or leſs intenſity, and an acrid ſaline taſte.

Its ſpecific gravity varies from 1.005 to 1.033 *.

1. It reddens paper ſtained with turnſol and with the juice of radiſhes, and therefore contains an acid.

310 Contains phoſphat of lime, 2. If a ſolution of ammonia be poured into freſh urine, a white powder precipitates, which has the properties of phoſphat of lime. The preſence of this ſubſtance in urine was firſt diſcovered by Scheele †. If lime water be poured into urine, phoſphat of lime precipitates in greater abundance than when ammonia is uſed; conſequently the acid which urine contains is the phoſphoric. Thus we ſee that the phoſphat of lime is kept diſſolved in urine by an exceſs of acid. This alſo was firſt diſcovered by Scheele ‡. This ſubſtance is moſt abundant in the urine of the ſick. Berthollet has obſerved, that the urine of gouty people is leſs acid than that of people in perfect health. The average quantity of phoſphat of lime in healthy urine is, as Cruickſhank has aſcertained, about $\frac{1}{965}$ of the weight of the urine §.

311 Phoſphat of magneſia, 3. If the phoſphat of lime precipitated from urine be examined, a little magneſia will be found mixed with it. Fourcroy and Vauquelin have aſcertained that this is owing to a little phoſphat of magneſia which urine contains, and which is decompoſed by the alkali or lime employed to precipitate the phoſphat of lime ¶.

312 Uric acid, 4. When freſh urine cools, it often lets fall a brick coloured precipitate, which Scheele firſt aſcertained to be cryſtals of uric acid. All urine contains this acid, even when no ſenſible precipitate appears when it cools. For if a ſufficient quantity of clear and freſh urine be evaporated to $\frac{1}{178}$ of its weight, a ſubtle powder precipitates to the bottom, and attaches itſelf in part very firmly to the veſſel. This part may be diſſolved in pure alkali, and precipitated again by acetous acid. It exhibits all the properties of uric acid *. The quantity of uric acid in urine is very various. During intermittent

---

† *Scheele*, i. 208.

‡ *Ibid.*

§ *Phil Mag.* ii. 241.

¶ *Ann. de Chim* xxxi. 66.

* *Scheele*, i. 207.

termittent fevers it is depoſited very copiouſly, and has been long known to phyſicians under the name of *lateritious ſediment*. This ſediment always makes its appearance at the criſis of fevers. In gouty people, the ſame ſediment appears in equal abundance towards the end of a paroxyſm of the diſeaſe (P). And if this ſediment ſuddenly diſappears after it has begun to be depoſited, a freſh attack may be expected *.

13 5. If freſh urine be evaporated to the conſiſtence of a ſyrup, and muriatic acid be then poured into it, a precipitate appears which poſſeſſes the properties of benzoic acid. Scheele firſt diſcovered the preſence of benzoic acid in urine. He evaporated it to dryneſs, ſeparated the ſaline part, and applied heat to the reſiduum. The benzoic acid was ſublimed, and found cryſtallized in the receiver. The method which we have given is much eaſier; it was firſt propoſed by Fourcroy and Vauquelin †. By it very conſiderable quantities of benzoic acid may be obtained from the urine of horſes and cows, where it is much more abundant than in human urine. In human urine it varies from $\frac{1}{1000}$ to $\frac{1}{10000}$ of the whole §.

14 6. When an infuſion of tan is dropt into urine, a white precipitate appears, having the properties of the combination of tan and albumen, or gelatine. Urine, therefore, contains albumen and gelatine. Theſe ſubſtances had been ſuſpected to be in urine, but their preſence was firſt demonſtrated by Seguin, who diſcovered the above method of detecting them. Their quantity in healthy urine is very ſmall. Cruikſhank found that the precipitate afforded by tan in healthy urine amounted to $\frac{1}{240}$th part of the weight of the urine ‡. It is to theſe ſubſtances that the appearance of the *cloud*, as it is called, or the mucilaginous matter, which is ſometimes depoſited as the urine cools, is owing. It is probable that healthy urine contains only gelatine and not albumen, though the quantity is too ſmall to admit of accurate examination; but in many diſeaſes the quantity of theſe matters is very much increaſed. The urine of dropſical people often contains ſo much albumen, that it coagulates not only on the addition of acids, but even on the application of heat §. In all caſes of impaired digeſtion, the albuminous and gelatinous part of urine is much increaſed. This forms one of the moſt conſpicuous and important diſtinctions between the urine of thoſe who enjoy good and bad health ‖.

15 7. If urine be evaporated by a ſlow fire to the conſiſtence of a thick ſyrup, it aſſumes a deep brown colour, and exhales a fetid ammoniacal odour. When allowed to cool, it concretes into a maſs of cryſtals, compoſed of all the component parts of urine. If four times its weight of alcohol be poured upon this maſs, at intervals, and a ſlight heat be applied, the greateſt part of it is diſſolved. The alcohol, which has acquired a brown colour, is to be decanted off, and diſtilled in a crucible in a ſand heat, till the mixture has boiled for ſome time, and acquired the conſiſtence of a ſyrup. By this time the whole of the alcohol has paſſed off, and the matter, on cooling, cryſtallizes in quadrangular plates which interſect each other. This ſubſtance is *urea*, which compoſes $\frac{19}{20}$ of the urine, provided the watery part be excluded. To this ſubſtance the taſte, ſmell, and colour of urine are owing. It is a ſubſtance which characterizes urine, and conſtitutes it what it is, and to which the greater part of the very ſingular phenomena of urine are to be aſcribed.

The colour of urine depends upon the urea; the greater the quantity, the deeper is the colour. It may be detected by evaporating urine to the conſiſtence of a ſyrup, and pouring into it concentrated nitric acid. Immediately a great number of white ſhining cryſtals appear in the form of plates, very much reſembling cryſtallized boracic acid. Theſe cryſtals are urea combined with nitric acid.

The quantity of urea varies exceedingly in different urines. In the urine voided ſoon after a meal, very little of it is to be found, and ſcarcely any at all in that which hyſterical patients void during a paroxyſm.

316 Muriat of ſoda, 8. If urine be ſlowly evaporated to the conſiſtence of a ſyrup, a number of cryſtals make their appearance in it. Two of theſe are remarkable by their form: one of them conſiſts of ſmall regular octahedrons; which, when examined, are found to poſſeſs the properties of muriat of ſoda. Urine, therefore, contains muriat of ſoda. It is well known that muriat of ſoda cryſtallizes in cubes; the ſingular modification of its form in urine is owing to the action of urea. It has been long known that urine ſaturated with muriat of ſoda depoſites that ſalt in regular octahedrons.

317 Muriat of ammonia, 9. Another of the ſalts which appear during the evaporation of urine has the form of regular cubes. This ſalt has the properties of muriat of ammonia. Now the uſual form of the cryſtals of muriat of ammonia is the octahedron. The change of its form in urine is produced alſo by urea.

318 Phoſphat of ammonia and of ſoda, 10. The ſaline reſiduum which remains after the ſeparation of urea from cryſtallized urine by means of alcohol, has been long known under the names of fuſible ſalt of urine and microcoſmic ſalt. Various methods of obtaining it have been given by chemiſts from Boerhaave, who firſt publiſhed a proceſs, to Rouelle and Chaulnes, who gave the method juſt mentioned. If this ſaline maſs be diſſolved in a ſufficient quantity of hot water, and allowed to cryſtallize ſpontaneouſly in a cloſe veſſel, two ſets of cryſtals are gradually depoſited. The lowermoſt ſet has the figure of flat rhomboidal priſms; the uppermoſt, on the contrary, has the form of rectangular tables. Theſe two may be eaſily ſeparated by expoſing them for ſome time to a dry atmoſphere. The rectangular tables effloreſce and fall to powder, but the rhomboidal priſms remain unaltered.

When theſe ſalts are examined, they are found to have the properties of phoſphats. The rhomboidal priſms conſiſt of phoſphat of ammonia united to a little phoſphat of ſoda; the rectangular tables, on the contrary,

* uik- ſh, Phil. M. ii. 2

§ uik- ſh, ibid. 2

‖ urcroy Vau- , Ann. de im. x. 61.

(P) The concretions which ſometimes make their appearance in gouty joints have been found to conſiſt chiefly of uric acid. This ſingular coincidence deſerves the attention of phyſiologiſts: it cannot fail, ſooner or later, to throw light, not only upon gout, but upon ſome of the animal functions.

trary, are phoſphat of ſoda united to a ſmall quantity of phoſphat of ammonia. Urine, then, contains phoſphat of ſoda and phoſphat of ammonia.

Thus we have found that urine contains the twelve following ſubſtances:

1. Water,
2. Phoſphoric acid,
3. Phoſphat of lime,
4. Phoſphat of magneſia,
5. Uric acid,
6. Benzoic acid,
7. Gelatine and albumen,
8. Urea,
9. Muriat of ſoda,
10. Muriat of ammonia,
11. Phoſphat of ſoda,
12. Phoſphat of ammonia.

319 Sometimes other ſalts.

Theſe are the only ſubſtances which are conſtantly found in healthy urine [*]; but it contains alſo occaſionally other ſubſtances. Very often muriat of potaſs may be diſtinguiſhed among the cryſtals which form during its evaporation. The preſence of this ſalt may always be detected by dropping cautiouſly ſome tartarous acid into urine. If it contains muriat of potaſs, there will precipitate a little tartar, which may eaſily be recogniſed by its properties [*].

Urine ſometimes alſo contains ſulphat of ſoda, and even ſulphat of lime. The preſence of theſe ſalts may be aſcertained by pouring into urine a ſolution of muriat of barytes, a copious white precipitate appears, conſiſting of the barytes combined with phoſphoric acid, and with ſulphuric acid, if any be preſent. This precipitate muſt be treated with a ſufficient quantity of muriatic acid. The phoſphat of barytes is diſſolved, but the ſulphat of barytes remains unaltered [†].

320 Putrefaction of urine.

No ſubſtance putrefies ſooner, or exhales a more deteſtable odour during its ſpontaneous decompoſition, than urine; but there is a very great difference in this reſpect in different urines. In ſome, putrefaction takes place almoſt inſtantaneouſly as ſoon as it is voided; in others, ſcarcely any change appears for a number of days. Fourcroy and Vauquelin have aſcertained that this difference depends on the quantity of gelatine and albumen which urine contains. When there is very little of theſe ſubſtances preſent, urine remains long unchanged; on the contrary, the greater the quantity of gelatine or albumen, the ſooner does putrefaction commence. The putrefaction of urine, therefore, is, in ſome degree, the teſt of the health of the perſon who has voided it; for a ſuperabundance of gelatine in urine always indicates ſome defect in the power of digeſtion [*].

The rapid putrefaction of urine, then, is owing to the action of gelatine on urea. We have ſeen already the facility with which that ſingular ſubſtance is decompoſed, and that the new products into which it is changed are, ammonia, carbonic acid, and acetous acid. Accordingly, the putrefaction of urine is announced by an ammoniacal ſmell. Mucilaginous flakes are depoſited, conſiſting of part of the gelatinous matter. The phoſphoric acid is ſaturated with ammonia, and the phoſphat of lime, in conſequence, is precipitated. Ammonia combines with the phoſphat of magneſia, forms with it a triple ſalt, which cryſtallizes upon the ſides of the veſſel in the form of white cryſtals, compoſed of ſix-ſided priſms, terminated by ſix-ſided pyramids. The uric and benzoic acids are ſaturated with ammonia; the acetous acid, and the carbonic acid, which are the products of the decompoſition of the urea, are alſo ſaturated with ammonia, and notwithſtanding the quantity which exhales, the production of this ſubſtance is ſo abundant, that there is a quantity of unſaturated alkali in the liquid. Putrefied urine, therefore, contains chiefly the following ſubſtances, moſt of which are the products of putrefaction:

Ammonia,
Carbonat of ammonia,
Phoſphat of ammonia,
Phoſphat of magneſia and ammonia,
Urat of ammonia,
Acetite of ammonia,
Benzoat of ammonia,
Muriat of ſoda,
Muriat of ammonia;

Beſides the precipitated gelatine and phoſphat of lime [*].

The diſtillation of urine produces almoſt the ſame changes; for the heat of boiling water is ſufficient to decompoſe urea, and to convert it into ammonia, carbonic and acetous acids. Accordingly, when urine is diſtilled, there comes over water, containing ammonia diſſolved in it, and carbonat of ammonia in cryſtals. The acids contained in urine are ſaturated with ammonia, and the gelatine and phoſphat of lime precipitate [†].

Such are the properties of the human urine. The urine of other animals has not hitherto been examined with equal care; but it is certain that it differs very conſiderably from that of men. The urine of cows and horſes, and of all ruminating animals, for inſtance, contains carbonat of lime, without any mixture of phoſphat of lime [‡]. It contains alſo a much greater proportion of benzoic acid than that of man.

SECT. XVII. *Of the URINARY CALCULUS.*

It is well known that concretions not unfrequently form in the bladder, or the other urinary organs, and occaſion one of the moſt diſmal diſeaſes to which the human ſpecies is liable.

321 Urinary calculi

Theſe concretions were diſtinguiſhed by the name of *calculi*, from a ſuppoſition that they are of a ſtony nature. They have long attracted the attention of phyſicians. Chemiſtry had no ſooner made its way into medicine than it began to exerciſe its ingenuity upon the urinary calculus; and various theories were given of their nature and origin. According to Paracelſus, who gave them the ridiculous name of *duelech*, urinary calculi were intermediate between tartar and ſtone, and compoſed of an *animal reſin*. Van Helmont pronounced them anomalous coagulations, the offspring of the ſalts of urine, and of a volatile earthy ſpirit, produced at once, and deſtitute of any viſcid matter [§]. Boyle extracted from them, by diſtillation, oil, and a great quantity of volatile ſalt. Boerhaave ſuppoſed them compounds of oil and volatile ſalts. Hales extracted from them a prodigious quantity of air. He gave them the name of *animal tartar*, pointed out ſeveral circumſtances in which they reſemble common tartar, and made many experiments to find a ſolvent of them [*]. Drs Whytt and Alſton pointed out alkalies as ſolvents of calculi. It was an attempt to diſcover a more perfect ſolvent that induced Dr Black to make thoſe experiments which terminated in the diſcovery of the nature of the alkaline carbonats.

