Apoplexy

An Inaugural Dissertation

by

Lacharials Merrick

Annapolis Maryland

Spring 1828

(M)

In speaking of Apoplexy, the disease of which I am about to treat, I shall not presume to claim originality. The disease has been called by several different names, or more properly, several diseases have been confounded with Apoplexy viz. Lethargy, Catalepsy, Trismus, and Coma, these are supposed to be the same disease, differing in degree only; but of these it is not my intention to speak, therefore I shall confine myself strictly to Apoplexy. The term Apoplexy has been given the disease from the suddenness of its attack, it is derived from the Greek word  $\alpha\pi\omicron\lambda\epsilon\chi\eta$  which signifies upon a sudden to strike suddenly. In this disease the whole of the external and internal <sup>senses</sup> ~~parts~~ and the whole of voluntary motion, are in great degree abolished, while respiration and

<sup>4</sup>  
the action of the heat continues to be performed  
it has also been called by the Latins Morbus Atticus  
and they have also called its Liceratio from a belief  
that it was produced by planetary influence

D. Cullen has placed this genus of disease in  
the class Neuroses and the order Comata he has also  
taken notice of nine Genera of this disease beside the  
which are symptomatic. First. Apoplexia Sanguinea  
and this he defines to be universal Plethora with a  
determination of blood to the head. Second. Apop-  
lexia Serena which generally happens in old  
and Leucophlegmatic persons. Third. Apoplexia  
Hydrocephalica in this genus the disease is produced  
by the pressure of water upon the brain. Fourth

• Apoplexia Atrialiaris observed in Atrialiaris  
 or melancholic temperaments Fifth. Apoplexia  
 Inflammatoria when the head is injured by violent  
 external force Sixth. Apoplexia Venenata from poisonous  
 matters whether taken internally or applied  
 externally Seventh. Apoplexia Mentalis from passion  
 of the mind Eighth. Apoplexia Cataleptica in  
 which respiration is not stertorous and though  
 the limbs maintain any occasional position  
 give way to force applied to their joints Apoplexia  
 Suffocata as happens from hanging or drowning.

The division of the disease into so many genera  
 tends more to confuse than to instruct the young  
 practitioner. Apoplexy most frequently attacks persons  
 at an advanced age and Dr. Cullen says especially

<sup>6</sup>  
those above sixty years of age but a great majority of  
the cases which I have seen have occurred in persons  
under fifty and in those of short necks and ~~flat~~ flat  
habits and who have passed a sedentary life, and used  
a full diet. Those who have been intemperate both in  
~~eat~~ <sup>diet</sup> and drink or those who have indulged in one  
and not in the other have been attacked by the  
disease. The sudden suppression of an accustomed  
menstruation. The most frequent precursory symptoms  
are fits of ziddiness, head ache or menbrage from the  
head some transitory intermission of vision and  
hearing and these two senses are also false in some  
cases a faulting of the tongue frequent drowsi-  
ness and repeated attacks of incubus but these  
precursory symptoms are by no means uniform both

For the disease in some cases suddenly attacks the patient without these symptoms having appeared but when these symptoms do occur they enable us to foresee the impending danger and to avert its fury by a proper attention to the present state of the patient's system and by a due regard to regimen we may enable our if not entirely to escape this too fatal disease at least to evade its attacks longer than he otherwise would have done. When the disease has come on suddenly it has <sup>been</sup> frequently observed to have been induced by violent exercise this remark I have seen verified in the case of a Farmer who though for some time previous to ~~the~~ <sup>his</sup> attack had led a very active life: had in the earlier part of his life been quite sedentary in consequence of his avocations at that time and had in the whole

of his life been a very free liver and by these two latter  
causes had acquired a predisposition to the disease  
he was of a plethoric habit answering very nearly the  
description already given of those most liable to the  
disease This gentleman after a severe exercise of almost  
a whole day was suddenly attacked in the absence  
of any premonitory symptoms of the approach of this  
malady. Although says Dr. Cullen the whole of the body  
is affected with the loss of sense and motion it sometimes  
takes place more upon one side than on the other and  
in this case the side least affected is frequently  
convulsed. Stertorous breathing is often present and  
has been supposed to indicate the violence of the  
disease but this is denied as it has not at all  
been present in a complete and most violent

state of the disease. After having thus enumerated  
most of the principal symptoms of the disease we  
will now advert to the causes and first to the  
proximate cause which has been defined to be,  
whatever interrupts the motion of the nervous power  
of the brain to the muscles thereby destroying  
voluntary motion or so far as sense is affected  
whatever interrupts the central connection the  
motion of the nervous power from the sentient ex-  
trimities of the nerves to the brain. Such interrup-  
tions are said to be produced by some compres-  
sion of the origin of the nerves or by something  
destroying the mobility of the nervous power  
the loss of sense and motion in particular  
parts of the body may be occasioned by a compaction

10  
of the origin of the nerves going to that part or by  
compression of the same nerves at a point interme-  
diate between their origin and the part diseased  
by such compression. Compression of the origin of the  
nerves may be produced in different ways viz:  
by a depression of a part of the Calvaria. A congestion  
of the vessels of the brain has also been said to ~~have~~  
produced it but on this subject there is a contrary  
of opinion. It is Dr. Nathaniel Putter's opinion that  
this is a frequent cause of the disease. It has on the  
contrary been maintained by Dr. Davidge as well  
as other distinguished Physiologists that a congest-  
ion of the vessels of the brain never does take place.  
It may be produced by tumours either of the bone  
or soft kind.

If comparison of the origin of the nerves be from a  
depressed portion of the brain case it is to be removed  
but this operation more properly appertains to surgery  
The consideration of bony tumours and also of  
fleshy tumours may be omitted as in most in-  
stances they are neither to be discerned nor cured  
by any means. The effused fluids are of two kinds  
they may be either a portion of the coarseness  
of the blood poured out by vessels carrying red blood  
or it may be serum or a fluid resembling serum  
which is poured out by the exhalants. This fluid  
alluded to resembling serum has been supposed  
not to be serum but to be a fluid changed by  
the action of the small vessels from which it  
escapes however be it serum or a changed fluid  
it makes no change of treatment in the dis-  
ease these effusions have been said to be pro-

proceed by whatever ~~is~~ increases the impetus  
 of the flow of blood in the arteries of the head the  
 same cause has been ascribed to the congestion of the  
 blood vessels of the brain this is a probable cause if  
 congestions of these does ever take place but as there  
 is a difference of opinion on this subject among  
 the most enlightened Physiologists it therefore cannot  
 be expected that one of my inexperienced  
 presumptions hazard an opinion in opposition to  
 either of the parties who thus dissent. An impediment  
 in the free return of blood from the vessels  
 of the brain has also been enumerated among  
 the causes of effusions of serum. There are two  
 other causes of this serous effusion. The one is  
 a relaxation of the exhalants. The second is an  
 over proportion of watery parts in the blood.

which is therefore ready to run off by the exhal-  
 ants - but whether conpulsions be produced  
 by a serous or a sanguine effusion the indicati-  
 on of cure are the same or nearly so so besides  
 these, other causes are taken notice of by authors  
 as the Mephitical, arising from fermenting  
 liquors the fumes which arise from mercury  
 lead and other metallic substances have  
 produced it. The means appearance of those  
 noxious poisons is I think very correctly given  
 in the 115<sup>th</sup> Dec: of the 1<sup>st</sup> lines of the practice by  
 D. Cullen and I think it will not be unprofitable  
 here to transcribe it I believe says the D.<sup>n</sup> their  
 immediate and direct action to be on the nervous  
 power destroying its mobility because the same  
 poisons show their power in destroying the

11  
inability of the muscles and of the nerves, can  
act <sup>with</sup> them when both of these are entirely separate  
from the rest of the body. Having thus taken notice  
of the chief causes of Apoplexy and of its symptoms  
I shall now proceed to give the treatment when there  
is evidently a predisposition to the disease all  
existing causes ought carefully to be avoided the  
most common causes of the disease have been ~~at~~  
already stated the immoderate use of spirituous  
liquours ought also to be carefully avoided an indulg-  
ence of the appetite in high seasoned dishes must  
be restricted in short all the causes calculated  
to induce Plethora should be avoided but when  
this Plethora or in other words this predisposition  
to Apoplexy is either hereditary or is acquired by  
intemperance in eating or drinking narcotics

should be employed for its cure if it be produced by  
 intemperance the cause should be removed and  
 blood letting and abstinence from animal food  
 should be enforced. The mode of bloodletting has  
 been considered of importance some have recom-  
 mended it to be taken from the Jugular vein from  
 the temporal artery &c. the operation <sup>of</sup> Phlebotomy  
 has also been thought more effectual when per-  
 formed in the side opposite to that most affected  
 but I think for the sake of dispatch the arm most  
 convenient to the Physician should be bled  
 from. Purging is also a very important remedy  
 this should be attempted by stimulating injec-  
 tions and if the power of deglutition remained  
 active cathartics should be administered. Emetics  
 have been recommended but these have been

16  
objection to our the presumption that it would  
impel the blood to the brain with so much vio-  
lence as to rupture the vessels or if they are already  
ruptured to cause a more copious effusion where  
the stomach contains a hearty meal it will  
generally be ejected from the stomach. if a  
considerable quantity of blood be drawn from the  
arm or jugular vein or from any convenient  
and safe vessel and in this case very beneficial  
effects have resulted. blistering has been recom-  
mended but I think an <sup>un</sup>~~im~~portant remedy  
in the early stage of the disease Stimulants  
have been almost universally employed but I  
think these might be employed advantageously

in cases of suspended animation but do not  
think them useful or their employment warrant-  
able in Apoplexy as the violent efforts in vom-  
iting will as before stated impel the blood  
to the brain with so much violence as to incre-  
ase the effusion or rupture the vessels which are  
not yet ruptured. If a poison introduced into  
the stomach produces Apoplexy and if a sponta-  
neous vomiting occur it should be encourage<sup>d</sup>  
by draughts of tepid water and by the remedies  
usually recommended in cases of poison. If  
stimulants in the later periods of the disease  
become necessary they are to be employed  
and the most proper will naturally be-

18  
resorted to by the skillfull and judicious prac-  
titioner. The affusion of cold water has been the  
most to be of much value <sup>in</sup> ~~from~~ rousing a person  
from the insensibled state. When there is a  
full habit or a plethora existing the specijes  
applied to the back of the neck has been used  
in curing this predisposition so also is a  
few introduced into the back of the neck these  
are merely used for the prevention of Apoplexy  
but when Apoplexy seriously threatens there is  
nothing which can be substituted for copious  
Vena section. If Apoplexy actually does occur  
bleeding is immediately to be employed and

if as above stated the powers of deglutition remain  
 to the patient cathartics should be administered  
 and their operation promoted by injections.  
 cupping the temples also leeching may be emp-  
 loyed with good effect. rest should be strenuously  
 enforced the head being considerably raised by  
 pillows above the level of the body and if the  
 patient receives a total avoidance of the pre-  
 disponent causes and <sup>likewise</sup> of plethora should be  
 strictly adhered to by the patient. A paroxysm  
 of deep intoxication has been confounded with  
 Apoplexy but may be distinguished by the ~~presence~~  
 generally by the history of the case and by the  
 smell of liquor being perceptible in the

breath deep sleep resembles it, in some degree  
 but is readily distinguished by the patient being  
 aroused by the application of volatiles applied  
 to the nose by pinching or by calling him  
 in a loud tone of voice it is also confus'd  
 with Palsy and Syncope but is distinguished  
 from the former by its being an affection of  
 the whole of the powers of sense and voluntary  
 motions  
 and from Syncope by its being attended with  
 the continuance of respiration and the action  
 of the heart,

26

Remarks on Tetanus.

The disease which I am about to give a description of, is one which has in former times excited terror in every medical Practitioner, who saw the misfortune to witness a case of it.

I mean Tetanus — a genus of disease, in the Class Furiosus, and order Spasmi, of Crises, characterised by a spasmodic rigidity of almost the whole body.

The varieties of this Disease which are described by De Cullen are, First, epistroticus when the body is rigid, drawn backwards by the contraction of the Dorsal muscles — Secondly, Emprostroticus, when the body is bent forwards — Thirdly, Picurostroticus, when the body is drawn to either side and Fourthly, Tismus, or locked jaw. — I thought I consider them one, and the same disease and these distinctions or course unnecessary.

CAUSES.

Tetanic complaints may arise from many and various causes such as, punctures, lacerations, or abrasions and fractures of the limbs — gunshot wounds, wounds in the hairs of the hands and soles of the feet by means of nails or splinters of wood. — The injury done to the feet by Frost, cutting the umbilical cord in new born Infants, and the sudden application of cold to the body after it has been exposed to extreme heat — It has also been sometimes induced by certain

[The page contains extremely faint, illegible text that appears to be bleed-through from the reverse side of the document. The text is too light to transcribe accurately.]

poisonous vegetables received into the stomach - as  
Sambucus - Stramonium &c. — This Disease is  
said to occur most frequently in warm climates,  
and in the warmest weather of those climates,  
but this is by no means a general rule, for we  
sometimes have it in our winters.

This Disease affects all ages, sexes, Temperaments  
and Complexions — but the nervous and indolent  
are most subject to it. — Some have said  
that negroes are more predisposed to contract it,  
than white people they are more frequently  
affected with it but this, probably arises from  
their being more exposed to injuries than the whites,  
and not from predisposition; they are more liable to  
tetanus, because they are more subject to injuries as  
they generally go barefooted and from that  
circumstance are very often wounded about the feet  
with nails, splinters of wood, broken glass &c. &c. —

Symptoms. —

This Disease sometimes comes on suddenly to a  
very violent degree but more generally it advances  
by slow degrees to its violent stage.

It commences with a sense of stiffness in the back  
part of the neck which, goes on increasing until  
it renders the motion of the head difficult and  
pains — After the rigidity of the neck has come  
on there is commonly at the same time a sense of

uneasiness felt about the root of the tongue - which, by degrees generally becomes a difficulty of swallowing and if the disease is not combated a merely at length an entire interruption of it.

While the rigidity of the neck goes on increasing there arises a pain often very violent at the scrovinculus cordis, and shooting from thence into the back - When this pain arises all the muscles of the neck and particularly those of the back part of it are affected with spasm pulling the head strongly backward. At the same time the mastication muscles are affected and the jaws are violently clenched, so that it is sometimes necessary to extract a tooth to introduce any thing into the stomach. - This is what writers have named Locke's jaw and is very troublesome; the tongue is sometimes very much injured in the teeth in consequence of its being thrust out of the mouth during the intervals of spasm and it is in that way that it is so often injured. - When the disease has advanced thus far the pain at the bottom of the sternum returns very frequently - and with it the spasm of the back part of the neck. As the disease thus proceeds a greater number of muscles come to be affected

with spasm. — In succession to those of the neck, and hands, those of the back bending the whole body strongly backwards and this is what has been called Opisthotonos. —

The muscles of the superior extremities are not the only muscles affected, for both the flexor and extensor muscles of the legs are very rigid, and the limbs are very stiff. —

During the whole of the disease the abdominal muscles are violently affected with spasm, so that the abdomen is strongly retracted and feels very hard.

At the height of the disease every organ of voluntary motion seems to be affected; and among the rest the muscles of the face: The forehead is drawn up in furrows, the eyes are sometimes distorted, are commonly rigid and immovable in their sockets; The cheeks are drawn backwards towards the ears so that the whole countenance expresses the most violent grining, under these universal spasms a violent convulsion commonly comes on once upon an eye to life.

The attacks of this disease are seldom attended with high fever although there may be occasionally some: — and it is said, by some that at the commencement of this disease the pulse is

often fulfil one treatment, some are slow. —  
 But I believe in the majority of cases,  
 there is no fever or consequence, and most  
 commonly the pulse is weak and quick.  
 In this disease the head is seldom affected  
 with delirium, or confusion of thought, till the  
 last stage of it.

In this disease I believe the natural functions  
 are not either immediately, or considerably  
 affected, however occasionally there is vomiting  
 in the early part of the disease but this  
 generality continues a very short time;  
 and it is quite usual in the appetite  
 of hunger to remain through the whole course  
 of the disease, and the food that is taken,  
 seems to be regularly digested, however this  
 is in very small quantity.

The excretions are sometimes affected but not  
 always — The urine is sometimes suppressed, or is  
 voided with difficulty.

The belly is sometimes costive this I think  
 originates from opiates, for we have no accounts  
 of it unless opiates were used.

This disease until very lately generally proved  
 fatal, this was owing very much to the manner  
 in which patients were treated by the older  
 practitioners; For we know that until very lately

Physicians were not acquainted with a method of cure and that, since a more proper method has been known and carried into effect, many have recovered:— It may be objected that the fatal tendency of it is not so unavoidable as has been supposed.—

In judging of the disease in particular cases, we may observe, that if it comes on very rapidly it is more severe than when it comes on more slowly.— (The first case of Tetanus, which I saw terminated fatally on the fourth day.)

This disease is not properly treated. It proves fatal before the sixth, or sixth day, and when a patient has passed this period he may be said to be in greater safety, and in general the disease is the sooner, the longer it has continued.

It is to be observed however that the disease is dangerous for many days after the sixth.

Treatment.

I come now to speak of the treatment which should be carried into effect with perseverance, and experience has taught us that Opium, and Mercury, has often proved an effectual remedy, but to render them so they must be given in large quantities so that we may have their full effects.

Faint, illegible text, possibly bleed-through from the reverse side of the page.

I am fully persuaded that opium is very seldom given in sufficient doses.

The practice has been, to give it either in a liquid, or solid form, not in very large doses at a time, but in moderate doses every one, two, or three hours; this practice will do if its effects are not suffered to go off, however it does not seem to operate in this disease, as it does in others; For although it procures some remission of the spasm, and pain, it hardly ever induces any sleep, or occasions that stupor, or delirium which it often does in other circumstances, when much smaller quantities have been given.

It is therefore observed that in this affection there should be no reticering, that it should be given by wholesale and it should be given as largely, and as frequently, as the symptoms of the Disease may seem to demand.

It must however be observed that though the first exhibition of the opium may have produced some remission of the symptoms yet, the effects of it do not long continue in the system and this disease being very ready to return, it is very necessary by the time that the effects of the opium given, are going off, and especially upon the

least appearance of the return of the spasms, to repeat the dose in the same quantities as before. — This practice should be very strictly pursued as long as ever the disease showed any disposition to return: And it is not until after the Disease has already subsisted for some time and when considerable and long continued remissions have taken place, that the doses of the Opium may be diminished and the intervals of exhibiting them, be more considerable.

Opium administered in this way, has in many cases been successful, and probably would have been so in many others if it had not been too sparingly used, either from timidity of Practitioners or from its exhibition being prevented by that insupportable or objection which so often attends this disease. Which latter circumstance requires that the medicine should be immediately and largely employed upon the very first approach of the disease, before the operation becomes difficult or if this opportunity be lost the medicine in sufficient quantity and with due frequency should be thrown into the return by gutters.

It has been recommended to employ opium with

some of the antispasmodics, such as musk, and camphor, this I think is a very weak practice and would answer a very little better purpose than opium alone, in one case I see opium and musk combined but it terminated fatally. Blesters to the neck were also used. — What would be the effect of Emetics in this disease — We know, that they produce powerful effects sometimes in relaxing the muscles in spasmodic and convulsive Disorders.

The warm bath has also been spoken of as a remedy. Purgatives has been very slightly recommended by some of the Continental Practitioners.

I do not know how they would answer as I have never seen them used.

Bloodletting should not be used except in plethoric subjects.

Blistering was at one time very much used, it is asserted by some Practitioners that it is always hurtful.

Moxa has been used with decided advantage in late years, it should be applica<sup>d</sup> upon the spine, and the eschars dress'd with mercurial ointment — so as to keep up a discharge, as a tonic and bathing, has also been recommended by the Continental Practitioners.

I am inclined to believe that not one may

of the remedies recommended are of any service. I think that wine, opium, blood, and Mercury are the principal remedies to be relied on in this disease. — If these remedies the Wine, Opium, and Blood, retard the progress of the disease. — Preventing death from exhaustion until the Mercury shall have time to eradicate it, by converting the Pétanic affection into a mercurial action. — However I should strongly recommend Opium and Wine, for without these aids the Mercury would not have time to act, although they are insufficient of themselves without mercury. The Mercury should always have its full effect, and this effect should be kept on for some time, for if it is not the Pétanic affection will certainly return.

The Mercury should be used by extending, applying it in large quantities in the form of Mercurial ointment.

Tobacco has also been found useful and spoken very highly of, by Dr. Lushington of Northumberland in Pennsylvania in a case which occurred in his practice — produced by an injury received in the back of the hand by a splinter of bone, the part had healed, and he made an incision into it, and applied a poultice over it, made of a strong decoction of Tobacco and Linseed meal. —

He applied it from the hand to the shoulder, and changed it every six hours: or similar application was made to the scapular cordis—in order, to operate on the whole system.

In six hours, the symptoms had ameliorated, and the same means were continued with the salivum of Castor oil to open the bowels—Within six hours from the first application, the Tobacco produced some nausea, and so much vomiting on the third day, that the whole complaint appeared to be subdued, his stomach was now restored in cordial nourishment—Drink. &c. Suxham's Tinct—

About the same time Erysipelas of the arm came on, succeeded by Maris a Potu which rendered the use of aium. Cum. super. &c. necessary;— vid. Med. Nic. det. 1724 page 315

Prophylactics.

The best preventives of Tetanus consist in the conversion of punctured into incised wounds by means of a scalpel, or some such instrument; and the exciting of suppuration in wounds that are lacerated.

These precautions should be used immediately after the injury is received, and before the Tetanic symptoms shall have made their appearance if circumstances exist to prevent the dilatation of punctured

usually the application of some escharotic should be used such as ley, corrosive sublimate, spirits of Turpentine, Tincture of Cantharides, and Nitrate of Silver.

These should be followed by poultices so as to bring on suppuration.

If the patient cannot swallow, food should be thrown into his stomach by means of a gumelastic tube.

This may be done by removing a tooth or two.

## Essay on Cantharides

Cantharides when applied to any part of the surface of the body produce inflammation of the skin, and in a few hours there is a preternatural discharge from the capillaries. This discharge being accumulated between the cuticle and cutis vera, is called blister.

A similar evacuation of fluid may be produced by other acrid substances such as sinapisms, and many others. But no experiments hitherto made have been attended with such success, as to entitle them (sinapis) to such general use as the cantharides, and they are seldom had recourse to, except, when the flies cannot be obtained or where in consequence of the extreme torpor of the system they have been found ineffectual.

The ancients were not entirely ignorant of the powerful effects of blisters although their application was confined to very few diseases. It is said that the Arabians were the first to use them with a view to rouse their patients from a lethargic state. The physicians that succeeded them for sometime used them indiscriminately in every state of morbid action in the system. From an ignorance of the <sup>proper</sup> period in which they were indicated (as it may be supposed they did great injury by too early an application of them. our knowledge of the efficacy of blisters may be attributed to a dispute which took place between some Italian physicians relative

1847

Dear Mother

I received your kind letter of the 10th and was glad to hear from you. I am well and hope these few lines will find you the same. I have not much news to write at present. I am still in the same place and doing the same work. I have not seen any of the old friends here. I have not time to write you more than a few lines at present. I will write you again when I have more news to write. I am your affectionate son

John Smith

they to their use in a plague which pre-  
 -ailed in the sixteenth century. Their  
 application cannot be considered as  
 yet regulated in all cases. they are  
 even now often prematurely applied  
 and seldom without manifest injury  
 to the patient. In the application of  
 blisters we have a very convincing illustr-  
 -ation of the necessity of attending to the  
 state of the system before we prescribe  
 a remedy. This principle is inculcated  
 with much ardour by a learned and  
 ingenious professor of the University of  
 Maryland - upon this principle is  
 founded the art of alleviating and  
 curing diseases and as such should never  
 be forgotten by a practitioner of  
 medicine - Much has been said about -

the manner in which blisters<sup>61</sup> operate  
one party maintaining that an absorption  
of the cantharides takes place, and that  
all their good effects are derived in this  
way— Another that they act by vesication  
only. It appears that the former party were  
led to their opinion by observing that  
strangury is produced by the absorption  
of the acid particles of the cantharides,  
This fact they conceived to be sufficient

That some part of the cantharides is  
sometimes taken up into the system by  
means of the absorbents is very cert-  
-ainly proved by the phenomenon of  
strangury— The absorbed part appears  
to be particularly determined to the urinary  
organs, sometimes producing by its irritating  
action inflammation on the neck of the

63

bladder and consequently pains of micturition  
Blisters are powerfully stimulant. we  
may infer this from the increased force  
and frequency of the pulse which is pro-  
duced by them. and from the great deter-  
mination of blood to the part which is  
in contact with the flies. occasioning infl-  
ammation and effusion. When blisters are  
applied to the extremities they give a centrip-  
etal determination to the disease. thereby  
saving parts essential to life as in yellow  
fever &c. The operation of blisters is both  
stimulant and sedative. They answer the  
purpose of metastasis better than any  
other medicine in use. Dr. Rush tells  
us " that it is from ignorance or inatt-  
ention to the proper period or stage of  
fevers in which blisters have been applied

that there have been so many disputes among physicians respecting their efficacy when applied in a state of great arterial action they do harm; when applied after that action has nearly ceased they do little or no good. The period in which blisters are useful is called by him the blistering point. Blisters are applicable in local and general diseases. We must keep in view the principle which I have before said is so strongly inculcated by a learned Professor

In the malignant state of fever which appears in the plague yellow fever &c blisters may be applied to the extremities. after the morbid action has been in some measure

1847

Dear Mother

I received your kind letter of the 10th and was glad to hear from you. I am well and hope these few lines will find you the same. I have not much news to write at present. I am still in the same place and doing the same work. I have not seen any of the old friends here. I have not time to write you more than a few lines at present. I will write you again when I have more news to write. I am your affectionate son

John Smith

67  
reduced by plentiful evacuations.

The determination which they produce to the surface often presents congestion and inflammation in parts essential to life. They have been used in the plague with great advantage, as the irritation which they occasioned invited the disease to parts not absolutely necessary to the vital functions, and thereby prevented the too often fatal consequences of congestion in the viscera.  
Dr. Rush in his treatise on yellow fever says that blisters when applied in the proper period of this disease (yellow fever), did great service. This time was when the fever was so much weakened by evacuations, that the

artificial pain which is produced by the stimulus of the blisters destroyed, and like a conductor conveyed off the natural pain of the body?

In typhus or the low state of fever, blisters may be applied as stimulants with considerable advantage. ~~and~~ to obtain this to the greatest extent, they must be small and repeated, and never suffered to discharge long: as the evacuation would counteract the purpose for which they are intended. In the typhoid or slow nervous ~~state~~ fever Dr. Goutam used them (blisters) with advantage, and from their operation in other states of fever: we can entertain no doubt of their application being attended

1871

Dear Mother

I received your letter of the 10th and was glad to hear from you. I am well and hope these few lines will find you the same. I have not much news to write at present. I am still in the same place and doing the same work. I have not seen any of the old friends here. I have not time to write you more than a few lines at present. I will write you again when I have more news to write. I love you all very much and hope to see you all soon. Give my love to all the folks. I am your affectionate son, John Smith.

with efficacy in this,

The intermittent fever is sometimes so obstinate, in consequence of marsh miasma producing so great a degree of action in the system, that the bark has been found inefficacious and in many cases extremely injurious, when such cases occur, the patient's pulse is found to be moderately tense. By premising blood letting, or the abstraction of the excitement from the blood vessels to the surface, by blisters to the wrists, the bark will always be found effectual.

Blisters are very important remedies in the treatment of the

different varieties of phlegmasial diseases.

In acute pulmonary affections especially blisters are recommended. Physicians disagreed as to the proper time for employing them in pneumonia.

That blisters may be employed early in this disease is proved. Without doubt however they will be more beneficial after the reduction of the vehement arterial excitement,

In relation to this point Dr. Boström makes the following remarks.

(It has sometimes ~~occurred~~ struck me very forcibly) says he. That the precipitate application of blisters to the

Chest. before general or local blood  
~~letting~~ <sup>letting</sup> is a prejudicial pro-  
 -actise; at least I have seen hyp-  
 -nothorax rapidly follow it, from  
 the increase of the general and top-  
 -ical excitement which blisters thus  
 applied had apparently produced.

This point is therefore worthy of  
 further investigation in the acute  
 pulmonary inflammation;

In the treatment

of hepatitis blisters are very useful;  
 and in inflammation of the bowels  
 and peritoneum they are indispensable

In all these affections the blisters should

77

be large and applied immediately  
over the parts affected.

In all those  
affections of the throat known by  
the names of cynanche, tonsillaris,  
parotidea, maligna, and trachealis,  
blisters are very useful applied  
in the proper time.

In rheumatism  
I believe every practitioner can  
testify to the efficacy of blisters,  
Their good effects must be as-  
-cribed to their producing a new  
action on the skin which is more  
violent than the inflammation  
seated within, and probably the

79

evacuation which they occasion  
contributes in some measure to  
relieve the inflammation of the  
ligaments by lessening the quantity  
of the determined fluids to the  
part—

In gout by determining  
the inflammation to external parts  
blisters often prevent morbid  
congestion from taking place  
in the viscera—

In the maniacal  
state of fever. as in all other states  
of morbid action we must be  
directed by the action of the

blood repels us to the proper time  
 for using them. for the application  
 of them when the system is highly  
 excited, or too enfeebled, would  
 not be attended with advantage  
 but on the contrary with very  
 great injury.