322 Analyſed by Scheele

Such was the ſtate of the chemical analyſis of calculus, when, in 1776, Scheele publiſhed a diſſertation on the ſubject in the *Stockholm Tranſactions*; which was ſucceeded by ſome remarks of Mr Bergmann. Theſe illuſtrious

inary culus

illuſtrious chemiſts completely removed the uncertainty which had hitherto hung over the ſubject, and aſcertained the nature of the calculi which they examined. Since that time conſiderable additional light has been thrown upon the nature of theſe concretions by the labours of Auſtin, Pearſon, and, above all, of Fourcroy and Vauquelin, who have lately analyſed above 300 calculi, and aſcertained the preſence of ſeveral new ſubſtances which had not been ſuſpected. The ſubſtances hitherto diſcovered in urinary calculi are the following:

23 ir com ent s.

1. Uric acid,
2. Urat of ammonia,
3. Phoſphat of lime (q),
4. Phoſphat of magneſia-and-ammonia,
5. Oxalat of lime,
6. Silica,
7. An animal matter.

24 acid.

1. The greater number of calculi conſiſt of uric acid. All thoſe analyſed by Scheele were compoſed of it entirely. Of 300 calculi analyſed by Dr Pearſon, ſcarcely one was found which did not contain a conſiderable quantity of it, and the greater number manifeſtly were formed chiefly of it. Fourcroy and Vauquelin found it alſo in the greater number of the 300 calculi which they analyſed.

The preſence of this acid may eaſily be aſcertained by the following properties: A ſolution of potaſs or ſoda diſſolves it readily, and it is precipitated by the weakeſt acids. The precipitate is ſoluble in nitric acid, the ſolution is of a pink colour, and tinges the ſkin red *.

* ourcroy, . de n. xxxii.

325 at of ammonia.

2. Urat of ammonia is eaſily detected by its rapid ſolubility in fixed alkaline leys, and the odour of ammonia which is perceived during the ſolution. It is not ſo often preſent in urinary calculi as the laſt mentioned ſubſtance. No calculus has hitherto been found compoſed of it alone, except the very ſmall polygonal calculi, ſeveral of which ſometimes exiſt in the bladder together.

It is moſt uſually in thin layers, alternating with ſome other ſubſtance, very eaſily reduced to powder, and of the colour of ground coffee †.

† bid. 218.

326 ſphat ime.

3 Phoſphat of lime is white, without luſtre, fiery, friable, ſtains the hands, paper, and cloth. It has very much the appearance of chalk, breaks under the forceps, is inſipid, and inſoluble in water. It is ſoluble in nitric, muriatic, and acetous acids, and is again precipitated by ammonia, fixed alkalies, and oxalic acid.

It is never alone in calculi. It is intimately mixed with a gelatinous matter, which remains under the form of a membrane when the earthy part is diſſolved by very diluted acids ‡.

‡ bid.

327 ſphat magne- and-am- nia.

4. Phoſphat of magneſia-and-ammonia occurs in white, ſemitranſparent, lameller layers; ſometimes it is cryſtallized on the ſurface of the calculi in priſms, or what are called *dog tooth* cryſtals. It has a weak ſweetiſh taſte, it is ſomewhat ſoluble in water, and very ſoluble in acids, though greatly diluted. Fixed alkalies decompoſe it.

It never forms entire calculi. Sometimes it is mixed with phoſphat of lime, and ſometimes layers of it cover uric acid or oxalat of lime. It is mixed with the ſame gelatinous matter as phoſphat of lime ‡.

‡ Fourcroy, Ann. de Chim. xxxii. 219.

328 Oxalat of lime.

5. Oxalat of lime is found in certain calculi, which, from the inequality of their ſurface, have got the name of *moriform* or *mulberry ſhaped* calculi. It is never alone, but combined with a peculiar animal matter, and forming with it a very hard calculus, of a grey colour, difficult to ſaw aſunder, admitting a poliſh like ivory, exhaling, when ſawed, an odour like that of ſemen. Inſoluble and indecompoſible by alkalies; ſoluble in very diluted nitric acid, but ſlowly, and with difficulty. It may be decompoſed by the carbonats of potaſs and ſoda. When burnt, it leaves behind a quantity of pure lime, which may be eaſily recogniſed by its properties *.

* Ibid. 220.

329 Silica.

6. Silica has only been found in two inſtances by Fourcroy and Vauquelin, though they analyſed 300 calculi. No other chemiſt has obſerved it. It muſt therefore be conſidered as a very uncommon ingredient of theſe concretions. In the two inſtances in which it occurred, it was mixed with uric acid and the two phoſphats above mentioned †.

† Ibid. 221.

330 Animal matters.

7. *Animal matter* appears to compoſe the cement which binds the different particles of the calculus together, and in all probability it is the cauſe which influences its formation. It is different in different calculi. Sometimes it has the appearance of gelatine or albumen, at other times it reſembles urea. It deſerves a more accurate inveſtigation ‡.

‡ Ibid.

No general deſcription of the different calculi has hitherto appeared; but Fourcroy and Vauquelin are at preſent occupied with that ſubject. They propoſe to claſſify them according to their compoſition; to point out their different ſpecies and varieties; to give a method of detecting them by their appearance; to analyſe the animal matter by which they are cemented; and to apply all the preſent chemical knowledge of the ſubject in the inveſtigation of the cauſe, the ſymptoms, and the cure, of that dreadful diſeaſe which the urinary calculi produce. As their labour is already very far advanced, it would be unneceſſary for us to attempt any claſſification of calculi. Indeed every attempt of that kind, by any perſon who has not had an opportunity of analyſing a very great number of calculi, muſt be ſo exceedingly imperfect as ſcarcely to be of any uſe.

We ſhall ſatisfy ourſelves with the following remarks, deduced almoſt entirely from the obſervations which theſe celebrated chemiſts have already publiſhed.

331 Method of diſſolving the calculi.

Many calculi conſiſt entirely, or almoſt entirely, of uric acid. The animal matter, which ſerves as a cement to theſe calculi, appears to be urea. Calculi of this kind may be diſſolved by injecting into the bladder ſolutions of pure potaſs or ſoda, ſo much diluted as not to act upon the bladder itſelf. The gritty ſubſtance, which many perſons threatened with the ſtone diſcharge along with their urine, which has been called *gravel*, conſiſts almoſt conſtantly of uric acid. It may therefore ſerve as an indication that the ſubſequent ſtone, if any ſuch form, is probably compoſed of uric acid.

The two phoſphats, mixed together, ſometimes compoſe calculi. Theſe calculi are very brittle, and generally

---

(q) Brugnatelli found alſo phoſphat of lime, with exceſs of acid, in calculi. See *Ann. de Chim.* xxxii. 183.

rally break in pieces during the extraction. Such calculi may be diſſolved by injecting into the bladder muriatic acid, ſo much diluted as ſcarcely to have any taſte of acid.

The phoſphats never form the nucleus of a calculus. They have never been found covered with a layer of uric acid, but they often cover that acid. Hence it would ſeem that the exiſtence of any extraneous matter in the bladder diſpoſes theſe phoſphats to cryſtallize. When extraneous bodies are accidentally introduced into the bladder, and allowed to lodge there, they are conſtantly covered with a coat of phoſphat of ammonia and magneſia, or of the two phoſphats mixed.

As the phoſphat of ammonia and magneſia is not an ingredient of freſh urine, but formed during its putrefaction, when it exiſts in calculi, it would ſeem to indicate a commencement of putrefaction during the time that the urine lodges in the bladder. But putrefaction does not take place ſpeedily in urine, unleſs where there is an exceſs of albumen and gelatine; conſequently we have reaſon to ſuppoſe, that theſe ſubſtances are morbidly abundant in the urine of thoſe patients who are afflicted with calculi conſiſting of the phoſphats: hence alſo we may conclude, that their digeſtion is imperfect. It will no doubt be objected, that dropſical people are not peculiarly ſubject to calculi; but their urine is only morbidly albuminous when the diſeaſe is beginning to diſappear, and then there ſeems to be a deficiency of urea; at leaſt their urine has not been obſerved to putrefy with uncommon rapidity. Beſides, there ſeems to be ſome animal matter preſent, which ſerves as a cement to the phoſphat in all caſes where calculi form.

Urat of ammonia is only found alone in the very ſmall polygonous calculi which exiſt, ſeveral together, in the bladder. In other caſes it is mixed with uric acid. It ſometimes alternates with uric acid or with the phoſphats. It is diſſolved by the ſame ſubſtance that acts as a ſolvent of uric acid.

Oxalat of lime often forms the nucleus of calculi compoſed of layers of uric acid or of the phoſphats. It forms thoſe irregular calculi which are called *moriform*. Theſe calculi are the hardeſt and the moſt difficult of ſolution. A very much diluted nitric acid diſſolves them but very ſlowly. As oxalic acid does not exiſt in urine, ſome morbid change muſt take place in the urine when ſuch calculi are depoſited. Brugnatelli's diſcovery of the inſtantaneous converſion of uric acid into oxalic acid by oxy-muriatic acid, which has been confirmed by the experiments of Fourcroy and Vauquelin, throws conſiderable light upon the formation of oxalic acid in urine, by ſhewing us that uric acid is probably the baſis of it; but in what manner the change is actually produced, it is not ſo eaſy to ſay.

The calculi found in the bladder of other animals have not been examined with the ſame care. Some of them, however, have been ſubjected to an accurate analyſis. No uric acid has ever been found in any of them.

332
Calculi of inferior animals.

Fourcroy found a calculus extracted from the kidney of a horſe compoſed of three parts of carbonat of lime, and one part phoſphat of lime *. Dr Pearſon examined a urinary calculus of a horſe; it was compoſed of phoſphat of lime and phoſphat of ammonia. Brugnatelli found a calculus extracted from the bladder of a ſow, which was exceedingly hard, compoſed of pure carbonat of lime, incloſing a ſoft nucleus of a fœtid and urinous odour †. Bartholdi examined another calculus of a pig, the ſpecific gravity of which was 1.9200. It conſiſted of phoſphat of lime ‡. Dr Pearſon found a calculus taken from the bladder of a dog compoſed of phoſphat of lime, phoſphat of ammonia, and an animal matter. He found the urinary calculus of a rabbit, of the ſpecific gravity 2, compoſed of carbonat of lime and ſome animal matter ||.

The compoſition of the different animal concretions hitherto examined may be ſeen in the following table.

We have now given an account of all thoſe ſecretions which have been attentively examined by chemiſts. The remainder have been hitherto neglected; partly owing to the difficulty of procuring them, and partly on account of the multiplicity of other objects which occupied the attention of chemical philoſophers (R). It remains for us now to examine by what proceſſes theſe different ſecretions are formed, how the conſtant waſte of living bodies is repaired, and how the organs themſelves are nouriſhed and preſerved. This ſhall form the ſubject of the following chapter.

CHAP. III. OF THE FUNCTIONS OF ANIMALS.

The intention of the two laſt chapters was to exhibit a view of the different ſubſtances which enter into the compoſition of animals, as far as the preſent limited ſtate of our knowledge puts it in our power. But were our enquiries concerning animals confined to the mere ingredients of which their bodies are compoſed, even ſuppoſing the analyſis as complete as poſſible, our knowledge of the nature and properties of animals would be imperfect indeed.

How are theſe ſubſtances arranged? How are they produced?

---

* Ann. de Chim. xvi, 95.

† Ibid. xxxii. 184.

‡ Ibid. 185.

|| Phil. Mag. ii. 134.

(R) The chief of theſe ſecretions are the following:

1. Cerumen, or ear-wax, is at firſt nearly liquid, and of a whitiſh colour. It gradually acquires conſiſtence. Its taſte is very bitter. Said to be inſoluble in alcohol; but ſoluble in hot water. Does not become rancid by keeping.
2. The humours of the eye.
3. The milky liquor, ſecreted by the thyroid gland.
4. Mucus of the lungs, inteſtinal canal, &c.
5. Smegma of the areola of the breaſts, glans penis, vagina, ſubcutaneous glands, &c.
6. Marrow.

Fu ions of A mals.

produced? What purpoſes do they ſerve? What are the diſtinguiſhing properties of animals, and the laws by which they are regulated?

3
Ani ls reſe le veg bles

Animals reſemble vegetables in the complexneſs of their ſtructure. Like them, they are machines nicely adapted for particular purpoſes, conſtituting one whole, and continually performing an infinite number of the moſt delicate proceſſes. But neither an account of the ſtructure of animals, nor of the properties which diſtinguiſh them from other beings, will be expected here. Theſe have been already treated of ſufficiently in the articles ANATOMY and PHYSIOLOGY (*Encycl.*), to which we beg leave to refer the reader. We mean only, in the preſent chapter, to take a view of thoſe proceſſes which are concerned in the *production* of animal ſubſtances, which alone properly belong to chemiſtry. The other functions are regulated by laws of a very different nature, which have no reſemblance or analogy to the laws of chemiſtry or mechanics.

4
Re ire foc

1. Every body knows that animals require food, and that they die ſooner or later if food be withheld from them. There is indeed a very great difference in different animals, with regard to the quantity of food which they require, and the time which they can paſs without it. In general, this difference depends upon the activity of the animal. Thoſe which are moſt active require moſt, and thoſe which move leaſt require leaſt food.

The cauſe of this is alſo well known; the bodies of animals do not remain ſtationary, they are conſtantly waſting; and the waſte is generally proportional to the activity of the animal. It is evident, then, that the body muſt receive, from time to time, new ſupplies, in place of what has been carried off. Hence the uſe of food, which anſwers this purpoſe.

5
Iti ture.

2. We are much better acquainted with the food of animals than of vegetables. It conſiſts of almoſt all the animal and vegetable ſubſtances which have been treated of in the former part of this article; for there are but very few of them which ſome animal or other does not uſe as food. Man uſes as food chiefly the muſcles of animals, the feeds of certain graſſes, and a variety of vegetable fruits. Almoſt all the inferior animals have particular ſubſtances on which they feed excluſively. Some of them feed on animals, others on vegetables. Man has a greater range; he can feed on a very great number of ſubſtances. To enumerate theſe ſubſtances would be uſeleſs; as we are not able to point out with accuracy what it is which renders one ſubſtance more nouriſhing than another.

Many ſubſtances do not ſerve as nouriſhment at all; and not a few, inſtead of nouriſhing, deſtroy life. Theſe laſt are called *poiſons*. Some poiſons act chemically, by decompoſing the animal body. The action of others is not ſo well underſtood.

36
C verted i chyme

3. The food is introduced into the body by the mouth, and almoſt all animals reduce it to a kind of pulpy conſiſtence. In man and many other animals this is done in the mouth by means of teeth, and the ſaliva with which it is there mixed; but many other animals grind their food in a different manner. See PHYSIOLOGY, (*Encycl.*) After the food has been thus ground, it is introduced into the ſtomach, where it is ſubjected to new changes. The ſtomach is a ſtrong ſoft bag, of different forms in different animals: in man it has ſome reſemblance to the bag of a *bag-pipe*. In this organ the food is converted into a ſoft pap, which has no reſemblance to the food when firſt introduced. This pap has been called *chyme*.

Functions of Animals.

4. Since chyme poſſeſſes new properties, it is evident that the food has undergone ſome changes in the ſtomach, and that the ingredients of which it was compoſed have entered into new combinations. Now, in what manner have theſe changes been produced?

At firſt they were aſcribed to the mechanical action of the ſtomach. The food, it was ſaid, was ſtill farther triturated in that organ; and being long agitated backwards and forwards in it, was at laſt reduced to a pulp. But this opinion, upon examination, was found not to be true. The experiments of Stevens, Reaumur, and Spallanzani, demonſtrated, that the formation of chyme is not owing to trituration; for on incloſing different kinds of food in metallic tubes and balls full of holes, in ſuch a manner as to ſcreen them from the mechanical action of the ſtomach, they found, that theſe ſubſtances, after having remained a ſufficient time in the ſtomach, were converted into chyme, juſt as if they had not been incloſed in ſuch tubes. Indeed, the opinion was untenable, even independent of theſe deciſive experiments, the moment it was perceived that chyme differed entirely from the food which had been taken: that is to ſay, that if the ſame food were triturated mechanically out of the body, and reduced to pap of preciſely the ſame conſiſtence with chyme, it would not poſſeſs the ſame properties with chyme; for whenever this fact was known, it could not but be evident that the food had undergone changes in its compoſition.

The change of food into chyme, therefore, was aſcribed by many to *fermentation*. This opinion is indeed very ancient, and it has had many zealous ſupporters among the moderns. When the word *fermentation* was applied to the change produced on the food in the ſtomach, the nature of the proceſs called fermentation was altogether unknown. The appearances, indeed, which take place during that proceſs, had been deſcribed, and the progreſs and the reſult of it were known. Chemiſts had even divided fermentations into different claſſes; but no attempt had been made to explain the cauſe of fermentation, or to trace the changes which take place during its continuance. All that could be meant, then, by ſaying that the converſion of food into chyme in the ſtomach was owing to fermentation, was merely, that the unknown cauſe which acted during the converſion of vegetable ſubſtances into wine or acid, or during their putrefaction, acted alſo during the converſion of the food into chyme, and that the reſult in both caſes was preciſely the ſame. Accordingly, the advocates for this opinion attempted to prove, that air was conſtantly generated in the ſtomach, and that an acid was conſtantly produced: for it was the vinous and acetous fermentations which were aſſigned by the greater number of phyſiologiſts as the cauſe of the formation of chyme. Some indeed attempted to prove, that it was produced by the putrefactive fermentation; but their number was inconſiderable, compared with thoſe who adopted the other opinion.

Our ideas reſpecting fermentation are now ſomewhat more preciſe. It ſignifies a ſlow decompoſition, which takes place when certain animal or vegetable ſubſtances are mixed together at a given temperature; and the

conſequent

conſequent production of particular compounds. If therefore the converſion of the food into chyme be owing to fermentation, it is evident that it is totally independent of the ſtomach any farther than as it ſupplies temperature; and that the food would be converted into chyme exactly in the ſame manner, if it were reduced to the ſame conſiſtence, and placed in the ſame temperature out of the body. But this is by no means the caſe; ſubſtances are reduced to the ſtate of chyme in a ſhort time in the ſtomach, which would remain unaltered for weeks in the ſame temperature out of the body. This is the caſe with bones; which the experiments of Stevens and Spallanzani have ſhewn to be ſoon digeſted in the ſtomach of the dog. Further, if the converſion of food into chyme were owing to fermentation, it ought to go on equally well in the ſtomach and œſophagus. Now, it was obſerved long ago by Ray and Boyle, that when voracious fiſh had ſwallowed animals too large to be contained in the ſtomach, that part only which was in the ſtomach was converted into chyme, while what was in the œſophagus remained entire; and this has been fully confirmed by ſubſequent obſervations.

Still farther, if the converſion were owing to fermentation, it ought always to take place equally well, provided the temperature be the ſame, whether the ſtomach be in a healthy ſtate or not. But it is well known, that this is not the caſe. The formation of chyme depends very much on the ſtate of the ſtomach. When that organ is diſeaſed, digeſtion is conſtantly ill performed. In theſe caſes, indeed, fermentation ſometimes appears, and produces flatulence, acid eructations, &c. which are the well-known ſymptoms of indigeſtion. Theſe facts have been long known; they are totally incompatible with the ſuppoſition, that the formation of chyme is owing to fermentation Accordingly that opinion has been for ſome time abandoned, by all thoſe at leaſt who have taken the trouble to examine the ſubject.

337 By the action of the gaſtric juice.

The formation of chyme, then, is owing to the ſtomach; and it has been concluded, from the experiments of Stevens, Reaumur, Spallanzani, Scopoli, Brugnatelli, Carimini, &c. that its formation is brought about by the action of a particular liquid ſecreted by the ſtomach, and for that reaſon called *gaſtric juice*.

That it is owing to the action of a liquid, is evident; becauſe if pieces of food be incloſed in cloſe tubes, they paſs through the ſtomach without any farther alteration than would have taken place at the ſame temperature out of the body: but if the tubes be perforated with ſmall holes, the food is converted into chyme.

This liquid does not act indiſcriminately upon all ſubſtances: For if grains of corn be put into a perforated tube, and a granivorous bird be made to ſwallow it, the corn will remain the uſual time in the ſtomach without alteration; whereas if the huſk of the grain be previouſly taken off, the whole of it will be converted into chyme. It is well known, too, that many ſubſtances paſs unaltered through the inteſtines of animals, and conſequently are not acted upon by the gaſtric juice. This is the caſe frequently with grains of oats when they have been ſwallowed by horſes entire with their huſks on. This is the caſe alſo with the ſeeds of apples, &c. when ſwallowed entire by men; yet theſe very ſubſtances, if they have been previouſly ground ſufficiently by the teeth, are digeſted. It appears, therefore, that it is chiefly the huſk or outſide of theſe ſubſtances which reſiſts the action of the gaſtric juice. We ſee alſo, that trituration greatly facilitates the converſion of food into chyme

338 Nature of gaſtric juice.

The gaſtric juice is not the ſame in all animals; for many animals cannot digeſt the food on which others live. The *conium maculatum* (hemlock), for inſtance, is a poiſon to man inſtead of food, yet the goat often feeds upon it. Many animals, as ſheep, live wholly upon vegetables; and if they are made to feed on animals, their ſtomachs will not digeſt them: others, again, as the eagle, feed wholly on animal ſubſtances, and cannot digeſt vegetables.

The gaſtric juice does not continue always of the ſame nature, even in the ſame animal: it changes gradually, according to circumſtances. Graminivorous animals may be brought to live on animal food; and after they have been accuſtomed to this for ſome time, their ſtomachs become incapable of digeſting vegetables. On the other hand, thoſe animals which naturally digeſt nothing but animal food may be brought to digeſt vegetables.

What is the nature of the gaſtric juice, which poſſeſſes theſe ſingular properties? It is evidently different in different animals; but it is a very difficult taſk, if not an impoſſible one, to obtain it in a ſtate of purity. Various attempts have indeed been made by very ingenious philoſophers to procure it; but their analyſis of it is ſufficient to ſhew us, that they have never obtained it in a ſtate of purity.

The methods which have been uſed to procure gaſtric juice are, *firſt*, to kill the animal whoſe gaſtric juice is to be examined after it has faſted for ſome time. By this method, Spallanzani collected 37 ſpoonfuls from the two firſt ſtomachs of a ſheep. It was of a green colour, undoubtedly owing to the graſs which the animal had eaten. He found alſo half a ſpoonful in the ſtomach of ſome young crows which he killed before they had left their neſt.

Small tubes of metal, pierced with holes, and containing a dry ſponge, have been ſwallowed by animals; and when vomited up, the liquid imbibed by the ſponge is ſqueezed out. By this method, Spallanzani collected 481 grains of gaſtric juice from the ſtomachs of five crows.

A *third* method conſiſts in exciting vomiting in the morning, when the ſtomach is without food. Spallanzani tried this method twice upon himſelf, and collected one of the times 1 oz. 32 gr. of liquid; but the pain was ſo great, that he did not think proper to try the experiment a third time. Mr Goſſe, however, who could excite vomiting whenever he thought proper by ſwallowing air, has employed that method to collect gaſtric juice.

Spallanzani has obſerved, that eagles throw up every morning a quantity of liquid, which he conſiders as gaſtric juice; and he has availed himſelf of this to collect it in conſiderable quantities.

It is almoſt unneceſſary to remark how imperfect theſe different methods are, and how far every concluſion drawn from the examination of ſuch juices muſt deviate from the truth. It is impoſſible that the gaſtric juice, obtained by any one of theſe proceſſes, can be pure; becauſe in the ſtomach it muſt be conſtantly

mixed

mixed with large quantities of ſaliva, mucus, bile, food, &c. It may be queſtioned, indeed, whether any gaſtric juice at all can be obtained by theſe methods: for as the intention of the gaſtric juice is to convert the food into chyme, in all probability it is only ſecreted, or at leaſt thrown into the ſtomach when food is preſent.

We need not be ſurpriſed, then, at the contradictory accounts concerning its nature, given us by thoſe philoſophers who have attempted to examine it; as theſe relate not ſo much to the gaſtric juice, as to the different ſubſtances found in the ſtomach. The idea that the gaſtric juice can be obtained by vomiting, or that it is thrown up ſpontaneouſly by ſome animals, is, to ſay the leaſt of it, very far from being probable.

According to Brugnatelli, the gaſtric juice of carnivorous animals, as hawks, kites, &c. has an acid and reſinous odour, is very bitter, and not at all watery; and is compoſed of an uncombined acid, a reſin, an animal ſubſtance, and a ſmall quantity of muriat of ſoda *. The gaſtric juice of herbivorous animals, on the contrary, as goats, ſheep, &c. is very watery, a little muddy, has a bitter ſaltiſh taſte, and contains ammonia, an animal extract, and a pretty large quantity of muriat of ſoda †. Mr Carminati found the ſame ingredients; but he ſuppoſes that the ammonia had been formed by the putrefaction of a part of their food, and that in reality the gaſtric juice of theſe animals is of an acid nature ‡.

The accounts which have been given of the gaſtric juice of man are ſo various, that it is not worth while to tranſcribe them. Sometimes it has been found of an acid nature, at other times not. The experiments of Spallanzani are ſufficient to ſhew, that this acidity is not owing to the gaſtric juice, but to the food. He never found any acidity in the gaſtric juice of birds of prey, nor of ſerpents, frogs, and fiſhes. Crows gave an acidulous gaſtric juice only when fed on grain; and he found that the ſame obſervation holds with reſpect to dogs, herbiverous animals, and domeſtic fowls. Carnivorous birds threw up pieces of ſhells and coral without alteration; but theſe ſubſtances were ſenſibly diminiſhed in the ſtomachs of hens, even when incloſed in perforated tubes. Spallanzani himſelf ſwallowed calcareous ſubſtances incloſed in tubes; and when he fed on vegetables and fruits, they were ſometimes altered and a little diminiſhed in weight, juſt as if they had been put into weak vinegar; but when he uſed only animal food, they came out untouched. According to this philoſopher, whoſe experiments have been by far the moſt numerous, the gaſtric juice is naturally neither acid nor alkaline. When poured on the carbonat of potaſs, it cauſes no efferveſcence.

Such are the reſults of the experiments on the juices taken from the ſtomach of animals. No concluſion can be drawn from them reſpecting the nature of the gaſtric juice. But from the experiments which have been made on the digeſtion of the ſtomach, eſpecially by Spallanzani, the following facts are eſtabliſhed.

The gaſtric juice attacks the ſurfaces of bodies, unites to the particles of them which it carries off, and cannot be ſeparated from them by filtration. It operates with more energy and rapidity the more the food is divided, and its action is increaſed by a warm temperature. The food is not merely reduced to very minute parts; its taſte and ſmell are quite changed; its ſenſible properties are deſtroyed, and it acquires new and very different ones. This juice does not act as a ferment; ſo far from it, that it is a powerful antiſeptic, and even reſtores fleſh already putrefied. There is not the ſmalleſt appearance of ſuch a proceſs; indeed, when the juice is renewed frequently, as in the ſtomach, ſubſtances diſſolve in it with a rapidity which excludes all idea of fermentation. Only a few air bubbles make their eſcape, which adhere to the alimentary matter, and buoy it up to the top, and which are probably extricated by the heat of the ſolution.

With reſpect to the ſubſtances contained in the ſtomach, only two facts have been perfectly aſcertained: The firſt is, that the juice contained in the ſtomach of oxen, calves, ſheep, invariably contains uncombined phoſphoric acid, as Macquart and Vauquelin have demonſtrated: The ſecond, that the juice contained in the ſtomach, and even the inner coat of the ſtomach itſelf, has the property of coagulating milk and the ſerum of blood. Dr Young found, that ſeven grains of the inner coat of a calf's ſtomach, infuſed in water, gave a liquid which coagulated more than 100 ounces of milk; that is to ſay, more than 6857 times its own weight; and yet, in all probability, its weight was not much diminiſhed.

What the ſubſtance is which poſſeſſes this coagulating property, has not yet been aſcertained; but it is evidently not very ſoluble in water: for the inſide of a calf's ſtomach, after being ſteeped in water for ſix hours, and then well waſhed with water, ſtill furniſhes a liquor on infuſion which coagulates milk *: And Dr Young found, that a piece of the inner coat of the ſtomach, after being previouſly waſhed with water, and then with a diluted ſolution of carbonat of potaſs, ſtill afforded a liquid which coagulated milk and ſerum.

It is evident, from theſe facts, that this coagulating ſubſtance, whatever it is, acts very powerfully; and that it is ſcarcely poſſible to ſeparate it completely from the ſtomach. But we know at preſent too little of the nature of coagulation to be able to draw any inference from theſe facts. An almoſt imperceptible quantity of ſome ſubſtances ſeems to be ſufficient to coagulate milk. For Mr Vaillant mentions in his Travels in Africa, that a porcelain diſh which he procured, and which had lain for ſome years at the bottom of the ſea, poſſeſſed, in conſequence, the property of coagulating milk when put into it; yet it communicated no taſte to the milk, and did not differ in appearance from other cups.

It is probable that the ſaliva is of ſervice in the converſion of food into chyme as well as the gaſtric juice. It evidently ſerves to dilute the food; and probably it may be ſerviceable alſo, by communicating oxygen.

339. Chyme converted into chyle and excrement.

5. The chyme, thus formed, paſſes from the ſtomach into the inteſtines, where it is ſubjected to new changes, and at laſt converted into two very different ſubſtances; chyle and excrementitious matter.