In the apoplectic, phre-  
 -nitic and lethargic states of fever,  
 blisters may be applied to the  
 head or neck with advantage,  
 we must consult the state of  
 the system, and bring it to  
 the point proper for their app-  
 lication, by evacuation

In the paralytic state of fever, blisters are often serviceable when applied to the limb or part affected.

In the hydrocephalic state of fever, they should be applied behind the ears, or to the back of the neck. ~~If effusion had taken~~ If used before effusion ~~place~~ has taken place, they generally prevent it by producing a determination of the morbid action to the skin, and an evacuation which seldom fails to remove the phlogistic diathesis, but even when we have reason to suppose that effusion has taken

place in the brain. they should  
be used, as they produce a  
discharge which often relieves  
the brain from the pressure of  
the effused fluid,

Blisters applied  
to the thighs in the aneurispheric  
state of fever produce an  
increased determination of the  
blood to the lower extremities, and  
some effusion, which seldom fails  
in lessening the activity of the pulse  
and restoring the natural evac-  
-uation

The hysterical and hypoch-

85

- onarchical states are not unfe-  
-quently accompanied with such  
force of action in the blood itself  
as to constitute the proper time  
for the application of blisters.

The wrists are the proper places  
in such cases for them.

The artificial action they  
produce abstracts the excitement  
from the blood itself and by  
directing the attention from the melan-  
-choly subjects, their train of gloomy  
associations is broken off.

In the waking or watching

state of fever. blisters may  
 be applied to the wrists. By  
 abstracting the excitement from  
 the blood vessels of the brain  
 and fixing it in the skin and  
 muscles. they often induce sleep

These are some  
 infantile diseases in which blisters  
 may be used with success

The whooping cough in some  
 instances may be called a very  
 distressing disease. The morbid  
 action is sometimes so virulent

1871  
The first of the year  
was a very dry one  
and the crops were  
very poor. The  
winter was also  
very dry and  
the ground was  
very hard. The  
spring was also  
very dry and  
the crops were  
very poor. The  
summer was also  
very dry and  
the crops were  
very poor. The  
autumn was also  
very dry and  
the crops were  
very poor. The  
winter was also

is to require blood letting and  
blistering to a considerable extent

To abate or remove the inflamm-  
-ation determination to the lungs  
blisters should be applied to the  
thoras as being more efficacious  
- than when applied to distant parts.

This disease often continues a  
long time after the contagion  
has ceased to act. and that form  
~~has~~ the power of habit alone.

In this case they have a powerful  
influence in destroying the force of  
habit. by the new disease which

they produce. Stranguria produced  
 by blistering has been attended with  
 an immediate removal of cough  
 in this disease.

In colera infantum  
 blisters applied over the stomach,  
 are very effectual in removing  
 the sickness at the stomach and  
 suppressing the diarrhoea. Their  
 efficacy is more certain combined  
 with the pure <sup>air</sup> of the country.

The fever which is sometimes produced  
 by the irritation of the gums in  
 dentition, is often cured by a blister

to the back of the neck, or one behind each ear, after evacuations have been made. The difficulty of getting blood from children and of exhibiting sufficient doses of medicines renders Epispastics, not unfrequently the only remedy to be depended on. Blisters are sometimes very efficacious when applied locally. The application of a blister to the base of an inflamed vein is a practice of much value. This treatment was first ~~used~~ introduced by Dr. Physic, a small plaister of simple cerate spread on linen, is to be applied to the orifice, and over this a blister large enough to cover the whole inflamed part

45

extending three or four inches from the  
orifice in every direction.

In concluding this essay permit me  
gentleman, to acknowledge the sentiments  
of gratitude I feel for the civil  
and polite attentions received from  
you individually, and the information  
derived from you collectively as Profes-  
sors of this institution. I fondly  
anticipate the day when this University  
will hold a rank distinguished  
in the records of medical history,  
where the true principles and pra-  
ctice of the different departments of  
the science of physic are ably tang-  
ht and the dogmas of ignorance  
and prejudice consigned to oblivion

The Nature, Cause, & Cure

of

Mental Derangement;

Submitted to examination before the  
Provost, and Professors of the Univer-  
sity of Maryland, for the degree of  
Doctor of Medicine,

by

W. H. Guins, of Maryland.

1828

To Mr Reynolds, M.D.

Sir

Under your  
direction I received the first rudiments of med-  
icine, & to you I dedicate, <sup>my</sup> ~~the~~ first effort in the  
course.

I am induced to do this by two consider-  
tions - first, because it is the only way I have at  
present of acknowledging the many obligations I am  
under to you: second, because I believe, that you  
will view favourably any imperfections the attempt  
my labour under.

I remain

in

yours very much

obliged

W. H. Green

### An Inquiry &c

In selecting mania as the subject of an inaugural thesis, my object was not so much to advance a new doctrine, as to establish an old one.

It is not without a considerable degree of "fear & trembling," that I enter upon so difficult & so abstruse a subject; but as my object is truth, I shall pursue it, at least, with firmness, if not correctness.

I define mania to be a disease of part, or of all the faculties, of the mind. But, before entering upon the inquiry, it may, perhaps, be proper to state what those faculties are; not that I intend to be so presumptuous as to attempt to say what is the nature of the mind, but that I may endeavour to ascertain the seat of some of its diseases.

The faculties of the mind, according to some writers, are "understanding, memory, imagination, passions, principle of faith, will, the moral faculty, conscience, & sense of the Deity." Its operations sensation, perception, judgement, volition &c.

The mind is put into operation, by impressions made upon it, thro' the medium of the external senses, as the different colors make impressions on the organs of vision, odours on the organs of smell, different surfaces on the sense of feeling, sounds on the auditory nerve, sweets & acids on

151

the organs of taste; thus a communication is preserved between man & the material world. When any of these organs are diseased, false impressions are conveyed to the mind - the mind directs the will improperly, we have incoherent actions: thus, a man imagines he sees a spectre, & he flies to avoid it. A disease in any of the faculties is the first step to madness.

In conducting our inquiry we should be led, as well as this as every other disease, first, to ascertain, if possible, the seat of the disease, second, its pathology, <sup>third</sup> its causes, & fourth its removal or palliation.

Concerning the seat or proximate cause of mental derangement, there have existed a variety of opinions. The ancients supposed that madness was derived from morbid functions of the liver; & as this viscus is very liable to disease, the opinion received considerable countenance from its being very often found in a morbid condition, on dissection after death. Subsequent writers refer it to the spleen; while more modern ones contend that it cannot be referred to either the one or the other, & that it has its seat in the blood-vessels of the brain, or in excessive arterial action, induced from the same causes, which produce fever. Without stopping to inquire into these different opinions, to ascertain their correctness, or to enter into a metaphysical speculation concerning them; I will merely remark, that, if the disease could, with propriety, be referred either to the liver, or spleen, or blood-vessels of the head, we might be led to expect, from the remedies successfully used in these diseases, more fre-

105

ent cures of madness, than we are in the habit of waiting.

In rejecting all the theories which have been advanced thro' subject, we should only be actuated by the hope of obtaining something which approximates nearer to the truth; whether we shall succeed or not, rests with future investigators to determine - We shall at least make steps towards it, if we fail in our attempt, we may perhaps, kindle a spark, by which some more successful genius may fire his torch, & thus penetrate the gloom which envelops this intricate subject.

We conceive madness to be entirely, a nervous disease.

To illustrate this position, we shall form the nervous system into three divisions: viz: - those of sensation, in which we believe the disease to be exclusively situated, when these nerves are in state of disease, & we can easily imagine an hundred causes, which may produce a derangement in their functions; those of motion, & those of sympathy.

That the disease is thus situated, we infer I. from a total absence of some of the senses, & a perversion of the rest in every madman: Thus, one will tear his blanket & roll it up, then cry most hideously until the "San Serpent" is removed from his cell - There is evidently a diseased nerve, transmitting false impressions to the brain. Another is insensible to taste & smell, & will swallow anything presented, even of the most disgusting char-

105

ter, without the least mania being produced. A  
bird is insensible to the temperatures of heat & cold  
so remarkable a degree, that he will burn his legs  
to blisters, without evincing the least concern at it;  
Rush related the case of a man in the Pennsylvania  
hospital, who would stand in one position, in the cold,  
until mortification was produced, without manifesting  
the least pain, or disposition to move.

II. From sudden impressions made upon the nerves,  
frequently removing the disease; such as fear, terror  
&c. For examples of this nature, consult Rush on the  
mind, Eschschon on mental derangement, and every  
other writer, who wrote on the subject.

III. From the disease disappearing on the accession of <sup>another</sup>  
such had a tendency to abstract morbid irritability  
from the diseased nerves: thus, the patient, who perceived  
the sea serpent in his blanket, took the confluent  
small pox in the Maryland hospital, & died; but pre-  
vious to his death he became perfectly sensible, &  
spoke as rational as any one.

And VI. From its seldom appearing in persons, who have  
not attained the years of maturity. The manner of account-  
ing for this, is, first external objects do not pro-  
duce the same impressions in youth, that they do in  
adult age; 2<sup>d</sup> impressions made in youth are of a  
transient nature, & soon forgotten, whereas in adult age,  
the impression, ~~the~~ of a beautiful object is continued un-  
till the nerve, on which it is made, becomes diseased, from

107

long action: just as the continued impressions from odours, & the olfactories, produce hysteria & other diseases, bordering on madness; or, just as the whole system becomes debilitated from long continued exertion, & then inducing disease by keeping up the exertion.

### Causes,

We come now to consider the most frequent causes of mental derangement. These are, hereditary predisposition;— this disposition exists in latent state, & is transmitted from the parent in the same manner that Gout is; but whether transmitted by bloodvessels, nerves, bones, or muscles, "is a mystery looked up in the strong box of nature;" but that the disease is inherited by the offspring from the parents, is a fact, which, I believe, is not at all questioned now. Injuries of the head, so as to make breach on the nerves of sensation, a constant habit of intoxication, onanism, extreme abstinence from coition, superstitious dread, religious fanaticism, all the passions, as, Excessive grief or disappointed love, A peculiarity in the formation of the cranium. out of all the maniacal patients now confined in the Maryland Hospital, more than two thirds of them have some peculiar formation of the skull. Some have remarkably small round heads, while others have long narrow heads, others again have their skulls narrow & small at the base and wide at the top, not unlike the heads of hydrocephalic children. Excessive use of Mercury, inordinate gratification of the venereal appetite, the sudden repulsion of

189

stagnant eruptions, violent arterial action, such as is found in puerperal convulsions, & in fevers which attack gross & plethoric habits, insolation, worms in the alimentary canal, continued attention to any one subject, & excessive use of narcotic medicines— Many more might be enumerated, but these are sufficient to show the variety of causes, which produce mental derangement, & some one of its forms.

Madness may be divided into three forms, viz:  
Furious madness, melancholy, ~~in~~ which is considered hypochondriasis; & madness from an imbecility of intellect, each of which will require a separate consideration— This paper, however we shall not attempt those delicate distinctions which mark the boundaries between eccentricity of character, & actual madness; but consider certain deviations from propriety, as another degree of the same disease.

### Symptoms.

Furious madness makes its approach by some peculiar symptom; such as restlessness & watchfulness, anxiety about imaginary things, incoherent expressions & eccentricity of conversation & conduct, considerable irritability of temper, hostility to friends & relatives, sadness & languor. The skin is pale & cool, sometimes the face is flushed, a singularly wild & vacant stare is visible on the countenance; there is either a total want of appetite, or there exists a morbidly increased one, the bowels are obstinately costive, a considerable degree of headach is frequently present. When nearly the whole of these symptoms are present, we may form a tol-

11

terrible correct prognosis of the character of the approaching disease. When these symptoms are completely formed, we have a wild, ferocious expression of the countenance, an appearance of fulvency in the ~~countenance~~ face, with red eyes & flushed cheeks, the patient becomes very boisterous & clamorous - he whistles or sings incoherently, makes long & ridiculous speeches, uses very obscene language, curses & swears most profanely, loses all sense of shame & delicacy, rends his clothes, stalks about in a complete state of nudity; and, finally, to finish the most melancholy picture, the patient degrades himself beneath the brute creation, by acting the most disgusting scenes imaginable.

In this stage of the disease, the skin is cool, & not the least moisture can be discovered on it; and, what is very remarkable, there is no secretion from the mucous membrane of the ~~nose~~ nose. It is mentioned by Dr. Rush, & to satisfy myself of the correctness of the observation, I made an examination of all the patients who were ranged in the Maryland Hospital, & found it to be the case in every one, with one exception. The pulse is sometimes hastened a little, but it is none frequently natural - the frequency of the pulse just alluded to, may be referred to nervous irritation. In this state of madness, one or more of the nerves of sensation are destroyed, and the others become very acute; just what occurs, when a man loses his sight, the sensation of feeling becomes very acute; hence, maniacs hear very acutely

though they taste nothing, and smell nothing. Different causes, however, produce different symptoms—thus the Sarcians, a poor, destitute, & naked horde of rags, unskilled in the use of arms, or the art of war, had their imaginations inflamed with a new doctrine, became partially <sup>very</sup> & their fearfully attacked fortified towns & citadels; nor did they raise the siege until the town capitulated. Here the continued idea, of beautiful virgins & plenty of wine, by long action on the nerves of sensation, brought on a disease of the mind, which caused them to devastate the most beautiful, fertile countries of Asia, Europe, & Africa. The same causes produced the same effect in the wild and visionary Crusaders, when they marched to the holy land. The remedies to be used in this disease, depend upon ~~upon~~ the cause that produced it; I shall therefore, say nothing of the treatment until we shall have described the different forms of disease.

The next form of mania is melancholly, or as some authors call it Hypochondriasis.

The elder physicians were often very unhappy in their use of terms in medicine. Of this we have sufficient proof, if we but open their nosological books. Technical words ~~we~~ <sup>we</sup> set our eyes in very distraction, and if they do not confound us, at least muddle our wits, in ascertaining their precise meaning, and original application.

Hypochondriasis is that term which was employed by the ancient nosologists, to denote an uneasy state of mind, produced, as they conceived

a derangement in the functions of the liver, or some other viscus of the hypochondriac region. but, it is, however, abundantly proven, that the disease is not derived from diseased liver, or any other of the viscera:—The term is therefore incorrect, and not applied with strict propriety.

As this form of mental derangement appears not so evident in an erroneous perception and judgment of things relating to the person & circumstances of the patient, Dr. Rush proposes to call it *Tristamem-*

Various epithets are applied to this disease in common conversation, the hyppos, spleen, vapours, low spirits &c. are all synonymous with hypochondriac in its various grades. As the author of this essay has been more in the habit of turning his attention to the phenomena of diseases than their characteristic distinction, it will be sufficient to observe that Dr. Cullen has given the following character of it, dyspepsia, languor, want of energy, sadness, & fear from uncertain causes; with a melancholic temperament."

Persons of nervous & hepatic predispositions are most subject to melancholy.

Hysteria sometimes resembles melancholy, but there are certain prominent features, by which they may be distinguished from each other. The bloodvessels are more affected in hysteria than in melancholy, the nervous system in the latter is always in a state of torpor, in the former great mobility prevails, hysteria ap-

as in paroxysms attended with occasional delirium,  
it is not so with the other - hysteria is alleviated by  
cold, melancholy by warmth.

That it combines with  
hysteria is proven by many facts. Some melancholic  
patients are dull & sad at the same moment, at another,  
they are gay & vivacious to an extreme. They are ex-  
actly the most boisterous laughers, & unaccustomed to  
seat weariness & mischievous. These are convulsive effects,  
and can only be explained on the supposition - that  
they are borrowed from hysteria.

Persons advanced in life are more subject to the dis-  
ease than the young.

### Cause

The remote causes operate, first on the body, se-  
cond on the body through the medium of the mind,  
& third on both at the same time.

Among the first,  
are all debilitating occupations of a sedentary kind,  
fatigue, irregular diet, hunger, watchings, un-  
wholesome food, chronic fevers &c.

The second variety  
comprehends all the excesses of the passions, & emotions,  
joy, grief, anger, shame, disappointment, vexation, reli-  
cious distress, intense study &c.

The third kind, on those  
which operate on the mind and body at the same time,  
are all perplexing employments, where the mind un-  
usually hurried, & the body fatigued, as professional  
practice, teaching school &c. the various forms of the  
nerve disease, by inducing debility, & at the same

117  
are exciting emotions of shame and sorrow in the mind,  
we made many a melancholly patient.

### Symptoms.

These are very various. In digestion, flatulency, costive ness of the most obstinate kind, which requires the most powerful incitants to move the bowels, diarrhoea, an excessive secretion of bile, dry skin; & an increased flow of urine, slimy stools, deficiency of appetite; preternatural appetite, cholice, burned abdomen, Tinnitus aurium, throbbings of the temples, indistinct vision, palpitations of the heart, burning of the hands & feet & c.

The mind is as variously effected as the body. It is languid, & inactive, and can seldom be employed in thinking on any subject, but that of personal distress. The imagination is in search of doleful images "with a wing that never tires." A thousand fancies are continually excited in the brain; almost every disease lends a share in forming the symptoms of this.

As consumption is the most frequent & fatal disease, it is not to be wondered that it should stand foremost among the chimeras of the patient's brain. If a cough happens to trouble him, he has an abscess in his lungs without doubt; his fears immediately create an hectic fever, should his hands & feet feel a little warmer than usual, it is a certain indication in his mind, that the wages of this direful malady are commencing.

Should the unfortunate patient have been lined by a shroud  
& attached by the veneer: notwithstanding the poison  
has been completely eradicated from his system; he is  
constant fear of having his palate, or the inside of his  
nose destroyed by the incursions of the resuscitated distemper.  
His imagination conjures up to his view the loss of repu-  
tation & of friends; & predicts ruin & misery through-  
out the remaining part of his life:— Again, he believes  
his heart is dilated into an aneurism, or has conceiv-  
ed a polypus, or peradventure through shame dilated  
it palpitated or beats with a little irregularity.  
Thus in turn he has a stone in his bladder; an  
abscess in his liver; and a tapeworm in his belly.

His mind is affected by certain- extraordinary  
visions. He is firmly convinced at one crisis  
that his body is transformed into a plant & needs the  
hale some showers of heaven to make him grow; or,  
perhaps, he may imagine himself a teapot, under  
his belief, he is in an awful situation if he be  
so roughly handled; and he shivers at the idea of  
being broken to pieces. Probably he has conversed  
himself with cold; or to sum up the conclu-  
sions of his fancies, he persuades himself that he is  
expiring, & with no more ado he suffers the pangs of  
isolation & lies a lifeless corpse. Nothing, under  
these circumstances will quicken him into life,  
but some application like the actual canterbury—  
This powerful stimulant cannot fail to in-  
flame his feelings to the most sensible belief  
that he has yet to die.

are not the worst of the patient's mental sufferings. He is sometimes in despair, here we irresistably exclaim "O poor Yonick!" This state of his mind is induced by a <sup>single</sup> persuasion that he cannot be saved in another world, and that eternal misery is to be his fate hereafter. This spiritual distress of the patient, is produced by wrong views of the character of the Deity, & of his own sins. Every little neglect in his religious exercises - former life, recoils upon his mind, with apprehensions that they were the most fatal remissions of duty, & he looks forward with all the horror imaginable, to the time when he will <sup>be</sup> cast into endless torment.

But it were an endless task to rehearse the almost innumerable symptoms attending this malady. Believing that enough has been given to enable the discerning to own a correct prognosis, we shall now proceed to the consideration of the last form of mania -

Imbecility of Intellect.

This is either congenital - adventitious - The first is the effect of some pre-disposition inherited from the parents; or some mal-formation of the brain - The second arises from long continued disease in the system; from sudden impressions made upon the mind, from grief, & joy, & several other causes, which it is unnecessary to mention -

Symptoms.

These are generally known, as there is scarcely a town that has not one or two in it - They are said to be "foolish;" that they are "cracked;"

that they are "hair brained" &c. The patient has an un-  
earning countenance; he laughs at every thing & continues  
to; he makes use of trifling expressions, & is fond of the  
society of children, he is irritable in his disposition, care-  
less about his dress, or extremely neat. Patients with this  
kind of madness, are remarkable for their loquacity, they  
seldom talk when in company, & always mutter when  
alone; they are amused with trifles, especially fond of  
needlework &c. to see an old noble one so fond of their grand-  
children, that they <sup>frequently</sup> spend all their time with them.

These symptoms are sufficient to enable us to form a  
diagnosis of the nature of the disease, as it is by no means  
difficult one to ascertain.

### Treatment.

We shall hasten on to con-  
sider the remedies which are necessary in each form of  
the disease— These are "moral & Medical."

When mania is the consequence of hereditary predisposi-  
tion, medicines are seldom if ever of use:— Our treatment  
must consist in rendering the situation of the unfortunate  
patient as comfortable as possible— This may be done in  
a variety of ways; by kind & gentle treatment from the  
attendants:— No excuse can be received in pollution of an  
home committed against one of those miserable beings—  
by keeping the apartments, in which they are confined,  
well cleansed & ventilated, by using Dr. Rush's brown  
miliver; thus preventing the patient from rending  
his cloaths, & injuring himself— in short, to treat  
them just as we would wish our selves to be treated,  
if we were in the same melancholly situation.

127

When it is produced by any other cause, such as injuries of the head; here the patient comes under the exigency of surgery & may be relieved by an operation—when from intoxication, we must abstract the stimulus slowly & administer emetics & cathartics. anodynes of pure narcotic, opium, perhaps is the best; from inflammation, the antiphlogistic treatment must be resorted to, cold applications to the head; the strictest regard must be had to his diet, he should be kept in a room where he would not be exposed to too much light; his meals should be kept soluble, with neutral salts &c. When from mania the patient must be confined in such a manner, as will prevent his continuing so shameful a practice, when from excessive venery, he must, in the same manner be prevented from indulging his sensual appetite. The man of feeling, may, therefore frequently alleviate the symptoms if he can not remove them. Labour has been recommended by some writers; but in that form of mania, to which the above treatment is applicable, it can seldom be resorted to, as the patient is in such a state, that he cannot be managed when at liberty.

The above treatment is applicable in that form of the disease, which has been called furious mania.

We shall now go on to consider the treatment in the second form of the disease, on that which we have called melancholly.

The remedies for this form themselves into two kinds: viz. those that act through the medium of the alimentary canal, & those that produce

peculiar effects on the organs of sensation —

When the disease is attended with symptoms of indigestion, costiveness, flatulency, diarrhoea &c. as already enumerated, medicines which relieve those symptoms must be given — Indigestion must be obviated by a strict attention to diet, costiveness must be prevented by laxative medicines, & diarrhoea by constringing & astringent secretions of the intestines. An excessive secretion of bile should be prevented by alterative medicines, such, as small doses of colomel, the blue pill, or a nitro-muriatic bath, exercise of various kinds may be resorted to, such as riding on horse back, or in a carriage, swinging & sailing; moderate exercise on foot has been recommended. Thus, the judicious practitioner, by a proper regard to symptoms, will generally insure success.

With respect to the remedies which act on the organs of sensation; there are such as may occur to the practitioner at the time. The disease occurs, as has already been stated under a variety of forms, & our treatment must be regulated accordingly: — Thus, if the patient imagine himself some great man, we must favour the belief, & treat him, with all the care & attention, as if his disease was a real one; & observe all the respect, in his presence, which such character is in the habit of receiving, until an opportunity may present itself to dispell his visionary greatness. If he imagine himself transformed into an animal, as is very frequently the case; such as a dog or a cat, or even a hog, he may have his food thrown to him in the same manner as we would feed those animals; we may by this cre-

An  
 Inaugural Dissertation  
 on the  
 Yellow Fever.  
 Submitted to the Examination  
 of the  
 Provost, Medical Professors, and Trustees,  
 of the  
 University of Maryland,  
 for the  
 Degree of Doctor of Medicine.  
 on the seventh day of April A.D. 1835.  
 by  
 James R. Ward.  
 of Maryland.

To  
Nathaniel Potter, M.D.  
Professor of the Theory & Practice of Medicine,  
in the  
University of Maryland.

This Dissertation is humbly inscribed, as a tribute  
of respect, for the great kindness and attention received  
from him; and which, will always be remembered, with  
gratitude by

his much indebted,  
and affectionate, Pupil,  
The Author.

# A Dissertation &c

137

1

From the prevalence of this disease in the United States, & from the mortality which has attended its appearance on our sea port towns... the attention of Medical men was generally attracted. The most distinguished of the age, in the profession of medicine made every exertion to discover the cause, the seat, & the best plan of treatment.

Great credit is due to Professor Rush, for the first correct theory of the Yellow fever. Its pathology was soon determined from Post mortem examination, accurate observation, & experience. No disease perhaps has had more talent engaged in its examination than the present one; & none perhaps has caused so much litigation; and still one or two points are sub-judice. I refer particularly to the doctrine of contagion. The physicians of the North, firmly believe it to be contagious; & some deny that it ever originated in this country, but that it is always imported;

In writing an inaugural dissertation on this subject, I am fully aware of the ability, with which it has already been handled, by men, who will be a lasting honor to the profession, & whose usefulness will not cease with their existence. This renders me more diffident in writing on this subject, however, having seen the disease in a climate that is not generally known & whose diseases have not been described. I thought, perhaps that some remarks might be made, which would throw some light on this important & very interesting subject. If this feeble attempt, should be useful in any way to the science of medicine, my exertions will be amply rewarded.

Authors in ascertaining this disease have given it various names. The yellow fever of the West Indies is the most common for this disease, but as yellowness is one of its symptoms, which can generally be prevented by proper treatment, it certainly cannot be properly used. Dr Rush calls it the Bilious remitting yellow fever, which is certainly a more appropriate name, & one expressive in some measure of the nature of the disease. It has also been called the plague, however I have adopted the common term —;

We have says professor Rush, this fever, like the steady blowing of the equinoctial gales, we have it again assuming a milder remittent type, sometimes imitating the character of common intermittent fevers but rapidly taking its insidious way to the destruction of the patient. From its ever varying type, he says Professor Potter, we find no two epidemics requiring the same treatment, & wearing the same livery. It will be admitted, that the disease as called by Dr Rush is the most appropriate it has yet received. If another should be given, any word that would define accurately the appearance & expression of the eye, would be the most appropriate. Language however will be found inadequate to describe it; yet once seen, it will never be forgotten.

#### Causes.

This is another point, which is not settled. many Physicians of the present, believe the disease is always imported, & hence the strictness observed, in some of our sea ports, as regards the Quarantine Law, which are a disgrace to all concerned in their enactment, for they carry on their very face, the strongest marks of folly & ignorance. There are so many facts, that prove beyond controversy, that the disease

has originated in places that have had no connection with foreigners, or  
 usually from places where the disease prevailed. Marsh & Hoffman is gen-  
 erally admitted, among those who have seen the disease frequently, to be  
 the cause, not only of the Yellow fever but also of the common bilious  
 & intermitting fevers of our country; as a necessary consequence they would  
 be deemed by those who believe it is a foreign disease. Let us examine  
 into the facts which present themselves, to those who reside in that part  
 of the country where these fevers are prevalent. On the Eastern Shore of Maryland,  
 where the bilious and intermitting fevers are common every year —  
 Foreigners who visit these countries, during the summer & early in the fall  
 are seized with the bilious & yellow fever, & die with the black vomit, which  
 those who are opposed to this doctrine consider as placing the character of  
 the disease beyond doubt, whilst those who have been raised & continue to  
 reside there, will enjoy good health, or have the ague & fever, which they do  
 not regard. Now the same cause is acting on both at the same time, & produ-  
 cing diseases, of the same kind only more violent in degree. Stronger evidence  
 could not be asked, than the disease of the American Colony of blacks at Cape  
 Mesurado on the coast of Africa. These people when they first settled on that  
 coast, died in great numbers with the yellow fever, so great was the mor-  
 tality, that it was thought it would be necessary to abandon the settlement, they  
 have however become acclimated, & now enjoy good health & what are the dis-  
 eases to which they are now most subject? Common mild intermitting;  
 when this fever is prevalent, what do we find among foreigners, who visit  
 that place? a violent & fatal fever, which destroys them in two or three days,  
 with the black vomit the last struggle comes on, & death soon closes the  
 scene. Let one of these blacks return to the United States, for a winter

and then return again to Africa & will have the Yellow fever. This has been repeatedly observed in the inhabitants of the West Indies, for, if after residing immediately on the shore, or in the large towns, they go into the interior of the islands, and remain for some time, upon coming down on the coast, they will be seized with <sup>the</sup> Yellow fever.

This is proof sufficient to convince the unprejudiced mind, that the Yellow fever & Bilious fever have a common cause & that they differ only in degree.

To account for this difference certainly cannot be difficult. The habitual Laudanum taker will, with impunity receive at one draught, a dose sufficient to destroy two persons who are unaccustomed to its use, without any inconvenience to himself; in the same way, the Constitution becomes accustomed to the action of this poison, so much so, that it may not produce any disease, but the atmosphere that one man breathes with impunity, who has been habituated to it, will, soon produce violent disease & death in him who has never been accustomed to its action.