6. The *chyle* is a white coloured liquid, very much reſembling milk. It is exceedingly difficult to collect it in any conſiderable quantity, and for that reaſon it has never been accurately analyſed. We know only in general that it reſembles milk; containing, like it, an albuminous part capable of being coagulated, a ſerum, and globules which have a reſemblance to cream †. It contains alſo different ſalts; and, according to ſome, a ſubſtance ſcarcely differing from the ſugar of milk. It is probable alſo that it contains iron; but if ſo, it muſt be

---

* opoli's quer's D

† d.

‡ rebier's rvat. aſtric j e.

* *Young.*

† *Fordyce on Digeſtion*, 121.

be in the ſtate of a white oxyd; for an infuſion of nut galls does not alter the colour of chyle ‡.

6. Concerning the proceſs by which chyle is formed from chyme, ſcarcely any thing is known. It does not appear that the chyme is preciſely the ſame in all animals; for thoſe which are herbivorous have a greater length of inteſtine than thoſe which are carnivorous. It is certain that the formation of the chyle is brought about by a chemical change, although we cannot ſay preciſely what that change is, or what the agents are by which it is produced. But that the change is chemical, is evident, becauſe the chyle is entirely different, both in its properties and appearance, from the chyme. The chyme, by the action of the inteſtines, is ſeparated into two parts, chyle and excrement: the firſt of which is abſorbed by a number of ſmall veſſels called *lacteals*; the ſecond is puſhed along the inteſtinal canal, and at laſt thrown out of the body altogether.

After the chyme has been converted into chyle and excrement, although theſe two ſubſtances remain mixed together, it does not appear that they are able to decompoſe each other; for perſons have been known ſeldom or never to emit any excrementitious matter *per anum* for years. In theſe, not only the chyle, but the excrementitious matter alſo, was abſorbed by the lacteals; and the excrement was afterwards thrown out of the body by other outlets, particularly by the ſkin; in conſequence of which, thoſe perſons have conſtantly that particular odour about them which diſtinguiſhes excrement. Now in theſe perſons, it is evident that the chyle and excrement, though mixed together, and even abſorbed together, did not act on each other; becauſe theſe perſons have been known to enjoy good health for years, which could not have been the caſe had the chyle been deſtroyed.

340
Uſe of bile.

7. It has been ſuppoſed by ſome that the decompoſition of the chyme, and the formation of chyle, is produced by the agency of the bile, which is poured out abundantly, and mixed with the chyme, ſoon after its entrance into the inteſtines. If this theory were true, no chyle could be formed whenever any accident prevented the bile from paſſing into the inteſtinal canal: but this is obviouſly not true; for frequent inſtances have occurred of perſons labouring under jaundice from the bile ducts being ſtopped, either by gallſtones or ſome other cauſe, ſo completely, that no bile could paſs into the inteſtines; yet theſe perſons have lived for a conſiderable time in that ſtate. Conſequently digeſtion, and therefore the formation of chyle, muſt be poſſible, independent of bile.

The principal uſe of the bile ſeems to be to ſeparate the excrement from the chyle, after both have been formed, and to produce the evacuation of the excrement out of the body. It is probable that theſe ſubſtances would remain mixed together, and that they would perhaps even be partly abſorbed together, were it not for the bile, which ſeems to combine with the excrement, and by this combination to facilitate its ſeparation from the chyle, and thus to prevent its abſorption. It alſo ſtimulates the inteſtinal canal, and cauſes it to evacuate its contents ſooner than it otherwiſe would do; for when there is a deficiency of bile, the body is conſtantly coſtive.

341
Of the excrementitious matter.

8. The excrement, then, which is evacuated *per anum*, conſiſts of all that part of the food and chyme which was not converted into chyle, entirely altered however from its original ſtate, partly by the decompoſition which it underwent in the ſtomach and inteſtines, and partly by its combination with bile. Accordingly we find in it many ſubſtances which did not exiſt at all in the food. Thus in the dung of cows and horſes there is found a very conſiderable quantity of benzoic acid. The excrements of animals have not yet been ſubjected to an accurate analyſis, though ſuch an analyſis would throw much light upon the nature of digeſtion. For if we knew accurately the ſubſtances which were taken into the body as food, and all the new ſubſtances which were formed by digeſtion; that is to ſay, the component parts of chyle and of excrement, and the variation which different kinds of food produce in the excrement, it would be a very conſiderable ſtep towards aſcertaining preciſely the changes produced on food by digeſtion, or, which is the ſame thing, towards aſcertaining exactly the phenomena of digeſtion. The only analyſis which has hitherto been made on human excrement is that of Homberg; and as it conſiſted merely in ſubjecting it to diſtillation, it is needleſs to give an account of it. Of late, as Mr Fourcroy informs us, the ſubject has been reſumed in France, and we may ſoon expect ſome very curious and important additions to our knowledge.

342
Excrements of fowls.

Mr Vauquelin has already publiſhed an analyſis of the fixed parts of the excrements of fowls, and a compariſon of them with the fixed parts of the food; from which ſome very curious conſequences may be deduced.

He found that a hen devoured in ten days 11111.843 grains troy of oats. Theſe contained

136.509	gr. of phoſphat of lime,
219.548	ſilica,
356.057.	

During theſe ten days ſhe layed four eggs; the ſhells of which contained 98.776 gr. phoſphat of lime, and 453.417 gr. carbonat of lime. The excrements emitted during theſe ten days contained 175.529 gr. phoſphat of lime, 58.494 gr. of carbonate of lime, and 185.266 gr. of ſilica. Conſequently the fixed parts thrown out of the ſyſtem during theſe ten days amounted to

	Grains.	
	274.305	phoſphat of lime,
	511.911	carbonat of lime,
	185.266	ſilica,
Given out	971.482	
Taken in	356.057	
	615.425	

Conſequently the quantity of fixed matter given out of the ſyſtem in ten days exceeded the quantity taken in by 615.425 grains.

The ſilica taken in amounted to	219.548 gr.
That given out was only	185.266 gr.
Remains	34.282

Conſequently there diſappeared 34.282 grains of ſilica.

The phoſphat of lime taken in was	136.509 gr.
That given out was	274.305 gr.
	137.796

Conſequently

---

‡ Fordyce on *Digeſtion*, 122.

Conſequently there muſt have been formed, by digeſtion in this fowl, no leſs than 137.796 grains of phoſphat of lime, beſides 511.911 grains of carbonat. Conſequently lime (and perhaps alſo phoſphorus) is not a ſimple ſubſtance, but a compound, and formed of ingredients which exiſt in oat-ſeed, water, or air, the only ſubſtance to which the fowl had acceſs. Silica may enter into its compoſition, as a part of the ſilica had diſappeared ; but if ſo, it muſt be combined with a great quantity of ſome other ſubſtance *.

Theſe conſequences are too important to be admitted without a very rigorous examination. The experiment muſt be repeated frequently, and we muſt be abſolutely certain that the hen has no acceſs to any calcareous earth, and that ſhe has not diminiſhed in weight ; becauſe in that caſe ſome of the calcareous earth, of which part of her body is compoſed, may have been employed. This rigour is the more neceſſary, as it ſeems pretty evident, from experiments made long ago, that *ſome* birds at leaſt, cannot produce eggs unleſs they have acceſs to calcareous earth. Dr Fordyce found, that if the canary-bird was not ſupplied with lime at the time of her laying, ſhe frequently died, from her eggs not coming forward properly †. He divided a number of theſe birds at the time of their laying eggs into two parties : to the one he gave a piece of old mortar, which the little animals ſwallowed greedily ; they laid their eggs as uſual, and all of them lived : whereas many of the other party, which were ſupplied with no lime, died ‡.

[342] 9. The inteſtines ſeldom or never are deſtitute of gaſes, which ſeem to be evolved during the proceſs of digeſtion ; and may therefore, in part, be conſidered as excrementitious matter. The only perſon who has examined theſe gaſes with care, is Mr Jurine of Geneva. The reſult of his analyſis is as follows. He found in the ſtomach and inteſtines of a man who had been frozen to death, carbonic acid gas, oxygen gas, hydrogen gas, and azotic gas. The quantity of carbonic acid was greateſt in the ſtomach, and it diminiſhed gradually as the canal receded from the ſtomach ; the proportion of oxygen gas was conſiderable in the ſtomach, ſmaller in the ſmall inteſtines, and ſtill ſmaller in the great inteſtines ; the hydrogen and azotic gaſes, on the contrary, were leaſt abundant in the ſtomach, more abundant in the ſmall inteſtines, and moſt abundant in the larger inteſtines ; the hydrogen gas was moſt abundant in the ſmall inteſtines. It is well known that the flatus diſcharged *per anum* is commonly carbonated hydrogen gas ; ſometimes alſo it ſeems to hold ſulphur, or even phoſphorus in ſolution §.

343 10. The chyle, after it has been abſorbed by the lacteals, is carried by them into a pretty large veſſel, known by the name of *thoracic duct.* Into the ſame veſſel likewiſe is diſcharged a tranſparent fluid, conveyed by a ſet of veſſels which ariſe from all the cavities of the body. Theſe veſſels are called *lymphatics*, and the fluid which they convey is called *lymph.* In the thoracic duct, then, the chyle and the lymph are mixed together.

344 Very little is known concerning the nature of the *lymph*, as it is ſcarcely poſſible to collect it in any quantity. It is colourleſs, has ſome viſcidity, and is ſaid to be ſpecifically heavier than water. It is ſaid to be coagulable by heat ; if ſo, it contains albumen ; and, from its appearance, it probably contains gelatine. Its quantity is certainly conſiderable, for the lymphatics are very numerous.

Functions of Animals.

345 And conveyed to the heart and lungs.

11. The chyle and lymph being thus mixed together, are conveyed directly into the blood veſſels. The effect produced by their union in the thoracic duct is not known, but neither the colour nor external properties of the chyle is altered. In man, and many other animals, the thoracic duct enters at the junction of the left ſubclavian and carotid veins, and the chyle is conveyed directly to the heart, mixed with the blood, which already exiſts in the blood veſſels. From the heart, the blood and chyle thus mixed together are propelled into the lungs, where they undergo farther changes.

346 Reſpiration

12. The abſolute neceſſity of *reſpiration*, or of ſome thing analogous, is known to every one ; and few are ignorant that in man, and hot blooded animals, the organ by which reſpiration is performed is the lungs. For a deſcription of the reſpiratory organs, we refer to the article ANATOMY, *Encycl.* and the reader will find an account of the manner in which that function is performed in the article PHYSIOLOGY, *Encycl.* But what are the changes produced upon the blood and the chyle by reſpiration ? What purpoſes does it ſerve to the animal ? How comes it to be ſo indiſpenſably neceſſary for its exiſtence ? Theſe are queſtions which can only be anſwered by a careful examination of the phenomena of reſpiration.

347 Requires oxygen gas.

It has been long known that an animal can only breathe a certain quantity of air for a limited time, after which it becomes the moſt deadly poiſon, and produces ſuffocation as effectually as the moſt noxious gas, or a total abſence of air. It was ſuſpected long ago that this change is owing to the abſorption of a part of the air ; and Mayow made a number of very ingenious experiments in order to prove the fact. Dr Prieſtley and Mr Scheele demonſtrated, that the quantity of oxygen gas in atmoſpheric air is diminiſhed ; and Lavoiſier demonſtrated, in 1776, that a quantity of carbonic acid gas, which did not previouſly exiſt in it, was found in air after it had been for ſome time reſpired. It was afterwards proved by Lavoiſier, and many other philoſophers, who confirmed and extended his facts, that no animal can live in air totally deſtitute of oxygen. Even fiſh, which do not ſenſibly reſpire, die very ſoon, if the water in which they live be deprived of oxygen gas. Frogs which can ſuſpend their reſpiration at pleaſure, die in about forty minutes, if the water in which they have been confined be covered over with oil *. Inſects and worms, as Vauquelin has proved, exhibit preciſely the ſame phenomena. They require oxygen gas as well as other animals, and die like them if they be deprived of it. They diminiſh the quantity of the oxygen gas in which they live, and give out, by reſpiration, the very ſame products as other animals. Worms, which are more retentive of life than moſt other animals, or at leaſt not ſo much affected by poiſonous gaſes, abſorb every particle of the oxygen gas contained in the air in which they are confined before they die. Mr Vauquelin's experiments were made on the gryllus viridiſſimus, the limax flavus, and helix pomatia †.

348 Changes produced by it.

The changes which take place during reſpiration are the following :

1\. Part of the oxygen gas reſpired diſappears.

---

* ...n. de ...C ...i. xxix

† Ann. de Chim. xii. 278.

2. Carbonic acid gas is emitted.
3. Water is emitted in the ſtate of vapour.

The firſt point is to aſcertain exactly the amount of theſe changes. Though a great many experiments have been made on this ſubject by different philoſophers, the greateſt confidence ought to be put in thoſe of Lavoiſier, both on account of his uncommon accuracy, and on account of the very complete apparatus which he always employed.

He put a guinea-pig into 708.989 grains troy of oxygen, and after the animal had breathed the gas for an hour, he took it out. He found that the oxygen gas now amounted only to 592.253 gr.
Conſequently there had diſappeared 116.736
The carbonic acid gas formed was 130.472
This was compoſed of about 94.234
oxygen, and 36.238
of carbon. Conſequently ſuppoſing, as Mr Lavoiſier did, that the oxygen abſorbed had been employed in the formation of the carbonic acid gas, there ſtill remained to be accounted for 22.502 grains of oxygen which had diſappeared. He ſuppoſed that this had been employed in the formation of water, a quantity of which had appeared. If ſo, the water formed muſt have amounted to 26.429 grains; which was compoſed of 3.927 hydrogen, the reſt oxygen *.

Since the water emitted was not actually aſcertained, this experiment can only be conſidered as an approximation to the truth. Accordingly that very ingenious philoſopher contrived an apparatus to aſcertain the quantity of oxygen gas abſorbed by man, and the quantity of carbonic acid gas and water emitted by him during reſpiration. This apparatus he had conſtructed at an expence at leaſt equal to L. 500 ſterling. The experiments were completed, and he was preparing them for publication, when, on the 8th of May 1794, he was beheaded by order of Robeſpierre, after having in vain requeſted a fortnight's delay to put his papers in order for the preſs. Thus periſhed, in the 51ſt year of his age, the man who, if he had lived a few years longer, promiſed fair to become the rival of Newton himſelf. Chemiſtry, as a ſcience, is deeply indebted to him. He ſaved it from that confuſion into which the thoughtleſs ardour of many of his contemporaries were plunging it headlong: he arranged and connected and ſimplified and explained the multitude of inſulated facts, which had been accumulating with unexampled celerity; and which, had it not been for his happy arranging genius, might have retarded, inſtead of advanced, the progreſs of the ſcience. He reduced all the facts under a few ſimple heads, and thus made them eaſily remembered and eaſily claſſified. In a few years more, perhaps, he would have traced theſe general principles to their ſources, eſtabliſhed the ſcience on the completeſt induction, and paved for his ſucceſſors a road as unerring as that which Sir Iſaac Newton formed in mechanical philoſophy.

Mr Lavoiſier's experiments have never been publiſhed, but fortunately Mr de la Place has given us the reſult of them †. He informs us that it was as follows: A man, at an average, conſumes, in twenty-four hours, by reſpiration, 32.48437 ounces troy of oxygen gas; that is to ſay, that a quantity of oxygen gas, equal to that weight, diſappears from the air which he reſpires in twenty-four hours; that he gives out by reſpiration, in the ſame time, 15.73 oz. troy of carbonic acid gas, and 28.55 of water in the ſtate of vapour.

Total 44.28 *Oxygen.*
The carbonic acid gas is compoſed of $10.48\dot{6}$
and $5.24\dot{3}$ carbon. The water of 24.2675
and 4.2825 hydrogen.
Total of the oxygen emitted $34.7541\dot{6}$
Total abſorbed 32.48437

So that there is $2.369791\dot{6}$
ounces of oxygen emitted more than is abſorbed by reſpiration. Thus it appears that, by reſpiration, the abſolute quantity of oxygen in the blood is diminiſhed.

Dr Menzies found that a man, at a medium, draws in at every reſpiration 43.77 cubic inches of air, and that $\frac{1}{20}$th of that quantity diſappears. Conſequently, according to him, at every reſpiration 2.1885 cubic inches of oxygen gas are conſumed. Now 2.1885 cubic inches of that gas amount to 0.68669 gr. troy. Suppoſing, with Hales, that a man makes 1200 reſpirations in an hour, the quantity of oxygen gas conſumed in an hour, will amount to 824.028 grains, and in 24 hours to 19776.672 grains, or 41.2014 ounces troy. This quantity exceeds that found by Lavoiſier conſiderably; but the allowance of oxygen for every reſpiration is rather too great. Indeed, from the nature of Dr Menzies's apparatus, it was ſcarce poſſible to meaſure it accurately.

The quantity of water given out by reſpiration, as determined by Hales, amounts in a day to 20.4 oz. *; but his method was not ſuſceptible of great accuracy. We may therefore, on the whole, conſider Lavoiſier's determination as by far the neareſt to the truth of any that has been given.

There is, however, a very ſingular anomaly, which becomes apparent when we compare his experiments on the reſpiration of the guinea-pig with thoſe on the reſpiration of man.

The guinea-pig conſumed in 24 hours 5.8368 oz. troy of oxygen gas, and emitted 6.5236 oz. of carbonic acid gas. Man, on the other hand, conſumes in the ſame time 32.48437 oz. of oxygen gas, and emits only 15.73 oz. of carbonic acid gas. The oxygen gas conſumed by the pig is to the carbonic gas emitted as 1 00 : 1.12; whereas in man it is as 1.000 : 0.484. If we could depend upon the accuracy of each of theſe experiments, they would prove, beyond a doubt, that the changes produced by the reſpiration of the pig are different, at leaſt in degree, from thoſe produced in man; but it is more than probable that ſome miſtake has crept into one or other of the experiments. We have more reaſon to ſuſpect the firſt, as it was made before 1778, at a time when a great many circumſtances, neceſſary to inſure accuracy, were unknown to Lavoiſier.

Such are the ſubſtances imbibed and emitted during reſpiration. It ſtill remains for us to determine what are the changes which it produces on the blood.

It has been long known that the blood which flows in the veins is of a dark reddiſh purple colour, whereas the arterial blood is of a florid ſcarlet colour. Lower obſerved that the colour of the veinous blood was converted into that of arterial during its paſſage through the

---

* *Ann. de Chim.* v. 261.

† *La Place's Eloge.*

* *Veget. Stat.* ii. 327.

ctions nimals.

the lungs. No chyle can be diſtinguiſhed by its white colour in the blood after it has paſſed through the lungs. The changes, then, which take place upon the appearance of the blood are two: 1*ſt*, It acquires a florid red colour; 2*d*, The chyle totally diſappears. Now to what are theſe changes owing?

Lower himſelf knew that the change was produced by the air, and Mayow attempted to prove that it was by abſorbing a part of the air. But it was not till Dr Prieſtley diſcovered that veinous blood acquires a ſcarlet colour when put in contact with oxygen gas, and arterial blood a dark red colour when put in contact with hydrogen gas, or, which is the ſame thing, that oxygen gas inſtantly gives veinous blood the colour of arterial; and hydrogen, on the contrary, gives arterial blood the colour of veinous blood: it was not till then that philoſophers began to attempt any thing like an explanation of the phenomena of reſpiration. Two explanations have been given; one or other of which muſt be true.

349 o hypo es to ex- n theſe ges.

The firſt is, that the oxygen of the air, which diſappears, combines with a quantity of carbon and hydrogen given out by the blood in the lungs, and forms with it carbonic acid gas and water in vapour, which are thrown out along with the air expired.

The ſecond is, that the oxygen gas, which diſappears, combines with the blood as it paſſes thro' the lungs; and that, at the inſtant of this combination, there is ſet free from the blood a quantity of carbonic acid gas and of water, which are thrown out along with the air expired.

The firſt of theſe theories was originally formed by Lavoiſier, and it was embraced by La Place, Crawford, Gren, and Girtanner, with a ſmall variation. Indeed it does not differ, except in detail, from the original hypotheſis of Dr Prieſtley, that the uſe of reſpiration is to rid the blood of phlogiſton; for if we ſubſtitute carbon and hydrogen for phlogiſton, the two theories preciſely agree. Mr Lavoiſier attempted not to prove its truth; he only tried to ſhew that the oxygen abſorbed correſponds exactly with the quantity of oxygen contained in the carbonic acid and the water emitted. This coincidence his own experiments have ſhewn not to hold; conſequently the theory is entirely deſtitute of proof, as far as the proof depends upon this coincidence.

The other hypotheſis was propoſed by Mr de la Grange, and afterwards ſupported and illuſtrated by Mr Haſſenfratz.

350 ts of ration ined.

In order to diſcover what the real effects of reſpiration are, let us endeavour to ſtate accurately the phenomena as far as poſſible.

In the *firſt* place, we are certain, from the experiments of Prieſtley, Girtanner, and Haſſenfratz, that when veinous blood is expoſed to oxygen gas confined over it, the blood inſtantly aſſumes a ſcarlet colour, and the gas is diminiſhed in bulk; therefore part of the gas has been abſorbed. We may conſider it as certain, then, that when the colour of veinous blood is changed into arterial, ſome oxygen gas is abſorbed [†].

In the *ſecond* place, no chyle can be diſcovered in the blood after it has paſſed through the lungs. Therefore the *white colour* of the chyle at leaſt, is deſtroyed by reſpiration, and it aſſumes a red colour. Now if the red colour of the blood be owing to iron, as many have ſuppoſed, this change of colour is a demonſtration that oxygen has combined with the iron; for we have ſeen already, that iron, if it exiſts in chyle, as it probably does, is in the ſtate of a white oxyd. Conſequently, when converted into a red oxyd, it muſt abſorb oxygen. Even though iron be not the colouring matter of the blood, it would ſtill be probable that the change of colour of the chyle depends on the fixation of oxygen; for Berthollet and Fourcroy have ſhewn that in ſeveral inſtances ſubſtances acquire a red colour by that proceſs.

Functions of Animals.

We may conſider it as proved, then, that oxygen enters the blood as it paſſes through the lungs.

In the *third* place, when arterial blood is put in contact with azotic gas, or carbonic acid gas, it gradually aſſumes the dark colour of veinous blood, as Dr Prieſtley found [*]. The ſame philoſopher alſo obſerved that arterial blood acquired the colour of veinous blood when placed in vacuo [†]. Conſequently this alteration of colour is owing to ſome change which takes place in the blood itſelf, independent of any external agent.

The arterial blood becomes much more rapidly and deeply dark coloured when it is left in contact with hydrogen gas placed above it [‡]. We muſt ſuppoſe therefore that the preſence of this gas accelerates and increaſes the change, which would have taken place upon the blood without any external agent.

If arterial blood be left in contact with oxygen gas, it gradually aſſumes the ſame dark colour which it would have acquired in vacuo, or in contact with hydrogen; and after this change oxygen can no longer reſtore its ſcarlet colour [§]. Therefore it is only upon a part of the blood that the oxygen acts; and after this part has undergone the change which occaſions the dark colour, the blood loſes the power of being affected by oxygen.

Mr Haſſenfratz poured into veinous blood a quantity of oxy-muriatic acid; the blood was inſtantly decompoſed, and aſſumed a deep and almoſt black colour. When he poured common muriatic acid into blood, the colour was not altered [||]. Now oxy-muriatic acid has the property of giving out its oxygen readily; conſequently the black colour was owing to the inſtant combination of a part of the blood with oxygen.

The facts therefore lead us to conclude, with La Grange and Haſſenfratz, that during reſpiration the oxygen, which diſappears, enters the blood; that during the circulation this oxygen combines with a certain part of the blood; and that the veinous colour is owing to this new combination. We muſt conclude, too, that the ſubſtance which cauſes this dark colour leaves the blood during its circulation thro' the lungs, otherwiſe it could not be capable of aſſuming the florid colour. Now we know what the ſubſtances are which are emitted during reſpiration; they are water and carbonic acid gas. It muſt be to the gradual combination of oxygen, then, during the circulation, with hydrogen and carbon, that the colour of veinous blood is owing. And ſince the ſame combination takes place every time that the blood paſſes through the lungs, we muſt conclude, that it is only a part of the hydrogen and carbon which is acted upon each time. Let us now attempt, with theſe data, to form ſome notion of the decompoſition which goes on during the circulation of the blood.

351 Contributes to the formation of blood,

It is probable that, during a conſiderable part of the day, there is a conſtant influx of chyle into the blood; and we are certain that lymph is conſtantly flowing in- to

---

[†] n de C. vii.

[*] Prieſtley, iii. 363

[‡] Fourcroy, Ann de Chim. vii. 149.

[§] Ibid ix. 168.

[||] Ibid.

to it. Now it appears, from the moſt accurate obſervations hitherto made, that neither chyle nor lymph contain fibrina, which forms a very conſpicuous part of the blood. This fibrina is employed to ſupply the waſte of the muſcles, the moſt active parts of the body, and therefore, in all probability, requiring the moſt frequent ſupply. Nor can it be doubted that it is employed for other uſeful purpoſes. The quantity of fibrina in the blood, then, muſt be conſtantly diminiſhing, and therefore new fibrina muſt be conſtantly formed. But the only ſubſtances out of which it can be formed are the chyle and lymph, neither of which contain it. There muſt therefore be a continual decompoſition of the chyle and lymph going on in the bloodveſſels, and a continual new formation of fibrina. Other ſubſtances alſo may be formed; but we are certain that this *muſt* be formed there, becauſe it does not exiſt previouſly. Now, one great end of reſpiration muſt undoubtedly be to aſſiſt this decompoſition of chyle and complete formation of blood.

It follows, from the experiments of Fourcroy formerly enumerated, that fibrina contains more azot, and leſs hydrogen and carbon, than any of the other ingredients of the blood, and conſequently alſo than any of the ingredients of the chyle. In what manner the chyle, or a part of it, is converted into fibrina, it is impoſſible to ſay: we are not ſufficiently acquainted with the ſubject to be able to explain the proceſs. But we can ſee at leaſt, that carbon and hydrogen muſt be abſtracted from that part of the chyle which is to be converted into fibrina: And we know, that theſe ſubſtances are actually thrown out by reſpiration. We may conclude, then, that *one* uſe of the oxygen abſorbed is, to abſtract a quantity of carbon and hydrogen from a part of the chyle by compound affinity, in ſuch proportions, that the remainder becomes fibrina: therefore one end of reſpiration is to form fibrina. Doubtleſs the other ingredients of the blood are alſo new modified, though we know too little of the ſubject to throw any light upon it.

352
Produces animal heat;

13. But the complete formation of blood is not the only advantage gained by reſpiration: the *temperature* of all animals depends upon it. It has been long known, that thoſe animals which do not breathe have a temperature but very little ſuperior to the medium in which they live. This is the caſe with fiſhes and many inſects. Man, on the contrary, and quadrupeds which breathe, have a temperature conſiderably higher than the atmoſphere: that of man is 98°. Birds, who breathe in proportion a ſtill greater quantity of air than man, have a temperature equal to 103° or 104°. It has been proved, that the temperature of all animals is proportional to the quantity of air which they breathe in a given time.

Theſe facts are ſufficient to demonſtrate, that the heat of animals depends upon reſpiration. But it was not till Dr Black's doctrine of latent heat became known to the world, that any explanation of the cauſe of the temperature of breathing animals was attempted. That illuſtrious philoſopher, whoſe diſcoveries form the baſis upon which all the ſcientific part of chemiſtry has been reared, ſaw at once the light which his doctrine of latent heat threw upon this part of phyſiology, and he applied it very early to explain the temperature of animals.

According to him, part of the latent heat of the air inſpired becomes ſenſible; and of courſe, the temperature of the lungs, and the blood that paſſes through them, muſt be raiſed; and the blood, thus heated, communicates its heat to the whole body. This opinion was ingenious, but it was liable to an unanſwerable objection: for if it were true, the temperature of the body ought to be greateſt in the lungs, and to diminiſh gradually as the diſtance from the lungs increaſes; which is not true. The theory, in conſequence, was abandoned even by Dr Black himſelf; at leaſt he made no attempt to ſupport it.

Lavoiſier and Crawford, who conſidered all the changes operated by reſpiration as taking place in the lungs, accounted for the origin of the animal heat almoſt preciſely in the ſame manner with Dr Black. According to them, the oxygen gas of the air combines in the lungs with the hydrogen and carbon emitted by the blood. During this combination, the oxygen gives out a great quantity of caloric, with which it had been combined; and this caloric is not only ſufficient to ſupport the temperature of the body, but alſo to carry off the new formed water in the ſtate of vapour, and to raiſe conſiderably the temperature of the air inſpired. According to theſe philoſophers, then, the whole of the caloric which ſupports the temperature of the body is evolved in the lungs. Their theory accordingly was liable to the ſame objection with Dr Black's; but they obviated it in the following manner: Dr Crawford found, that the ſpecific caloric of arterial blood was 1.0300, while that of veinous blood was only 0.8928. Hence he concluded, that the inſtant veinous blood is changed into arterial blood, its ſpecific caloric increaſes; conſequently it requires an additional quantity of caloric to keep its temperature as high as it had been while veinous blood. This addition is ſo great, that the whole new caloric evolved is employed: therefore the temperature of the lungs muſt neceſſarily remain the ſame as that of the reſt of the body. During the circulation, arterial blood is gradually converted into veinous; conſequently its ſpecific caloric diminiſhes, and it muſt give out heat. This is the reaſon that the temperature of the extreme parts of the body does not diminiſh.