The Yellow fever is described by Professor Rush Potter, as it occurred in the United States, at or soon after they wrote, bore the same general character as that I was witness to, in the West Indies, & required the same active treatment. I had an opportunity of feeling that state of the skin, which is produced by Mercury & which Dr Good calls a "desponoe", this was the first evidence I had of the Mercury affecting the system. From Dr Good's accurate description of this state of the skin, I remarked as soon as I felt the patient that the Mercury had had the desired effect, which was manifested in a few hours from the patient's complaining of his mouth. It is not requisite that I should describe the Yellow fever of this country which has been so ably done, by men whose celebrity will be the proud incentive to see.

tion in the youthful candidate, for Medical distinction, his remarks, I thought, necessary to make before attempting to describe the disease, as it occurred on board the United States Schooner Shark during a cruise of six weeks on the coast of Africa. The Shark sailed from the U. S. in November & arrived at the American Colony at Cape Mesurado on February, some few of the Colonists were labouring under chills & fever, generally they were healthy, our crew was remarkable so, when we arrived & continued so for some time, as we generally were at sea every day or two & the men were <sup>not</sup> much exposed. Before describing this disease, as it occurred on board the Shark, I think it necessary in order to elucidate the subject as much as possible to make a few remarks on the country & climate. these cannot be as accurate as I could wish, but shall be as perfect as my limited observation extended. The country is thickly covered with low wood and large timber. The soil is very rich, more perhaps more so; none, where vegetation is more rapid, & luxuriant. The seasons are divided into wet & dry. During the wet season the rain falls in torrents & almost deluges the face of the country after a hours shower the air is close, & together with the perpendicular rays of the sun renders it almost insupportable. When the dry season comes on vegetation thrives, astonishingly it soon grows rank, falls, & putrefaction takes place; large collections of stagnant water filled with vegetable matter in a state of putrefaction, are to be found along the banks of the river. We have the diseases arising from Marsh Effluvia prevailing during the year as putrefaction is continually going on, they are more violent at one time of <sup>the</sup> year than at another. Our stay was during the dry season. In the morning until the sea

keep sets in the air is warm & oppressive; about 9 o'clock we have the sea breeze which is refreshing & invigorating. In the afternoon we have the land breeze which produces a change in the temperature of the air, that is truly surprising. It becomes cold, chilly, & dark, & warm clothing is necessary. Many degrees difference will be found in the Thermometer during the twenty four hours. In the afternoon the mist is always so great that the sun becomes obscured about 4, o'clock.

It may easily be conceived that the air coming over such a country, would be loaded with moisture & the poisonous effluvia which is continually evolved from these wide extended marshes.

What constitution <sup>could</sup> stand with these changes occurring every day, told the great enemy of our race, here acts with certainty; predisposing the body to receive the disease, the cause of which disease is continually acting & surrounding him, his anxiety & dread which a knowledge of the unhealthiness of the climate increases, also renders him a more easy & certain victim to his insidious foe.

All those who were taken with this fever complained of violent pain in the head & back, great uneasiness in the Epigastric region, & more or less irritability of the Stomach. All had the red, muddy & glassy eyes. From the want of the written account of the <sup>most</sup> <sup>recent</sup> case that occurred, I am unable to be as accurate as I could wish.

The patient, was a stout man & of good constitution, he was seized with a violent chill, soon after rising in the morning, succeeded by a high fever, pain in the head and back great irritability of the Stomach & great uneasiness at the epigastric region,

The state of the pulse, I do not, correctly remember, but to the best of my recollection, it was depressed. he was bled freely that night, & took Calomel during the day, no evacuation from the bowels took place, & an injection was administered. the next day the patient was able to walk <sup>on</sup> the deck, & complained but little, every thing looked favourable, except the eye which still continued to have the same unnatural appearance as at first. On the third day in the morning, he was again seized with a chill followed by fever, in the afternoon he had another chill. On every other day he was better, the patient not appearing to be much debilitated for the first 2 or 3 days. the active treatment, was continued, as the evacuations showed that the liver was deeply involved; for notwithstanding the continual vomiting no bile was thrown up from the Stomach. On the fifth day the debility became very apparent & his countenance indicated much distress. it was now found necessary to change the treatment. Tonics & Stimulants were ordered. On the morning of the sixth he was evidently sinking, about 4 in the afternoon he was seized with convulsions, followed by the black vomit & delirium. the patient on being asked how he felt answered, horribly! at 8 he was again seized with convulsions & expired with the black vomit running out of his mouth. Yellowness here did not take place to any degree until after death, when the whole surface became yellow, this was the first case that occurred & the only one that terminated fatally. In another who was seized with same symptoms a large dose of Calomel was administered, & the patient was sponged

with vinegar and water during the continuance of the fever to great advantage. Tonics were given as soon as possible & the patient soon convalesced.

The sponging has been much recommended, & it certainly has been found highly useful. It is hazardous, in fact impossible to pursue the same active treatment, as in the disease of this country & the West Indies, as experience warrants me in asserting. On our passage to the United States from Havana, several of our men were seized with the yellow fever, the symptoms were not so strongly characteristic of yellow fever, as those on the coast of Africa, but yet required several bleedings & active cathartics, & the fever was not removed until some mercurial impression had been made on the system. This fact shows the difference between the disease of the two countries. One of the Colonists who has paid attention to the disease, after considerable observation, remarked, that he found that foreigners would not bear an active treatment more than a day or two & then required to be supported. The most successful treatment of the disease was, to use strong Mercurial cathartics in the first instance, venesection being cautiously used, together with sponging & diaphoretics. They have an article indigenous to the country which is found to be highly useful, as a diaphoretic & also a decoction of the leaves of the orange & lime tree is also useful.

The early use of tonics is absolutely necessary, as they otherwise soon sink. Under this plan of treatment the disease is found manageable and a voyage to sea soon restores your patient.

Connected with this subject, there are two circumstances of some importance, the one is that remaining on shore all night, is almost always attended with sickness. Out of 4 who remained on shore all night 3 were sick and one died.

A physician who resided there for some time, informed me, that after he got well enough to go on board ship, to sleep if he left the shore before sun set, he escaped his chills but he invariably had it if he remained for any time, after that period. Johnson on the diseases of tropical climates, has also mentioned a fact of this kind. The other is, that continuation for two or three days is followed by high fever & is often fatal to the foreigner, whereas those, who reside there feel no inconvenience whatever. This, say some, is easily explained, the liver is in a state of congestion & the intestines have not then accustomed themselves from there being no bile secreted. If this be the cause, ought a cathartic, which only evacuates the contents of the alimentary canal relieve the liver and restore the secretions. I am of opinion that, <sup>it may be</sup> a congestion might be produced in the liver, which has already been debilitated by the action of heat & consequently and consequently more sensible to the effects of Marsh Effluvia, by the operation of an active cathartic. What is the effect of a warm climate on this viscus? it stimulates the organ & we find the quantity of bile increased: the long continued application of stimulus to <sup>any</sup> organ will debilitate it, heat as the writer on warm climates <sup>proves</sup> has a stimulant effect upon the liver. It consequently produces debility of the organ, & it becomes more liable to disease, Marsh Miasma acts on it with power & the result is disease. The faeculent contents of the alimentary

If there be, and if there be not, that  
the sugar of the world is in the hands of the  
merchants, and the only way to get it is to

Canal I should suppose must have some effect on the fevers of this kind. The Physicians of <sup>the</sup> West Indies endeavor to restore the secretion of the liver by the use of Calomel in large doses, but they also pay great attention to the removal of the faeces, & keep the bowels soluble. My attention was called to this subject, from a case of typhus fever under the care of Professor Rush & mentioned <sup>by</sup> Professor Potter in his lectures. This patient had been stimulated for some time, Dr Rush raised him to a certain degree by tonics &c, but he became stationary, notwithstanding the most powerful tonics were used, a diarrhoea seized him & his convalescence was rapid & the use of tonics was no longer necessary, after having heard of this case. I saw a patient who had a low mulling delirium, stupor, & difficult to be roused & scarcely answering the questions that were put to him.

Yet all these symptoms were removed by the free action of a cathartic, which had been given whilst the patient was labouring under these symptoms and the pulse which was before weak & small became fuller & softer & the patient fell tranquilly to sleep.

I think if more attention were paid to the bowels in these fevers, our attention would be rewarded by the speedier convalescence of our patients. Let it not be understood, that, I approve of purgatives in all stages of fever. If I did patients in certain stages of fever, would soon be hurried into clarity. From the sympathy that is observed to exist, between the bowels & various other organs in different diseases, I am induced to believe, that a soluble state of the bowels would be more advantageous than is generally supposed, & that we are not often deterred from this practice.

The first part of the paper is devoted to a description of the  
 physical and chemical properties of the substance, and to a  
 comparison of its behavior with that of other known  
 compounds. The author then proceeds to a detailed  
 examination of the reaction of the substance with  
 various reagents, and to a study of its  
 thermal and optical properties. The results of these  
 experiments are discussed in the following pages, and  
 the author concludes with a summary of his findings  
 and a few remarks on the general character of the  
 substance.

from our too great fear of debilities. The prophylaxis is the same on the coast of Africa, as advised by Dr Porter & others as regards the disease in the United States. The bowels to be kept soluble, diet moderate, abstaining from ardent spirits unless accustomed to their use, carefully guarding against exposure in the sun, & to the night air; keeping the feet & body dry, never remaining on shore after sunset, & by no means all night, a careful attention to these directions, will prevent the disease or render it light. As to the question of its contagious character I am decidedly an anti contagionist. Were these disease contagious, we should have had none left to tell the dismal story of our miserable end, as ten persons in one case slept in one apartment, with a man who died of the disease, & the marine guards <sup>who</sup> were the only sufferers in the West Indies, from being exposed at night, on post. were confined during the whole of their sickness, on the same small deck where 20 or 30 sailors slept, every night, & they slept almost in contact with each other, & yet not one had the disease, for my own part I visited these men frequently, & never had the least fear on account of its being contagious.

These remarks have been made with diffidence to be an author so young, was far from my wish. Yet necessity hath compelled me to the task. The inaccuracies of youth must be looked over, when improvement may be expected from the stimulus to exertion that is given to the youthful enquiring mind, from reading the writings of a Rush & many others, who have done honor to their age, & country, & last, though not the

least the deserved celebrity of the professors of the University of Maryland, which has been & will continue to be the proud Alma Mater of many worthies of our country & profession.

# Dissertation upon Phthisis Pulmonalis.

Should to its manes in original flames,  
And mitigate those ills we cannot shun.

The disease which it becomes us to treat has been  
anobscured, as well as justly ranked among the "a-  
crobica medicorum", and as an incontrovertible evidence  
of this fact our bills of mortality are a lamentable tes-  
timony: to use the words of an immortal sage whose time  
and talent were shamelessly, zealously, and indefea-  
sibly directed to the advancement of his profession  
in a degree almost bordering upon enthusiasm - "Phthi-  
sis Pulmonalis as it is justly denominated is of all  
diseases one of the most fatal." When we take a cir-  
cum-spective view over the extended field of nature  
and as idle spectators animadvert upon our insig-  
nificance and imbecility, what description of

subjects some kind of witness to the steady influence  
 of the mind. But amongst them stand conspicuous those who  
 have failed at the most engaging crisis of life and  
 those perhaps the fairest of our race. Must talent  
 then be spent in vain? Must researches then be  
 spent in vain? That same enterprize which snatches  
 lightning from the clouds. That same philosophy,  
 and erudition, which has thus high elevated a sci-  
 entific profession; it yet remains for to discover a  
 specific for what we conceive to be the great-  
 est enemy to the human race.

Tubercle Pulmonalis is understood to be that dis-  
 ease in which a general wasting or consumption  
 of the body arises from a disease of the lungs.  
 Notwithstanding the want of Information upon  
 this disease, which has been manifested by some  
 of the most enlightened of the Profession much

diversity of opinion as regards its Pathology has been ex-  
 amined. Whilst by some it has been doubted whether  
 the disease strictly speaking can be considered as  
 a bathic. By others it is considered to be invariably sym-  
 ptomatic of other diseases. Pneumonia - Catarrh - Scar-  
 a - Haemoptesis and several other names have  
 been mentioned as being the exciting causes of  
 Anthesis; but this with the rest of the Patholo-  
 gy must yet remain a desideratum. The true nature  
 of the disease being one "singulare" appears in it-  
 self reasonable and we find it substantiated  
 from the circumstances in the disease mak-  
 ing its appearance and approaching in such  
 an insidious and formidable manner so fre-  
 quently to be beyond the reach of human skill  
 before its deadly effects shall have been  
 promulgated.

It has been remarked that a peculiar  
 description of subjects was...

of the disease has been well described in a paper  
set at liberty by a respectable author. The  
real advantage is to be derived from this kind of  
distinction or not it yet remains to be discovered

Phthisis Pulmonalis has received attention in every instance  
in modification of fever termed " hectic" this great  
and prominent characteristic has been described as mak-  
ing its appearance sometime before a fatal termi-  
nation takes place - much controversy of opinion has  
been entertained as regards this of all most distin-  
ging symptoms it therefore becomes us to remain si-  
lent until further and more satisfactory investi-  
gation be reported.

Writers when describing disease have thought  
proper to adopt by way of perspicuity certain con-  
significations, and in order that our present in-  
vest may be facilitated we for similar causes  
will adopt a plan approved; although disapproved

it by some who whom the mass of brain has not been  
 considered individually. The cause and symptoms of  
 these have been modified and magnified to so great  
 an extent by nearly every one who has attempted the  
 subject; that it is less a source of astonishment than  
 of mortified feeling, why so much yet remains undis-  
 covered. We will now proceed to a description by ob-  
 serving an arrangement which to us appears, plausible  
 as well systematic.

Those species have been denominated the Catarrhal,  
 the Apothematous, and the Tuberculous. In every  
 modification of Phthisis, the symptoms have  
 been referred to three heads — the Pneumonic or Pul-  
 monary symptoms, the symptoms of  hectic fever &  
 the supervening or what has been termed consequent  
symptoms. We will briefly commence by describing  
 the Pneumonic symptoms as occurring in Catarrhal Phthisis

Cold is looked upon as being the great source and cause of all Catarrhal diseases; this modification of Pathology may be approached with that same undeviating train of symptoms which characterize this class of disease. After the more violent Pneumonic symptoms shall have subsided, others of a more distressing character are said to develop themselves, and first "Dyspnea" which may be described as being one of the most prominent features of incipient Pleuritis this peculiar disagreeable and troublesome cough we find much aggravated when in the recumbent posture, at the same time we do not find it wanting for disagreeable sensation with in any other position. After this the effusion of the ven shall have proceeded with an almost irreparable devastation, others, of an equally alarming character follow up the declining scene. Dyspnoea - sense of soreness in the Thoracic region -

and with these attend an expectoration which is in  
a yellow aspect disagreeable taste, and  
small: occasionally, indolence in food is complained of  
the matter expectorated thick and of blood stain by  
discerning men to be an indication of a scrofulous di-  
athesis. Upon this latter clause it remains not for the  
inexperienced to animadvert, suffice it to say that  
the medical opinions of medical men should al-  
ways be open to impartial investigation, as well as a  
scrutiny and if erroneous or inconsistent with medi-  
cal philosophy, talent, and experience, and as being  
unfounded, it becomes to controvert. We regret that  
it is not in our power to dwell here extensively on  
this as we conceive to be important points;  
the confined limits of a inaugural dissertation to-  
gether with the reflection, of not being in a  
uninteresting to the gentleman who has  
has should an consideration of the

to put it by in a box or in a casket, or in a similar arrangement.

Another variety has been described as being the Pneumonic Symptoms occurring in Spontaneous Phthisis.

This variety has been described also as being much less frequent than former, its symptoms more prominently characterized and its result a more fruitful source of lamentable contemplation.

Spontaneous Phthisis is a consequence upon a large abscess, formed within the cavity of the thorax; the former has been described as being ushered in with cough, and other catarrhal symptoms and as being a consequence upon atmospheric vicissitudes: whilst the spontaneous or the stage we are about to describe would be by those who advocate the theory of the disease being a con-

course in such a large number of cases and in  
 all cases with great uniformity in all parts of  
 the Province, than the most obvious and  
 explanatory cause; we do not consider that  
 any important mistake can result from this  
 or distinction, but we do endeavor to take  
 into consideration whether such diseases  
 they are supposed to be the exciting causes of  
 the Pulmonitis or what plausibility would make  
 them appear to be many necessary conditions.  
 Upon this point much of a speculating nature  
 has been involved in, which has not only been  
 a labor, to render intricate what might otherwise  
 have been considered simple and to some  
 still more intricate and complicated subjects.

seen as the most frequent cause in cases where the  
 disease goes to the lungs. Dr. Cullen has written a number of  
 subjects with a view to the treatment of the disease. It is  
 not to be considered as the same as the disease which is  
 usually produced in the lungs by the action of the  
 - that afflicts the variety of *Pithecis Pul-*  
*monalis* does, or commences with a spilling of blood  
 no one pretends to deny; but it would be equally ration-  
 al and equally justifiable to place *Pithecis* itself  
 under the genus *Cholera*, because it has also frequent  
 precursory symptoms *nausea* and *vomiting*. *Vomica*  
 may then be considered as a consequence of *Chol-*  
*era*, or as a spilling of blood from *Pulmonaria*,  
 predisposition. It would though emanating from the  
 lungs, be to be considered as the same as the

of this variety of disease, Inflammation of the Lungs, as well as external thoracic injuries deserve a conspicuous place in this of all most afflicting tragedies. Pain, Dyspnoea, and other pathological symptoms attendant upon the incipient stage of Asthma are said to be comparatively speaking inconsiderable, in this state of things severe fits of coughing will frequently supervene attended with but little expectoration; and in this point consists the first diagnosis between catarrhal and asthmatic Phthisis. We had intended dwelling more at length upon this variety of the disease, but when we find Philosophical sages here drop their pen, surely, it must be an indication of their having reached a "ne plus ultra" point.

a point not to be transcended by the inexperienced  
however in practice. We come now to a descrip-  
tion of the most frequent as well as most  
dangerous of all the species of Phthisis.

The Pneumonic symptoms attendant upon these  
tuberculous Phthisis approach in many respects  
the variety just described it would there-  
fore be superfluous to recapitulate what  
has already been said. Tuberculous Phthisis  
in consequence of its arising from the greatest  
variety of exciting causes, is of course of most  
frequent occurrence. But however numerous  
and varied those exciting may be all of them  
operate as giving rise to this variety or mod-  
ification of Phthisis, or one general principle,

ly. resembling those peculiar to the variety which has been found in the lungs of patients who have died in this stage of P<sup>h</sup>th<sup>is</sup>is: the symptoms attendant upon this variety of the disease are comparatively speaking inconsiderable, in the incipient stage cough and other Pneumonic symptoms are by no means urgent, and in most cases no remarkable pain of breast attends, and when it does it is neither fixed or constant; and contrary to what happens in Acute Catarrhs of P<sup>h</sup>th<sup>is</sup>is the patient can lie with equal facility on either side. Most frequently the matter expectorated in this stage of the disease is a thin watery fluid slightly tinged with

blood, it has been described as having <sup>very</sup> much that appearance of sanies which is often discharged from seropulcous sores. When this state of expectation takes place "Ecthi fever" is seldom wanting to a considerable degree.

Much contrivety of opinion as regards the pathology of "Ecthi" has been entertained by some of the most enlightened of the profession. After viewing strictly the different theories advanced upon this subject we are inclined to consider that which arises from a certain irritable state of the system induced by an absorption of pus to be the most probable as well as plausible conjecture.

The hectic fever is very generally not of the continued form - but consisting of remissions and exacerbations; and from this circumstance it has been justly described as being a variety of Intermittent.

All that is necessary to mention in this state of things is the description of Pulse attendant upon hectic fever, which in most instances is seldom observed to be under 100 and frequently above 120 strokes in the minute. In some instances of hectic the pulse is full and hard; but more frequently small and hard during the paroxysm as well as intermission. After this distressing symptom shall have been observed for some time, other s

of essentially alarming character make the  
 bearing, they have been termed the "subacute"  
 and then again they have been considered as  
 sequelae of "Ectetic." It is doubtful in our minds  
 whether they can be considered strictly sand-  
 ing either; they may be perhaps like Ectetic  
 symptomatic of the progress of the disease  
 from an absorption of ill-conditioned matter  
 from the Lungs, the probability is though that  
 if not induced they are at least much ex-  
 gravated by the Ectetic fever.

A picture in itself less than the 'tis now we ap-  
 proach with a feeling on the brain full than a  
 consciousness of our indelicacy to do right.

The main source is in instances more strikingly ex-  
 emplified than in the one which now presents itself to  
 our consideration, and the one which now it is our  
 province to describe. After all the foregoing dis-  
 tressing symptoms, we all have more than appear-  
 ance upon the stage of humanity, a number of  
 usually conspicuous terminate the trigical scene.  
 Emaciation in waiting, has been partly numbered  
 amongst the prominent Pathognomies, of experi-  
 ment *Sarcina vulgaris*, and in no part of the  
 system is this symptom more obvious than on  
 the face, hence, it has been termed the "Face  
 Hippocrates" in short the whole system becomes  
 completely reduced that it has ever presented

to be as it were a single kind. With nu-  
erical apertures, into both the top and mouth, which is the most frequent and is rate into the conditioned uses. These apertures and consequent alterations are particularly seen in the botanical stomach, when the expec-  
toration is considerable, and in place of the absence of mild food, the dis-  
charge has been evacuated into an obscured state. This affection is seen in the mouth.  
As some have written, and probably not the best reason, to the action of the expectoration in the mouth. To the same cause, acting for other parts of the alimentary canal, especially

in the... and... another...  
 very common and... the...  
 race, as well as...  
 secrets. With these is the...  
 time, and the... it is...  
 surprising, that the...  
 state should in almost every case...  
 termination. Having thus...  
 the causes, and symptoms of...  
 now proceed to a part of our subject, which  
 we promise shall neither be tedious...  
 which has been said about the treatment  
 of this disease, and as in every other...  
 it is our province to remove... as is practi-

cable and as soon as is practicable, all exciting causes; and thus it must be an object with the practitioner, to counteract, as far as is practicable the consequences of purulent absorption. The means of affecting this consent must, in the different species, be accommodated to the nature of that particular source from whence the purulence is furnished.

In the Catarrhal Phthisis the source of that purulent matter which produces the symptoms is a mere inflamed surface; hence, our first indication of cure is to diminish that impetu. with which the blood passes through the systemic but more particularly

the pulmonary circulation, a termination of this impetus may be obtained in different ways. The second indication requiring to be fulfilled in the cure of this variety of the disease, is the restoration of a natural condition to the vessels of the lungs, and with a view of fulfilling this indication, much more is to be derived from regimen than from medicines, and particularly from gentle exercise, pure air, and a mild nutritious diet. In the treatment of asthmatic Phthisis much cannot be said, and we regret much that the same words are applicable, to the third and last or that stage termed Tubercular Phthisis. Near-

By all of these means, however, the medicinal  
 articles in the treatment of P. this S. disease  
 possessed by them as specified in the disease, we  
 must content ourselves by briefly mentioning those  
 which have mostly excited the attention of the  
 medical world.

We had occasion before to remark that  
 different means had been employed for the  
 purpose of lessening the size of the heart and  
 arteries, and for this purpose the Digitalis  
 of Dr. Beddoes has not held an obscure rank,  
 but to speak in the words of an illustrious  
 Potter like its author has sunk or has to  
 no more, this remedy we conceive to be not

is dangerous in its effects, but inefficient in its  
consequences, it should therefore deservedly  
be abandoned from the catalogue of medi-  
cines employed in the treatment of *Tuberculis*  
*Pulmonalis*. As the article the deleterious  
effects of which upon the animal economy  
stands unrivalled within the cover of ra-  
tional medicine, has excited attention in no  
small degree from the notices of the heal-  
ing art; and notwithstanding the train of pecu-  
sive symptoms, necessarily consequent upon its  
administration, says worn out in the shafts  
of professional prosecution, says whose emine-

and whose immortality, has strengthened with  
their strength, are given with the quantity; and  
placed it as a curative in a superlative degree.

M. Guy Lussac says he has constant-  
ly found that the Glysteramic-acid adminis-  
tered to the unhealed consumptive, not only  
arrests the pain, but diminished frequency  
cough, moderated and rendered more easy  
expectoration, and lastly procured the patient  
sleep at night, without any colliquative sweats;  
he goes on still further to state, that those  
who are accustomed to follow the march &  
progress of Phthisis and witness the suffering  
without number of these individuals attacked

by this terrible malady and by which they are overpowered, will easily appreciate the benefit of this practice. Some inquiries have been cavilled upon the article, by men equally eminent, and perhaps equally aspiring. With regard to the employment of Emetics in this disease: they have been mentioned as being in all probability serviceable, when not given in large or frequent repeated doses, of this class of medicines Sert: Aurt: has been selected as being most serviceable. All the class of Emmetics have been employed and as Purgatives are considered to be very appropriate remedies. Another important remedy yet remains to be

treated of; the administration of Calomel, partic-  
 ularly in the insamitory form of the disease,  
 which we view as being the only form that can  
 be cured, has acquired celebrity in a degree of  
 no small consequence. Bloodletting in conjunc-  
 tion with the last mentioned remedy appear  
 to be means placed in our hands by which we  
 are to guard from inevitable destruction my-  
 riads of the human family.

With those crude and undigested remarks we  
 close, soliciting from the generous donor a  
 perusal of the same, and reminding him that  
 upon our part it has been a matter of compulsion  
 and not of choice.

Yellow fever

271

This is a disease apparently of modern origin. It has apparently been introduced into the West Indies, but it has not been described by any of the Ancients with even a tolerable degree of accuracy. To Dr. Meade of Philadelphia is justly due the credit of having first called the attention of the Physicians to this interesting subject. Dr. Meade has given the fullest and best account of this disease. Since the engraving of Dr. Meade into the Travels it has been noticed by many authors most of whom have at least given a distinct appellation to the disease, of

have advanced nothing new  
 with regard to its Pathology. Dr Scott  
 of Edinburgh has called it Asimina  
genua, from the difficulty of the  
 thing which consistently attends the  
 disease. By Dr. Russel it has been termed  
Angina Proclamatoria. Grants & of  
 other names have been given to it; by  
 one, it is called Catarrhus suboculorum  
 by another. Morison Strom, Gulerow  
 and by a third Cyananche & Leucanthe  
 But of all its names that which may  
 seem to be the most proper is Asimina  
 to me most proper. The Asimina  
 the Asimina mostly attacks children  
 between the fourth and seventh years  
 of their age, & is completely immunitary  
 from the disease is however being  
 seen by me age. Adults are much less  
 liable to attacks of this formidable  
 malady than infants. This seems to  
 be owing to the "alteration" to some  
 alteration which the structure undergoes  
 about the age of Puberty. & It is  
 the disease generally appears in a  
 sporadic form, yet it sometimes

25

prevail, as an epidemic, as was  
lamentably case in Virginia in the  
year 1789, when the Father of our  
Country fell a victim to it.

It is not my intention in this essay  
to enquire concerning the exact nature  
of opinion which exists among  
Medical men, with regard to the  
Pathology of the Disease. It is generally  
supposed to be an inflammation of the  
Mucous Membrane lining the Intes-  
tines, from which it is often exten-  
ded to the Muscles surrounding the  
Rectum; the case however is sometimes  
reversed, the disease commencing in  
the Muscles, and travelling downwards.

In the latter instance it must be  
confessed that some degree of spas-  
modic contraction of the Muscles  
will occur; such however is the  
situation and office of these Mus-  
cles that a complete closure of  
the Rectum cannot be effected.

This disease generally arises from  
improper exposure to cold or damp  
Atmosphere. Those persons who are  
exposed to great vicissitudes of the

27

we then are much more liable to the disease, than they who reside in Countries uniformly cold and it is on this account that Cases of <sup>the</sup> <sup>2d</sup> <sup>sort</sup> are most generally met with in the United States during the winter & spring. The violent cases will produce the disease in those Children who have once had an attack of it in such constitutions a common Catarrh will almost invariably be followed by the Croup. It is however a fortunate circumstance that second attacks of the disease are seldom so violent as the first, they nevertheless require the utmost caution on the part of the Physician.

Trachelytis, has been thought by some very eminent Physicians to be a contagious disease even the acute <sup>of</sup> Gregory seems inclined to adopt this opinion there are however so far as I have been able to learn no evidences of the fact there is on the contrary every reason to believe that the disease is not contagious. The same cause which produced it in one kind of a family may give rise

to it, in another; and if we admit  
the contagious character of Typhoid,  
we must extend the doctrine so as  
to include all those diseases con-  
sequent upon the application  
of cold to the Body. But will any  
that individual be found who will  
assert that Catarrhs, Pneumonia or  
Rheumatism are contagious diseases?  
The same cause evidently producing  
all these diseases, and no reason can  
be assigned why any one of them  
is contagious, and the others not.  
But whilst I deny the contagious  
character of this disease, I am  
willing to admit, that it may  
be founded on Hereditary Pre-  
disposition. Dr Pater asserts that  
it is as certain an hereditary dis-  
ease, as Gout or Phtisis. I shall  
not attempt to discuss this question  
as it is one which can only be  
decided by experience, but shall  
proceed to enumerate some of  
the most common symptoms of  
the disease. Some days previous to  
to an attack of the disease the child

appear inactive and so that the upper  
 dull and heavy - symptoms of Catarrh  
 succeed, a hoarse and attended with a  
 peculiar shrill and ringing sound  
 in speaking and some times, which  
 has been happily compared to the  
 rattling of a small bag or to that  
 that has been supposed to resemble  
 the noise from a Brazier Tube (Chil-  
 inep sometimes attends the first stage  
 of the disease, a rumbling about  
 the throat, a great difficulty of in-  
 athing, a commixture with a whizz-  
 ing sound in inspiration, the  
 cough is commonly dry but if  
 anything is spit out it is generally  
 a purulent matter, sometimes how-  
 ever slim are discharged, resem-  
 bling portions of a membrane  
 together with these symptoms  
 the pulse is hard and frequent  
 the patient is restless and complains  
 of an extremely uneasy sense of  
 heat. The External Tissues on the  
 examination sometimes exhibit no  
 appearance of Inflammation.

most frequently however a simple  
 and slow motion is observed. It  
 is remarkable that the natural dimen-  
 sions as well as those of the Brain  
 are seldom much disturbed. Phil-  
 ides are often seen running about  
 taking their food, indulging in  
 the amusements peculiar to their  
 age, and pursuing in good health  
 their habits, in reality the disease is  
 rapidly advancing. if its progress  
 be not dramatically checked all the  
 symptoms soon become much ex-  
 aggerated the respiration is the  
 more laborious, the cough dif-  
 ficult and troublesome, and ex-  
 pectorations more difficult  
 and in a few hours suffocation closes  
 the scene.

The duration of the disease  
 depends generally upon the violence  
 and the means which have been em-  
 ployed for its cure; when medical  
 aid has been resorted to,  
 it is almost frequently terminated  
 fatally in about 24 or 36 hours

273

It is all important, that the alarming symptoms should be moderated, the being the first twelve hours of the disease; unless this can be effected the patient generally dies soon after 48 hours by the efforts of nature or by the assistance of art. The state between from what has been called the second stage of the disease, the convalescence is various, tedious and attended with expectoration of purulent or membranous matter. In milder cases when the breathing is less difficult in the commencement, about the second day the skin becomes moist, the fever abates, the cough is less troublesome, and the voice gradually recovers its natural tone.

A peculiar morbid appearance is observable in the examinations of those who have died of this disease - a membrane or tube of coagulable lymph, is found lining the whole extent of the trachea descending even to the bifurcation of the bronchia. Dr. Pallet says this body is found not only through out the bronchial ramifications

at least about many of their extreme  
 ramifications into the smallest vessels  
 as was beautifully illustrated in a sub-  
 ject prepared by the Dr for the demon-  
 stration of the late Professor Wilson  
 Philadelpia. This contains the Dr  
 in a section from the inflamed re-  
 sets of the part, and in all connect-  
 ing from the smallest change from  
 health to the secretory process perfect-  
 ly formed in inflammation. The  
 direction of the more compact form  
 to which the appellation of membrane  
 has been given seems to be the fibrine  
 of the Blood semi-organized. Al-  
 tho' this membrane is generally found  
 in the Trachea of those who have  
 died of Croup, still it is not to be  
 considered either a constant or  
 necessary part of the disease. Dr  
 Gregory has observed that its for-  
 mation is always indicated by the  
 manner in which the child breath-  
 es - throwing the head back so  
 as to put the Trachea on the stretch.

With regard to the treatment of this  
 disease there seems to be some diversity

the most honourable medical men. A  
 doctrinal distinction has been made by  
 one which is of no practical impor-  
 tance. Is there be such a thing at all  
 as a primary spasmodic Croup, it must  
 invariably depend upon an Inflamma-  
 tion of the muscles of the glottis, and  
 therefore the same remedies are to  
 be employed in the first stage of  
 the disease, whether it be an inflam-  
 matory or spasmodic affection.

The Croup has been divided  
 into two stages; the first being that  
 of high inflammatory action. The  
 second is distinguished by the forma-  
 tion of that preternatural mem-  
 brane already spoken of. In the  
 first stage it should be our ob-  
 ject to subdue Inflammation  
 by all the means in our power and  
 thereby prevent the formation of that  
 membrane which blocks up the pas-  
 sage of air into the Lungs, inducing  
 suffocation and consequently death.  
 To accomplish this first indication  
 the most powerful antiphlogistic  
 remedies should be promptly em-

employed - our chief reliance is to be  
 placed in general and Local Bleeding  
 emetics, the warm bath, and purgatives  
 if however we do not succeed in  
 relieving the first stage of the disease,  
 it then becomes our duty to endeavor  
 to promote expectoration, and  
 to support the strength of the system,  
 which is generally much weak-  
 ened by the previous depletion  
 measures. For the purpose of an-  
 relieving these indications recourse  
 may be had to to squills, Camphor  
 Gum, and other Loric medicines  
 an occasional emetic may also be  
 exhibited and as a last resort  
 Bronchotomy - not recommended

I shall now say a word or two  
 with regard to the particular reme-  
 dies which have been recommended  
 for the cure of this disease, and  
 first of Blood-letting. This in my  
 humble opinion is our chief Anchor  
 it is never injurious, it may have  
 ever some times be unnecessary  
 In the milder form of the disease  
 where there is not much inflam-

243

ator's action, an Emetic will often  
surpass the necessity, for the em-  
ployment of any other remedy. One  
bleeding in the first stage of the  
disease is of more importance  
than half a dozen afterwards.

Emetics are always necessary and  
should never be omitted. For this  
purpose the calar Emetic or Spasac  
wankes may be employed. If  
however after being given in very  
large doses they fail to produce  
the desired effect, the Emetic  
Sublimata may be resorted to  
with the greatest advantage. <sup>the exhibition of</sup> mal  
and repeated doses of Calomel from  
the commencement of the  
disease, has been strongly recom-  
mended. <sup>"</sup> This practice <sup>"</sup> is  
in whose skill and experience  
have an almost unlimited con-  
ference <sup>"</sup> is rather calculated to  
injure the reputation of the  
medicine than to cure the pa-  
tient - it should be given in doses  
so large as to shock most of the

mid Practitioners of the present day  
who are deterred from employing this  
valuable remedy to any useful extent  
by the fear of salivating their Patients  
Dr. Waller says there is but little danger  
of producing a severe Phlogism by  
Calomel in this disease. he has seen  
but one case out of several hundred  
in which no one of these remedies should  
be used as in violent cases to the  
exclusion of the others. Bloodletting  
being promised a judicious com-  
bination of Calomel & Tartar Emlic  
will generally cure the Patient.  
Warm bath should be abstained of the  
location of Water to the throat has  
been recommended - its propriety is  
to me that the correlation of the  
phlogism, may sometimes extend to  
the inflamed membrane, and  
consequently aggravate the dis-  
ease. The decoction of Polygala  
Seneca has been lately introduced  
into the practice as a remedy for  
this disease by Dr. Strober of Maryland.  
It is my opinion too stimu-  
lating to be of any advantage in

27

the first stage of the disease. We have  
in the initial stage, as in those, have  
us in a great or the solidity - ~~to~~ em-  
ployment will <sup>generally</sup> ~~be~~ <sup>be</sup> ~~all~~ <sup>all</sup> ~~of~~  
with the most beneficial results. It  
unnecessary for me to say any thing with  
regard to the other medicines which  
have been recommended in this disease. At  
the first stage they ~~may be~~ ~~of~~ ~~any~~ ~~use~~  
must be ~~of~~ ~~use~~ ~~but~~ they  
may be useful. Bronchotomy is al-  
together inadvisable in Oropus, as this  
simple reason, that we are unable then  
to remove the membrane which is  
the cause of the obstruction - and besides  
it prevents us from employing other me-  
dics -

An Inaugural Dissertation  
ON  
Pulmonary Consumption.

Submitted to the Consideration  
of the  
Provost, Professors and Trustees  
in the  
University of Maryland  
for the degree of  
Doctor of Medicine  
by  
Bennett Bussey  
of  
Maryland.

1828.

Pulmonary Consumption is a disease, concerning which  
 a great number of opinions have been given, and even at the present  
 day Physicians widely differ with regard to its pathology;  
 some contend that the disease never appears without the pres-  
 ence of tubercles in the lungs, while others say that Pulmonary  
 Consumption can exist independent of a scrophulous pec-  
 -disposition,

As it would be not only tedious but also useless, to attempt  
 an elaborate discussion of a subject, which probably may never  
 be decided, I will merely submit my opinions with regard to the  
 real nature of the disease, in which the principal symptoms  
 are mentioned, and the remedies which appear to be most effectual.  
 By the term Pulmonary Consumption, I mean, simply, that dis-  
 ease, which is the consequence of Tubercles, seated in the  
 serous connecting membrane of the lungs. Whether or not this  
 term could be properly applied to other diseases of the lungs  
 it is not for me to decide, but merely for the sake of preci-  
 sion, I am disposed to think, that the peculiar wasting of  
 the body, and of the lungs, caused by the inflammation and suppu-  
 ration of tubercles seated in the lungs, alone deserves the  
 name of Pulmonary Consumption.

Those who have tubercles in the lungs are evidently of the  
 Strumous Temperament, and it still remains to be proved

whether or not tubercles have formed in the lungs without any hereditary disposition to them.

The Mucous Imperiument appears under two modifications, the one is found in those who have naturally pale skins, loose flabby fibres and a sluggish pulse; The other in those who have ruddy complexions, firmer fibres and a brisk circulation. And in both modifications there is an unusual irritability of the capillary arteries;

In children we can generally determine whether or not they are predisposed to Plethoria by the smooth and easy appearance of their cheeks, their fair hair and delicate blue eyes; The forehead is generally prominent, and it is remarked that the lips of scrophulous children are tumid;

As the child advances in years we perceive the maturing of different glands of the body, which as the patient progresses in age progress in growth; and I am disposed to think that almost all of those diseases which we hear spoken of as affecting different points, are no more, merely than the effects of Scrophula;

As the general character of Scrophula is well known I will not long dwell upon them, but proceed to describe its appearance in the form of tubercles in any condition;

This disease seldom appears before the age of puberty. It is usually excited by causes which produce Inflammations. The patient complains of a weight or uneasiness in the chest, this sensation is attended by a cough which is generally dry, short and tickling, then appears to be considerable excitement, and the face is usually flushed.

The pulse is frequent and sometimes tense. As the disease progresses, the pain in the chest becomes more acute and often extends to one shoulder.

The cough becomes more troublesome, and at length the expectoration comes on. The lips of the patient are generally peculiarly florid.

At this stage of the disease the tie symptoms are more apparent, the patient is harassed with evening, fore and night sweats. These symptoms continue till the pus is formed by the suppuration of the tubercle in the lung, and has been expectorated, which in the early part of life will be accomplished in a short time.

The patient is then considerably relieved for that period and has few if any more or a warning symptoms, until the same process of Inflammation and suppuration comes on.

The patient however is not entirely relieved from the symptoms; some cough and fever still remain—

As the patient still advances in life, the general health becomes more impaired, from the repeated struggles which he has pursued, and his whole system becomes reduced & grows long continued hectic fever: Nights are spent without repose, and each returning day presenting the same or a worse condition of his system, renders life almost a burden;

In the forming stage of Pulmonary Consumption, we have many remedies which exert a very beneficial influence, in warding off the disease, but when Pthrosis becomes confirmed very little can be accomplished, by the Physicians. In the forming stage or before inflammation of the tubercles has progressed in any considerable degree, Bloodletting is a remedy of inestimable value, Digitalis has been used with the same view but it has been observed that the injurious effects of Digitalis often precede its good effects; and I would suppose that in every case of Consumption the lancet will accomplish every object which could be expected from Digitalis: Blood should be drawn in small quantities, and the operation should be frequently repeated. Thus are many cases of Pthrosis in which Mercury given with precaution, exerts the most salutary effects; Cases in the forming stages, which are not attended with considerable action, have often been prevented from terminating in suppuration, by using

the Blue pill so as slightly to effect the gums.

Those who are predisposed to Pulmonary Consumption, should be very cautious in their dress. Flannel should be worn next the skin in winter, by all, and in summer also, by the more delicate. It preserves the equilibrium of temperature, and prevents the system from being injured by every change of weather. As our climate is so very precarious, it is my opinion, that this prescription should by no means be neglected.

Another important prescription, is Exercise; The Consumptive patient, in clear weather, should take exercise freely, particularly in the mornings, it gives tone to the digestive organs, and invigorates the whole system.

Attention should be paid to regimen and diet. The patient should take animal food in moderation, and it should be the principal article of food. All irritating and indigestible articles should be avoided.

Blisters or petons are almost indispensable in the prosecution of this disease. A discharge from the surface should constantly be promoted by either a blister or a peton.

The Cold Bath has also been highly recommended by some Physicians - and - But the most effectual means for preventing this disease is a removal to a warm climate, and to a climate which is free

From many vicissitudes of weather,

These are the principal means which are used for the prevention of this disease. When Consumption becomes confirmed, as I before observed, very little can be done by the Physicians.

However we have some medicines which afford some relief. Opium is generally freely used in the latter stages of Consumption. When the patient passes nights without sleep, has great irritability, and is harassed by a continual cough, I am of opinion that Morphia might be given with great advantage as it possesses all the sedative but none of the stimulative qualities of Opium. This also will answer every purpose for which Pepsic acid has been given;

When the Colliquative sweats are copious, the Balsam of Perilla given as a Purotic generally lessens the sweat.

As I intended merely to make some general remarks on this disease, I will end, after mentioning some diseases which may be mistaken for Pulmonary Consumption, and mentioning some differences which distinguish them, from True Phthisis.—

Ulcerations in the Trachea has often been mistaken for Pulmonary Consumption. This often arises from an insidious inflammation. It is attended with a tickling cough, the voice is slightly

changed, and uneasiness is experienced in some part of the  
 Trachea, the breathing is sometimes oppressive, and there is  
 generally slow increasing Fever. Inflammation of the adjacent  
 parts also very often exists at the same time; In the first stage  
 of this affection Mucus and Lymph are expectorated, but  
 as soon as ulceration takes place the Sputa are mixed with  
 pus. After this disease may have continued for some length  
 of time fever is manifested but it is not attended with the  
 copious night sweats which characterize the True Plectid.  
 When inflammation of the Trachea becomes chronic, soreness  
 is felt by pressing on the Trachea, which sensation is not  
 experienced in Pulmonary Consumption.

Chronic Inflammation of the Bronchiae is another disease  
 which may be mistaken for Consumption, It at first assum-  
 -bles a common Catarrh, but by the increasing Fever, and dur-  
 -ation of the disease we are made sensible of its nature.  
 When it has progressed so far as to make an abscess in  
 the lungs themselves it is very difficult to distinguish it  
 from Tubercular Consumption, In the first stage it may be  
 distinguished by the wheezing and Catarrhal character of the  
 disease and by the patient not wasting flesh and strength  
 as always happens in Tubercular Consumption; The face

103

from the onset appears a sickly palidity, and the lips are of a leaden hue, whereas in Tubercular Consumption the face is alternately pale and flushed and the lips are beautifully tinged with a bright red.

When the more acute forms of Pleurisy have been put down, an obscure kind of increased action is often left which <sup>sometimes</sup> ~~it~~ becomes chronic, this however may arise without being preceded by acute Inflammation, the patient has slow fever at night and has oppression in the chest: There is occasional cough, which is most troublesome in the morning. Tenderness will be felt in the integuments of the side affected, particularly if papiers be made. The disease progresses until dyspnea and emaciation are the two principal symptoms. In this stage it can be distinguished from Pthisis by the colour of the patients skin, and the difficulty of breathing which is increased by using the least exercise.

Chronic Inflammation of the lungs themselves has very often been mistaken for Tubercular Consumption, this disease in its progress bears a strong resemblance to Tubercular Consumption, but a history of the patients life preceding the attack, and by procuring a knowledge of the health of the patients predecessors, we can generally ascertain whether or not the latter disease exists,

guidance and fostering care

Charles F. Hughes

March 16<sup>th</sup> 1828.

Introduction

The many difficulties which present themselves to the mind of the writer, in selecting the subject of his <sup>own</sup> annual Essay, influence in a great degree his choice. It cannot however be expected that one who has neither age nor experience to support him, can produce anything new in relation to disease. — I shall therefore content myself by going as far as my limited abilities and time will enable me, a history of the causes, symptoms and treatment of the disease under consideration, known by the term Myxocephalus Stomatidis; Various cases on this subject in the following pages, it is my intention "safely to tread the beaten track;" and with this view shall quote the opinions advanced by Whistler, Quin, Rush & others.

### Hydrocephalus Internus.

The earliest correct description of this very interesting and too frequently fatal disease was, as well as the first information given to the world, by Whist, whose observations on it, were not published until the year 1768. This valuable author describes with great accuracy the cause and adonement of the disease.

Cullen in the edition of his nosology, published in 1785 recognizes this disease under the term Apoplexia Hydrocephalica.

Quin of Dublin, in his Inaugural dissertation published at Edinburgh, in 1779, and a subsequent Essay in 1790 describes Apoplexia Hydrocephalica with much more accuracy and propriety than at together, now as to its theory.

Rush, our celebrated countryman not long afterwards adopted a similar theory of the disease to that of Quin, & in his works, has given us a paper in which he maintains the inflammatory nature of Hydrocephalus Internus.

Whist in speaking of its proximate cause, seems to make it depend upon a loss of balance between exhalation and absorption; and indeed this was the opinion of the

1840

Faint, illegible handwritten text, likely bleed-through from the reverse side of the page.

1  
vincent as well as the morbid contents, are coming deposited in  
the tracts of the brain.

Diirij suggested the inflammatory nature of this disease in  
his Inaugural Essay, written in 1749, and in a treatise subse-  
quently, confirms this view of the disease, by additional observations  
and numerous cases of dissection.

The same opinion was adopted by Cuthbertson, Med. Essay Vol. 2  
page 193, about the same time, to which increasing weight is given  
by discoveries on dissection, shewing the fortunate issue of many  
cases treated by Antiphlogistic remedies.

The writer would venture to defend the opinions of the two  
last named authors, and for this purpose, he conceives it will  
be necessary, attentively to consider the causes of this disease, the  
symptoms and the mode of practice, which has been found  
most successful in treating it.

Hydrocephalus Internus, may, probably be divided into  
primary and secondary.

Cuthbertson enumerates the following causes "fall a blow upon  
the head, certain positions of the body and childish play,  
which tend to unaided congestion, inflammation and subsequen-  
tly an effusion of water in the brain."— Now we have every  
reason to conclude from these very valuable remarks, that  
fall, bruises a blow on the head, do produce inflammation

Faint, illegible handwriting on aged paper, possibly a letter or document. The text is mostly obscured by blurring and fading.

27

not only of the external integuments, but also the lining membrane of the Cranium; which too frequently terminate in suppuration and gangrene. The other direct causes mentioned by Rush to which may be added, especially the influence of the Sun and a reduced temperature, can scarcely be supposed to act in any other way than by increasing the quantity of blood in the vessels of the brain, and resulting in an inflammatory action in them. — The causes enumerated by Rush as acting indirectly in producing the disease under consideration, are surely fitted to produce an inflammatory or irritative disease; these are states, either of inflammation or irritation in other parts of the system; and when the disease is thus produced there is a mere translation of it, and not a change of morbid action; Surely, the membranes and the structure of the brain are different from that of other parts of the system, but then, they have not the power of producing an action in the vessels, sui generis. The effect of their operation, therefore, upon the brain must be an excitement of irritation or inflammation. These causes are, 1<sup>st</sup> Intermittents 2<sup>nd</sup> Remittent and continued fevers, 3<sup>rd</sup> Rheumatism, 4<sup>th</sup> Intussus Pulmonalis, 5<sup>th</sup> Eruptive fevers & Worms. —

Having briefly noticed the causes of this disease, I now propose next to take notice of the symptoms which attend it, and also of the appearances upon dissection after death, being further

proof of its inflammatory nature.

The symptoms of *Hydrocephalus Interius* as related by *Wright* appear to me to be as minute, at least, as any correct of those detailed by those who wrote subsequent to him, however, as the work of *Quin* is more modern and sufficiently correct, I will insert his description of the symptoms.

In general the patient is at first languid and inactive often drowsy and feverish, but at intervals, cheerful and apparently lively and free from any complaint. The appetite is bad, often nausea and vomiting occurs through the day, the skin not much dry towards evening. Soon after these symptoms appear, the patient is attacked with sharp headache, chiefly in the forehead, and if not there, in the crown of the head, it is sometimes however confined to the side or sides of the head, and in that case when the posture of the body is erect, the head often inclines to one side, particularly that side affected. This headache is also frequently accompanied with an affection of the stomach, the vomiting being more troublesome when the pain is less violent and vice versa.

The light is disagreeable to the patient at this period, he sleeps but little, and when he awakes, grinds his teeth, picks his nose, appears to be uneasy, often screaming as if greatly terrified. The bowels in a majority of cases

and much confined, though it sometimes happens, that they are in an opposite state. The pulse in this early stage does not indicate any material derangement.

When the symptoms above mentioned, have continued for a few days, subject as they always are in this disease to great fluctuation, the axis of one eye is generally found turned inward, to the nose, and the pupil upon that side rather more dilated than the other. And when both eyes have their axes turned inward, which sometimes happens, both pupils are observed to be larger than in health. The vomiting, becomes more constant, and the headache more excruciating. At this period every symptom of fever makes its appearance; the pulse is frequent, the breathing very quick and exacerbations of fever take place towards evening, the face occasionally flushes, usually one cheek more than the other, temporary perspiration breaks out, but does not alleviate the condition of the patient. Epistaxis takes place about this period, also delirium and that of the most violent kind, particularly if the patient has arrived at the age of puberty, which together with all the preceding symptoms of fever, continues for a while to increase, until about the fourteenth day, often a much shorter space of time shall have elapsed since the appearance of the symptoms which were first mentioned in the above detail.

37

The disease undergoes that change which, suddenly, points out the commencement of what has been termed the second stage. The pulse becomes slow, but unequal, both as to its strength and the interval between the pulsations. The pain of the head or whatever part of the body, had previously been affected, seems to abate, or at least the patient is less sensible to it, the interrupted slumbers or perpetual restlessness which prevailed during the earlier period of the disease are succeeded, by an almost total torpor, the strabismus and dilatation of the pupil increases, the patient lies with one or both eyes half closed, which, when minutely examined will be found almost completely insensible to light, the vomiting ceases, and whatever food or medicine is offered, is usually swallowed with apparent voracity, the bowels at this period generally remain obstinately costive.

"If every effort made by art fail to raise the sinking powers of life, the symptoms of what has been called the 2<sup>d</sup> stage are soon succeeded, by others which more certainly announce the approach of death. The pulse again becomes equal, but so weak and so quick, that it is almost impossible to enumerate it. A difficulty of breathing nearly resembling stertor or apnoeicus is often observed, sometimes the eyes are suffused with blood, the flushing of the face is more frequent than before, but of shorter duration, and followed

Faint, illegible handwriting on aged paper, possibly a letter or document. The text is too blurry to transcribe accurately.

by a deadly paleness; red blotches sometimes appear on the body  
or limbs, deglutition becomes difficult and convulsions general-  
ly close the scene.

The symptoms not less than the cause of  
Hydrocephalus Internus, demonstrate its inflammatory nature.  
The intolerance of light, the morbid sensibility of the auditory  
nerve, the delirium and flushings of the face can be explain-  
ed upon no other principle. —

One or two more points shall be noticed under this head  
in favour of the inflammatory nature of this disease; since  
first of the discoveries after dissection. — In relating to  
the evinces of purged action shewn by human dissection,  
especially when connected with a knowledge of the progress  
of the symptoms during the continuance of the disease, we may  
be considered as appealing to the highest source of information,  
with regards to the phenomena of diseases. Three particulars  
are to be noticed in attending to the appearances after  
death. — 1<sup>st</sup>. The thickening of the membranes of the brain  
the existance of inflammatory exudata, and the engorged &  
distended state of the blood vessels. The frequent occurrence  
of these things as consequences of inflammatory diseases of the  
Thorax and Abdomen, cannot or ought not to leave the  
least shadow of doubt with a candid and intelligent  
mind, that the same appearances of these kinds of

Handwritten text, likely a letter or document, written in cursive script. The text is extremely faint and illegible due to the quality of the scan. The page appears to be a single sheet of paper with horizontal lines, possibly a ledger or a notebook page. The handwriting is dense and fills most of the page.

Hydrocephalus arise from the same cause.

29

10

In speaking of the appearances on dissection of those who die of Phrenitis, a highly respectable author says "There is often a quantity of watery effusion into the ventricles" (When we compare these appearances, with those who have died of Hydrocephalus, we cannot help, I think, regarding this disease as a species of Phrenitis; (Wilson on febrile dis. abstr. 2 pag 96) The effusion into the joints which follows acute Rheumatism, & that which succeeds inflammation of the Pleura, Peritonaeum and other inflamed internal surfaces, would seem, at least to give countenance to the supposition that the fluid in Hydrocephalus is produced, by the same cause. — I admit that the analogy here presented does not unambiguously prove this to be the case, for by assuming this position, we must deny that Dropsical affections ever, do arise from any other cause than inflammation, which I am not prepared to do. — The thought just pointed at, leads to the consideration of the last particular, in relation to the appearances upon dissection; (34) which is the peculiarity of the fluid, viz, its refusal to coagulate by heat; and this property distinguishes it from ordinary Serum, and thus proves it to be a fluid thrown off from the circulating blood either, by secretion, or some equivalent process. Quercet Professor of the Theory and Practice has taught us that incoagulability, is a property belonging to Dropsical effusions

20  
11

into every cavity, and therefore infer that Dropsy, in whatever part of the body it may occur, is an inflammatory disease. In Quin's treatise (apparently I call it so), there is an instance of fluid formed in the brain being coagulated by heat; With the exception of this single case, I neither know nor ever heard of any circumstance to oppose the general doctrine.

This property of in-coagulability, as before mentioned distinguishes it very pointedly from serum. It is a charged fluid, and from the symptoms of the disease, of which it is an immediate consequence, we have sufficient reason to believe that it is the result of inflammatory action. This theory of the inflammatory nature of the disease under consideration, receives additional confirmation from the condition and temperament of the subject whom it most frequently attacks. It is, says Fothergill vol. 1 page 71, a disease, that happens, so far as I have had an opportunity of observing, more commonly to lively, healthy active children in whom of course acute diseases rather than of a low active, or debilitated may be supposed to prevail. The next point to be noticed according to the arrangement of this treatise, will be the means of cure, which have been found most effectual in the treatment of Hydrocephalus Intermittens. However, before entering upon this part of my subject, I will say a few words relative to a prevention of this fatal disease.

The means of prevention may be classed under two general heads, each embracing many particulars, too numerous to be related here. The first general means of prevention is, avoiding all the direct causes which tend to excite the disease. Second, by endeavouring to remove as speedily and effectually as possible, all those diseases which act as, main causes, in producing it. — The first head of precaution, may be addressed to the nurse, or the patient, if the disease is not confined to children alone; and the second more properly is addressed to the Physician.

Having premised these reflections on the preventive method, I will now return to the consideration of the remedies which have been found most useful.

The first means to be noticed is bloodletting. Another exhibit another most decisive proof of the consistency of the theory adopted in this treatise. Venesection, though recognized by Quin in his list of remedies, was unfortunately but seldom resorted to by him, if we may be permitted to draw any conclusion from the cases, reported to have been treated by him. In seven cases, successfully treated by our celebrated Quin, venesection was practised more or less in every case. This course should be adopted in the early part of the disease, and should be frequently repeated, always taking care to consult the pulse. Bloodletting from the

13

Regular, pain has been recommended by some, this however has its disadvantages. Blood drawn from the arm, in a proper manner, will reduce the general excitement as effectually and equally as quick as if taken away from any other part. —

Local Bloodletting, I conceive to be of great advantage — The great importance of this will be very evident, for while general bloodletting only reduces the force of the circulation, local bloodletting tends to relieve the distended and engorged state of the vessels of the part affected; which state is not only the cause of the effusion so much to be dreaded, but also acts as the cause of excitement of the general system. — The second remedy is Blestems. — There has been and still is much diversity of opinion relative to the modus Operandi of blisters among Medical writers and practitioners. That they act as a stimulus to the part applied as well as generally, cannot be denied; A secondary, tho' not less important, is the abstraction of a portion of the more fluid part of the blood. Rush says they are proper in every stage of Symplicus Intermittens. In the early part of this disease their application should be preceded by general bleeding; and it is proper to keep up the discharge from the blistered surface for a short time, the better to secure your aim; and for this purpose the Ungt. Epispast. may be used to great advantage. Leech and Issues have been recommended by some, but in my

249  
14

since they are too slow in their operation for a disease of this nature.

Cathartics, are the third class of remedies to be noticed. They should be assiduously employed from the commencement. And the best agents for this purpose are, probably the cooling salts. They are more speedy in their operation, and seem to occasion larger watery discharges. A combination of sulph. sat. & tart. emetic. in a tubo: Calap. or Calap. ana. nitrate of tartar will be found very useful. Calomel is more readily recommended by all writers. When used, to procure a purgative effect, it should be combined with one or more of the above named remedies. In an advanced stage of the disease, Mercurial friction may be resorted to, but should not be depended upon alone. As the bowels are disposed to be torpid in this disease, much larger doses will be requisite, than under ordinary circumstances. Cold applications cannot be considered. - Cold water, vinegar and water, or powdered Ice put into a bladder, have all been found of much service in abstracting heat from the head. The application of Ether or other vapourizable fluids, by their sudden absorption of a large portion of caloric, are undoubtedly calculated to produce a good effect. The position of the patient is by no means an unimportant

301  
14

consideration. The head should be as much elevated as  
convenient; the room kept perfectly dark and very cool,  
much light being very injurious. All noise should be  
avoided in cases of morbid sensibility of hearing.

A premises in the introduction nothing original is  
introduced on my part. — In my humble opinion, however,  
the credit of first showing this to be an inflammatory disease  
belongs to Quin. This theory, plausible and defensible  
as it really is, would indeed merit but little estimation  
were it not that it leads to a system of practice, which  
experience has proven to be far more successful than  
any other which has been recommended. It is this cor-  
respondence between the theory and the results of practice  
which gives to the former, their only value.

By a course of strict investigation and close observation,  
Quin and Rush, have exhibited the true nature of the  
disease which has been the subject of this Essay; and  
they have instituted and recommended a course of practice  
which if attentively pursued, promises more than any  
other, to restrain the ravages of <sup>the</sup> Pyrexia helix Intermittens.