This explanation is certainly ingenious; but it is not quite ſatisfactory; for the difference in the ſpecific caloric, granting it to be accurate, is too ſmall to account for the great quantity of heat which muſt be evolved. It is evident that it muſt fall to the ground altogether, provided, as we have ſeen reaſon to ſuppoſe, the carbonic acid gas and water be not formed in the lungs, but during the circulation.

Since the oxygen enters the blood, and combines with it in the ſtate of gas, it is evident that it will only part at firſt with ſome of its caloric; and this portion is chiefly employed in carrying off the carbonic acid gas and the water. For the reaſon that the carbonic acid leaves the blood at the inſtant that the oxygen gas enters it, ſeems to be this: The oxygen gas combines with the blood, and part of its caloric unites at the ſame inſtant to the carbonic acid, and converts it into gas: another portion converts the water into vapour. The reſt of the caloric is evolved during the circulation when the oxygen combines with hydrogen and carbon, and forms water and carbonic acid gas. The quantity of caloric evolved in the lungs ſeems not only ſufficient to carry off the carbonic acid and water, which the diminution

nution of the ſpecific caloric (if it really take place) muſt facilitate; but it ſeems alſo to raiſe the temperature of the blood a little higher than it was before. For Mr John Hunter conſtantly found, that the heat of the heart in animals was a degree higher than any other part of the body which he examined. Now this could ſcarcely happen, unleſs the temperature of the blood were ſomewhat raiſed during reſpiration.

353 ſup- s the ulation. Thus we have ſeen two uſes which reſpiration ſeems to ſerve. The firſt is the completion of blood by the formation of fibrina; the ſecond is the maintaining of the temperature of the body at a particular ſtandard, notwithſtanding the heat which it is continually giving out to the colder ſurrounding bodies. But there is a third purpoſe, which explains why the animal is killed ſo ſuddenly when reſpiration is ſtopped. The circulation of the blood is abſolutely neceſſary for the continuance of life. Now the blood is circulated in a great meaſure by the alternate contractions of the heart. It is neceſſary that the heart ſhould contract regularly, otherwiſe the circulation could not go on. But the heart is ſtimulated to contract by the blood: and unleſs blood be made to undergo the change produced by reſpiration, it ceaſes almoſt inſtantaneouſly to ſtimulate. As the blood receives oxygen in the lungs, we may conclude that the preſence of oxygen is neceſſary to its ſtimulating power *.

354 dneys ployed the formation of od. 14. Thus we have reaſon to ſuppoſe, that chyle and lymph are converted into blood during the circulation; and that the oxygen gas ſupplied by reſpiration is one of the principal agents in this change. But beſides the lungs and arteries, there is another organ, the ſole uſe of which is alſo to produce ſome change or other in the blood, which renders it more complete, and more proper for the various purpoſes to which it is applied. This organ is the *kidney*.

For the ſtructure of the kidneys, which in man and quadrupeds are two in number, we refer to ANATOMY, *Encycl.* A very great proportion of blood paſſes thro' them; indeed, we have every reaſon to conclude, that the whole of the blood paſſes through them very frequently.

Theſe organs ſeparate the urine from the blood, to be afterwards evacuated without being applied to any purpoſe uſeful to the animal.

The kidneys are abſolutely neceſſary for the continuance of the life of the animal; for it dies very ſpeedily when they become by diſeaſe unfit to perform their functions: therefore the change which they produce in the blood is a change neceſſary for qualifying it to anſwer the purpoſes for which it is intended.

As the urine is immediately excreted, it is evident that the change which the kidneys perform is intended ſolely for the ſake of the blood. It is not merely the abſtraction of a quantity of water and of ſalts, accumulated in the blood, which the kidney performs. A chemical change is certainly produced, either upon the whole blood, or at leaſt on ſome important part of it; for there are two ſubſtances found in the urine which do not exiſt in the blood. Theſe two ſubſtances are urea and uric acid. They are formed, therefore, in the kidneys; and as they are thrown out, after being formed, without being applied to any uſeful purpoſe, they are certainly not formed in the kidneys for their own ſake. Some part of the blood, then, muſt be decompoſed in the kidney, and a new ſubſtance, or new ſubſtances, muſt be formed; and the urea and uric acid muſt be formed at the ſame time, in conſequence of the combined action of the affinities which produce the change on the blood; and being uſeleſs, they are thrown out, together with a quantity of water and ſalts, which, in all probability, were uſeful in bringing about the changes which take place in the arteries and in the kidneys, but which are no longer of any ſervice after theſe changes are brought about.

The changes operated upon the blood in the kidneys are hitherto altogether unknown; but they muſt be important.

Provided the method of analyſing animal ſubſtances were ſo far perfected as to admit of accurate concluſions, conſiderable light might be thrown upon this ſubject, by analyſing with care a portion of blood from the emulgent vein and artery ſeparately, and aſcertaining preciſely in what particulars they differ from each other. 355 Cutaneous veſſels

15. Thus we have ſeen that the principal changes which the blood undergoes, as far at leaſt as we are at preſent acquainted with them, take place in the lungs, in the kidneys, and in the arteries. In the lungs, a quantity of water and carbonic acid gas is emitted from the blood, and in the kidney the urine is formed and ſeparated from it. There ſeems alſo to be ſomething thrown out from the blood during its circulation in the arteries, at leaſt through thoſe veſſels which are near the ſurface of the body: For it is a fact, that certain ſubſtances are conſtantly emitted from the ſkins of animals. Theſe ſubſtances are known in general by the name of *perſpirable matter*, or *perſpiration*. They have a great reſemblance to what is emitted in the lungs; which renders it probable, that they are both owing to the ſame cauſe; namely, to the decompoſition produced in the blood by the effects of reſpiration. They conſiſt chiefly of water in a ſtate of vapour, carbon, and oil.

The quantity of aqueous vapour differs very conſiderably, according to circumſtances. It has been ſhewn to be greateſt in hot weather, and in hot climates, and after great exerciſe; and its relation to the quantity of urine has been long known. When the aqueous vapour perſpired is great, the quantity of urine is ſmall, and *vice verſa*. 356 Emit aqueous vapour,

The moſt accurate experiments on this matter that we have ſeen are thoſe of Mr Cruikſhank. He put his hand into a glaſs veſſel, and luted its mouth at his wriſt by means of a bladder. The interior ſurface of the veſſel became gradually dim, and drops of water trickled down. By keeping his hand in this manner for an hour, he collected 30 grains of a liquid, which poſſeſſed all the properties of pure water*. On repeating the ſame experiment at nine in the evening (thermometer 62°), he collected only 12 grains. The mean of theſe is 21 grains. But as the hand is more expoſed than the trunk of the body, it is reaſonable to ſuppoſe that the perſpiration from it is greater than that from the hand. Let us therefore take 30 grains per hour as the mean; and let us ſuppoſe, with Mr Cruikſhank, that the hand is $\frac{1}{60}$th of the ſurface of the body. The perſpiration in an hour would amount to 1800 grains, and in 24 hours to 43200 grains, or 7 pounds 6 ounces troy.

---

* Girtanner, r. de ſ. xxxix.

* *On Inſenſible Perſpiration*, p. 68.

He repeated the experiment again after hard exerciſe, and collected in an hour 48 grains of water*. He found alſo, that this aqueous vapour pervaded his ſtocking without difficulty; and that it made its way thro' a ſhamoy leather glove, and even through a leather boot, though in much ſmaller quantity than when the leg wanted that covering†.

It is not difficult to ſee why the quantity of watery vapour diminiſhes with cold. When the ſurface of the body is expoſed to a cold temperature, the capacity of the cutaneous veſſels diminiſhes, and conſequently the quantity which flows through them muſt decreaſe

When the temperature, on the other hand, is much increaſed, either by being expoſed to a hot atmoſphere, or by violent exerciſe, the perſpired vapour not only increaſes in quantity, but even appears in a liquid form. This is known by the name of *ſweat*. In what manner ſweat is produced, is not at preſent known; but we can ſee a very important ſervice which it performs to the animal.

No ſooner is it thrown upon the ſurface of the ſkin than it begins to evaporate. But the change into vapour requires heat; accordingly a quantity of heat is abſorbed, and the temperature of the animal is lowered. This is the reaſon that animals can endure to remain for ſome time in a much higher temperature without injury than could have been ſuppoſed.

The experiments of Tillet, and the ſtill more deciſive experiments of Fordyce and his aſſociates, are well known. Theſe gentlemen remained a conſiderable time in a temperature exceeding the boiling point of water.

357 Carbon,

Beſides water, it cannot be doubted that *carbon* is alſo emitted from the ſkin; but in what ſtate, the experiments hitherto made do not enable us to decide. Mr Cruikſhank found, that the air of the glaſs veſſel in which his hand and foot had been confined for an hour, contained carbonic acid gas; for a candle burned dimly in it, and it rendered lime-water turbid*. And Mr Jurine found, that air which had remained for ſome time in contact with the ſkin, conſiſted almoſt entirely of carbonic acid gas†. The ſame concluſion may be drawn from the experiments of Ingenhouſz and Milly‡.

Now it is evident, that the carbonic acid gas which appeared during Mr Cruikſhank's experiment, did not previouſly exiſt in the glaſs veſſel; conſequently it muſt have either been tranſmitted ready formed through the ſkin, or formed during the experiment by the abſorption of oxygen gas, and the conſequent emiſſion of carbonic acid gas. The experiments of Mr Jurine do not allow us to ſuppoſe the firſt of theſe to be true; for he found, that the quantity of air allowed to remain in contact with the ſkin did not increaſe. Conſequently the appearance of the carbonic acid gas muſt be owing either to the emiſſion of carbon, which forms carbonic acid gas by combining with the oxygen gas of the air, or to the abſorption of oxygen gas, and the ſubſequent emiſſion of carbonic acid gas; preciſely in the ſame manner, and for the ſame reaſon, that theſe ſubſtances are emitted by the lungs. The laſt is the more probable opinion; but the experiments hitherto made do not enable us to decide.

358 And an oily matter.

Beſides water and carbon, or carbonic acid gas, the ſkin emits alſo a particular odorous ſubſtance. That every animal has a peculiar ſmell, is well known: the dog can diſcover his maſter, and even trace him to a diſtance by the ſcent. A dog, chained ſome hours after his maſter had ſet out on a journey of ſome hundred miles, followed his footſteps by the ſmell, and found him on the third day in the midſt of a crowd*. But it is needleſs to multiply inſtances of this fact; they are too well known to every one. Now this ſmell muſt be owing to ſome peculiar matter which is conſtantly emitted; and this matter muſt differ ſomewhat either in quantity or ſome other property, as we ſee that the dog eaſily diſtinguiſhes the individual by means of it. Mr Cruikſhank has made it probable that this matter is an oily ſubſtance; or at leaſt that there is an oily ſubſtance emitted by the ſkin. He wore repeatedly, night and day for a month, the ſame veſt of fleecy hoſiery during the hotteſt part of the ſummer. At the end of this time he always found an oily ſubſtance accumulated in conſiderable maſſes on the nap of the inner ſurface of the veſt, in the form of black tears. When rubbed on paper, it makes it tranſparent, and hardens on it like greaſe. It burns with a white flame, and leaves behind it a charry reſiduum†.

It has been ſuppoſed that the ſkin has the property of *abſorbing moiſture* from the air; but this opinion has not been confirmed by experiments, but rather the contrary.

359 Whether the ſkin abſorbs moiſture,

The chief arguments in favour of the abſorption of the ſkin, have been drawn from the quantity of moiſture diſcharged by urine being, in ſome caſes, not only greater than the whole drink of the patient, but even than the whole of his drink and food. But it ought to be remembered that, in diabetes, the diſeaſe here alluded to, the weight of the body is continually diminiſhing, and therefore part of it muſt be conſtantly thrown off. Beſides, it is ſcarcely poſſible in that diſeaſe to get an accurate account of the food ſwallowed by the patients; and in thoſe caſes where very accurate accounts have been kept, and where deception was not ſo much practiſed, the urine was found not to exceed the quantity of drink*. In a caſe of diabetes, related with much accuracy by Dr Gerard, the patient was bathed regularly during the early part of the diſeaſe in warm water, and afterwards in cold water: he was weighed before and after bathing, and no ſenſible difference was ever found in his weight†. Conſequently, in that caſe, the quantity abſorbed, if any, muſt have been very ſmall.

It is well known, that thirſt is much alleviated by cold bathing. By this plan, Captain Bligh kept his men cool and in good health during their very extraordinary voyage acroſs the South Sea. This has been conſidered as owing to the abſorption of water by the ſkin. But Dr Currie had a patient who was waſting faſt for want of nouriſhment, a tumor in the œſophagus preventing the poſſibility of taking food, and whoſe thirſt was always alleviated by bathing; yet no ſenſible increaſe of weight, but rather the contrary, was perceived after bathing. It does not appear, then, that in either of theſe caſes water was abſorbed.

Farther, Seguin has ſhewn that the ſkin does not abſorb water during bathing, by a ſtill more complete experiment: He diſſolved ſome mercurial ſalt in water, and found that the mercury produced no effect upon a perſon that bathed in the water, provided no part of the

---

† *Ibid.* ii. 73.

the cuticle was injured; but upon rubbing off a portion of the cuticle, the mercurial ſolution was abſorbed, and the effects of the mercury became evident upon the body. Hence it follows irreſiſtibly, that water, at leaſt in the ſtate of *water*, is not abſorbed by the ſkin when the body is plunged into it, unleſs the cuticle be firſt removed.