Handwritten text, likely a letter or document, written in cursive script. The text is extremely faint and illegible due to fading or low contrast. It appears to be a single page of writing on aged paper.

An  
Inaugural Dissertation  
On  
Hydrocephalus Internus  
By  
Edward H. Louder

For  
The Degree  
Of Doctor of Medicine

Maryland. March 15<sup>th</sup> 1828

701

Perhaps there is no disease in Nosology  
which is described, by such a variety of  
names, as the one which I have selected  
as the subject of my Inaugural Dissertation.  
Although we call Hydrocephalus a disease,  
it is more from the tyranny of custom  
than strict pathological accuracy; as the  
derivation of the term implies, it is a col-  
lection of a watery fluid ~~secreted~~ in some  
part of the brain, and is the effect of a  
slow chronic inflammation of that organ.  
It is described by Doctor Cullen under  
the title of serous apoplexy, but the  
fluid which is found in the brain of  
those who have died of this affection does  
not resemble serum, except in appearance,  
as it will not coagulate by heat or any  
chemical agent; therefore we cannot

with strict propriety, subscribe the ~~with~~  
 serous apoplexy; others again describe the  
 disease, as a chronic inflammation of the  
 brain, *Tumoris chronica vel subacuta*, this  
 appellation is more suitable than any  
 to the condition, in which the vessels are  
 in, at the time, the fluid is deposited  
 and is therefore, a more appropriate term  
 I think than any which has, as yet been  
 applied; Doctor Good in his excellent work  
 on the study of medicine; calls it *Cephalitis*  
*profunda*, what his object could have been  
 for adding *profunda*, I cannot conceive  
 otherwise than he intended that the water  
 secretion always commenced in the  
 ventricles, which are situated in the interior  
 of the Brain; if that was the Doctor's object  
 he is certainly correct, as that is the usual  
 situation of the incipient secretion.

311

the seat of the disease - cannot subscribe  
to his opinion, concerning the proximate  
the Doctor thinks, debility to be, the proximate  
cause of this, as of all other forms of dropsy,  
by debility. I understand a relaxation of the  
exhalents, and consequently an infiltration  
of the serous or thin ~~parts~~ parts of the blood  
through the patent mouths of the exhalents  
in this respect he does not differ from  
Doctor Cullen, except in the name of  
the affection, as both, perfectly, as to the  
nature of the fluid agree; there are some  
who suppose the proximate cause of all  
dropsies to be a debility of the absorbents  
and among the advocates of this theory  
Doctor Darwin was the most prominent  
who is deservedly more celebrated for his  
philosophical than medical productions

313  
It was at one <sup>time</sup> popular opinion, but which  
is no more, but another name for popular error,  
that this affection, was generally, intimately  
associated with a scrophulous matter of  
the general system, there are instances of congeni-  
tal Hydrocephalus, where a separation of the  
meningeal bones has taken place to an almost  
incredible distance, and children under  
such circumstances, have lived in apparent  
ease and comfort for several years.  
Such occurrences as these are sometimes supposed  
to depend upon, an hereditary scrophulous taint,  
but it is a subject as yet speculative, and  
would afford abundant materials, for the  
theoretic speculations of those, whose genius  
may unravel the mysterious and almost  
insoluble intricacies of its cause, such  
instances are comparatively rare, and general

71<sup>5</sup>  
come under the cognizance of the <sup>medical</sup> <sup>profession</sup>  
the few remaining advocates of the impropriety  
of the gastric pathology, think Hydrocephalus  
to be frequently connected with a  
disordered state of the chylificative viscera  
when this is the case the Brain is  
pre-disposed, and the congestion of the  
viscera, excites the action of the heart, and  
the Brain being the weakest part, it consequently  
must be the first to suffer and when it  
suffers, the vessels in a regular manner  
deposit the fluid in the ventricles. The presence  
of worms in the intestinal canal, occasionally  
give rise to symptoms of Hydrocephalus  
but such symptoms are speedily removed by  
the exhibition of proper Anthelmintic  
medicines. our illustrious countryman Doctor  
Rush who is deservedly acknowledged, to have

written on of the best chapters, on his nervous  
 on sly droopness, that has ever been presented  
 to the medical world. I think, that in the  
 very highly acute form of Phrenitis, the inflamma<sup>m</sup>  
 tion is so great, as to transcend the pro  
 of secretion, as is frequently the case in croup  
 trachealis, and hence the term croup  
 The Doctor thinks that the vessels of the Brain  
 are in a condition, intermediate between that  
 of spoplexy, and the high inflamma<sup>m</sup> stage  
 of Phrenitis, consequently they are labouring under  
 chronic inflamma<sup>m</sup>tion, a condition which is  
 certainly the most favourable for that secret  
 y process which takes place, at the time the  
 fluid is deposited. now if we impartially take  
 into consideration the causes which operate  
 on the <sup>brain</sup> in producing this disease and the  
 nature of the fluid, which is deposited

317

we must certainly view Hydrocephalus to be the  
effect of a chronic inflammation <sup>m</sup> in the  
vessels, & some the junction of several, & as  
it has frequently been observed, when it  
evolves, permanent lameness, the greater  
source of error in the treatment of this disease  
with many Practitioners was in considering  
it a disease of debility; but the great oppo-  
nent languor and debility which attends  
those labouring under it, is always partially  
removed by bloodletting, &ally as much blood  
can be frequently abstracted in such cases  
as in gastritis where the pulse is not the  
surest and most infallible criterion before  
bloodletting, we cannot for a moment suppose  
that it is debility which induces the patient  
to complain in a low muttering <sup>tone</sup> of his  
head, debility would not in the first instance

cause the pupil to contract, and the <sup>321</sup> retina <sup>to be</sup> morbidly sensible to light; as the disease advances, and the pressure on the Brain increases, the origin of the nerves must be equally affected and deprived of their usual energy and power. The pupil then dilates, and the retina is capable of bearing a stronger light. From the records of medicine, and personal observation, it would appear, that this disease was in some families constitutional; the regions of the Brain in those persons so affected, I imagine are in a very excitable state, and the first exciting cause, which is applied induces them to take on a secretory action as this disease is always in my opinion produced by the vesical causes of inflammation; and most frequently succeeds

those inflammatory foci which have not been  
properly treated by bloodletting, and the  
antiphlogistic remedies, where there is a  
determination to the head. I am confident  
I do not stand alone, in considering  
chronic inflammation, as exclusively its  
proximate cause, and in considering  
the disease as the effects of inflammation  
I shall adopt a course of treatment  
entirely antiphlogistic, as the  
means which I think is generally  
according to the views I have taken and the  
theory I have adopted of its cause.

Although the absorbents are never primarily  
affected, in the incipient stages of dropsy  
they are concerned in its cure and that  
actively, from the circumstance of taking  
up the fluid which is deposited, and

327  
and removing it from the system by the  
different humours and from the circumstance  
of the doubt, which has, for a long time agitated  
the votaries of medical science, as to the presence  
of absorbents in the Brain, this formidable  
affection has been looked upon as an incurable  
disease, although, the diligent and  
persevering Anatomist has failed to prove  
the existence of lymphatics in the Brain  
by ocular demonstration. Nevertheless can  
we for a moment doubt their existence  
we certainly admit, the Brain, the sup-  
posed seat of all our intellectual opera-  
tions, to be <sup>an</sup> organized body, and as such it  
must be endowed with lymphatics.

But we have a stronger proof than this  
in favour of our position; have we not both  
read and heard of large portions of Bra

being removed, and what other secret  
 could there have been, except - it was  
 through the medium of the Lymphatic  
 system; then if large portions of disor-  
 ganized Brain could <sup>be</sup> removed and  
 without the least detriment to the  
 Patient, surely, the watery secretion can  
 be, which very much disturbs the general  
 health; our object, should then be in the  
 first place to lessen the action of the  
 and thereby, put a check to this secretory  
 action which is going on in the vessels  
 of the Brain, which is most promptly  
 and effectually done by the lancelet, - we should  
 not be intimidated at or hindered by the delirium  
 which the patient is apparently almost  
 overcome to with, such symptoms usually arise from  
 compression of the Brain from other causes

329

such as a threatened loss, and situations  
of matter - within the encephalon,  
because we cannot draw ten or twelve ounces  
of blood from a child labouring under this  
disease, we should not, on that account  
refuse to draw any; how many valuable  
lives have been rescued from the confines of  
the grave, by the abstraction of four or five  
ounces of blood, by a judicious practitioner.  
If we turn our attention to the state of the  
circulation, we will generally find it to be  
in that condition, which imperiously deman-  
ds the use of the lancet; we should not  
be deterred in small pulses provided they be  
hard and tense, from drawing blood  
particularly in cephalic affections, as they  
almost invariably improve after the operation  
has been performed; after the exhibition

has been carried to its proper extent, & mes-  
 sion natured, arises than we no auxiliaries,  
 to it; I would answer - in the affirmative  
 Colonel from its well known power of  
 promoting <sup>excretion</sup> would be an excellent adju-  
 vant in the treatment of this formida-  
 ble affection, especially when it is carried  
 to that extent as to affect the salivary  
 glands; more have recovered from this disease  
 under a salivary premises or in some  
 operations by the lancet, than under any  
 other mode of treatment; issues to 4 times

affection

A Dissertation on  
Pneumonia

Submitted to the

Professors and Trustees of the  
University of Maryland

For the degree of Doctor of Physic

By Leander W. Goldsborough

of Frederick City Md.

March 15<sup>th</sup> 1828

To Dr Charles H. Goldsborough  
This essay is affectionately inscribed  
as a testimonial of gratitude for  
his care and attention whilst super-  
intending the authors advancement  
to professional life.

Introduction. The difficulty of writing without experience and the hazard of attempting subjects about which there exists great diversity of opinion is sufficient to make every one cautious in selecting the subject of his inaugural thesis. Influenced by these considerations we have fixed upon a disease which although pretty well understood is still supposed of sufficient interest to require the attention of physicians. As to originality we claim none, none can be expected, all we wish to do and all we shall attempt is to treat the disease as it has been treated and to point out what we shall presume to consider as errors too generally received.

# Pneumonia.

341

Pneumonia derived from *pneumon* a lung is a genus of disease in the class *pyrexia* and order *plegmasia* of Dr Cullen. Under this title he comprehends "the whole of the inflammations affecting either the viscera of the thorax or the membrane lining the interior surface of that cavity." This is certainly the most judicious plan of treating the matter, for had he attempted to distinguish between the varieties of different authors he must have failed, but if he had succeeded, what advantages would have resulted from it? In a practical point of view none. The rapidity with which inflammation of the serous membranes spread is itself sufficient to upset the

notion of giving names in this disease derived from the part supposed to be affected. As to the term Peripneumony although some may doubt the existence of such a case, it is more than probable that it frequently occurs, and is always characterized by greater violence than the inflammation of the pleura. But as we cannot always distinguish the one from the other and as perhaps in neither case is the inflammation exclusively confined to either the substance of the lungs or their investing membrane the word might be abolished; or if retained, retained only to express a more violent pneumonia.

*Symptoms.* This disease comes on with occasional chills and flushes of heat, accompa-  
nied

with the usual disagreeable sensations ushering in all febrile affections. The patient becomes restless, the pulse quick and the skin, hotter naturally warm. He begins to cough and complains of pain in some part of the thorax.

These symptoms continue to increase the skin becomes hot, the pulse quick strong hard and full. The cough which at first was moist is now dry and excessively painful.

The breathing is difficult and irregular in consequence of the pain being increased by a full inspiration. which (the pain) is now completely developed. It is not always fixed, sometimes it is felt in one part of the thorax and sometimes in another. It is generally more severe on one side, frequently the right

but as often on the left, in either case the patient cannot lie well on the side affected.

As in all violent inflammations the secretions are ~~are~~ checked, the tongue is furred and the urine high-coloured. Having detailed the symptoms as well as I could we shall proceed to say a few words about the

Causes. This disease most frequently happens in persons of vigorous constitutions, and those who are much exposed to the vicissitudes of weather.

It most frequently happens in the spring though it may occur at any season of the year and to all ages sexes and conditions. Cold applied to the body in some form or other is univer-

sally admitted as the most frequent remote cause, though it may arise from others as excess

exertion of the lungs, drinking cold water when warm and perspiring is mentioned in Johnson's journal as having caused the disease.

Terminations. The most frequent termination of pneumonia is by resolution this may be known by the gradual manner in which the pulse is restored to its natural standard at the same time that the cough pain and difficulty of breathing subside with the return of the different secretions. Suppuration is another termination of this disease; the tendency to which may be ascertained by the pulse becoming softer and more frequent if the patient being affected with slight chilly sensations with a pale and anxious countenance. The pain is less acute and

51

when together with these symptoms or rather as they advance, the difficulty of breathing continues the pain subsides or is remarkably dull and obscure with a weighty sensation in the side we may generally infer the existence of matter. Other terminations of pneumonia are shewn of as gangrene which is very rare.

A much more frequent when it ends fatally is effusion of blood and serum into the bronchia and cellular texture of the lungs producing suffocation.

Treatment. The first step in the treatment consists in copious bloodletting. This is the most powerful means we have of reducing the excitement equalising the circulation and preparing the system for other remedies.

By drawing off a sufficiency of the circulating fluid we prevent many ill consequences ~~too~~

253

frequently the result of a protracted pneumonia.

Besides all these advantages it relieves immediately the violent pain which the patient suffers, relaxes the surface of the body, promotes expectoration and the operation of sweating medicines, the advantages of which you cannot always profit by unless preceded by bleeding. Some writers talk much about the cautious use of the lancet in this disease, they tell us that we should be governed by the age constitution and condition of the patient, that the quantity necessary to be taken from one man would sink another &c. Now the fact of the business is that although we admit in part the correctness of this reasoning we see that as a general rule the pulse is the only criterion by which we are to be governed; every body knows that an old man will not bear the loss of as much blood as a young

ne, neither is as much required for the very reason that he does not so rapidly redeem it. So long as the pulse is hard and the pain and difficulty of breathing continues we must bleed.

The blood should be drawn from a large orifice in order that a decided impression be made at once. The physician should keep his fingers upon the pulse and not be satisfied until it is reduced below the natural standard. If it be the first or second bleeding and the pulse very high and bounding he should carry it to the extent of inducing sickness or fainting, for in this disease as in all inflammatory cases the pulse will rise and become more irresistible unless you at once adopt decisive measures. Generally two such attacks with the lancet will be sufficient to bring the

ase under the controul of milder measures and as  
 pneumonia is sometimes cured by expectorants and  
 diaphoretics we shall proceed to some remarks  
 about them - And first of - Digitalis. This  
 article has been employed by Dr Barton and  
 others with a view to its expectorant and seda-  
 tive effects. We should certainly not expect  
 much advantage from it as an expectorant  
 it has not we believe answered the purpose  
 of physicians generally, besides the theory  
 & its operation is perhaps more obscure  
 than that of any other article of the class.  
 As to its power of controuling the action of  
 the arterial system I've know nothing, never  
 having it used the difficulty however of  
 regulating the dose and the admitted supe-  
 riority of other means are sufficient reasons  
 for abandoning its use. The best expectorant  
 undoubtedly is antimony. This may be given

77  
a combination with Nitre in the dose of a  
quarter of a grain of the former with eight or  
ten of the latter every two hours or so. Antimony  
is said by some to be beneficial by its sedative  
qualities independant of its nauseating effects.

That this artical acts directly as a sedative  
is a new idea, it may be correct, though  
we believe we have seen it injurious in  
high inflammatory fevers where its appli-  
cation had not been premised by bleeding.

If in the advanced stage of the disease  
there is still pain with a difficulty of ~~breath~~  
~~restoration~~ and a weak pulse, one or two grains of  
camphor added to each of the above powder  
will be of great service, especially if aided  
by the action of a blister. After sufficiently  
reducing vascular action some gentler ~~are~~  
in the habit of giving antimony alone in tepid  
water so as to produce copious diaphoresis

34

if not to obtain some emetic effect. This is said to be an excellent practice though perhaps alternate doses of nitre would be an improvement.

In the low stage of pneumonia hinted at in the preceding sentence Dr Potter states that there is a diminished susceptibility in the nerves of the lungs and bronchia and recommends mercury though he says that squills, seneka and the balsam have been given with great benefit. The Eupatorium Perfoliatum has proved highly serviceable in this typhoid condition of the system. So also is the Asclepias Tuberosa, given ~~in~~ as Dr Thacher recommends in the form of a strong infusion. That physician states that it possesses "the peculiar and almost specific quality of acting on the organs of respiration, powerfully promoting the suppressed expectoration and thereby relieving the breathing of pleuritic patients in the most advanced stage of the disease". Inhalations are said to be good in pulmonic affections the

Handwritten text, likely bleed-through from the reverse side of the page. The text is extremely faint and illegible due to the quality of the scan and the nature of the bleed-through. It appears to be a continuous paragraph of text.

363

am of hot water, vinegar and of the decoctions of Chamomile flowers are mostly used in pneumonia after the violence of the inflammatory action has abated. While the patient is under the use of these medicines he should drink freely of flaxseed tea, barley water and solutions of Gum-Arabac. In the last stage of the disease when the cough continues with but little pain and no fever, a mixture of Gum-Arabac, Tinct Opium and liquorice in warm water is a very admirable preparation. The temperature of the patients room should be carefully regulated. Dr Cullen says it should never exceed 60 degrees of Fahrenheit's thermometer. His diet must also be attended to. It should be of the lightest and most digestible kind, His drinks should be acidulated and moderately warm, and finally the whole of the antiphlogistic regimen ought to be rigorously enforced. We now come to speak of blisters in

The handwriting is extremely faint and illegible. The text appears to be a series of lines, possibly a list or a set of instructions, but the specific words and numbers are not discernible. The page is aged and yellowed.

365

is disease. They are in a few cases unnecessary though  
much oftener indispensable, particularly when the  
patient is much weakened by morbid action before the  
physician sees him, in which case it is not always  
possible to draw a sufficiency of blood to supersede  
their use. They should never be applied when there  
is much action, but after two or three bleedings they  
answer every indication. A fine large one should  
be applied immediately over the seat of the pain  
and suffered to remain on twelve hours. By  
the proper use of blisters we frequently prevent  
chronic coughs and other dangerous affections of  
the thoracic viscera. We shall now conclude  
with a few remarks on the use of Cathartics.

Almost all writers agree that medicines of this description  
will not answer in thoracic affections. The utility of keeping  
the bowels regularly open with cooling laxatives is agreed  
upon by all. Perhaps they might be carried to a  
greater extent. We think we have seen purging  
profitably induced in the first stage of the disease

361

the manifest advantage, the expectoration was very little  
any diminished. But the truth is, in this stage of  
the disease the expectoration is always ~~is always~~  
leaving whether you use purgatives or not. As we  
know of nothing to which we can refer this circumstance  
less it be excess of action, why not use this most pow-  
erful auxiliary to bloodletting until we have suffi-  
ciently lowered the tone of the pulse to trust the  
ure to other means? However we are not very  
tenacious upon the subject, we merely propose the  
question, with a hope that we shall some day or  
other be better able to judge after a more extensive  
examination of that best of all books Experience.

To

Doctor M. H. Blendinen,

This Dissertation, is  
respectfully inscrib'd;

1  
Dissertation  
on the  
Atmosphere

Since the days of the alchemists it is well known that the science of Chemistry has been considered in a new light and as subservient to various valuable and usefull purposes to mankind in general. The minds of the learned and scientific devoted with the beauty and importance of its resources entered into the field of research with unmitigated ardours and the recent improved state of the Science tell us what they realize.

In the period between the years 1777, 1787 a new mine of experimental research which promises the most curious and interesting results had been opened out first by the genius of Dr. Black and already pursued with much sagacity and industry by Dr. Priestly. But it was Lavoisier of France one of the most celebrated chemical philosophers of his time; a man whose views were far above any pecuniary considerations who succeeded the former gentlemen in their particular views, and who devoted the last days of his life in experimental research that bled the most in literature in that branch of Chemistry; of which we are about

to make some brief remarks. We allude now to the discovery of the properties of certain aeriform substances, gases, or (as they have been called) gaseous airs. They are bodies which Chemists have called elementary or bodies which are not in the present state of Chemical science considered as compounds. They are bodies which have never been isolated they have been found only in combination with other bodies, and which had hitherto escaped the attention of Chemical inquirers.

After having said thus much as a preliminary introduction to the after part of our dissertation; we will remark that it is our purpose to make some general observations on the atmosphere or the common air which surrounds our globe. As it would be very proper we think and for the better understanding of the subject we shall proceed analytically, and first with

### Oxygen.

This elementary body forty or fifty years ago was unknown to the scientific world; it fortunately happened however to P. Priestley in the year 1774, when going through the experiment of heating the red powder which was called the precipitate red &c; but now more properly called by the name of the red oxide of mercury; in a glass vessel; a quantity of air was driven off from the powder while the mer-

375

-any resumed its metallic form, he collected this air  
in a convenient vessel and examined it; he found it  
possessed of certain properties different from the at-  
mosphere and in one respect he said it was much  
surer than the common air; he called it from the  
theory of the time *dephlogisticated Air*.

Wolfe a Swedish Chemist shortly afterwards  
discovered this same gas without any previous  
knowledge of Priestley's discovery; he called it  
*Impure Air*; it was also called *Vital Air*  
by some. Soon after this P.<sup>r</sup> Priestley com-  
municated his experiment to M. Lavoisier who  
with great ardour investigated the truth of Priest-  
ley's experiments; and from his investigations and  
observations are we indebted for the explanation  
of various phenomena: Lavoisier showed  
that the mercurial precipitate per se, or being  
heated in a retort, and the retort being adapted  
to the pneumatic trough the mouth of which  
terminated under a gas bottle filled with wa-  
ter; that an air passed over from the retort  
into the gas bottle, which was rendered evident  
by the displacement of the water in the vessels  
and also a very important change had been  
effected in the red powder, which was variously  
seen noticed by Priestley which was that it  
had resumed its metallic lustre and brilliancy  
and consequently was no longer a red powder  
but in fact running mercury. But the non-

- Her ~~did~~ not end here; the ingenuity and curiosity  
 of the able Chemist led him to examine the  
 air which he had collected: he did so, and  
 found that it was an air highly respirable  
 and ~~had~~ <sup>possessed</sup> combustion in an eminent  
 degree: or on putting a lighted candle or  
 any other burning body in a jar of the air  
 it burnt with increased brilliancy and force.  
 We called it Oxygen gas: Oxygen in combin-  
 -ation with the matter of heat or Caloric, for  
 we do not speak of the gas in the abstract  
 but in combination with a principle for  
 which it had a great tendency to combine  
 and to pass into a gaseous state.

This gas can be procured in a variety of dif-  
 ferent ways and from a variety of substances.

1. From the black oxide of manganese heat-  
 -ed to ignition in an iron retort; or by mixing  
 the same powder with twice its weight of  
 Sulphuric acid in a glass retort and apply-  
 -ing the heat of a lamp; very pure Oxygen  
 Gas can be procured in this manner.
2. It can be obtained from Saltpetre; by  
 putting a quantity of this salt in a cast  
 glass retort and applying a red heat oxygen  
 gas is formed. But there are two objections  
 to this mode of preparation: for first the sub-  
 -stance which remains in the retort can never  
 without a great deal of trouble be got out.

579  
in another circumstance, is if you are not very  
carefull in pushing the operation at the end  
to obtain the greatest portion of gas, another  
substance will come over so as to render the  
gas so produced very impure. A great  
quantity of the gas is generated in this way  
for it is said one ounce of Salt yields 1200  
cubic inches of gas.

3. It may also be procured from the Ex-  
-mural of Potash a salt that yields it in  
great abundance; by heating it in a small  
glass vessel over an argand lamp. The gas  
obtained in this manner is much purer than  
that produced by any other process. These  
are the principal substances from which Ex-  
-xygen gas is obtained: but it can be obtained  
in a variety of other ways which it is not ne-  
-cessary to mention at this time. It should  
be observed that very oxygen gas is generated  
by immersing some green vegetables (such as  
the leaves of mint) in a vessel of water covered  
as a receiver to the rays of the sun; in a short  
time small bubbles will have collected over the  
surfaces of the leaves and subsequently rise through  
the water to the surface. -

The gas when produced by any of the above  
processes is inodorous, colourless and therefore  
transparent like the atmosphere; it is heavier  
than the atmosphere according to Sir H. Davy  
100 cubic inches at 60° Fahrenheit weigh 34 grs.  
All combustibles burn in oxygen gas with greatly

increased splendour or in other words it is eminent-  
ly a supporter of Combustion.

It was once supposed that Oxygen gas alone  
was necessary to combustion; but it has since  
been found out that other bodies beside Oxy-  
gen gas have an equal right to be con-  
sidered as supporters of Combustion.

Oxygen gas is very necessary for the support  
of animal life; without the use of this gas  
every breathing creature would cease to exist.

This gas when respired produces all the effects  
of a powerful stimulant; it at first increases  
the strength and vigour of the body producing  
a degree of burning heat in the lungs; after  
continuing to respire it for a long time the  
stimulus of the gas is more than the animal  
body can bear; Vertigo, Coma, Convulsions  
and Death eventually would be the consequence  
no doubt from the long continued respiration  
of this gas; yet it is a fact well known  
that a mouse, bird, or other small ani-  
mal will live four or five times longer in  
a vessel of Oxygen gas than in one filled  
with atmospheric Air of the same dimension.

But a circumstance of great moment and one  
of the highest importance to us, is the rela-  
tion which this gas bears to the function of  
respiration; for the perfect performance  
of which it seems necessary that Oxygen gas  
should be introduced into the lungs there to effect

a very important Change in the dark coloured venous blood so as to render it fit for the usefulness of the animal economy.

It appears that G. T. Priestly was the first of the modern Chemists who turned his attention to respiration and he concluded from his experiments that the blood as it passed through the lungs gave out phlogiston to the air which was expired loaded with that substance (and of consequence that the purpose of respiration was to free the blood of phlogiston).

According to Lavoisier the blood absorbs no air in the lungs but it gives out hydrogen and carbon which combining with the oxygen of the air inspired form water and carbonic acid. Now there has been an objection to this hypothesis of Lavoisier in as much as the quantity of Carbonic Acid formed is exactly equal to the bulk of the oxygen which disappears; therefore this oxygen must be changed into carbonic acid in the lungs for it is known that oxygen when changed into carbonic acid does not sensibly alter its bulk. From this it has been concluded by Dr. Thompson that the blood must emit Carbon and that to an extent of about 3/4ths of a pound in a day: this he considers is all that remains in the lungs; the watery vapour he allows is secreted from the blood to mix with the air expired;

385  
but probably the secretion takes place in appropriate organs. Then by the loss of Carbon Venous is changed into arterial blood.

Our distinguished professor of Chemistry Dr. De Balle with his usual ingenuity accounts for the phenomena in a different way.

From the doctor's view of the function of digestion &c. he concludes that the colour of venous blood is owing to a portion of the Carburet of iron and as it has been proved that the colour of arterial blood is dependent on a portion of the phosphate of iron it is reasonable to suppose that the object of respiration is to change venous into arterial blood for that purpose is the blood carried to the lungs from the right side of the heart loaded with Carburet of iron and also having in connection with it a quantity of free phosphoric acid; when this blood then arrives in the lungs it is exposed to the contact and action of atmospheric oxygen the moment the oxygen comes in contact with the venous blood it combines with the carbon which is expired in the state of Carbonic acid; the liberated air then finding free phosphoric acid (which is always found in venous blood) combines with it and in that state passes with the other ingredients constituting arterial blood into the left side of the heart.

Oxygen in combination with the metals form a class of substances called Oxides. Carbon, Sulphur, Phosphorus &c combine with ox-

- oxygen as to form a very interesting class of substances called acids; some of the metals are capable of combining with a very great proportion of oxygen - and thus forming not only oxides but acids.

From these circumstances, the v. ronian chemists considered oxygen as the only acidifying principle this is not the fact for in the progress of the science it has been found that there are other principles that are the cause of acidity in some cases without the interference of oxygen at all.

Oxygen is an essential constituent of atmospheric air, of water, of saline and earthy bodies; it is also a principle of animal and vegetable matter. From all this it would appear that the relations of this principle are more numerous than any other body knows.

### Nitrogen.

This gas had ~~been~~ been considered as an elementary aerial body until the time of Berzelius who with many experiments and theoretical calculations endeavoured to prove that it was a compound body composed of oxygen (and an unknown base for which he first proposes the name of Nitricum. This base however is considered by some and perhaps with great propriety as merely hypothetical and as it never

281  
has been produced in an insulated state Chemists  
cannot at present know any thing of its properties.  
A series of experiments to prove that nitrogen  
was a compound body had been got up, by Mr.  
Piers of London who precisely agrees with Ber-  
zelius in his views of the subject. Sir H. Davy's  
attention was next directed to the subject on the  
presumption that nitrogen was an oxide; which  
however was not attended with any better success  
than those of the former gentlemen. The gen-  
eral statement of the inquirers therefore have  
been found to lend no strength to the supposition  
that nitrogen like oxygen is any more than a  
simple elementary body according to the present  
state of chemical knowledge.

Nitrogen is said to have been discovered by D.<sup>r</sup>  
Rutherford in the year 1772. It was found  
that after separating all the oxygen of any  
quantity of the atmosphere that there rem-  
ained a gas which possessed peculiar  
properties and differed from oxygen gas  
or any other kind of gas which had hitherto  
been discovered. It was discovered that  
when a small animal was inclosed in a  
glass vessel containing common atmospheric-  
air and the vessel being stopp'd tight; that  
after a certain period the animal would die,  
and inserting the mouth of the vessel into wa-  
ter and then taking out the stopper; that  
the water would rise and occupy a certain  
portion of the vessel: the air that remained  
was examined; and it was found to be a gas

unfit for respiration or combustion; it was also found that fixed air was formed in this case. Now it is not to be supposed that all the air which was left was fixed air on the contrary there was comparatively but a very small quantity; for on reentering the globe of the fixed air by lime water it was found that just  $\frac{1}{5}$ th. of the certain portion of air had disappeared and that the remainder  $\frac{4}{5}$ ths. was that air which we have just mentioned as unfit for respiration or combustion: it was called azotic gas, azotes a name given it by Lavoisier from the circumstance of its not supporting animal life.

Now it is well known that there are various gases which are unfit for the support of animal life beside this one; for this reason the name Azote was dropped and the term Nitrogen has been substituted from the circumstances of its having been found to exist in a number of nitrous proportions.

Nitrogen gas may be procured though not absolutely pure yet sufficiently so for the purpose of exhibiting its general properties in either of the following manners.

1. Mix equal weights of iron filings and sulphur into a paste with water and place the mixture in proper vessel over water supported on a stand; then invert over it a jar full of common air and allow this to stand exposed to the mixture for a

day or two. The air contained in the jar will gradually diminish as water appears from the ascent of the water within the jar till at last only about  $\frac{4}{5}$ ths. of its original bulk will remain. The vessel containing the iron and sulphur must next be removed by withdrawing it through the water, and the remaining air may be made the subject of experiment.

2. By burning phosphorus in a glass jar containing common air the phosphorus will combine with the oxygen and form phosphoric acid which will fill the jar with dense white fumes, after a short time these fumes will be condensed and the remaining air will be tolerably pure nitrogen.

3. Nitrogen gas can also be procured from the lean part of flesh meats, put into a glass retort the lean of beef cut into small pieces and pour on it very dilute nitric acid then connect the retort with the pneumatic tub and apply a heat of  $100^{\circ}$  gas will be disengaged and is collected in the gas bottle.

This gas as well as oxygen is not absorbed or not in any very appreciable quantity by water. It is lighter than the atmosphere 100 cubic inches according to air H. weighs at  $60^{\circ}$  Fahrenheit's weight 27.3 grains, consequently it is also lighter than oxygen gas. It is not a supporter of animal life for, it immediately proves fatal to animals that are confined in it. It is also a non-supporter of combustion for it immediately extinguishes all burning bodies when they are

*[The text on this page is extremely faint and illegible due to the quality of the scan. It appears to be a handwritten document with several paragraphs.]*

immersed in a jar containing it.

Nitrogen is susceptible of combination with various bodies and the compounds possess in many instances remarkable properties.

In the proportions of your parts of nitrogen with one of oxygen it composes a mixture resembling the atmosphere in all its properties: for it can be respired with safety for any length of time by an animal and burning bodies burn in it as in the atmosphere.

In combination with different proportions of oxygen it forms nitrous and nitric acids. It is also essential to animal matter; from the putrefactive decomposition of animal matters nitrogen and another elementary principle hydrogen are evolved; they combine and form the Volatile Alkali or ammonia.

Nitrogen in combination with Carbon forms a carburet of nitrogen or Cyanogen which combined is the base of the Hydro Cyanic acid (Cyanogen in combination with hydrogen) or Prussic acid as it is still called which is well known as one of the most violent of the vegetable poisons.

Although nitrogen is a necessary constituent of animal matter yet it appears to form a very small ingredient indeed as an ultimate principle of vegetable matter.

From this it appears that nitrogen bears great relations to other

947  
bodies and is little inferior to oxygen in point of importance in the great theatre of scientific pursuit.

## The Atmosphere.

It appears then from the facts stated in the preceding pages that the atmosphere is a compound or mixture of two different gases.

It is to Dr Scheele that we are indebted for the fact that the atmosphere is a compound: or it is well known that to his time it was considered as an elementary body: Fire, air, earth and water being considered as four elements. Yet it had come to pass even before the present day that those bodies that ~~had~~ were once considered as elementary have been ranked as compound bodies and on the contrary those that were once considered as compound bodies are now placed among the simple elementary bodies.

This celebrated and illustrious Chemist Dr Scheele in the course of some experiments after he had found out oxygen gas had reason to infer that the atmosphere was not a simple body. He took a glass bottle with the bottom ground and he placed it on the shelf of the pneumatic tub and in this way repeated in places a small quantity of

Faint, illegible text at the top of the page, possibly a header or title.

Third paragraph of faint, illegible text.

399

of the substance called Sulphuret of Potash; it was supported on a stand above the surface of the water of the trough in the Vessel. After letting it remain in this situation for a time he found that a portion of the air in the vessel was taken away & the water in the pneumatic tub had risen to a certain height in the vessel. On after this took out the Sulphuret of Potash and examined it he found that it was no longer a Sulphuret of Potash but a Sulphate of Potash: Potash containing Sulphuric acid. Dr Scheele found in this experiment that just 1/10th of the air which was originally contained in the vessel had disappeared and the remainder was no longer fit for respiration or Combustion.

The analysis of the atmosphere was most satisfactorily demonstrated by Lavoisier by the following experiment as explained in his Elements of Chemistry more enlarged. He took a glass vessel shaped like a matrass placed in it a small quantity of quicksilver and connected the superior part of the vessel with a right angular tube the one end of which being connected with the matrass and the other end with a gas bottle which was placed on the shelf of the pneumatic tub

He took care that the whole apparatus should be air tight and well adjusted in its place.

He then had a portion of mercury in the matrass and all the parts ~~occupied~~ of the apparatus except that occupied by the small portion of mercury was necessarily filled with the atmosphere. An argand's lamp was placed under the vessel containing the mercury and after keeping up a gentle heat for about 12 days he found that the mercury had suffered a considerable change, a part of it was no longer a shining fluid metal but was changed into a red powder; and also the water of the pneumatic tub had rose in the gas bottle and occupied a certain height in it. Lavoisier then examined the air which remained in the apparatus after the experiment and found that it was unfit for respiration or combustion. He next collected the red powder which was in the matrass and dissolved it in a retort by which operation the mercury was regenerated it appeared in fact in its original metallic state and an air was given out which being collected in a gas bottle and examined he found that it indicated the usual phenomena of supporting combustion respiration &c; and that it was the same gas which Dr Priestly had discovered, viz; oxygen gas.

These results then afford a the

Faint, illegible text, possibly bleed-through from the reverse side of the page. The text is arranged in several paragraphs and is mostly illegible due to fading and low contrast.

most satisfactory evidence that the atmosphere is composed of two distinct fluids. The one is capable of giving its base to mercury, and when separated is eminently adapted to the support of animal life and combustion; the other has no affinity for mercury and does not possess the other important qualities.

The object then of Lavoisier was to calculate the proportions which these two gases bore to each other; it was very easy to measure them and accordingly he did so. His report was that the atmosphere was composed of  $\frac{1}{5}$ th. oxygen gas and the other  $\frac{4}{5}$ th. of mephitic air. - But it appears that Lavoisier was not altogether correct in his calculations for according to the experiments of the best Chemists the atmosphere is now found to be composed of  $\frac{1}{5}$ th. of oxygen gas or 21 parts in the hundred and the remainder  $\frac{4}{5}$ th. or 79 parts in the hundred is azote or nitrogen gas as it is more properly called.

It would seem then that oxygen gas is the only ingredient on which the chemical effects of the atmosphere depends. Hence combustible bodies burn in the atmosphere only in consequence of the oxygen it contains and it is only adapted to support animal life from the same circumstance.

But as it has been before observed oxygen gas is not <sup>fit</sup> of itself for respira-

The first part of the book is devoted to a general  
introduction to the subject of the history of the  
United States. It is a very interesting and  
valuable work, and one which every student  
of the subject should read. The author has  
written in a clear and concise style, and  
has given a very full and complete account  
of the history of the United States from  
the first settlement to the present time.  
The book is well illustrated, and is  
very attractive in appearance. It is  
a very good book, and one which every  
student of the subject should read.

CHAPTER I

The first part of the book is devoted to a general  
introduction to the subject of the history of the  
United States. It is a very interesting and  
valuable work, and one which every student  
of the subject should read. The author has  
written in a clear and concise style, and  
has given a very full and complete account  
of the history of the United States from  
the first settlement to the present time.  
The book is well illustrated, and is  
very attractive in appearance. It is  
a very good book, and one which every  
student of the subject should read.

-tion and for this purpose is the negative principle nitrogen gas added to weaken the powerful effects of the oxygen gas or to dilute it as it were. -

The atmosphere (from aqueous, air and oxygen a globe) or the Common air as it is emphatically called is well known to be that diaphanous inodorous fluid which surrounds our globe. It is inferred to extend to the distance of 110 or 115 miles in height at the level of the ocean it is capable to sustain a column of water 35 feet high or one of mercury of the height of 30 inches and it presses with the weight of about 15 ~~inches~~ pounds on every square inch of surface. As we ascend the atmosphere decreases in density in geometrical proportion to equal ascents.

The weight of the atmosphere was ascertained with great care by Mr. Brande from a number of experiments at the Royal Institution he found that 100 cubic inches of air at a mean temperature and pressure of the thermometer and barometer to weigh only 30.199 grs.

The atmosphere acts a very important part in equalizing temperatures; the great body of air is always in constant motion; over the torrid zones it is expanded by the concentrated rays of the sun's it being expanded its specific gravity would be lessened and consequently it would rise to the superior regions and flow over towards the poles; while the air from the temperate and frigid zones would press forward to fill up

1848

...

...

...

...

the vacuum. This process still going on and the heated portions coming in contact with colder portions and with various parts of the earth's surface which may be hotter or colder is supposed to occasion the various currents of air which we meet with on the earth's surface. In this manner also are the different currents at the surface and at various depths of the ocean accounted for; the water of the other parts of the globe mixing with the tropical water. Thus we find a beautiful provision of nature for supporting a uniform temperature. The atmosphere then possesses all those properties which are eminently suited for the comfort and convenience of creation; a deprivation of this fluid would annihilate all nature; all the vegetable and animal creation would cease to exist; the sun would cease to send us cheerful and invigorating rays on earth, the moon would be blotted from the sight; all nature would pass into darkness and chaos would regain its pristine domain.

The air is accused as the cause of numerous diseases; and it really is so. Sudden cold shocking the perspiration will apparently produce almost every form of pyrexia. Partial cold will produce Rheumatism, Pneumonia, &c; Damp air, Catarrhs. The continued heat of summer occasion bilious disorders and

The first part of the document discusses the importance of maintaining accurate records of all transactions. It emphasizes that every entry should be clearly documented and supported by appropriate evidence. The text then moves on to describe the various methods used to collect and analyze data, highlighting the need for consistency and reliability in the process. It also touches upon the challenges faced in data collection and the strategies employed to overcome them. The final section concludes with a summary of the findings and a call to action for further research and improvement in the field.

the cold of winter a return of more serious inflammation.

The pure air we breathe is often charged with bodies foreign to our comfort and health. We allude to the infinite variety of adventitious bodies which are found floating or mixed as it were with the atmosphere. Every reading man knows whether high or low wet or dry the atmosphere is always in connection with various substances the principles of which are these and they are the only ones that we shall notice in this place.

1. Carbonic Acid.
2. Watery Vapour?
3. Principle of Infection; which last has occupied the attention of men for a long time and we shall endeavour to give it some share of our attention.

Carbonic Acid, is at all times present in the atmosphere and is estimated by Mr Dalton not to exceed one thousandth of its bulk. By Van Helmont it was called, gas sylvestro from being produced in vast quantities from burning Charcoal; from its apparatus acid properties, aerial acid; and Carbonic acid; and fixed air as readily losing its elasticity and fixing itself in many bodies. It is an invisible and permanently elastic fluid; superior in gravity to the common air and most other aerial fluids.

It consists of twenty eight parts of

Faint, illegible handwritten text, possibly bleed-through from the reverse side of the page.

Carbon and seventy-five of Oxygen and undoubtably with some Caloric. It is unfit for respiration; easily absorbed by water exceedingly destructive to animal life and produced in great quantities naturally from combustible bodies and many Chemical processes. It is found at the bottom of pits and caverns; near Naples there exists the famous Grotto del Cani which is constantly filled with it; it arises from fermenting liquors. It is heavier than the atmosphere 100 cubic inches according to Sir H. Davy at 60° Fahrenheit weigh 47.11 grains. This gas is powerfully antiseptic destroying the putrefactive decomposition. When introduced into the stomach it is agreeable and grateful and is administered with advantage in some disorders: but though it may be introduced into the stomach and intestines with good effect if breathed into the lungs it is mortal. In the respiration of animals comparatively a large quantity of Carbonic acid is formed; this results from the union of the Oxygen of the atmosphere with the carbon of the venous blood.

Plants absorb carbonic acid gas and evolve in their turn pure Oxygen which combining with azote may imperceptibly to our senses renovate the atmosphere. Thus nature very completely restores the various changes in the con-

*[The text on this page is extremely faint and illegible due to low contrast and blurring. It appears to be a handwritten document or letter.]*

- Situation of our atmosphere which the dif-  
- ferent processes constantly going on may  
in her regular course have occasioned.

Waters Vapour. That watery vapour exists  
in the atmosphere sometimes requires not the  
mind of a philosopher to prove. Every  
man of reason know very well that the  
atmosphere very often contains water in  
a state of Vapour - Now it has been found  
that the atmosphere contains watery Va-  
- pour at all times, at all seasons even in  
the coldest weather. It is well known that  
beside water; Camphor, Volatile Salt &c if  
placed exposed to the air will evaporate; &  
even if we view ice exposed to the air still  
a portion of it is lost by evaporation and  
we are told that the vapour produced in  
this way is different from that produced  
by boiling namely that it is not elus-  
- tive. This sort of evaporation is called spon-  
- taneous in order to distinguish it from that  
produced by more obvious sources of heat.

It is the opinion of Dr. Dalton that ma-  
- ter existing in the atmosphere constitutes a  
- distinct an independent atmosphere of its-  
- self; this opinion of Dalton's has been con-  
- sidered by many and perhaps with truth  
as very erroneous; for as Dr. Henry says it  
is certainly more reasonable to suppose that  
water whenever it exists as an elastic fluid  
rather distinct from or mixed with others, is

*[The text on this page is extremely faint and illegible. It appears to be a handwritten document or letter, possibly containing a list or a series of entries. The handwriting is cursive and difficult to decipher.]*

Maintained as such by me and the same cause viz, the Caloric which enters into it, and not by Chemical solution in any gas or mixture of gases. It is stated that the reason vapour is raised is that its specific gravity is less than that of water. The explanation which is now generally received is that of D. Hally's.

We compared the case to a solution of salt in water considering the air as the water and the vapour as the salt he still farther states in corroborations of his hypothesis that the collateral circumstances which favour solution are favourable to spontaneous evaporation; such as an increase of temperature, extent of surface, agitation, &c. After the philosophic world had received this explanation of D. Hally's a circumstance was remarked which threw over the whole. It was found by putting a cup of water on the plate of an air pump and exhausting all the air from the bell that evaporation would go on and to an extent greater in a given time than when placed in the open atmosphere the evaporation went on under the bell of the air pump until it was filled with vapour which put a stop to the farther evaporation of the fluid. This simple experiment then proves the inconsistency of D. Hally's supposition for in this case the collateral causes which he alludes to as assisting the evaporation in the open atmosphere could not have operated here and another thing

917  
to be attended to, was that in the experiment with the air pump the pressure of the atmosphere was taken off the surface of the water.

It is stated that water itself exists in the atmosphere in the form of small particles which are vesicular or little hollow globes.

Different portions of vapour are found at different altitudes and in different latitudes of the earth; in the torrid zones it is most abundant; in the temperate belts and in the frigid zones little less vapour is found in the atmosphere; the quantity is however governed very much by the seasons of the year.

In the torrid zones very little rain falls. Vegetation is supplied by the profuse dew which is formed in the night after the sun passes the horizon of these regions the same quantity of vapour is no longer kept suspended in atmosphere it consequently falls unobserved through the atmosphere to the ground in the form of dew and supplies the place of profuse rains which fall only in the temperate zones. In the northern part of the temperate and in the frigid zones the power of the sun not being strong enough to re-  
-pound the water in the form of vapour  
-condenses it which descends to the sur-  
-face of the earth through the atmosphere  
in the form of hail, frost, snow &c these  
are the products of varying nature pro-  
-duced by climate and change of season.

### Principle of Infection.

It was an object of great interest among the medical world in those days when the constitution of the atmosphere was first discovered to suppose that the cause of some peculiar diseases was owing to a too less quantity of oxygen in certain portions of the atmosphere; it was supposed that in high situations there was more oxygen than in low situations and especially in low marshy places there was a considerable less quantity of it. Now it was very natural for men to draw this inference, yet like the fate of all hypotheses it has to fall when opposed by facts. The Chemists turned their attention to this point and to prove whether the atmosphere suffered any deterioration in this respect they collected the air of marshy places; they took it from jails, from prison ships, and from every infectious place and examined it and yet they found the very same principles in the very same quantity always they could detect no loss of either the one or the other of the principles composing the atmosphere.

A very celebrated Chemical philosopher Gay Lussac ascended to a very great height in a balloon (and he took with him a glass jar filled with water; when he had arrived at a very great distance from the earth's surface he emptied it and immediately corked

42

it might be brought it down into him to his labor-  
-atory; he first examined the air of his labor-  
-atory that there might be no mistake and  
found that it contained the usual propor-  
-tions of the two ingredients, viz; oxygen  
and Nitrogen gases. He then examined  
the air which was contained in the glass  
jar and he found it to contain the usu-  
-al quantities to a fraction of a the gases  
which was in the air of his laboratory.

This then was proof enough to any  
honest minded man that the cause of  
an infectious disease was not to be attrib-  
-uted to a too great quantity of oxygen  
in the atmosphere in any given place.

But when this hypothetical notion  
had been put down by Chemical inves-  
-tigation; some who wished to explain  
the subject in a new way were bent to their  
imagination in bringing forth the ideal  
agency of the existence of inflammable-  
-air; Hydrogen; in the atmosphere as the  
cause of the insidious disease Yellow  
Fever we not ~~find~~ stop to refute this opin-  
-ion for it has been shown by Gay that  
hydrogen cannot exist alone for any length  
of time in the atmosphere without combining  
with it; and if this be the case and its all  
probability it is the case; it would soon be  
diffused equally throughout the whole at-  
-mosphere and therefore is deluded as to be

altogether innocuous.

It was the opinion of some that the existence of the nitrous acid vapour in the atmosphere was all the cause of the fatal and pestilential disease, yellow fever, and it was furthermore supposed that the exhilarating gas of Oary had some connection as the cause of a pestilential disease; yet from the experiments of Beddoes and Oary it cannot be supposed to exert any deleterious influence; on the contrary it has the effect of a cordial or invigorating remedy must be a depressing or debilitating effect. -

A very ingenious physician of the South Dr. Thout advanced the doctrine that the infectious disease yellow fever is dependent on the existence of an aerial fluid in the atmosphere in consequence of a derangement of the Electrical Equilibrium in the air. That when by the emanation of lightning the Electrical Equilibrium is restored it is impossible for the gaseous poison or yellow fever infection to exist in such a degree as to produce the epidemic yellow fever. In support of his doctrine the author adduces a number of facts as derived from the medical history and annual meteorological observations for South America. Like many

other reputed points in medical sciences authors for the most part speak delightfully as to the precise nature of the infection which produces fevers of various degrees of malignancy; we allude now principally to that fever which has received the name of yellow fever. - It is now settled by the majority of the learners of the medical world that the greatest quantity of this peculiar principle which has been designated Marsh miasmata arises from marshy grounds more or less impregnated with nitrous exhalations from the decomposition of vegetable substances.

Its activity in producing fevers is promoted by all those circumstances as increase the putrefactive decomposition and promote the exhalation of it; such as heat and moisture. When marshy grounds are at particular seasons of the year covered with water this prevents the miasma from rising in any considerable quantity and of consequence the diseases are fewer and less violent. But when from the great evaporation occasioned by a hot and dry summer; the ground is uncovered leaving it in a swampy state then aquatic plants, trees, &c; undergoing the vegetable decomposition, produce an exhalation which is highly

solitaneous.

Although authors appear to agree that marsh miasma is the most general cause of the epidemic yellow fever and give the most undeniable proofs of its effects; yet we are not to conclude marshes to be the only source of this miasma. For every place where there is vegetable matter combined with moisture and heat decomposition of the vegetable matter will necessarily take place and give rise to miasma which may be as prolific in producing its peculiar disease as that arising from a marsh.

From the preceding short view of the nature and origin of miasma it will appear that with the concurrence or absence of particular circumstances tending to increase or diminish its noxious power it must in different times and places exist with various degrees of strength.

Sometimes it is scarcely capable without the conjunction of other causes of producing fever; whilst at other times it may be of so noxious a nature as to affect the most robust in a short time after it has been received; and we can frequently observe intermediate degrees of its malignancy both with regard to the power of the noxious effluvia and also to the force

of the system, from habit, to resist their effects.

429

The manner in which miasma affects our system so as to prove the cause of disease is not clearly ascertained although physicians of the present day believe that it is taken in by the saliva swallowed and then taken into the stomachs or either by Respiration. Some are inclined to one opinion and some to the other. The first opinion that the infectious effluvia mixes with the saliva and afterwards gets into the stomach has been embraced by several physicians of great character and learning; and as a proof of this opinion they find by not swallowing their spittle when attending the diseased they are exempt from the disease;

This appears very plausible; but we never could in our mind be led to suppose that the first impression of the cause operated in this way; for in the very few instances that might be all'd<sup>d</sup> in proof of this hypothesis it may be referred to peculiarity of constitution &c and not to that of the miasma mixing with the saliva and afterwards getting into the stomach and there fermenting with the contents of the prima via and so causing an increased secretion of bile &c!

That of aspiration is more plausible the miasma is taken into the lungs during the act of inspiration it is consequently

bring into contact with the sentiments extrem-  
-ities of the period and there probably  
produce its peculiar impression as a cause  
producing the disease. By this view of the  
subject we think the phenomena of the dis-  
-ease can be more rationally accounted for.

It would require volumes to  
illustrate and examine the various points  
in dispute among medical men relative  
to this peculiar principle of infection  
as the cause of Yellow Fever we have said  
thus much on this part of the subject the  
rest we leave to those who have more time  
knowledge and experience;

Nale.

433

On the Hydrocele of the Tunica vaginalis Testis,

an Inaugural Dissertation,

submitted to,

The Faculty of Physic

of the

University of Maryland.

by

John Berry,

of Nashville Tennessee,

for the

Degree of Doctor of Medicine,

March 1823.

It is true Hydrocele applies to any watery tumour, but the subject of this essay is confined to that disease which is denominated the Hydrocele of the Tunica vaginalis Testis.

This is a disease from which no period of life is exempt. Not only adults but young children are frequently affected with it, and infants are sometimes born with a congenital Hydrocele. The earliest account of this species of Hydrocele was drawn up by M<sup>r</sup>. Biquerie a surgeon at Toulouse and communicated to the Academy of Surgeons at Paris. From numerous observations it is said to be much more frequent in Germany than in England. It is likewise remarked that this species of Hydrocele, is frequent and of long continuance in Jewish children.

The parts concerned in the Hydrocele of the vaginal tunic, are the following. The common bag in which both the testis are enclosed, called the scrotum, which consists of epidermis, skin, and that loose cellular membrane called the dartos, to which may be added the expanded fibres of the cremaster muscle.

The proper coats of the testicle are the tunica-

-albuginea, and tunica vaginalis. The former of these immediately invests the vascular portion of the testis, and is that coat which covers them while within the cavity of the ~~serotum~~, abdomen, before they descend into the scrotum.

The latter is spread ~~over the~~ <sup>over</sup> ~~the~~ <sup>the</sup> ~~of~~ <sup>of</sup> the said cavity and is a recess of the peritoneum, placed ready for the reception of <sup>the</sup> testicle, when it shall have passed down to its destined situation.

Between the vascular structure of the testicle and the tunica-albuginea there is no cavity, but the external surface of the gland is in every part adherent to, and connected ~~with~~ with, the internal side of the investing coat. The tunica vaginalis forms a hollow cavity or bag which is unconnected at the superior anterior and lateral parts of the testicle, being at the same time firmly united to it posteriorly ~~part~~, in such a manner, that if the cavity of the tunica vaginalis was to be distended with air, such air would occupy or fill the loose and unconnected part, and produce a tumour, not unlike hydrocele, while the testis would be found firmly attached to the hinder part of the distended cavity.

Mr. Pott supposed that whatever tends to increase the secretion of fluid into the cavity of that membrane beyond the due and necessary quantity, or to prevent its being taken up and carried off by the absorbent vessels, contributed to the production of this disease. Weysh entertained the opinion that Hydrocele might arise from a varicose ~~state~~ state of the spermatic veins. Mr. Ramsden conjectured, that it arose sometimes from an irritated state of the urethra.

This disease has been known to originate during an attack of rheumatism, Exposure to cold and the pressure of ill constructed trusses on the spermatic cord, has sometimes been alleged as the cause of this disease. It is also said to be of more frequent occurrence among soldiers and persons who ride much on horse back.

Dropsy in general and this disease often arises from an increased secretion of the arteries, or a diminished action of the absorbents; but dropsical swellings are

1862

Received of the Treasurer of the  
City of New York the sum of  
Twenty Dollars for the  
Year 1862

this 1st day of January 1862

John A. King

generally the result of an increased secretion from the  
arteries. The proofs are found in the increased vascularity  
of the membranous surface from which this secretion is  
exhaled out, as is seen upon injection of the parts post mortem,  
and also in the change which is found to be produced in  
membranes of similar structure after long continued torpors;  
and in <sup>the</sup> glands with which Hydrocele succeeds inflammation  
of the testis and tunica vaginalis, Hydrocele is most com-  
monly the result of a relaxation of the arteries from whose  
palatous mouths an inordinate effusion of fluid takes place.  
It more frequently arises from this cause than from inflam-  
mation. In Hydrocele the absorbent vessels of the sperma-  
tic cord, on the diseased side, are said to be very much larger  
than on the opposite and healthy side. It is sometimes though  
rarely consequent upon inflammation of the testicle, which sub-  
siding leaves the tunica vaginalis filled with water. It is generally  
a local disease but is sometimes connected with an universal  
hydropic diathesis

Symptoms and progress.

In general on its first appearance, the tumour is rather round, but as it increases it frequently assumes a pyriform figure, with its largest extremity downwards; sometimes it is hard, and almost imcompressible, so much so, that in some few instances, it has been mistaken for an induration of the testicle; at other times it is soft and lax, so that both the testicle and fluid surrounding it are easily discoverable. It is perfectly indolent in it self, though its weight sometimes produces a small degree of uneasiness in the back.

Mr Pott states the transparency of the tumour to be the most uncertain sign belonging to it; he says it is a circumstance which does not depend on the quantity colour or consistence of the fluid constituting the disease, much as on the unevenness thickness of the containing bag, and the concave unevenness of the scrotum.

According to Sir A Cooper, upon accurate examination of the swelling, it is found to be transparent. The direct is to examine the tumour in the following way. The room is first to be darkened, the patient must then hold a candle burning brightly close to the side of the scrotum; the surgeon must grasp the posterior part of the swelling so as to render it as firm as possible and then shake at the swelling from the side opposite to the candle; placing his feet

hand on the fore part of the scrotum he will immediately discover the transparency, the strong light or the sun, losing on the part answers equally well in showing its transparency. 449

The quality and consistence of the contained fluid is various it is thin, aqueous,ropy, viscid, limpid, yellow, greenish, brown, bloody, clear, or turbid. It has a distinct fluctuation which may be observed by placing the hand upon one side of the tumour and gently striking it upon the opposit side. When excessively distended it feels hard. The quantity of fluid varies in different cases a hydropne of ordinary size contains about eight or ten ounces, but instances are on record in which four and even six pints of water have been drawn off.

The progress of the disease is generally so slow that six or seven months often elapse before the tumour approaches the abdominal-ring. This disease is more inconvenient on account of its size and weight, than painful or dangerous. When large and not supported in a bag trap it drags the spermatic cord and creates pain in the testis. It also interferes with every kind of labour in which the lower extremities are concerned, and prevents the individual from riding on horse-back. Among other characters of the case the contraction of the scrotum disappears by the distention of the parts, and the manner in which the swelling draws the integuments from the penis prevents the full erection of that organ; a circumstance which

is, frequently a source of great anxiety to the patient, who is apt to suppose his virility irrecoverably impaired. When the swelling is very large, the penis is completely retracted, and the urine dribbling over the front of the scrotum, is liable to bring on a gradual inflammation and troublesome ulceration of the parts.

In the Hydrocele of children the testis occupies a lower situation than the same organ in the Hydrocele of adult persons, and the swelling appears farther up towards the abdominal-ring; however the testis is generally placed two thirds of the swelling, downwards, and at the posterior part of the scrotum.

Pressure at that part gives the sensation of squeezing the testis, It is a very moveable swelling and does not distend the part much in the course of the spermatic cord; it bends easily upon the abdomen and moves readily in all directions.

### Diagnosis.

Hydrocele may be distinguished from Hernia by the occasional return of the tumour swelling into the abdomen, by the duration of the tumour in coughing, and by tumour discarding from the abdomen. In Scrotum in which the testis is itself diseased, the tumour is more heavy and flatter on the side than Hydrocele, and more cord. Much pain is also produced by-

symping, the testis, <sup>or the</sup> epididymis is often capable of being felt as a distinct  
tumour; the cord may be traced with facility. There is also great  
vascularity of <sup>the</sup> scrotum, and the general health is often impaired.