This may perhaps be conſidered as a complete proof that no ſuch thing as abſorption is performed by the ſkin; and that therefore the appearance of carbonic acid gas, which takes place when air is confined around the ſkin, muſt be owing to the emiſſion of carbon But it ought to be conſidered, that although the ſkin cannot abſorb water, this is no proof that it cannot abſorb other ſubſtances; particularly, that it cannot abſorb oxygen gas, which is very different from water. It is well known, that water will not paſs through bladders, at leaſt for ſome time; yet Dr Prieſtley found that veinous blood acquired the colour of arterial blood from oxygen gas, as readily when theſe ſubſtances were ſeparated by a bladder as when they were in actual contact. He found, too, that when gaſes were confined in bladders, they gradually loſt their properties. It is clear from theſe facts, that oxygen gas can pervade bladders; and if it can pervade them, why may it not alſo pervade the cuticle? Nay, farther, we know from the experiments of Cruikſhank, that the vapour perſpired paſſes through leather, even when prepared ſo as to keep out moiſture, at leaſt for a certain time. It is poſſible, then, that water, when in the ſtate of vapour, or when diſſolved in air, may be abſorbed, although water, while in the ſtate of water, may be incapable of pervading the cuticle. The experiments, then, which have hitherto at leaſt been made upon the abſorption of the ſkin, are altogether inſufficient to prove that air and vapour cannot pervade the cuticle; provided at leaſt there be any facts to render the contrary ſuppoſition probable.

Now that there are ſuch facts cannot be denied. We ſhall not indeed produce the experiment of Van Mons as a fact of that kind, becauſe it is liable to objections, and at beſt is very undeciſive. Having a patient under his care who, from a wound in the throat, was incapable for ſeveral days of taking any nouriſhment, he kept him alive during that time, by applying to the ſkin in different parts of the body, ſeveral times a day, a ſponge dipt in wine or ſtrong ſoup *. A fact mentioned by Dr Watſon is much more important, and much more deciſive. A lad at Newmarket, who had been almoſt ſtarved in order to bring him down to ſuch a weight as would qualify him for running a horſe race, was weighed in the morning of the race day; he was weighed again juſt before the race began, and was found to have gained 30 ounces of weight ſince the morning: yet in the interval he had only taken a ſingle glaſs of wine. Here abſorption muſt have taken place, either by the ſkin, or lungs, or both. The difficulties in either caſe are the ſame; and whatever renders abſorption by one probable, will equally ſtrengthen the probability that abſorption takes place by the other (R).

Functions of animals.

361 Blood ſupplies the waſte of the ſyſtem.

16. We have now ſeen the proceſs of digeſtion, and the formation of blood, as far at leaſt as we are acquainted with it. But to what purpoſes is this blood employed, which is formed with ſo much care, and for the formation of which ſo great an apparatus has been provided? It anſwers two purpoſes. The parts of which the body is compoſed, bones, muſcles, ligaments, membranes, &c. are continually changing. In youth they are increaſing in ſize and ſtrength, and in mature age they are continually acting, and conſequently continually liable to waſte and decay. They are often expoſed to accidents, which render them unfit for performing their various functions; and even when no ſuch accident happens, it ſeems neceſſary for the health of the ſyſtem that they ſhould be every now and then renewed. Materials therefore muſt be provided for repairing, increaſing, or renewing all the various organs of the body. Phoſphat of lime and gelatine for the bones, fibrina for the muſcles, albumen for the cartilages and membranes, &c. Accordingly all theſe ſubſtances are laid up in the blood; and they are drawn from that fluid as from a ſtorehouſe whenever they are required. The proceſs by which the different parts of the blood are made part of the various organs of the body is called *aſſimilation*.

362 Aſſimilation.

Over the nature of aſſimilation the thickeſt darkneſs ſtill hangs; there is no key to explain it, nothing to lead us to the knowledge of the inſtruments employed. Facts, however, have been accumulated in ſufficient numbers to put the exiſtence of the proceſs beyond the reach of doubt. The healing, indeed, of every fractured bone, and every wound of the body, is a proof of its exiſtence, and an inſtance of its action.

363 Every aſſimilating organ produces a peculiar change,

Every organ employed in aſſimilation has a peculiar office; and it always performs this office whenever it has materials to act upon, even when the performance of it is contrary to the intereſt of the animal. Thus the ſtomach always converts food into chyme, even when the food is of ſuch a nature that the proceſs of digeſtion will be retarded rather than promoted by the change. If warm milk, for inſtance, or warm blood, be thrown into the ſtomach, they are always decompoſed by that organ, and converted into chyme; yet theſe ſubſtances are much more nearly aſſimilated to the animal before the action of the ſtomach than after it. The ſame thing happens when we eat animal food.

364 And no other change.

On the other hand, a ſubſtance introduced into an organ employed in aſſimilation, if it has undergone preciſely the change which that organ is fitted to produce, is not acted upon by that organ, but paſſed on unaltered to the next aſſimilating organ. Thus it is the office of the inteſtines to convert chyme into chyle. Accordingly, whenever chyme is introduced into the inteſtines, they perform their office, and produce the uſual change; but if chyle itſelf be introduced into the inteſtines, it is abſorbed by the lacteals without alteration. The experiment, indeed, has not been tried with true chyle, becauſe it is ſcarce poſſible to procure it in ſufficient quantity; but when milk, which reſembles chyle pretty accurately, is thrown into the jejunum, it is abſorbed unchanged by the lacteals *.

Again,

---

* Fordyce on *Digeſtion*, p. 159.

(R) The Abbé Fontana alſo found, that after walking in moiſt air for an hour or two, he returned home ſome ounces heavier than he went out, notwithſtanding he had ſuffered conſiderable evacuation from a briſk purge purpoſely taken for the experiment. This increaſe, indeed, might be partly accounted for by the abſorption of moiſture by his clothes.

Again, the office of the blood veſſels, as aſſimilating organs, is to convert chyle into blood. Chyle, accordingly, cannot be introduced into the arteries without undergoing that change; but *blood* may be introduced from another animal without any injury, and conſequently without undergoing any change. This experiment was firſt made by Lower, and it has ſince been very often repeated.

Alſo, if a piece of freſh muſcular fleſh be applied to the muſcle of an animal, they adhere and incorporate without any change, as has been ſufficiently eſtabliſhed by the experiments of Mr J. Hunter. And Buvina has aſcertained, that freſh bone may, in the ſame manner, be engrafted on the bones of animals of the ſame or of different ſpecies †.

In ſhort, it ſeems to hold, at leaſt as far as experiments have hitherto been made, that foreign ſubſtances may be incorporated with thoſe of the body, provided they be preciſely of the ſame kind with thoſe to which they are added, whether fluid or ſolid. Thus chyle may be mixed with chyle, blood with blood, muſcle with muſcle, and bone with bone. The experiment has not been extended to the other animal ſubſtances, the nerves, for inſtance; but it is extremely probable that it would hold with reſpect to them alſo.

On the other hand, when ſubſtances are introduced into any part of the body which are not the ſame with that part, nor the ſame with the ſubſtance upon which that part acts; provided they cannot be thrown out readily, they deſtroy the part, and perhaps even the animal. Thus foreign ſubſtances introduced into the blood very ſoon prove fatal; and introduced into wounds of the fleſh or bones, they prevent theſe parts from healing.

365
Their power limited.

Although the different aſſimilating organs have the power of changing certain ſubſtances into others, and of throwing out the uſeleſs ingredients, yet this power is not abſolute, even when the ſubſtances on which they act are proper for undergoing the change which the organs produce. Thus the ſtomach converts food into chyme, the inteſtines chyme into chyle, and the ſubſtances which have not been converted into chyle are thrown out of the body. If there happen to be preſent in the ſtomach and inteſtines any ſubſtance which, though incapable of undergoing the changes, at leaſt, by the action of the ſtomach and inteſtines, yet has a ſtrong affinity, either for the whole chyme and chyle, or for ſome particular part of it, and no affinity for the ſubſtances which are thrown out, that ſubſtance paſſes along with the chyle, and in many caſes continues to remain chemically combined with the ſubſtance to which it is united in the ſtomach, even after that ſubſtance has been completely aſſimilated, and made a part of the body of the animal. Thus there is a ſtrong affinity between the colouring matter of madder and phoſphat of lime. Accordingly, when madder is taken into the ſtomach, it combines with the phoſphat of lime of the food, paſſes with it through the lacteals and blood veſſels, and is depoſited with it in the bones, as was proved by the experiments of Duhamel. In the ſame manner muſk, indigo, &c. when taken into the ſtomach, make their way into many of the ſecretions.

Theſe facts ſhew us, that aſſimilation is a chemical proceſs from beginning to end; that all the changes are produced according to the laws of chemiſtry; and that we can even derange the regularity of the proceſs by introducing ſubſtances whoſe mutual affinities are too ſtrong for the organs to overcome.

365
Aſſimilation a chemical proceſs;

397
But the agent not chemical.

It cannot be denied, then, that the aſſimilation of food conſiſts merely in a certain number of chemical decompoſitions which that food undergoes, and the conſequent formation of certain new compound. But are the *agents* employed in aſſimilation merely chemical agents? We cannot produce any thing like theſe changes on the food out of the body, and therefore we muſt allow that they are the conſquence of the action of the animal organs. But this action, it may be ſaid, is merely the ſecretion of particular juices, which have the property of inducing the wiſhed-for change upon the food; and this very change would be produced out of the body, provided we could procure theſe ſubſtances, and apply them in proper quantity to the food. If this ſuppoſition be true, the ſpecific action of the veſſels conſiſts in the ſecretion of certain ſubſtances; conſequently the cauſe of this ſecretion is the *real* agent in aſſimilation. Now, can the *cauſe* of this ſecretion be ſhewn to be merely a chemical agent? Certainly not. For in the ſtomach, where only this ſecretion can be ſhewn to exiſt, it is not always the ſame, but varies according to circumſtances. Thus eagles at firſt cannot digeſt grain, but they may be brought to do it by perſiſting in making them uſe it as food. On the contrary, a lamb cannot at firſt digeſt animal food, but habit will alſo give it this power. In this caſe, it is evident that the gaſtric juice changes according to circumſtances. Now this is ſo far from being a caſe of a chemical law, that it is abſolutely incompatible with every ſuch law. The agent in aſſimilation, then, is not a chemical agent, but one which acts upon different principles. It is true, indeed, that every ſtep in the proceſs is chemical; but the agent which regulates theſe chemical proceſſes, which prevents them from acting, except in particular circumſtances and on particular ſubſtances, and modifies this action according to circumſtances, is not a mere chemical agent, but endowed with very different properties.

The preſence and power of this agent will be ſtill more evident, if we conſider the immunity of the ſtomach of the living animal during the proceſs of digeſtion. The ſtomach of animals is as fit for food as any other ſubſtance. The gaſtric juice, therefore, muſt have the ſame power of acting on it, and of decompoſing it, that it has of acting on other ſubſtances; yet it is well known that the ſtomach is not affected by digeſtion while the animal retains life; though, as Mr Hunter aſcertained, the very gaſtric juice which the living ſtomach ſecrets often diſſolves the ſtomach itſelf after death. Now what is the power which prevents the gaſtric juice from acting on the ſtomach during life? Certainly neither a chemical nor mechanical agent, for theſe agents muſt ſtill retain the ſame power after death. We muſt, then, of neceſſity conclude, that there exiſts in the animal an agent very different from chemical and mechanical powers, ſince it controuls theſe powers according to its pleaſure. Theſe powers therefore in the living body are merely the ſervants of this ſuperior agent, which directs them ſo as to accompliſh always one particular end. This agent ſeems to regulate the chemical powers, chiefly by bringing only certain ſubſtances together which are to be decompoſed, and by keeping at a diſtance thoſe ſubſtances which would interfere with, or diminiſh, or ſpoil the product, or

injure

---

† *Phil. Mag.* vi. 308.

injure the organ. And we ſee that this ſeparation is always attended to even when the ſubſtances are apparently mixed together. For the very ſame products are not obtained which would be obtained by mixing the ſame ſubſtances together out of the body that are produced by mixing them in the body; conſequently all the ſubſtances are not left at full liberty to obey the laws of their mutual affinities. The ſuperior agent, however, is not able to exerciſe an unlimited authority over the chemical powers; ſometimes they are too ſtrong for it: ſome ſubſtances accordingly, as madder, make their way into the ſyſtem; while others, as arſenic, decompoſe and deſtroy the organs of the body themſelves.

But it is not in digeſtion alone that this ſuperior agent makes the moſt wonderful diſplay of its power; it is in the laſt part of aſſimilation that our admiration is moſt powerfully excited. How comes it that the preciſe ſubſtances wanted are always carried to every organ of the body? How comes it that fibrina is always regularly depoſited in the muſcles, and phoſphat of lime in the bones? And what is ſtill more unaccountable, how comes it that prodigious quantities of ſome one particular ſubſtance are formed and carried to a particular place in order to ſupply new wants which did not before exiſt? A bone, for example, becomes diſeaſed and unfit for the uſe of the animal; a new bone therefore is formed in its place, and the old one is carried off by the abſorbents. In order to form this new bone, large-quantities of phoſphat of lime are depoſited in a place where the ſame quantity was not before neceſſary. Now, who informs this agent that an unuſual quantity of phoſphat of lime is neceſſary, and that it muſt be carried to that particular place? Or granting, as is moſt probable, that the phoſphat of lime of the old bone is partly employed for this purpoſe, who taught this agent that the old bone muſt be carried off, new modelled, and depoſited, and aſſimilated anew? The ſame wonders take place during the healing of every wound, and the renewing of every diſeaſed part.

Theſe operations are incompatible with the ſuppoſition that the body of animals is a mere chemical and mechanical machine; and demonſtrate the preſence of ſome agent beſides, which acts according to very different laws.

But neither in this caſe is the power of this agent over the chemical agents, which are employed, abſolute. We may prevent a fractured bone from healing by giving the patient large quantities of acids. And unleſs the materials for the new wanted ſubſtances be ſupplied by the food, they cannot, in many caſes, be formed at all. Thus the canary bird cannot complete her eggs unleſs ſhe be furniſhed with lime.

It is evident that the ſupreme agent of the animal body, whatever that agent may be, acts according to fixed laws; and that when theſe laws are oppoſed by thoſe which are more powerful, it cannot overcome them. Theſe laws clearly indicate deſign; and the agent has the power of modifying them ſomewhat according to circumſtances. Thus more phoſphat of lime is ſent to a limb which requires a new bone, and more lime than uſual is taken into the ſyſtem when the hen is laying eggs. Deſign and contingency are conſidered by us as infallible marks of conſciouſneſs and intelligence. That they are infallible marks of the agency of mind is certain; but that they are in all caſes the proofs of immediate conſciouſneſs and intelligence, as the Stahlians ſuppoſed, cannot be affirmed without running into inconſiſtencies. For we ourſelves are not conſcious of thoſe operations which take place during *aſſimilation*.

To ſay that a being can act with deſign without intelligence, we allow to be a flat contradiction, becauſe deſign always implies intelligence. There muſt therefore be intelligence ſomewhere. But may not this intelligence exiſt, not in the agent, but in the being who formed the agent? And may not the whole of the deſign belong in reality to that being?