From Hematocele we may distinguish it by the greater <sup>weight</sup> of the former  
by the want of transparency by its obscure fluctuation, and  
particularly by its being usually the result of a blow upon the  
part.

From Cistern it may be distinguished by placing the  
patient in the recumbent posture in which situation by pres-  
sure in the distended veins the tumour may be made to disap-  
pear.

From Hydrocele of the cord by the latter disease extending  
some times above the ring; it is also globular, coherent and  
ruled; it appears of a light blue colour is very transparent and  
extremely firm to the touch unattended with pain; it is  
an inconvenience to the patient from the impression it produces  
in his mind.

Hydrocele may distinguished from Hernia tum-  
=ours by the Hernia involving the whole scrotum, by its being attended  
with much inflammation and generally resulting from gonorrhoea.

### General Treatment.

In general when a Hydrocele is left <sup>to</sup> itself in an adult  
subject, no cure can be effected by nature alone. In young-

= seasons the cure is more easy, in children under six years of age nature without any assistance sometimes disperses the complaint. Sometimes the tumour bursts or is ruptured by external violence, or from an accidental effort of the patient, Accidents of this kind sometimes terminate in a radical cure.

Internal remedies have no effect in this disease, unless employed in a very early stage, in cases of young children cold affusions of water have been found useful, when this remedy is used it is recommended to be poured in the part out of a tea-pot four or five times a day. Cold purging, may in some instances effect a speedy cure of this disease however it is rarely found to be useful.

### Salivary Treatment.

Hydrocele is not a painful disease. In many cases the patient generally prefers submitting to the inconvenience it occasions for some time, rather than have recourse to any surgical operation. However its weight and size finally become so disagreeable that he is obliged to wear a bag-truss, a painful extension of the spermatic-cord takes place -

and the patient is very much annoyed by a troublesome excoriation  
caused by the friction of the tumour against the sides of  
the vagina. Hence the greater number of patients are very  
anxious for relief.

On the anterior superior and lateral parts  
the vaginae does not loose and detached from the ab-  
surgula, but on its posterior part those two trunks make one,  
and consequently the testicle is as it were affixed to the posterior  
part of the cavity of the sack in hydrocele. This being the  
state of the parts the operation ought always to be performed  
in that part of the tumour where the two coats are at  
the greatest distance from each other and where the  
fluid must be accumulated in the largest quantity.

The two instruments used for this opera-  
tion are the common lancet and the trocar. For the purpose  
of discharging the fluid, the latter instrument is generally  
preferred, as the canula facilitates the escape of the water  
and prevents its diffusing itself in the cellular texture  
of the serotum, when the hydrocele is small or the

Maugural Dissertation  
On Tetanus

Submitted to an examination  
by the Faculty of the University  
of Maryland  
for the degree of Doctor of Medicine  
by Joseph V. Stuart  
of Virginia  
1828.

Tetanus as defined by all authors is a contraction of several of the muscles of greater or less violence and extent with tension and rigidity of the parts affected. Tetanus may be divided according to its severity into acute and chronic. The first is very dangerous, and generally mortal. Chronic tetanus is less dangerous and by reason of its more gradual progress and allows time for the employment of more numerous remedies.

Tetanus may from certain causes occur in every climate, with which we are acquainted but it occurs most frequently in the warmest climates and generally in the warmest seasons of those climates. It affects all ages and constitutions. The causes from whence it commonly proceeds are cold and moisture applied to the body while it is very warm, and especially the sudden vicissitudes of heat and cold, or by punctures, lacerations or other ~~wounds~~ <sup>lesions</sup> of nerves in any part of the body. Possibly there are many other causes of this dreadful disease; but they are neither distinctly known, nor accurately ascertained.

If the disease proceed from cold it most frequently comes on in a few days after its application; but if it arise from a puncture of a nerve the disease does not commonly come on for many days after the injury has happened, very often when there is neither pain or uneasiness in the part, and frequently when the wound has cicatrized. Sometimes this disease comes on insensibly to a very violent degree, but it approaches more generally very gradually to its most violent state. In this case it comes on with a sense of stiffness in the back part of the neck, which gradually increas-

ng renders the motion of the head difficult and extremely painful. As the rigidity of the neck comes on and increases there is commonly at the same time a sense of uneasiness felt about the root of the tongue, which by degrees becomes a difficulty or an inability, and at length an entire interruption of it; when this pain arises all the muscles of the neck and particularly those on the back part of it are immediately affected with spasm pulling the head very strongly backwards. At the same time the temporal and masseter muscles which upon the first approach of the disease were affected with some rigidity are now affected with violent spasm, and set the teeth so closely together that they admit not of the smallest opening. This is what commonly has been called Locked-jaw, and often is the principal part of the disease.

When the disease has advanced thus far a pain at the bottom of the sternum returns, and leaves the patient very frequently, and with it the spasms of the muscles of the back part of the neck and lower jaw are renewed with great violence, and severe pain. As the disease proceeds a greater number of muscles become affected with spasm. After those of the neck, those along the whole spinal column are affected, bending the trunk of the body backwards; and this constitutes what has been called Opisthotonos. Both the extensor and flexor muscles of the inferior extremities are commonly at the

same time affected, and keep the limbs rigidly extended; though the extensors of the head and neck are usually more strongly affected, yet the flexors & those muscles that pull down the lower jaw are often strongly affected with a spasm at the same time. During the whole of this disease the abdominal muscles are violently affected with spasm so that the belly is much retracted and feels very hard. When the disease has made some progress the flexors of the head and trunk are equally affected with the extensors, so as to keep the head and trunk straight and strongly extended, incapable of being moved in any way, to this state the term tetanus has been strictly applied. At this time the arms which were little affected before become rigidly extended, and the whole of the muscles belonging to them being affected with spasm, except those that move the fingers which often in the most violent stage of the disease retain some mobility; The tongue also retains its mobility for a long time, but at length it also becomes affected with spasms which attacking only some of its muscles, forces it sometimes between the teeth, by which it is much injured. At the height of the disease every organ of voluntary motion seems to be affected and among the rest the muscles of the face.

The forehead is wrinkled the eyes are sometimes

distorted and immovable in their sockets, the cheeks  
 are drawn towards the ears, & the countenance is expres-  
 -sive of most violent agony. Under these universal  
 spasms the patient does not long remain, for a con-  
 -vulsion soon terminates his existence. In this disease  
 the spasms are every where attended with great pain  
 The utmost violence of spasm is however not  
 constant, but after subsisting for a short time,  
 the muscles admit of some relaxation, although  
 not so much as can allow the action of their an-  
 -tagonists. This remission of contraction gives  
 a short remission of pain, but neither is of long  
 duration. These violent contractions & pains  
 are removed from time to time, & often times  
 without any evident exciting cause. Every attempt  
 to speak, to move or to swallow, gives occasion  
 to the renewal of the spasms over the whole  
 body. The attacks of the disease are not always  
 but generally attended with febrile action at  
 the commencement of the disease, the pulse is  
 full & frequent, tense & strong. When the spasms are  
 general and violent the pulse is contracted, hurried and

irregular; and the respiration is affected in a like manner. 469  
But during the remission both the pulse and respiration  
usually return to their natural standard.

Frequently the face is pale with a cold sweat upon  
it and very often the extremities are cold with a cold sweat  
over the whole body. In this disease the head is  
seldom affected with delirium, or even confusion of  
thought, till the last stage - so that the patient is  
sensible of all the changes of this distressing disease  
his pain is insupportable he sees the desponding countenances  
of his attendants and feels as if his departure  
could not be avoided. In this disease the natural  
functions are not immediately affected. Vomiting  
sometimes appears early but it is not continued,  
the appetite commonly remains good nearly through the  
whole course of the disease, & the food taken seems  
to be well digested. The excretions are generally  
deranged. It is not certain whether costiveness is  
the effect of the disease or of the opium which  
is administered, probably the latter as it is used in  
large quantities. The urine is sometimes suppressed,  
or it is voided with difficulty and pain. This disease  
has commonly proved fatal as we are told by Dr Cullen

and fatality might be considered as a natural  
consequence as long as the disease was badly treated  
but since a more proper method has been known  
and practiced, the disease has not struck the patient  
or the physician with such terror as formerly and  
many now are cured. Judging of the tendency of the  
disease in particular cases, we may remark, that  
when it arises from a laceration of the nerves it is  
commonly more violent, than when it is the effect  
of cold; that the disease which comes on suddenly  
and advances quickly to a violent degree is always  
more dangerous than that which is slower in its  
progress. This disease often proves fatal before the fifth  
day and if the patient has passed this period he may  
be supposed to be in greater safety and generally the  
longer it continues, the safer the disease and consequently  
the eyes are near the result. However it is to be re-  
marked that many days after the sixth the disease  
continues to be dangerous; and when it is considerably  
abated, it is ready to recur again with its former  
danger. No evacuation or eruption has been known  
suddenly to check its career and when it terminates sa-  
vourably it always recedes gradually and often a long  
time elapses before all its symptoms disappear entirely.  
When the disease is known to arise from the laceration

a nerve in any part of the body, the first and most im-  
 portant step to be taken towards the cure is by every means  
 in our power to cut off that part from all communication  
 with the sensorium either by cutting through it the nerves  
 in their course, or by destroying the affected part to  
 some distance. We have several instances of great bene-  
 fit from early amputation of a wounded extremity when  
 tetanic symptoms first appear. This however should  
 not be done unless the injury from which the disease  
 results be inflicted on some of the smaller members  
 such as the fingers or toes; to amputate the thigh  
 would be putting the patient to useless torture.

Opium as taught by experience has often ~~been~~  
 proved a very effectual remedy when we attempt to  
 cure the disease by medicine. The remedies have been  
 divided into external and internal when the disease  
 arises from the injury of a nerve it will be necessary  
 to cut down and divide it or to apply stimulating remedies  
 or warm emollient poultices & at the same time to give  
 Laudanum under this treatment the disease will be  
 frequently removed. Both the warm & cold bath have  
 been strongly advocated, but they cannot be relied on alone.  
 Caustic has been often used successfully in traumatic  
 tetanus. Of the internal remedies opium is the best & should

ne is the symptom in the treatment of tetanus and cannot  
 be omitted, it should be given as soon as you suspect that  
 the disease is approaching, wine or brandy may be give in  
 very large quantities, in this disease it is almost impossible  
 to induce uterication, The whole class of antispasmodics  
 have been used the oil of Anise among the best, it used  
 in larger quantity would more often prove successful  
 it should be given in the dose of half a dram. Then opium  
 is administered it should be given in small & frequently repeated  
 doses at the interval of 2 or 3 hours as the violence of the  
 symptoms may require, it seldom induces ~~to~~  
 it is or is not which it does so often does under other cir-  
 cumstances when much smaller doses have been taken.  
 therefore we should not be sparing in its use.

Purgatives have been administered & recommended did we  
 ever recollect a Authority in this case - Dr Hamilton of  
 Edinburgh remarks that he ascribed to our confidence.  
 But if they be useful it must be in cases of tetanus  
 resulting from internal irritation, where the disease  
 originates in the alimentary canal. In such cases  
 probably emetics combined with purgatives might be  
 useful, or besides assisting in the removal of irritation  
 they would contribute by their nauseating quality  
 to the relaxation of spasm. Bloodletting however  
 was used with advantage in the disease In all these  
 cases, regard must be paid to the state of the  
 system in the as in all other complaints. Bloodletting  
 is common in this disease, but it is asserted that they were

constantly used, & are never employed.

Mercury in its turn was tried, - report says with success; & is now one of the principal remedies in use. This, with Opium & Wine, appear to be the only remedies, upon which we can confidently rely, in the treatment of tetanus. If these, the two latter retard the progress of the disease, preventing exhaustion, & death, from violence of the Spasm, until the former has had time to eradicate it entirely, by converting the tetanic into the mercurial action. Opium & wine being palliative rather than curative remedies are not sufficient of themselves without mercury, which without their aid Mercury is too slow in its operations to arrest the rapid march of the disease. The usual - best preventatives of tetanus from external injuries consist in the conversion of punctures into incised wounds by means of the scalpel - the excitement of suppuration in lacerated wounds.

These things if done immediately after the injuries have been received - before the occurrence of tetanic symptoms are of great importance - but they are worse than the thing if delayed until the disease shall have made its appearance. When the tetanic disease is fairly formed all local applications to the injured part are unavailing even the amputation of a limb has been found insufficient to arrest its progress. Should circumstances exist to prevent the dilation of a punctured wound, the application of caustic alkali & sinapisms to the part are the best substitutes. Whatever is calculated to excite common inflammation is useful at this time. In the production of suppurative action in lacerated wounds Spirit of turpentine or a solution of the mercurate of mercury - used by poultices frequently repeated are the best applications. When from a neglect of preventative remedies, or in despite of their use tetanus has made its appearance a different course of practice must be commenced and pursued diligently. To the state of

system a direct and steady attention must be paid.  
 If the patient be lethargic and the excitement very high, or  
 if the latter, without the former blood must be drawn and  
 the operation repeated as often as circumstances may re-  
 -quire. If costiveness prevail & any irritation be suspected  
 in the bowels purgatives are to be administered as in  
 other diseases; but as has been mentioned above as soon  
 as the condition of the system will admit them, wine,  
 opium, & mercury are to be given according to their  
 effects on the system without regard to quantity.  
 They should be given until the system has sorely  
 felt their action or they will be unavailing.  
 Opium should be administered in injection  
 in doses of from five to ten grains & repeated  
 at short intervals until the spasms are overcome  
 and some anodyne effect produced, applying  
 in the meantime to various parts of the body  
 quantities of mercurial ointment, when the  
 power of swallowing has for a long time  
 ceased, nutritive clysters should be substi-  
 tuted. After surgical operations, as a prophylactic  
 precaution, & the use of the tincture of opium  
 mixed with the dressing has been employed to  
 prevent symptomatic tetanus with success.

An  
Inaugural Dissertation  
on  
Sclerosis

Submitted to the examination

University of Maryland

Permit me Sir to <sup>dedicate</sup> this dissertation to you as a  
small tribute of gratitude and esteem for the po-  
lite attention and benefits derived from your instruc-  
tions during the prosecution of my medical stu-  
-dies under your guidance they were always grate-  
-fully received and will ever be remembered by  
your former pupil Edward McCuey

# Essay on Pteris

481

Upon entering upon the subject of Pteris I propose to make a few general remarks on the liver considering the size of this organ in all animals that possess it and how generally it is possessed being common to all red blooded animals there can be no doubt that it is of great importance in the animal economy. Whether it serves to separate any alimentitious material from the blood or produce any other effect upon it has not yet been decided certainly its most obvious office is the secretion of the bile which in most animals in its passage from the liver to its place of destination the duodenum communicates by means of a duct <sup>with</sup> a near the great reservoir denominated the vesicula fellea or gall bladder in which it is supposed to accumulate and as ~~the~~ it ~~is~~ is generally believed that the symptoms of jaundice depend upon a obstruction to the free passage of the bile from the excretory ducts of the liver into the azygos canal and its return into the circulation. Although such is the case in general yet there have been instances in which there was a copious absorption and

return of bile into the blood and at the same time  
 a redundant flow of it into the alimentary canal. How-  
 ever the most general causes of icterus may be referred  
 to mechanical obstructions to the biliary ducts. Many  
 disputes have arisen concerning the manner in which the  
 bile is resorbed into the system but it is now general-  
 ly believed that it is taken up by the absorbents of  
 the gall bladder and ducts. Hence it is that jaundice  
 may be produced by any thing obstructing the passage  
 of the bile into the duodenum. Biliary concretions,  
 appear to be the most frequent cause of this disease.  
 With respect to their formation we are yet unacquainted  
 the liver appears in many instances to be sound but  
 in other cases it is undoubtedly diseased and from the  
 morbid secretion it may become more disposed to crys-  
 tallize. From the analysis of biliary concretions they ap-  
 pear to contain ~~not~~ the ingredients of the bile. From  
 their peculiar crystallized structure we are led to be-  
 lieve that something more is necessary to their forma-  
 tion than the mere inspissation of the bile but what  
 that consists in physiologists have not yet been able  
 to detect. Indolence of body & anxiety of mind appear

49<sup>3</sup>

particularly to predispose to their formation therefore they are much more frequently found in women in the upper walks of life and men much addicted to sedentary occupations especially after the more active period of life Haller noticed the frequent occurrence of biliary concretions among criminals whose deaths had been preceded by long confinements but the anxiety of mind also might contribute to their formation as long as biliary concretions remain undisturbed in the gall bladder so they are generally formed there they appear to produce little or no inconvenience but from violent compression or from irritation the gall bladder and ducts contract and thus the offending substance will gradually be moved in the direction where least resistance is offered this will of course be toward the mouth of the duct not solely because the duct gradually enlarges but because there is constantly an impulse given from the accumulated secretion from behind. When biliary concretions of large size are thus thrust into the ducts they produce the most excruciating pain to which the human fabric is liable and it is generally referred to the pit of the stomach

495

corresponding to the opening of the duct into the duodenum  
and shooting from thence towards the spine accompanied  
at intervals with rigors and nausea. During the paroxysm  
the respiration is hurried with great anxiety restlessness and  
occasionally with delirium followed by extreme languor and  
faintness with vomiting & occasionally with spasmodic  
twitchings in different parts of the body. Profuse sweats  
often break out apparently from the severity of the pain.  
In the intervals of the paroxysms there is generally a  
fullness and soreness in the epigastrium and right hypo-  
chondrium &c. The patient generally experiences  
most relief when his body is bent forward. The pa-  
roxysm will continue to recur at intervals until the con-  
cretion makes its escape into the biliary canal which  
it will do in some instances within a few minutes in  
others it will be for weeks in passing along the duct  
thus obstructing the passage and producing the disease  
which in some instances will continue for a considerable  
time after the cause has ceased to act. Biliary con-  
cretions of such large size have sometimes passed  
as to make physicians doubt whether they did not  
make their way by ulceration into some part of the

491

intestinal canal which is highly probable a <sup>then</sup> ~~then~~  
an case when they have been known to make their  
way through the walls of the abdomen

Natural acidity of the bile has often been advanced as  
a frequent cause of jaundice. It appears that this state  
of the bile may take place from a variety of causes  
from the removal of the bile in the gall bladder and  
sucts produced by particular positions of the body  
from pregnancy and from vascular tension of the  
liver itself. At the same time the absorbents of  
the gall bladder are sucts still continuing to act  
if not increased in action will take up the more  
alimentary particles of the bile and thus under it  
acid augmented secretion from the gall bladder  
and sucts has also been apprehended as a frequent  
cause and also a too viscid consistence of the bile  
in its secretion in the liver. This species of jaun-  
dice is most frequently met with in autumn  
and it generally commences very insidiously there  
is in this variety a diminution of appetite restles-  
ness disturbed sleep and a disinclination to exertion  
of any kind together with the general symptoms of Sclerus

Inflammation appears to be a very frequent cause of jaundice by preventing the free discharge of the bile probably by a thickening of the paries of the ducts thus lessening their caliber. It may take place from a variety of causes it may either extend from the intestines or pass the liver itself from cold and especially from taking in large quantities of cold water when the liver is much heated. The symptoms attending this species of obstruction are those attending general inflammation tubercles of the stomach and generally commences with a chill. It has been questioned by some whether jaundice is ever produced by mere spasm of the ducts themselves. The arguments in favour of this opinion are that it has been a frequent attendant on the liver and other spasmodic diseases and that the attack is sometimes very transitory and from dissections there has been discovered no mechanical obstructions whatsoever in the ducts and also without any appearance of biliary concretions in the ducts. It occurs more frequently in persons of very irritable habits from sudden emotions of the mind. Op. papious have a remarkable effect on the secretions

501

-tion of the bile and they may also cause a spasm  
of the ducts themselves. The symptoms attending spas-  
modic constrictions of the ducts are sometimes, as  
violent as when biliary concretions are impacted  
in the duct. The spasm indeed appears to be the  
cause of the pain in both cases. Enlargements of  
the visceribiliary organs is not an unfrequent cause  
of this disease such as schistosis of the pancreas  
scrophulous glands tuberculi of the liver may as-  
sist the irritates of the ducts as to prevent the dis-  
charge of the bile and thus produce the disease In this  
variety the pain is not so acute and does not come  
on suddenly general emaciation attended with vom-  
itings and hiccups in the epigastric region jaundice  
is also described to have been produced by mechan-  
ical distention of the duodenum by closing the valve  
of the duct jaundice arising from this cause  
appears to be peculiar to infants and is very easy  
of removal It only requires the exhibition of some  
mild aperient medicine to clear the bowels  
of the unobscured viscid meconium

Having spoken of the principal causes which

93

give rise to the disease I shall now enumerate  
some of the most characteristic symptoms jaundice  
generally commences with a want of appetite a  
sense of lassitude and languor depression of  
spirits disinclination to exertion of any kind  
I mention and general emaciation In some cases  
there is a great propensity to sleep in others ma-  
sted dulness the secretions are pale or clay colour-  
ed with the absence of the perceptible smell &c.

The disease increases the yellow colour ma-  
ifests its appearance showing itself first in the tunica al-  
buginea the urine becomes high coloured with a  
yellowish sediment so as to be capable of imparting  
the same colour to lime The yellow colour at first  
is not confined to the skin alone but is diffused  
over the whole body so that the bones have been  
found tinged yellow for a very long time after the dis-  
appearance of the disease There is generally great  
itching over the whole body The bile appears to  
be diffused in the whole mass of fluids so that the  
secretions are affected even the blood itself is  
said to possess a yellow colour.

505

As jaundice may arise from so many different causes, some of which it is impossible to discover during the patients life and some which may be considered incurable we ought therefore to ascertain if possible the real nature of the cause which has given rise to the disease which can in general be done by attending to the various circumstances which present themselves for certainly such a discrimination must be of the greatest importance when it is considered that the mode of treatment must be varied according to the nature of the cause by which the disease is produced whether the passage of the bile be obstructed by biliary concretions or spasmodic constrictions the plan of treatment to be adopted must be nearly the same For the passage of biliary concretions of very large size through the common duct they very frequently produce from their great distention not only very acute pain but also when long continued a considerable degree of inflammation to guard against which it will often be necessary in full lithoric habits to take away blood proportionable to the

501

state of the pulse and severity of the pain This should be succeeded by the use of the warm bath warm fomentations together with opiates The opiate should be given in the solid form for the stomach will often be so irritable as to reject liquids of every kind Two or three grains of opium should be given at first and if relief is not obtained in half an hour the same quantity should be repeated with the intention of facilitating the passage of biliary concretions or viscid bile emetics have been used with great advantage During the act of vomiting the diaphragm and abdominal muscles concurrently contract and the whole of the abdominal viscera are thus forcibly pressed upon which must necessarily cause the gall bladder and ducts to pour out their contents freely For this purpose the antimonial emetics are preferable because they are best apt to be rejected and also excite a much stronger stimulus After the operation of emetics the bowels should be freely opened by some purgative medicine Exercise has also been useful particularly

501

- by that of riding on horse back by the concussion which it gives to the liver quillons and the like have been used with the same view Purgatives have been found very useful in some cases of jaundice especially in those cases where the disease arises from a too viscid state of the bile in consequence of a torpid condition of the liver In this case mercury must be used to change the condition of the Liver In cases of infants where the passage is obstructed by viscid mucus purgative medicines must be principally relied upon The Nitro-muriatic acid bath hath been much recommended in cases of Sclerus It should consist of three ounces of diluted aqua regia to every gallon of water The strength of the bath should never be greater at any time for otherwise it may produce a very troublesome rash and give a yellow hue to whatever part is exposed to its action Dr Ferri used it with decided advantage in almost all cases dependant on a morbid secretion of bile There has been a great variety of other remedies recommended in Sclerus such as the Alkalies electricity the seed of the common hemp &c but none of them much used at the present time

A

Inaugural Essay,  
On the,

Cause of sudden death,

And the means of preventing it,  
Submitted to the examination,

Of the,

Medical Professors,

Of the,

University of Maryland,

For the degree of,

Doctor of Medicine,

On the day of, 1828,

By Duce, Wilson,

Of Alabama,

No. 11

London, 17th

Dear Sir,  
I have the honor to acknowledge  
the receipt of your letter of the  
15th inst. in relation to the  
above mentioned business.

I am, Sir, very respectfully,  
Your obedient servant,

J. H. Johnson  
17th Street  
New York

On, the,

Causes of Sudden death,

And the,

Means of preventing it,

Death is the inevitable lot of all mankind; but there are few persons, whose business, or whose conduct in life, do not render it a greater evil to themselves and their families when it takes place suddenly than when it occurs after a previous indisposition. It point out the principal causes of the sudden and unexpected extinction of life, and the means of preventing it. Shall be the Subjects of the following dissertation. It will be necessary that I promise to adopt the opinion of the professor of the Institute that life consists in such a peculiar organization of matter, as to be capable of producing by certain impressions, those motions and sensations which have been hypothetically ascribed, by some, writers to the mind and by others to an independent vital principle. Death of course consists in the destruction of that peculiar organization of matter, or an incapacity

The 1st

Received of Mr. John Smith

the sum of

Twenty pounds

for the purchase of a quantity of  
the same as per bill of exchange  
of the 15th inst. and as per  
bill of exchange of the 20th inst.  
of the same amount. The bill  
of exchange of the 15th inst.  
was for the sum of twenty  
pounds and the bill of exchange  
of the 20th inst. was for the  
sum of twenty pounds. The  
total amount of the bills of  
exchange is the sum of forty  
pounds. The bill of exchange  
of the 15th inst. was  
payable to the order of  
Mr. John Smith and the bill  
of exchange of the 20th inst.  
was payable to the order of  
Mr. John Smith. The bills of  
exchange were cashed on the  
15th and 20th inst. and the  
amount of the bills of exchange  
was paid to Mr. John Smith.  
The bills of exchange were  
received from Mr. John Smith  
on the 15th and 20th inst. and  
the amount of the bills of  
exchange was paid to Mr. John  
Smith. The bills of exchange  
were cashed on the 15th and  
20th inst. and the amount of  
the bills of exchange was paid  
to Mr. John Smith. The bills

and 20th inst. and the amount  
of the bills of exchange was  
paid to Mr. John Smith.

519

with those impressions, which produce the motions and sensations of life, the causes which produce this incapacity in the matter of the human body, and thereby induce sudden death, act more or less certainly, according as they are more or less combined, according to the nature of the parts of the body on which they act, according as the system is in a state of healthy excitement, or more or less predisposed to death, by previous debility, or by a previous disease. They appear to induce death by a sudden destruction of the excitement of the system, from the excessive force of impression or the sudden abstraction of them, whereby the system is rendered incapable of performing its natural office.

I shall briefly enumerate the causes, which, by inducing the above changes in the system, bring on sudden death. Extreme heat and extreme cold. Both these act with most certainty upon old and sickly people. Dr. Housham remarks, that old people are often found dead in their beds, after an extreme cold or warm night; and their are few physicians who have not had patients suddenly and unexpectedly snatched out of their hands by the extremes of heat and cold. Fatal effects have likewise followed or rather been observed when heat and cold in their extremes, have followed each other

511  
in a rapid succession. The rays of the sun acting upon the  
head have often produced death, by means of what is called  
by the french *coup de soleil*; and cold combined with moisture  
has so often produced it in the form of Apoplexy, as in  
some instances to create a belief that disease had assumed  
the character of an epidemic. Sudden changes in the weight  
of the atmosphere, some cases of kind are mentioned by  
writers. Certain matters contained in the air, these are  
several of the gases, particularly Azote or according to modern  
nomenclature nitrogen gas, the Carbonic Acid, and inflammable  
Air. The black at Calcutta will be a lasting monument  
to the deadly effects of Azote or respired Air. Many people  
perish from sleeping in unventilated cabins and rooms, in  
consequence of Carbonic Acid eliminated from burning  
candles, and it is well known that miners are often de-  
stroyed by breathing the inflammable Air which is discharged  
from subterraneous caverns. There are also some have  
discovered certain vegetable poisons which are said to float  
in the atmosphere; but since the rejection of the fable  
of the East India Opus tra, sudden death from this cause  
has been discarded from medicine. The Air in the vicin-  
ity of the Rhus Radicans has been known to induce  
inflammation and to inflame the skin, but I believe in no instance

The handwriting is extremely faint and illegible. The text appears to be a dense block of cursive script, possibly a letter or a page from a manuscript. The ink is very light, and the lines are closely spaced, making it difficult to discern individual words or sentences. The overall appearance is that of a heavily faded or overexposed document.

534

has it. Suddenly extinguished the vital. To this head belongs the  
~~vital~~ Miasmas which exist in the atmosphere from the putre-  
faction of Animal and vegetable substances. The history of  
the plague in the Old world, and of the yellow fever, in the Uni-  
ted States, furnish many proofs of sudden death from this  
cause. This is not the place to inquire whether those diseases  
or death can be induced by a matter secreted in a morbid  
body, and conveyed into a healthy one; Sudden death has  
sometimes been brought on by entering a small and filthy  
room, crowded with persons ill with the plague! But  
the matter which induces it is not secreted. It is like the  
original miasms, the offspring of putrefaction, and in these  
cases, derived from stagnated excretions from the bodies of  
sick people. As I am only relating facts at present,  
I hope I shall be excused from deciding on the long  
agitated question of the part of the body, on which  
the Airs and Miasms, that have been mentioned, prima-  
rily and chiefly act, in producing their deadly effects.  
Some of them certainly act upon the body, through the  
medium of the lungs; some of them upon the whole nervo-  
us system through the medium of the brain; And some  
act upon the sanguiferous system through the me-  
dium of the stomach, It is possible, Miasms may convey death  
to the body through the avenues of all the parts that have

Faint, illegible handwriting on aged paper, possibly a letter or document. The text is mirrored across the page, suggesting bleed-through from the reverse side. The ink is very light and the paper shows signs of wear and discoloration.

been mentioned. I have said nothing of sudden death from  
contagions. They are extremely limited in their numbers, and  
seldom so powerful, in their first impressions as to destroy  
with life. Cases of sudden death from the small pox,  
measles and the hooping cough, and I believe rarely  
to be met with in the records of medicine. Lightning  
is often a cause of sudden death. It seems to act prim-  
arily upon the nervous system, but the blood and all the  
muscles of the body appear to partake of its forcible  
impression. Hence the quick putrefaction of the  
body after death from this cause. Sudden and violent  
emotions of the mind. Anger has in instantaneous  
produced death terror has often produced it. Sol-  
diers has often been found among the slain in bat-  
tles whose bodies have been found free from wounds.  
Their deaths have been ascribed to the wind of cannon  
balls, Is it not probable they were occasioned by the  
violent impression of terror upon their systems; Strip-  
ping wounds, it is well known, have now and then  
produced death, from being combined with a sud-  
den paroxysm of fear. The passions of fear and grief  
have occasionally induced sudden death, but it is more  
common for them to produce it by a previous chronic  
disease. Under this head we may bring in as a cause of

527

sudden death, a sudden sense of guilt and shame. Of his there are several instances to be met with in practical authors. Great bodily exertion in labours, lifting weights and in marching, have sometimes suddenly destroyed life. Fatigue or the reduction of excitement of the system in marching more certainly induces sudden death, it be combined with excessive heat. The histories of the late French and English Campaigns in Egypt furnish a number of instances of Soldiers expiring on the public roads, from the combined effects of the rays of the sun, and great fatigue acting upon their bodies. Great bodily pain has sometimes induced sudden death. The cold often kills, by excessive pain. Mr Hunter relates an instance of the pain occasioned by the extirpation of a diseased vessel producing death. In fevers sudden death is sometimes brought on by the inability of the blood vessels to react in the chilly fit; by convulsions; and by the extreme debility which follows. The termination of a paroxysm of fever, affections of the head, from Gout, and the frequent cause of sudden death. The most common of these are profuse of water or blood upon the brain inducing apoplexy. Death is sometimes the effect of a sudden effusion of blood or water in <sup>the lungs</sup> constituting what has been called by Dr Keck in his lectures the apoplexy of the lungs. A Spasm of the heart, produced by the gout, as in several instances, induced the sudden extinction of life. Certain poisons and many substances of an irritable nature, also cold liquors, when the body is naturally heated, receive into the stomach by their sympathy with the head, heart, or blood vessels, induced sudden death. It has sometimes followed a Spasm of the stomach from gout, also a rupture of that important viscus. The discharge of pus from the liver into the thorax, and into the abdomen, has often hurried persons

adversely. out of life. Worms, in the alimentary canal  
have now and then suddenly, produced death, especially  
in the children, by exciting Apoplexy or general convulsions,  
a sudden rupture of an Arterium, in the large vessels  
near the heart, has often become an instantaneous  
cause of human life. It has passed away with nearly  
equal rapidity from a rupture of the bladder and  
uterus. It has been induced by Syncope, from partial  
obstruction of the cause. The sudden reduction of the vitality  
of the system, by Hemorrhage, by parturition, by a large  
flux, by a copious discharge of matter, from an abscess  
and perhaps, by the operation of pain, has in sundry instances  
produced sudden death. Derangement produces  
sudden death, I have observed this cause of sudden death to a  
great extent is its contrariety to the natural principles  
of action in man, that I believe it rarely takes  
place in the perfect exercise of his reason. I shall  
say nothing of the cause, of sudden death from drouth  
external causes removed, and accidents, so been per-  
taining to the subject, and briefly to mention the means of  
prevention. I shall confine my self only to such cases,  
and within the power of Medicine.

Art. 3<sup>d</sup>. To prevent death from the storms of L<sup>t</sup>, cool  
air, or is in situations should be averse. As it  
frequently occurs in the night, and during sleep, in  
cold weather, by a warm blanket to  
be constantly on the thorax, to prevent it from cold;  
but light bed cloths, should be prescribed; and as death  
occurs its first appearance <sup>appears</sup> though it is not possible  
to lead us to the cause of warm, means of warm  
clothes rapped in warm blankets, or I have seen filled with  
warm water. To prevent the stroke of the sun  
to be prevented, by constant and gentle exercise, when  
persons, are exposed to its rays, or if persons, the head

an umbrella, or a deep crowned hat, covered with white  
 linnen or papers. in egyptians, &c, it was use a turban  
 for this purpose, It is true it accumulates the heat of the head  
 but it is cool in the parts, is kept, and far more tolerable than  
 the heat of the sun, which in the climate of egypt is  
 often between 120 and 130 degrees. Ulinia these degrees, heat  
 but I have seen the natives of Senegal wear  
 their coats, on the river Hooghly, exposed to a meridian sun,  
 and bear headed, without experiencing any ill effects.  
 the only precaution they use, was to keep their heads cool  
 only wet by pouring some them large coars of water  
 by these means the neck, shoulders, and chest, which  
 the head is exposed to a sun, and kept cool from  
 evaporation of the water. During the prevalence of the wind  
 and that air of rain which is a great cause  
 death from apoplexy, great care should be taken to open  
 the predisposition is it by temperate diet and gentle opening  
 physic. To prevent the fatal effects of the gas, that is  
 mentioned, places which are supposed to contain the gas  
 should be visited, and they have been examined by a lighted  
 candle. The extinction of its light, is a sign of its contain  
 of or carbonic gas. A flame or explosion excited by the  
 rays of the candle, indicates the presence of inflammable  
 air. The deadly effects of the Miasms from putrid vegetable  
 and animal substances, are to be prevented by avoiding the  
 acids which generate them, by using the pre-digestion  
 be effected by them, by means of abstinence gently pe  
 physic, and a temporary use, excited by a blister  
 of the skin, or vomit. If the effects of these prevent  
 these and many proofs in the history of pestilential fevers  
 diseases. The means of preventing or avoiding sudden  
 death from lightning, belong to naturalists not to medical  
 philosophers. The preventions of death from violent

of the mind, should be sought for. Those who are in the habit of  
of all is practiced, and operations should be  
to the strength of the body, should be careful  
avoided by all means which is avoid or escape a sudden  
heat and fatigued upon life from labour and ma  
are generally been resorted to for this purpose, but garlic  
Onions are to be preferred to them. By the constant  
of these medicinal vegetables, the Hebrew nation were incited  
to the labour of digging such in the garden, &c.  
to the intense heat of the climate of Egypt.  
the deadly effects of heat and fatigued were prevented  
a part of the British Army in the late war, by  
during the late war, by allowing the Soldiers, but a small  
quantity of water, similar advantages are derived from  
abstaining from water altogether, by the Indians of North  
America, during the day, in their long and fatiguing  
marches, in hot weather. Death from extreme pain may  
be prevented by bleeding, Opium, and wine, and  
to sensations by cries and groans. The following is  
a case which I lately met with: In  
travelling through Germany, he came to a village, where a  
criminal was ordered to torture, i.e. a work, in order to extract  
from him a confession, for an accomplice in his crimes, three days  
before he suffered he avoided tasting any food. The sensation  
hence the individual was so painful and it had a  
warmth in its effects upon life, as to be never balanced  
in any danger of the tortures inflicted upon him. Unex-  
pected death in the chilly fit of a fever, should be avoided  
(and drunk) from excessive force of reaction in the blood.

by bleedings from convulsions, by Remedies suited to the Stage  
the disease in which they occur, and from the debility  
allow a paroxysm of fire by cordial Medicines, trunks and  
ointments. Sudden death in persons predisposed to it, from apoplexy  
should be avoided by temperance moderate exercise,  
in bowels; not supposing usual evacuations, or chrym  
to; to be... the signs... the promonitory sign of  
hips; And head ac... tate places; by avoiding tight ligatures  
round the neck, by sleeping with the head a little elevated  
and... a mattress instead of a feather bed  
and by now sleeping upon the back, but alternately  
on each side Dr Rush mentions several cases of palsy  
as Dr Fuller is tedious, a disease produced by a  
one feble operation... cases... produce apoplexy  
Rush mentions that patients sleep upon their left side.  
... at... of lips by the Apoplexy of the lung  
Dr Rush would call it an accident appropriate and  
stimulate, by Dr Fuller in his lectures, by poison or an  
digestible matters received into the stomach, by worms  
the elementary canal; and by Spasm of the heart,  
could be prevented by the usual remedies for that purpose  
mentioned in the books of medicine.

... a liquor, taken into the stomach when the  
... is proportionally heated, has been often prevented  
plunging or rather conducting off the heat of the body  
plunging the hand... into cold water, or to was  
... with vinegar, or by grasping the vessel contain  
the liquor, provided it be made of a metal or  
... kind of earth. 12<sup>th</sup> persons... disposed to  
... Spasms in the stomach or heart, should  
avoid the remote or exciting cause of fork; but  
when attacked by it, should flee to Laudanum, untill  
advice of a physician can be obtained.

main danger is apprehended of the Sudden discharge of  
pus from the liver into the thorax, or abdomen it should  
if possible, be diverted stomachally, by means of a cast  
Purges. vice versa the bile from the liver into the  
stomach and bowels, would perhaps have the same effect,  
for its purulent contents, the ducts which lead to the  
duodenum, could ~~perhaps~~ <sup>probably</sup> yield to the agitation excited  
by a vomit, sooner than any other part of the  
bowels. 14<sup>th</sup> Sudden death from aneurisms has often been  
prevented by a temperate diet, tranquility of body  
and mind, and by small and frequent bleed-  
ings. When sudden death is apprehended from  
apoplexy, great pains should be taken to avoid  
remote and exciting causes and to strengthen  
the system by tonic remedies. The sudden extinction  
of life from sudden depletion, or the sudden  
collapse from distention, or cessation of pain,  
should be obviated by vicarious stimuli of other  
kinds, when they cannot be prevented by other  
means. 16<sup>th</sup> When there is reason to apprehend  
sudden death from suicide, persons suspected of  
it should be narrowly watched, and all the  
means of death should be removed from them.  
Solitude should be prevented, and a cheerful society or  
cheerful glass, should be advised. The exertion of  
strong emotion of terror and pity has prevented it  
in numerous instances. 17, In cases of sudden death from  
any of the causes which have been mentioned, it is  
well that resuscitation might be effected by the usual  
means, if judiciously applied, in the use of them

shall only deliver the following directions: 1.<sup>st</sup> In cases  
with such as are of a gentle nature, and gradually  
sort to such as are more powerful, in all cases where  
the cessation of the functions of life has been induced  
by causes which leave the excitability of the system  
in an accumulated state. 2.<sup>nd</sup> In cases where by great  
effort to preserve life, the excitability of the system  
is over expended, let no stimulus be applied for some  
time after the cessation of apparent life. By observing  
this delay, time will be given for the accumulation  
of some of the fluids remains of excitability in the sys-  
tem. 3.<sup>rd</sup> In addition to the common remedies employed  
to affect resuscitation, gentle or loud sounds applied  
to the ears, are calculated to produce the most salu-  
tary effects, life often lingers longer on the  
ears, so says Dr Rush in his lectures on asphyxia.  
This has been proved by the shrieks of distressed persons  
sometimes calling their apparently dead friends to  
life. By availing our selves of this fact, a new  
& powerful remedy, may be added to those which  
are now in common use for promoting resuscitation.  
As the motions of life are destroyed last in the  
ears (and of course in the vicinity of the ears),  
think highly probably from the placid or gloomy  
countenance which succeeds death. They are probably  
effects of the pleasant or painful operations of  
the mind, which survive the extinction of life in  
the parts of the body.

Inaugural Dissertation

on

Inflammation

Submitted

To The

Commencement of the Provost

and

Professors of the University of Maryland

By the

Author

William H. Kirk

of

Stafford County

Virginia

on 3<sup>rd</sup>

of

April

1838

In the perusal of our medical studies, there is no subject which presents itself to our view more interesting, than inflammation, or one for which we as surgeons are more frequently called to treat - therefore a perfect acquaintance is every necessary.

Inflammation has been divided by surgeons into acute and chronic, simple, or complicated with disease; acute or healthy inflammation has been often termed phlegmon, and is of one kind only - What is called morbid inflammation is subdivided into many kinds, as erysipelas, scrophulous, venereal &c. &c.

They must, or really, inflammation is that which has for its object the restoration of diseased parts - chronic inflammation is that which has some morbid action added to that of unhealthy, such as in cancerous, &c.

The general characteristics of phlegmonous inflammation are an increased sensibility of the part, pain, preternatural redness, accompanied with tumefaction, and throbbing. The increased redness is supposed to arise from an increased flow of blood through the small arteries of the part; sometimes it may be dependant upon a generation of new vessels, Samuell Cooper says that the swelling is dependant upon a dilatation of the vessels, to a plethoric state of the arterial system, & owing to the exclusion of coagulation of lymph into the

interstices of the cellular substance and also to an interruption of the absorption.

With regard to the increased heat this seems to be unimaginable, as the degree of heat scarcely ever surpasses the natural temperature of the body but we may readily account for this when we remember the extreme sensibility of the nervous system, by which they convey false impressions.

The remote causes of inflammation are numerous consisting in those of a mechanical or chemical nature such as lures, wounds, splinters, acrid substances &c. Inflammation sometimes arising as consequent on some febrile disease acting upon the system and when this is the case is called symptomatic. Sometimes it seems to arise without any obvious cause & then it is commonly called spontaneous but improperly, as there can be no effect produced without there be a cause to produce that effect.

The proximate cause of inflammation, has been a source of much litigation the one side, it was supposed by the ancients that it was dependant on some morbid condition of the acids, whilst the moderns, as Boerhaave and others, that it is dependant on a change of the vessels & not a disease of the acids, the absurdity of the latter may be clearly seen from a local inflammation, for were it dependant upon acid one of the fluids we could have no inflammation

him recover a slight without bringing the whole system  
 into a state of disease. It seems more probable to de-  
 pend upon a disease of the vessels, in the fact that  
 new vessels are sometimes formed, this may be proved  
 by tumours, which may be extirpated without oc-  
 casioning much hæmorrhage when at the same time  
 we are to cut into the tumour, the hæmorrhage would  
 be great. It seems to me that all inflammation must  
 be dependant upon an increased action of the ves-  
 sels in the part affected, for it cannot be doubted that  
 there is more blood sent to the part when inflamed than  
 when in a state of health, this seems clear from the  
 circumstances, that if we cut into an inflamed part  
 it will bleed much more freely, than when in a na-  
 tural state, neither can this be done by any increa-  
 sed action of the heart, for the heart sends its blood equal-  
 ly to the whole system, but from this circumstance it  
 will seem, that besides the elasticity peculiar to the ar-  
 teries, themselves they have also a power of dilating  
 and contracting of themselves, we can scarcely ex-  
 plain on any other principle, the increased flow of  
 blood through the inflamed part.

It has been thought by some that it is depend-  
 ant upon a spasm of the external vessels of  
 the part, but I think that an effusion of lymph  
 besides the increased size of the vessels would be  
 sufficient to overturn an such an idea as this.

Very peculiar circumstance attending, pterygoid, or  
 inflammation, is that it is situated, when it may be  
 in what part seen it will always point externally  
 if inflammation invade the sockets of the teeth the  
 osseous will point externally, immediately in the vicinity  
 of the socket, thus in the inflammation of the alveolar  
 process

Inflammation differs in these varieties, in their pro-  
 gress, and their termination, as they differ in their si-  
 tuation, position, structure, and direction of vessels. Parts  
 through which the blood circulates, very can under-  
 go inflammation much better than are situated in  
 the solid condition, except when the part is essen-  
 tial to life and then though the part may be pro-  
 tected with a great deal of vasculature still it is owing  
 to the uniformity which is required for the support  
 of health dependent upon a sound condition. Having  
 reviewed the symptoms, and causes, in what we  
 think the most reasonable, from some considerations and  
 considerable study, we will next endeavour to give the  
 treatment - as recommended by the best modern Surge-  
 ons. In the treatment of inflammation the first to  
 be considered is the removal of the remote cause, for if  
 there be a splinter or any foreign substance lodged  
 in the socket we should first extract that, and then  
 we should have an eye to the proximate cause, it  
 will seem at once from what has been said that

our principal motive must be to remove that cause  
this is to be effected by those remedies which is necessary  
say to subdue the increased action of the enlarged  
vessels;

Bleeding

eds we have advanced the idea that in inflammation  
is dependant upon an increased action of the blood  
vessels in the part affected it will not be doubted that  
blood letting forms one of the most prominent agents  
in the reduction of this action, this should be  
done either by topical or general-bleeding. Topical  
bleeding seems in many cases to be more essential  
at than general, when the part affected is local and  
does not bring the system into concern, topical bleed-  
ing is more beneficial than general, but when any  
part is affected which is essential to life then we  
should use general and topical both, thus where the  
brain is affected if the inflammation is not speedily sub-  
dued death will be the inevitable consequence, we should  
use general blood letting when the part is not possessed  
with that power of restoration which is peculiar to the  
muscles, as in tendons about the joints, also when sup-  
puration would be the result and that perhaps to the  
destruction of the patient - Ophthalmia is a case of this  
kind as though it would not destroy the patients life  
the organ itself would be destroyed, General bleed-  
ing should not be admitted when the inflammation

is trivial and occurs in an old rebeled subject  
 When it takes place in a young and palestrick we  
 should use the remedies as early in the disease as  
 possible, when the action runs very high we should  
 always use general bleeding first, to make our  
 topical remedies act the more effectual, we should  
 draw the blood from a large surface, as to the quan-  
 tity of blood to be taken we should be governed  
 entirely by circumstances, the time of the disease  
 when taken and the general excitement in the  
 system, which may always be told by the strength  
 and fulness of the pulse.

Purging

These form the next grand feature in the catalogue  
 of our remedies for the cure of inflammation, they  
 should be of the saline kind, they not only assist  
 blood letting in diminishing the circulation, but they  
 act by producing a secretion they may be used  
 even when blood letting cannot be admitted, these  
 most commonly used is the Sulph of Soda, Sulph of  
 magnesia, and the nitrate of Potash.

Antimonialz.

emulsifying, cooling, antimonialz, preparing are some-  
 times very beneficial they act by removing the oppres-  
 sive dryness of the skin, and from the sympathy which  
 exist through the nervous system diminish administering  
 the action of the inflamed vessels, this is accomplished

by the noxia which is produced occasioning a tempo-  
rary debility and through these the progress of the in-  
flammation is subdued —

Opium

When there is great constitutional irritation together  
with great pain opium may be employed, although  
in the most cases of inflammation opium cannot  
be administered in account of its stimulating  
etc.

Diet

This in the cure of inflammation is very essential, the  
patients should be kept from all animal food, from  
fermented & Spirituous liquors, a neglect on the part  
of the Surgeon, to enforce, and the patient to adhere  
to a strict antiphlogistic regimen, often is the cause  
of the inflammation terminating in that way which  
brings reproach upon our science and in some  
cases to the destruction of our patients.

Cold applications

This remedy has been recommended from the know-  
ledge that heat or rather apparent heat has always  
been the concomitants of inflammation, and by  
the abstraction of that heat the part affected will be  
restored, this is done by keeping up a constant eva-  
poration on the surface. The remedies which are  
generally employed by Surgeons are of an escharotic  
or scabrous nature, such as the acetate of Lead &c.

it in water. Mr Cooper recommends the following  
 formula. acetate of lead ℥ss vinegar ℥iv distilled water  
 ℥ss, but I am inclined to think that the water & vinegar  
 containing all the virtues, because I cannot perceive what  
 the virtues of the lead can consist - as it cannot have  
 any specific action on the part, but the whole be-  
 nefit must be owing to the evaporation which takes  
 place, as the modus operandi of the lead has not  
 as yet been explained. Doctor Smith the professor  
 of surgery in this institution has recommended an  
 evaporating ~~potter~~ lotion composed of spirit and  
 water both equal parts, which has much the ad-  
 vantage of the lead & water in subduing the inflam-  
 mation as I have had the opportunity of seeing the  
 wonderful effects during the last winter in a case  
 in our Infirmary of a man who had punctured  
 his foot with a nail, when he was brought into the  
 Infirmary there was a violent inflammation taken  
 place and in the course of forty eight hours all the  
 symptoms were almost subdued. Again I have seen  
 the formula which Cooper recommends fail entirely

Warm application

this has been also recommended but it seems strange  
 that any two remedies so very opposite to each other  
 should be employed in the same case with a view to  
 cure - as it is experience has shown that it is so, and it  
 thought by some surgeons that it is dependent

in some peculiar idiosyncrasy of the patients constitution, or some difference in the structure in the part affected. Of the warm applications emollient potlices, have been the most frequently employed & the best is that made of Linseed meal and warm water this is made by putting the meal into the water until they are of a proper consistence to form a potlice and then add a little oil to prevent the potlice from becoming hard

Termination of Inflammation

Inflammation after continuing for some time, disappears without any apparent cause, or exhibits a disposition to form pus, or runs on to such a high state of inflammation as to terminate at last in the entire death of the part. The first is called resolution, the second called suppuration, & the third and last is called mortification.

First or Resolution

The most fortunate way in which inflammation terminates is resolution this consists in a spontaneous cessation of all the symptoms, a subsiding of the redness pain swelling, throbbing & heat of the part

Second or Suppuration

Suppuration is the next most frequent termination of inflammation this consists in the formation of pus which modifies the symptoms rather than an entire cessation of them

Classification

561

The worst manner in which information is  
terminated is in mere returns but chiefly it is the  
most rare, this consists in the entire loss of the  
part: I shall conclude with the subject here leaving  
a particular description of these three varieties alone  
leaving that they be being more strictly to systematic  
form than to the place.

Necrosis

presented to the Faculty of the

University of Maryland

for

the degree of Doctor of Medicine

By

George F. Carmichael

of

Virginia

1828.

# A Dissertation on Necrosis.

565

The strict interpretation of this term is the death of some portions of the bony structure, but is applied by surgeons to a disease characterized by peculiar symptoms, a frequent termination of which is the death or exfoliation of a portion of bone.

This disease commences with an acute inflammation of the bone itself or of its periosteum, accompanied with violent pain which is not at first referred to the immediate seat of the attack but to the nearest joint, it however locates itself finally on the part inflamed; The symptomatic fever which generally occurs at the same time with the pain, is of a highly inflammatory character. The termination of the local affection, is most frequently in suppuration.

tion, the matter is deposited between the <sup>37</sup>external periosteum and the bone, If the disease can be located in the shaft of the long bones, at the same time, that the matter forms beneath the external periosteum, there is a corresponding collection between the internal lining and the bone, This circumstance has been repeatedly ascertained by the use of the trophine.

Shortly after the attack the limb becomes swollen which is uniform until the matter escapes from beneath the periosteum, when the swelling is now circumscribed and confined to the immediate seat of inflammation. At this period there is a subsidence of the severe pain & fever in some degree, but they do not leave the patient entirely, The death of the bone in this disease

is not attributable to any peculiar <sup>3</sup>pecu-  
liarity of the inflammation, but to the vessels which give nourishment to it, being destroyed by the intervention of matter between it & its perosteum.

When the matter contained beneath the perosteum, has made its way to the surface and that within the cavity of the bone, has escaped through fissures in the same, relieving the parts from irritation and pressure the symptomatic fever in a great degree subsides, if however the collection be considerable and the destruction of bone extensive, hectic fever supervenes, showing a continuation of irritation tho' changed, as to its character.

The process instituted for the purpose of removing the dead bone, depends upon the

571<sup>4</sup>

extent of injury, for instance if merely a small portion, situated on the shaft of a long bone be necrosed, granulations will shoot from the sound and living bone, and as occurs in the mortification of the soft parts separate the dead from the living portion, and finally urge it through the opening previously formed, and discharge it from the body, this is more likely to happen when the soft parts have been fully divided at the beginning of the disease.

When the whole circumference is destroyed it is covered by an osseous structure which envelops the sequestra and is attached to the sound & living portions not however embracing it closely, and thus giving the limb an enlarged appearance,

573  
Necrosis is almost exclusively confined to young persons, seldom or never occurring under five or over twenty two.

No bone in the human system is exempt from this disease, long bones however are most liable, to its attacks, and of these the Tibias most particularly, The articulations are never assailed by this kind of inflammation in the first instance, sometimes however the joints are secondarily affected from the disease being communicated to them along the shaft of the long bones, where it first existed.

The line of separation is often accurately defined by the junction of the shaft & epiphysis of the bone, the articular portions remaining uninjured, it sometimes happens however that the disease reaches the joint and matter is formed when it becomes necessary to amputate the limb to

and the life of the patient,  
 Necrosis is not always confined to one  
 bone, it may occur simultaneously in re-  
 mote parts or successively which is more com-  
 mon, In regard to general prognosis a  
 very great majority of patients survive the  
 attack after long confinement and pro-  
 tracted suffering, it sometimes proves  
 fatal but generally early in the attack  
 from the high degree of symptomatic fe-  
 ver and constitutional irritation.

Diagnostic symptoms according to Dr Smith.  
 "The pain" As the disease says the gentleman is  
 an acute inflammation characterised by the  
 peculiar vital properties of the parts affected  
 In any of the symptoms must be analagous to  
 those of other inflammatory affections, he has  
 often known it to be mistaken and for a con-  
 siderable time treated <sup>for</sup> acute Rheumatism, even

altho' suppuration may have been observed,  
 It frequently happens that when the disease fix-  
 es on one of the long bones and mar its ex-  
 tremity the pain is complained of in the ad-  
 jacent joint, it is not long however confined  
 to the joint, but fixes itself in the inflamed  
 part, This circumstance of pain referred  
 to the joint has often caused the disease  
 to be denominated Rheumatism,

The pain experienced in Necrosis is extreme-  
 ly acute, unremitting, and not much in-  
 fluenced by the motions nor position of the  
 limb, The pain is often antecedent to the  
 swelling, and when the latter first occurs  
 it is generally diffused over a considerable  
 part of the limb, especially below the part  
 affected, The surface is rather firm to the  
 touch but the skin is not discoloured till  
 after matter is formed and advanced tow-

across the surface;

57<sup>a</sup>

The symptomatic fever is cerebral with the pains both usually occurring on the same day, the pulse both frequent and quick the strokes sudden and acting small and hard to the touch, At first the patient has occasional chills but when he complains of a sensation of cold the skin to another person feels hot. The pain is so violent that he gets little or no sleep, during the night he is often delirious. The tongue is furrowed with a soft white coat, the face is not flushed but rather pale with the exception of occasional red spots on the cheeks, the appetite for food is lost the thirst considerable the stomach and bowels are not so much affected as in other febrile diseases.

It has been before observed that the oppressed  
the pain in the early stage of the disease

Has caused necrosis to be sometimes confound-  
-ed with Rheumatism, Most, even of its early  
symptoms however are very different from those  
of that disease, the symptomatic fever and  
constitutional irritation come on sooner after  
the local attack and are much more re-  
-vived, the pulse smaller, harder, and much  
more easily compressed, and finally sup-  
-puration occurring removes all ambiguity,  
Necrosis however usually attacks, at that  
period of life, when rheumatism is not li-  
-able to occur; It is distinguishable from  
Typhus by the local affection, by the pulse  
which is harder and less easily compressed  
and by its not being attended with so  
much stupor,

Cancer. The inflammation which produces  
necrosis is often excited by blows and injuries  
inflicted upon the limbs, sudden suppression of

perspiration, and immersion in cool water <sup>253</sup> when  
the body is warm, it however often attacks with-  
out an obvious exciting cause, by which the  
disease is developed or concentrated upon  
a particular part.

Treatment. In the treatment of this disease  
the first step, as in all other inflammatory  
diseases should be to effect a resolution,  
The remedies however, which are most gen-  
-eral employed as Venesection, cathartics  
emetics blisters, evaporating lotions, cataplas-  
ms &c, have rarely succeeded in preven-  
-ting suppuration, the most efficient rem-  
-edies as directed and practiced by  
Professor Smith, of N. Haven is a free in-  
-cision of the soft <sup>parts</sup> and periosteum down  
to the bone through the whole extent of the  
inflammation, thus reducing the disease  
to a simple incised wound, which is the

to be treated accordingly,

265  
In the second stage of the disease when matter has formed beneath the periosteum the cure may still be effected without the loss of bone. In this stage of the disease an incision should be made thro' the soft parts as before directed and the periosteum divided as far as its separation from the bone, and a portion of the bone be cut out or perforated in the denuded part down to the medullary substance, that the matter collected between that substance and the bone, may escape and thus the death of the bone prevented. The best instrument for perforating the bone is a small trephine.

In the third stage when the matter has made its escape through the periosteum and obtained a lodgment in the soft parts, the treatment is precisely the same

as in the second stage, but the favourable <sup>231</sup> result is by no means so certain, as the circulation in it may have been too long destroyed, or the separation of the dead and living bond commenced. Anæsthetics however as in the former cases the incision in the soft parts should be made, taking care, to avoid important parts, such as tendons, nerves and bloodvessels, this will not only give free vent to the matter contained within, but facilitate the expulsion of the bone, if its destruction should have been extensive.

The general treatment consists in cooling purgatives nauseating doses of Antimony & opium sufficient to allay irritation and proceed rest.