368
Not material.

May not this agent, then, be material, and may not the whole of aſſimilation be performed by mere matter, acting according to laws given it by its maker? We anſwer, that what is called *matter*, or the ſubſtances enumerated in the firſt part of CHEMISTRY (*Suppl.*) act always according to certain attractions and repulſions, which are known by the name of mechanical and chemical laws.

The phenomena of aſſimilation are ſo far from being caſes of theſe laws, that they are abſolutely inconſiſtent with them, and contrary to them; conſequently the agent which preſides over *aſſimilation* is not *matter*. Concerning the nature of this ſubſtance it is not the buſineſs of this article to inquire; but as it poſſeſſes properties different from matter, and acts according to very different laws, it would be an abuſe of terms to call it *matter*.

369
Animal principle.

We would give it the name of *mind*, were it not that metaphyſicians have choſen to conſider intelligence as the eſſence of mind; whereas this ſubſtance may be conceived to act, and really does act, without intelligence. There is no reaſon, however, to ſuppoſe, with ſome, that there are two ſubſtances in animals: one poſſeſſed of conſciouſneſs as its eſſence, and therefore called *mind* or *ſoul* in man; another, deſtitute of conciouſneſs, called the *living principle*, &c. employed in performing the different functions of aſſimilation, abſorption, &c. It is much more reaſonable to ſuppoſe, that in every animal and vegetable there is a peculiar ſubſtance, different from matter, to which their peculiar properties are owing; that this ſubſtance is different in every ſpecies of animal and vegetable; that it is capable of acting according to certain fixed laws which have been impoſed upon it by its Creator, and that theſe laws are of ſuch a nature that it acts in ſubſervience to a particular end; that this ſubſtance in plants is probably deſtitute of intelligence; that in man and other animals it poſſeſſes intelligence to a certain extent, but that this intelligence is not eſſential to its exiſtence nor to its activity; that it may be deprived of intelligence altogether, and afterwards recover it without altering its nature. Phyſiologiſts have given it the name of *living principle*, becauſe its preſence conſtitutes life. Perhaps it would be proper to diſtinguiſh that of animals by the name of *animal principle*. Upon what the intelligence of the animal principle depends, it is impoſſible to ſay; but it is evidently connected with the ſtate of the brain. During a trance, or an apoplectic fit, it has often been loſt for a time, and afterwards recovered.

370
Secretion.

17. Beſides aſſimilation, the blood is alſo employed in forming all the different ſecretions which are neceſſary for the purpoſes of the animal economy. Theſe have been enumerated in the laſt chapter. The proceſs is ſimilar to that of aſſimilation, and undoubtedly the agents in both caſes are the ſame; but we are

equally ignorant of the preciſe manner in which ſecretion is performed as we are of aſſimilation.

371
Animals at length die, and why.

18. After theſe functions have gone on for a certain time, which is longer or ſhorter according to the nature of the animal, the body gradually decays, at laſt all its functions ceaſe completely, and the animal dies. The cauſe of this muſt appear very extraordinary, when we conſider the power which the animal has of renewing decayed parts; for it cannot be doubted that death proceeds, in moſt caſes at leaſt, from the body becoming incapable of performing its function. But if we conſider that this power is limited, and that it muſt ceaſe altogether, when thoſe parts of the ſyſtem begin to decay which are employed in preparing materials for future aſſimilation, our ſurpriſe will, in ſome meaſure, ceaſe. It is in theſe parts, in the organs of digeſtion and aſſimilation accordingly, that this decay uſually proves fatal. The decay in other parts deſtroys life only when the waſte is ſo rapid that it does not admit of repair.

What the reaſon is that the decay of the organs cauſes death, or, which is the ſame thing, cauſes the living principle either to ceaſe to act, or to leave the body altogether, it is perfectly impoſſible to ſay, becauſe we know too little of the nature of the living principle, and of the manner in which it is connected with the body. The laſt is evidently above the human underſtanding, but many of the properties of the living principle have been diſcovered; and were the facts already known properly arranged, and ſuch general concluſions drawn from them as their connection with each other fully warrant, a degree of light would be thrown upon the animal economy which thoſe, who have not attended to the ſubject, are not aware of.

No ſooner is the animal dead, than the chemical and mechanical agents, which were formerly ſervants, uſurp the ſupreme power, and ſoon decompoſe and deſtroy that very body which had been in a great meaſure reared by their means. But the changes which take place upon animal bodies after death, are too important, and too intimately connected with the ſubject of this article to be paſſed over ſlightly. They ſhall therefore form the ſubject of the next chapter.

Chap. IV. Of the Decompoſition of Animal Subſtances.

372
Decompoſition of animal ſubſtances expoſed to the air.

All the ſoft and the liquid parts of animals, when expoſed to a moderate temperature of ſixty-five degrees or more, paſs with more or leſs rapidity through the following changes. Their colour becomes paler, and their conſiſtence diminiſhes; if it be a ſolid part, ſuch as fleſh, it ſoftens, and a ſerous matter ſweats out, whoſe colour quickly changes; the texture of the part becomes relaxed, and its organization deſtroyed; it acquires a faint diſagreeable ſmell; the ſubſtance gradually ſinks down, and is diminiſhed in bulk; its ſmell becomes ſtronger and ammoniacal. If the ſubject be contained in a cloſe veſſel, the progreſs of putrefaction, at this ſtage, ſeems to ſlacken; no other ſmell but that of a pungent alkali is perceived; the matter effervеſces with acids, and converts ſyrup of violets to a green. But if the communication with the air be admitted, the urinous exhalation is diſſipated, and a peculiar putrid ſmell is ſpread around with a kind of impetuoſity; a ſmell of the moſt inſupportable kind, which laſts a long time, and pervades every place, affecting the bodies of living animals after the manner of a ferment, capable of altering the fluids: this ſmell is corrected, and as it were confined by ammonia. When the latter is volatilized, the putrefactive proceſs becomes active a ſecond time, and the ſubſtance ſuddenly ſwells up, becomes filled with bubbles of air, and ſoon after ſubſides again. Its colour changes, the fibrous texture of the fleſh being then ſcarcely diſtinguiſhable; and the whole is changed into a ſoft, brown, or greeniſh matter, of the conſiſtence of a poultice, whoſe ſmell is faint, nauſeous, and very active on the bodies of animals. The odorant principle gradually loſes its force; the fluid portion of the fleſh aſſumes a kind of conſiſtence, its colour becomes deeper, and it is finally reduced into a friable matter, rather deliqueſcent, which being rubbed between the fingers, breaks into a coarſe powder like earth. This is the laſt ſtate obſerved in the putrefaction of animal ſubſtances; they do not arrive at this term but at the end of a conſiderable time†.

373
Buried in the earth.

In carcaſes buried in the earth, putrefaction takes place much more ſlowly; but it is ſcarcely poſſible to obſerve its progreſs with accuracy. The abdomen is gradually dilated with elaſtic fluids which make their appearance in it, and at laſt it burſts and diſcharges a horribly fetid and noxious gas; at the ſame time a dark coloured liquid flows out. If the earth be very dry, and the heat conſiderable, the moiſture is often abſorbed ſo rapidly, that the carcaſe, inſtead of putrefying, dries, and is transformed into what is called a *mummy*.

374
When a
cumulate
together.

Such are the phenomena when dead bodies are left to putrefy ſeparately. But when great numbers of carcaſes are crowded together in one place, and are ſo abundant as to exclude the action of external air, and other foreign agents, their decompoſition is entirely the conſequence of the reciprocal action of their ingredients themſelves upon each other, and the reſult is very different. The body is not entirely diſſipated or converted into mould, but all the ſoft parts are found diminiſhed remarkably in ſize, and converted into a peculiar *ſaponaceous matter*. This ſingular change was firſt accurately obſerved in the year 1786.

375
Convert
into a ſa
naceous
matter.

The burial ground of the Innocents in Paris having become noxious to thoſe who lived in its neighbourhood, on account of the diſagreeable and hurtful odour which it exhaled, it was found neceſſary to remove the carcaſes to another place. It had been uſual to dig very large pits in that burial ground, and to fill them with the carcaſes of the poorer ſort of people, each in its proper bier; and when they were quite full, to cover them with about a foot depth of earth, and to dig another ſimilar pit, and fill it in the ſame manner. Each pit held between 1000 and 1500 dead bodies. It was in removing the bodies from theſe pits that this ſaponaceous ſubſtance was found. The grave-diggers had aſcertained, by long experience, that about thirty years were required before all the bodies had undergone this change in its full extent*. Every part of the body acquired the properties of this ſubſtance. The inteſtines and viſcera of the thorax had completely diſappeared; but what is ſingular enough, the brain had loſt but little of its ſize or appearance, though it was alſo converted into the ſame ſubſtance.

37
Its pr
ties.

This ſaponaceous matter was of a white colour, ſoft and unctuous to the touch, and melted, when heated,

like

---

† Fourcroy

* Four
Ann. de
Chim.
154.

mpoſi f Ani l Sub- ances.

like tallow. It exhibited all the properties of a *ſoap*, containing, however, an exceſs of fatty matter. Fourcroy, who analyſed it, found that it was compoſed of a fatty matter combined with ammonia, and that it contained alſo ſome phoſphat of lime and ammonia. Diluted acids decompoſed it, and ſeparated the fatty matter: alkalies and lime, on the other hand, drove off the ammonia. When expoſed to the air, it gradually loſt its white colour; the ammonia, in a great meaſure, evaporated, and what remained had ſomething of the appearance of wax. It abſorbed water with great avidity, and did not part with it readily. Its white colour was owing to the preſence of that liquid. The oily matter, when ſeparated by means of a diluted acid, was concrete, and of a white colour, owing to the mixture of a quantity of water. When dried, it acquires a greyiſh brown colour, a lamellar and cryſtalline texture, like that of ſpermaceti; but if it has been rapidly dried it aſſumes the appearance of wax It melts, when heated, to 126°; when properly purified, by paſſing it through a linen cloth while fluid, it has ſcarcely any ſmell. Alcohol does not act upon it while cold, but at the temperature of 120° it diſſolves it: when the ſolution cools, the fatty matter precipitates, and forms a gritty maſs. With alkalies it forms a ſoap; and when ſet on fire it burns preciſely like oil or fat, only that it exhales a more unpleaſant odour †.

377 oduced o in running water.

Mr Smith Gibbes found the ſame ſubſtance in the pit into which animal matters are thrown at Oxford after diſſection. A ſmall ſtream of water conſtantly paſſes through this pit; a circumſtance which induced him to try whether animal muſcle expoſed to the action of a running ſtream underwent the ſame change. The experiment ſucceeded completely: he attempted, in conſequence, to render this ſubſtance, to which he gave the name of *ſpermaceti*, uſeful in thoſe manufactures which required tallow; but the fetid odour which it conſtantly exhales was an inſurmountable objection. Attempts were indeed made to get over it; but as we do not hear that Mr Smith Gibbes's ſpermaceti has been introduced into any manufacture, we have reaſon to conclude that none of theſe attempts ſucceeded ‡.

Decompoſition of Animal Subſtances.

378 Theory of putrefaction imperfect.

Such are the phenomena of putrefaction, as far as they are at preſent known to chemiſts. Any attempt to explain the manner in which theſe changes take place, would be exceedingly imperfect indeed; not only becauſe we are ignorant of the ſtrength of the affinities of the different elementary parts of animal bodies for each other, but becauſe we do not even know the manner in which theſe elements are combined, and conſequently we cannot know by what particular forces theſe compounds are deſtroyed. We know only that a certain degree of heat, and the preſence of moiſture, are in all caſes neceſſary for the putrefactive proceſs; for animal bodies may be kept almoſt any length of time, without decompoſition, at the freezing temperature; and when dried quickly, and kept in that ſtate, they undergo no farther change.

PART III. OF DYEING.

MANKIND have in all periods of ſociety manifeſted a fondneſs for beautiful and gaudy colours Naked ſavages at firſt applied them to their ſkin. This was the caſe with the Britons, and with the Gauls, too, in the time of Cæſar; it is even ſtill the practice in the South Sea iſlands, and many parts of America. When mankind had advanced ſo far towards civilization as to wear garments, they naturally transferred to them the colours which they admired. Hence the origin of *dyeing*; which is of ſuch antiquity, that it precedes the earlieſt records left us by profane authors. We ſee from the book of Geneſis the great progreſs which it had made in the time of the patriarchs.

379 rigin of eing.

Dyeing ſeems to have originated in India, and to have ſpread gradually from that country to the weſt. The Indians were the inventors of the method of dyeing cotton and linen, which was not underſtood in Europe before the conqueſts of Alexander the Great. The Phenicians excelled in the art at a very early period. It was from them that the Jews purchaſed all the dyed ſtuffs deſcribed in Exodus. The Phenician dyers ſeem to have confined their art to wool: ſilk was unknown to them, and linen was uſually worn white. From them the art of dyeing paſſed to the Greeks and Romans.

During the fifth century, the Weſtern Empire was overturned by the northern nations, and with it the arts and ſciences, which had flouriſhed under the protection of the Romans, diſappeared. A few of the arts, indeed, were preſerved in Italy, but they were obſcured and degraded. By degrees, however, a ſpirit of induſtry began to revive in that country. Florence, Genoa, and Venice, becoming rich commercial cities, carried on a conſiderable intercourſe with the Grecian empire, where many of the arts had been preſerved. This intercourſe was much increaſed by the cruſades. The Italian cities became rich and powerful: the arts which diſtinguiſh civilized nations were cultivated with emulation, and dyeing, among others, was rapidly improved.

380 Its progreſs in modern Europe.

In the year 1429, the firſt treatiſe on dyeing made its appearance at Venice, under the name of *Moriegola del'arte de tentori*. Giovanne Ventura Roſetta collected, with great induſtry, all the proceſſes employed by the dyers of his time, and publiſhed them in 1548, under the title of *Plictho* *. For many years dyeing was almoſt excluſively confined to Italy; but it gradually made its way to France, the Low Countries, and to Britain. The miniſter Colbert, who employed his talents in extending the commerce and manufactures of France, paid particular attention to the art of *dyeing*. In the year 1672, he publiſhed a table of inſtructions, by which thoſe who practiſed the art were laid under ſeveral very improper reſtrictions. But the bad effects of theſe were in a good meaſure obviated by the judicious appointment of men of ſcience to ſuperintend the art. This plan, begun by Colbert, was continued by the French government. Accordingly, Dufay, Hellot, Macquer, and Berthollet, ſucceſſively filled the office. It is to this eſtabliſhment, and to exertions of the celebrated chemiſts who have filled it, that France is indebted for the improvements ſhe has made in the art of dyeing during the courſe of the 18th century. Under the direction of Dufay, a new table of regulations was publiſhed in 1737, which ſuperſeded that of Colbert. Hellot,
